   b) filter results are written to the buffer A in the row order,
5. Deblocking columns of the macroblock 2:
   a) the macroblock 2 is read from the buffer A in the column order for mode decision and filtering,
   b) filter results are written to the buffer A in the column order.
6. Deblocking rows of the macroblock 3:
   c) the macroblock 3 is read from buffer A in the row order for mode decision and filtering,
   d) filter results are written to the buffer A in the row order,
   e) the first page of the buffer A contents are moved to the system memory by the IDMAC.
7. Toggle a page pointer in buffer A and return to the step 2.

Eight DMA channels service the PF in H.264 mode: three input data channels for each color component, three output data channels for each color component and two parameter channel. The DMAPF_0 parameter channel supplies the Quantization Parameter for luma (QP), Quantization Parameter for Chroma (QPC), Filter Offset A (FOA) and Filter Offset B (FOB) parameters. The DMAPF_1 parameter channel supplies BS parameters for each macroblock.

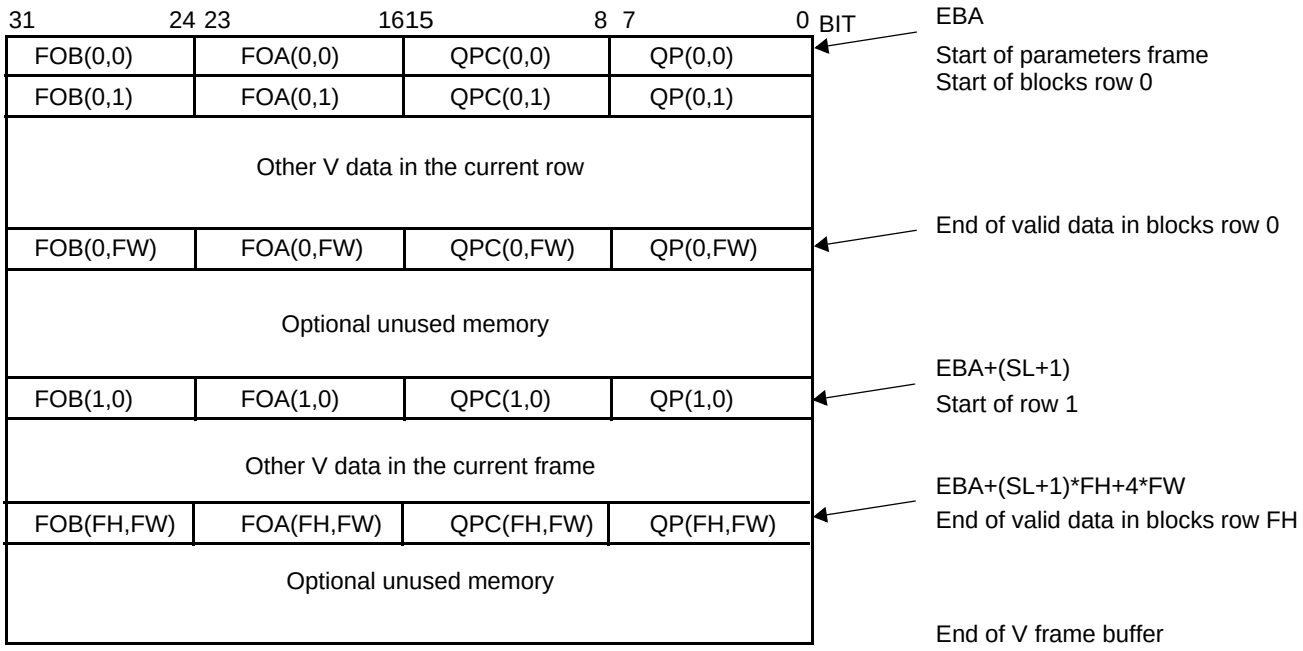
The QP, QPC, FOA, FOB parameters are packed into a 32-bit word as shown in Table 31-144. The DMAPF_0 channel should read these parameters with BPP corresponding to 32.

Table 31-144. QP, QPC, FOA, FOB Parameters Format in the External Memory (Little Endian)

bit	31	28 … 24	23	20 … 16	15	13 … 8	7	5 … 0
contents	X	FOB	X	FOA	X	QPC	X	QP

The QP parameter is an unsigned integer, assuming values from 0 to 51 (6 bits). The QPC parameter is an unsigned integer, assuming values from 0 to 39 (6 bits). The FOA and FOB parameters are signed integers,

assuming values from -12 to 12 (5 bits) in 2’s complement representation. The parameters has to be written to the external memory as shown in Figure 31-131.



Parameters for DMAPF_0 channel:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width/16 - 1
FH - Y Frame Height/16 - 1

Figure 31-131. QP, QPC, FOA, FOB Parameters Allocation in the System Memory (Little Endian)

The BS parameters are calculated by the core. There are two BS parameters for each 4x4 pixel block - for left block edge (BSL) and for upper block edge (BSU) (see Figure 31-132). Both parameters are stored as a single BSB parameter occupied one byte in the memory (see Table 31-143). The BSB parameters should be stored in the external memory in the same order as pixel data (see Figure 31-133).

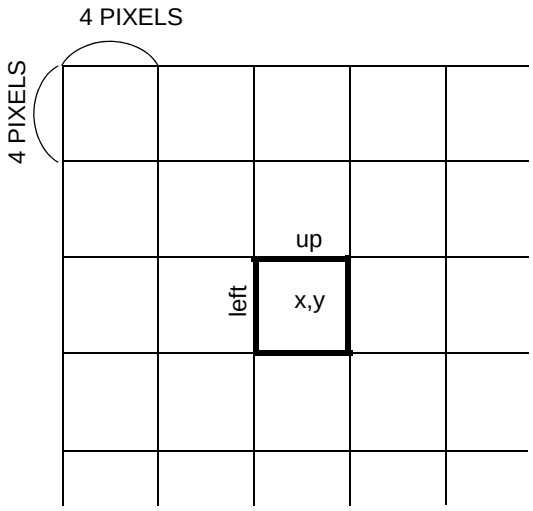


Figure 31-132. BSB Parameter Definition

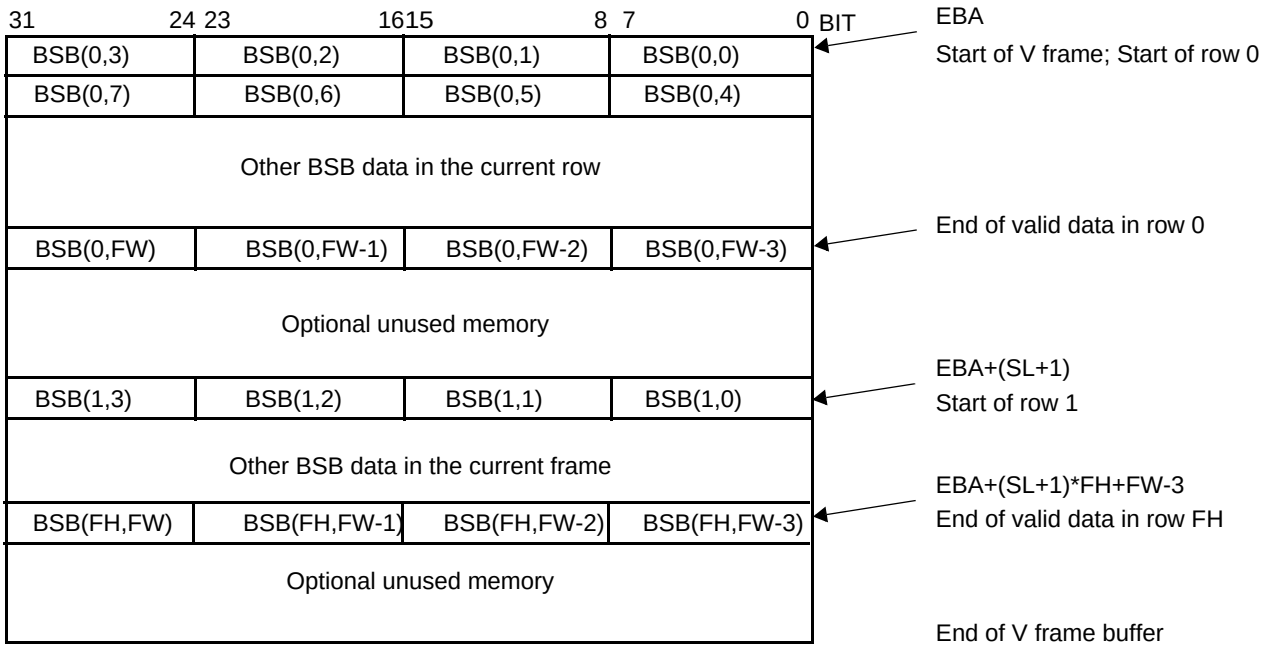
Table 31-145. BSB Parameter Format

bit	7			0
contents	X	BSU	X	BSL



Parameters for DMAPF_1 channel:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width/4 - 1
FH - Y Frame Height/4 - 1

Figure 31-133. BSB Parameters Allocation in the System Memory (Little Endian)

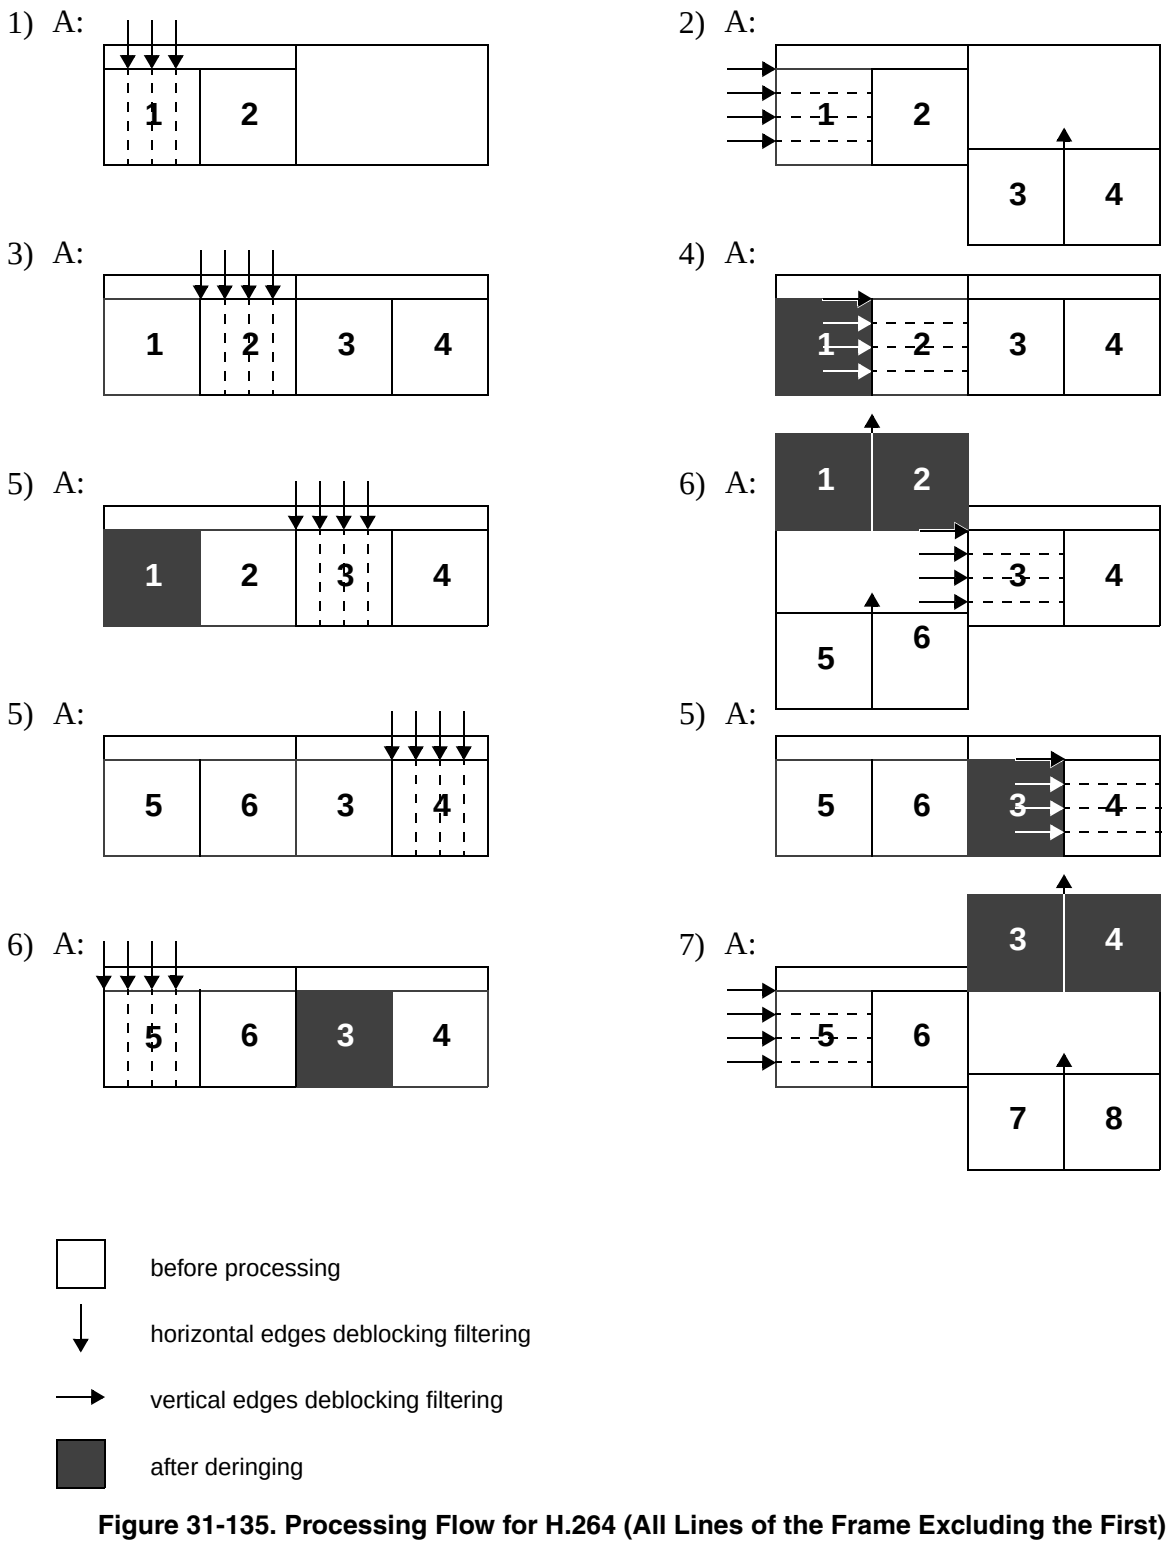

Figure 31-135. Processing Flow for H.264 (All Lines of the Frame Excluding the First)

31.4.3.3 Mode Decision Unit

The Mode Decision Unit is responsible for selection of a filter type to be used for calculation of the given output pixel. The unit reads and analyzes a row or a column of macroblock pixels. The analysis includes a number of steps (from 1 to 3 steps for MPEG-4 deblocking, from 1 to 4 steps for MPEG-4 deringing and for H.264 deblocking). At the finish step, the type of the filter to be applied is selected. The most of data path submodules in the Mode Decision Unit are reused for all tasks and operation modes. The analysis is controlled by tables defining a sequence of steps. For each algorithm, a specific control table is used.

31.4.3.4 Filter Arithmetic Unit

The derived filter number is fed to the Filter Arithmetic Unit which performs calculation of a single filter output in one clock cycle for MPEG-4 mode and in one or two clock cycles in H.264 mode. The unit The same filter data path are used for all operation modes. The difference between modes is reflected by separate control which defines a filter length and filter coefficients according to the selected filter type.

31.4.3.5 Postfilter Flow Control

The Postfilter Flow Control contains a set of finite state machines for each of performed tasks. An appropriate task state machine is invoked by the task control finite state machine according to the selected operation mode (MPEG-4 or H.264) and the current processing stage (deblocking or deringing, color component). The operation mode is selected via the PF_CONF Register.

In MPEG-4 mode, the software driver can request execution of only deblocking or only deringing or both of them. If just deringing is performed, only Y color component is processed.

In H.264 mode, the PF can operate with pauses. The core performs decoding in software. Decoder intermediate results should be processed by the PF. The PF output is sent back to the core to proceed decoding of the next frame. PF operation pauses allow parallel work of the core and the PF.

In this case, the core processes a portion of the frame (for example, a half). After that, it defines the number of rows to be processed by the PF (via programming the H264_Y_PAUSE_ROW parameter in the PF_CONF Register) and enables the postfilter task The PF performs processing of the Y component frame until the desired row and stops after that. The core updates the H264_Y_PAUSE_ROW parameter on readiness of the next frame portion. The PF resumes operation. After finishing the whole Y component frame, the PF processes the U and V component frames without pauses.

31.4.4 Synchronous Display Controller (SDC)

31.4.4.1 Block Diagram

The SDC Block Diagram is shown in Figure 31-136. The SDC data path includes the Synchronous Display Buffer Memory, the Combining Unit, the Cursor Generator and the Synchronous Display Adapter.

The Parameter Buffer is used for double buffering of all the parameters received from the configuration registers and synchronous their change on frame boundaries. The Synchronous Display Adapter provides the required timing control and display signal interface for VSYNC, HSYNC, etc.

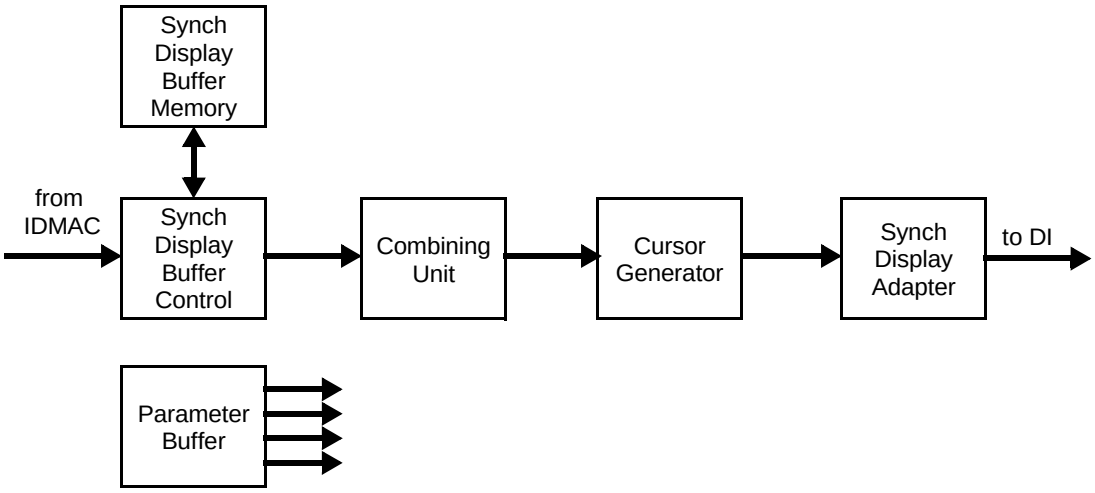

Figure 31-136. SDC Block Diagram

31.4.4.2 Input Data Formats

The pixel data to be displayed is written to the Synchronous Display Buffer Memory. There are two FIFO in the memory - for background and foreground planes.

Each FIFO contains sixteen pages, the page size is eight 64-bit words. Each word contains two color pixels in the RGBA/YUVA formats or eight 8-bits monochrome pixels or four 8-bits monochrome graphics pixels with four 8-bits alpha parameters. Table 31-146 shows used pixel formats and burst sizes.

Table 31-146. Supported Pixel Formats and Bursts

Pixel Format		Number of Pixels in 8-Word AHB Burst	Internal IPU 32-Bits Word Format	AHB Burst Parameters		Internal IPU Burst Parameters		Max Page Size in Pixels
Type	Bits Per Pixel			Burst length, 32-bits words	Number of Bursts Per Page	Burst Length, 32-Bits Words	Number of Bursts Per Page	
Mono-chrome video	8	32	$D_3D_2D_1D_0$(8888)	8-9	1	8	1	32
Mono-chrome graphics	16	16	$D_1A_1D_0A_0$(8888)	8-9	1	8	1	16
Color video or graphics	4	64	RGBA(8888)	1-2	1	8	1	8
	8	32	RGBA(8888)	2-3	1	8	1	8
	16	16	RGBA(8888)	4-5	1	8	1	8
	32	8	RGBA(8888)	8-9	2	8	1	8

Additionally, one 64-bits mask word is stored in a register. The mask is used for disabling some regions in the display window. This provides windowing function for smart displays with a synchronous interface.

31.4.4.3 Displayed Planes

Figure 31-137 shows the planes displayed on a synchronous display. There are foreground and background planes. A background frame position (BGXP and BGYP) defined relative to the VSYNC start point and a whole screen size (SCREEN_WIDTH and SCREEN_HEIGHT) are set via the SDC_BG_POS, SDC_HOR_CONF and SDC_VER_CONF Registers correspondingly. A foreground frame position (BGXP and BGYP) defined relative to the VSYNC start point is set via the SDC_FG_POS Register. Sizes of both planes are set by programming the corresponding IDMAC channels (see Table 31-29 through Table 31-33).

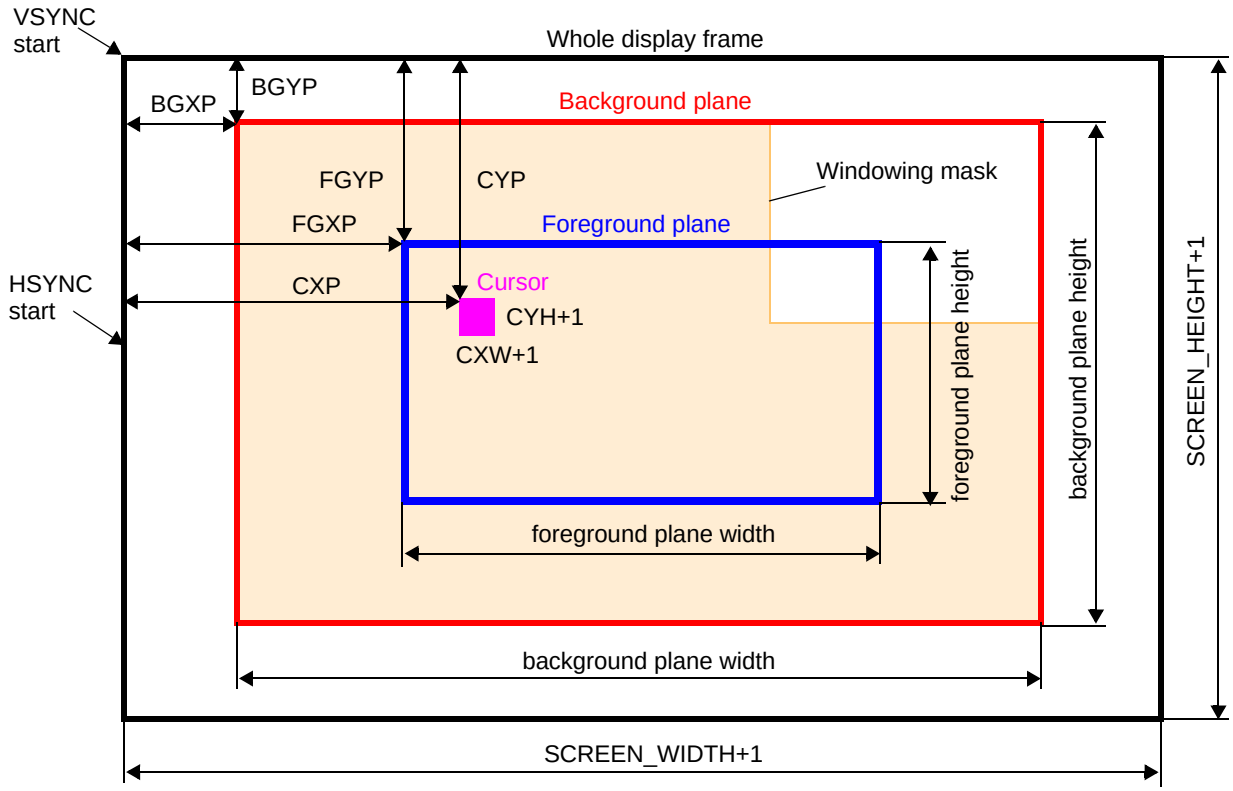

Figure 31-137. Displayed Planes

One of the planes can be graphics, another plane displays video. Selection of the graphics plane can be done via the SDC_COM_CONF Register.

Cursor position and parameters are set in the SDC_CUR_POS, SDC_CUR_BLINK_PWM_CTRL and SDC_CUR_MAP Registers.

The SDC is able to provide the windowing function on displays that have data enable control. This is achieved by masking of some screen regions according to a 1-bit/pixel mask prepared by core software. When the mask value is zero, the corresponding both background, foreground and cursor pixels are not displayed. This feature can be used for dual-port smart displays.

For memory-less displays, both foreground and background planes are sent to the display every refresh cycle. For dual-interface smart displays, data transfer depends on changes in plane and cursor positions, arriving of a new data, combining parameters and cursor parameters. If no data or parameters are changed, transfer to the display is not performed at the current refresh cycle. If only the foreground plane data and/or combining parameters have been changed, the foreground data and underlying background plane part are transferred to the display at the current refresh cycle. In all other cases, both foreground and background planes are send to the display.

31.4.4.4 Combining Unit

The Combining Unit performs combining foreground and background planes. The background plane may be a video image while the foreground plane is a graphics image or vice versa.

There are the following combining options:

- local alpha blending,
- global alpha blending,
- use of key color.

Combining mode is selected via the SDC_COM_CONF Register. The combining equation is:

$$OP = IGP \cdot \alpha + IVP \cdot (1 - \alpha)$$

where IGP - an input graphics pixel, IVP - an input video pixel, α=(A+floor(A/128))/256 - an alpha value, A - a global or local transparency parameter. The global A is written in the SDC_GRAPH_WIND_CTRL Register, the local A arrives together with the graphics pixel.

A graphics pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter).

Combining takes 3 cycles per color pixel or 1 cycle per monochrome pixel. The Combining Unit outputs 24-bit words in the RGB/YUV format for color pixels or 8-bit words for monochrome pixels.

31.4.4.5 Cursor Generator

The Combining Unit output is passes through the Cursor Generator. Cursor size and position are set via the SDC_CUR_POS Register, a cursor color - via the SDC_CUR_MAP register. Different logic functions of combining the cursor with the image are supported as defined by the SDC_COM_CONF register. The cursor can be blinking as defined by the SDC_CUR_BLINK_PWM_CTRL register.

31.4.4.6 Display Refresh Rate

The SDC_HOR_CONF and SDC_VER_CONF registers define screen width and screen height in pixels, the DI_DISP3_TIME_CONF registers defines the synchronous display (display 3) clock period, and the DI_DISP_ACC_CC Register defines the number of display clock cycles in one pixel clock cycle.

The display refresh rate is as follows:

$F_{REF} = F_{HSP} / ((SCREEN\_WIDTH+1) * (SCREEN\_HEIGHT+1) * (DISP3\_IF\_CLK\_PER\_WR / HSP\_CLK\_PERIOD1,2) * (DISP3\_ IF\_ CLK\_ CNT\_ D+1))$

31.4.5 Asynchronous Display Controller (ADC)

31.4.5.1 Block Diagram

The ADC Block Diagram is shown in Figure 31-138.

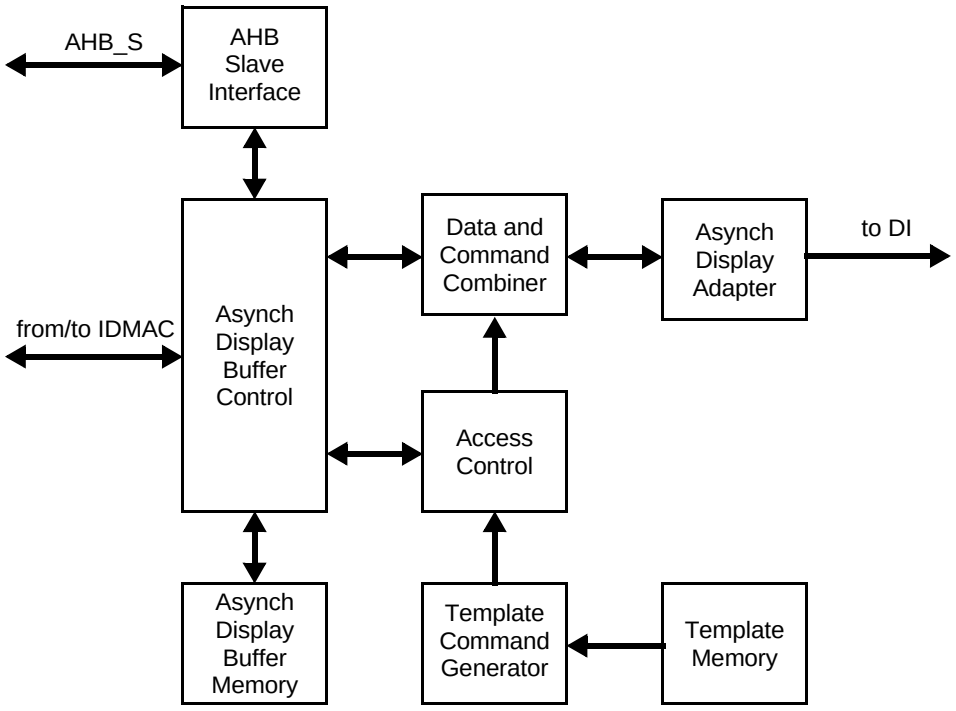

Figure 31-138. ADC Block Diagram

Data to be written/read to/from a smart display or a graphics controller arrives from/to the IDMAC or directly from/to the core. The data is temporarily stored in the Asynchronous Display Buffer Memory. The Access Control manages the generation of display commands and the combining of command and data is done by the Data and Command Combiner. The Asynchronous Display Adapter controls display frame timings and provides interface to the DI.

The ADC is able to support up to three smart displays simultaneously with time multiplexed access.

All ADC control registers are not double buffered, meaning that for reprogramming the access channels or the display parameters, the core should wait for the DMA channel to complete its current frame transfer.

31.4.5.2 Display Access Modes

There are two display types to be supported. For the first type, display addressing is done by pointing the corresponding X, Y coordinates. For the second type, the full linear address is sent to the display. The

display type is selected via the DISP#_TYPE parameter in the ADC_DISP0_CONF - ADC_DISP2_CONF Registers.

The data to be sent to the display can be treated by the IPU as pixels or a generic data with a word width of 16 or 24 bits (packed in a 32-bit word).

There are three possible sources of display data. the system memory, internal IPU processing parts (preprocessing and postprocessing) and the core (direct access to the display).

Five access channels allow to support up to five windows on different displays:

1. System memory channel 1 which can be configured for write or read access
2. System memory channel 2 which can be configured for write or read access
3. Preprocessing channel for write access (internal transfer of data for viewfinder application)
4. Postprocessing channel for write access (internal transfer of data with bypass of the system memory)
5. Core direct access channel

Each of five windows may be displayed on one of three displays.

The ADC supports the display access modes listed in Table 31-147.

Table 31-147. Asynchronous Display Access Modes

Display Type	Source	Command Generation Method	Access Type	IDMAC/Core Interface Format	Display Interface Format	Programming ADC/IDMAC Parameters
X,Y addressing, 6/8/9/12/16/18-bit interface	System memory	command buffer	write	32[1]-bit pixel data	up to 24-bit pixel data, data/command mapping format, 1/2/3/4-cycles transfer	DISP#_TYPE = 10, SYS1/2_MODE = 101 or 110 or 111, SYS1/2_ADDR_INC unused, PFS (DMAADC_2/3) = 000 or 100, BPP (DMAADC_2/3) - according to external pixel size

	Core	template	write, read	16-bit generic data	16-bit generic data, data/command mapping, single 1/2-cycle 16-bit transfer	DISP#_TYPE = 00, MCU_DISP#_DATA_WIDTH = 0
				32-bit generic data	24-bit generic data, data/command mapping, single 2/4-cycle 32-bit transfer	DISP#_TYPE = 00, MCU_DISP#_DATA_WIDTH = 1

1 32-bit pixel data format on IDMAC internal interface assumes that only 24 MSB bit are occupied by pixel data and 8 LSB bits are not used

2 32-bit generic data format on IDMAC internal interface of core interface assumes that only 24 LSB bit are occupied by data and 8 MSB bits are not used

3 Single transfer means that the ADC sends a whole 16- or 24-bit word to the DI, two transfers mean that the ADC splits a 32-bit word to two 16-bit words

31.4.5.3 Control Sequence Generation Modes

Two modes are exploited for display control sequence generation: command buffer mode and template mode.

For the first mode, the generic data flow from the system memory is interleaved with commands taken from a command buffer. This mode can be used only for the system memory channels 1 and 2. The mode is selected via the ADC_CONF Register.

The command buffer consists of 32-bit words. Each of the words contains 16- or 24-bits display command and a RS parameter. For 16-bit command, there are two byte enable (BE) bits - low and high. The command formats are shown in Table 31-148 and Table 31-149. The command buffer is prepared by the core in the system memory as shown in Figure 31-139.

Table 31-148. 16-bits Display Command Format

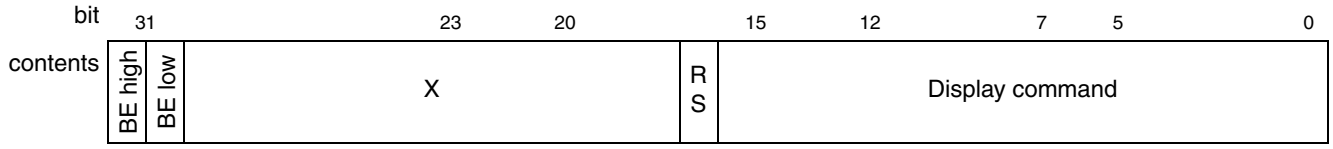

Table 31-149. 24-bits Display Command Format

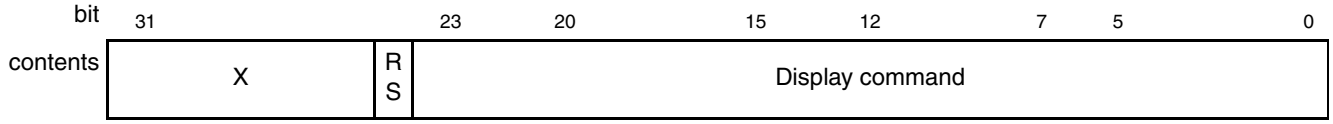

For the template mode, the command sequence is generated automatically according to command templates prepared by the core. There are different templates for read and write operations and for each of displays. The templates are explained in detail in Section 31.4.5.10, “Template Command Generator.”

Selection of command generation mode is done via the ADC_CONF Register.

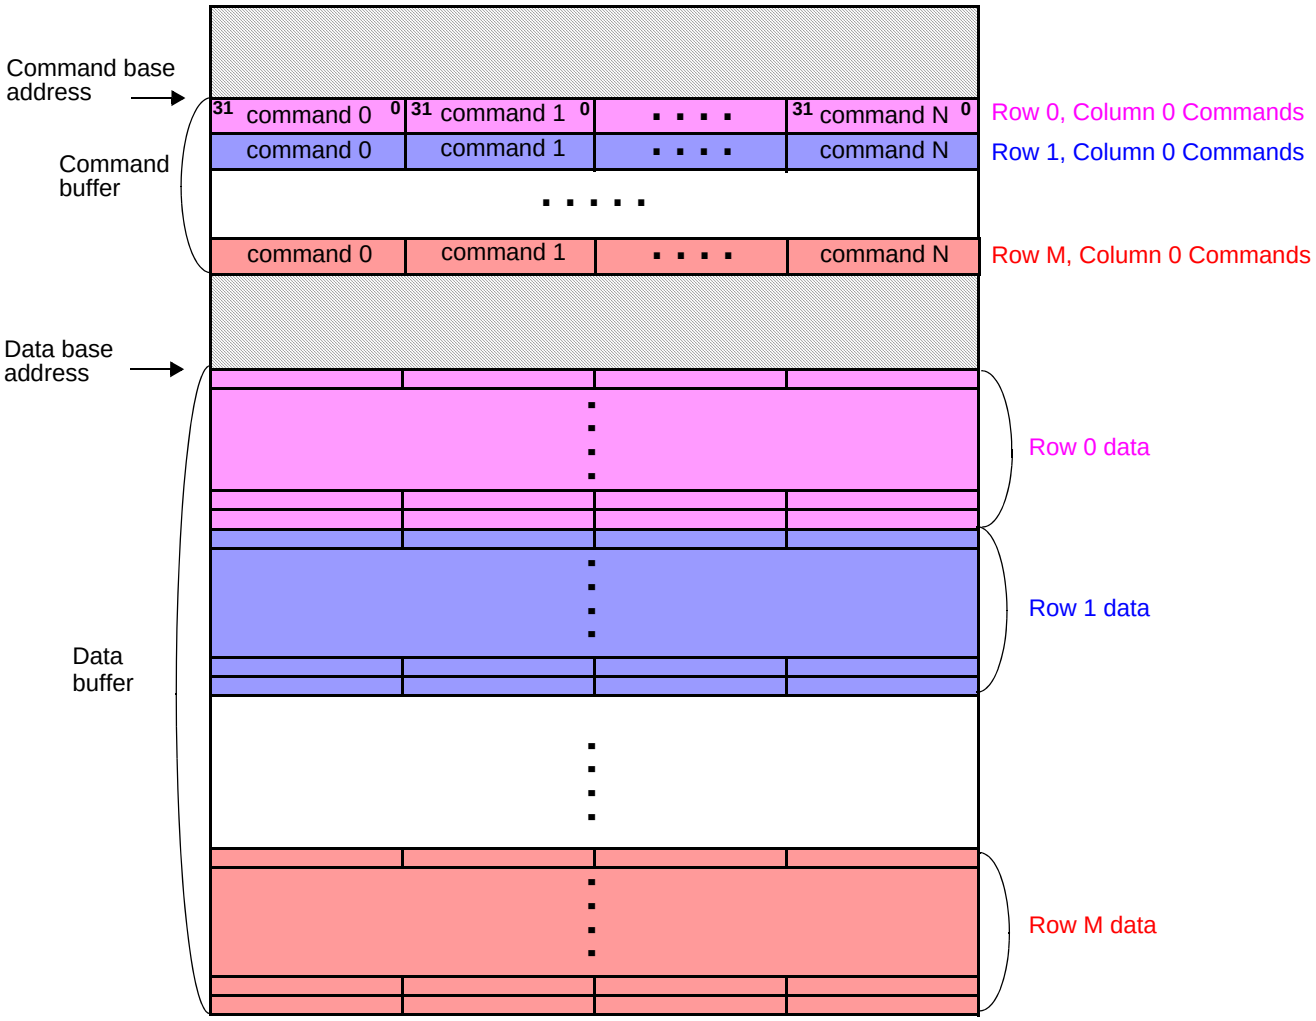

Figure 31-139. Data and Command Buffers in the System Memory

31.4.5.4 Byte Enable Support

The ADC supports byte enable feature used by some display controllers and graphic accelerators. The interface width of such device must be 16 bits. There are the following conditions of byte enable support:

1. If the core is an initiator of display access via the slave AHB bus then
   a) Allowed data type is generic data,
   b) AHB single access widths are 8 (16 bit with byte enable), 16 and 32 bits. According to the ARM specification, byte enable options (on the slave AHB bus) are:
   — for 8-bit AHB access - 0001, 0010, 0100, 1000
   — for 16-bit AHB access - 0011, 1100
   — for 32-bit AHB access - 0111, 0110, 1110, 1111

c) AHB burst access width is only 32 bits. Only aligned accesses are allowed (these are ARM limitations for burst access to AHB bus). Byte enable bits are always 1111.

d) Little End Big Endian AHB modes are supported.

2. If the IDMAC is an initiator of display access (system, pre- or postprocessing ADC channels) then

a) Allowed data types are pixels or generic data.

b) Data width may be 8 (16 bit with byte enable), 16 or 32 bits.

c) Generic data is transferred from a two dimensional buffer in the system memory, the buffer row length must be a multiple of 16 bits (for 8- and 16-bit data) or of 32-bits (for 32-bit data) and start from an even address (for 8- and 16-bit data) or an address which is a multiple of 4 (for 32-bit data). This system memory buffer exactly matches the display memory buffer.

d) For non-aligned 8-bit write access (when only 8 bits should be written to the first word in a row of the display memory), an odd display start address has to be set in the corresponding IPU register (ADC_SYSCHA1_SA, ADC_SYSCHA2_SA, ADC_PRPCHAN_SA or ADC_PPCHAN_SA). For aligned 8-bit access (when whole 16 bits should be written to the first word in a row of the display memory), an even display start address has to be set in this register. Read operation is allowed only for 16-bit access (the display start address must be even).

e) Pixel data width in display memory may be 8, 16 or 24 bits.

The ADC translates slave AHB or IDMAC accesses to 16-bit display accesses with the corresponding byte enable bits. The display bus has only Little Endian mode. If sequential writes or reads to/from the display are performed at incremental addresses, the ADC does not send an address to the display (it chains accesses). Otherwise the address is sent before data every time when address incremental order is violated.

The ADC assumes that the display increments the address by 2 after write/read of full 16 word or most significant byte of the word. The address has no change after write/read of least significant byte of the word.

Writing addresses to the display memory and registers are performed by 16-bit access with byte enable bits ‘11’. For command buffer mode, byte enable bits can be used only with 16-bit command. They are located in the 32-bit command word (see Table 31-148).

31.4.5.5 Windows Displayed on a Smart Display

Figure 31-140 illustrates how windows are displayed on an asynchronous display. Each of windows corresponding to the system memory, pre- and post processing access channels have the start address defined in the ADC_SYSCHA1_SA, ADC_SYSCHA2_SA, ADC_PRPCHAN_SA, ADC_PPCHAN_SA Registers. The start address format matches to the display addressing type. The same registers control a display number for the specific window. The start address refers to the VSYNC start point. Sizes of the windows are set by programming the corresponding IDMAC channels (see Table 31-29 through Table 31-33). A whole screen size (SCREEN#_WIDTH and SCREEN#_HEIGHT) are set via the corresponding registers. Sizes of the windows are set by programming the corresponding IDMAC channels (see Table 31-29 and Table 31-33).

The total number of windows which can be displayed on all displays is five. The maximum number of windows which can be displayed on the same display is up to five, when the template mode of operation

is used. The number of windows on the specific display is restricted to one when command buffer mode of operation is used.

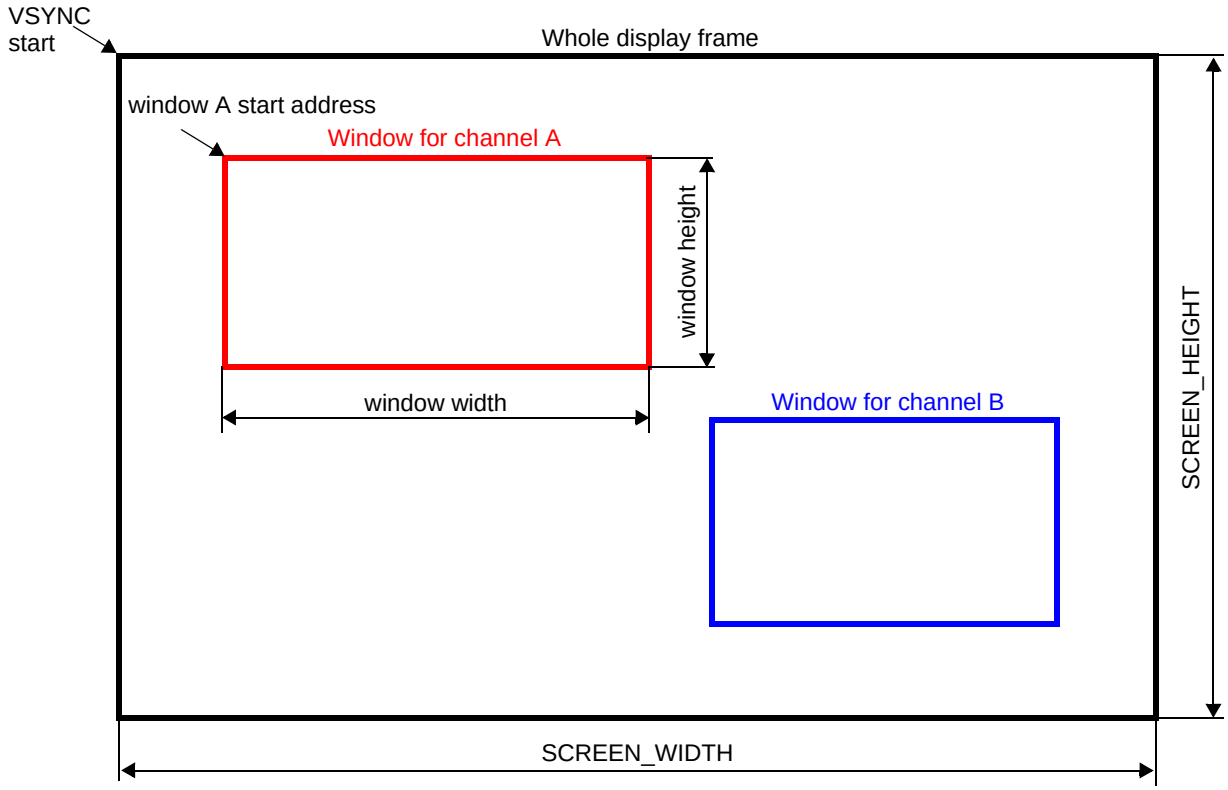

Figure 31-140. Windows on a Smart Display

31.4.5.6 AHB Slave Interface

The AHB Slave Interface is responsible for data transfer from/to the core when the core accesses a smart display directly. The Interface supports 8 (with byte enable), 16- or 32-bits single accesses or 32-bit burst accesses. For burst access, only aligned addressing is allowed. All endian modes (LE, BE32) are supported. The AHB clock rate may be equal or lower than the HSP_CLK clock rate.

31.4.5.7 Asynchronous Display Buffer Memory

Data is written to or read from the Asynchronous Display Buffer Memory. The Memory includes 7 FIFOs: two system memory data FIFOs, two command FIFOs, one preprocessing data FIFO, one postprocessing data FIFO and one core write data FIFO. Each FIFO has eight pages of eight 64-bit words.

Two data transfer channels associated with the transfer from/to the system memory are bidirectional and can be used both for read and write operations according to the ADC_CONF Register settings. The core FIFO is used only for write operations. Core reading is enabled after finish of previously requested core write operations (releasing the core FIFO).

31.4.5.8 Access Control

31.4.5.8.1 Access Priorities

The Access Control arbitrates data sources/destinations channels. According to an access address and a source type, the display number and access attributes are selected. The priorities order is as follows:

1. Preprocessing and core access channels (the highest priority). Selection between these channels is done according to the round-robin algorithm.
2. Postprocessing channel.
3. System memory channel 1.
4. System memory channel 2 (the lowest priority).

31.4.5.8.2 Tearing Elimination

The ADC has capability to avoid image tearing. If the source is the system memory or postprocessing, the Access Control monitors position of a display refresh pointer. Writing to the display is started only after crossing the window start point by the display refresh pointer. After that, writing to the display is allowed only when a write pointer does not advance beyond the refresh pointer. To provide anti-tearing mode, a window start time (in rows) must be defined in the ADC_SYSCHA1_SA, ADC_SYSCHA2_SA, ADC_PPCHAN_SA registers for the corresponding channels.

Anti-tearing mode requires that the IPU controls display refresh timing by generation of the VSYNC signal and a display clock (for dual-port displays). There is a separate VSYNC generator for display 0. For displays 1 and 2, the VSYNC generator is shared, so only one of displays 1 or 2 can be in vertical synchronization mode as determined by the DISP12_VSYNC_SEL bit in the ADC_DISP_VSYNC register.

In the case when tearing cannot be avoided (when the refresh rate is too high and the refresh pointer overtakes the write pointer after full refresh cycle), an error interrupt is generated. Tearing elimination mode can be disabled via the ADC_CONF register.

When the data arrives directly from preprocessing, tearing can be avoided only for the 2:1 ratio between a sensor scan rate and a display refresh rate. The additional conditions for tearing elimination in this case are to synchronize the sensor and display VSYNCs (by programming the appropriate bits in the ADC_DISP_VSYNC registers) and full-screen image from the preprocessing channel.

31.4.5.8.3 Snooping

This function allows to reduce a rate of write accesses from the system memory to a smart display. When snooping is enabled by configuration of the ADC2_SRC_SEL and ADC3_SRC_SEL fields in the IPU_FS_DISP_FLOW Register, writing to the display is performed only if the corresponding system memory buffers has been changed. Any change of data in the system memory buffers is registered by the External Memory Controller of the chip. When writing to the system memory is performed, the External Memory Controller asserts the SYSCH_SNOOP pin of the IPU. After receiving these signals, the CM initiates transfer of the corresponding buffer to a smart display window.

31.4.5.8.4 Automatic Window Refresh

By programming the IPU_FS_DISP_FLOW Register, Core software can enable automatic refresh of a window on the smart display. The refresh period is defined via the AUTO_REF_PER field (the time unit is 2^{17} periods of the HSP_CLK clock). The actual value of refresh period is equal to $T_{HSP}*2^{17}$ *(AUTO_REF_PER+1). Auto-refresh can be conditional. In this case, it is accomplished only if the SYSCH_SNOOP pin is asserted.

31.4.5.8.5 Sequential Addressing Access

The Access Controller includes a mechanism allowing to skip transfer of addresses and commands before a data when access addresses are sequential. This mechanism works only in template mode.

First of all, addresses and commands are skipped within a burst sent or received by the IDMAC or by the core. Each burst occupies one page in the corresponding FIFO of the Buffer Memory. At start of the burst that should be sent/received to/from a display, the Access Controller compares a new burst start address and channel number with a last address and channel number for previous access to this display. If the channel number has not changed and the new start address follows the previous last address, the Access Controller does not send the new address and commands to the display. Otherwise both the address and the commands are sent.

31.4.5.8.6 Core Direct Access to Display/Graphic Accelerator Memory

The core can directly access display or graphic accelerator memories of all three smart displays through the slave AHB bus. The display memories are mapped to the core memory space. The display memory start address in the core memory space is as follows:

DISPLAY_MEM_START_ADDRESS = SLAVE_AHB_BASE_ADDRESS + DISPLAY_MEM_START_ADDRESS _OFFSET

where

SLAVE_AHB_BASE_ADDRESS is a 32-bit slave AHB base address defined as {AHB_S_BA[6:0], 25'b0} (binary quotation). The AHB_S_BA[6:0] value is programmed by VIA.

DISPLAY_MEM_START_ADDRESS_OFFSET is 25-bit offset which is a constant for each display. It is 0 for display 0, 0x0800000 for display 1, and 0x1000000 for display 2. so each display memory can occupy up to 0x0800000 bytes.

The ADC translates the slave AHB address to the display address. For displays with full addressing (like ATI W2300) the address transferred to the displays is

DISPLAY_ADDRESS = SLAVE_AHB_ADDRESS - DISPLAY_MEM_START_ADDRESS

When sending to the display, DISPLAY_ADDRESS can be split to two or more portions by the template WR_XADDR and WR_YADDR commands. For displays with XY- addressing (like Epson L2F50032T00), the IPU firstly calculates the pixel number in the frame:

```
PIXEL_NUMBER = (SLAVE_AHB_ADDRESS - DISPLAY_MEM_START_ADDRESS) / BYTES_PER_PIXEL,
```

where

BYTES_PER_PIXEL=2 if the MCU_DISP#_DATA_WIDTH parameter in the ADC_DISP#_CONF Register is 0,

BYTES_PER_PIXEL=4 if the MCU_DISP#_DATA_WIDTH parameter in the ADC_DISP#_CONF Register is 1,

After that, the IPU calculates X and Y addresses using the template WR_XADDR and WR_YADDR commands. The WR_XADDR command defines what are low significant bits of PIXEL_NUMBER to be sent as the X address. The WR_YADDR command defines what are most significant bits of PIXEL_NUMBER to be sent as the Y address. The templates should be downloaded to the internal memory before enabling the core channel. The display should be configured via the low level access mechanism using the DI_DISP_LLA_CONF and DI_DISP_LLA_DATA Registers. This mechanism allows to access both the display memory and control registers.

31.4.5.9 Data and Command Combiner

The Access Control manages the Data and Command Combiner according to the access method. The Data and Command Combiner contains muxes and aligners. Its output may be 16/24 bits data or 16/24 bits address or 16/24 bits command.

In command buffer mode, it toggles between command and data rows on the end-of-line signal. In template mode, it invokes the Template Command Generator to produce a command sequence and to interleave the commands with the data.

In template mode, commands are taken from the Template Command Generator.

31.4.5.10 Template Command Generator

31.4.5.10.1 Template Functions and Structure

A template is a microprogram executed every time when a data burst should be written to or read from a smart display. A typical template structure include the following parts:

1. Sending a pre-command sequence to the display.
2. Sending an address to the display.
3. Waiting for display acknowledge or for given number of display clocks. Waiting is needed for read access only.
4. Sending a data sequence to the display or receiving a data sequence from the display. This step is repeated while addressing is sequential (see Section 31.4.5.8.5, “Sequential Addressing Access”).
5. Sending a post-command sequence to the display.

Depending on access type (read or write) and access sequentially the template structure can be varied. For the sequential access (see Section 31.4.5.8.5, “Sequential Addressing Access”) neither commands and not address are sent to the display. Therefore, for the sequential access the templates are not used. Two templates (write and read) exist for each of three displays. The maximal template length is 32 commands.

The Template Command Generator receives a template command sequence from the Template Memory (Table 31-150). Each command consists of the following fields:

1. Display register address RS (1 bit) selects the index or data register.
2. Template flow control (2 bits) modifies order of template commands (step-by-step, pause, stop). Flow control commands are shown in Table 31-150.

Table 31-150. Template Flow Control

Code	Flow control command	Description
00	Step-by-step	Sequential template execution
01	Pause	Flag for breaking and resuming template execution. Used for displays required post-commands. The template part preceding this flag (pre-command and address) is performed before write/read a data sequence. The template part after this flag (post-command) is performed after the data sequence. Has to be located in the command preceding the post-command part of the current template.
10	Stop	Template last command. Has to be located on the last command
11	-	Reserved

3. Opcode (3 bits) controls an action according to Table 31-151.

Table 31-151. Command Opcode

Opcode	Command	Description
000	RD_DATA	Read data from the display
001	RD_ACK	Wait for display acknowledge
010	RD_WAIT	Wait for given number of display clock cycles
011	WR_XADDR	Send X address or LSB of full address to the display
100	WR_YADDR	Send Y address or MSB of full address to the display
101	WR_ADDR	Send whole address to the display
110	WR_CMND	Send command field to the display
111	WR_DATA	Send data from the Buffer Memory to the display

4. Command/data (24 bits) to be sent to the display.

The templates have to be loaded to the Template Memory before enabling any of the ADC channels used templates.

31.4.5.10.2 Format of Template Commands

RD_DATA

Description: Read data from the display. This command is repeated while there is read data with sequential addresses. The RS value is hold all this time.

Table 31-152. RD_DATA Command Format

	29 28 27	26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
Field	RS / Flow control	Opcode	Data
Contents	RS	FC	000	not used

RD_ACK

Description: Wait for display acknowledge. The ADC receives data from the display, performs bitwise AND with the mask and compares the result with the acknowledge pattern. Acknowledge patterns and masks are defined in the ADC_DISP0_RD_AP, ADC_DISP0_RDM, ADC_DISP1_RD_AP, ADC_DISP1_RDM, ADC_DISP2_RD_AP, ADC_DISP2_RDM Registers,

Table 31-153. RD_ACK Command Format

	29 28 27	26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0	
Field	RS / Flow control	Opcode	Data	
Contents	RS	FC	001	not used	TimeOut

TimeOut The maximal number minus 1 of display read access cycles to wait before beginning read. If TimeOut access cycles occur, data read is started independently on display acknowledge.

RD_WAIT

Wait for given number of display interface clock cycles.

Table 31-154. RD_WAIT Command Format

	29 28 27	26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0	
Field	RS / Flow control	Opcode	Data	
Contents	RS	FC	010	not used	Wait Tme

WaitTime The number minus 1 of display interface clock cycles to wait.

WR_XADDR

Send the X address or LSB of full address to the display. This command is repeated while there is write data with sequential addresses. The RS value is hold all this time.

Table 31-155. WR_XADDR Command Format

	29 28 27	26 25 24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0	
Field	RS / Flow control	Opcode	Data	
Contents	RS	FC	011	Mask	XCodedWidth

XCodedWidth Coded width of LSB address bits to be send to the display:

Table 31-156. XCodedWidth Values

Value	Meaning
0000	send address bits [6:0]
0001	send address bits [7:0]
0010	send address bits [8:0]
0011	send address bits [9:0]
0100	send address bits [10:0]
0101	send address bits [11:0]
0110	send address bits [12:0]
0111	send address bits [13:0]
1000	send address bits [14:0]
1001	send address bits [15:0]
1010	send address bits [16:0]
1011	send address bits [17:0]
1100	send address bits [18:0]
1101	send address bits [19:0]
1110	send address bits [20:0]
1111	send address bits [21:0]

Mask MSB bits of the mask word which is ORed with the address before sending to the display.

The resulting address word to be sent to the display is calculated by the following operations:

1. Select LSB address bits according to the XCodedWidth value.
2. Complement the derived word to 24 bits by adding zero MSB bits.
3. Complement the *Mask* value to 24 bits by adding 4 zero LSB bits
4. Perform OR operation between results of the steps 2 and 3.

The mask can be used for mixing command and address in a single 24-bit word.

WR_YADDR

Description: Send Y address or MSB of full address to the display.

Table 31-157. WR_YADDR Command Format

	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Contents	RS	FC		100			Mask																						YCodedWidth	

YCodedWidth Coded width of MSB address bits to be send to the display:

Table 31-158. YCodedWidth Values

Value	Meaning
0000	send address bits [22:7]
0001	send address bits [22:8]
0010	send address bits [22:9]
0011	send address bits [22:10]
0100	send address bits [22:11]
0101	send address bits [22:12]
0110	send address bits [22:13]
0111	send address bits [22:14]
1000	send address bits [22:15]
1001	send address bits [22:16]
1010	send address bits [22:17]
1011	send address bits [22:18]
1100	send address bits [22:19]
1101	send address bits [22:20]
1110	send address bits [22:21]
1111	send address bits [22:22]

Mask MSB bits of the mask word which is ORed with the address before sending to the display.

The resulting address word to be sent to the display is calculated by the following operations:

1. Select MSB address bits according to the *YCodedWidth* value and align them to the right (LSB) side.
2. Complement the derived word to 24 bits by adding zero MSB bits.
3. Complement the *Mask* value to 24 bits by adding 4 zero LSB bits
4. Perform OR operation between results of the steps 2 and 3.

The mask can be used for mixing command and address in a single 24-bit word.

WR_ADDR

Description: Send the whole address to the display.

Table 31-159. WR_ADDR Command Format

	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	RS	Flow control		Opcode			Data																							
Contents	RS	FC		101			Mask																					not used		

Mask MSB bits of the mask word which is ORed with the address before sending to the display.

The resulting address word to be sent to the display is calculated by the following operations:

1. Complement the address to 24 bits by adding one zero MSB bit.
2. Complement the *Mask* value to 24 bits by adding 4 zero LSB bits
3. Perform OR operation between results of the steps 2 and 3.

The mask can be used for mixing command and address in a single 24-bit word.

WR_CMND

Description: Send the command field to the display.

Table 31-160. WR_CMND Command Format A

	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31.4.5.11 Asynchronous Display Adapter

The Asynchronous Display Adapter contains a set of counters for generation of the VSYNC signal for display 0 and display 1 or 2. The counters may be synchronized to the sensor VSYNC signal with a programmable delay or to the display VSYNC signal if display operates in self-refresh mode. Vertical synchronization is controlled by the ADC_DISP_VSYNC Register. The Asynchronous Display Adapter provides interface to the DI.

31.4.6 Display Interface (DI)

31.4.6.1 Block Diagram

The DI Block Diagram is shown in Figure 31-141.

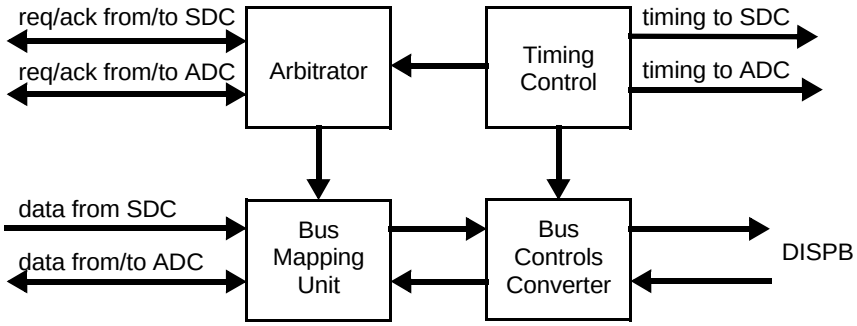

Figure 31-141. DI Block Diagram

The DI provides arbitrates access to up to four displays with time multiplexing. It converts a data from the SDC, the ADC or the core via the IP bus interface (low-level access) to a format suitable for the specific display interface. The DI generates display clocks and other display control signals with programmable timings. The DI outputs data to or inputs from parallel and/or serial interfaces.

The DI is controlled via the peripheral bus registers. All the registers are not double buffered. Therefore they should be programmed before use of the corresponding display.

31.4.6.2 Supported Display Interface Types

The DI supports simultaneously synchronous interface to display 3 and asynchronous interfaces to displays 0, 1, 2. Display 0 interface is parallel only, while displays 1, 2 interfaces can be parallel or serial. Common configuration of the interfaces is done via the DI_DISP_IF_CONF Register. All display interfaces have programmable timing.

31.4.6.2.1 Synchronous Interfaces

The DI supports the following synchronous display interfaces:

1. Synchronous generic interfaces to TFT dumb displays or RGB interfaces of smart displays.
2. Synchronous interfaces to Sharp displays.

3. Synchronous interfaces to TV encoders:
   a) PAL
   b) NTSC

   TV interfaces can operate in progressive or interlaced modes.

31.4.6.2.2 Asynchronous Parallel Interfaces

The DI supports the following asynchronous parallel interfaces:

1. System 80 interface
   a) Type 1 (sampling with the chip select signal) with and without byte enable signals.
   b) Type 2 (sampling with the read and write signals) with and without byte enable signals.
2. System 68k interface
   a) Type 1 (sampling with the chip select signal) with or without byte enable signals.
   b) Type 2 (sampling with the read and write signals) with or without byte enable signals.

For each of four system interfaces there are three burst modes:

1. Burst mode without a separate clock. The burst length is defined by the corresponding parameters of the IDMAC (when data is transferred from the system memory) of by the HBURST signal (when the core directly accesses the display via the slave AHB bus). For system 80 and system 68k type 1 interfaces, data is sampled by the CS signal and other control signals changes only when transfer direction is changed during the burst. For type 2 interfaces, data is sampled by the WR/RD signals (system 80) or by the ENABLE signal (system 68k) and the CS signal stays active during the whole burst.
2. Burst mode with the separate clock DISPB_BCLK. In this mode, data is sampled with the DISPB_BCLK clock. The CS signal stays active during whole burst transfer. Other controls are changed simultaneously with data when the bus state (read, write or wait) is altered. The CS signals and other controls move to non-active state after burst has been completed.
3. Single access mode. In this mode, slave AHB and DMA burst are broken to single accesses. The data is sampled with CS or other controls according the interface type as described above. All controls (including CS) become non-active for one display interface clock after each access. This mode corresponds to the ATI single access mode.

Both system 80 and system 68k interfaces are supported for all described modes.

Additionally, the DI allows a programmable pause between two burst. The pause is defined in the HSP_CLK cycles. It allows to avoid timing violation between two sequential bursts or two accesses to different displays. The range of this pause is from 4 to 19 HSP_CLK cycles.

Asynchronous Parallel Interfaces with Byte Enable Support

Figure 31-142 illustrates burst access mode with sampling by WR/RD signals

- WR_0/1 indicate write access according to different byte
- RD_0/1 indicate read access according to different byte
- DISP#_IF_MODE = 00 (80b)

- DRCT_BE_MODE = 1
- BE_PIN_SEL = 1

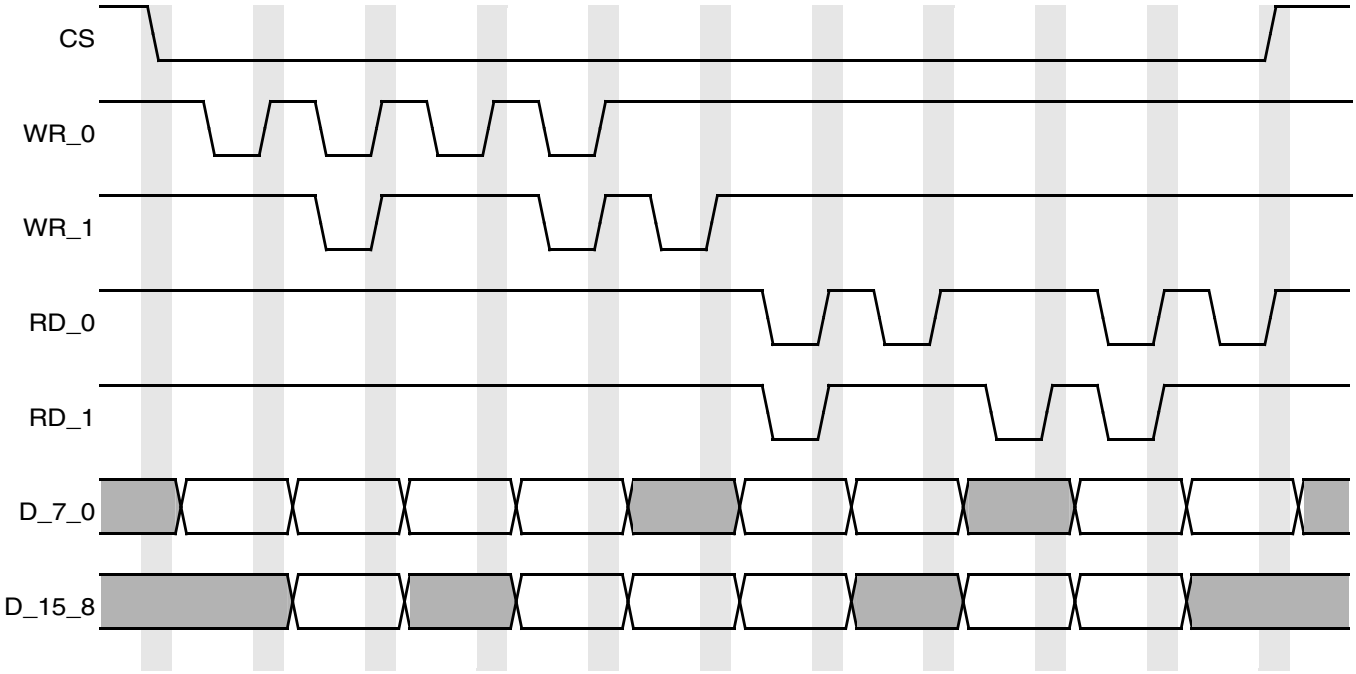

Figure 31-142. System 80 Interface (Type2) with BE

Figure 31-143 illustrates burst access mode with sampling by WR/RD signals

- BE_0/1 select the byte for access
- DISP#_IF_MODE = 01 (80A)
- DRCT_BE_MODE = 1
- BE_PIN_SEL = 1

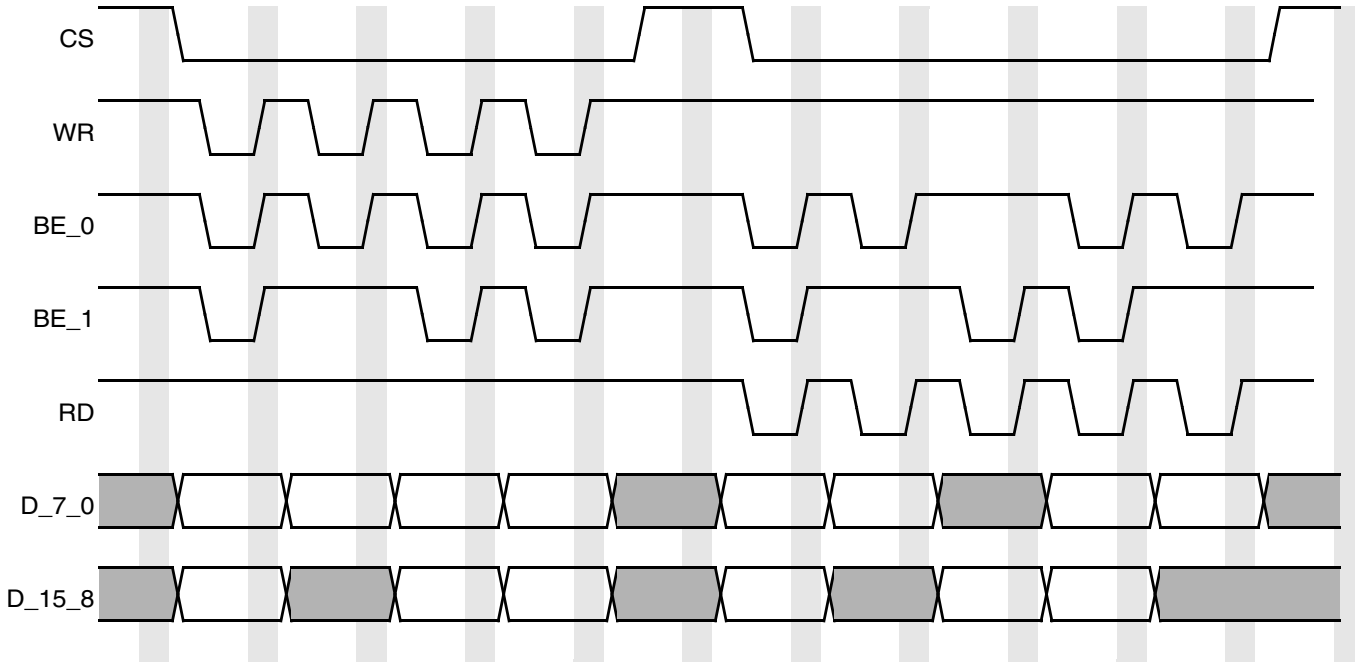

Figure 31-143. System 80 Interface (Type 1) with BE

- DISP#_IF_MODE = 11 (68k b)
- DRCT_BE_MODE = 1
- BE_PIN_SEL = 1

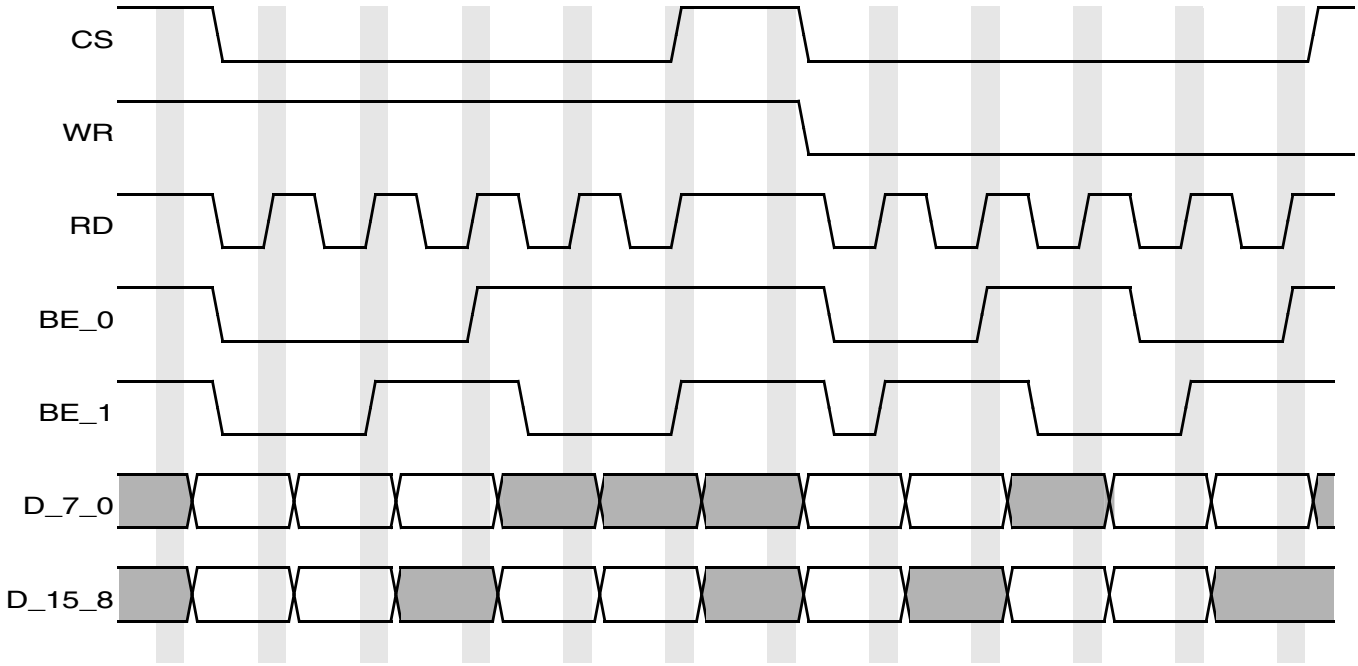

Figure 31-145. System 68 K Interface (Type2) with BE

31.4.6.2.3 Asynchronous Serial Interfaces

The DI supports the following asynchronous serial interfaces:

1. 3-wire (with bidirectional data line).
2. 4-wire (with separate data input and output lines).
3. 5-wire type 1 (with sampling RS by the serial clock).
4. 5-wire type 2 (with sampling RS by the chip select signal).

For serial interfaces, data and preamble lengths and other parameters are controlled via the DI_SER_DISP1_CONF and DI_SER_DISP2_CONF Registers.

31.4.6.3 Display Access Priorities

Display 0 is the primary display. It corresponds to the asynchronous (smart) type with parallel interface. It can be used as the asynchronous part of a dual-port smart display which has both synchronous and asynchronous interfaces.

Displays 1 and 2 are secondary displays. Both of them can be accessed via parallel or serial interfaces. Assignment of the display to one of the interface types via the DI_DISP_IF_CONF Register.

Display 3 is related to the synchronous interface. It can be a dumb display or TV or synchronous part of a dual-port smart display.

Table 31-163 describes the display interfaces and access priorities supported by the DI.

Table 31-163. Display Interfaces and Access Priorities

Access initiator	Priority	Access Type	Information Sent to Display	Data/Command Packing/ Unpacking	Display Number	Interface Type	Comments
SDC	high	write	data	yes	3	parallel	
Core via IP bus interface (low-level access)	medium	write and read	data and commands	yes	0, 1, 2	parallel	
				no	1, 2	serial	access can be performed in parallel with access to parallel interface by other sources
ADC	low	write and read	data and commands	yes	0, 1, 2	parallel	
					1, 2	serial	

According to the priorities, the Arbitrator decides which of initiators request display access will be granted. The Arbitrator takes into account two types of interface resources:

1. Parallel or serial interface required data packing/unpacking (See Table 31-163.)
2. Serial interface without data packing/unpacking (This resource is used only by core low level access.)

When the SDC or the ADC communicates with one of four displays via the parallel interface, the core is allowed to access another display via the serial interface simultaneously.

After grant reception, the initiator asserts a lock signal until access completion. The Arbitrator postpones the next arbitration waiting for negation of the lock signal. Arbitration is postponed for all displays excluding the core access case described above. When the lock signal is negated, arbitration is repeated.

The SDC sends access request just (one row) before start of the active synchronous display frame. It asserts lock signal until end of the active frame. Thus, other initiators can access a display during vertical blanking intervals of the synchronous display or when the SDC skips frames (for dual-port displays, see Section 31.4.4, “Synchronous Display Controller (SDC)”).

31.4.6.4 Bus Mapping Unit

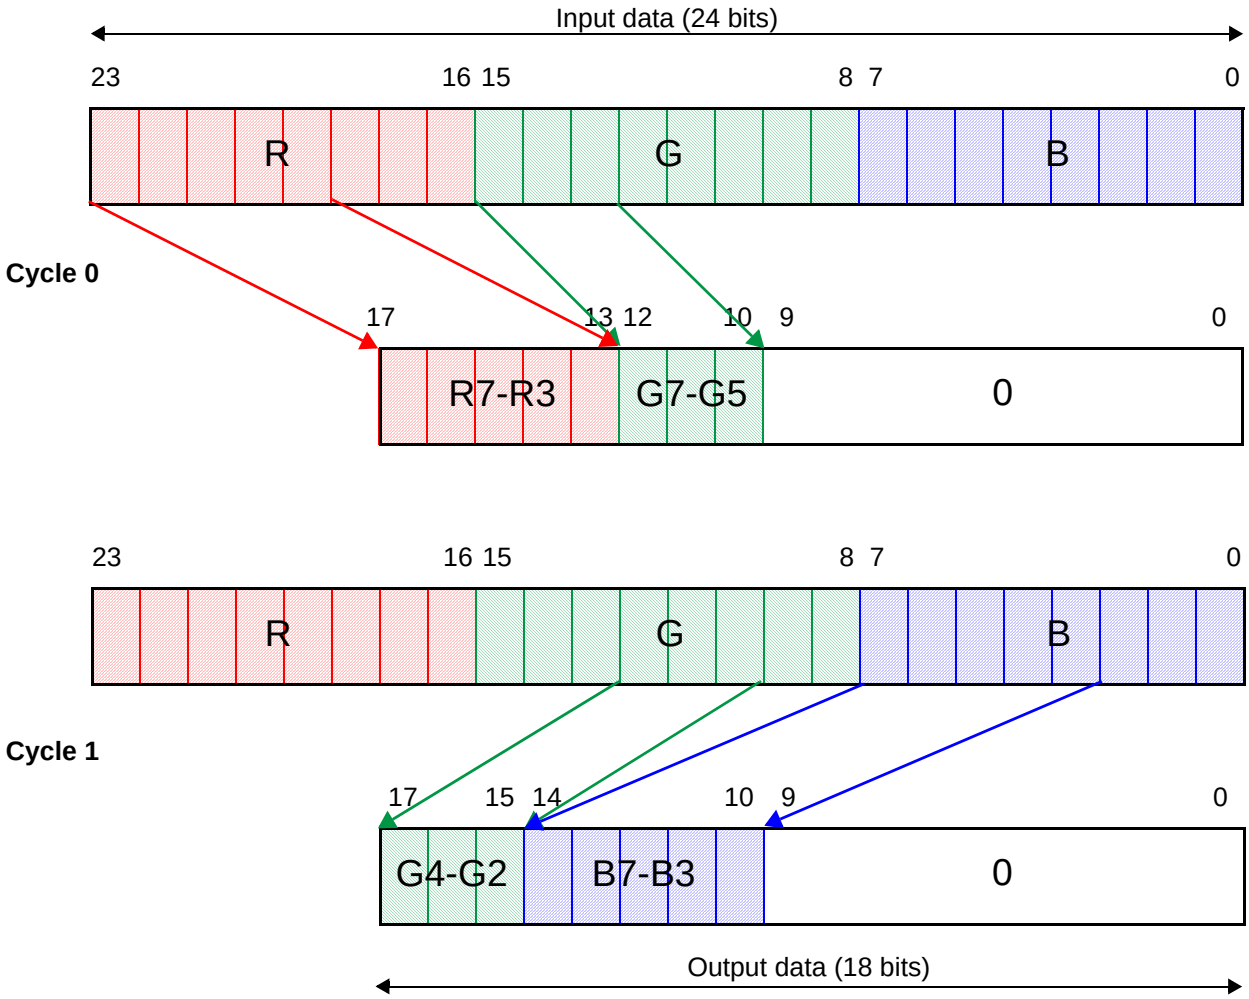
The Bus Mapping Unit is responsible for programmable mapping of the input data and commands to the display interface format and vice versa. The internal DI format for data and commands is a 24-bits word divided into three byte components (eight zeroes are added to MSB for 16-bits words from the ADC). This word can be output or input in one, two, three or four cycles of the display clock.

There are 21 Registers for programming bus mapping: DI_DISP0_DB0_MAP - DI_DISP2_DB2_MAP, DI_DISP0_CB0_MAP - DI_DISP2_CB2_MAP, DI_DISP3_B0_MAP - DI_DISP3_B2_MAP. The registers have identical format. Each of the registers specifies an output/input rule for a certain display (‘DISP0’ - ‘DISP3’ indexes in the Register name) and a certain byte component (‘B0’ - ‘B2’ indexes in the Register name). For all displays excluding display 3 with synchronous interface, there are two different rules: one for a data word and the second for the command word. The corresponding Registers are marked by the ‘_D’ and ‘_C’ suffixes.

The mapping rule written in each of the Registers defines two types of parameters for the specific byte component and display:

1. Offsets of the byte component MSB relative to the output word LSB. Because the offsets can change dynamically, they are defined separately for the display clock cycles zero, one and two.
2. Numbers of display clock cycles at which every bit of the byte component should be valid on the display bus. There are eight such 2-bit numbers in the Register.

Figure 31-146 presents an example of programming data packing for one of displays.



Byte 2 (red)	OFFS0=17	OFFS1=0	OFFS2=0	M0=11	M1=11	M2=11	M3=00	M4=00	M5=00	M6=00	M7=00

31.4.6.5 Timing Control

The timing control provides clocking and other timing signals for each of displays. The following timing parameters are programmable for each display via the DI_HSP_CLK_PER, DI_DISP0_TIME_CONF_1 - DI_DISP2_TIME_CONF_3, DI_DISP3_TIME_CONF Registers:

1. Period of the HSP_CLK clock. It is required for holding unchanged display timing when the HSP_CLK rate is changed on-the-fly (see Section 31.1.1.3.2, “Changing Clock Rates and Disabling Clocks”). The period has an integer part (3 bits) and a fractional part (4 bits).
2. Period of the display interface clock (DISP#_IF_CLK) for display write access. It has an integer part (8 bits) and a fractional part (4 bits). The fractional part allows to define an average period of the clock with high resolution. An current value of the period has the resolution of one HSP_CLK period.
3. Positions of the display interface clock positive and negative edges relative to data timing for display write access. The positions include an integer part (9 bits) and a fractional part (1 bits). The resolution of the positions is a half of the HSP_CLK period.
4. Period of the display interface clock (DISP#_IF_CLK) for display read access (excluding display 3). It has an integer part (8 bits) and a fractional part (4 bits). The fractional part allows to define an average period of the clock with high resolution. An current value of the period has the resolution of one HSP_CLK period.
5. Positions of the display interface clock positive and negative edges relative to data/address timing for display read access (excluding display 3). The positions include an integer part (9 bits) and a fractional part (1 bits). The resolution of the positions is a half of the HSP_CLK period.
6. Period of the display pixel clock (DISP#_PIX_CLK) for display read access. For display 3, this parameter is derived from the display interface clock period and the number of clocks required to output one pixel (see the DI_DISP_ACC_CC Register). It has an integer part (8 bits) and a fractional part (4 bits). The fractional part allows to define an average period of the clock with high resolution. An current value of the period has the resolution of one HSP_CLK period.

   The display clock period is required for generation of the VSYNC and HSYNC signals in the SDC and the ADC and fulfilling the tearing elimination function in the ADC.
7. Position of data sampling point relative to address timing (excluding display 3) for display read access. This timing includes two parts: a position within the display interface clock period and a number of display interface clock cycles before reading (the number of wait states). The position within the display interface clock period includes an integer part (9 bits) and a fractional part (1 bits). The resolution of the current position value is one HSP_CLK period.

Clock rates and phases relative to data are programmable. The Timing Control allows on-the-fly change of the reference clock frequency as described in Section 31.1.1.3.2, “Changing Clock Rates and Disabling Clocks.”

31.4.6.6 Bus Controls Converter

This unit provides control over interface signals polarity according to the settings of the DI_DISP_SIG_POL Register. All display bus outputs have identical delays relative to the HSP_CLK clock positive or negative edge (depending on which edge the signal is generated).

31.4.7 Image DMA Controller (IDMAC)

31.4.7.1 Block Diagram

Figure 31-154 shows the IDMAC block diagram.

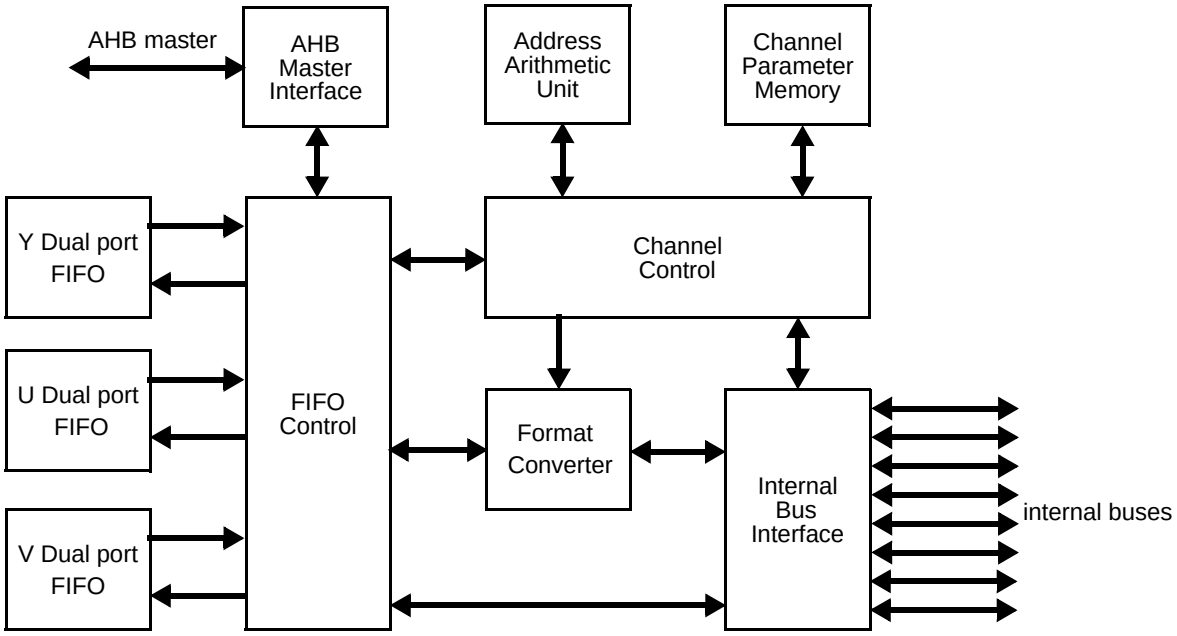

Figure 31-154. IDMAC Block Diagram

The IDMAC consists of three dual port FIFOs, the FIFO control, format converter, address arithmetic unit, channel parameter memory, channel control, internal bus interface, and AHB master interface.

The IDMAC is controlled via the peripheral bus registers and the channel parameter memory.

31.4.7.2 DMA channels

There are 32 DMA channels. Table 31-164 contains description of all the channels.

Table 31-164. IDMAC Channels

Number	Name	Source	Destination	Processing Flow Purpose
0	DMAIC_0	IC	Memory	Preprocessing data from IC (encoding task) to memory
1.A[1]	DMAIC_1	IC	Memory	Preprocessing data from IC (viewfinder task) to memory
1.B	DMAADC_0	IC	ADC	Preprocessing data from IC (viewfinder task) to smart display
2.A[2]	DMAIC_2	IC	Memory	Postprocessing data from IC to memory
2.B	DMAADC_1	IC	ADC	Postprocessing data from IC to smart display
3	DMAIC_3	Memory	IC	Graphics data for combining (viewfinder task)
4	DMAIC_4	Memory	IC	Graphics data for combining (post-processing task)

Table 31-164. IDMAC Channels (Continued)

Number	Name	Source	Destination	Processing Flow Purpose
5	DMAIC_5	Memory	IC	Postprocessing data from memory
6	DMAIC_6	Memory	IC	Preprocessing data from sensor stored in memory (for example Bayer)
7	DMAIC_7	IC	Memory	Direct data from IC (sensor data) to memory
8	DMAIC_8	IC	Memory	Preprocessing data after rotation (encoding task)
9	DMAIC_9	IC	Memory	Preprocessing data after rotation (viewfinder task)
10	DMAIC_10	Memory	IC	Preprocessing data for rotation (encoding task)
11	DMAIC_11	Memory	IC	Preprocessing data for rotation (viewfinder task)
12	DMAIC_12	IC	Memory	Postprocessing data after rotation
13	DMAIC_13	Memory	IC	Postprocessing data for rotation
14	DMASDC_0	Memory	SDC	Background data (full refresh)
15	DMASDC_1	Memory	SDC	Foreground data
16	DMASDC_2	Memory	SDC	Mask data
17	DMASDC_3	Memory	SDC	Background data (partial refresh)
18	DMAADC_2	Memory	ADC	System channel 1 write data
19	DMAADC_3	Memory	ADC	System channel 2 write data
20	DMAADC_4	Memory	ADC	Commands stream for system channel 1
21	DMAADC_5	Memory	ADC	Commands stream for system channel 2
22	DMAADC_6	ADC	Memory	System channel 1 read data
23	DMAADC_7	ADC	Memory	System channel 2 read data
24	DMAPF_0	Memory	PF	PF parameters (quantization parameters for MPEG-4 and H.264 and filter offsets for H.264)
25	DMAPF_1	Memory	PF	PF parameters (boundary strength for H.264)
26	DMAPF_2	Memory	PF	Y input data
27	DMAPF_3	Memory	PF	U input data
28	DMAPF_4	Memory	PF	V input data
29	DMAPF_5	PF	Memory	Y output data
30	DMAPF_6	PF	Memory	U output data
31	DMAPF_7	PF	Memory	V output data

1 Channels 1.A and 1.B, 2.A and 2.B do not work simultaneously. Therefore they use the same channel parameters.

2 Channels 2.A and 2.B, 2.A and 2.B do not work simultaneously. Therefore they use the same channel parameters.

The channel parameters are stored in the channel parameter memory. For each channel, two 132-bits parameter words are used. The parameters are explained in Table 31-29 through Table 31-33. There are two types of the parameters: constant and variable. Most of the constant parameters should be written by the core before enabling the channel. Only the base address for non-active data buffer allowed to be changed during channel operation. The variable parameters are written by the IDMAC during channel operation. The core is not allowed to change the variable parameters in this time interval but it should clear them before channel enabling. The core can access the channel parameter memory via the IPU_IMA_ADDR and IPU_IMA_DATA registers.

According to the channel type, two parameter formats can be used: for channels transferred YUV non-interleaved data with interleaving/de interleaving and for channels transferred YUV or RGB interleaved data.

31.4.7.3 Address Calculation

The following main addressing parameters are used:

- XB—Horizontal pixel position in frame
- YB—Vertical pixel position in frame
- SL—Stride line minus 1 (gap in bytes between two pixels in the same column in two consecutive rows).
- SX—Horizontal pixel scrolling offset
- SY—Vertical pixel scrolling offset
- EBA—Frame buffer base address in bytes (there are two such parameters to support double buffering)
- BPP—Bits per pixel
- FW—Frame width minus 1
- FH—Frame height minus 1

Relations between the addressing parameters and image frame are shown in Figure 31-155.

The system memory address in bytes is calculated as:

$$ADDR = EBA + (XB + SX) \cdot BPP + (YB + SY) \cdot (SL + 1)$$

with $0 < XB =< FW$ and $0 < YB =< FH$.

When double buffering is used, the EBA0 is the base address of the buffer 0 and the EBA1 is the base address of the buffer 1. The IPU_CHA_CUR_BUF register is a status register. It contains 1-bit pointers to the current working buffers for all IPU DMA channels. The IPU automatically toggles a pointer after completion of the current buffer processing. If the core is a data source for specific double-buffered channel, it should check this status bit in order to know what is the IPU current buffer. The core is allowed to write to the buffer only when a working DMA channel does not use it. After the core has been fill the buffer, it has to set the corresponding bit in the IPU_CHA_BUF0_RDY and IPU_CHA_BUF1_RDY registers. If needed, the core can only clear the pointer by writing 1 but not set it.

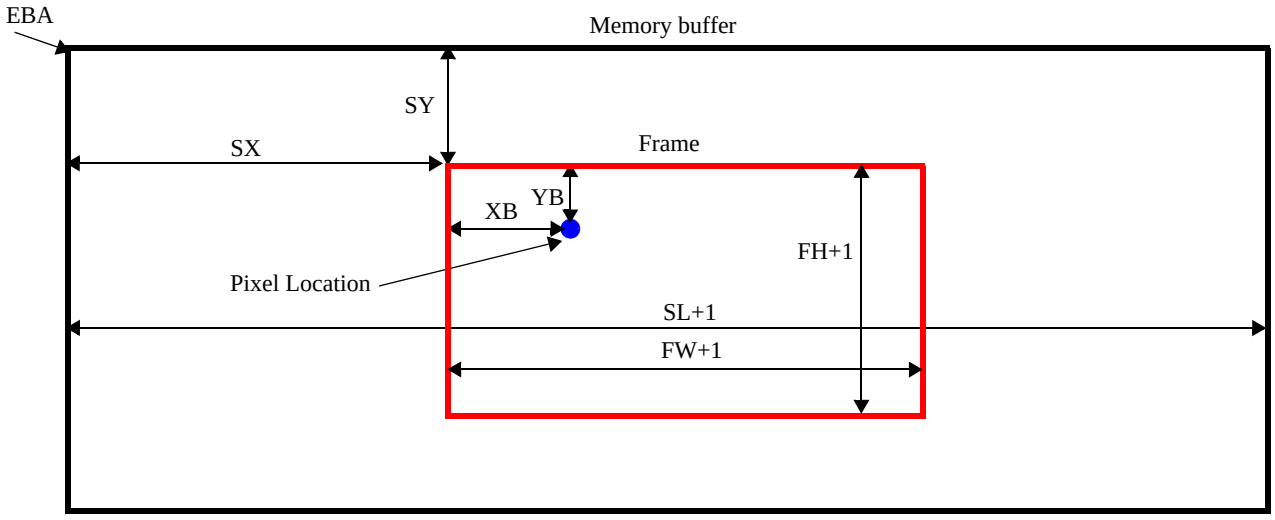

Figure 31-155. Addressing Parameters and Image Frame

The XB and YB coordinates are calculated according to addressing mode. There are two addressing modes:

- 2D mode
- Block mode

In 2D mode the pixel data is transferred to the memory row-by-row. There are two ways to use 2D mode: start from YB = 0 and finish at YB =< FH (YB is incremented) or start from YB = FH and finish at YB =< 0 (YB is decremented). The second option provides vertical flip of the image.

In block mode the frame is divided into blocks. This is needed for rotation or post-filtering, where the order used for data transfers is block-by-block. The order of the block transfer is according to the BAM bits in the IDMAC channel parameter memory. The order within the block is row-by-row where the block size is limited by the block width (BW) and block height (BH) parameters. The BW and BH parameters are set by the PF or the IC rotation section and cannot be configured through the channel parameter memory.

The channel control is responsible for the address calculation flow. It takes channel parameters from the channel parameter memory, updates them and controls the address arithmetic unit.

31.4.7.4 Format Converter

The Format Converter performs packing/unpacking the pixels with programmable position and width of color components, decoding 4- or 8-bits coded pixels according to a loaded look-up table, panning of an image read from the system memory according to a panning offset (start pixel address). The format converter supports formats with a pixel width of 4, 8, 16, 24 or 32 bits. Formatting parameters are written in the channel parameter memory (see Table 31-29 through Table 31-33). The following parameters are used:

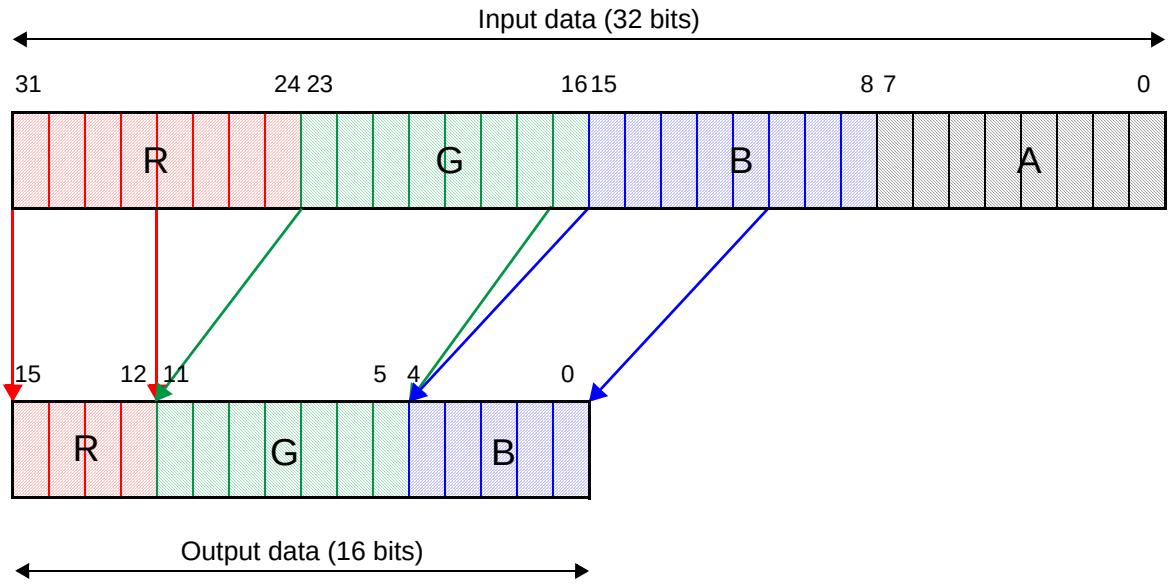
- Offset OFS0 between MSB position of the color component 0 and MSB position of packed pixel. The color component 0 occupies the most significant bits of the unpacked pixel (mostly this is the

R component). For read specified DMA channels, the OFS0 range is from 0 to 31. For write specified DMA channels, the OFS0 range is from 0 to 23.

- Color component 0 width WID0 minus 1.
- Offset OFS1 between MSB position of the color component 1 and MSB position of packed pixel. The color component 1 occupies the middle left bits of the unpacked pixel (mostly this is the G component). For read specified DMA channels, the OFS1 range is from 0 to 31. For write specified DMA channels, the OFS1 range is from 0 to 23.
- Color component 1 width WID1 minus 1.
- Offset OFS2 between MSB position of the color component 2 and MSB position of packed pixel. The color component 2 occupies the middle right bits of the unpacked pixel (mostly this is the B component). For read specified DMA channels, the OFS2 range is from 0 to 31. For write specified DMA channels, the OFS2 range is from 0 to 23.
- Color component 2 width WID2 minus 1.
- Offset OFS3 between MSB position of the color component 3 and MSB position of packed pixel. The color component 3 occupies the least significant bits of the unpacked pixel (mostly this is the A component). For read specified DMA channels, the OFS3 range is from 0 to 31. For write specified DMA channels, the OFS3 value is ignored and the real offset is set to 24 bits. The A value is undefined in these cases.
- Color component 3 width WID3 minus 1. For write specified DMA channels, the OFS3 value is ignored and the real offset is set to 24 bits.

The format converter is bypassed for internal IPU data transfers, for monochrome data transfer to the SDC (but panning is still performed), for generic data transfers and for data transfers to/from the PF.

Figure 31-156 and Figure 31-157 show examples of data packing and unpacking.



Byte 0 (red) **OFS0 = 0** **WID0 = 3**
Byte 1 (green) **OFS1 = 4** **WID1 = 6**
Byte 2 (blue) **OFS2 = 11** **WID2 = 4**

Figure 31-156. Example of Packing

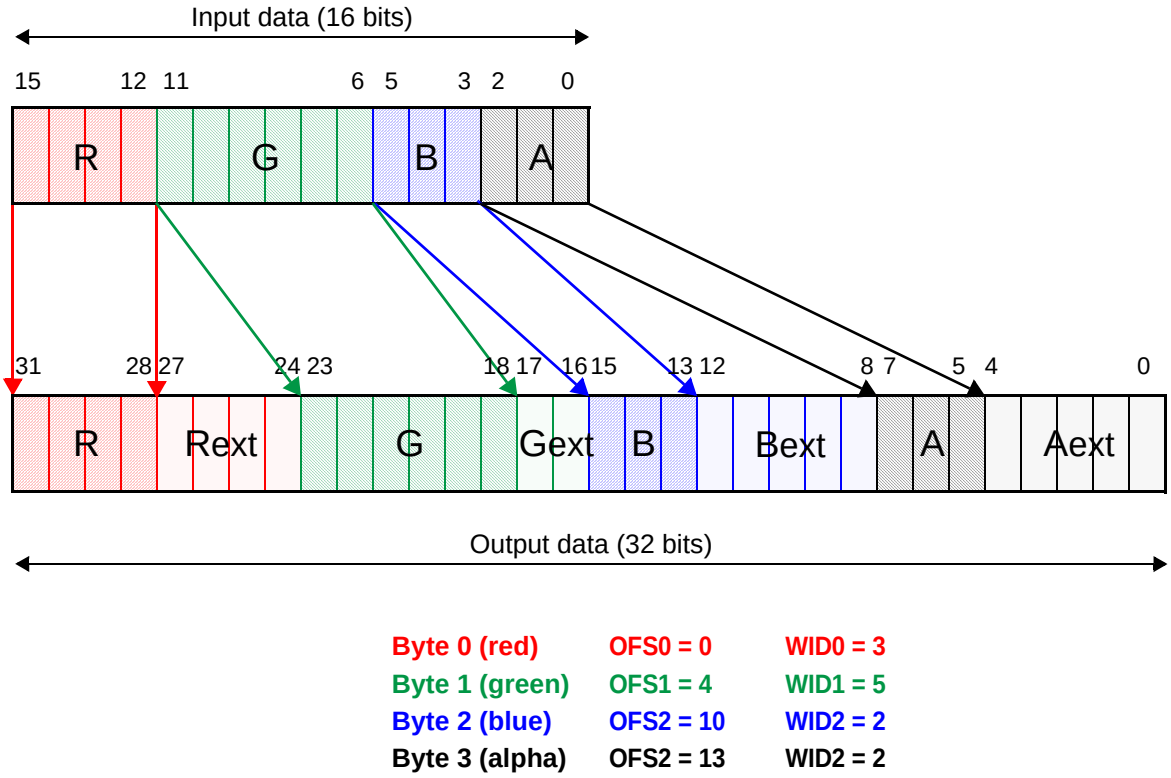


Figure 31-157. Example of Unpacking

If read data has the coded format, it is decoded via the look-up table. The Look-Up Table Memory (see Section , “IDMAC Look-Up Table Memory) must be loaded at the IDMAC initialization step. The LUT output format must match the IPU internal format RGBA 8888 where R is placed in MSB and A is placed in LSB. The A field is used only for graphics data.

31.4.7.5 Internal Bus Interface

The internal bus interface provides arbitration of internal DMA requests. There are two groups of DMA priorities—high and low. Each channel can get one of two priorities according to the IDMAC_CHA_PRI Register. Within a group, channel priorities are changed cyclically (round-robin method). If a channel has been granted for data transfer, it can transfer up to 4 bursts sequentially.

The internal bus interface supports internal DMA buses protocol. If a DMA channel is enabled it can start data transfer after receiving both the new frame signal and the transfer request from an internal module. Transfer continues every time when the request is active. At the end of the frame, data transfer for the channel is paused until the next new frame is arrived.

31.4.7.6 Dual Port FIFOs

The dual port FIFOs are used only for access to the external memory. They store different color components in the case of non-interleaved pixel formats. For interleaved pixel formats, only the Y dual port is used. Each FIFO contains two pages.

The FIFO control provides read/write access to the FIFOs and supports pixel components interleaving/deinterleaving.

31.4.7.7 AHB Master Interface

The AHB master interface is responsible for data transfer from/to the system memory. The Interface supports only 32-bits burst accesses. For burst access, non-aligned addressing with 8-, 16- or 24-bits offsets is allowed. Two byte endian modes (LE, BE32) and two pixel endian modes are supported. The Interface swaps bytes and pixels according to the byte endian mode signal, the pixel endian parameter from the IPU_CONF register and the BPP and BEM channel parameters. The AHB clock rate may be equal or lower than the HSP_CLK clock rate.

31.4.8 Control Module (CM)

31.4.8.1 Block Diagram

Figure 31-158 shows the CM block diagram.

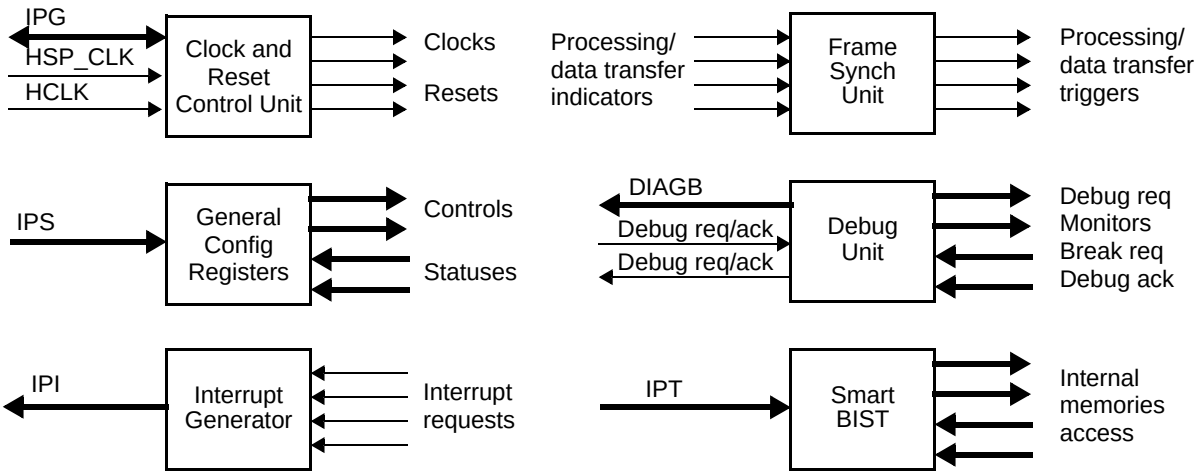

Figure 31-158. CM Block Diagram

The CM consists of the frame synchronization unit (FSU), the Interrupt generator (IG), the Debug unit (DU), the general configuration registers (GCR), the clock and reset control unit (CRCU).

31.4.8.2 Frame Synchronization Unit (FSU)

31.4.8.2.1 General Description

The FSU provides synchronization of tasks performed by different IPU submodules and core tasks. This allows to build complex processing flows which are performed automatically (without core involvement in synchronization IPU tasks). The FSU supports double buffering of image frames stored in the external memory and allows chaining IPU processing flows in automatic mode. Table 31-165 describes the most important use cases of chaining the IPU tasks.

Table 31-165. Use Cases of Chaining the IPU Tasks

Flow	Tasks chain	DMA Channels		
		Video Input	Other Input	Output
Capturing image from sensor and storing it in the memory without processing[1]	CSI --> IC --> MEM	---	---	DMAIC_7
Preprocessing raw image from dumb sensor for encoding	CSI --> IC --> MEM	---	---	DMAIC_7
	MEM or CSI[2] --> IC (PRP ENC) --> MEM	DMAIC_6	---	DMAIC_0
Preprocessing image from smart sensor for encoding	CSI --> IC (PRP ENC) --> MEM	---	---	DMAIC_0
Preprocessing and rotation of raw image from dumb sensor for encoding	CSI --> IC --> MEM	---	---	DMAIC_7
	MEM or CSI[2] --> IC (PRP ENC) --> MEM	DMAIC_6	---	DMAIC_0
	MEM --> IC (ROT ENC) --> MEM	DMAIC_10	---	DMAIC_8
Rotation and preprocessing of raw image from dumb sensor for encoding	CSI --> IC --> MEM	---	---	DMAIC_7
	MEM --> IC (ROT ENC) --> MEM	DMAIC_10	---	DMAIC_8
	MEM --> IC (PRP ENC) --> MEM	DMAIC_6	---	DMAIC_0
Preprocessing and rotation of image from smart sensor for encoding	CSI --> IC (PRP ENC) --> MEM	---	---	DMAIC_0
	MEM --> IC (ROT ENC) --> MEM	DMAIC_10	---	DMAIC_8
Preprocessing raw image from dumb sensor for viewfinder and displaying it on synchronous display	CSI --> IC --> MEM	---	---	DMAIC_7
	MEM or CSI[2] --> IC (PRP VF) --> MEM	DMAIC_6	DMAIC_3	DMAIC_1
	MEM --> SDC (BG/FG)	DMASDC_0/1	DMASDC_2	---

Table 31-165. Use Cases of Chaining the IPU Tasks (Continued)

Flow	Tasks chain	DMA Channels

Flow	Tasks chain	DMA Channels		
		Video Input	Other Input	Output
Postfiltering (optional before any PP path)	MEM --> PF --> MEM	DMAPF_0/1/2/3/4	---	DMAPF_5/6/7
Synchronous display refresh	MEM --> SDC (BG/FG)	DMASDC_0/1	DMASDC_2	---
Asynchronous display refresh	MEM --> ADC (SYS1/2)	DMAADC_2/3	DMAADC_4/5	---
Reading data from asynchronous display	ADC (SYS1/2) --> MEM	---	---	DMAADC_6/7

1 In order to provide this flow, the RWS_EN bit should be 1, and the DMAIC_ 6_ BUF0_ RDY and DMAIC_ 6_ BUF1_ RDY bits for the DMAIC_6 channel should not be set.

2 If RWS_EN=0, the source is the CSI, else the source is the external memory

The FSU provides two mode of tasks synchronization: manual (when the core starts the task) and automatic (when the task is started automatically after finishing a previous chained task). Programming the IPU flows and tasks via the FSU is described by Table 31-166.

Table 31-166. Programming IPU Flows and Tasks

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from sensor directly to the system memory: (CSI --> MEM)	Manual on output (destination - the core)	Task is enabled by at least one of the following conditions: a) CSI_MEM_WR_EN = 0 and RWS_EN = 1 and at least one of PRPENC_EN/PRPVF_EN is 1 or b) CSI_MEM_WR_EN = 1 and RWS_EN = 0 Task is triggered for option (a) by internal signal which comes from CSI (CSI_IC_NF) if DMAIC_7_BUFn_RDY is set. For option (b), task is enabled asynchronously to the sensor frame boundaries. The CSI_MEM_WR_EN bit in the IC configuration register should be set/cleared either when the CSI is disabled or during the ICal blanking interval.	For option (a), the FSU waits for the trigger after the task has been enabled. If the trigger arrives and the output buffer in the system memory is ready, then the FSU signals the IC to start data transferring from the CSI to the system memory. If the trigger arrives and output buffer in the system memory is not ready then the FSU signals the IC to stop working and frame is dropped (the BAYER_FRM_LOST_ERR interrupt is set).
Video coming from the system memory to the IC for preprocessing for encoding and sent back to the system memory. (MEM --> IC (PRP ENC) --> MEM)	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-out flow by setting PRPENC_DEST_SEL to 0 for the core. Task is enabled by RWS_EN = 1 and PRPENC_EN = 1. Task is triggered when both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_6_BUFn_RDY. ENC Input buffer ready is valid by setting ENC_IN_VALID. ENC output buffer ready is indicated by setting DMAIC_0_BUFn_RDY by the core.	After the task is enabled and If input buffer is ready and valid there are two cases: a) the VF task is enabled and its input buffer valid. b) the VF task is not enabled or its input buffer is not valid. In the first case the FSU will signals the IC to start working on encoding task only if both output buffers of VF and ENC are ready. In the second case the FSU will signals the IC to start working on encoding task when ENC output buffer is ready.
	Manual on input (source - the core), automatic on output (destination - the IC (ROT ENC))	Choose auto-out flow by setting PRPENC_DEST_SEL to1 for ROTENC. Task is enabled by RWS_EN = 1 and PRPENC_EN = 1. Task is triggered when both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_6_BUFn_RDY. ENC input buffer ready is valid by setting ENC_IN_VALID. ENC output buffer ready is indicated set by EOF of rotation for encoding channel (DMAIC_10_LBF).	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for pre-processing for view-finder and back to the system memory or directly to the ADC. (MEM --> IC (PRP VF) --> MEM)	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-out flow by setting PRPVF_DEST_SEL to 0. Task is enabled by RWS_EN = 1 and PRPVF_EN = 1. Task is triggered when both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_6_BUFn_RDY. VF input buffer ready is valid by setting VF_IN_VALID. VF output buffer ready is indicated by setting DMAIC_1_BUFn_RDY by the core.	After the task is enabled and If input buffer is ready and valid there are two cases: a) the ENC task is enabled and its input buffer valid. b) the ENC task is not enabled or its input buffer is not valid. In the first case the FSU will signals the IC to start working on encoding task only if both output buffers of VF and ENC are ready. In the second case the FSU will signals the IC to start working on encoding task when VF output buffer is ready.
	Manual on input (source - the core), automatic on output (destination - the IC (ROT VF) or the SDC (BG/FG) or the ADC (SYS1/2))	Choose auto-out flow by setting PRPENC_DEST_SEL to: - 1 for ROTVF - 2 for the ADCSYS1 - 3 for the ADCSYS2 - 4 for the SDCBG - 5 for the SDCFG - 6 for the ADC direct. Task is enabled by RWS_EN = 1 and PRPVF_EN = 1. Task is triggered when both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_6_BUFn_RDY. VF input buffer ready is valid by setting VF_IN_VALID. VF output buffer ready is indicated by EOF of the DMA channel which is defined by PRPENC_DEST_SEL. For SDCBG, SDCFG, ADC direct output buffer is always ready	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from sensor to the IC for pre-processing for encoding and back to the system memory. (CSI --> IC (PRP ENC) --> MEM)	Manual on output (destination - the core)	Choose manual-out flow by setting PRPENC_DEST_SEL to 0 for the core. Task is enabled by RWS_EN = 0 and PRPENC_EN = 1. Task is triggered by CSI internal output (CSI_IC_NF) if output buffer is ready. ENC input is valid by SKIP_ENC_FRM = 0. ENC output buffer ready is indicated by setting DMAIC_0_BUFn_RDY by the core.	After the task is enabled, the FSU waits for its trigger. If the trigger arrives and the output buffer in the system memory is ready, then the FSU signals the IC to start processing the data from the CSI and send it to the system memory after processing. If the trigger arrives and output buffer in the system memory is not ready then the FSU signals the IC to stop working and frame is dropped (ENC_FRM_LOST_ERR interrupt is set).
	Automatic on output (destination - the IC (ROT ENC))	Choose auto-out flow by setting PRPENC_DEST_SEL to 1for the core. Task is enabled by RWS_EN = 0 and PRPENC_EN = 1. Task is triggered by CSI internal output (CSI_IC_NF) if output buffer is ready. ENC input is valid by SKIP_ENC_FRM = 0. ENC output buffer ready is indicated by EOF of rotation for encoding channel (DMAIC_10_LBF).	
Video coming from sensor to the IC for pre-processing for view-finder and back to the system memory. (CSI --> IC (PRP VF) --> MEM), CSI --> IC (PRP VF) --> ADC (PRP))	Manual on output (destination - the core)	Choose manual-out flow by setting PRPVF_DEST_SEL to 0 for the core. Task is enabled by RWS_EN = 0 and PRPVF_EN = 1. Task is triggered by CSI internal output (CSI_IC_NF) if output buffer is ready. VF input is valid by SKIP_VF_FRM = 0. ENC output buffer ready is indicated by setting DMAIC_1_BUFn_RDY by the core.	After the task is enabled, the FSU wait for its trigger. If the trigger arrives and the output buffer in the system memory is ready, then the FSU signals the IC to start working - process the data from CSI and send it to the system memory after processing. If the trigger arrives and output buffer in the system memory is not ready then the FSU signals the IC to stop working and frame is dropped (VF_FRM_LOST_ERR interrupt is set).
	Automatic on output (destination - the IC (ROT VF) or the SDC or the ADC)	Choose auto-out flow by setting PRPVF_DEST_SEL to: - 1 for ROTVF. - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for the SDCBG. - 5 for the SDCFG. - 6 for the ADC direct. Task is enabled by RWS_EN = 0 and PRPVF_EN = 1. Task is triggered by CSI internal output (CSI_IC_NF) if output buffer is ready. VF input is valid by SKIP_VF_FRM = 0. VF output buffer ready is indicated by EOF of the DMA channel which is defined by PRPVF_DEST_SEL.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for rotation for encoding and back to the system memory. (MEM --> IC (ROT ENC) --> MEM)	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-in flow by setting PRPENC_ROT_SRC_SEL to 0 for the core. Task is enabled by PRPENC_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_10_BUFn_RDY by the core. Output buffer ready is indicated by setting DMAIC_8_BUFn_RDY by the core.	After the task is enabled and If input buffer and output buffer are ready, the FSU will signal rotation unit to start working on rotation for encoding task.
	Automatic on input (source - the IC (PRP ENC), manual on output (destination - the core)	Choose auto-in flow by setting PRPENC_ROT_SRC_SEL to 1 for ENC. Task is enabled by PPRPENC_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of encoding task (DMAIC_0_LBF). Output buffer ready is indicated by setting DMAIC_8_BUFn_RDY by the core.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for rotation for view-finder and back to the system memory. (MEM --> IC (ROT VF) --> MEM)	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-in flow by setting PRPVF_ROT_SRC_SEL to 0 for the core. Choose manual-out flow by setting PRPVF_ROT_DEST_SEL to 0 for the core. Task is enabled by PRPVF_ROT = 1. Task is triggered if both input and output buffers are ready. input buffer ready is indicated by setting DMAIC_11_BUFn_RDY by the core. Output buffer ready is indicated by setting DMAIC_9_BUFn_RDY by the core.	After the task is enabled and If input buffer and output buffer are ready, the FSU will signal rotation unit to start working on rotation for view-finder task.
	Automatic on input (source - the IC (PRP VF)), manual on output (destination - the core)	Choose auto-in flow by setting PRPVF_ROT_SRC_SEL to 1 for VF. Choose manual-out flow by setting PRPVF_ROT_DEST_SEL to 0 for the core. Task is enabled by PRPVF_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of encoding task (DMAIC_1_LBF). Output buffer ready is indicated by setting DMAIC_9_BUFn_RDY by the core.	
	Manual on input (source - the core), automatic on output (destination - the SDC or the ADC)	Choose manual-in flow by setting PRPVF_ROT_SRC_SEL to 0 for the core. Choose auto-out flow by setting PRPVF_ROT_DEST_SEL to: - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for the SDCBG. - 5 for the SDCFG. Task is enabled by PRPVF_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_11_BUFn_RDY by the core. Output buffer ready is indicated by EOF of the DMA channel which is defined by PRPVF_ROT_DEST_SEL.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for rotation for view-finder and back to the system memory. (MEM --> IC (ROT VF) --> MEM)	Automatic on input (source - the IC (PRP VF)), automatic on output (destination - the SDC or the ADC)	Choose manual-in flow by setting PRPVF_ROT_SRC_SEL to 1 for VF. Choose auto-out flow by setting PRPVF_ROT_DEST_SEL to: - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for the SDCBG. - 5 for the SDCFG. Task is enabled by PRPVF_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of encoding task (DMAIC_1_LBF). Output buffer ready is indicated by EOF of the DMA channel which is defined by PRPVF_ROT_DEST_SEL.	
Video coming from the system memory to the IC for post-processing and back to the system memory or to the ADC. (MEM --> IC (PP) --> MEM MEM --> IC (PP) --> ADC (PP))	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-in flow by setting PP_SRC_SEL to 0 for the core. Choose auto-out flow by setting PP_DEST_SEL to 0 for the core. Task is enabled by PP_EN = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_5_BUFn_RDY by the core. Output buffer ready is indicated by setting DMAIC_2_BUFn_RDY by the core.	After the task is enabled and If input buffer and output buffers are ready then the FSU will signal the IC to start working on post-processing (PP) task. From now on, the FSU will check if input and output buffers are ready after completion frame processing. If they are ready, it will signal the IC again to start working, else it will wait until the buffer are ready or until task is disabled.
	Manual on input (source - the core), automatic on output (destination - the IC (ROT PP) or the SDC or the ADC)	Choose manual-in flow by setting PP_SRC_SEL to 0 for the core. Choose auto-out flow by setting PP_DEST_SEL to: 1 for ROTPP. 2 for the ADCSYS1. 3 for the ADCSYS2. 4 for the SDCBG. 5 for the SDCFG. 6 for the ADC direct. Task is enabled by PP_EN = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_5_BUFn_RDY by the core. Output buffer ready is indicated by EOF of the DMA channel which is defined by PP_DEST_SEL.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for post-processing and back to the system memory or to the ADC. (MEM --> IC (PP) --> MEM MEM --> IC (PP) --> ADC (PP))	Automatic on input (source - the PF or ROTPP), manual on output (destination - the core)	Choose auto-in flow by setting PP_SRC_SEL to: 1 for the PF. 2 for ROTPP. Choose manual-out flow by setting PP_DEST_SEL to 0 for the core. Task is enabled by PP_EN = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of the DMA channel which is defined by PP_SRC_SEL. Output buffer ready is indicated by setting DMAIC_2_BUFn_RDY by the core.	
	Automatic on input (source - the PF or ROT), automatic on output (destination - ROTPP or the SDC or the ADC)	Choose auto-in flow by setting PP_SRC_SEL to: 1 for the PF for ROTPP. Choose auto-out flow by setting PP_DEST_SEL to: - 1 for ROTPP. - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for the SDCBG. - 5 for the SDCFG. - 6 for the ADC direct. Task is enabled by PP_EN = 1. Task is triggered by EOF of this task (DMAIC_5_LBF). Input buffer ready is indicated by output EOF of the DMA channel which is defined by PP_SRC_SEL. Output buffer ready is indicated by EOF of the DMA channel which is defined by PP_DEST_SEL.

Input buffer ready is indicated by setting DMAIC_13_BUFn_RDY by the core. Output buffer ready is indicated by setting DMAIC_12_BUFn_RDY by the core.	After the task is enabled and If input and output buffers are ready, the FSU will signal the rotation unit to start working on rotation for PP task. From now, the FSU will check if input and output buffers are ready after completion frame processing. If they are ready, it will signal the rotation unit again to start working, else it will wait until the buffer are ready or until task is disabled.
	Manual on input (source - the core), automatic on output (destination - the IC (PP) or the SDC or the ADC)	Choose manual-in flow by setting PP_ROT_SRC_SEL = to 0 for the core. Choose auto-out flow by setting PP_ROT_DEST_SEL to: - 1 for PP. - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for the SDCBG. - 5 for the SDCFG. Task is enabled by PP_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAIC_13_BUFn_RDY by the core. Output buffer ready is indicated by EOF of the DMA channel which is defined by PP_ROT_DEST_SEL.	
	Automatic on input (source - the IC (PP) or the PF), manual on output (destination - the core)	Choose auto-in flow by setting PP_ROT_SRC_SEL to: - 1 for PP. - 2 for the PF. Choose manual-out flow by setting PP_DEST_SEL to 0 for the core. Task is enabled by PP_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of the DMA channel which is defined by PP_ROT_SRC_SEL. Output buffer ready is indicated by setting DMAIC_12_BUFn_RDY by the core.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video coming from the system memory to the IC for rotation for post-processing and back to the system memory. (MEM --> IC (ROT PP) --> MEM)	Automatic on input (source - the IC (PP) or the PF), automatic on output (destination - the IC (PP) or the SDC or the ADC)	Choose auto-in flow by setting PP_ROT_SRC_SEL to: 1 for PP. 2 for the PF. Choose auto-out flow by setting PP_ROT_DEST_SEL to: - 1 for PP. - 2 for the ADCSYS1. - 3 for the ADCSYS2. - 4 for SDCBG. - 5 for the SDCFG. Task is enabled by PP_ROT = 1. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by output EOF of the DMA channel which is defined by PP_ROT SRC_SEL. Output buffer ready is indicated by EOF of the DMA channel which is defined by PP_ROT_DEST_SEL.	
Video coming from the system memory for post-filtering and back to the system memory. (MEM --> PF --> MEM)	Manual on input (source - the core), manual on output (destination - the core)	Choose manual-out flow by setting the PF_DEST_SEL to 0 for the core. Task is enabled by the PF_TYPE ≠ 0b00. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAPF_0/1/2/3/4_BUFn_RDY by the core. Output buffer ready is indicated by setting DMAIC_5/6/7_BUFn_RDY by the core.	After the task is enabled and If input buffer and output buffers are ready, the FSU will signal the PF unit to start working on the post-filtering task. From now on, the FSU will check if input and output buffers are ready after completion current frame processing. If they are ready it will signal the PF unit again to start working, else it will wait until the buffer are ready or until task is disabled.
	Manual on input (source - the core), automatic on output (destination - the IC (ROT PP) or the IC (PP))	Choose manual-out flow by setting the PF_DEST_SEL to: 1 for PP. 2 for PP_ROT. Task is enabled by the PF_TYPE ≠ 0b00. Task is triggered if both input and output buffers are ready. Input buffer ready is indicated by setting DMAPF_0/1/2/3/4_BUFn_RDY by the core. Output buffer ready is indicated by EOF of the DMA channel which is defined by the PF_DEST_SEL.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video or graphics coming from the system memory for display by the SDC as foreground. (MEM --> SDC (FG))	Manual on input (source - the core)	Choose manual-out flow by setting the SDC0_SRC_SEL to 0 for the core. Task is enabled by the SDC_EN = 1. Task is triggered by the FG_EN = 1. Input buffer ready is indicated by setting DMASDC_0_BUFn_RDY.	Task is enabled by the SDC_EN. The SDC sends a request to the FSU for asking if there is a new foreground buffer. The FSU acknowledges if the foreground input buffer is ready. For dumb displays, the SDC sends DMA request for refreshing the foreground plane independently on the FSU acknowledge.
	Automatic on input (the IC (PRP VF) or the IC (PP) or the IC (ROT VF) or the IC (ROT PP))	Choose auto-out flow by setting the SDC0_SRC_SEL to: - 1 for ROTVF. - 2 for ROTPP. - 3 for VF. - 4 for PP. Task is enabled by the SDC_EN = 1. Task is triggered by the FG_EN = 1. Input buffer ready is indicated by EOF of the DMA channel which is defined by the SDC0_SRC_SEL.	
Video or graphics coming from the system memory for display by the SDC as background. (MEM --> SDC (BG))	Manual on input (source - the core)	Choose manual-out flow by setting the SDC0_SRC_SEL to 0 for the core. Task is enabled by the SDC_EN = 1. Task is triggered by the BG_EN = 1. Input buffer ready is indicated by setting DMASDC_0_BUFn_RDY.	Task is enabled by the SDC_EN. The SDC sends a request to the FSU for asking if there is a new background buffer. The FSU acknowledges if the foreground input buffer is ready. For dumb displays, the SDC sends DMA request for refreshing the background plane independently on the FSU acknowledge.
	Automatic on input (the IC (PRP VF) or the IC (PP) or the IC (ROT VF) or the IC (ROT PP))	Choose auto-out flow by setting the SDC1_SRC_SEL to: - 1 for ROTVF. - 2 for ROTPP. - 3 for VF. - 4 for PP. Task is enabled by the SDC_EN = 1. Task is triggered by the BG_EN = 1. Input buffer ready is indicated by EOF of the DMA channel which is defined by the SDC1_SRC_SEL.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video or graphics coming from the system memory for display by the ADC channel 1. (MEM --> ADC (SYS1))	Manual on input (source - the core)	Choose manual-out flow by setting the ADC2_SRC_SEL to 0 for the core. Task is enabled when SYS1_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated by setting DMAADC_2_BUFn_RDY by the core. If SYS1_MODE = 7 (command mode), setting DMAADC_4_BUFn_RDY by the core is also required.	After the task is enabled and If input buffer is ready, the FSU will signal the ADC to start transferring data from memory to display on the system channel 1. From now on, the FSU will check if input and buffer is ready after current frame transfer. If buffer is ready it will signal the ADC again to start working, else it will wait until the buffer is ready or until task is disabled.
	Automatic on input (source - the IC (PRP VF) or the IC (PP) or the IC (ROT VF) or the IC (ROT PP))	Choose manual-out flow by setting the ADC2_SRC_SEL to: - 1 for ROTVF. - 2 for ROTPP. - 3 for VF. - 4 for PP. Task is enabled when SYS1_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated by EOF of the DMA channel which is defined by the ADC2_SRC_SEL. If SYS1_MODE = 7 (command mode), setting DMAADC_4_BUFn_RDY by the core is also required.	
	Snooping mode	Choose snoop mode by setting the ADC2_SRC_SEL to 5. Task is enabled when SYS1_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated when SNOOP signal for channel 1 comes from the EMI towards the IPU.	
	ADC autorefresh	Choose ADC refresh by setting the ADC2_SRC_SEL to 6. Task is enabled when SYS1_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Configure AUTO_REF_PER to the wanted autorefresh period (see the IPU_FS_DISP_FLOW register). Task is triggered if the input buffer is ready. Input buffer ready is indicated when the ADC_REFRESH signal for channel 1 is asserted.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video or graphics coming from the system memory for display by the ADC channel 1. (MEM --> ADC (SYS1))	ADC autorefresh with snooping	Choose ADC refresh with snooping by setting the ADC2_SRC_SEL to 7. Task is enabled when SYS1_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Configure AUTO_REF_PER to the wanted period of refresh time (see IPU_FS_DISP_FLOW register). Task is triggered if the input buffer is ready. Input buffer ready is indicated when the ADC_REFRESH signal for channel 1 is asserted after or with snoop signal.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video or graphics coming from the system memory for display by the ADC channel 2. (MEM --> ADC (SYS2))	Manual on input (source - the core)	Choose manual-out flow by setting the ADC3_SRC_SEL to 0 for the core. Task is enabled when SYS2_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated by setting DMAADC_3_BUFn_RDY by the core. If SYS2_MODE = 7 (command mode), setting DMAADC_5_BUFn_RDY by the core is also required.	After the task is enabled and If input buffer is ready, the FSU will signal the ADC to start transferring data from memory to display on the system channel 2. From now on, the FSU will check if input and buffer is ready after current frame transfer. If buffer is ready it will signal the ADC again to start working, else it will wait until the buffer is ready or until task is disabled.
	Automatic on input (source - the IC (PRP VF) or the IC (PP) or the IC (ROT VF) or the IC (ROT PP))	Choose manual-out flow by setting the ADC3_SRC_SEL to: - 1 for ROTVF. - 2 for ROTPP. - 3 for VF. - 4 for PP. Task is enabled when SYS2_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated by EOF of the DMA channel which is defined by the ADC3_SRC_SEL. If SYS2_MODE = 7 (command mode), setting DMAADC_5_BUFn_RDY by the core is also required.	
	Snooping mode	Choose snoop mode by setting the ADC3_SRC_SEL to 5. Task is enabled when SYS2_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Task is triggered if the input buffer is ready. Input buffer ready is indicated when SNOOP signal for channel 2 comes from the EMI towards the IPU.	
	ADC autorefresh	Choose ADC refresh by setting the ADC3_SRC_SEL to 6. Task is enabled when SYS2_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Configure AUTO_REF_PER to the wanted autorefresh period (see the IPU_FS_DISP_FLOW register). Task is triggered if the input buffer is ready. Input buffer ready is indicated when the ADC_REFRESH signal for channel 2 is asserted.	

Table 31-166. Programming IPU Flows and Tasks (Continued)

Tasks Chain	Frame Synchro-nization Mode	Control Bits Configuration	Description
Video or graphics coming from the system memory for display by the ADC channel 2. (MEM --> ADC (SYS2))	ADC autorefresh with snooping	Choose ADC refresh with snooping by setting the ADC3_SRC_SEL to 7. Task is enabled when SYS2_MODE = 1 or 3 or 5 or 6 or 7 (write to display). Configure AUTO_REF_PER to the wanted period of refresh time (see IPU_FS_DISP_FLOW register). Task is triggered if the input buffer is ready. Input buffer ready is indicated when the ADC_REFRESH signal for channel 2 is asserted after or with snoop signal.	

31.4.8.2.2 Frame Synchronization Flow

1. Initialization

   The core initializes all parameters for a task by writing to the GCR and to the parameters memories which reside in IPU submodules. The initialization must occur before the core enables the task.

2. Enabling

   After the initialization step has been completed, the core enables the task by setting its enable bit in a appropriate register.

3. Triggering

   After the task is enabled, the FSU waits for triggering signal. The triggering signals is a combination of the enable bit and the buffer ready signal which can be driven by the core (DMA<BL>_<#>_BUF_RDY) and/or by the preceding task (DMA<BL>_<#>_EOF).

   The trigger causes the FSU to invoke the relevant unit to start by assertion of the <TASK>_NEW_FRM_RDY signal. In some cases triggering occurs at the enabling step (when the enable bit is the trigger for the task).

4. Operating

   The triggering step cause the task to move to active mode, this is the operating step. In this step, the FSU monitors the synchronization signals from core, IDMAC and the corresponding processing units, and controls the units operation. The FSU also controls the IDMAC buffer toggling when double buffer page flipping is used.

   The FSU checks at end of each frame if the next frame can be served. If the answer is yes, the FSU stays in active mode with re-sending the <TASK>_NEW_FRM_RDY signal and updating the relevant flags (e.g. DMA<BL>_<#>_CUR_BUF and DMA<BL>_<#>_BUF_RDY). If the answer is no, the FSU moves to pause mode and pauses the task waiting until the next frame can be served.

5. Disabling

   When the task is disabled by the core (by negating the enable bit), it moves back to non-active mode.

31.4.8.2.3 Frame Synchronization Example

The following example describes the flow of the pre-processing task in the IC. The example will be explained step by step.

1. Initialization

   The core should initialize all relevant parameters:

   — Initialize the GCR parameters which relevant for this task.

   — Initialize the Task Parameter Memory of the IC with the relevant parameters for this task.

   — Initialize the Channel Parameter Memory of IDMAC: post-processing video input channel (DMAIC_CB5), post-processing graphics input channel (DMAIC_CB4).post-processing video output channel (DMAIC_CB3).

   — Initialize the first input buffer of video and graphics and allocate the buffer for output video, and then set the “BUF0/1_RDY” bits for each ready channel.

2. Enabling

   The core should set the proper bit in GCR for enabling the task. In this example the bit is PP_EN in IC_CONF Register (Figure 31-159).

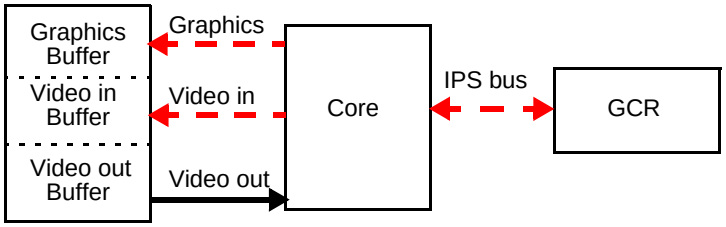

Figure 31-159. Initialization and Enabling Steps

3. Triggering

   In this case, trigger condition is when buffers of input and output video are ready (DMAIC_5(2)_BUF0_RDY is set) and task is enabled (PP_EN are set). Then the FSU sends the PP_NEW_FRM_RDY signal to the IC (Figure 31-160).

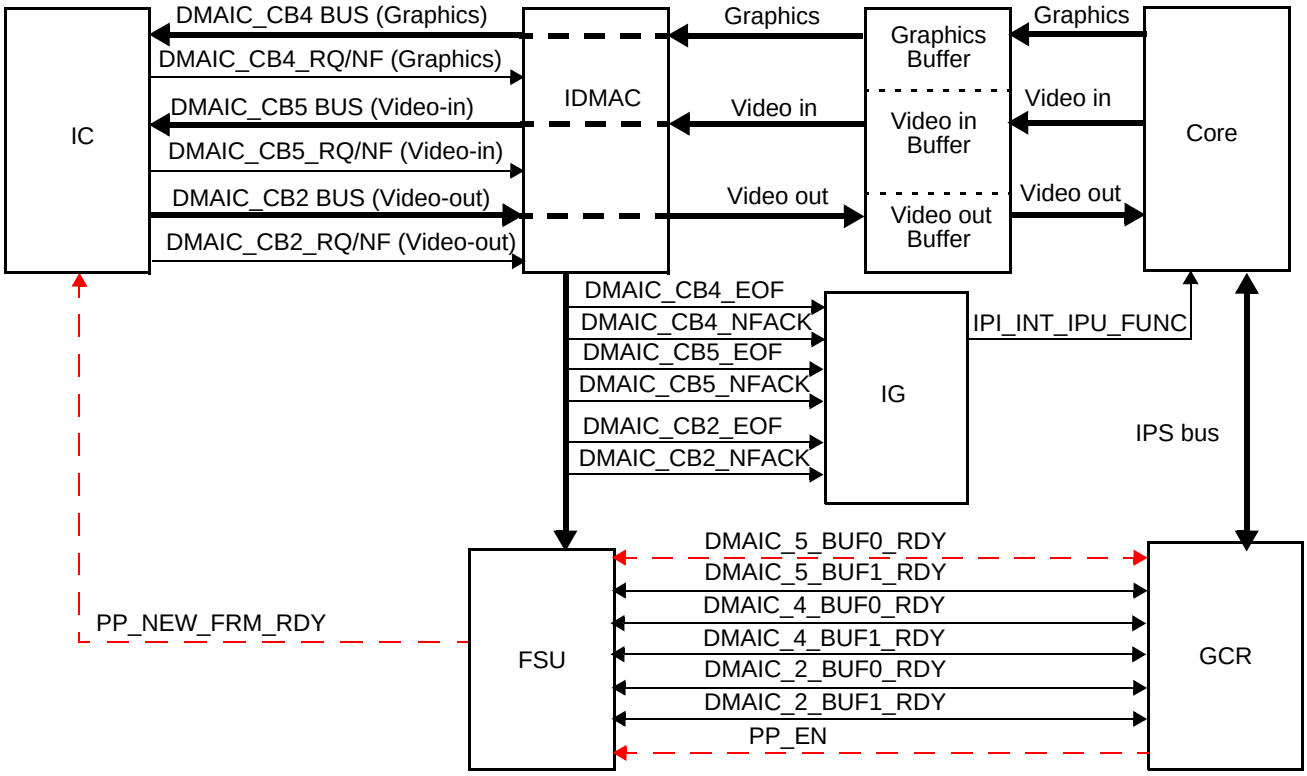

Figure 31-160. Triggering Step

4. Operating

   After the IC has got PP_NEW_FRM_RDY, it sends the DMAIC_CB5_RQ request to the IDMAC for fetching input video from the system memory. (In this case, the IC also sends DMAIC_CB5_NF indicating the first request for the frame).

   The IDMAC starts fetching data from the input video buffer and send it to the IC using DMA internal protocol ((see Figure 31-161). When IDMAC sends acknowledge to IC (DMAIC_CB5_ACK), it also generates the DMAIC_CB5_NFACK signal which indicate that the current request was accompanied with the new frame signal from the IC. This signal is sent to the FSU for buffer toggling when double buffer mode is set and also as an interrupt to the core.

   The FSU resets DMAIC_5_BUF0_RDY to indicate the core that this buffer is read. Meanwhile the core can prepare buffer 1 (in double buffer mode) or wait for end of frame (in single buffer mode).

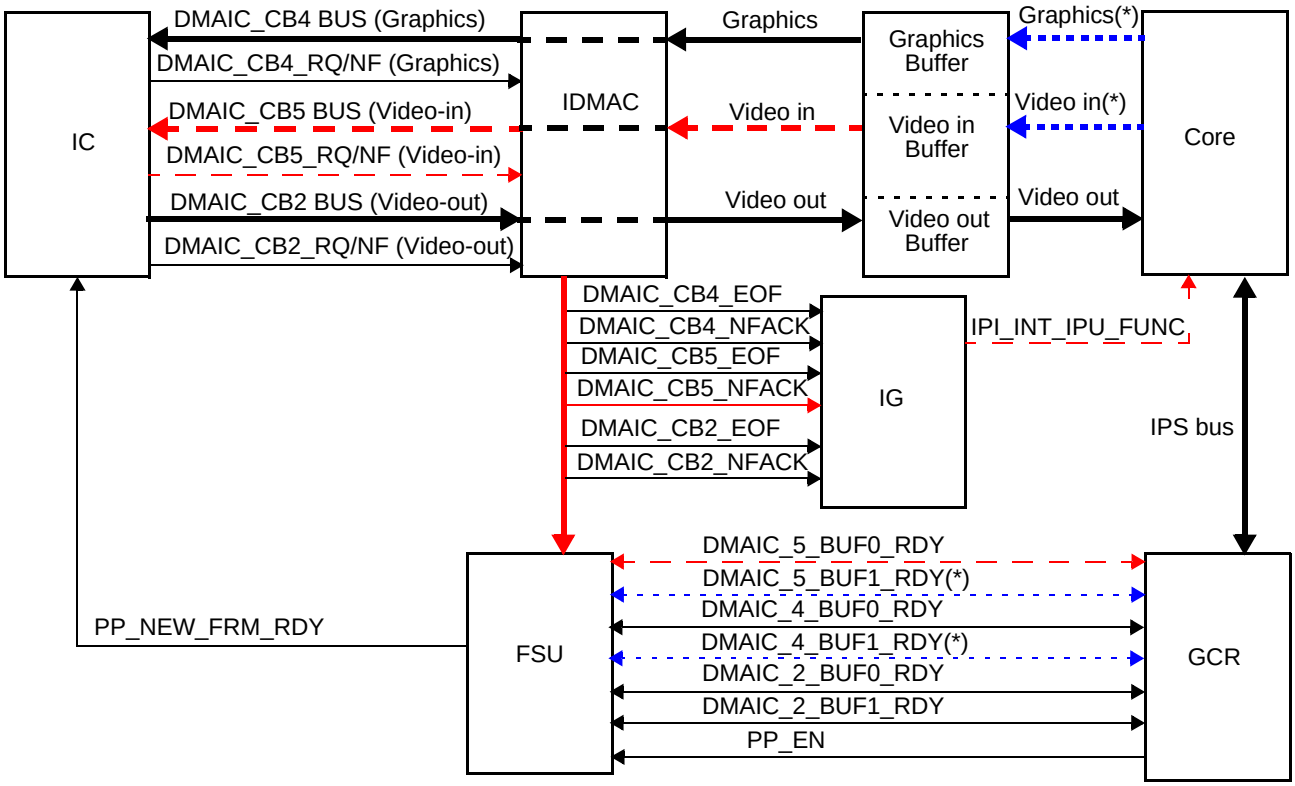

Figure 31-161. Operating Step—First Input Data Fetching

When the IC begins combining (if needs) it should receive graphics data from the DMA channel 4 (see Figure 31-162). The IC sends the request and the new frame signals. The IDMAC fetches graphics data from the input graphics buffer and send it to the IC. The IDMAC also sends DMAIC_CB4_NFACK which causes toggling in the FSU in double buffer mode. The FSU resets DMAIC_4_BUF0_RDY to indicate that the graphics buffer is read.

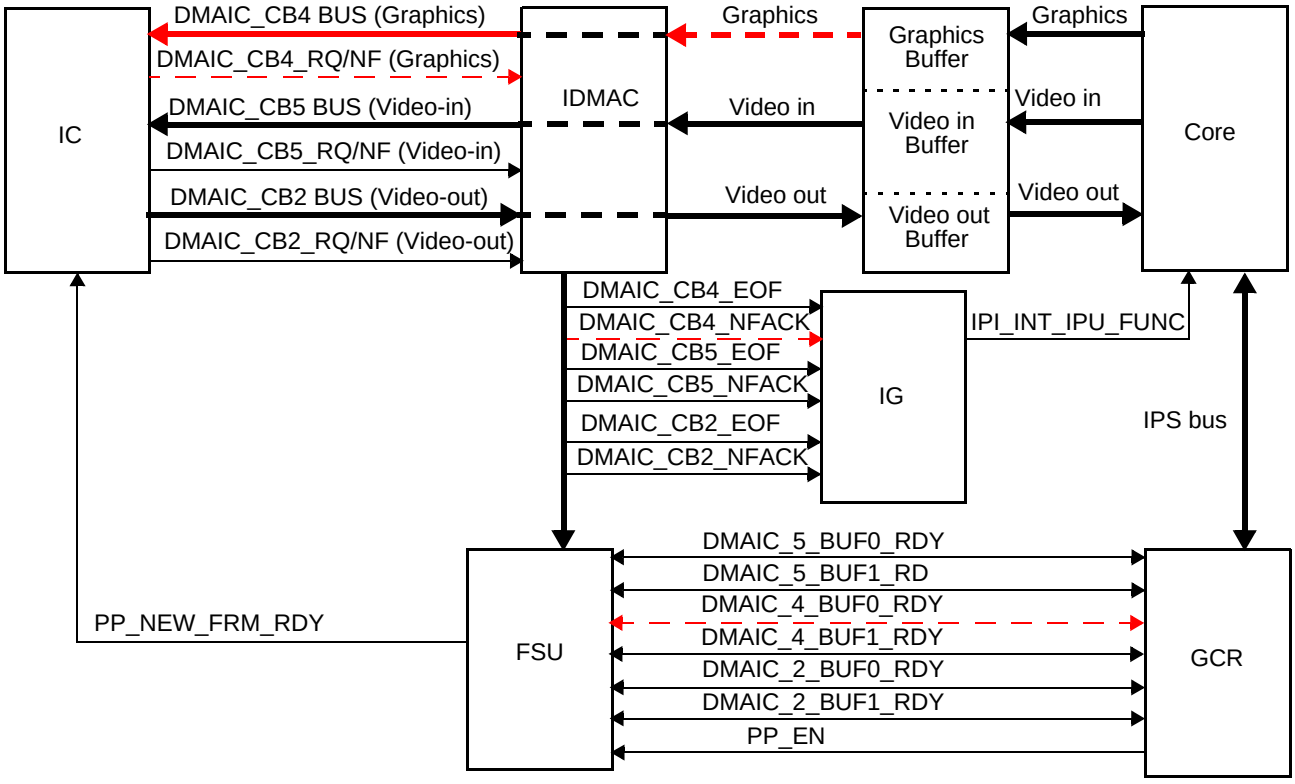

Figure 31-162. Operating Step—First Input Graphics Fetching

When the IC finishes processing the first burst (video and graphics) it send to the IDMAC the request and the new frame signal for output of the video buffer (see Figure 31-163). The IDMAC should transfer the burst to the video output buffer in the system memory. It sends DMAIC_CB2_NFACK to the FSU which causes toggling in the FSU in double buffer mode. The FSU resets DMAIC_2_BUF0_RDY to indicate that the output buffer is being written. The core should wait for finish of writing into output buffer (DMAIC_CB2_EOF) before reading it (*).

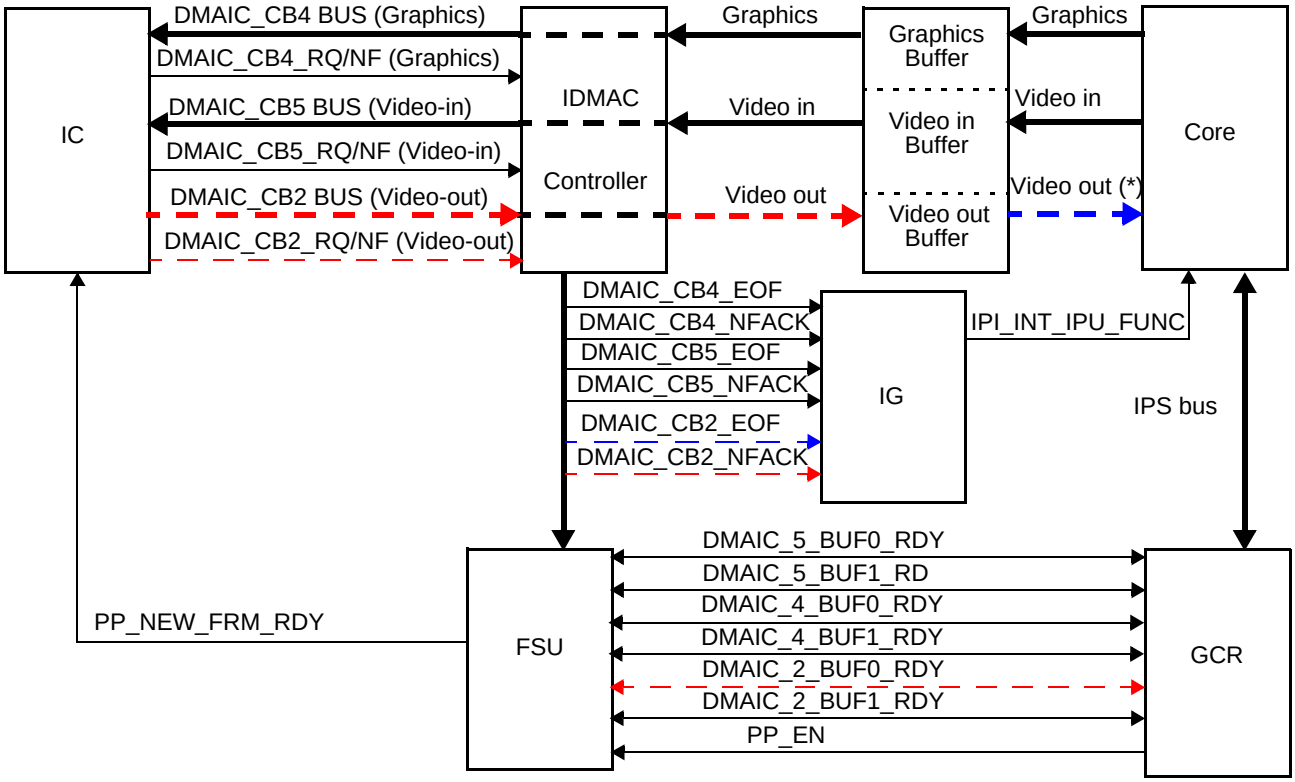

Figure 31-163. Operating Step—First Output Data Writing to the System Memory

When the IC continues processing the current frame, the last three steps are repeated without asserting the new frame signal and the FSU is not involved in the process.

When the whole input frame is read, the IDMAC sends the DMAIC_CB5_EOF signal and masks this channel. The same happens for other channels (graphics channel is masked after all graphics was read and output channel is masked after all output was written to the memory). The FSU monitors only the video input channel end of frame signal (DMAIC_CB5_EOF). When it arrives (also interrupt to the core is sent), the FSU checks if task is still enabled and if the next buffer is ready (BUF1 in double buffer mode and BUF0 in single buffer mode).

The FSU waits for readiness of the buffers. If the buffer is ready, the FSU sends PP_NEW_FRM_RDY to the IC and the whole process starts again. If task is not enabled, then the FSU returns to the idle state.

During current frame processing, the core should fill the next input graphics and video buffers, read the previous output buffer and then set the relevant frame ready bits for each channel. The core can re-configure parameters in the GCR and in parameter memory but only when the task is not active.

31.4.8.3 Interrupt Generator (IG)

The interrupt generator (IG) produces two interrupts to the core—the functional interrupt and the error interrupt. All the interrupts are maskable.

Table 31-167 and Table 31-168 describe both the functional interrupts and the error interrupts.

Table 31-167. Functional Interrupts Summary

Location	Submodule	Interrupt Status Bit Name	Description
IPU_INT_STAT_1	IDMAC	DMAIC_0_EOF	End of frame for IC DMA channel 0
		DMAIC_1_EOF	End of frame for IC DMA channel 1
		DMAIC_2_EOF	End of frame for IC DMA channel 2
		DMAIC_3_EOF	End of frame for IC DMA channel 3
		DMAIC_4_EOF	End of frame for IC DMA channel 4
		DMAIC_5_EOF	End of frame for IC DMA channel 5
		DMAIC_6_EOF	End of frame for IC DMA channel 6
		DMAIC_7_EOF	End of frame for IC DMA channel 7
		DMAIC_8_EOF	End of frame for IC DMA channel 8
		DMAIC_9_EOF	End of frame for IC DMA channel 9
		DMAIC_10_EOF	End of frame for IC DMA channel 10
		DMAIC_11_EOF	End of frame for IC DMA channel 11
		DMAIC_12_EOF	End of frame for IC DMA channel 12
		DMAIC_13_EOF	End of frame for IC DMA channel 13
		DMASDC_0_EOF	End of frame for SDC DMA channel 0

	DI	DI_ADC_LOCK_ERR	Display interface locked for ADC access while SDC access should begin
		DI_LLA_LOCK_ERR	Display interface locked for low level access while SDC access should begin
	IDMAC	AHB_M1_ERR	AHB master 1 error response
		AHB_M2_ERR	AHB master 2 error response

31.4.8.4 Debug Unit (DU)

The debug unit (DU) is able to break IPU data/control flows on a core request on an internal event. The DU is controlled by the IPU_BRK_CTRL_1, IPU_BRK_CTRL_2 and IPU_DIAGB_CTRL Registers. Debug status is reflected by the IPU_BRK_STAT Register.

The internal break event may correspond to a selected point in one of processed data frames or an internal signal or simultaneous fulfillment of both conditions. The DU contains an event counter that allows to perform break after given repetition number of the event.

The break data point is selected by definition of the following conditions:

- DMA channel number or CSI output.
- Frame row number in the IDMAC or in the CSI.
- Frame column number in the IDMAC or in the CSI.

Each of the break data point conditions can be masked independently on other conditions. The masked condition is considered as fulfilled and does not affect break.

Internal break signals are composed in five groups corresponding to IPU interrupts.

There are the following modes of entering debug:

1. IPU internal break forces the core to enter debug. Core entering debug forces the IPU to enter debug.
2. IPU internal break forces the core to enter debug. Core entering debug does not force the IPU to enter debug.
3. IPU internal break does not force the core to enter debug. Core entering debug forces the IPU to enter debug.
4. IPU internal break does not force the core to enter debug. Core entering debug does not force the IPU to enter debug.

Exiting debug mode can be done by setting the DBG_EXIT bit.

The IPU has two debug modes:

- DMA transfer stop without freezing of the HSP_CLK clock
- Freeze of the HSP_CLK clock.

In the first mode, all requests to the IDMAC are masked at the break event. The IDMAC completes current data transfers and stops. Other IPU submodules can continue operation for some time. They stop after filling or emptying the corresponding data FIFOs. The core can check IPU data buffers in the external memory for debug purposes. Proper IPU operation can be resumed by assertion the DBG_EXIT bit in the IPU_BRK_CTRL_1 Register.

In the second mode, all IPU clocks excluding clocks used for IP bus interface registers, memories and the DU are stopped immediately. the core can read all internal IPU memories or monitor the DIAGB bus. Proper IPU operation cannot be resumed on exiting freeze mode.

Additionally, the DU provides real-time monitoring of IPU internal signals via the DIAGB bus, which is output to chip external pins. DIAGB signals are arranged in 19 groups (bus configurations). The core change selection of bus configuration during IPU operation.

31.4.8.5 General Configuration Registers

The GCR contains a set of control/status/data registers. It provides IPU interface to the IPS bus. The IPG_CLK rate can be equal to or lower than the HSP_CLK rate. The detail description of the registers is found in Section 31.3, “Memory Map and Register Definition.”

Chapter 32
JSYNC

32.1 Introduction

The main purpose of the JSYNC module is to synchronize the JTAG interface to the ARM_CLK domain. Additionally, the debug reset signal (**dbg_clear_b**) is generated from the asynchronous resets **jtag_trst_b** and **por_b**. **dbg_clear_b** is asserted asynchronously and negated synchronously.

The debugger detector circuit will detect a debug request and sync it to the ARM_CLK. The debug request is captured and held until the debug acknowledge signal (**dbgack**) from the ARM11 is asserted.

Finally, the JSYNC module will monitor the ARM11's DR and DW AHB HADDR[31:28] bits in order to decode the **HSELRS1** and **HSELRS2** inputs to the L2CC module. These inputs will assert upon accesses to the L2CC configuration registers.

Figure 32-1 is a block diagram of the JSYNC module. See Figure 32-8 for a block diagram detailing the miscellaneous portion of the JSYNC module.

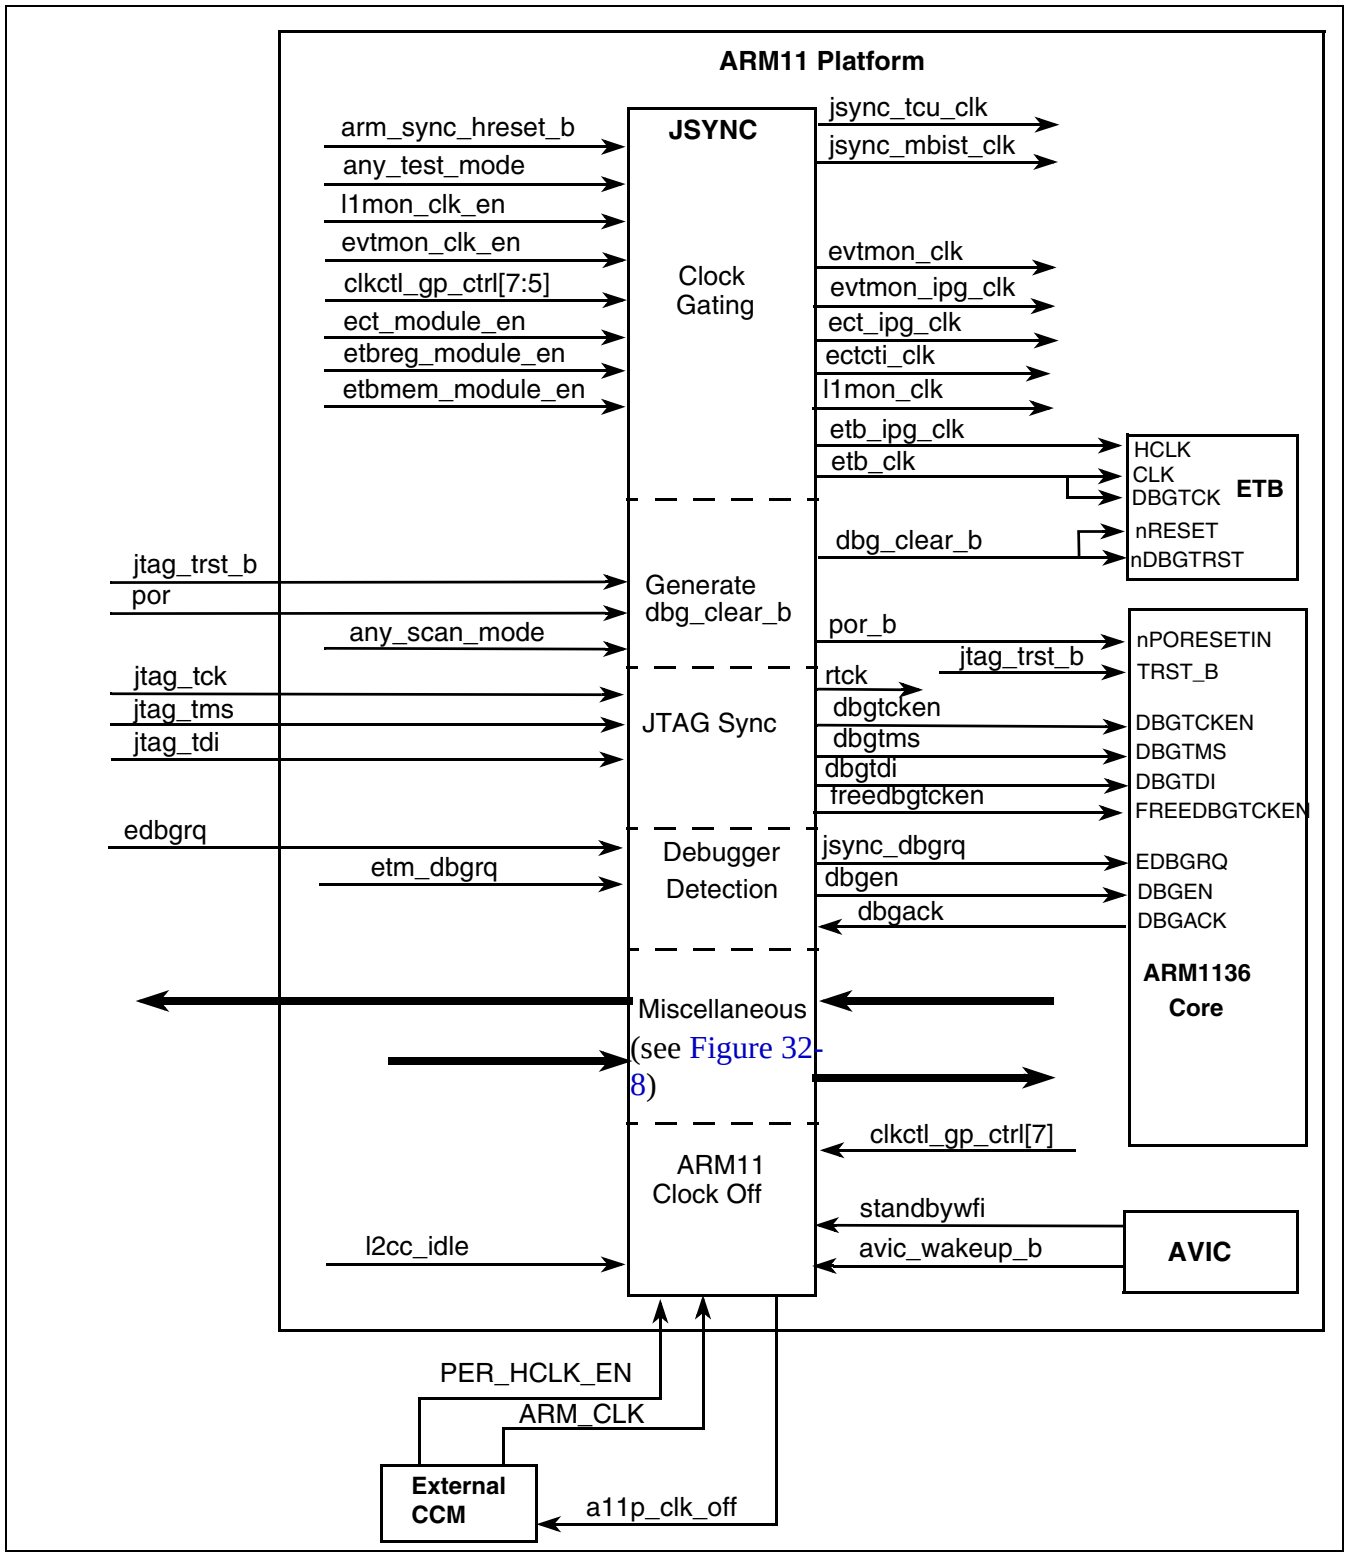

Figure 32-1. JSYNC Block Diagram

Table 32-1 lists the input/output signals for the JSYNC.

Table 32-1. JSYNC I/O Signals

Signal	Input or Output	Purpose
arm_sync_hreset_b	Output	Synchronized arm_hreset_b signal
bist_sync_hreset_b	Output	Synchronized hreset_b signal
dbg_clear_b	Output	Debug reset signal
dbgtcken	Output	Synchronous JTAG debug clock enable
freedbgtcken	Output	Debug clock enable for the FREECLK domain
dbgtms	Output	Synchronous JTAG debug test mode select
dbgtdi	Output	Synchronous JTAG debug data in
dbgtdo	Output	Used in ETB
dbgen	Output	Debugger detection signal
rtck	Output	Return clock
a11p_clk_off	Output	Indicates to external CCM clocks can be turned off for low-power state
jsync_dbgrq	Output	Synchronized dbgrq signal
dbgack_hclk_sync	Output	dbgack sync'd to hclk
hsel_l2cc_rs1	Output	L2CC HSELRS1 input
hsel_l2cc_rs2	Output	L2CC HSELRS2 input
evtmon_clk	Output	evtmon clk signal
evtmon_ipg_clk	Output	evtmon ipg clk signal
l1mon_clk	Output	L1 performance monitor clk signal
ect_ipg_clk	Output	ect clk signal
etb_ipg_clk	Output	etb hclk signal
jsync_tcu_clk	Output	clk to arm_clk domain head/tail registers
jsync_mbist_clk	Output	gated clk for l1cc_bist, l2cc_bist
java_mode	Output	ijbit flopped
thumb_mode	Output	itbit flopped
arm11_active	Output	Indicates ARM11 has come out of reset
por_b	Output	inverted por
jsync_disable_trace	Output	ARM_CLK synchronized version of disable_trace platform input signal
etb_clk	Output	etb clk signal
ectcti_clk	Output	ectcti clk signal
htrans_i_out[1:0]	Output	Registered ARM1136 HTRANSI output
htrans_r_out[1:0]	Output	Registered ARM1136 HTRANSR output
htrans_w_out[1:0]	Output	Registered ARM1136 HTRANSW output

Table 32-1. JSYNC I/O Signals (Continued)

Signal	Input or Output	Purpose
htrans_p_out[1:0]	Output	Registered ARM1136 HTRANSP output
vfpabusy_out]	Output	Flopped version of vfpabusy from ARM11 Core
arm_clk	Input	System clock (fast)
per_hclk_en	Input	System clock (slow) enable signal
por	Input	Power-on reset
arm_hreset_b	Input	arm reset signal
per_sync_hreset_b	Input	Synchronized per_hreset_b signal
jtag_tck	Input	JTAG clock
jtag_trst_b	Input	JTAG reset
jtag_tms	Input	JTAG test mode select
jtag_tdi	Input	JTAG data in
arm_tdo	Input	From ARM1136
etm_tdo	Input	From etm
etm_tdo_sel	Input	From etm
edbgrq	Input	Debug request
dbgack	Input	Debug acknowledge from ARM1136
etm_dbgrq	Input	ETM debug request
ect_dbgrq	Input	ECT debug request
avic_wakeup_b	Input	Interrupt request
standbywfi	Input	Stand by and wait for interrupt
l2cc_idle	Input	L2CC is idle
haddr_r [31:28]	Input	arm1136jf-s data read address
haddr_w [31:28]	Input	arm1136jf-s data write address
evtmon_clk_en	Input	Clock enable for evtmon_clk
evtmon_module_en	Input	Clock enable for evtmon_hclk
l1mon_clk_en	Input	Clock enable for l1mon_clk
ect_module_en	Input	Module en used in ect_ipg_clk
etbreg_module_en	Input	Module en used in etb_ipg_clk
etbmem_module_en	Input	Module en used in etb_ipg_clk
mbist_rst_l1cc	Input	l1cc bist signal
ijbit	Input	ijbit from the arm1136jf-s
itbit	Input	itbit from the arm1136jf-s
htrans_i[1:0]	Input	From ARM1136 HTRANSI, used in arm11_active, HTRANS regs

Table 32-1. JSYNC I/O Signals (Continued)

Signal	Input or Output	Purpose
htrans_r[1:0]	Input	Registered ARM1136 HTRANSR
htrans_w[1:0]	Input	Registered ARM1136 HTRANSW
htrans_p[1:0]	Input	Registered ARM1136 HTRANSP
vfpabusy	Input	ARM1136JF-S signal
disable_trace	Input	Signal to disable ARM11 platform's real-time trace port (ETM11)
clkctl_gp_ctrl[7:5]	Input	Bits 5-7 from clkctl's control register
any_scan_mode	Input	SCC Scan mode
any_test_mode	Input	SCC Test mode
scan_enable	Input	Scan mode enable

32.2 A11P_CLK_OFF

The platform's **a11p_clk_off** output signal is connected to the external clock control module (CCM) and determines if the ARM_CLK and MEM_CLK should be running (**a11p_clk_off** = LOW) or turned off (**a11p_clk_off** = HIGH.) This signal asserts according to the following equation:

a11p_clk_off = **avic_wakeup_b** & (!**dbgen** || **clkctl_gp_ctrl[7]**) & **standbywfi** & **l2cc_idle** & **clkctl_gp_ctrl_15_12[12]**;

The **avic_wakeup_b** term in this equation from the AVIC module and is a combination of the asynchronous versions of fast and normal interrupts in that module. The **dbgen** term is necessary since the clock to the ARM11 must stay on at all times if a debugger is being used or else the JTAG sequences will not work. The **clkctl_gp_ctrl[7]** is added to allow the option of either allowing the clocks to continue or to be turned off in debug mode by modifying this bit. The **standbywfi** equation assures the ARM11 has executed the wait-for-interrupt instruction, drained the write buffer and has no outstanding transactions in progress. The **l2cc_idle** signal assures that the L2CC module also has no outstanding transactions on any of its slave or master ports.

NOTE

The **a11p_clk_off** output signal is an asynchronous signal and must be synchronized in the external CCM.

NOTE

Care should be taken such that wake-up interrupts are level sensitive rather than edge so that no clocks are needed for avic_wakeup_b to assert

32.3 Hardware Clock Control

Clock gating will be done for the modules within the processor domain. The modules in the peripheral domain will use the CLKCTL module for clock gating.

Hardware clock control is performed as shown in Table 32-2.

Table 32-2. Hardware Clock Control Truth Tables

Scan Enable	Module Enable	Gated Clock
0	0	OFF
0	1	ON
1	0	ON
1	1	ON

Figure 32-2 shows the clock control circuit.

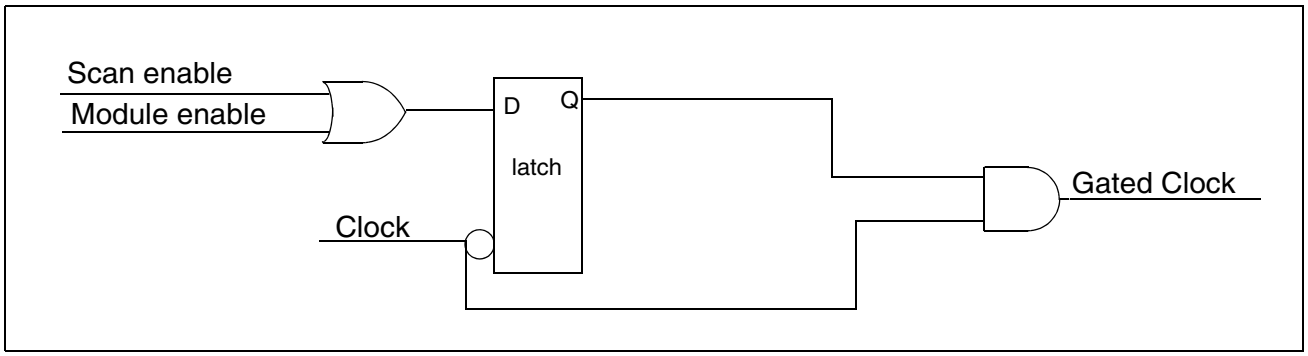

Figure 32-2. Clock Control Circuit

See Table 32-3 for clocking control information.

Table 32-3. Clocking Controls

Clock	Module Enable	Scan Enable
l1mon_clk	l1mon_clk_en	any_scan_mode
evtmon_clk	evtmon_clk_en	any_scan_mode
evtmon_ipg_clk	(evtmon_module_en & per_hclken)	any_scan_mode
ect_ipg_clk	ect_module_en & per_hclken	any_scan_mode
etb_ipg_clk	(etbreg_module_en || etbmem_module_en || (per_sync_hreset_b && !per_sync_hreset_b_delayed))s & per_hclken	any_scan_mode
etb_clk	(clkctl_gp_ctrl_6 || dbgen) && !jsync_disable_trace	any_test_mode
ectcti_clk	(clkctl_gp_ctrl_5 || dbgen) && !jsync_disable_trace	any_scan_mode
jsync_tcu_clk	any_scan_mode	any_scan_mode
jsync_mbist_clk	any_test_mode	any_test_mode

32.4 ARM1136EJ-S JTAG Port Clocking and Synchronization Considerations

The ARM1136EJ-S does not support direct connection to the JTAG interface. The JTAG interface must be synchronized to the CLK domain. A JTAG synchronizer will need to have an “always” clock running to it in order to detect JTAG activity. The JTAG TCLK synchronizer circuit is show in Figure 32-3.

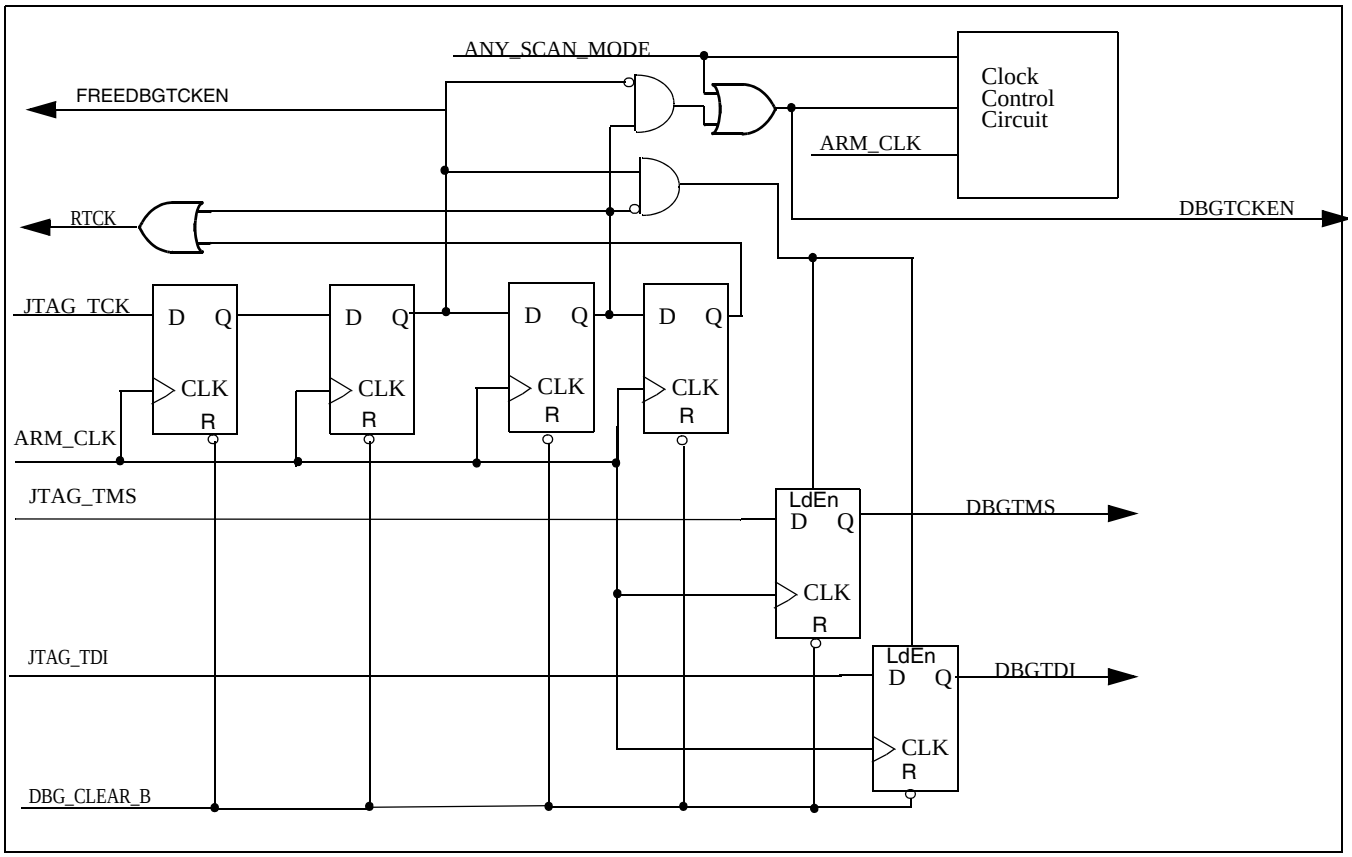

Figure 32-3. JTAG TCLK Synchronizer Circuit

32.5 DBG_CLEAR_B Generation

The power-on-reset (**por**) and the JTAG reset (**jtag_trst_b**) will be combined to drive the **dbg_clear_b** signal to the ARM11. The **dbg_clear_b** output of the JSYNC module can be considered as the JTAG or debug reset of the platform. The **dbg_clear_b** signal will assert asynchronously when either **jtag_trst_b** asserts or **por** deasserts, and will negate synchronously to ARM_CLK (through a synchronizer.) Figure 32-4 shows the **dbg_clear_b** circuit diagram while Figure 32-5 is a timing diagram for **dbg_clear_b**.

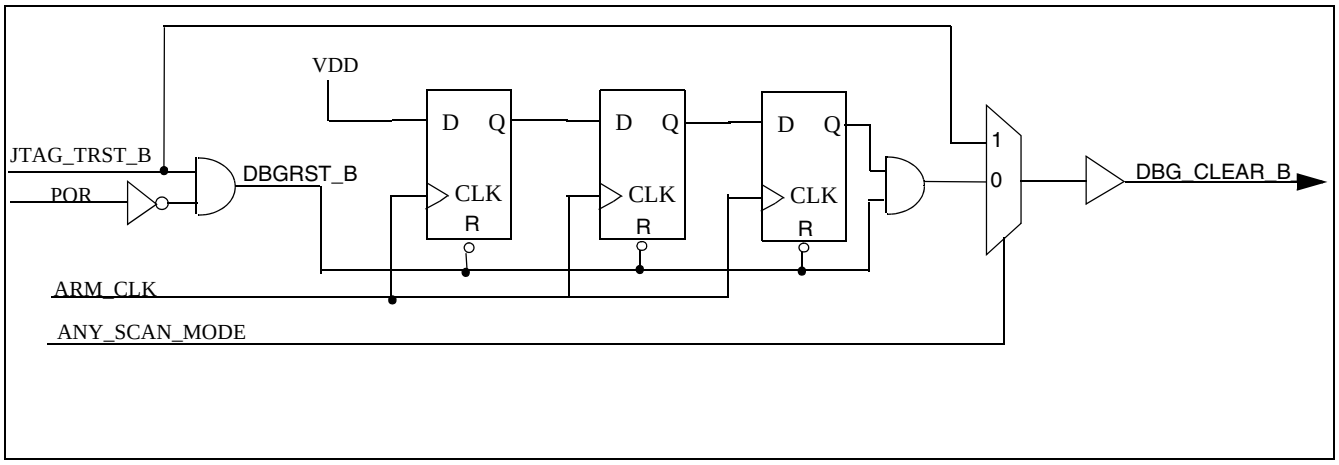

Figure 32-4. DBG_CLEAR_B Circuit

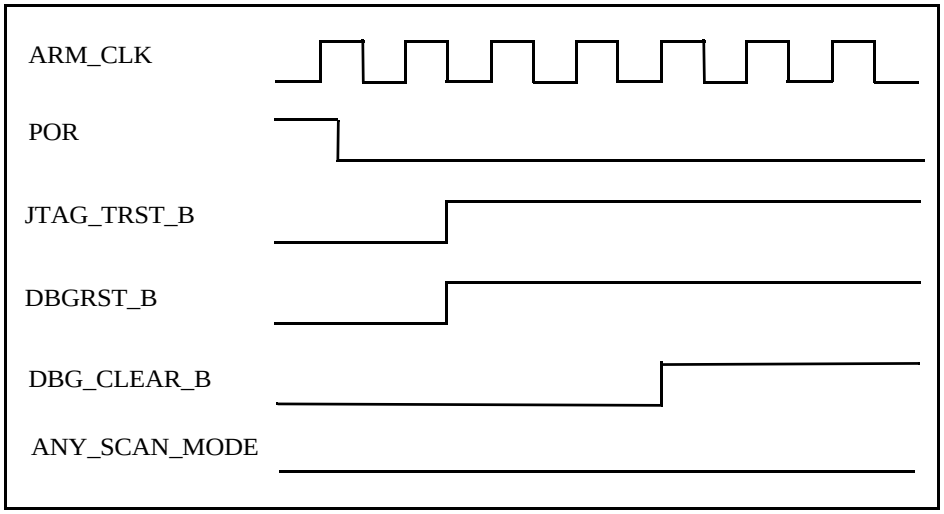

Figure 32-5. DBG_CLEAR_B Timing

32.6 Debugger Detector

The ARM1136EJ-S must have ARM_CLK running whenever a JTAG debugger is present and active.The presence of an active JTAG debugger will be detected by monitoring to see if the JTAG tap-controller exits the test-logic-reset. The JTAG tap-controller will exit the test-logic-reset state if TMS is driven low on a rising edge of TCK while TRST is negated. The signal **dbgen** will assert to indicate a debugger is connected.

The **jsync_dbgrq** signal will also be asserted if an etm debug request is received (**etm_dbgrq**) or if an ect debug request is received (**ect_dbgrq**.) The etm debug request and the ect debug request come straight from flops, so they can go directly to debug request and to the core. The **dbgen** signal will stay asserted until a **dbgack** signal is received from the ARM11. The detection circuit is shown in Figure 32-6 and Figure 32-8.

NOTE

edbgrq must be asserted for at least 2 ARM_CLK cycles.

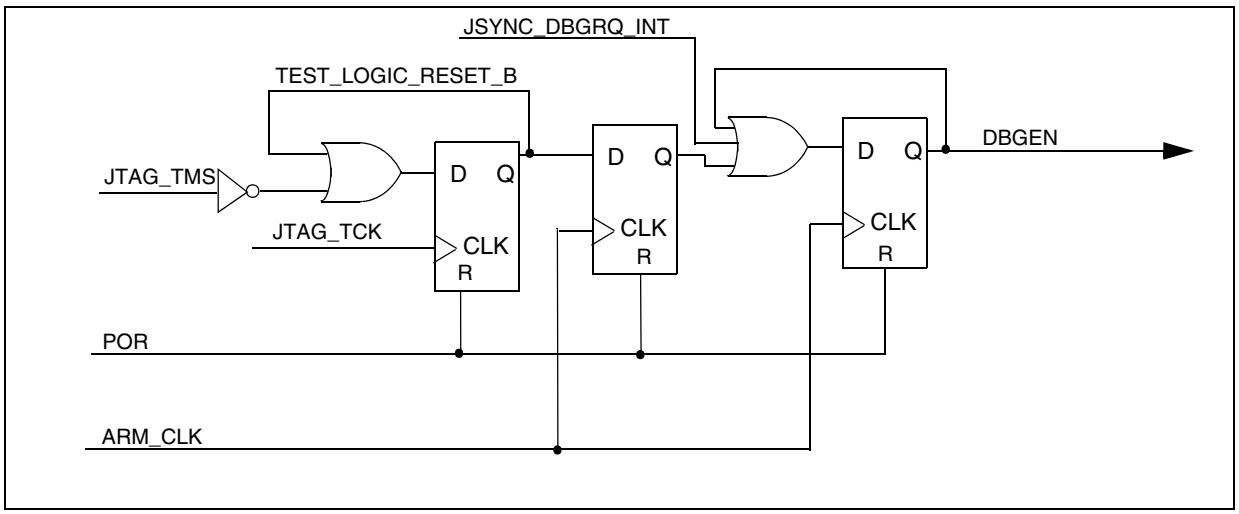

Figure 32-6. Circuit Indicating a Debugger Is Present

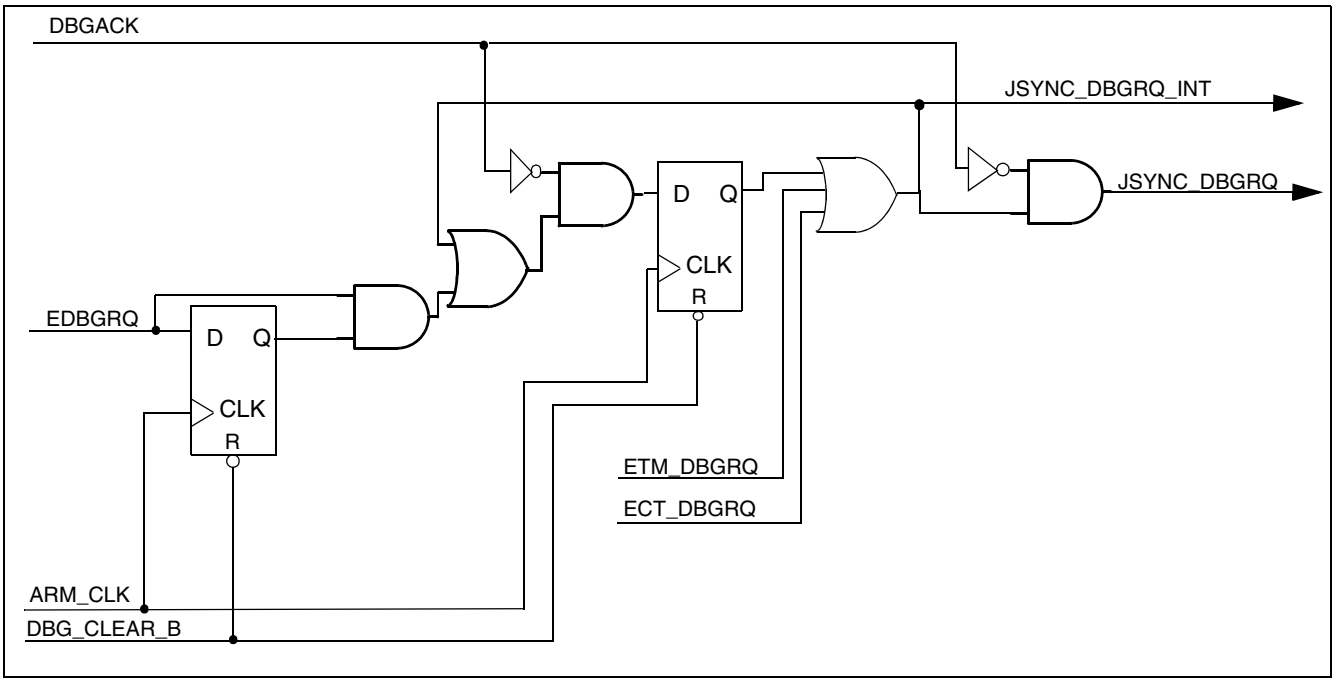

Figure 32-7. jsync_dbgrq Circuit

32.7 Miscellaneous Functionality

This section covers all of the miscellaneous functionality that is included in the JSYNC. Figure 32-8 is a block diagram detailing the miscellaneous functionality in the JSYNC.

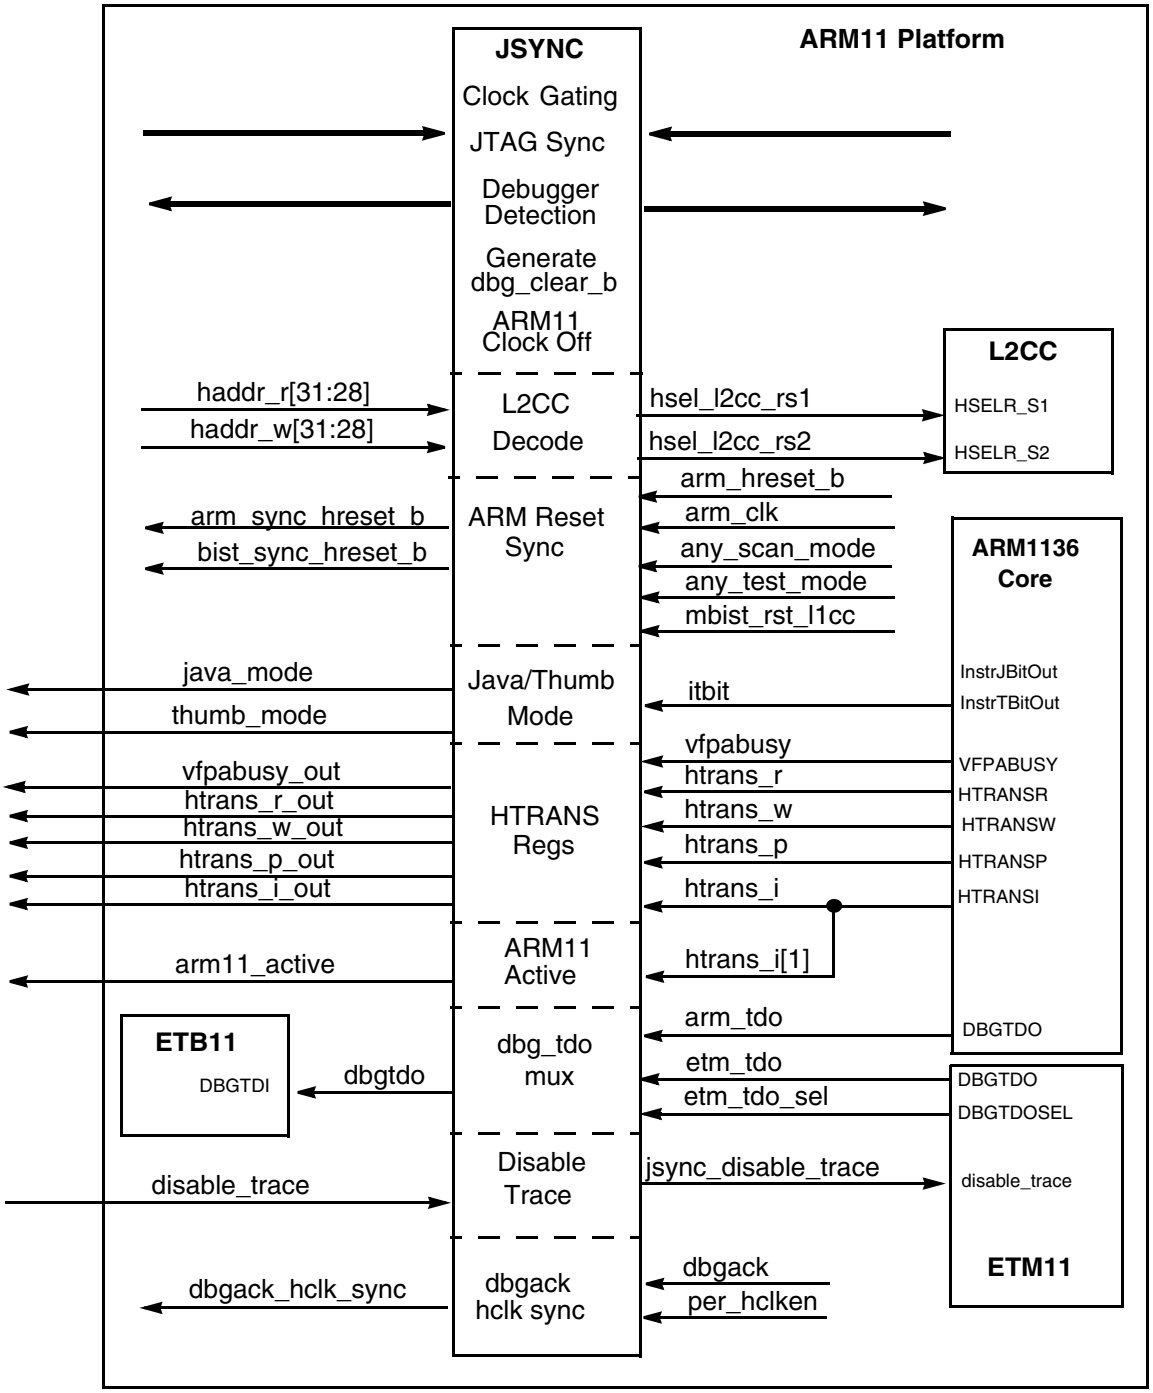

Figure 32-8. JSYNC Block Diagram: Miscellaneous Functionality

32.7.1 L2CC Decode

The JSYNC module will monitor the ARM11's DR and DW AHB HADDR[31:28] bits in order to decode the **HSELRS1** and **HSELRS2** inputs to the L2CC module. These inputs will assert on accesses to the L2CC configuration registers.

32.7.2 Java Mode and Thumb Mode Bits

The JSYNC module will store the input values of **ijbit** and **itbit** in flip-flops clocked by ARM_CLK. **ijbit** is the ARM1136 Java Mode Indicator. **itbit** is the ARM1136 Thumb mode indicator. The output values for these inputs are **java_mode** and **thumb_mode** for ijbit and itbit, respectively.

32.7.3 Multiplexor For "dbgtdo"

The **dbgtdo** signal is the output of a mux with **etm_tdo_sel** as the select line. **etm_tdo_sel** is coming from the etm block. If asserted, the **dbgtdo** signal from the etm block will be selected (**etm_tdo** in the JSYNC). If not asserted, the **dbgtdo** signal will be the **dbgtdo** signal from the ARM1136 (**arm_tdo** in the JSYNC).

32.7.4 Generation of "arm11_active"

The **arm11_active** signal is the output of a flop clocked by arm_clk. The input of the flop is **htrans_i_1**, which is the HTRANSI[1] signal from ARM1136. **arm11_active** indicates that the ARM1136 has come out of reset.

32.7.5 The Disable Trace Function

The **disable_trace** signal is a platform-level input signal and will disable the ARM11 platform's real-time trace port (ETM11). The input signal **disable_trace** is synchronized to TCLK. The **jsync_disable_trace** output signal is a flopped version of **disable_trace** that has been synchronized to ARM_CLK.

The Disable Trace function controls access to the ETM trace and therefore visibility to any internal information that is accessible through the ETM. In most systems the **disable_trace** input is related to security. When the part is in one of the secured modes, tracing is disabled. Our platform is designed such that off-platform chip logic can turn the **disable_trace** signal on and off without needing to go through reset.

32.7.6 The htrans, vfpabusy Registers

The **htrans_i**[1:0], **htrans_r**[1:0], **htrans_w**[1:0], and **htrans_p**[1:0] signals coming from the ARM1136 core are flopped in the JSYNC. The enable bit to flop these signals is bit 7 of the CLKCTL GP control register. The output of these flops is a platform-level output.

Additionally, bit 7 of the CLKCTL GP control register is an enable bit to flop the **vfpabusy** signal coming from the ARM1136. The output of this flop is also a platform-level output (**jsync_vfpabusy**).

32.7.7 Synchronized Resets

The JSYNC module generates a synchronized reset for the **per_hreset_b** signal. This synchronized reset has asynchronous assertion and synchronous negation using a 2-flop synchronizer. Additionally, the **bist_sync_hreset_b** is a synchronized reset signal that has also been synchronized to the **arm_hreset_b** reset signal.

32.7.8 dbgack_hclk_sync

The **dbgack** signal is synchronized to the hclk signal in the JSYNC through the **per_hclken** signal. The resulting flopped signal is **dbgack_hclk_sync**.

Chapter 33
Keypad Port (KPP)

33.1 Introduction

The keypad port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). Figure 33-1 shows the KPP block diagram.

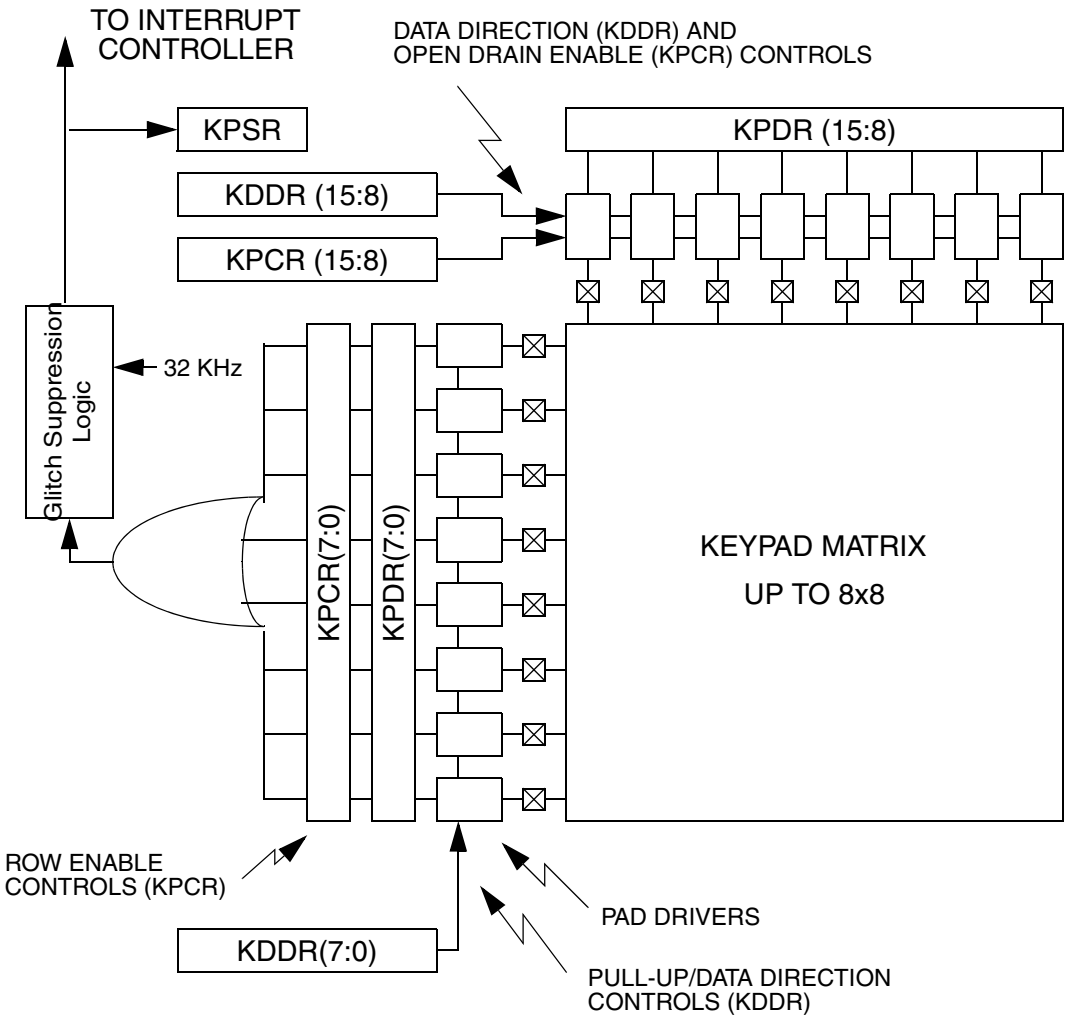

Figure 33-1. KPP Peripheral Block Diagram

33.2 Overview

The KPP is designed to interface with the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

33.2.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a two-point and three-point contact key matrix

33.2.2 Modes of Operation

This module supports the following modes of operation:

- Run mode—This is the normal functional mode in which the KPP can detect any key press event.
- Low power modes—The keypad can detect any key press even in low power modes (when there is no core clock).

33.3 External Signal Description

33.3.1 Overview

There are 16 pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See Table 33-1 for the list of external signals.

Table 33-1. Signal Properties

Name	Port	Function	Reset State	Pull up
ipp_ind_col[7:0]	—	Column input pin, from chip	0	Active[1]
ipp_ind_row[7:0]	—	Row input pin, from chip	1	Active[1]

Table 33-1. Signal Properties (Continued)

Name	Port	Function	Reset State	Pull up
ipp_do_col[7:0]	—	Column output pin going to chip	0	—
ipp_obe_col[7:0]	—	Enables the corresponding column outputs	0	—
ipp_ode_col[7:0]	—	Used to set the column outputs	0	—
ipp_do_row[7:0]	—	Row output pin going to chip	0	—
ipp_obe_row[7:0]	—	Enables the corresponding row output	0	—

1 The corresponding pads are required to be pull-up enabled.

33.3.1.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a “0” to the appropriate bits in the keypad data direction register (KDDR). Additionally, the least significant 8 bits (ROW inputs) corresponding to KDDR[7:0] have internal pull-ups, which are enabled when the pin is used as an input.

33.3.1.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the keypad data direction register to a “1”. Additionally, the 8 most significant bits (15–8) can be designated as open drain outputs by writing a “1” to the appropriate bits in the keypad control register. See Table 33-2 for register settings and corresponding pin functions. The lower 8 bits (7–0) are always in “totem pole” style, driven when configured as outputs.

Table 33-2. Keypad Port Column Modes

KDDR (15:8)	KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a “1” during the scan routine. With this configuration, a time delay between the scanning of two subsequent columns is reduced.

33.4 Memory Map and Register Definition

The KPP module contains four registers. Section 33.4.3, “Register Descriptions,” provides detailed descriptions of the KPP registers.

33.4.1 KPP Memory Map

Table 33-3 shows the KPP memory map. For the base address of a particular module instantiation, see the system memory map.

Table 33-3. KPP Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (KPCR)	Keypad control register	R/W	0x4000	33.4.3.1/33-5
0x0002 (KPSR)	Keypad status register	R/W	0x0000	33.4.3.2/33-6
0x0004 (KDDR)	Keypad data direction register	R/W	0x0000	33.4.3.3/33-7
0x0006 (KPDR)	Keypad data register	R/W	0xXXXX	33.4.3.4/33-8

33.4.2 Register Summary

Figure 33-2 shows the key to the register fields and Table 33-4 shows the register figure conventions.

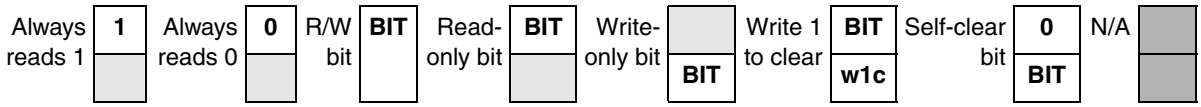

Figure 33-2. Key to Register Fields

Table 33-4. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 33-5 shows the KPP register summary.

Table 33-5. KPP Register Summary

Base Address Offset (Name Abbreviation)		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

33.4.3 Register Descriptions

This section consists of register descriptions; the registers are listed in address order.

33.4.3.1 Keypad Control Register (KPCR)

The keypad control register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPCR register is byte- or half-word–addressable.

Figure 33-3 shows the valid bits in the KPCR register, and Table 33-6 provides its field descriptions.

Offset 0x0000 (KPCR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	KCO7	KCO6	KCO5	KCO4	KCO3	KCO2	KCO1	KCO0	KRE7	KRE6	KRE5	KRE4	KRE3	KRE2	KRE1	KRE0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 33-3. KPCR Register

Table 33-6. Keypad Control Register Field Descriptions

Field	Description
15–8 KCO	Keypad column strobe open-drain enable. Setting a column open-drain enable bit (KCO7–KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. 0 Column strobe output is totem pole drive. 1 Column strobe output is open drain. **Note:** Configuration of external port control logic (for example, GPIO) should be done properly so that the KPP module controls an open-drain enable of the pin.
7–0 KRE	Keypad row enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a “0” to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

33.4.3.2 Keypad Status Register (KPSR)

The keypad status register reflects the state of the key press detect circuit. The KPSR register is byte- or half-word–addressable.

Figure shows the KPSR register, and Table 33-7 provides its field descriptions.

0x0002 (KPSR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	KRIE	KDIE	0	0	0	0	0	0	KPKR	KPKD
W													KRSS	KDSC	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 33-4. KPSR Register Diagram

Table 33-7. Keypad Status Register Field Descriptions

Field	Description
15–10	Reserved
9 KRIE	Keypad release interrupt enable. The software should ensure that the interrupt for a key release event is masked until it enters the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.

Table 33-7. Keypad Status Register Field Descriptions (Continued)

Field	Description
8 KDIE	Keypad key depress interrupt enable. Software should ensure that the interrupt for a key release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4	Reserved, should be cleared
3 KRSS	Key release synchronizer set. Self-clear bit. The key release synchronizer is set by writing1 to this bit. Reads return a value of 0. 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key depress synchronizer clear. Self-clear bit. The key depress synchronizer is cleared by writing 1 to this bit. Reads return a value of 0. 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad key release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. 0 No key release detected 1 All keys have been released Reset value of register is “0” as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become “1”.
0 KPKD	Keypad key depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the 32 KHz clock) elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

33.4.3.3 Keypad Data Direction Register (KDDR)

The bits in the KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KDDR register is byte- or half-word–addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in row DDR is cleared.

Figure 33-5 shows the valid bits in the KDDR register, and Table 33-8 provides its field descriptions.

Offset 0x0004 (KDDR) Access: User read/write

Field	Description
15–8 KCDD	Keypad column data direction register. Setting any bit configures the corresponding pin as an output. 0 COL*n*[1] pin is configured as an input. 1 COL*n*[1] pin is configured as an output.
7–0 KRDD	Keypad row data direction. Setting any bit configures the corresponding pin as an output. 0 ROW*n*[1] pin configured as an input. 1 ROW*n*[1] pin configured as an output.

[1] *n*=7-0

33.4.3.4 Keypad Data Register (KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPDR register is byte- or half-word–addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Figure 33-6 shows the KPDR register, and Table 33-9 provides its field descriptions.

Offset 0x0006 (KPDR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7-0 KRD	Keypad row data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write “0” from/to row ports 1 Read/Write “1” from/to row ports

33.5 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes providing that a 32 KHz clock is on. The KPP may generate a CPU interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

33.5.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

33.5.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the keypad control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

33.5.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

33.5.4 Keypad Standby

There is no need for the CPU to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the CPU can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the CPU if any key is pressed.

Upon receiving a keypad interrupt, the CPU should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

33.5.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the CPU. The circuit is a 4-state synchronizer clocked from a 32 KHz clock source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the CPU interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods (for 32 KHz clock: 93.75 μs) in duration. Noise filtering of the duration between three to four clock periods (for the 32 KHz clock: between 93.75 μs and 125 μs) cannot be guaranteed. The interrupt output is latched in an SR latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See Figure 33-7 for a functional diagram of the keypad synchronizer.

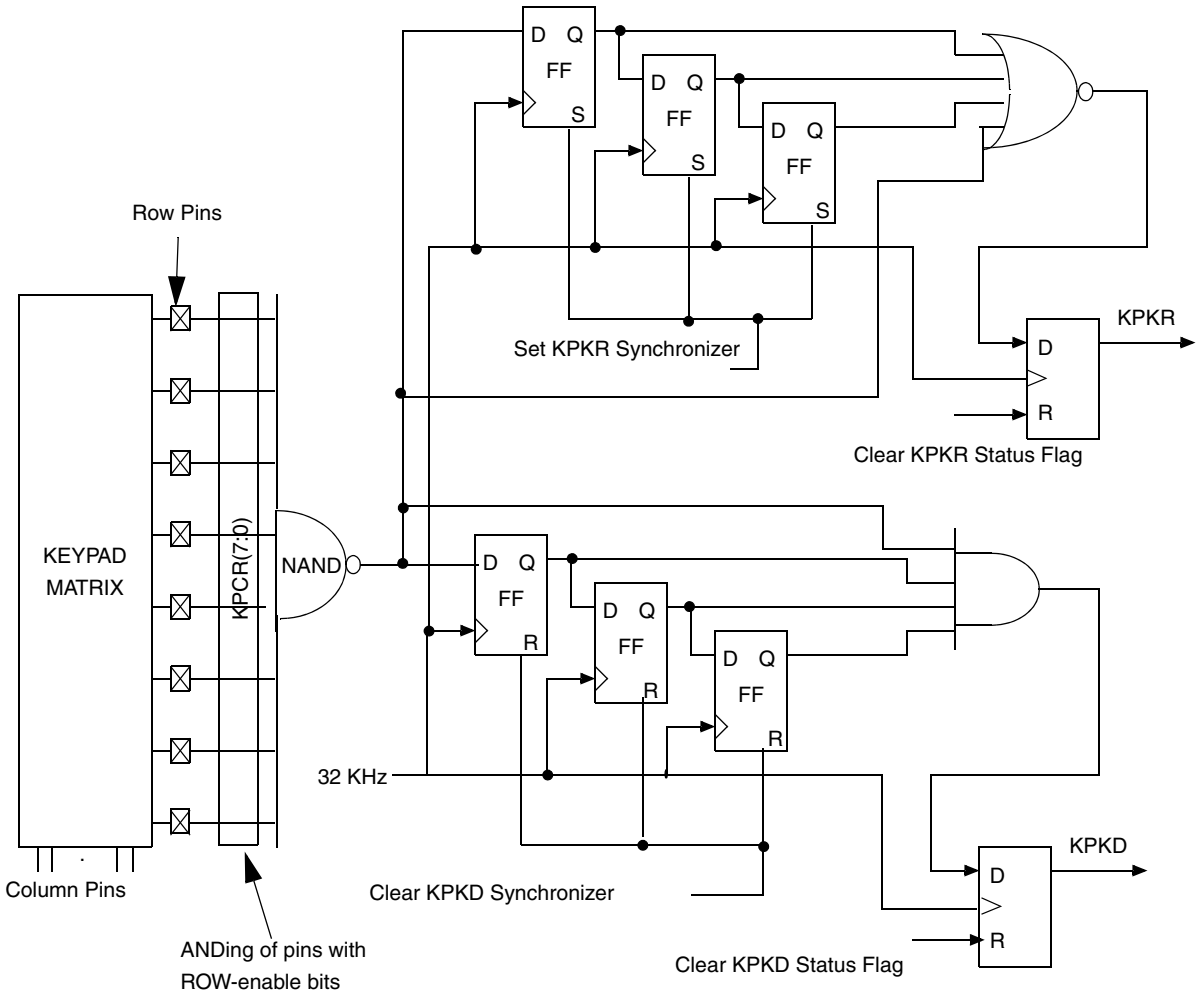

Figure 33-7. Keypad Synchronizer Functional Diagram

33.5.6 Multiple Key Closures

Using the key press and key release interrupts, the software can detect multiple keys or achieve N-key rollover. The key scanning routine can be programmed accordingly. See Section 33.6, "Initialization/Application Information" for more information.

See Figure 33-6 and Figure 33-9 for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the keypad data register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

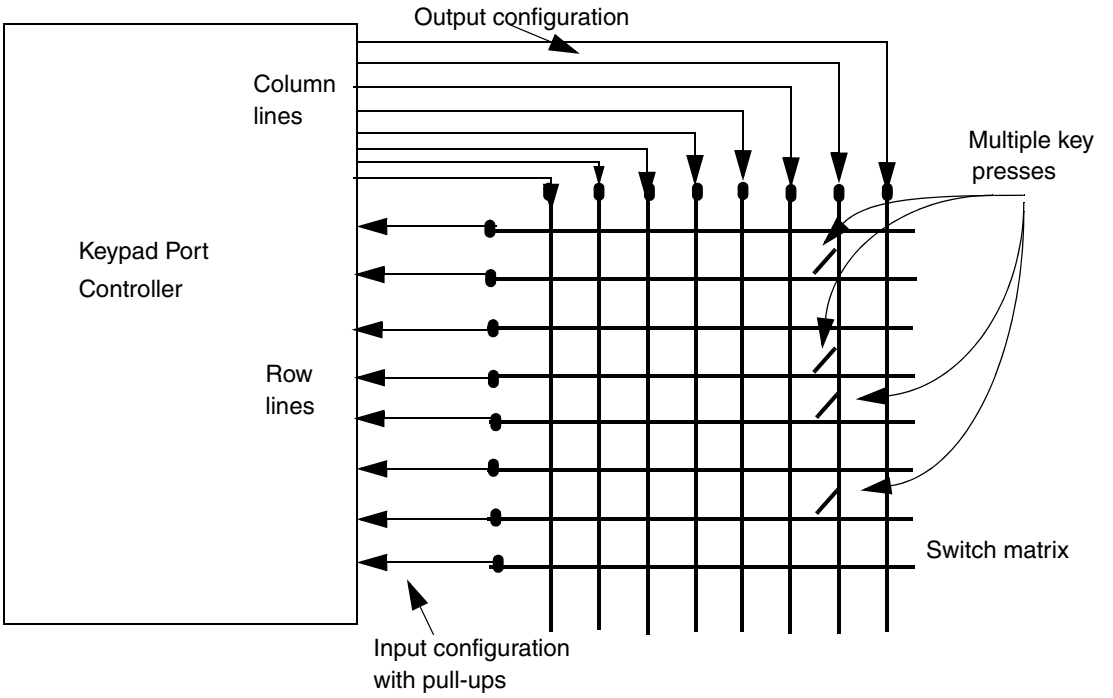

Figure 33-8. Multiple Key Presses on Same Column Line (Simplified View)

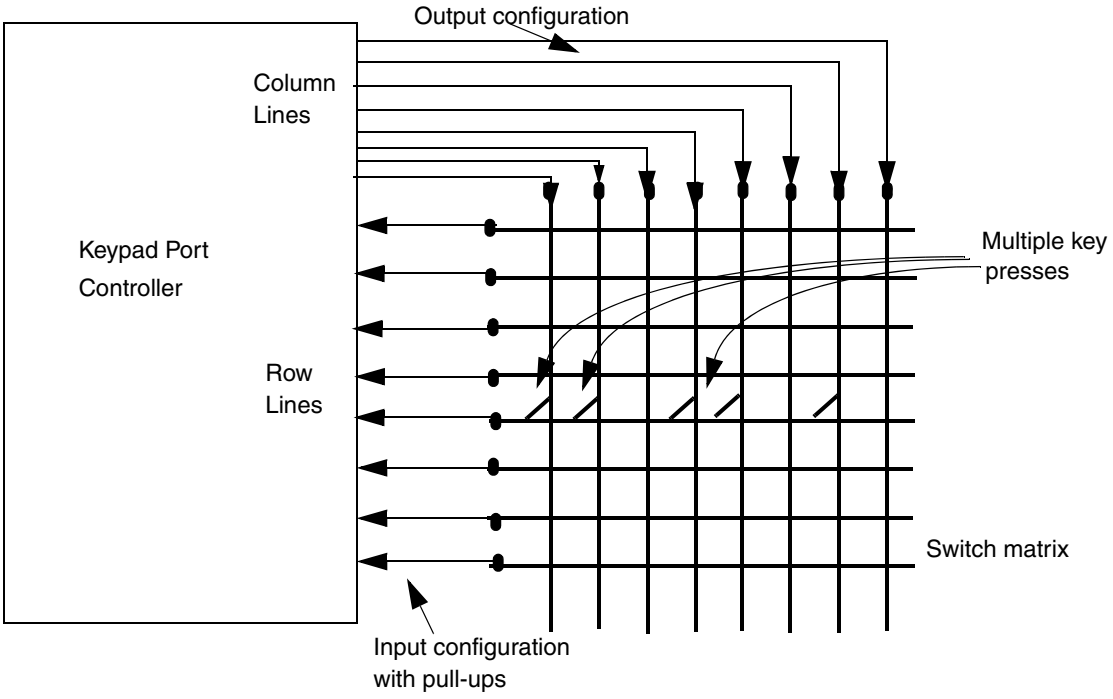

Figure 33-9. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An N-key rollover is a technique with which the system can recognize the order in which keys are pressed.

33.5.6.1 Ghost Key Problem and Correction

The KPP module detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of “ghost” key detection when three or more keys are pressed. However, this can be corrected by using a keypad matrix that provides “ghost” key protection. Such a matrix implements a one-way “diode” at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key.

3-Point Contact Keys Support

The KPP module supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 33-10, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic). The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

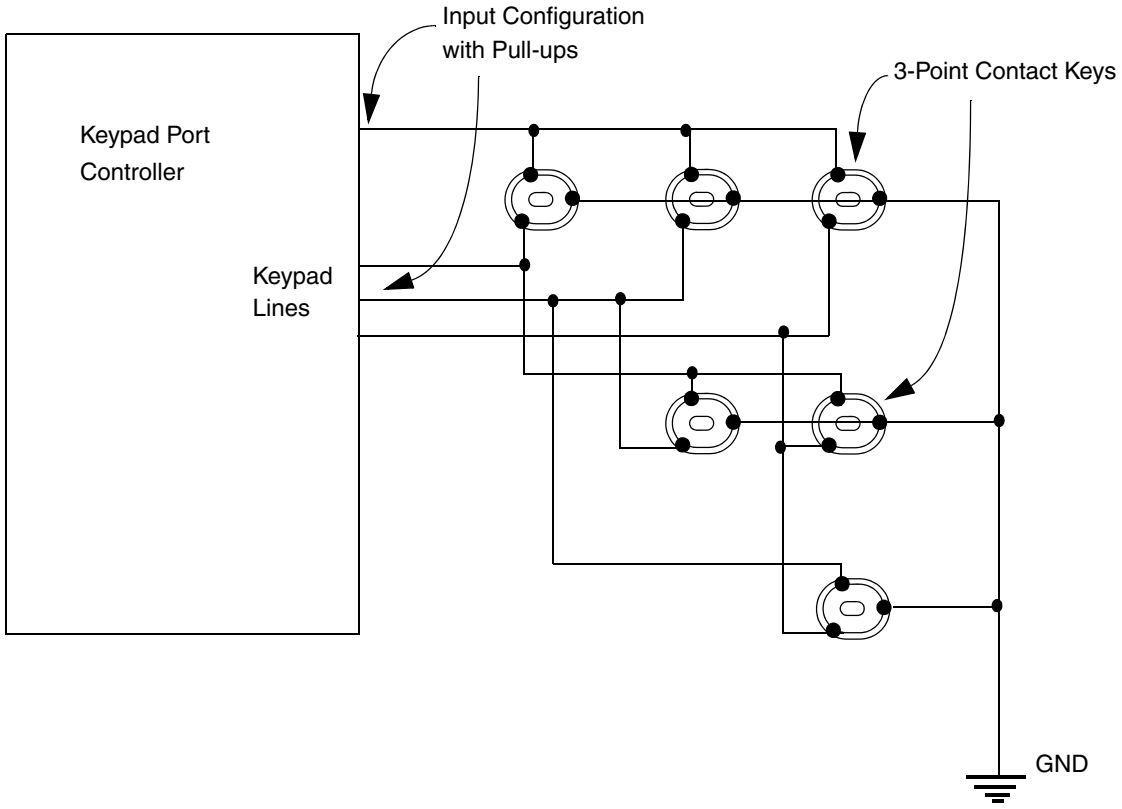

Figure 33-10. KPP Interface with 3-point Contact Key Matrix (Simplified View)

33.6 Initialization/Application Information

33.6.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPCR[7:0]).
2. Write 0's to KPDR[15:8].
3. Configure the keypad columns as open-drain (KPCR[15:8]).
4. Configure columns as output and rows as input (KDDR[15:0]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

33.6.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1's to KPDR[15:8], setting column data to 1's.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2–6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing 1; set the KPKR synchronizer chain by writing a 1 to the KRSS status bit; and clear the KPKD synchronizer chain by writing 1 to the KDSC status bit (in the KPSR register).
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

33.6.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP module is that the module is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

Chapter 34
Multi-Master Memory Interface (M3IF)

The multimaster memory interface (M3IF) controls memory accesses (read/write/erase/program) from one or more masters through different port interfaces to three different external memory controllers:

- Enhanced SDRAM mobile / low power DDR and DDR2 controller (ESDRAMC/MDDRC, subsequently abbreviated as ESDRAMC)
- NAND Flash controller (NFC)
- Wireless external interface module (WEIM).

Figure 34-1 shows the M3IF module's functional organization at top level.

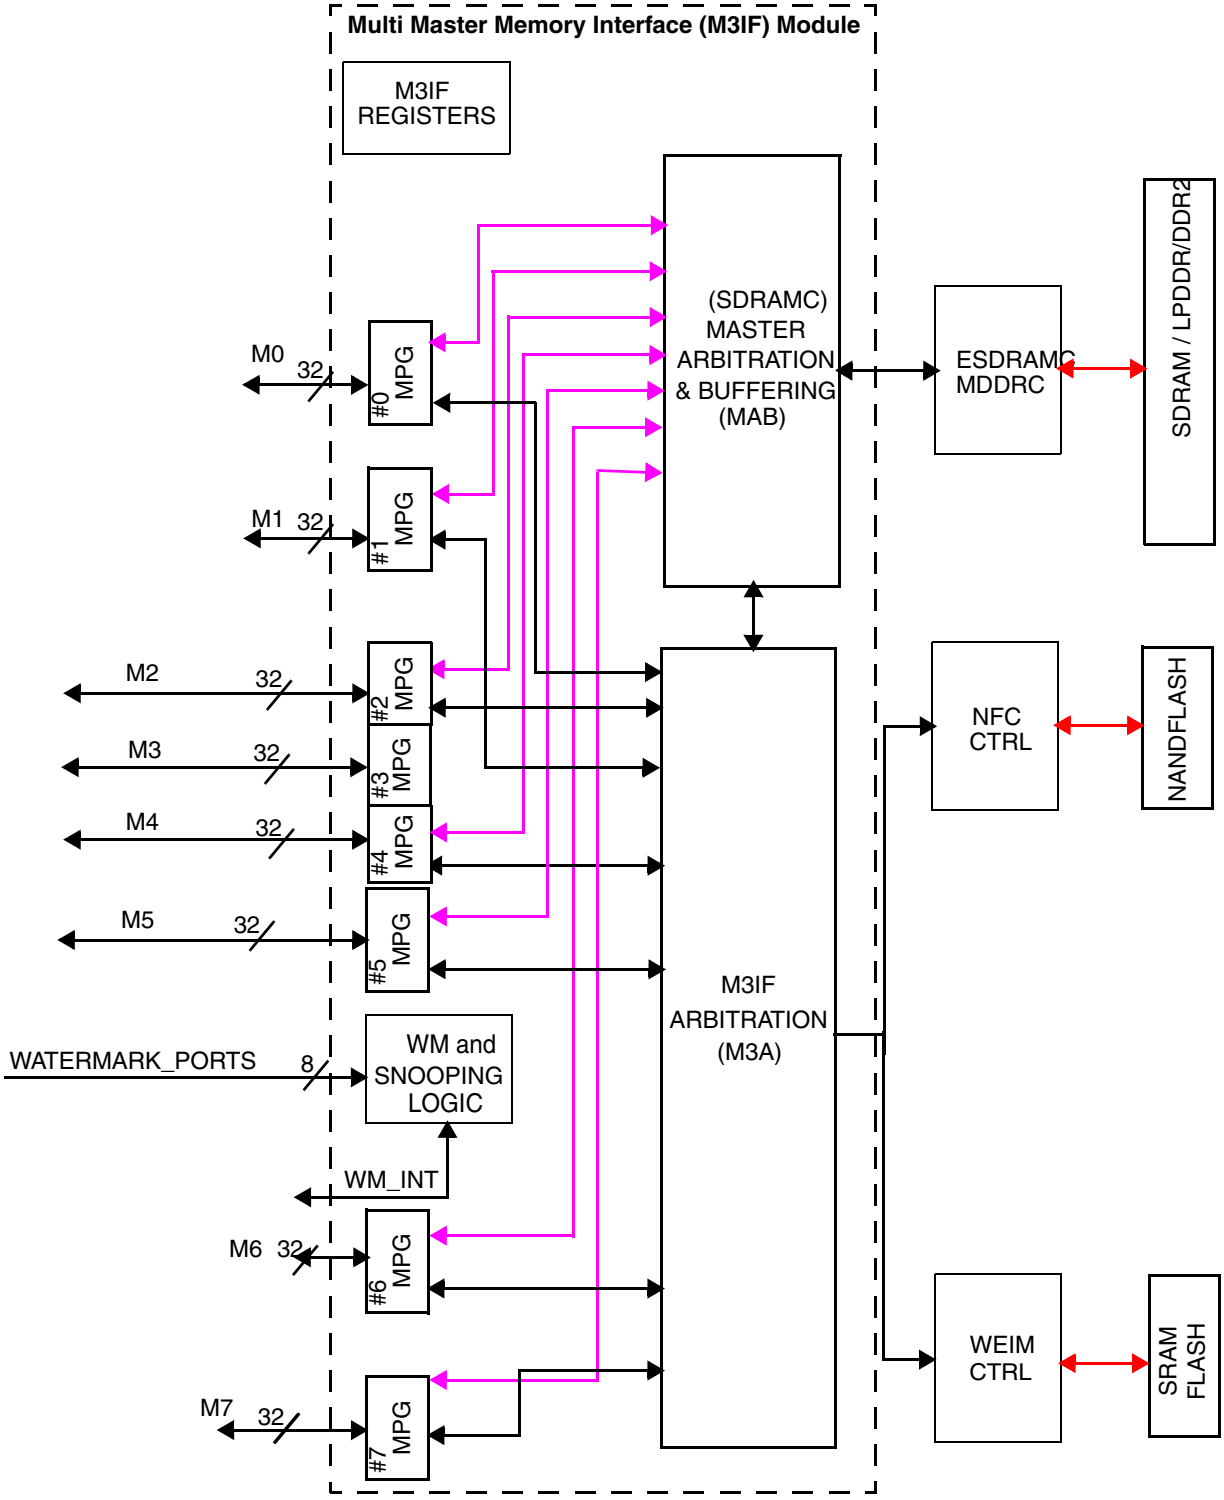

Figure 34-1. M3IF Schematics Connection.

34.1 Overview

The M3IF-ESDRAMC interface is optimized and designed to reduce access latency by generating multiple accesses through the dedicated ESDRAMC arbitration (MAB) module, which controls the access to/from the ESDRAMC. For the other port interfaces, the M3IF only arbitrates and forwards the master requests received through the master port gasket (MPG) interface and M3IF arbitration (M3A) module toward the respective memory controller.

When a master requests a memory access, the access is immediately taken by the M3IF if no other access is in progress. The M3IF forwards the access to the respective memory controller (slave), and depending on the state of the respective memory controller, a command to the memory is generated. If the access cannot be started due to a previous active access, the master request remains pending (HREADY held negated) until it is executed by the memory controller. When the access execution is complete, the HREADY is asserted and a new request can be processed.

Accesses to the SDRAM, LPDDR or DDR2 external devices are optimized through command anticipation (MIF2 strategy). For example, the next access control phase (memory address and command) is driven during the previous access data phase (data flow to/from the memory). This creates an overlap between accesses that partially or fully hide the latency.

34.1.1 M3IF Interfaces

The interface between the M3IF and the controllers can be divided into two different types: M3IF-ESDRAMC, and M3IF-all others. The M3IF-to-ESDRAMC interface reduces access latency by generating multiple accesses using the dedicated ESDRAMC arbitration (MAB) module.

For the other port interfaces, the M3IF arbitrates and forwards the masters' requests received through the Master Port Gasket (MPG) interfaces and the M3IF arbitration (M3A) module toward the respective memory controller. To support multiple accesses to the ESDRAMC, the MAB includes a FIFO which controls the access traffic from/to the ESDRAMC.

The M3IF can be viewed as a device with multiple SDRAM/LPDDR/DDR2 controllers, plus one controller per non-SDRAM/LPDDR/DDR2 memory type.

The M3A arbitrates memory access requests with a round robin that chooses the next master granted access to the bus, as follows:

- If this master is requesting access to the ESDRAMC, the M3A waits until the previous access finishes, then passes the request.
- If the master is requesting access to ESDRAMC-controlled memory, the M3IF arbitration passes the access to the MAB as follows:
  - If the previous access is to non–ESDRAMC-controlled memory, the M3IF arbitration passes the request after the previous access is completed.
  - If the previous access was to ESDRAMC-controlled memory, the M3IF arbitration passes the request immediately, without waiting for the previous access to complete.

The M3IF Arbitration (M3A) and the ESDRAMC Master Arbitration and Buffering (MAB) supports a round-robin arbitration scheme that can be programmed to non-equal probability. If two masters request access to the memory port on the same cycle, the master with the token gains control on the bus (for more details, see Section 34.3.3.2, “M3A—Find First 1 (FF1) Algorithm”). To support multiple accesses to the ESDRAMC, the MAB includes a FIFO which controls the access traffic from/to the ESDRAMC.

34.1.2 Features

The M3IF Master Port Gasket (MPG) converts the master request (data write, data read, address, and controls) to a set of bus/signals that the M3IF arbitration, the ESDRAMC arbitration, and other memory controllers need. The MPG is also responsible to give the right response to the master after getting the response from the relevant memory controller. The M3IF supports both 32bits interfaces and 64bits interfaces. The number of gaskets and the bus width is set according to SOC requirements,.

The M3IF includes these distinctive features:

- Supports multiple requests up to 8 masters through input port interfaces:
  - Master Port Gasket (MPG) - ARM11 AMBA AHB lite bus protocol.
  - Master Port Gasket (MPG64) - AMBA AHB access with 64 bits data bus width.
- Arbitrates requests to three different memory controllers (that share some of their I/O pads)
  - Enhanced SDRAM/LPDDR/DDR2 controller (ESDRAMC)
  - NAND Flash Controller - (NFC)
  - Wireless External Interface Memory Controller - (WEIM)
- Multiple requests capabilities to ESDRAMC through a dedicated arbitration mechanism.
- Flexible round robin access arbitration, with equal priority or 50% priority to selective masters.
- Programmable master that controls (lock) accesses to SDRAM/DDR and programmable master that controls (lock) accesses to other memories (= general: NFC, WEIM).
- Support for multi-endian byte order to all memory controllers.
- Supports memory watermark protection for up to 8 different chip selects for preselected masters. Watermark is enabled according to SOC requirements.
  - Configurable protected memory region (base address with 1-Kbyte resolution) for each one of the 8 predefined chip selects.
  - One status bit for each memory region that indicates security violation.
  - Maskable watermark interrupt generation capability.
- Supports memory snooping, an example of which would be monitoring a region in external memory for write accesses:
  - The region’s location is specified by a base address (from 2 Kbytes up to 16 Mbytes), which is divided into 64 equal segments.
  - Each segment has an access status and enable bit in the M3IF register definition.
  - M3IF generates a one cycle DMA_ACCESS for each snooping detection.

34.2 Memory Map and Register Definition

The M3IF programming model consists of several classes of registers, M3IF control and lock registers, watermark configuration and status registers, and snooping configuration and status registers as shown in Table 34-2. The control and master lock general register defines the M3IF configurable logic functionality. The configuration and status registers set and monitor watermark and snooping activity respectively.

All M3IF registers are 32-bits in length with bit fields defined in Figure 34-3 to Figure 34-11. All implemented bits are fully readable and writable in supervisor mode only (an error response is generated in case of user mode access to M3IF registers). All M3IF (and ESDRAMC) registers can be accessed only by a SINGLE word (32-bit) access, through the AHB bus protocol. Accesses of any other size or type cause undetermined behavior.

All registers can be accessed by only one master at a time. Multi access to M3IF register causes undetermined behavior. The only exception is the M3IF Master Lock General register that can be accessed by more than one master at a time.

The reset state of each bit is shown underneath the bit field name. An asterisk indicates that the value is dependent on the operating mode selected during reset. Details are provided in the following bit field descriptions.

34.2.1 Memory Map

Table 34-2 shows the memory map for the M3IF registers. Table 34-3 shows the M3IF memory space allocated to the three different memory controllers (ESDRAMC, NFC, and WEIM).For the base address of a particular module instantiation, see the system memory map.

Table 34-2. M3IF Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page

0x0054 (M3IFMLWE5)	M3IF Master Lock WEIM CS5 Register	R/W	0x0000_0000	34.2.3.9/34-19

[1]All 9 watermark registers are accessible (read/write) only by the predefined (hardware) master in a supervisor mode access, HPROT signal high.

Table 34-3. M3IF Memory Space Summary

Address	Use	Access
ESDRAMC Memory Space		
0x8000_0000 - 0x8FFF_FFFF	CSD0 SDRAM/LPDDR/DDR2 memory region (256MB)	Read/write
0x9000_0000 - 0x9FFF_FFFF	CSD1 SDRAM/LPDDR/DDR2 memory region (256MB)	Read/write
WEIM Memory Space		
0xA000_0000 - 0xA7FF_FFFF	WEIM CS0 memory region (128MB)	Read/write
0xA800_0000 - 0xAFFF_FFFF	WEIM CS1 memory region (128MB)	Read/write
0xB000_0000 - 0xB1FF_FFFF	WEIM CS2 memory region (32MB)	Read/write
0xB200_0000 - 0xB3FF_FFFF	WEIM CS3 memory region (32MB)	Read/write
0xB400_0000 - 0xB5FF_FFFF	WEIM CS4 memory region (32MB)	Read/write
0xB600_0000 - 0xB7FF_FFFF	WEIM CS5 memory region (32MB)	Read/write
NFC Memory Space		
0xBB00_0000 - 0xBB00_1FFF	NAND Flash memory region[1] (4KB)	Read/write

[1] Can be used as a boot memory region.

34.2.2 Register Summary

Figure 34-2 shows the key to the register fields, and Table 34-4 shows the register figure conventions.

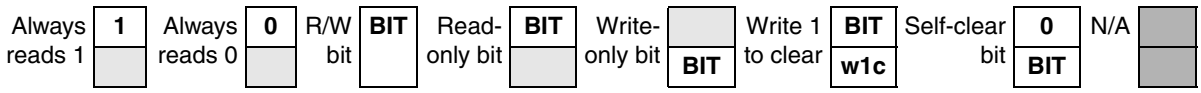

Figure 34-2. Key to Register Fields

Table 34-4. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

34.2.3 Register Descriptions

This section contains the detailed register descriptions for the M3IF registers.

34.2.3.1 M3IF Control Register (M3IFCTL)

The M3IFCTL register contains access status and provides access control for SDRAM/LPDDR/DDR2 memory devices, and sets arbitration priority for M3IF port masters. The field assignments for this register are shown in Figure 34-3 and the field descriptions are listed in Table 34-6.

Offset 0x0000 (M3IFCTL) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 34-3. M3IF Control Register

Table 34-6. M3IF Control Register Field Descriptions

Field	Description
31 SDA	SDRAM/LPDDR/DDR2 Memory Active. This is a read-only status bit that, if set, indicates that an active/pending access to SDRAM/LPDDR memory exists. The SDA bit is set on one of the following conditions: • If MLSD_EN (bit 11) is cleared, then any active/pending access to SDRAM/LPDDR/DDR2 memory space sets the bit (until the access is completed). • If MLSD_EN is set, then any accesses to SDRAM/LPDDR/DDR2 memory space initiated previously to MLSD_EN assertion, keeps the SDA status bit set. The bit clears after all pending/active accesses are completed. Access from the master indicated by the MLSD field (bits 10:8) do not assert the status bit. **Note:** When the MLSD_EN is set, any new accesses (initiated after MLSD_EN assertion) to SDRAM/LPDDR/DDR2 not from MLSD master will be pending without setting SDA to 1. Only the SDRAM/LPDDR/DDR2 memory space region will be locked to the MLSD port. Accesses to M3IF/ESDRAMC registers are available to all masters in the system: the software is responsible not to access those registers during the lock period. 0 No active/pending access to SDRAM/LPDDR/DDR2 memory exists. 1 Indicates an active/pending access to SDRAM/LPDDR/DDR2 memory exists.
30–12	Reserved
11 MLSD_EN	Master Lock SDRAM/LPDDR/DDR2 Access. This bit enables the Master Control SDRAM/LPDDR/DDR2 access (MLSD). The reset value of this bit is “0”. 0 Master Control SDRAM/LPDDR/DDR2 access (MLSD) disabled. 1 Master Control SDRAM/LPDDR/DDR2 access (MLSD) enabled.

Table 34-6. M3IF Control Register Field Descriptions (Continued)

Field	Description
10–8 MLSD	Master Lock SDRAM/LPDDR/DDR2 Access. This 3-bit field defines the master port number (MPG) that is the only master in the system to be served by the ESDRAMC. All accesses toward the SDRAM/LPDDR/DDR2 from the other masters will be postponed, until the MLSD master clears the MLSD_EN bit. The reset value of the MLSD is 0b000. **Note:** Accesses to ESDRAMC registers are not effected by the MLSD field. For example, they can be accessed by any master even if MLSD_EN is set. Prior to lock accesses, the MLSD master should perform the following steps: 1. Set the MLSD_EN bit and the MLSD field (with the desired value) in the M3IFCTL register. 2. Read M3IFCTL register and check: 3. SDA status bit is cleared (no pending/active accesses to SDRAM/LPDDR/DDR2 memory space exists). 4. MLSD_EN bit is set. 5. MLSD (value) points to the required port number (master port number that requires lock accesses). 000 Master Port Gasket 0 001 Master Port Gasket 1 010 Master Port Gasket 2 011 Master Port Gasket 3 100 Master Port Gasket 4 101 Master Port Gasket 5 110 Master Port Gasket 6 111 Master Port Gasket 7
7–0 MRRP	Master Round Robin Priority. MRRP field is an 8-bit field with one bit per master (bit #i to master #i). Masters with their MRRP bit set are added to a priority arbitration “list” so that together they have 50% probability to gain access through both M3A and MAB arbitration processes (50% probability for each one of the arbitration separately). Assertion of MRRP bit for an unused master is forbidden. If all MRRP bits are cleared, the masters have equal probability to pass the arbitration processes. For more details about the M3IF arbitration see Section 34.3.3.2, “M3A—Find First 1 (FF1) Algorithm.” 0 The respective master is not on the priority arbitration “list”. 1 Add the respective master to the priority arbitration “list” with a 50% probability to pass the arbitration processes.

34.2.3.2 M3IF Watermark Configuration Registers (M3IFWCFG0–M3IFWCFG7)

The M3IF Watermark Control Register contains the base address for each specific watermark space in the selected memory region. The first six registers are reserved for WEIM (CS0-CS5), and the last two registers are for SDRAM/LPDDR/DDR2 (CSD0-CSD1) system memory address space. The watermark feature is described in detail in Section 34.3.5.2, “Watermark Overview” on page 1-58. The field assignments for this register are shown in Figure 34-4 and the field descriptions are listed in Table 34-7.

0x0014 (M3IFWCFG4)
0x0018 (M3IFWCFG5)
0x001C (M3IFWCFG6)
0x0020 (M3IFWCFG7)

Access: User read-write

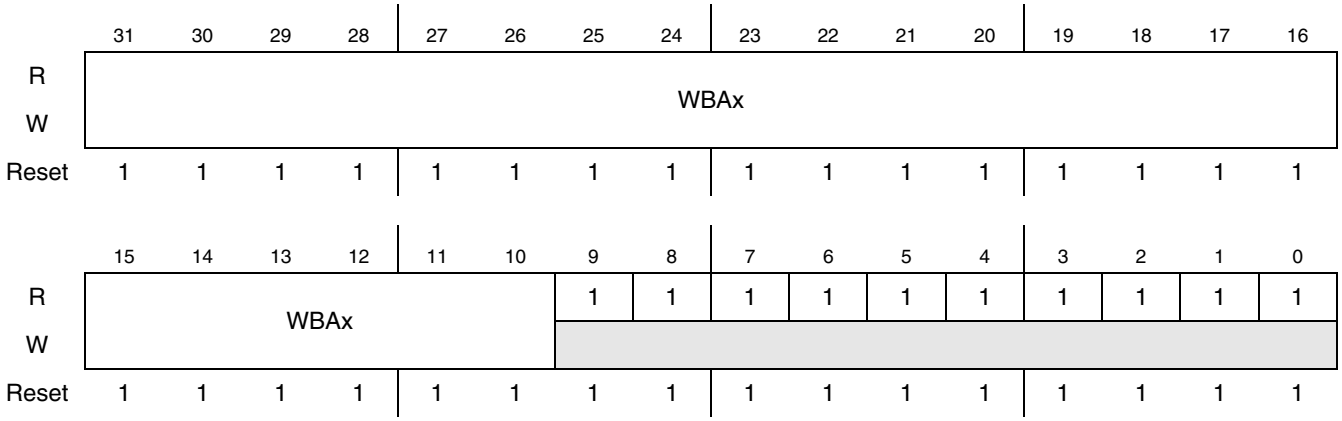

Figure 34-4. M3IF Watermark Configuration Register

Table 34-7. Watermark Configuration Register

Field	Description
31–10 WBAx	Watermark Memory Region (x) Base Address. The WBAx field gives the watermark base address for memory region x, x = 0…7. The watermark configuration registers are reserved for WEIM CS0 to CS5 and SDRAM/LPDDR/DDR2 CSD0 and SDRAM/LPDDR/DDR2 CSD1 system memory space address only. Writing an address which is not mapped to these respective address regions cause undefined functionality of watermark logic operation.
9–0	Reserved

34.2.3.3 M3IF Watermark Control and Status Register (M3IFWCSR)

The Watermark feature is described in detail in Section 34.3.5.2, “Watermark Overview.” The field assignments for this register are shown in Figure 34-5 and the field descriptions are listed in Table 34-8.

Offset 0x0024 (M3IFWCSR) Access: User read-write

Figure 34-5. M3IF Watermark Control and Status Register

Table 34-8. M3IF Watermark Control and Status Register Field Descriptions

Field	Description
31 WIE	Watermark Interrupt Enable. This bit enables the watermark interrupt generation. For example, if WIE is set and a watermark violation is detected (by the M3IF) a watermark interrupt is generated. 0 Watermark interrupt is disabled. 1 Watermark interrupt is enabled.
30–8	Reserved
7 WS7	Watermark Status 7. This bit indicates if watermark violation had occurred in the watermark memory region of SDRAM/LPDDR/DDR2 CS1 as defined by the M3IFWCFG7 register (WBA7). WS7 is cleared by writing a one to the bit. 0 SDRAM/LPDDR/DDR2 CSD1 watermark violation did not occur. 1 SDRAM/LPDDR/DDR2 CSD1 watermark violation had occurred.
6 WS6	WS6 - Watermark Status 6. This bit indicates if watermark violation had occurred in the watermark memory region of SDRAM/LPDDR/DDR2 CS0 as defined by the M3IFWCFG6 register (WBA6). WS6 is cleared by writing a one to the bit. 0 SDRAM/LPDDR/DDR2 CSD0 watermark violation did not occur. 1 SDRAM/LPDDR/DDR2 CSD0 watermark violation occurred.
5 WS5	Watermark Status 5. This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS5 as defined by the M3IFWCFG5 register (WBA5). WS5 is cleared by writing a one to the bit. 0 WEIM CS5 watermark violation has not occurred. 1 WEIM CS5 watermark violation occurred.
4 WS4	WS4 - Watermark Status 4. This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS4 as defined by the M3IFWCFG4 register (WBA4). WS4 is cleared by writing a one to the bit. 0 WEIM CS4 watermark violation has not occurred. 1 WEIM CS4 watermark violation has occurred.
3 WS3	WS3 - Watermark Status 3 This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS3 as defined by the M3IFWCFG3 register (WBA3). WS3 is cleared by writing a one to the bit. 0 WEIM CS3 watermark violation has not occurred. 1 WEIM CS3 watermark violation has occurred.

Table 34-8. M3IF Watermark Control and Status Register Field Descriptions (Continued)

Field	Description
2 WS2	WS2 - Watermark Status 2 This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS2 as defined by the M3IFWCFG2 register (WBA2). WS2 is cleared by writing a one to the bit. 0 WEIM CS2 watermark violation has not occurred. 1 WEIM CS2 watermark violation has occurred.
1 WS1	WS1 - Watermark Status 1 This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS1 as defined by the M3IFWCFG1 register (WBA1). WS1 is cleared by writing a one to the bit. 0 WEIM CS1 watermark violation has not occurred. 1 WEIM CS1 watermark violation has occurred.
0 WS0	WS0 - Watermark Status 0 This bit indicates if watermark violation had occurred in the watermark memory region of WEIM CS0 as defined by the M3IFWCFG0 register (WBA0). WS0 is cleared by writing a one to the bit. 0 WEIM CS0 watermark violation had not occurred. 1 WEIM CS0 watermark violation has occurred.

34.2.3.4 M3IF Snooping Configuration Register 0 (M3IFSCFG0)

The M3IFSCFG0 register contains the snooping window base address, the size of snooping window and the snooping control bit fields which are used by the M3IF to monitor the write access. The snooping feature is described in detail in Section 34.3.5.3, “Snooping Overview.” The field assignments for this register are shown in Figure 34-6 and the field descriptions are listed in Table 34-9.

Offset 0x0028 (M3IFSCFG0) Access: User read-write

1111	Reserved	-	-

34.2.3.5 M3IF Snooping Configuration Register 1 (M3IFSCFG1)

The M3IFSCFG1 register contains the enable bits for the lower 32 segments [31:0] in M3IFSCFG0 register. The Snooping feature is described in detail in Section 34.3.5.3, “Snooping Overview.” The field assignments for this register are shown in Figure 34-7 and the field descriptions are listed in Table 34-11.

Offset 0x002C (M3IFSCFG1) Access: User read-write

Figure 34-7. M3IF Snooping Configuration Register 1 (M3IFSCFG1)

Table 34-11. M3IF Snooping Configuration Register 1 Field Descriptions

Field	Description
31–0 SSE0	Snooping Segment Enable 0. This register contains the enable bits for the lower 32 segments [31:0] in the snooping window (defined by the M3IFSCFG0 register). If snooping is enabled for segment #*x* (respective SSE0 bit is high), than any write access detected to that segment sets the DMA_ACCESS for one cycle, and the respective snooping status bit is set. If the SSE0 bit is low, and a write access to the respective segment is detected by the M3IF, only the relevant status bit in the snooping status register is set, but the DMA_ACCESS is be generated. 0 Snooping segment #x is disabled. 1 Snooping segment #x is enabled.

34.2.3.6 M3IF Snooping Configuration Register 2 (M3IFSCFG2)

M3IFSCFG2 register contains the enable bits for the upper 32 segments [63:32] in the M3IFSCFG0 register.The Snooping feature is described in detail in Section 34.3.5.3, “Snooping Overview.” The field assignments for this register are shown in Figure 34-8 and the field descriptions are listed in Table 34-12.

Offset 0x0030 (M3IFSCFG2) Access: User read-write

Figure 34-8. M3IF Snooping Configuration Register 2 (M3IFSCFG2)

Table 34-12. M3IF Snooping Configuration Register 2 Field Descriptions

Field	Description
31–0 SSE1	Snooping Segment Enable 1. This register contains the enable bits for the higher 32 segments [63:32] in the snooping window (defined by the M3IFSCFG1 register). If snooping is enabled for segment #x (respective SSE1 bit is high), than any write access detected to that segment sets the DMA_ACCESS for one cycle, and the respective snooping status bit is set. If the SSE1 bit is low, and a write access to the respective segment is detected by the M3IF, only the relevant status bit in the snooping status register is set but the DMA_ACCESS is not generated. 0 Snooping segment #x is disabled. 1 Snooping segment #x is enabled.

34.2.3.7 M3IF Snooping Status Register 0 (M3IFSSR0)

The M3IFSSR0 register contains the snooping status bits for the lower 32 segments. The Snooping feature is described in detail in Section 34.3.5.3, “Snooping Overview” on page 34-47. The field assignments for this register are shown in Figure 34-9 and the field descriptions are listed in Table 34-13.

Offset 0x0034 (M3IFSSR0) Access: User read-write

Figure 34-9. M3IF Snooping Status Register 0 (M3IFSSR0)

Table 34-13. M3IF Snooping Status Register 0 Field Descriptions

Field	Description
31–0 SSS0	Snooping Segment Status 0. This register contains the snooping status bits for the lower 32 segments [31:0] in the snooping window (defined by the M3IFSCFG0 register). A bit in the SSS0 register is asserted if snooping to the respective segment occurred. **Note:** If snooping occurred the status bit is updated regardless of the respective snooping segment enable bit SSE0[x]. The DMA_ACCESS is asserted only if the respective snooping segment enable bit SSE0[x] is enabled. 0 Snooping for segment #x did not occur. 1 Snooping for segment #x occurred.

34.2.3.8 M3IF Snooping Status Register 1 (M3IFSSR1)

The M3IFSSR1 register contains the snooping status bits for the upper 32 segments. The snooping feature is described in detail in Section 34.3.5.3, “Snooping Overview.” The field assignments for this register are shown in Figure 34-10 and the field descriptions are listed in Table 34-14.

Figure 34-11. M3IF Lock WEIM CS*x* Register (M3IFMLWE*x*)

Table 34-15. M3IF Lock WEIM CS*x* Register Field Descriptions

Field	Description
31 WEMAx	WEIM CSx (0-5) Memory Active. This is a read-only status bit, that if set indicates that an active/pending access to a WEIM CSx memory exists. The WEIMx bit is set on one of the following conditions: • MLWEx_EN cleared - any active/pending access to WEIM CSx memory space sets the bit (until the access is completed). • MLWEx_EN is set - any accesses to WEIM CSx memory space initiated previously to MLWEx_EN assertion, keeps the WEMAx status bit set. The bit clears after all pending/active accesses execution is completed. Access from master number equal to MLWEx field does not assert the status bit. **Note:** When MLWEx_EN is set, any new accesses (initiated after MLWEx_EN assertion) to WEIM CSx memories (or to M3IFMLWEx register**)** not from MLWEx master are pending without setting WEMAx to 1. Both the M3IFMLWEx register and the WEIM CSx space region are locked to the MLWEx port. 0 No active/pending access to WEIM CSx memory exists. 1 Indicates an active/pending access to WEIM CSx memory exists.
30–4	Reserved

Table 34-15. M3IF Lock WEIM CS*x* Register Field Descriptions (Continued)

Field	Description
3 MLWEx_EN	Master Lock WEIM CS*x* Access Enable. This bit enables the Master Lock WEIM CSx access (MLWEx). The reset value of this bit is 0. **Note:** After MLWEx master does not need the lock any more, the master should clear MLWEx_EN bit, so WEIM CSx memory region is open to all masters. 0 Master Lock WEIM CSx access (MLWEx) disabled. 1 Master Lock WEIM CSx access (MLWEx) enabled
2–0 MLWE*x*	MLWEx - Master Lock WEIM CS*x* Access. This 3-bit field defines the master port number (MPG) that is the only one in the system served by the WEIM controller. All accesses to the WEiM CS*x* memory space from the other masters are postponed. The reset value of the MLWE*x* is 0. 1. Prior to lock accesses, the MLGE master should perform the following steps: 2. Set the MLWEx_EN bit and the MLWEx field (with the desired value) in the M3IFMLWEx register. 3. Read M3IFMLWEx register and check: WEMAx status bit is cleared (no pending/active accesses to WEIM CSx memory space exists). MLWEx_EN bit is set. MLWEx (value) points to the required port number (master port number that requires lock accesses). 000 Master Port Gasket 0 001 Master Port Gasket 1 010 Master Port Gasket 2 011 Master Port Gasket 3 100 Master Port Gasket 4 101 Master Port Gasket 5 110 Master Port Gasket 6 111 Master Port Gasket 7

34.3 Functional Description

This section provides the functional description for the M3IF module.

34.3.1 Master Port Gasket (MPG)

The MPG is a flexible port gasket. Up to 8 masters can be connected to the M3IF with any combination of the following MPG port types:

- MPG: Master port gasket for ARM11 AMBA AHB-Lite 32-bit data bus.
- MPG64: Master port gasket AMBA AHB-Lite 64-bit data bus.

The number and type of ports in use is system-dependent, and the unused ports are disconnected at the system level. Each of the MPG gaskets is assigned a single port type, and communicates with a single master.

34.3.1.1 Overview of MPG Operation

The MPG port gasket is used for those system masters that are 32-bit ARM11 AHB-Lite bus compatible. The MPG port gasket appears as a slave to any master it connects to. Table 34-16 lists the access types supported by the MPG.

Table 34-16. MPG Supported Burst Accesses

HBURST	TYPE	M3IF SLAVES		
		ESDRAMC 32-bit	WEIM 32-bit	NFC[1] 16/32-bit
000	SINGLE	YES[2]	YES	YES
001	INCR	YES	YES	YES
010	WRAP 4	YES	YES	NO
011	INCR 4	YES	YES	YES
100	WRAP 8	YES	YES	NO
101	INCR 8	YES	YES	YES
110	WRAP 16	NO	YES	NO
111	INCR 16	NO	YES	YES

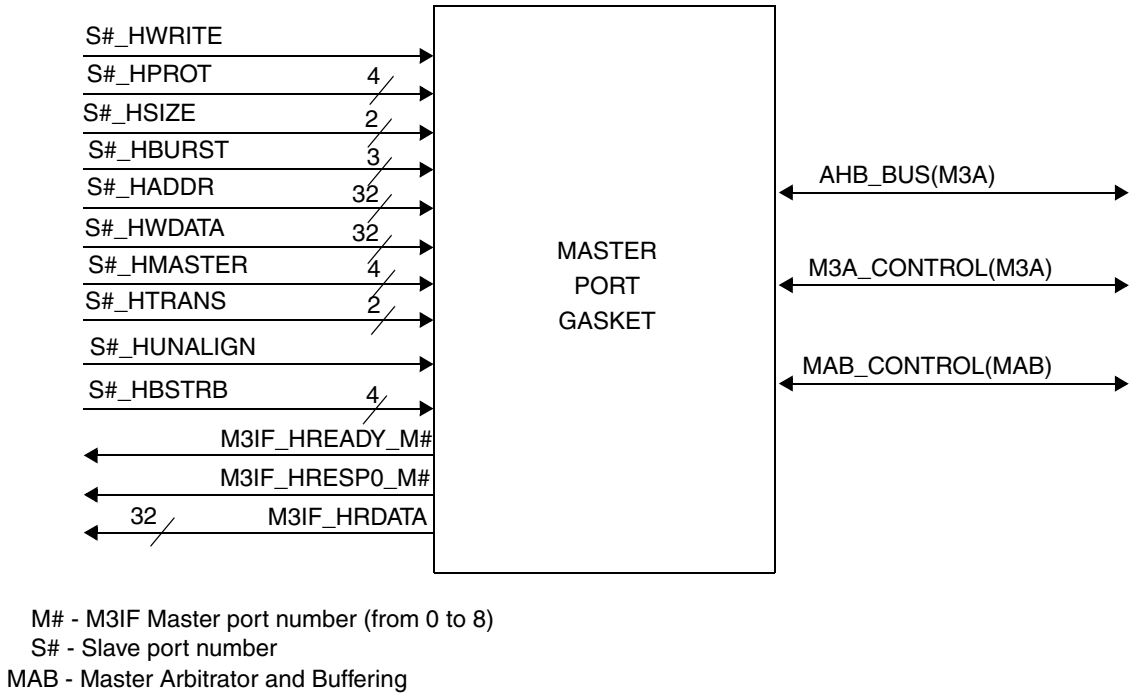
1 NFC does not support accesses of 8-bit data width.

2 ESDRAMC and WEIM supports only word-size bursts (32 bits). Since SINGLE access is not a burst type access, byte (8 bits) or half -word (16 bits) is supported as well.

NOTE

Unsupported access types produce undefined behavior, but an error response is not generated.

Figure 34-12 shows the MPG port interface diagram. The interface is ARM 11 AMBA AHB-Lite compatible (does not support RETRY and SPLIT transfers).



M# - M3IF Master port number (from 0 to 8)
S# - Slave port number
MAB - Master Arbitrator and Buffering

Figure 34-12. Master Port Gasket (MPG) Interface Diagram

The MPG works with both M3A and MAB, and outputs AHB_BUS and CONTROL signals to/from M3A (including requests to ESDRAMC and other controllers). The MPG decodes AHB bus inputs, converts them to pass through the MAB_CONTROL bus as address, data, and control signals (for instance suspend and abort commands).

After an accesses is initiated by one of the M3IF masters, the access reaches the respective MPG. The MPG asserts the request signal toward the M3A which starts the arbitration process. Once the arbitration is completed and the request can gain access to the bus, the request is accepted by the MPG and the handshake between the MPG and the M3A is completed for that access. If the access was not targeted toward the ESDRAMC, the master can start the access (by passing the master AHB bus) toward the respective slave (NFC, WEIM).

If the initiated access is targeted to the ESDRAMC after the M3A arbitration process is completed, the request is transferred toward the MAB, which arbitrates and schedules the access toward the ESDRAMC as a function of ESDRAMC state. An internal handshake between the MAB and ESDRAMC is used to schedule the new access, and once the handshake is completed, the MAB asserts the request accept signal toward the MPG. All ESDRAMC-related AHB signals are transferred from the master to the MPG which convert them to an internal protocol between the MPG and the MAB.

The MPG also converts MAB or M3A outputs to the AHB standard interface. Table 34-17 presents the signals name in both modules.

Table 34-17. MPG MAX Signals

AHB master - Signal Name	MPG - Signal Name	Description
S#_HWRITE (o)	M3IF_HWRITE_M# (I)	HWRITE high indicates a write transfer. HWRITE low indicates a read transfer.
S#_HPROT[3:0] (O)	M3IF_HPROT_M#[3:0] (I)	The protection control signals provide additional information about a bus access. For more information on this signal see Protection paragraph at the AHB specification. M3IF is using only HPROT[1] signal - user/supervisor access.This signal is used to protect both registers and restricted memory regions. An error response is generated in case of protection violation—for example, access supervisor registers/memory regions in user mode.
S#_HSIZE[1:0] (O)	M3IF_HSIZE_M#[1:0] (I)	Indicates the size of the transfer 00 8-bits (Byte) 01 16-bits (Half-word) 10 32-bits (Word) 11 Not define for MPG
S#_HMASTER[3:0] (O)	not defined	Not used by M3IF.
S#_HBURST[2:0] (O)	M3IF_HBURST_M#[2:0] (I)	Burst information is provided using HBURST signal, and the 8 possible types are: 000 SINGLE (Single transfer) 001 INCR (Incrementing burst of unspecified length) 010 WRAP4 (4-beat wrapping burst) 011 INCR4 (4-beat incrementing burst) 100 WRAP8 (8-beat wrapping burst) 101 INCR8 (8-beat incrementing burst) 110 WRAP16 (16-beat wrapping burst)[1] 111 INCR16 (16-beat incrementing burst)[1]
S#_HADDR[31:0] (O)	M3IF_HADDR_M#[31:0] (I)	Indicates the 32 bits memory ADDRESS bus.
S#_HWDATA[31:0] (O)	M3IF_HWDATA_M#[31:0] (I)	The write data bus is driven by the master during write transfers (on data phase). If the transfer is extended then the bus master hold the data valid until the transfer completes, as indicated by HREADY HIGH.

Table 34-17. MPG MAX Signals (Continued)

AHB master - Signal Name	MPG - Signal Name	Description
S#_HTRANS[1:0] (O)	M3IF_HTRANS_M#[1:0] (I)	Each transfer can be classified into one of four different types, as indicated by the HTRANS[1:0] signals: 00 IDLE. Indicates that no data transfer is required. The IDLE transfer type is used when a bus master is granted the bus, but does not wish to perform a data transfer. M3IF provides a zero wait state OKAY response to IDLE transfers. 01 BUSY. The BUSY transfer type allows bus masters to insert IDLE cycles in the middle of bursts of transfers. This transfer type indicates that the bus master is continuing with a burst of transfers, but the next transfer cannot take place immediately. M3IF provides a zero wait state OKAY response to IDLE transfers. When a master uses the BUSY transfer type the address and control signals reflects the next transfer in the burst. 10 NONSEQ. Indicates the first transfer of a burst or a single transfer. Single transfers on the bus are treated as bursts of one and therefore the transfer type is NONSEQUENTIAL. 11 SEQ. The remaining transfers in a burst are SEQUENTIAL and the address and control are related to the previous transfer. In the case of a wrapping burst the address of the transfer wraps at the boundary equal to the size (in bytes) multiplied by the number of beats in the transfer (4,8 or 16).
S#_HBSTRB[3:0] (O)	M3IF_HBSTRB_M#[3:0] (I)	Indicates which byte lanes are valid for each word transfer.[2]
S#_HUNALIGN (O)	M3IF_HUNALIGN (I)	Signal to indicate an unalign access requiring HBSTRB information.[2]
S#_HMASTLOCK (O)	M3IF_HMASTLOCK (I)	Indicates that the current master is performing a locked sequence of transfers.
S#_HREADY (I)	M3IF_HREADY_M# (O)	M3IF uses HREADY signal to insert the appropriate number of wait states in to the transfer (the M3IF adds wait states as long as the HREADY in signal is negated). The transfer completes with HREADY HIGH (and an OKAY response, which indicates the successful completion of the transfer). One wait state is added for every cycle that has HREADY negated.

Table 34-17. MPG MAX Signals (Continued)

AHB master - Signal Name	MPG - Signal Name	Description
S#_HRESP0 (I)	M3IF_HRESP0_M# (O)	The (HRESP0) response is used by the M3IF to indicate some form of error condition with the associated transfer. Since M3IF is AHB Lite compatible (AHB SPLIT and RETRY protocols are not supported) means that only one response signal is needed. HREPS0 encoding is: 0 OKAY. When HREADY is HIGH this shows the transfer has completed successfully. The OKAY response is also used for any additional cycles that are inserted, with HREADY LOW. 1 ERROR. This (two cycle) response shows an error has occurred. The error condition is signalled to the bus master so it is aware the transfer has been unsuccessful. M3IF response with Error on cases as specified in Section 34.3.1.4, “MPG Transfer Response” on page 1-40.
S#_HRDATA[31:0] (I)	M3IF_HRDATA[31:0] (O)	The read data bus is driven by the M3IF during read transfers. If M3IF extends the read transfer by holding HREADY low, then M3IF provides valid data at the end of the final cycle of the transfer, as indicated by HREADY high.

[1]INCR16/WRAP16 are supported only for accesses addressed to the WEIM.
[2]HUANLIGN and HBSTRB are supported only by ESDRAMC and WEIM.

A granted bus master starts an AMBA AHB transfer by driving the address and control signals. These signals provides information on the address, direction and width of the transfer, as well as indication if the transfer forms parts of a burst. Two different forms of burst transfers are allowed:

- Incrementing bursts, which do not wrap at address boundaries.
- Wrapping bursts, which wrap at particular address boundaries.

A write data bus is used to move data from the master to M3IF, while read data bus is used to move data from M3IF to the master.

Every transfer consists of:

- An address and control cycle (address phase)
- One or more cycles for the data (data phase)

Since the first address phase cannot be extended (since it always get HREADY asserted high) M3IF samples all control bus during first address phase, so if the master does not gain access immediately, the address phase information is saved. The data, however, can be extended by using M3IF_HREADY_MX signal. When LOW this signal causes wait states to be inserted into the transfer and allows extra time for M3IF (ESDRAMC or memories) to provide or sample data. In this way, back to back access between different/same slave can be performed and MPG stores all needed bus/signals so that when the master gains access, all the needed bus/signals are available.

During a transfer the M3IF shows the status using only one response signal HRESP0 (since M3IF is only AHB Lite compatible),

- 0 - OKAY—The OKAY response is used to indicate that the transfer is progressing normally and when M3IF_HREADY_MX goes high this shows the transfer has completed successfully.
- 1 - ERROR—The ERROR response indicates that a transfer error has occurred and the transfer has been unsuccessful.

34.3.1.2 MPG Basic Transfer

An AMBA AHB transfer consists of two distinct sections:

- The address phase.
- The data phase, which may require several cycles. This is achieved using the M3IF_HREADY_MX signal.

Figure 34-13 shows the simplest transfer, one data with no wait states.

- The AHB lite bus compatible master drives the address and control signals onto the bus after the rising edge of the clock.
- M3IF then samples the address and control information in the next rising edge of the clock and access starts (memory is not busy).
- After M3IF has sampled the address and control (and derived the appropriate command to the memory) it can start to drive the appropriate response and this is sampled by the bus master on the third rising edge of the clock.

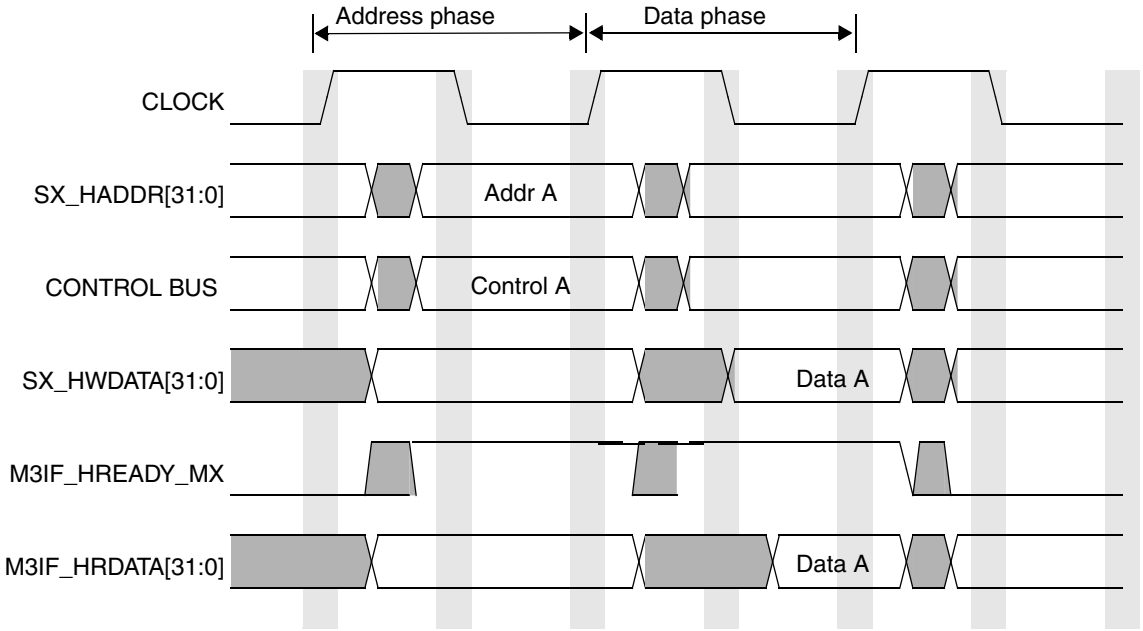


Figure 34-13. MPG Simple Transfer

The address phase of any transfer occurs during the data phase of the previous transfer. This overlapping of address and data is at the pipelined nature of the AHB bus and allows for high performance operation.

M3IF may insert wait states into any transfer, as shown in Figure 34-14, which extends the transfer allowing additional time for completion.

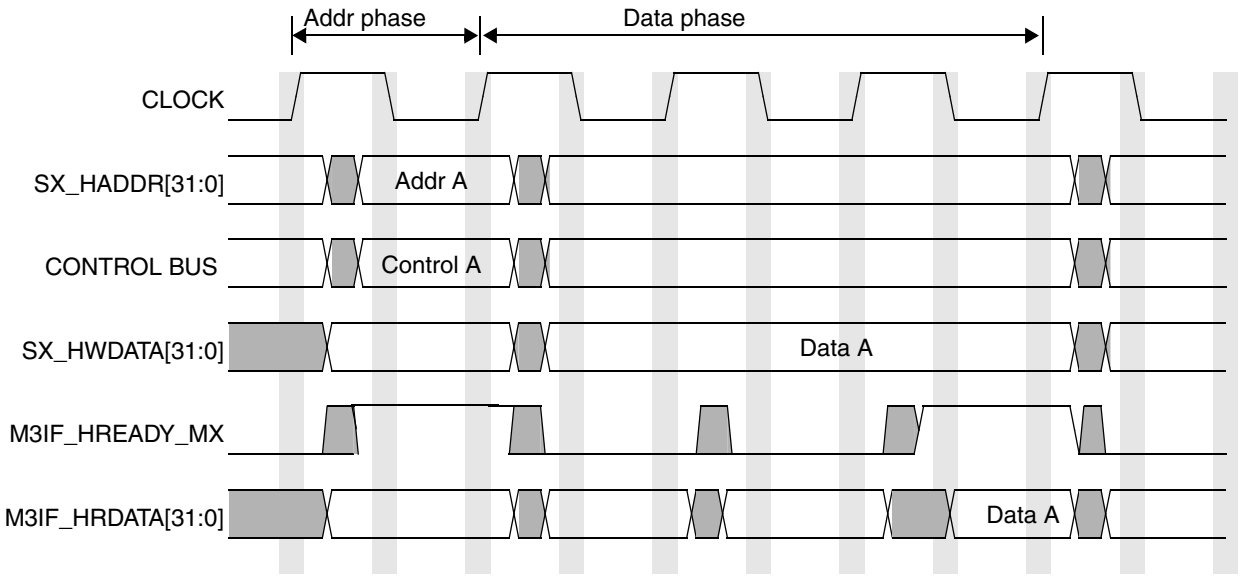

Figure 34-14. MPG with Wait States

- For write operations the bus master holds the data stable throughout the extended cycles.
- For read transfer the M3IF does not have to provide valid data until the transfer is about to complete.

When a transfer is extended in this way it has the side effect of extending the address phase of the following transfer. This is illustrated in Figure 34-15, which shows three transfers to unrelated addresses, A, B, and C.

- The transfers to addresses A and C are both zero state.
- The transfer to address B is one wait state.

Extending the data phase of the transfer to address B has the effect of extending the address phase of the transfer to address C.

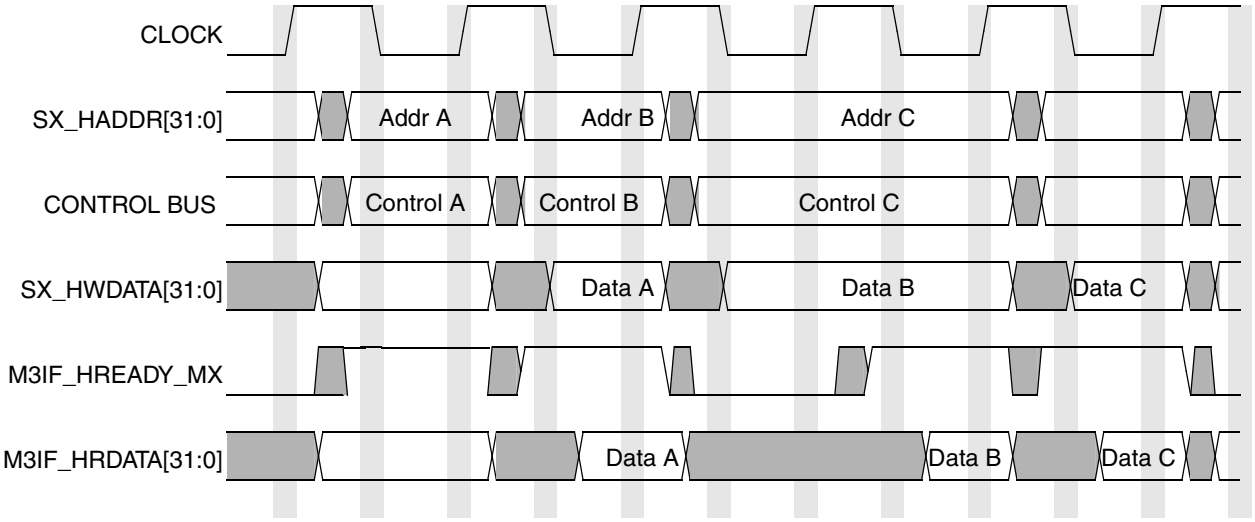

Figure 34-15. MPG Multiple Transfers

34.3.1.3 MPG Transfer Type

Every transfer can be classified into one of four different types, as indicated by SX_HTRANS[1:0] signals as described in Table 34-17. Figure 34-16 shows a number of different transfer types being used.

- The first transfer is the start of a burst and therefore is NON-SEQUENTIAL.
- The master is unable to perform the second transfer of the burst immediately and therefore the master uses BUSY transfer to delay the start of the next transfer (after M3IF sees BUSY with HREADY high it continues to give HREADY high until HTRANS bus changes from BUSY and then HREADY acts as usual). In this example the master requires only one cycle before it is ready to start the next transfer in the burst, which completes with no wait states.
- The master performs the third transfer of the burst immediately, but this time the M3IF is unable to complete and uses M3IF_HREADY_MX to insert a single wait state.
- The final transfer of the burst completes with zero wait states.

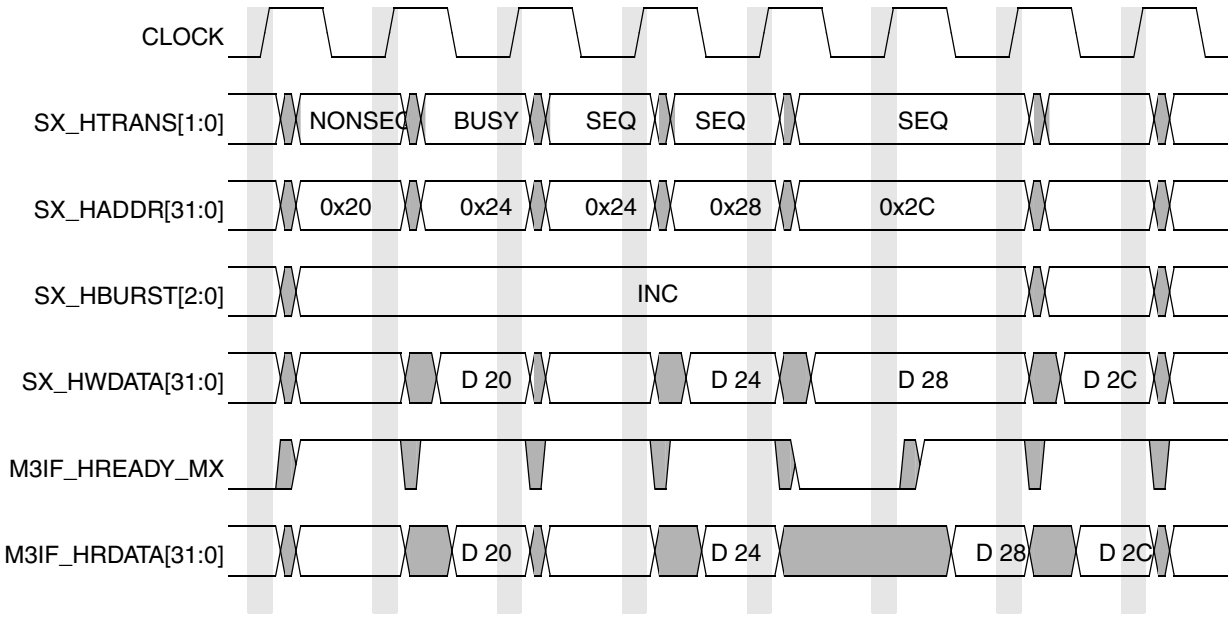

Figure 34-16. MPG - Transfer Type Examples

34.3.1.4 MPG Transfer Response

Whenever M3IF is accessed it provides a response which indicates the status of the transfer. The M3IF_HREADY_MX signal is used to extend the transfer and this works in combination with the response signals, M3IF_HRESP_MX, which provide the status of the transfer. M3IF can complete the transfer in a number of ways:

- Complete the transfer immediately.
- Insert one or more wait states to allow time to complete the transfer.
- Signal error to indicate that the transfer has failed.

The M3IF_HREADY_MX signal is used to extend the data portion/phase of a transfer. When LOW the M3IF_HREADY_MX indicates the transfer is to be extended and when HIGH indicates that data transfer had completed. Both M3IF_HREADY_MX and M3IF_HRESP0 encoding is described in Figure 34-13. It should be noted that M3IF does not support AMBA AHB, SPLIT and RETRY transfer response.

A transfer completes successfully (as defined by the AHB bus protocol) with M3IF_HREADY_MX HIGH and an OKAY response (M3IF_HRESP[1] LOW). A transfer completes unsuccessfully (ERROR response) with two consecutive cycles of M3IF_HRESP[1] HIGH, while during the first cycle M3IF_HREADY_MX is LOW and during the second cycle M3IF_HREADY_MX is HIGH (as defined by the AHB bus protocol). The ERROR response is used by the M3IF to indicate one of the following error types (which can be associated with the transfer):

- Master is trying to access a disabled CSD in the ESDRAMC system register.
- Master in user mode is trying to access a CSD that is configured to SUPERVISOR access only.
- System gave software reset command to ESDRAMC while access to ESDRAMC is in progress.
- A non predefined master that accesses a region that is marked as a Watermark region.

- Error response coming from all other memory controllers (except ESDRAMC).
- Access to ESDRAMC registers during an active access to SDRAM memory.

NOTE

The M3IF controls/handles ESDRAMC error response logic, and only transfer the error response signal from all other memory controllers (NFC and WEIM). For more details regarding the error response generation from the other memory controllers, consult the respective memory controller specification document available in the respective system architecture.

If an error response is generated by the MPG on the beginning of an access, the access is not executed and none of the data that is supposed to be read/written is transferred. However, if the error response has been given after few data transfers (in a burst access), the status of the first data transfer before the error response, for write access, is unknown (data maybe written or not) and the master should treat the data of the whole access as unknown data. In the case that this access was a read access the data that has been transferred until the error response is valid data and master can use it. If an error occurs during a burst access, the M3IF generates an (AHB) error response for all remaining beats from the burst.

34.3.1.5 MPG Burst Operation

Four, eight and sixteen-beat bursts are defined in the AMBA AHB protocol, as well as incremental undefined length bursts and single transfers. Both incrementing and wrapping bursts are supported in the protocol. A detailed description of the supported access type by the MPG is shown at Table 34-16.

Burst information is provided using SX_HBURST[2:0] signal and the eight possible types are defined in Figure 34-13. It is acceptable to perform single transfers using an unspecified length incrementing burst which only has a burst length of one.

The burst size indicates the number of beats in the burst, not the number of bytes transferred. The total amount of data transferred in a burst is calculated by multiplying the number of beats by the amount of data in each beat, as indicated by SX_HSIZE[1:0]. SX_HSIZE[1:0] encoding is shown in Figure 34-13. The size is used in conjunction with the SX_HBURST[2:0] signals to determine the address boundary for wrapping bursts.

All transfers within a burst must be aligned to the address boundary equal to the size of the transfer (that must be a word as mentioned). For example, word transfers must be aligned to word address boundaries (that is A[1:0]=00). If an unalign access is being perform HUNALIGN signal must be asserted high and the respective HBSTRB bus must be given by the master.

NOTE

Unaligned burst crossing bus width boundary is supported only if the eventual number of transfers on the bus is not higher than the value implied by the HBURST.

Four-beat wrapping and incrementing burst are shown in Figure 34-17 and Figure 34-18 respectively.

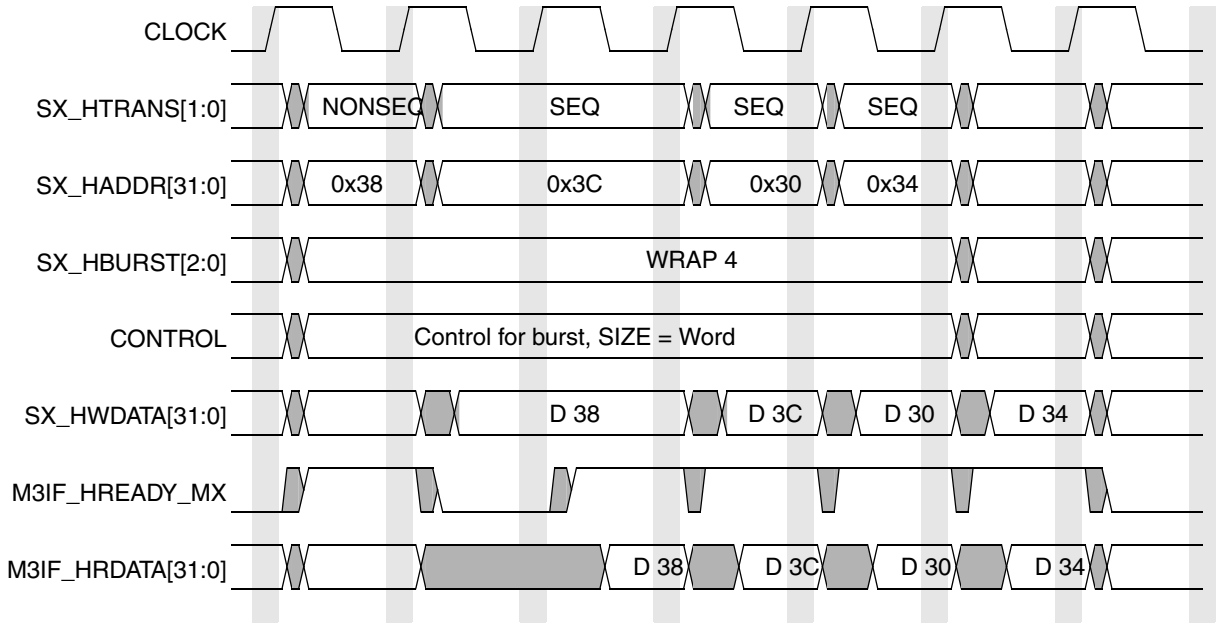

Figure 34-17. MPG Four Beat Wrapping Burst

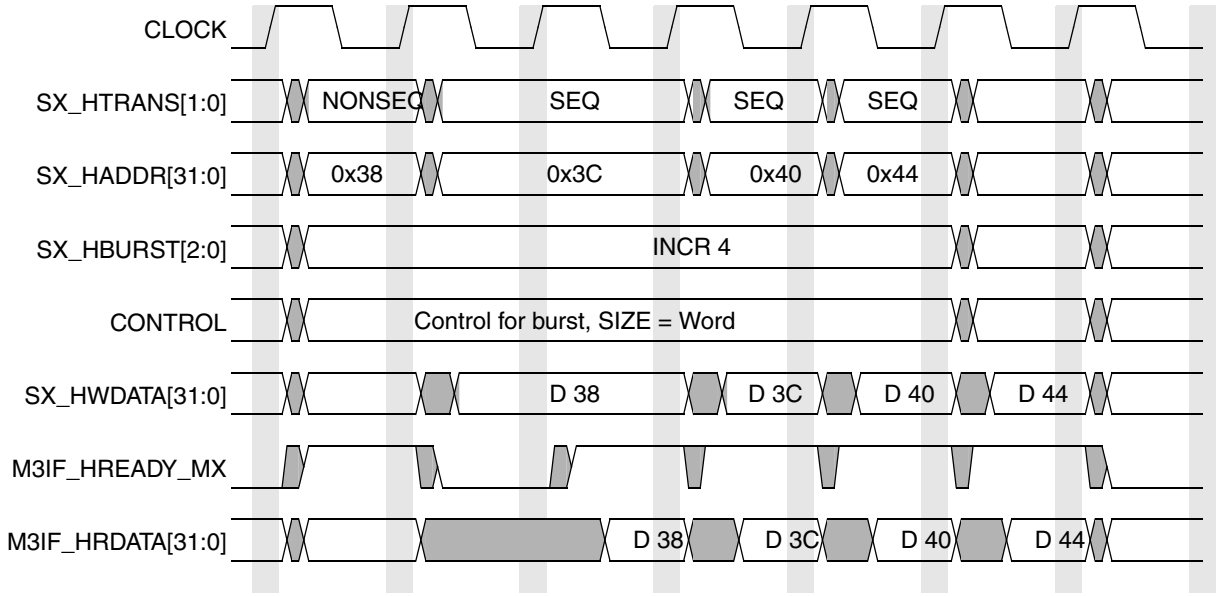

Figure 34-18. MPG Four Beat Incrementing Burst

34.3.1.6 MPG Early Burst Termination

M3IF can determine when a burst has terminated early by monitoring the SX_HTRANS[1:0] signals and ensuring that after the start of the burst every transfer is labelled as SEQUENTIAL or BUSY. If a

NON-SEQUENTIAL transfer occurs in middle of a burst it indicates that a new burst has started and therefore the previous one must be terminated immediately. If an IDLE transfer occurs in middle of a burst, it indicates the burst should be terminated immediately.

If a master cannot complete a burst because it loses ownership of the bus (for example, MAX slave port SX_HTRANS[1:0] is IDLE during a burst access due to MAX internal arbitration logic, means that the served MAX master port loses ownership of the bus) then it must rebuild the burst appropriately when it re-gains access to the bus. For example, if a master has only completed one beat of a four-beat burst then it must use an undefined-length burst to perform the remaining three transfers. Figure 34-19 shows incrementing bursts of undefined length that starts after aborting previous INCR 4 burst access.

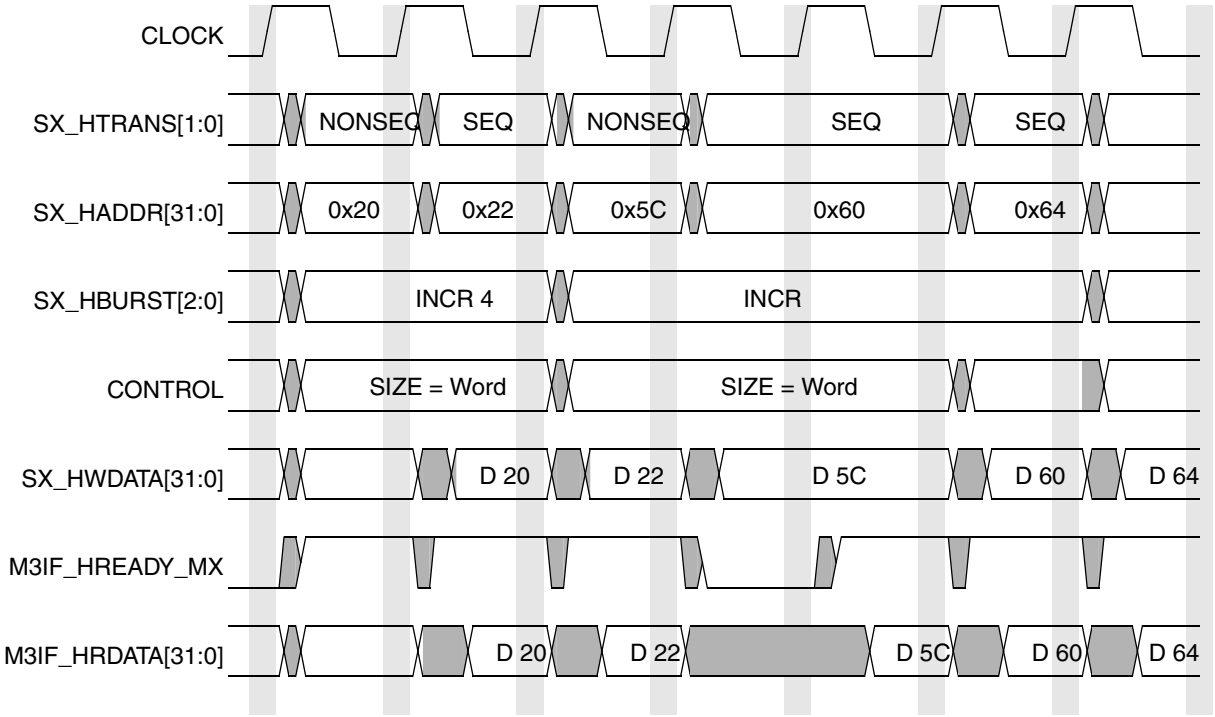

Figure 34-19. MPG Undefined Length Bursts

NOTE

To perform burst access length not equal to 4 or 8 words, it is possible to start INCR access of undefined length and to abort it after the desired words, or to start 4/8 burst length access and to abort it after the desired word., Both ways are supported by the M3IF and it is the master's decision which way to choose.

34.3.1.7 Multi-Endian Byte Order

M3IF supports multi-endian byte order. For example, there is an endian signal input to each one of the MPGs. The endian signal from each master should be static after reset, which means that all accesses from each master have the same byte order. If, in a given system, there are masters connected to the M3IF that do not drive endian signals (that is, they support only one endian type, big or little) the respective MPGs

big-endian signal should be static, meaning connected to 0 or 1 (depends on the byte order supported by the master connected to it). M3IF does NOT support shared external memory areas for masters with different endian modes. This feature should be handled by software or other additional hardware in the system.

34.3.2 Master Port Gasket 64 (MPG64)

34.3.2.1 Overview

The MPG64 port gasket is used for those system masters that have 64 bits data bus. Currently this gasket is used by the Layer2 Cache module. Table 34-18 presents the access types supported by the MPG.

Table 34-18. MPG64 Supported Burst Accesses

HBURST	TYPE	M3IF SLAVES					
		ESDRAMC		WEIM		NFC[1]	
		32 bit	64 bit	32 bit	64 bit	16/32 bit	64 bit
000	SINGLE	YES[2]	YES	YES[3]	YES	YES	YES
001	INCR	YES	YES	YES	YES	YES	YES
010	WRAP 4	YES	YES	YES	YES	NO	NO
011	INCR 4	YES	YES	YES	YES	YES	YES
100	WRAP 8	YES	NO	YES	NO	NO	NO
101	INCR 8	YES	YES	YES	YES	YES	YES
110	WRAP 16	NO	NO	YES	NO	NO	NO
111	INCR 16	NO	NO	YES	NO	YES	NO

1 NFC does not support accesses of 8 bit data width.

2 M3IF MPG64 supports only double word (64 bits) or word (32 bits) size bursts. Since SINGLE access is not a burst type access, byte (8 bits) or half word (16 bits) is supported as well.

NOTE

Unsupported accesses type cause undetermined behavior (that is, an error response is not generated).

For MPG64 brief overview description see Section 34.3.1.1, “Overview of MPG Operation.” Table 34-19 only shows the buses that have different widths, all other signals are the same as described in Table 34-18.

Table 34-19. MPG64 Additional Signals

64-Bit Master - Signal Name	MPG64 - Signal Name	Description
S#_HBSTRB[7:0] (O)	M3IF_HBSTRB_M#[7:0] (I)	Indicates which byte lanes are valid. (each bit for each byte)—extended to 8 bits.[1]
S#_HWDATA[63:0] (o)	M3IF_HWDATA_M#[63:0] (I)	The write data bus extended to 64 bit width

Table 34-19. MPG64 Additional Signals (Continued)

64-Bit Master - Signal Name	MPG64 - Signal Name	Description
S#_HSIZE[1:0] (O)	M3IF_HSIZE_M#[1:0] (I)	Indicates the size of the transfer 00 - 8 bits (Byte) 01 - 16 bits (Halfword) 10 - 32 bits (Word) 11- 64 bits (Double-Word) (defined only for MPG64)
S#_HBURST[2:0] (O)	M3IF_HBURST_M#[2:0] (I)	Burst information is provided using HBURST signal, and the 8 possible types are; 000- SINGLE (Single transfer) 001- INCR (Incrementing burst of unspecified length) 010- WRAP4 (4-beat wrapping burst) 011 - INCR4 (4-beat incrementing burst) 100 - WRAP8 (8-beat wrapping burst) 101 - INCR8 (8-beat incrementing burst) 110 - WRAP16 (16-beat wrapping burst) 111 - INCR16 (16-beat incrementing burst)
S#_HRDATA[63:0] (I)	M3IF_HRDATA_M#[63:0] (O)	The read data bus extended to 64 bit width

[1]HUANLIGN and HBSTRB are supported only by ESDRAMC and WEIM.

34.3.2.2 MPG64 Basic Transfer

All Basic transfer for 32 bits access are perform as AMBA-AHB usual access as described at Section 34.3.1.2, “MPG Basic Transfer.”

All 64 bits access are performed differently. Since the output data port is 32 bits wide, each 64 bit (double word) access is translated into 2 separated access, so a single read/write access of 64 bits is translated by the MPG64 into two single read/write 32 bits access. Burst length of 4 double words is being translated into 8 words (32 bits) burst length and 8 double words burst length is translated into 2 bursts of 8 words (32 bits) length. For 32-bit LPDDR there is no need for the MPG64 gasket to translate the access since 64 bits can be transferred by the LPDDR each cycle.

34.3.2.3 MPG64 Transfer Type

See Section 34.3.1.3, “MPG Transfer Type.”

34.3.2.4 MPG64 Transfer Response

See Section 34.3.1.4, “MPG Transfer Response.”

34.3.2.5 MPG64 Burst Operation

There are few things different than what is described in Section 34.3.1.5, “MPG Burst Operation.”

The size of each beat can be either 8, 16, 32 or 64-bits (byte/half word/word/double word), as shown in Table 34-18. If a burst access of double word is issued, WRAP8, INCR16 and WRAP16 are not supported by the M3IF.

34.3.2.6 MPG64 Early Burst Termination

See Section 34.3.1.6, “MPG Early Burst Termination.”

34.3.2.7 MPG64 Multi-Endian Byte Order

See Section 34.3.1.7, “Multi-Endian Byte Order.”

34.3.3 M3IF Arbitration (M3A)

34.3.3.1 Overview

The M3A is a programmable arbiter. All incoming requests from the different masters are on hold until access is granted by the arbiter. The arbitration is performed by a round robin algorithm which grants the access to the master that holds the token. In the case that a master holds the token but does not request access (to one of the M3IF slaves), the bus is granted to the nearest requesting master with a higher round robin number.

The internal signal bus free indicates the FF1 algorithm to choose a new master. The bus_free signal is asserted high by the M3A by monitoring HTRANS bus of the active master (the master that grants access). As soon as the M3A notices that the access has been accomplished (HTRANS equal to NONSEQ or IDLE with HREADY asserted high) it allows to a new master to gain access according to the round robin value. When a new master gains an access, the M3A transfers the AHB bus coming from this master to all memory controllers with an hsel signal to the specific memory controller (all others get low hsel).

Because MAB can get multiple access to the ESDRAMC and pass accesses to the ESDRAMC according to internal handshake between the ESDRAMC and the MAB, the M3A allow multiple access to pass to the MAB without waiting for previous accesses to be completed.

The M3A passes the request to the MAB if the access is to the ESDRAMC, and passes a new access to the MAB (before the previous/active master access is completed) if the master with the token is accessing the ESDRAMC If the request is for a different memory controller the M3A holds the access until all pending transfers in the MAB (ESDRAMC accesses) are finished, after which the bus_free signal asserts high to indicate the MAB has completed all incoming requests.

There are two different access paths, as follows:

- Access requests to SDRAM/LPDDR/DDR2. These involve the ESDRAMC memory controller. The access path is as follows:
  a) Master #*x* initiates access to memory by asserting the M#_ESDCTL_REQ signal.
  b) M3A arbitrates the master request.
  c) After successful arbitration, M3A passes the request to MAB by asserting the MASTER_REQ_EN signal.
  d) MAB and the respective MPG (that initiated the access) handle the access directly from/to the ESDRAMC, without involving the M3A.
  e) All data transfer is accomplished by the ESDRAMC and the external memory.

- Access requests to non–ESDRAMC-controlled memories. These accesses involve the respective memory controller. The access path is as follows:
  a) Master #*x* initiates access to non–ESDRAMC-controlled memory, by asserting the M#_GENERAL_REQ signal.
  b) M3A arbitrates the master request.
  c) After successful arbitration M3A passes the AHB bus (address, data, control signals) of the respective master to the relevant memory controller.
  d) M3A and the respective MPG (the one that initiated the access) handle the access from/to the relevant memory controller (MAB is not involved).
  e) All data transfer is accomplished by the relevant memory controller and the external memory.

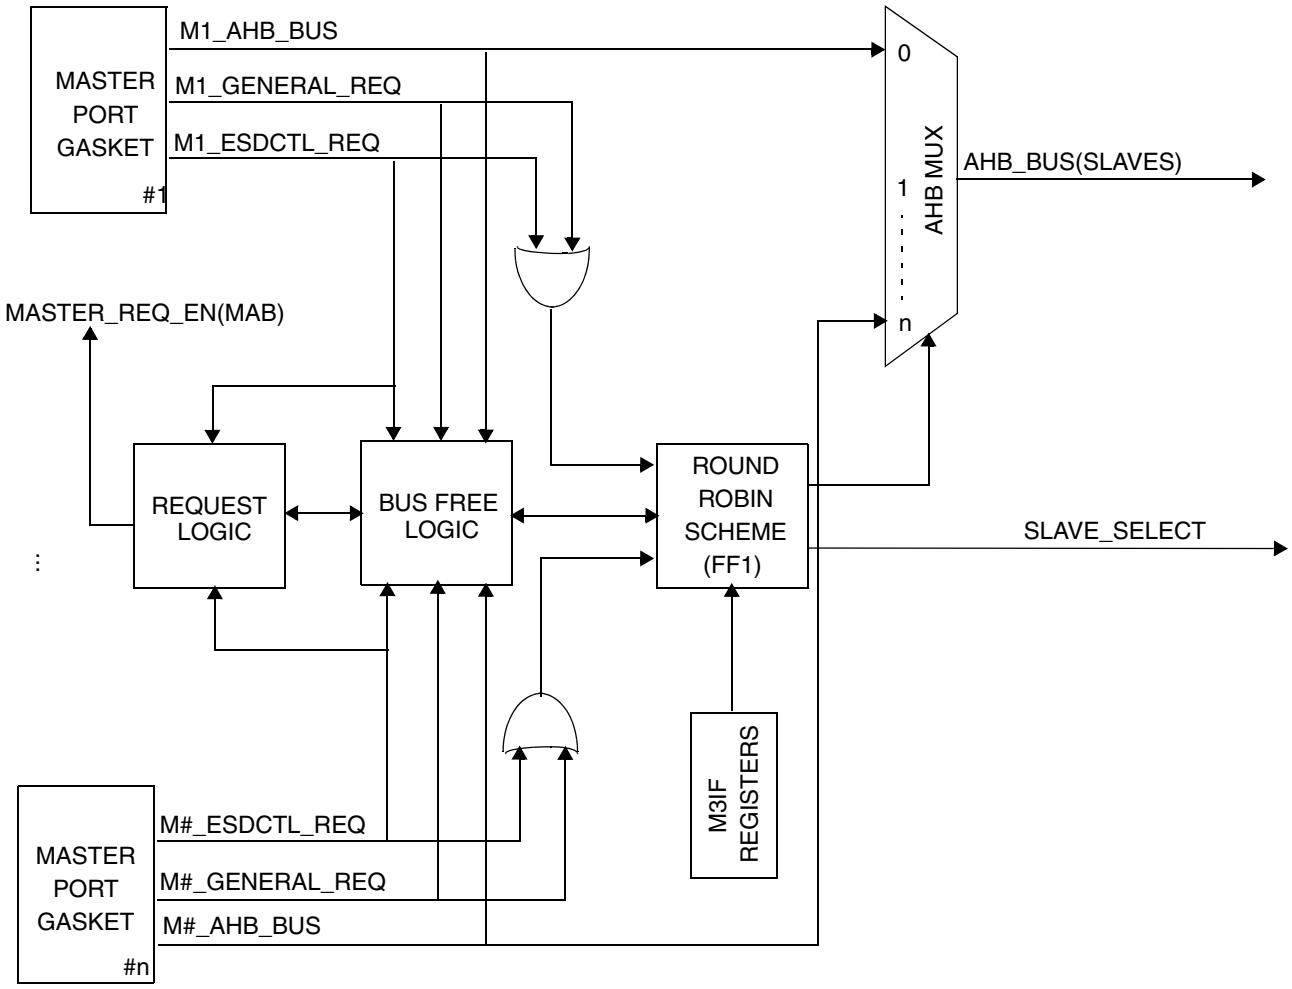

Figure 34-20. M3A Block Diagram

NOTE

Although the AHB bus indicates only one direction, the round robin scheme demultiplexes the AHB response signals (HREADY, HRESP, and HRDATA) from all slaves except for ESDRAMC (which directly to the MPG).

Figure 34-21 illustrates a simple transfer (all previous accesses are completed, and there are no other pending requests) between one of the M3IF masters and the WEIM module. There is one cycle penalty at the beginning of the access. The MPG samples the access relevant signals and de-asserts HREADY signal toward the master, until the target slave confirms the access (WEIM_HREADY high with WEIM_NONSEQ cycle). After the target slave (WEIM in this example) confirms the request (HREADY high with WEIM_NONSEQ cycle) the access traffic (control and data) is direct between the master and the target slave (WEIM).

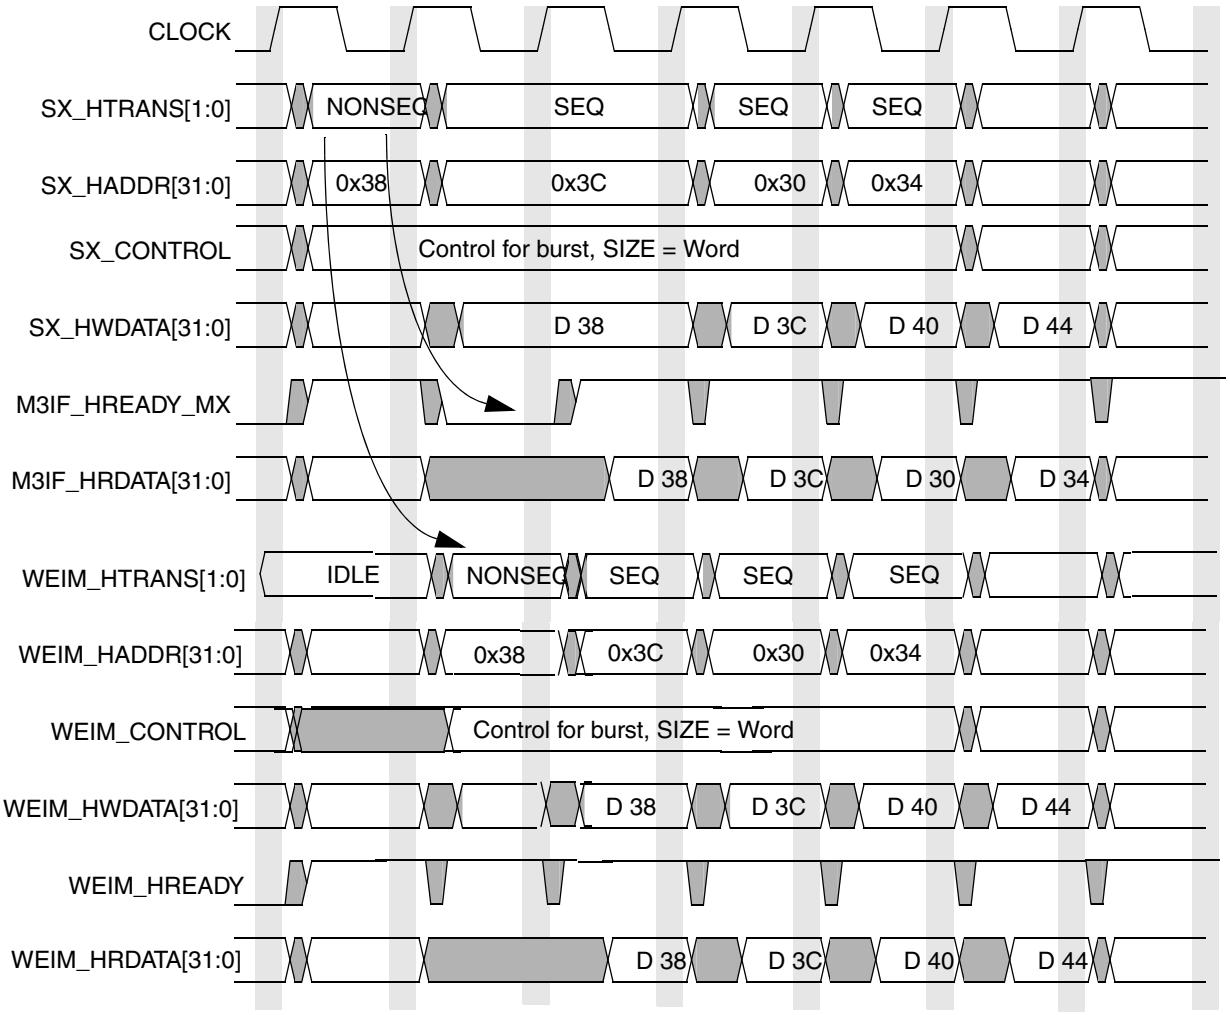

Figure 34-21. M3A Simple Transfer Timing Diagram

34.3.3.2 M3A—Find First 1 (FF1) Algorithm

Arbitration between the various requests is done by Find First 1 algorithm based on round robin algorithm (see Figure 34-22). If two or more masters request access to the M3IF the master with the token, or the master that is the first to receive the token (in case the master with the token does not request access) gains control over the AHB bus or enables his request signal to the MAB. For example, if masters 0, 1, and 6 requesting access at the same time and the token is at master 2, then master 6 gains control over the AHB bus or his request signal to the MAB is enabled, since it is the first to receive the token (this is done to reduce arbitration time, in this example 4 clock cycles are saved). The round robin pointer increase its value in two cases, if the master with the token does not request access or if the master with the token requests access and gains the AHB bus/enable request - on the cycle that the master gains the AHB bus/enable request the round robin pointer increases its value. If a master requests an access and has the token but does not gain access because no new access can pass on, the round robin does not increase until the master gains the AHB bus/enable request.

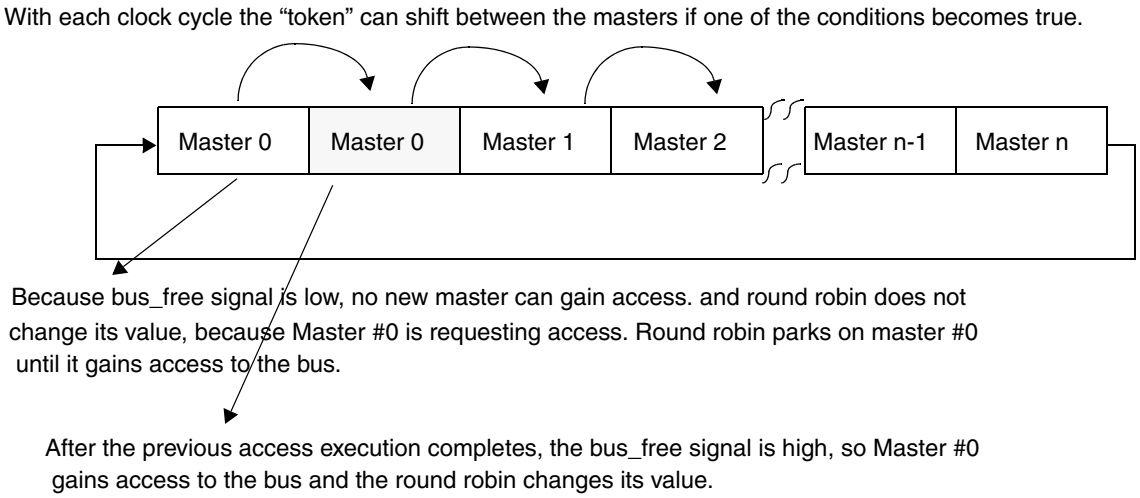

Figure 34-22. M3A—Round Robin Token Chain—Equal Priority

There is an option to program the round robin to work with different priority using MRRP field of the M3IF control register. When the MRRP equals 0, no priority is given to any master, so the probability of gaining access is equal for each one of the masters.

If one or more bits of the MRRP are set to 1, the priority changes, and all master whose bits are set to 1 get together 50% priority of gaining access. For example, if both master 1 and master 4 bits set to 1 in the MRRP field, the priority to gain access of master 1 and 4 together is 50%. If only one bit is set the respective master (that his bit is set) alone has 50% priority to gain access.

NOTE

By default (after reset) all MRRP bits are cleared, means that all M3IF masters have the same priority.

The 50% priority refers only to the round robin mechanism. If a non priority master (MRRP respective bit is not set) with the token is already waiting to gain the bus the new coming request from the priority master (MRRP respective bit is set) does not gain access before the previous master request is completed. Additionally, the priority master cannot terminate an ongoing access of any other masters. Figure 34-23 shows the round robin chain in case that MRRP configured to 8'b00010010 - master 1 and 4 set to 1.

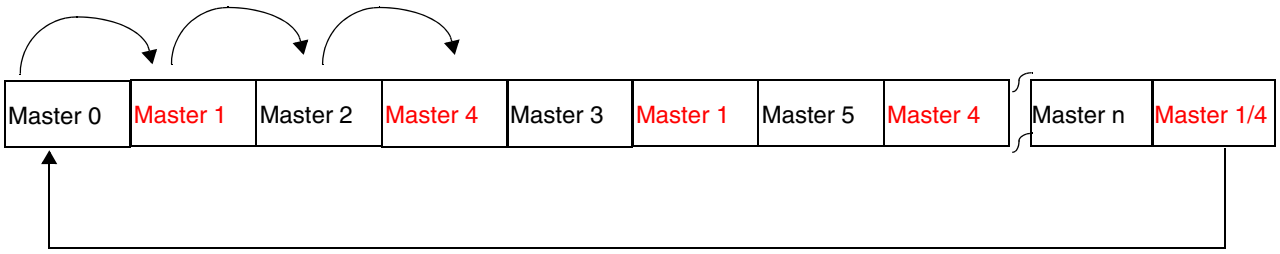

Figure 34-23. M3A—Round Robin Token Chain—Masters 1 and 4 has 50% Priority

34.3.3.3 bus_free Signal Algorithm

When the bus_free signal asserts high, it indicates the new master can gain access. The bus_free asserts high in the following cases:

- When the previous access is a non-ESDRAMC access, the HTRANS bus of the previous master that gained the access is equal to NON SEQUENTIAL or IDLE, and HREADY is asserted high.
- When the previous access is an ESDRAMC access, and the new master that gains access was also an ESDRAMC access.
- When the previous access or accesses are ESDRAMC accesses and all previous accesses are finished.

NOTE

To avoid contention between the memory controllers/memories, there is a special signal from the MPGs and from the MAB to the M3A that goes to the bus_free algorithm indicating which kind of slave is still using shared I/O pins, so no new access to a different memory begins.

34.3.4 Master Arbitration and Buffering (MAB)

34.3.4.1 Overview of MAB Operation

The MAB arbiter uses the same programmable arbiter as the M3A (Section 34.3.3.2, "M3A—Find First 1 (FF1) Algorithm"). All incoming requests from the different masters are put on hold until access is granted by the arbiter. The MAB communicates with the ESDRAMC and grants access at the earliest possible time, for example when the ESDRAMC is ready to handle a new memory request. Each time ESDRAMC can get a new access, the new access is sampled into the CONTROL and DATA buffers so ESDRAMC

receives stable inputs during the time the access is in progress. The DATA buffer is sampled according to ESDRAMC write acknowledge response. Figure 34-24 shows MAB operation block diagram.

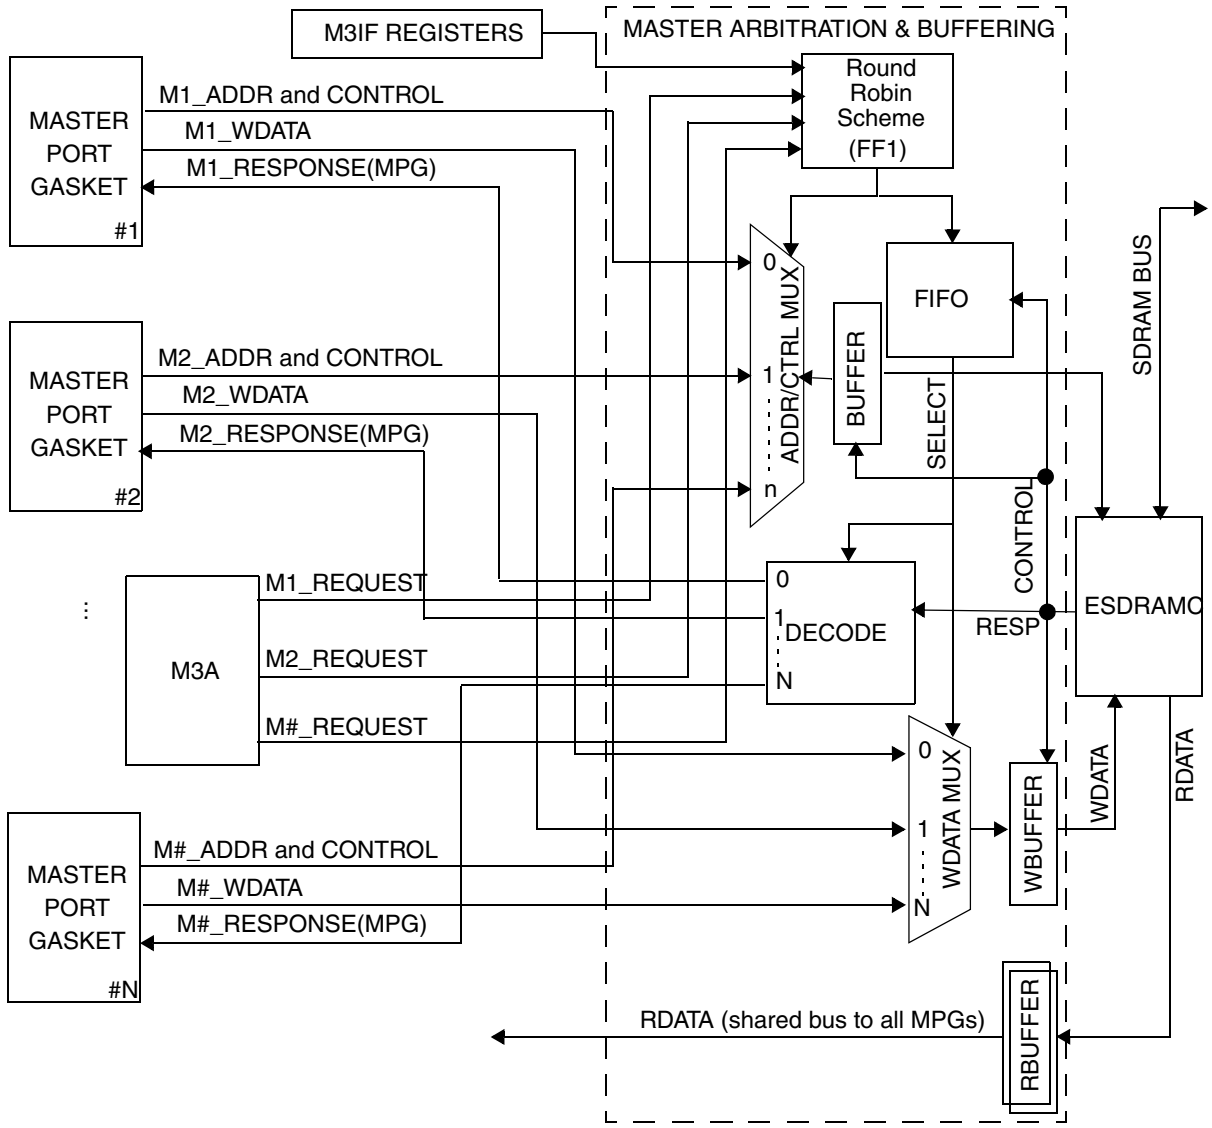

Figure 34-24. MAB Overview Block Diagram

34.3.4.2 M3B—Find First 1 (FF1) Algorithm

This operation of the arbiter algorithm is identical to the M3A arbiter algorithm described in Section 34.3.3.2, “M3A—Find First 1 (FF1) Algorithm.”

Each time NEW_ACCESS goes HIGH it indicates that the EDRAMC is ready to handle a new memory request, meaning that the previous request is either completed or controlled by the SDRAM memory. During the same cycle the memory port is granted to the master with the token. Figure 34-25 shows the arbitration process for 4 master requests. At the first clock cycle masters M0, M1, and M2 simultaneously request the memory port. At the rising edge of the clock (while NEW_ACCESS is HIGH) master M0 has

the token, so the memory port is controlled by M0 (see MASTER_CONTROL signals). During that time all M3IF_HREADY_M# signals are low, besides M3IF_HREADY_M3 which was the previous served master.

The same arbitration process occurs for the following requests. Master M1 has the token and grant access to the ESDRAMC (see MASTER_CONTROL). HREADY of master M0 asserted high and accomplished the previous access. After several cycles M0 assert the REQUEST signal again due to a new access.

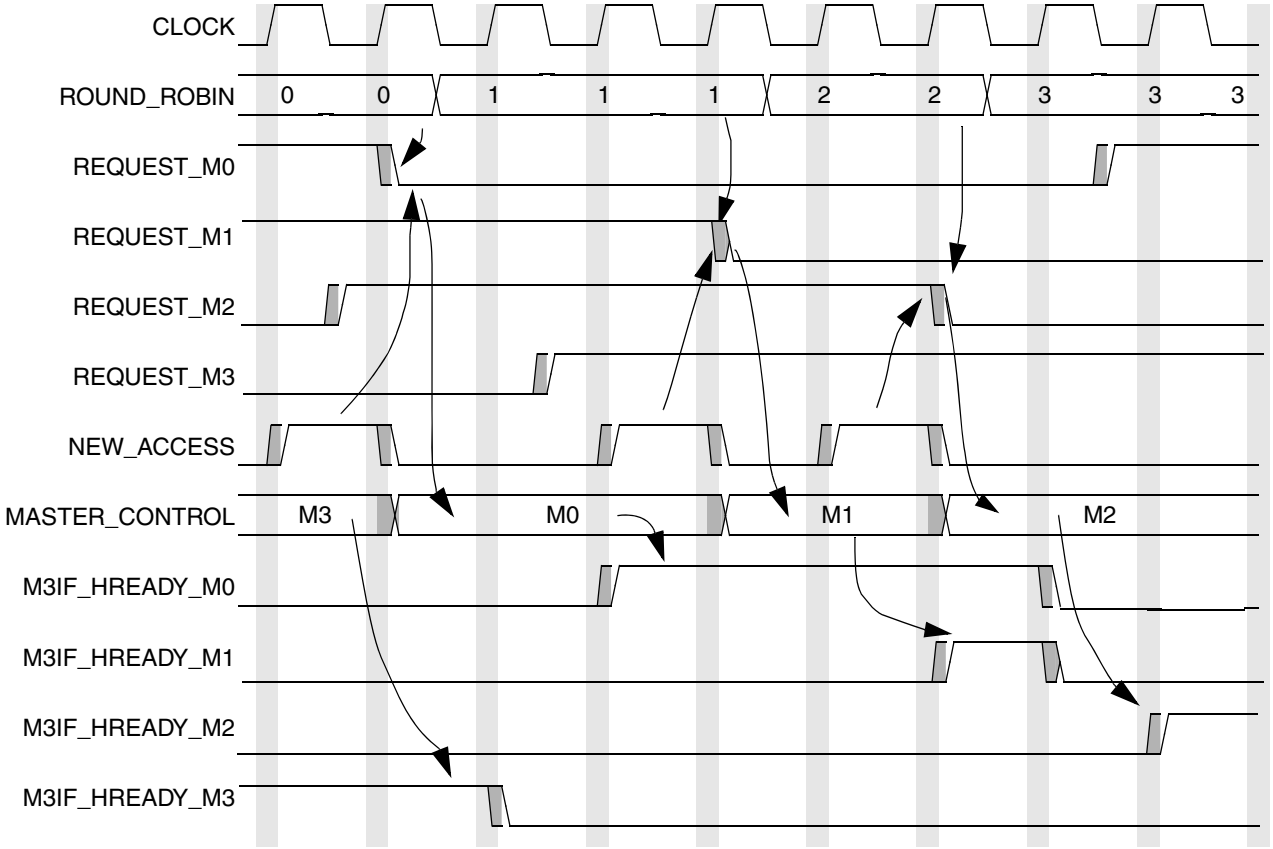

Figure 34-25. MAB Arbitration Process Time Diagram

Once a master has control over the port, the other requests remain on hold, meaning that their M3IF_HREADY_M# is LOW. The current master has control over the memory port until it completes the requested transfer. The new master gaining access to the memory port is the master with the new token.

The MAB ADDR/CTRL MUX and WDATA MUX connect (using the round robin algorithm) the selected master and when NEW_ACCESS arrives the MUX output is sampled by the MAB so that a stable bus is provided to ESDRAMC. After a new access is detected by the ESDRAMC, data transfer between the memory and the masters can start. In order for the MAB to serve more than one master at a time, a cyclic 4 entry FIFO with two pointers (read/write) is used. The FIFO read pointer is used (by the Decode block) as the selector for the memory RESPONSE signals and for the WDATA MUX, while the FIFO write pointer is used to add a new master to the FIFO entries. (since ESDRAMC hides latency a new access can start before previous access ended. This why this MUX control should work separately for information to the ESDRAMC and ESDRAMC response.

Figure 34-26 shows a detailed multi master memory request time diagram. The diagram shows two masters presenting memory request (AMBA AHB) signals and their conversion by the MPG and MAB to the ESDRAMC. The HRDATA timing is also shown with the respective M3IF_HREADY_M# signal. The HRDATA bus from the memory (during READ transfers) is shared with all present masters (except 64-bit masters that become a 64-bit bus after decoding by MPG64), while the arbitration is completed by the use of the M3IF_HREADY_M# signals at the master level.

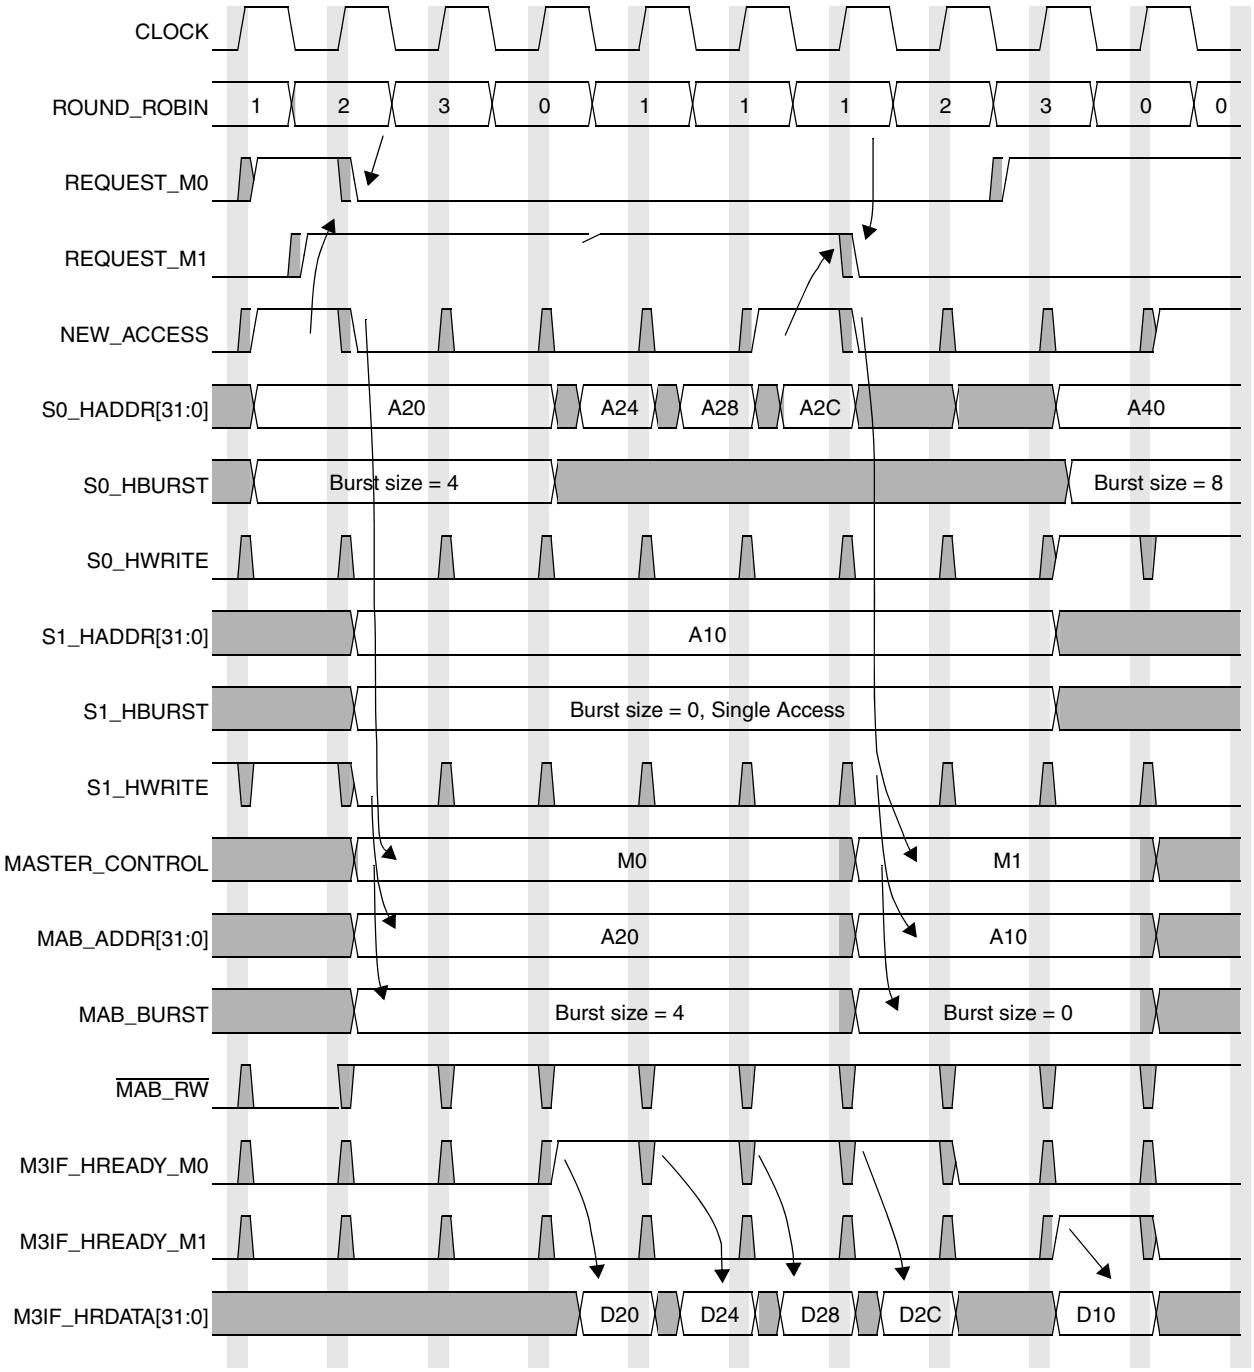

Figure 34-26. MAB Multi-Master Request Time Diagram

34.3.4.3 M3IF Operation During HMASTLOCK Accesses

If a HMASTLOCK access to any memory controller (memory space) is initiated by one of the M3IF masters, the request need to pass the arbitration like a regular access. After the access passes the arbitration

it “locks” the arbitration and all other accesses (regardless to memory space destination) remain pending until the HMASTLOCK signal negates (from the master that initiated the HMASTLOCK access).

While HMASTLOCK is asserted, all accesses initiated by the locking master are executed without arbitration, while all other masters accesses remain pending.

NOTE

During HMASTLOCK high, the locking master is not allowed to change the memory space destination from SDR/DDR SDRAM space to non-SDR/DDR SDRAM, or vice versa.

34.3.4.4 DVFS Protocol

When CCM needs to perform a frequency change (due to the DVFS algorithm) the CCM asserts the dvfs_req signal. After dvfs_req assertion, the M3IF blocks all new accesses to the ESDRAMC (accesses to other memory controllers are not affected). More on, the M3IF (MAB) requests the ESDRAMC to place the external SDR/LPDD R SDRAM memory into self-refresh mode.

Once, all active accesses to the ESDRAMC (prior to dvfs_req assertion) are completed and the external SDR/LPDDR/DDR2 SDRAM memory is in self refresh mode the M3IF asserts the dvfs_grant signal, which indicates the CCM that the EMI is ready for the frequency change.

After the frequency change is completed, the CCM negates the dvfs_req. After dvfs_req negation the M3IF signals to the ESDRAMC to exit from self refresh mode, and all pending accesses to the ESDRAMC resume.

NOTE

Accesses to non- ESDRAMC memory controllers are not affected during the MAB DVFS protocol.

34.3.5 Watermark and Snooping Logic

34.3.5.1 Watermark in a System

M3IF has watermark capability. However, not all chips require watermarks. Therefore, in some chips the watermark pins of the M3IF are not connected and are assigned with a constant value to disable this capability. See the design specification to determine whether M3IF should have a watermark enabled or not.

34.3.5.2 Watermark Overview

The watermark is a security feature, that is used to protect a configurable memory region (watermark space) for up to 8 predefined different CS. The access to the watermark space is permitted only to one or more preselected M3IF ports, means that only the masters that are connected to those M3IF ports can access the watermark space. The masters are system dependent and cannot be changed by the software. The watermark ports are via programming and constant in a given system (the watermark port is connected by the system architecture to VCC/GND). The preselected ports are MPG5 and MPG6, which means that all masters that access the M3IF via those ports can access the memory regions that are defined as

watermark regions. Access to the watermark space by other masters is considered as a watermark violation, and a watermark interrupt is generated if enabled through the M3IFWCSR register (register details at Section 34.3.5, “Watermark and Snooping Logic”).

One watermark space can be defined for each predefined CS mapped by the M3IF. The watermark space is configurable through a set of 8 configuration registers that contains the watermark space base address for each chip select. The base address has a resolution of 1Kbyte, means:

- The lower base address can be set at the end of the first Kbyte at address 0x3FF.
- The base address can be set in steps of 1 Kbyte.

Figure 34-27 illustrates a watermark space of 48 Mbyte in SDRAM CSD0 memory region. The red shaded area in the figure is the watermark space defined in SDRAM CSD0 memory region. This memory region is accessible only by those masters that are connected to the predefined M3IF watermark ports. Accesses to this region by other masters generates an interrupt (if enabled through the watermark control and status register) and sets the respective watermark space (clear by one) status bit. The blue shaded area is the non protected SDRAM CSD0 memory region, means that it is accessible by all masters connected to the M3IF.

NOTE

In case that WEIM operates in collapse mode (CS0 and CS1 are combined as one space) the watermark region definition works as if CS0 and CS1 where separate spaces, for example, there are two watermark spaces. For example, if a watermark is defined in M3IFWCFG0 register as A3FF_FFFF, then the watermark region ends at A7FF_FFFF and accesses to A800_0000 and up are enabled for all masters (the region A800_0000 - AFFF_FFFF although belong to CS0 (due to collapse mode) is not seen as a watermark region). An additional watermark need to be defined in M3IFWCFG1 in order to define it as a watermark region as well.

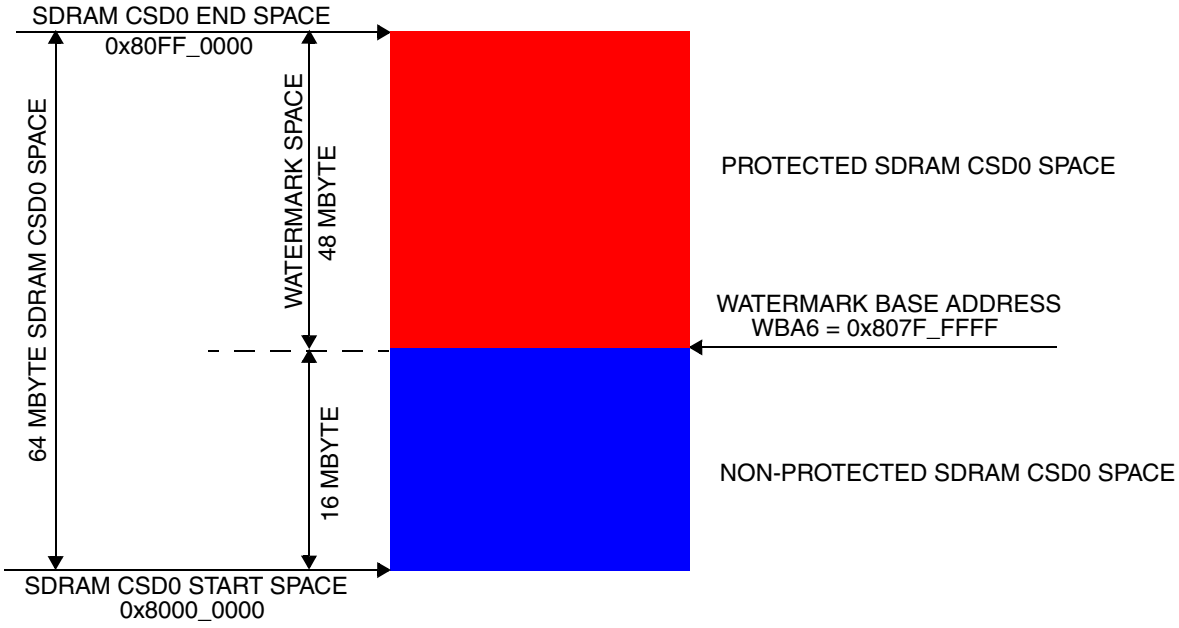

Figure 34-27. SDRAM CS0 Watermark Space Visualization

34.3.5.3 Snooping Overview

The M3IF snooping feature (used by the Image Processor Unit, IPU), monitors and detects write accesses to a configurable window (snooping window) in one of the memory regions mapped by the M3IF. The snooping window base address, memory region, and window size are configurable parameters through the M3IFSCFG0 register (register details at Section 34.2.3.4, "M3IF Snooping Configuration Register 0 (M3IFSCFG0)"). The snooping window is further divided into 64 equally sized segments.

A detected write access to the snooping window results in:

- The respective segment status bit in M3IFSSR0 and/or M3IFSSR1 registers is set.
- DMA_ACCESS strobe is asserted for 1 clock cycle if the snooping segment enable bit is set for the snooped segment. The snooping segment enable bit is configured via 2 snooping configuration registers, M3IFSCFG1 and M3IFSCFG2.

It is the software's responsibility to clear the snooped segment status bits, but the snooped segment status bit is set for each snooping detection regardless of its value.

34.4 Initialization/Application Information

34.4.1 M3IF in a System

This section provides an example of M3IF initialization, integration and configuration in a given system.The system requirements are listed below:

- Several masters with external memories access capabilities.
  - ARM I-Cache - 32/64-bits data bus, according to chip demands.
  - ARM D-Cache - 32/64-bits data bus, according to chip demands.
  - DSP Platform - 32 bit data bus via watermark ports (according to SOC requirements)
    - Watermark space (0xA00E_FFFF) in WEIM CS0 and WEIM CS1 (0xA81F_FFFF)
    - Watermark Interrupt enable
  - Layer 2 Cache - 64 bit data bus
  - Layer 2 Cache - 32 bit data bus
  - IPU - 32-bit data bus with the following snooping requirements
    - 512Kbyte snooping window in SDRAM CSD1 memory region
    - Snooping window base address 0x9000_F000
    - Enable snooping for segments, 3, 7, 12-27, 32, 36-56
- The system uses 2 SDRAM memory devices (32 bits), a 32-bit Flash (via WEIM CS0) and one SRAM (via WEIM CS1). The number of memory devices depends on the chip definitions.

34.4.1.1 Watermark Requirements Settings

The following M3IF settings are needed to implement the system watermark requirements.

- WATERMARK_ PORT[7:0] connected to VCC or GND according to system definition (hard connecting to VCC/GND in the system level).

- Write address 0xA00E_FC00 to M3IFWCFG0 register, in order to set the watermark base address for WEIM CS0 memory region.
- Write address 0xA81E_FC00 to M3IFWCFG1 register, in order to set the watermark base address for WEIM CS1 memory region.
- Write 0x8000_0000 to M3IFWCSR register in order to enable the watermark interrupt generation.

34.4.1.2 Snooping Window Settings

The following M3IF settings are needed to implement the system snooping requirements.

- Write 0x9000_F011 to M3IFSCFG0 register to set the snooping window base address and size.
- Write 0x0FFF_F088 to M3IFSCFG1 register to enable snooping for the specified lower segments.
- Write 0x01FF_FFF1 to M3IFSCFG2 register to enable snooping for the specified higher segments.

Chapter 35
Multi-Layer AHB Crossbar Switch (MAX)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

35.1 Overview

This section provides an overview of the MAX. The purpose of the MAX is to concurrently support up to five simultaneous connections between master ports and slave ports. The MAX supports a 32-bit address bus width and a 32-bit data bus width at all master and slave ports. A simplified block diagram is shown in Figure 35-1.

NOTE

The ARM11 platform implements a 6 master by 5 slave configuration.

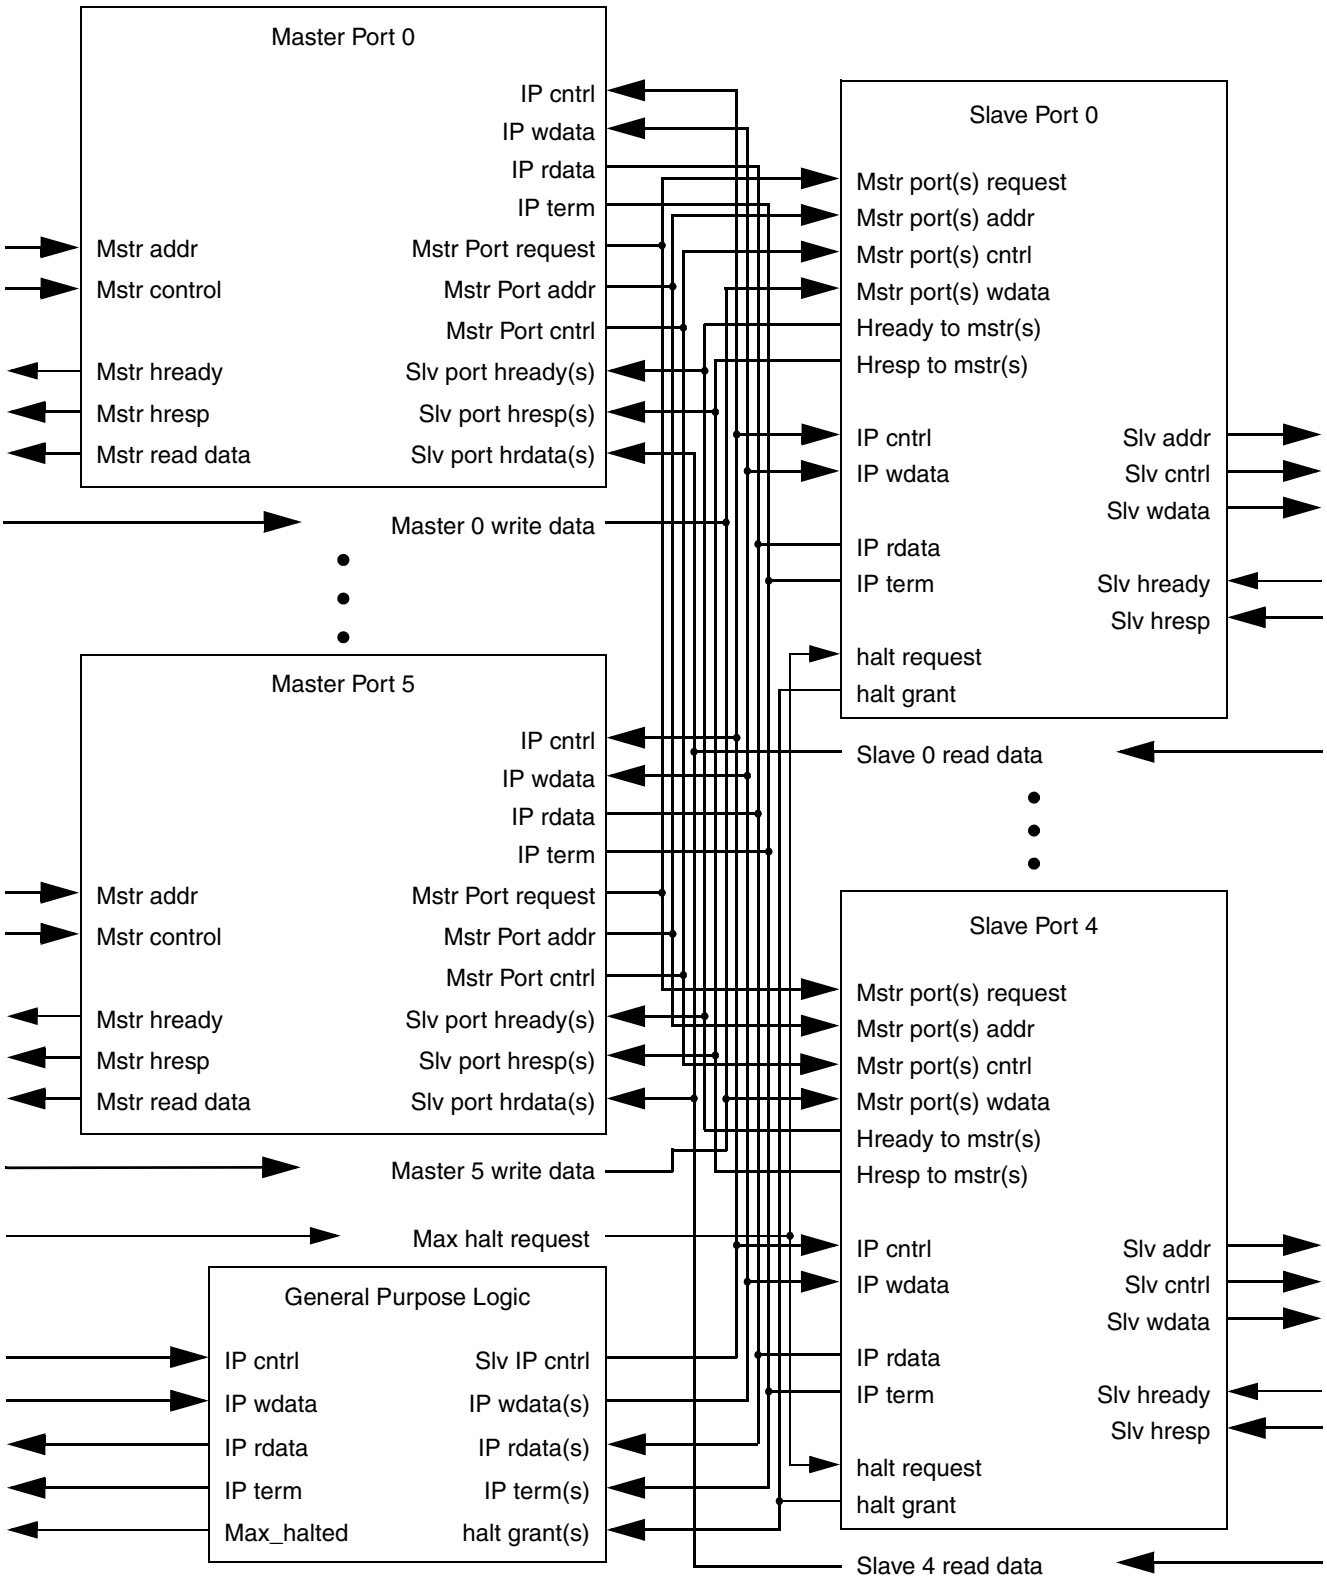

Figure 35-1. MAX Block Diagram

35.1.1 Features

The MAX has the ability to gain control of all the slave ports and prevent any masters from making accesses to the slave ports. This feature is useful when the user wishes to turn off the clocks to the system and needs to ensure that no bus activity is interrupted.

The MAX can put each slave port into a low-power park mode so that slave port does not dissipate any power by transitioning address, control or data signals when not being actively accessed by a master port.

Each slave port can also support multiple master priority schemes. Each slave port has a hardware input which selects the master priority scheme so the user can dynamically change master priority levels on a slave port by slave port basis.

The MAX allows for concurrent transactions to occur from any master port to any slave port. It is possible for four master ports and all slave ports to be in use at the same time as a result of independent master requests. If a slave port is simultaneously requested by more than one master port, arbitration logic selects the higher priority master and grant it ownership of the slave port. All other masters requesting that slave port are stalled until the higher priority master completes its transactions.

35.1.2 Limitations

The MAX routes bus transactions initiated on the master ports to the appropriate slave ports. There is no provision included to route transactions initiated on the slave ports to other slave ports or to master ports. Simply put, the slave ports do not support the bus request/bus grant protocol, the MAX assumes it is the sole master of each slave port.

Since the MAX does not support the bus request/bus grant protocol, if multiple masters are to be connected to a single master port an external arbiter must be used, as shown in Figure 35-14. In the case of a single master connecting to a master port the single master's bus grant signal must be tied off in the asserted state, as shown in Figure 35-15.

Each master and slave port is fully AHB-Lite and AMBA V6 extensions compatible. The ports are not fully AHB compatible because the MAX does not support SPLITs or RETRYs.

35.1.3 General Operation

When a master makes an access to the MAX the access is immediately taken by the MAX. If the targeted slave port of the access is available then the access is immediately presented on the slave port. It is possible to make single clock (zero wait state) accesses through the MAX. If the targeted slave port of the access is busy or parked on a different master port, the requesting master sees wait states inserted (**hready** held negated) until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding peripheral's access time.

Since the MAX appears to be just another slave to the master device, the master device has no knowledge of whether or not it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it is wait-stated.

A master is given control of the targeted slave port only after a previous access to a different slave port has completed, regardless of its priority on the newly targeted slave port. This prevents deadlock from

occurring when a master has an outstanding request to one slave port that has a long response time, has a pending access to a different slave port, and a lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

Once the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a locked or fixed length burst transfer it retains control of the slave port until that transfer is completed. Based on the AULB bit in the master general purpose control register (MGPCR) the master either retains control of the slave port when doing undefined length incrementing burst transfers or loses the bus to a higher-priority master.

The MAX terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port the MAX drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port. When the MAX is controlling the slave bus (i.e. during low-power park or halt mode) the **hmaster** field indicates 0b0000.

When a slave bus is being IDLEd by the MAX it can park the slave port on the master port indicated by the PARK bits in the slave general purpose control register (SGPCR). This can be done in an attempt to save the initial clock of arbitration delay that would otherwise be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power.

35.2 MAX Interface Signals

This section provides information on MAX interface signals, including AHB master and slave interface signals as well as IP bus interface signals.

35.2.1 MAX Signal Overview

Table 35-1 provides an overview of MAX module interface signals.

Table 35-1. MAX Signals

Signal	Type	Description
System Signals		
hclk	Input	System clock
hreset_b	Input	System reset
max_halt_request	Input	Transfer lockdown request
max_halted	Output	All transfers halted
Master Port Interface Signals		
m0_hlock	Input	Master port 0 AHB locked transfer signal.
m0_hmastlock	Input	Master port 0 AHB locked transfer signal
m0_hmaster[3:0]	Input	Master port 0 AHB master identification

Table 35-1. MAX Signals (Continued)

Signal	Type	Description
m0_htrans[1:0]	Input	Master port 0 AHB transfer type
m0_hprot[3:0]	Input	Master port 0 AHB protection control
m0_hwrite	Input	Master port 0 AHB transfer direction
m0_hsize[1:0]	Input	Master port 0 AHB transfer size
m0_hburst[2:0]	Input	Master port 0 AHB burst type
m0_haddr[31:0]	Input	Master port 0 AHB address bus
m0_hwdata[31:0]	Input	Master port 0 AHB write data bus
m0_hrdata[31:0]	Output	Master port 0 AHB read data bus
m0_hready_out	Output	Master port 0 AHB transfer done out
m0_hresp0	Output	Master port 0 AHB response
m1_hlock	Input	Master port 1 AHB locked transfer signal.
m1_hmastlock	Input	Master port 1 AHB locked transfer signal
m1_hmaster[3:0]	Input	Master port 1 AHB master identification
m1_htrans[1:0]	Input	Master port 1 AHB transfer type
m1_hprot[3:0]	Input	Master port 1 AHB protection control
m1_hwrite	Input	Master port 1 AHB transfer direction
m1_hsize[1:0]	Input	Master port 1 AHB transfer size

s1_hmastlock	Output	Slave port 1 AHB locked transfer signal
s1_hmaster[3:0]	Output	Slave port 1 AHB master identification
s1_htrans[1:0]	Output	Slave port 1 AHB transfer type
s1_hprot[3:0]	Output	Slave port 1 AHB protection control
s1_hwrite	Output	Slave port 1 AHB transfer direction
s1_hsize[1:0]	Output	Slave port 1 AHB transfer size
s1_hburst[2:0]	Output	Slave port 1 AHB burst type

Table 35-1. MAX Signals (Continued)

Signal	Type	Description
s1_haddr[31:0]	Output	Slave port 1 AHB address bus
s1_hwdata[31:0]	Output	Slave port 1 AHB write data bus
s2_hrdata[31:0]	Input	Slave port 2 AHB read data bus
s2_hready	Input	Slave port 2 AHB transfer done
s2_hresp0	Input	Slave port 2 AHB response
s2_hmastlock	Output	Slave port 2 AHB locked transfer signal
s2_hmaster[3:0]	Output	Slave port 2 AHB master identification
s2_htrans[1:0]	Output	Slave port 2 AHB transfer type
s2_hprot[3:0]	Output	Slave port 2 AHB protection control
s2_hwrite	Output	Slave port 2 AHB transfer direction
s2_hsize[1:0]	Output	Slave port 2 AHB transfer size
s2_hburst[2:0]	Output	Slave port 2 AHB burst type
s2_haddr[31:0]	Output	Slave port 2 AHB address bus
s2_hwdata[31:0]	Output	Slave port 2 AHB write data bus
s3_hrdata[31:0]	Input	Slave port 3 AHB read data bus
s3_hready	Input	Slave port 3 AHB transfer done
s3_hresp0	Input	Slave port 3 AHB response
s3_hmastlock	Output	Slave port 3 AHB locked transfer signal
s3_hmaster[3:0]	Output	Slave port 3 AHB master identification
s3_htrans[1:0]	Output	Slave port 3 AHB transfer type
s3_hprot[3:0]	Output	Slave port 3 AHB protection control
s3_hwrite	Output	Slave port 3 AHB transfer direction
s3_hsize[1:0]	Output	Slave port 3 AHB transfer size
s3_hburst[2:0]	Output	Slave port 3 AHB burst type
s3_haddr[31:0]	Output	Slave port 3 AHB address bus
s3_hwdata[31:0]	Output	Slave port 3 AHB write data bus
s4_hrdata[31:0]	Input	Slave port 4 AHB read data bus
s4_hready	Input	Slave port 4 AHB transfer done
s4_hresp0	Input	Slave port 4 AHB response
s4_hmastlock	Output	Slave port 4 AHB locked transfer signal
s4_hmaster[3:0]	Output	Slave port 4 AHB master identification
s4_htrans[1:0]	Output	Slave port 4 AHB transfer type
s4_hprot[3:0]	Output	Slave port 4 AHB protection control

Table 35-1. MAX Signals (Continued)

Signal	Type	Description
s4_hwrite	Output	Slave port 4 AHB transfer direction
s4_hsize[1:0]	Output	Slave port 4 AHB transfer size
s4_hburst[2:0]	Output	Slave port 4 AHB burst type
s4_haddr[31:0]	Output	Slave port 4 AHB address bus
s4_hwdata[31:0]	Output	Slave port 4 AHB write data bus
IP Bus V2.0 Interface Signals		
ipg_clk	Input	IP system clock
ips_addr[11:2]	Input	IP address bus
ips_supervisor_access	Input	Supervisor mode access signal
ips_wdata[31:0]	Input	IP write data bus
ips_module_en	Input	Module enable bus
ips_rwb	Input	Read/write access signal
ips_byte_31_24, ips_byte_23_16, ips_byte_15_8, ips_byte_7_0	Input	Byte enables
ips_xfr_wait	Output	IP bus peripheral wait signal
ips_xfr_err	Output	IP bus peripheral error signal
ips_rdata[31:0]	Output	IP read data bus

35.2.2 MAX Signal Descriptions

See the AMBA Specification Rev 2.0 for a description of the AHB signals in the MAX and the IP Bus Specification Rev 2.0 for a description of the IP Bus signals in the MAX.

35.2.2.1 max_halt_request

This input signal is a request to halt all slave port bus activity (run MAX originated IDLE cycles on each slave port bus, blocking all master port accesses). This signal can be used to gracefully shut down the MAX so the system clock can be stopped for low-power mode. This signal is captured by a flop inside the MAX before use.

Once the MAX is halted, it remain halted until **max_halt_request** is negated.

35.2.2.2 max_halted

This output is asserted once the MAX is in control and running IDLE cycles on each slave port.

35.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers. For the base address of a particular module instantiation, see the system memory map.

35.3.1 Register Access and Timing

There are four registers that reside in each slave port of the MAX and one register that resides in each master port of the MAX. These registers are IP bus–compatible registers. Read and write transfers both require two IP bus clock cycles. The registers can only be read from and written to by 32-bit accesses in supervisor mode.

The registers are fully decoded and an error response is returned if an unimplemented location is accessed within the MAX.

The slave registers also feature a bit, which when written with a 1, prevents the registers from being written to again. The registers are still readable, but write attempts have no effect on the registers and are terminated with an error response.

Any register modifications take effect as soon as the register is written. The values of the registers do not track with slave port-related AHB accesses, but instead track only with IP bus accesses. The only exception to this rule are the AULB bits in MGPCR*n*. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the IP bus cycle to write them has long since terminated successfully. If the AULB bits in MGPCR*n* are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle has been initiated by the master on that master port.

35.3.2 Memory Map

Table 35-2 shows the MAX memory map.

Table 35-2. MAX Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000(MPR0)	Master priority register for slave port 0	R/W	0x0054_3210	35.3.4.1/35-13

35.3.3 Register Summary

Figure 35-2 shows the key to the register fields and Table 35-3 shows the register figure conventions.

Figure 35-2. Key to Register Fields

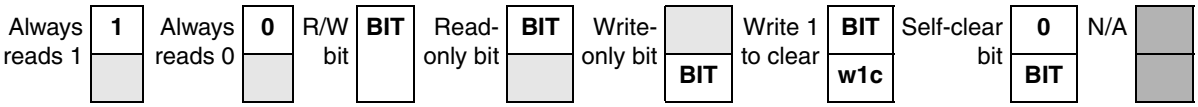

Table 35-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 35-4 shows the MAX register summary.

35.3.4 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 35-3 and Table 35-3 explain conventions used in register diagrams and tables.

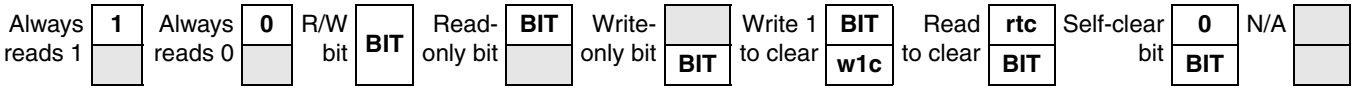

Figure 35-3. Register Field Conventions

Table 35-5. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.

Table 35-5. General Register Conventions (Continued)

Convention	Description
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

35.3.4.1 Master Priority Register (MPR0-MPR4)

The master priority register (MPR) sets the priority of each master port on a per–slave port basis and resides in each slave port. See Figure 35-4 for illustration of valid bits in the MPR and Table 35-6 for description of the bit fields.

Offset 0x0000(MPR0)

Figure 35-4. Master Priority Register (MPR0–MPR4)

Table 35-6. Master Priority Register Descriptions

Field	Description
31–23	Reserved. They are read as zero and should be written with zero for upward compatibility.
22–20 MSTR_5	Master 5 priority. These bits set the arbitration priority for master port 5 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
19	Reserved. They are read as zero and should be written with zero for upward compatibility.

Table 35-6. Master Priority Register Descriptions (Continued)

Field	Description
18–16 MSTR_4	Master 4 priority. These bits set the arbitration priority for master port 4 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
15	Reserved. They are read as zero and should be written with zero for upward compatibility.
14–12 MSTR_3	Master 3 priority. These bits set the arbitration priority for master port 3 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
11	Reserved. They are read as zero and should be written with zero for upward compatibility.
10–8 MSTR_2	Master 2 priority. These bits set the arbitration priority for master port 2 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
7	Reserved. They are read as zero and should be written with zero for upward compatibility.
6–4 MSTR_1	Master 1 priority. These bits set the arbitration priority for master port 1 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
3	Reserved. They are read as zero and should be written with zero for upward compatibility.
2–0 MSTR_0	Master 0 priority. These bits set the arbitration priority for master port 0 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.

NOTE

- The master priority register can only be accessed in supervisor mode with 32-bit accesses. Once the RO bit has been set in the slave general purpose control register, the master priority register can only be read from—attempts to write to it have no effect on the MPR and result in an error response.
- No two available master ports can be programmed with the same priority level. Attempts to program two or more available masters with the same priority level results in an error response, and the MPR is not updated.

35.3.4.2 Slave General-Purpose Control Register (SGPCR0-SGPCR4)

The slave general-purpose control register (SGPCR) controls several features of each slave port.

When set to 1, the read only (RO) bit prevents any registers associated with this slave port from being written to. This bit may be written with 0 as many times as the user desires, but once written with 1 only a reset condition enables it to be written again.

The halt low priority (HLP) bit sets the priority of the **max_halt_request** input to the lowest possible priority for initial arbitration of the slave ports. By default it is the highest priority. Note that setting this bit does not effect the **max_halt_request** from attaining highest priority once it has control of the slave ports.

The PCTL bits determine how the slave port parks when no master is actively making a request. The available options are:

- Park on the master defined by the PARK bits
- Park on the last master to use the slave port
- Go into a low-power park mode which forces all the outputs of the slave port to inactive states when no master is requesting an access.

The low-power park feature can result in an overall power savings if the slave port is not saturated; however, it forces an extra clock of latency whenever any master tries to access it when it is not in use, because it is not parked on any master.

The PARK bits determine which master the slave parks on when no master is making an active request and the **max_halt_request** input is negated. The bits must select a master port that is actually present in the design—otherwise, undefined behavior will result.

See Figure 35-5 for illustration of valid bits in the SGPCR and Table 35-7 for description of the bit fields.

Figure 35-5. Slave General-Purpose Control Register *n*

Table 35-7. Slave General-Purpose Control Register Descriptions

Field	Description
31 RO	Read Only. This bit is used to force all of a slave port's registers to be read only. Once written to 1 it can only be cleared by hardware reset. This bit is initialized by hardware reset. 0 All this slave port's registers can be written. 1 All this slave port's registers are read only and cannot be written (attempted writes have no effect and result in an error response).
30 HLP	Halt low priority. This bit is used to set the initial arbitration priority of the max_halt_request input. This bit is initialized by hardware reset. 0 The max_halt_request input has the highest priority for arbitration on this slave port 1 The max_halt_request input has the lowest initial priority for arbitration on this slave port.
29–10	Reserved. They read as zero and should be written with zero for upward compatibility.
9–8 ARB	Arbitration mode. These bits are used to select the arbitration policy for the slave port. These bits are initialized by hardware reset. 00 Fixed Priority. 01 Round Robin (rotating) Priority. 10 Reserved 11 Reserved
7–6	Reserved. They read as zero and should be written with zero for upward compatibility.
5–4 PCTL	Parking control.These bits determine the parking control used by this slave port. These bits are initialized by hardware reset. 00 When no master is making a request the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master is making a request the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master is making a request the arbiter parks the slave port on no master and drives all outputs to a constant safe state. 11 Reserved
3	Reserved. They read as zero and should be written with zero for upward compatibility.
2–0 PARK	Parking master.These bits are used to determine which master port this slave port parks on when no masters are actively making requests and the PCTL bits are set to 00. These bits are initialized by hardware reset. 000 Park on Master Port 0 001 Park on Master Port 1 010 Park on Master Port 2 011 Park on Master Port 3 100 Park on Master Port 4 101 Park on Master Port 5 110 Reserved 111 Reserved

NOTE

The SGPCR*n* registers can only be accessed in supervisor mode with 32-bit accesses. Once the read only (RO) bit has been set in SGPCR*n*, the register can only be read—write attempts have no effect on SGPCR*n* and result in an error response.

35.3.4.3 Master General-Purpose Control Register (MGPCR0–MGPCR5)

The master general-purpose control registers (MGPCR0–5), shown in Figure 35-6, control whether or not the corresponding master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters.

The arbitrate on undefined length bursts (AULB) bit field determines whether (and when) the MAX arbitrates away the slave port the master owns when the master is performing undefined length burst accesses.

Name	Description
31–3	Reserved. They read as zero and should be written with zero for upward compatibility.
2–0 AULB	Arbitrate on undefined length bursts. These bits are used to select the arbitration policy during undefined length bursts by this master. These bits are initialized by hardware reset. 000 No arbitration is allowed during an undefined length burst. 001 Arbitration is allowed at any time during an undefined length burst. 010 Arbitration is allowed after four beats of an undefined length burst. 011 Arbitration is allowed after eight beats of an undefined length burst. 100 Arbitration is allowed after 16 beats of an undefined length burst. 101 Reserved 110 Reserved 111 Reserved

NOTE

The MGPCR*n* registers can only be accessed in supervisor mode with 32-bit accesses.

35.4 Functional Description

This section describes the functionality of the MAX in greater detail.

35.4.1 Arbitration

The MAX supports two arbitration schemes; a simple fixed-priority comparison algorithm, and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

35.4.1.1 Arbitration During Undefined Length Bursts

Arbitration points during an undefined length burst are defined by the current master's AULB field setting (MGPCR register). When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed length burst accesses.

For illustrative purposes, an example of arbitration during undefined length bursts is as follows. A master runs an undefined length burst, and the master's AULB bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be an 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The MAX does not allow an arbitration point until the fourth overall access (second beat of the second burst). At that point all remaining accesses are be open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. Once the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the (now continued) burst (ninth beat of the second burst from the master's perspective) is taken all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third (now continued) burst (10th beat of the second burst from the master's perspective). Once the master regains control of the slave port it is allowed to complete its final two beats of its burst without facing arbitration.

Fixed length burst accesses are not affected by the AULB bits. All fixed length burst accesses lock out arbitration until the last beat of the fixed length burst.

35.4.1.2 Fixed-Priority Operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the master priority register (MPR). If two masters both request access to a slave port, the master with the highest priority in the selected priority register gains control over the slave port.

Any time a master makes a request to a slave port, the slave port checks to see if this master's priority level is higher than that of the master that currently controls the slave port (unless the slave port is in a parked state). The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently controls the slave port, the new master is granted control over the slave port at the next clock edge. Exceptions to this rule are as follows:

- If the master that currently controls the slave port is running a fixed length burst transfer or a locked transfer, then the new requesting master must wait until the end of the transfer before it is granted control of the slave port.
- If the master that currently controls the slave port is running an undefined length burst transfer, the new requesting master must wait until an arbitration point for the undefined length burst transfer before it is granted control of the slave port. Arbitration points for an undefined length burst are defined in the MGPCR for each master.

If the new requesting master's priority level is lower than that of the master that currently controls the slave port, the new master is forced to wait until the current controlling master runs either an IDLE cycle or a non-IDLE cycle to a location other than the current slave port.

35.4.1.3 Round-Robin Priority Operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. The highest-priority master corresponds to the port number next in cyclic order to the last master's port number. The highest-priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers).

Once granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next assertion of **s*n*_hready**, or possibly on the next clock cycle if the current master has no pending access request.

For illustrative purposes, an example of arbitration in round-robin mode is as follows. Assume the MAX is implemented with master ports 0, 1, 2, 3, 4 and 5. If the last master of the slave port was master 1, and master 0, 4 and 5 make simultaneous requests, (master ports 2 and 3 make no requests), they are serviced in the order 4, 5 and then 0.

Parking may still be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Hand-off occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, then the round-robin pointer is reset to point at master port 0, giving it the highest priority.

35.4.2 Priority Assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within a register (MPR) the MAX responds with an error and the registers are not updated.

35.4.3 Master Port Functionality

35.4.3.1 General

Each master port consists of two decoders, a capture unit, a register slice, a multiplexer and a small state machine.

The first decoder is used to decode the **haddr** and control signals coming directly from the master, telling the state machine where the master's next access is and if it is in fact a legal access. The second decoder gets its input from the capture unit, so it may be looking directly at the signals coming from the master or it may be looking at captured signals coming from the master, depending entirely on the state of the targeted slave port. The second decoder is then used to generate the access requests that go to the slave ports.

The capture unit is used to capture the address and control information coming from the master in the event that the targeted slave port cannot immediately service the master. The capture unit is controlled by outputs from the state machine which tell it to either pass through the original master signals or the captured signals.

The register slice contains the registers associated with the specific master port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The multiplexer is used simply to select which slave's read data is sent back to the master. The multiplexer is controlled by the state machine.

The state machine controls all aspects of the master port. It knows which slave port the master wants to make a request to and controls when that request is made. It also has knowledge of each slave port, knowing whether or not the slave port is ready to accept an access from the master port. This determines whether or not the master may immediately have its request taken by the slave port or whether the master port has to capture the master's request and queue it at the slave port boundary.

For a block diagram of a master port see Figure 35-7.

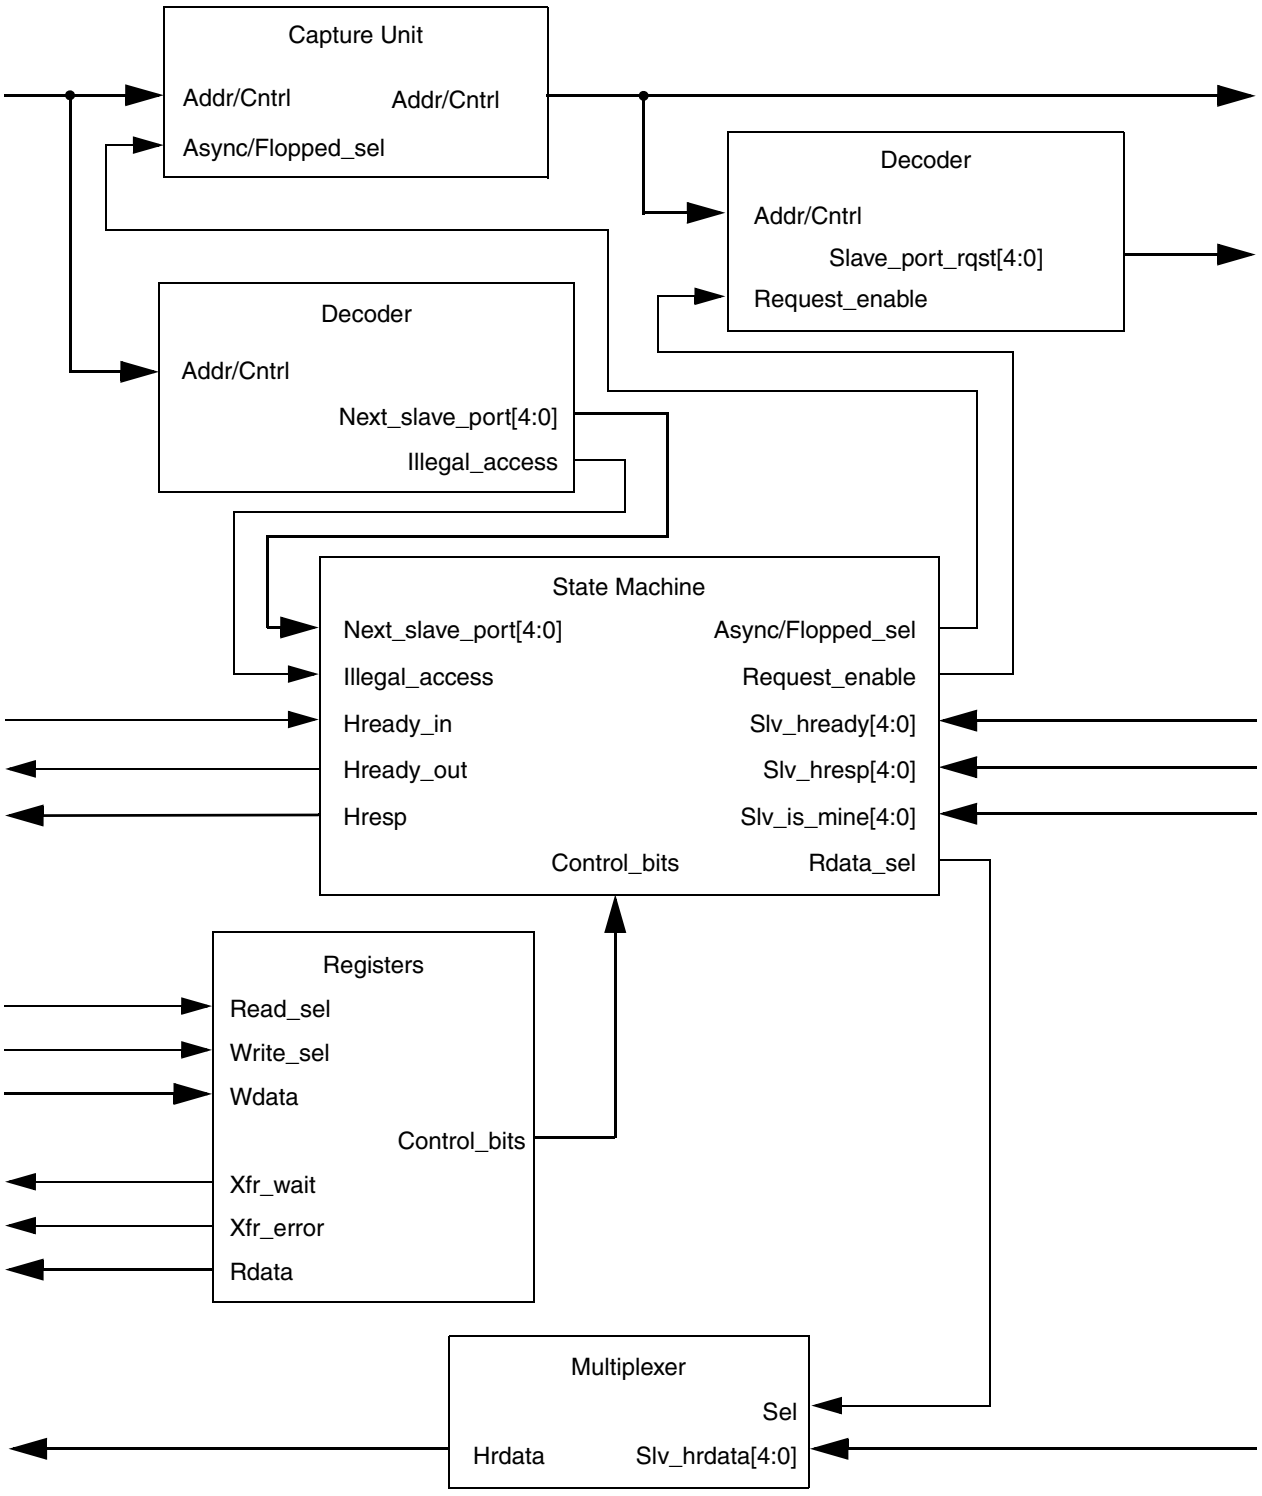

Figure 35-7. MAX Master Port Block Diagram

35.4.3.2 Master Port Decoders

The decoders are very simple as they ensure an access request is allowed to be made and that the slave port targeted is actually present in the design. The decoders feeding the state machine are always enabled. The decoders that select the slave are enabled only when the master port controlling state machine wants to make a request to a slave port. This is necessary so that if a master port is making an access to a slave port and is being wait stated, and its next access is to a different slave port, the request to the second slave port can be held off until the access to the first slave port is terminated.

The decoders also output a “hole decode” or illegal access signal which tells the state machine that the master is trying to access a slave port that does not exist.

35.4.3.3 Master Port Capture Unit

The capture unit simply captures the state of the master’s address and control signals if the MAX cannot immediately pass the master’s request through to the proper slave port. The capture unit consists of a set of flops and a multiplexer which selects either the asynchronous path from address and control or the flopped (captured) address and control information.

35.4.3.4 Master Port Registers

The registers in the master port are only those registers associated with this particular master port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

There is a register control block at the same level of the master port and slave port instantiations in the MAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master ports.

The register outputs are connected directly to the state machine.

35.4.3.5 Master Port State Machine

35.4.3.5.1 Master Port State Machine States

The master side state machine’s main function is to monitor the activities of the master port. The state machine has six states: **busy**, **idle**, **stalled**, **steady state**, **first cycle error response** and **second cycle error response**.

The **busy** state is used when the master runs a BUSY cycle to the master port. The master port maintains its request to the slave port if it currently owns the slave port; however, if it loses control of the slave port it no longer maintains its request. If the master port loses control of the slave port it is not allowed to make another request to the slave port until it runs a NSEQ or SEQ cycle.

The **idle** state is used when the master runs a valid IDLE cycle to the master port. The master port makes no requests to the slave ports (disables the slave port decoder) and terminates the IDLE cycle.

The **stalled** state is used when the master makes a request to a slave port that is not immediately ready to receive the request. In this case the state machine directs the capture unit to send out the captured address

and control signals and enables the slave port decoder to indicate a pending request to the appropriate slave port.

The **steady state** is used when the master port and slave port are in fully asynchronous mode, making the MAX completely transparent in the access. The state machine selects the appropriate slave's **hresp0, hready** and **hrdata** to pass back to the master.

The **first cycle error response** and **second cycle error response** states are self explanatory. The MAX responds with an error response to the master if the master tries to access an unimplemented memory location through the MAX (i.e. a slave port that does not exist).

35.4.3.5.2 Master Port State Machine Slave Swapping

The design of the master side state machine is fairly straight forward. The one real decision to be made is how to handle the master moving from one slave port access to another slave port access. The approach that was taken was to minimize or eliminate, when possible, any "bubbles" that would get inserted into the access due to switching slave ports.

The state machine does not allow the master to request access to another slave port until the current access being made is terminated. This prevents a single master from owning two slave ports at the same time (the slave port it is currently accessing and the slave port it wishes to access next).

The state machine also maintains watch on the slave port the master is accessing as well as the slave port the master wishes to switch to. If the new slave port is parked on the master then the master is able to make the switch without incurring any delays. The termination of the current access also acts as the launch of the new access on the new slave port. If the new slave port is not parked on the master then the master incurs a minimum one clock delay before it can launch its access on the new slave port.

This is the same for switching from the **busy** or **idle** state to actively accessing a slave port. If the slave port is parked on the master the state machine goes to the **steady state** and the access begins immediately. If the slave port is not parked on the master (serving another master, parked on another master or in low-power park mode) then the state machine transitions to the **stalled** state and at least a one clock penalty is paid.

35.4.4 Slave Port Functionality

35.4.4.1 General

Each slave port consists of a register slice, a bank of multiplexers and a state machine.

The register slice contains the registers associated with the specific slave port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The multiplexers are a series of 6-to-1 multiplexers that take in all the address, control and write data information from each of the master ports and then pass the correct master's signals to the slave port. The state machine controls all the multiplexers.

The state machine is where the main slave port arbitration occurs. It decides which master is in control of the slave port and which master is in control of the slave port in the next bus cycle.

For a block diagram of a slave port see Figure 35-8.

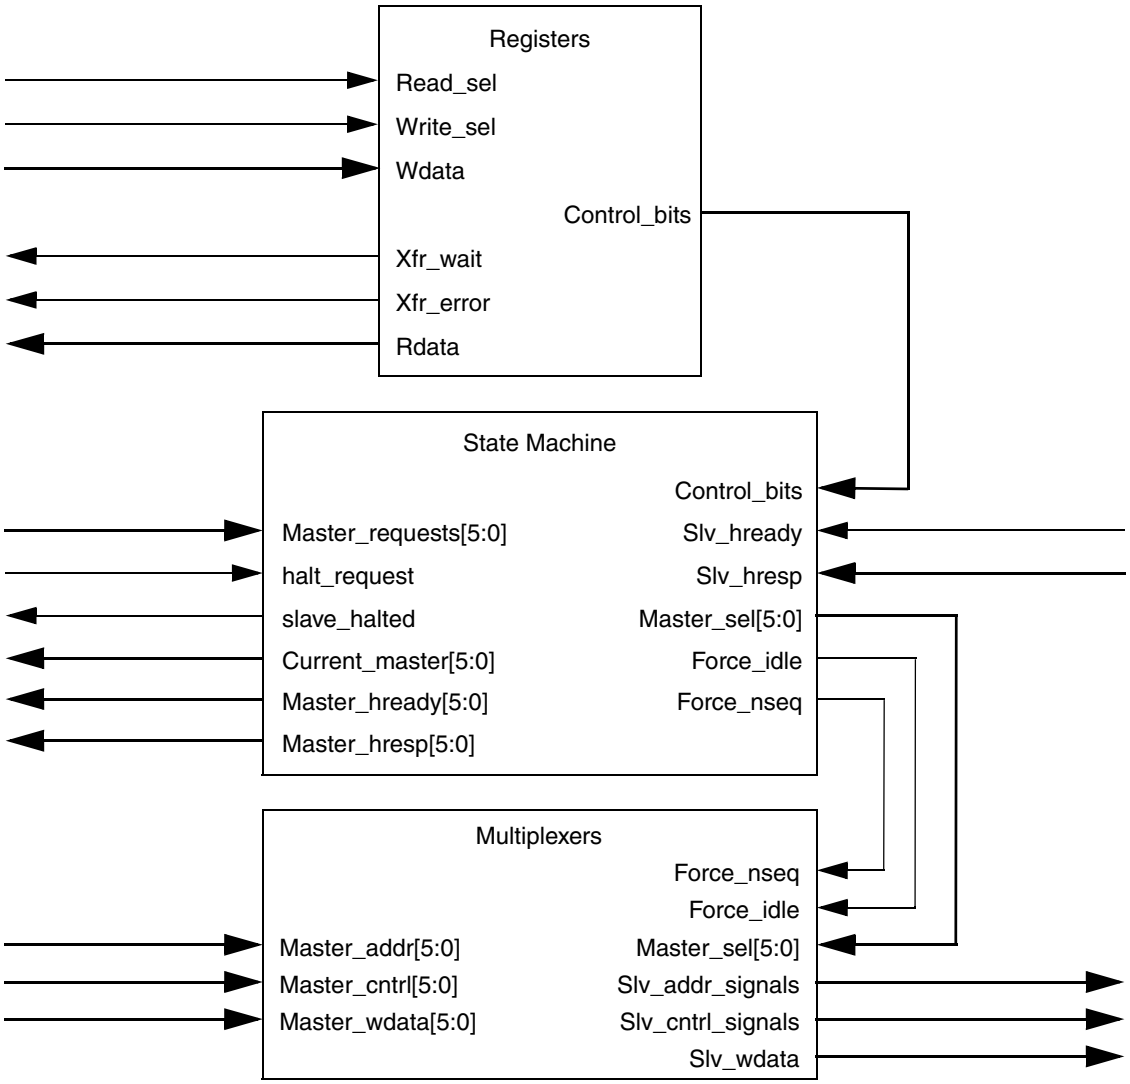

Figure 35-8. MAX Slave Port Block Diagram

35.4.4.2 Slave Port Multiplexers

The block diagram (Figure 35-8) shows only one block for all the multiplexers. In reality that block instantiates many 6 to 1 multiplexers, one for each master-to-slave signal in fact. All the multiplexers are designed in an AND - OR fashion, so that if no master is selected the output of the multiplexers is zero. (This is an important feature for low-power park mode.)

The multiplexers also have an override signal which is used by the slave port to asynchronously force IDLE cycles onto the slave bus. When the state machine forces an IDLE cycle it zeros out **htrans** and **hmastlock**, making sure the slave bus sees a valid IDLE cycle being run by the MAX.

The enable to the multiplexer controlling **htrans** also contains an additional control signal from the state machine so that a NSEQ transaction can be forced. This is done any time the slave port switches masters

to ensure that no IDLE-SEQ, BUSY-SEQ or NSEQ-SEQ transactions are seen on the slave port when they shouldn't be. If the state machine indicates to run both an IDLE and an NSEQ cycle, then the IDLE directive has priority.

NOTE

IDLE-SEQ is in fact an illegal access, but a possible scenario given the multi-master environment in the MAX unless corrected by the MAX.

35.4.4.3 Slave Port Registers

There is a register control block at the same level of the master port and slave port instantiations in the MAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master and slave ports.

The registers in the slave port are only those registers associated with this particular slave port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

The register outputs are connected directly to the slave state machine. The registers can be read from an unlimited number of times. The registers can only be written to as long as the RO bit is cleared in the SGPCR, once it is set to 1 only a hardware reset enables the registers to be written again.

35.4.4.4 Slave Port State Machine

35.4.4.4.1 Slave Port State Machine States

At the heart of the slave port is the state machine. The state machine is simplicity itself, requiring only four states - **steady state**, **transition state, transition hold state** and **hold state**. Either the slave port is owned by the same master it was in the last clock cycle (either by active use or by parking), it is transitioning to a new master (either for active use or parking), it is transitioning to a new master during wait states or it is being held on the same master pending a transition to a new master.

35.4.4.4.2 Slave Port State Machine Arbitration

The real work in the state machine is determining which master port is in control of the slave port in the next clock cycle, the arbitration. Each master is programmed with a fixed 3 bit priority level. The MAX uses these bits in determining priority levels when programmed for fixed priority mode of operation.

Arbitration always occurs on a clock edge, but only occurs on edges when a change in mastership does not violate AHB-Lite protocols. Valid arbitrations points include any clock cycle in which **s*n*_hready** is asserted (provide the master is not performing a burst or locked cycle) and any wait state in which the master owning the bus indicates a transfer type of IDLE (provided the master is not performing a locked cycle).

Since arbitration can occur on every clock cycle the slave port masks off all master requests if the current master is performing a locked transfer or a protected burst transfer, guaranteeing that no matter how low its priority level it is allowed to finish its locked or protected portion of a burst sequence.

35.4.4.4.3 Slave Port State Machine Master Handoff

The only times the slave port switches masters when programmed for fixed priority mode of operation is when a higher priority master makes a request or when the current master is the highest priority and it gives up the slave port by either running and IDLE cycle to the slave port or running a valid access to a location other than the slave port.

If the current master loses control of the slave port because a higher priority master takes it away the slave port does not incur any wasted cycles. The current master gets its current cycle terminated by the slave port at the same time the new master's address and control information is recognized by the slave port. This looks like a seamless transition on the slave port.

If the current master is being wait stated when the higher priority master makes its request, then the current master is allowed to make one more transaction on the slave bus before giving it up to the new master. Figure 35-9 illustrates the effect of a higher priority master taking control of the bus when the slave port is programmed for a fixed priority mode of operation.

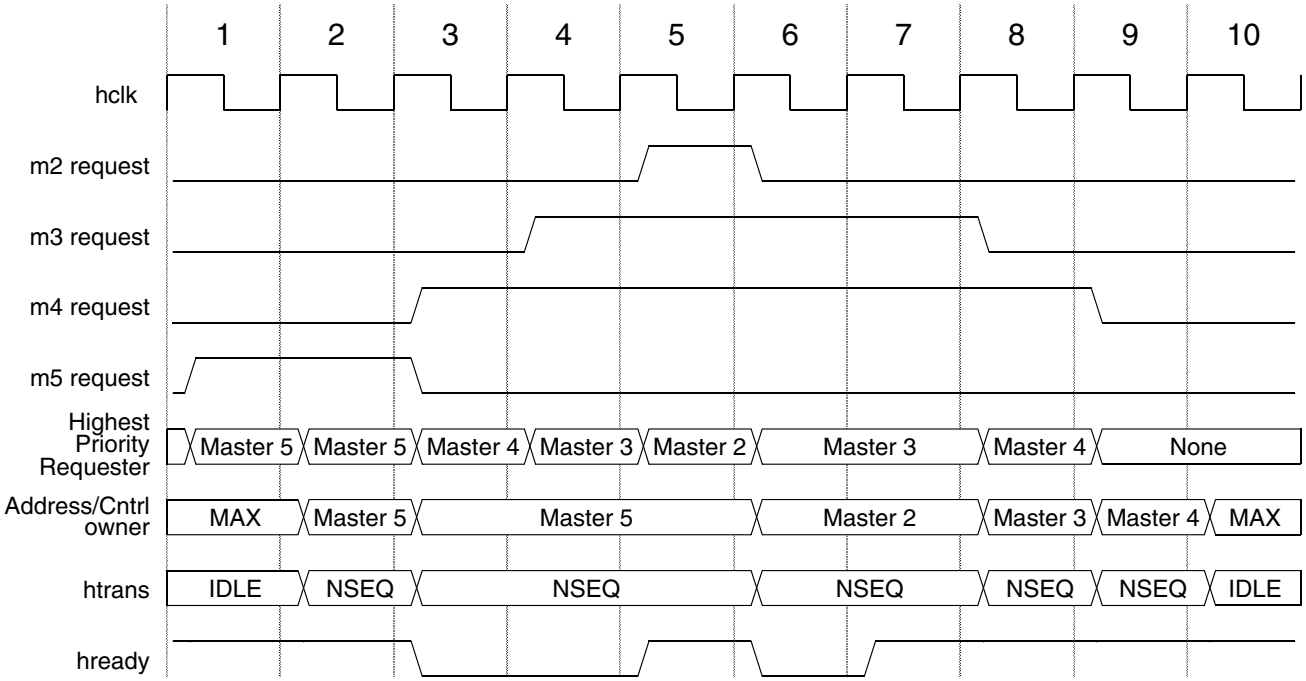

Figure 35-9. Low to High Priority Mastership Change

If the current master is the highest priority master and it gives up the slave port by running an IDLE cycle or by running a valid cycle to another location other than the slave port the next highest priority master gains control of the slave port. If the current access incurs any wait states then the transition is seamless and no bandwidth is lost; however, if the current transaction is terminated without wait states then one IDLE cycle is forced onto the slave bus by the MAX before the new master is able to take control of the slave port. If no other master is requesting the bus then IDLE cycles are run by the MAX but no bandwidth is actually lost since no master is making a request. Figure 35-10 illustrates the effect of a higher priority master giving up control of the bus.

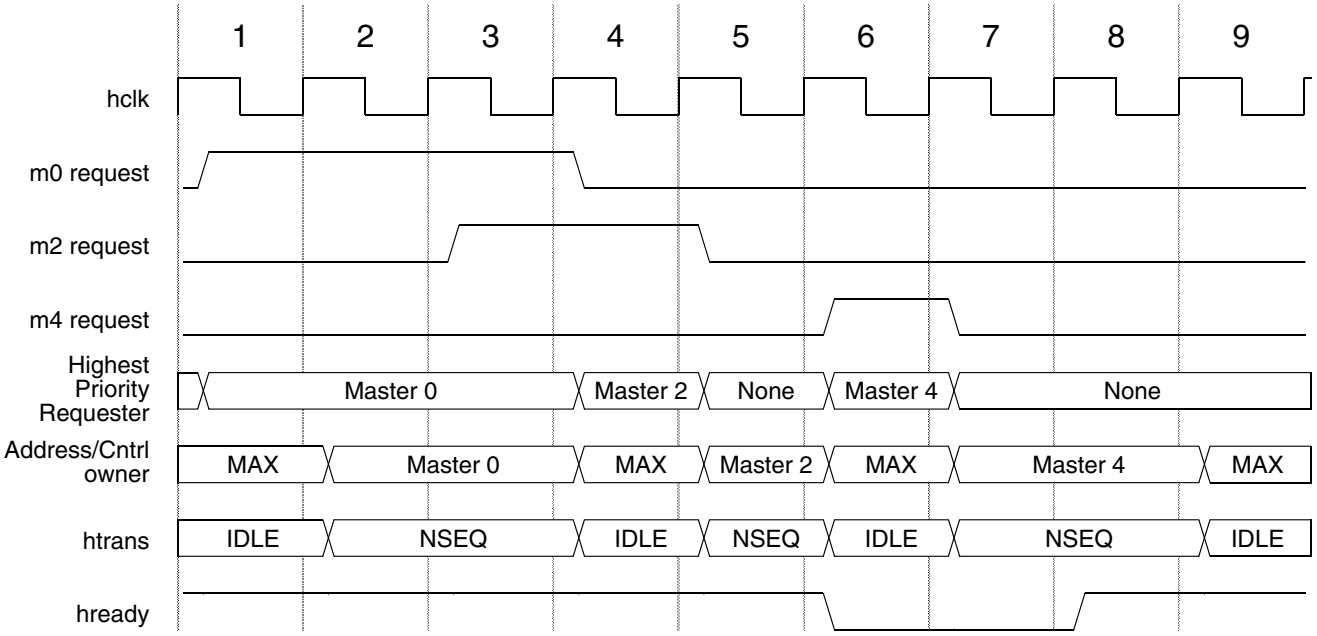

Figure 35-10. High to Low Priority Mastership Change

When the slave port is programmed for round-robin mode of arbitration then the slave port switches masters any time there is more than one master actively making a request to the slave port. This happens because any master other than the one which presently owns the bus is considered to have higher priority. Figure 35-11 shows an example of round-robin mode of operation.

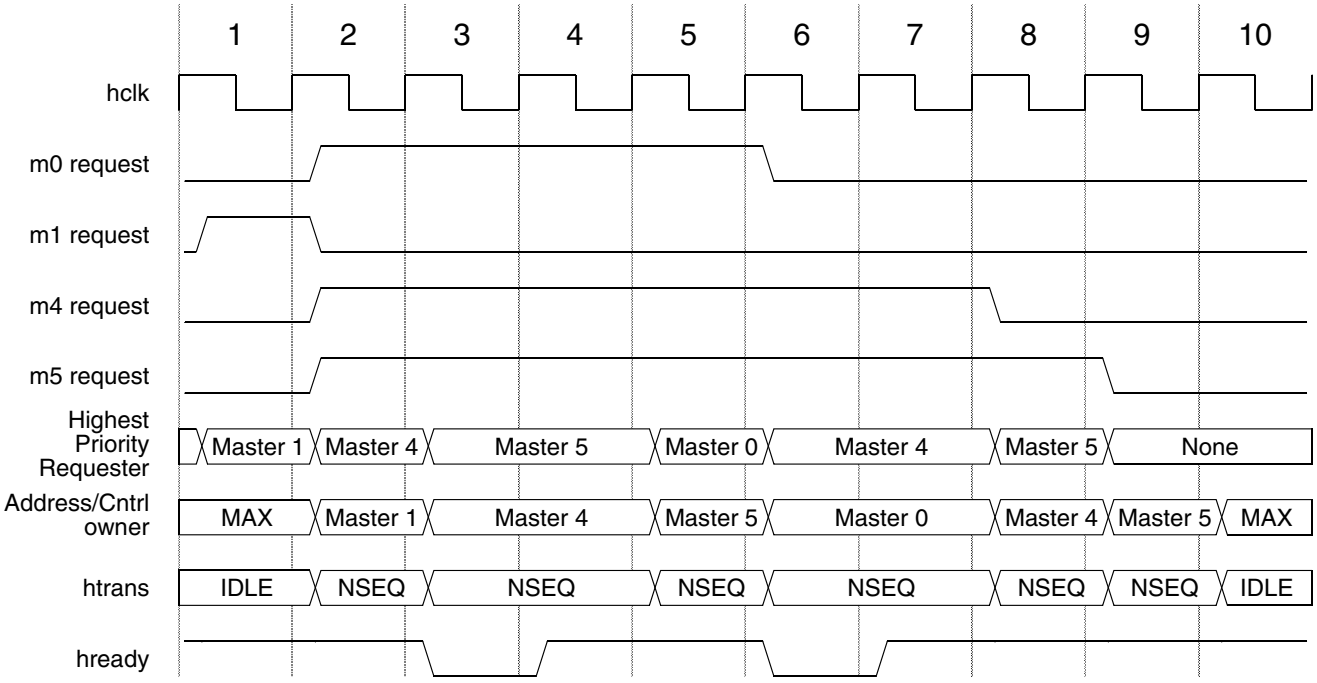

Figure 35-11. Round-Robin Mastership Change

35.4.4.4.4 Slave Port State Machine Parking

If no master is currently making a request to the slave port, then the slave port is parked. It parks in one of four places, dictated by the PCTL and PARK bits in the SGPCR and the locked state of the last master to access it.

If the last master to access the slave port ran a locked cycle and continues to run locked cycles even after leaving the slave port the slave port parks on that master without regard to the bit settings in the SGPCR and without regard to pending requests from other masters. This is done so a master can run a locked transfer to the slave port, leave it, and return to it and be guaranteed that no other master has had access to it (provided the master maintains all transfers are locked transfers). If locking is not an issue for parking, the SGPCR bits dictate the parking method.

If the PCTL bits are set for “low-power park” mode then the slave port enter low-power park mode. It does not recognize any master as being in control of it, and does not select any master’s signals to pass through to the slave bus. In this case all slave bus activity is effectively halted because all slave bus signals being driven from the MAX are 0. This of course can save quite a bit of power if the slave port is idle for some time. However, when a master does make a request to the slave port it is delayed by one clock since it has to arbitrate to acquire ownership of the slave port.

If the PCTL bits are set to “park on last” mode then the slave port parks on the last master to access it, passing all that masters signals through to the slave bus. The MAX asynchronously forces **htrans[1:0]**, **hmaster[3:0]**, **hburst[2:0]** and **hmastlock** to 0 for all access that the master does not run to the slave port. When that master access the slave port again it does not pay any arbitration penalty; however, if any other master wishes to access the slave port a one-clock arbitration penalty is imposed.

If the PCTL bits are set to “use PARK” mode then the slave port parks on the master designated by the PARK bits. The behavior here is the same as for the “park on last” mode with the exception that a specific master is parked on instead of the last master to access the slave port. If the master designated by the PARK bits tries to access the slave port it does not pay an arbitration penalty while any other master pays a one-clock penalty. Figure 35-12 illustrates parking on a specific master.

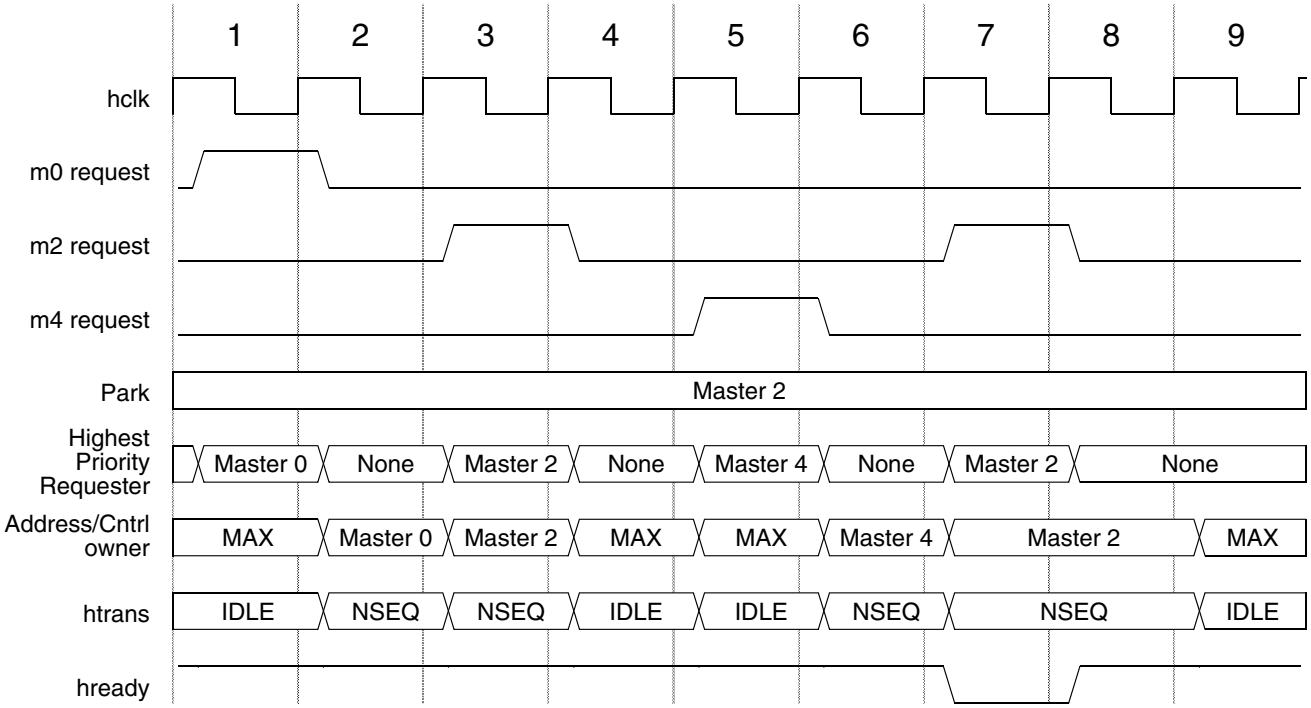

Figure 35-12. Parking on a Specific Master

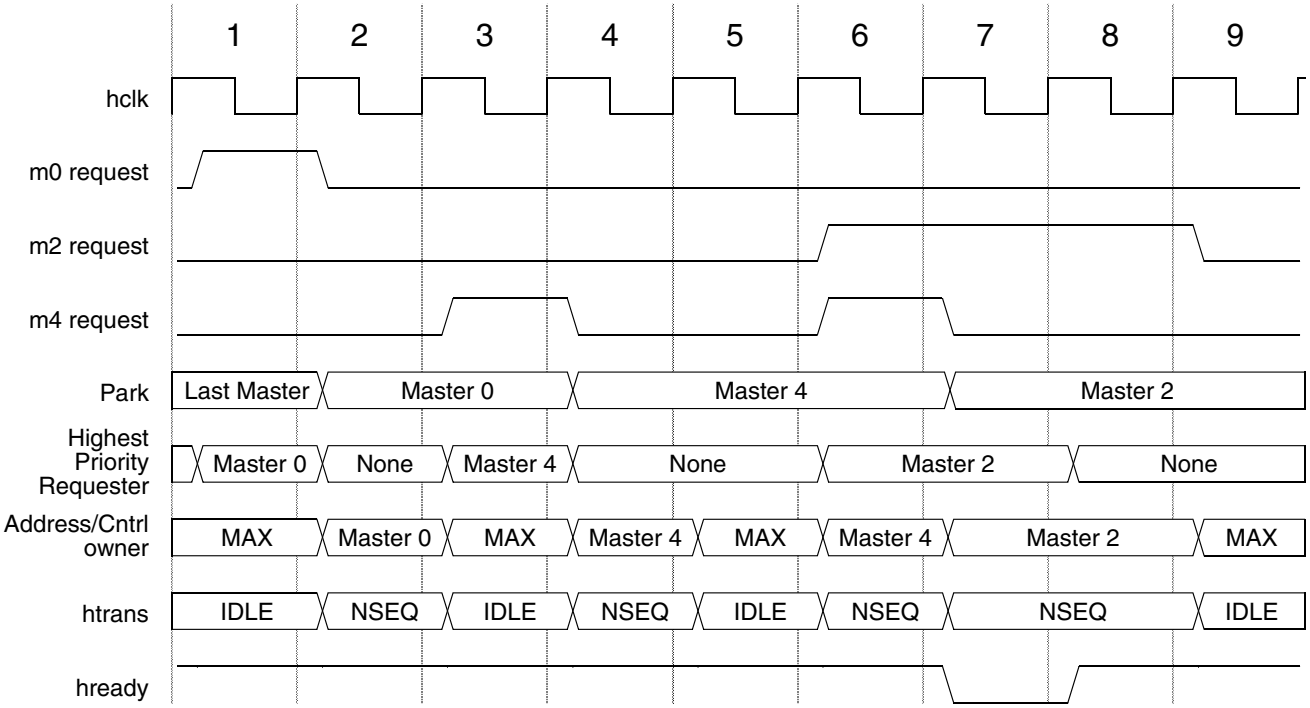
Figure 35-13 illustrates parking on the last master. Note that in cycle 6 simultaneous requests are made by master 2 and master 4. Although master 2 has higher priority, the slave bus is parked on master 4 so master 4’s access is taken first. The slave port parks on master 2 once it has given control to master 2. This same situation can occur when parking on a specific master as well.

Figure 35-13. Parking on Last Master

35.4.4.4.5 Slave Port State Machine Halt Mode

If the **max_halt_request** input is asserted, the slave port eventually halts all slave bus activity and goes into halt mode, which is almost identical to low-power park mode. The HLP bit in the SGPCR controls the priority level of the **max_halt_request** in the arbitration algorithm. If the HLP bit is cleared, then the **max_halt_request** has the highest priority of any master and gains control of the slave port at the next arbitration point (most likely the next bus cycle, unless the current master is running a locked or fixed length burst transfer). If the HLP bit is set, then the slave port waits until no masters are actively making requests before moving to halt mode.



Regardless of the state of the HLP bit, once the slave port goes into halt mode due to the assertion of **max_halt_request** it remains in halt mode until **max_halt_request** is negated, regardless of the priority level of any masters that make requests.

In halt mode no master is selected to own the slave port, so all the outputs of the slave port are set to 0.

35.5 Initialization/Application Information

No initialization is required by or for the MAX. Hardware reset ensures all the register bits used by the MAX are properly initialized.

35.6 MAX Interface

This section provides information on the MAX interface.

35.6.1 Overview

The main goal of the MAX is to increase overall system performance by allowing multiple masters to communicate in parallel with multiple slaves. In order to maximize data throughput it is essential to keep arbitration delays to a minimum.

This section examines data throughput from the point of view of masters and slaves, detailing when the MAX stalls the masters or insert bubbles on the slave side.

35.6.2 Master Ports

Master accesses receive one of four responses from the MAX. They are either terminated, taken, stalled, or responded to with an error.

35.6.2.1 Terminated Accesses

A master access is terminated if the transfer type is IDLE. The MAX terminates the access and it is not allowed to pass through the MAX.

35.6.2.2 Taken Accesses

A master access is taken if the transfer type is non IDLE and the slave port to which the access decodes is either currently servicing the master or is parked on the master. In this case the MAX is completely transparent and the master's access is immediately seen on the slave bus and no arbitration delays are incurred.

35.6.2.3 Stalled Accesses

A master access is stalled if the transfer type is non IDLE and the access decodes to a slave port that is busy serving another master, parked on another master or is in low-power park mode. The MAX indicates to the master that the address phase of the access has been taken, then queues the access to the appropriate slave port to enter into arbitration for access to that slave port.

If the slave port is currently parked on another master or is in low-power park mode and no other master is requesting access to the slave port then only one clock of arbitration is incurred. If the slave port is currently serving another master of a lower priority and the master has a higher priority than all other requesting masters then the master gains control over the slave port as soon as the data phase of the current access is completed (burst and locked transfers excluded). If the slave port is currently servicing another master of a higher priority then the master gains control of the slave port once the other master releases control of the slave port (if no other higher priority master is also waiting for the slave port).

35.6.2.4 Error Response Terminated Accesses

A master access is responded to with an error if the transfer type is non IDLE and the access decodes to a location not occupied by a slave port. This is the only time the MAX responds with an error response. All other error responses received by the master are the result of error responses on the slave ports being passed through the MAX.

See Section 35.7.1, "Address Map," for information on locations that are not occupied by a slave port.

35.6.3 Slave Ports

The goal of the MAX with respect to the slave ports is to keep them 100% saturated when masters are actively making requests. In order to do this the MAX must not insert any bubbles onto the slave bus unless absolutely necessary.

There is only one instance when the MAX forces a bubble onto the slave bus when a master is actively making a request. This occurs when a higher priority master has control of the slave port and is running single clock (zero wait state) accesses while a lower priority master is stalled waiting for control of the slave port. When the higher priority master either leaves the slave port or runs an IDLE cycle to the slave port, the MAX takes control of the slave bus and run a single IDLE cycle before giving the slave port to the lower priority master that was waiting for control of the slave port.

The only other cases where MAX has control of the slave port is when the MAX is halting, or when no masters are making access requests to the slave port and the MAX is forced to either park the slave port on a specific master or put the slave port into low-power park mode.

In most instances when the MAX has control of the slave port it indicates IDLE for the transfer type, negates all control signals and indicates ownership of the slave bus via the **hmaster** encoding of 4'b0000. One exception to this rule is when a master running locked cycles has left the slave port but continues to run locked cycles. In this case the MAX controls the slave port and indicates IDLE for the transfer type, but does not affect any other signals.

NOTE

When a master runs a locked cycle through the MAX, the master is guaranteed ownership of all slave ports it accesses while running locked cycles for one cycle beyond when the master finishes running locked cycles.

35.7 Integration

This section describes integrating the MAX into a design.

35.7.1 Address Map

The address map implemented in the MAX is shown in Table 35-9.

Table 35-9. MAX Address Map

haddr[31:28]	Destination
0x00	Slave Port 3
0x01	Slave Port 4
001x	Reserved
0110	Reserved
0111	Slave Port 2
10xx	Slave Port 1
11xx	Slave Port 0

35.7.2 Master Ports

Each master port takes on the appearance of a standard AHB-Lite slave device. The master port can only service one master, so if multiple masters are needed the integrator must provide an arbiter to determine which master is connected to the master port. This configuration is shown in Figure 35-14

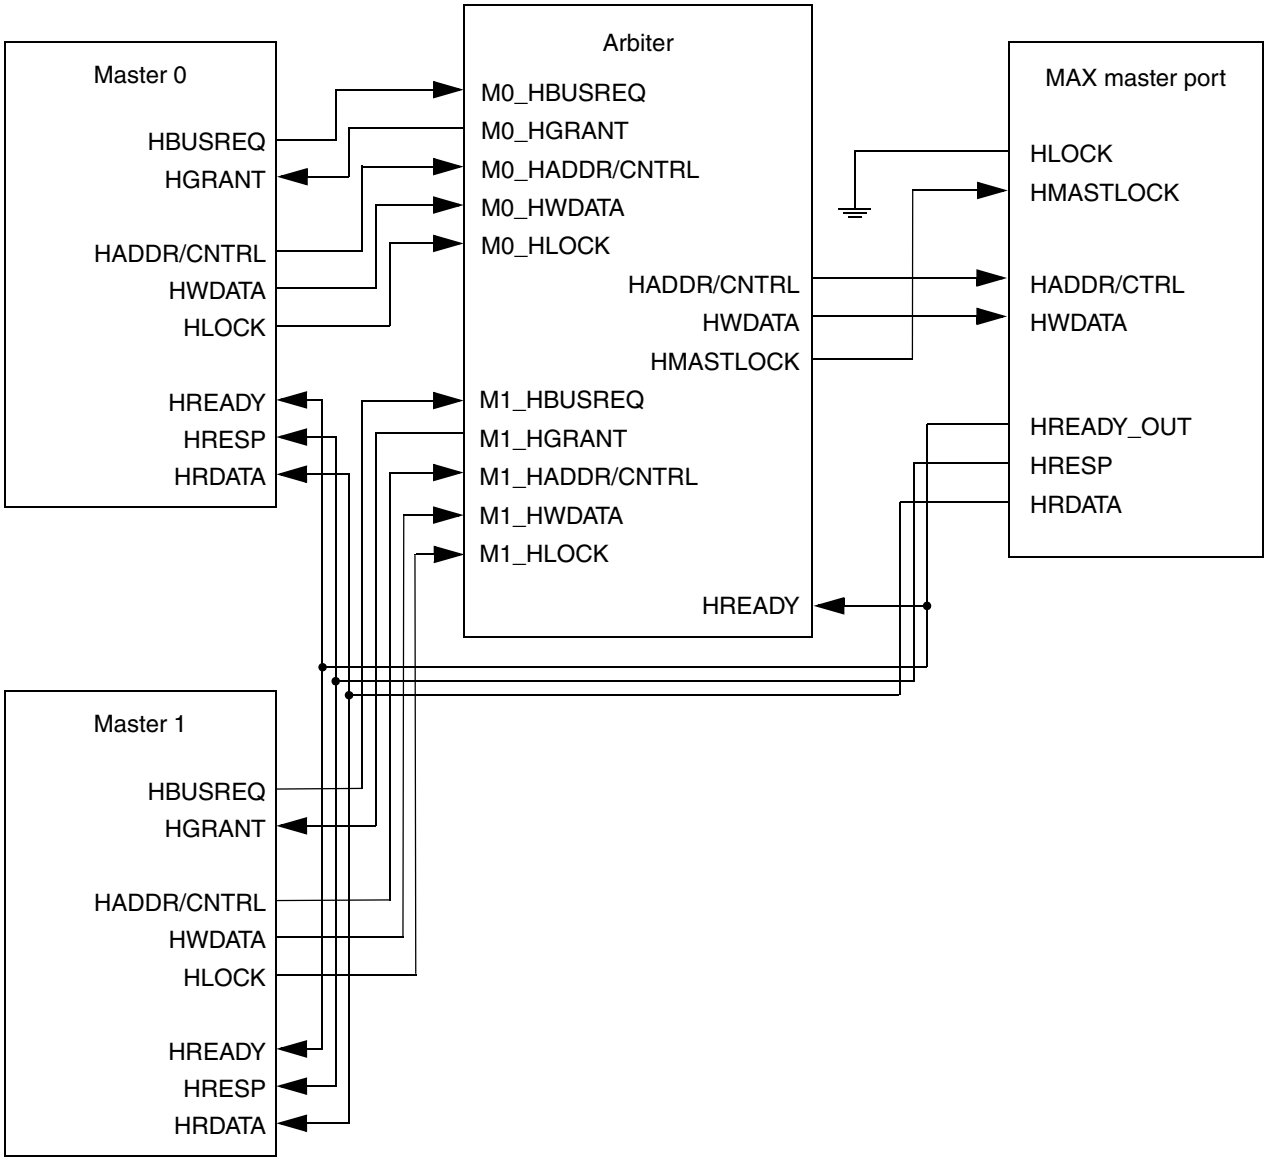


Figure 35-14. Multiple Master Configuration

The simplest approach is connecting a single master to the master port. In this instance all wiring is direct connect; however, since the MAX does not support the bus request/bus grant protocol the master's bus grant input must be tied asserted. This configuration is shown in Figure 35-15.

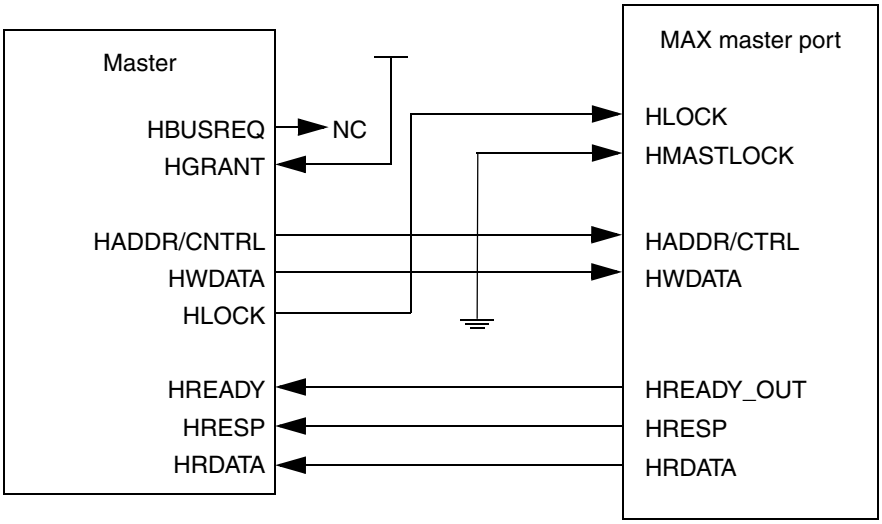

Figure 35-15. Single Master Configuration

35.7.3 Slave Ports

Each slave port takes on the appearance of a standard AHB-Lite master device. Since the slave ports do not support the bus request/bus grant protocol they assume that they are the only master driving the AHB-Lite interface they are connected to.

35.7.4 Registers

The MAX registers are read and written via an IP bus interface. The registers also have their own clock input, **ipg_clk**. The register clock and the MAX clock must be in phase. The reason for separate clock inputs is to allow for power saving features such as turning off the **ipg_clk** when no register accesses are being performed. When in doubt connect the **ipg_clk** to the same clock driving the MAX **hclk** input.

Chapter 36
MediaLB Device Module (MLB)

36.1 Overview

The MediaLB module implements the Physical Layer and Link Layer of the MediaLB specification, interfacing the MCIMX35 to the MediaLB controller. The MLB implements the 3-pin MediaLB mode and can run at speeds up to 1024 Fs. It does not implement MediaLB controller functionality.

All MediaLB devices support a set of physical channels for sending data over the MediaLB. Each physical channel is 4 bytes in length (quadlet) and grouped into logical channels with one or more physical channels allocated to each logical channel. These logical channels can be any combination of channel type (synchronous, asynchronous, control, or isochronous) and direction (transmit or receive).

The MLB provides support for up to 16 logical channels and up to 31 physical channels with a maximum of 124 bytes of data per frame. Each logical channel is referenced using an unique channel address and represents a unidirectional data path between a MediaLB device transmitting the data and the MediaLB device(s) receiving the data.

Once per MOST network frame, the MediaLB controller generates a unique frame sync pattern. This pattern defines the frame and channel boundaries of the signal information and data lines.

The MediaLB Controller initiates all communication over the MediaLB by sending out the logical channel address on the signal information line for each physical channel. This logical address indicates to the appropriate MediaLB device that it can transmit data for that logical channel during the next physical channel slot. One quadlet later, the transmitting MediaLB device send out a MediaLB command byte on the signal information line and the corresponding data on the data line. All other MediaLB devices (including the controller) have already compared the logical channel address with their internal table of addresses to determine if they are the intended recipient of the data on this logical channel.

The receiving MediaLB device responds with a receive status response on the signal information line one byte after the transmitting device sends the MediaLB command byte. Note that synchronous data transmissions (which is the only data format to support multiple receivers) are not acknowledged, but asynchronous, control and isochronous data transmissions are acknowledged.

For more information about the MediaLB protocol, see the *Media Local Bus Specification*.

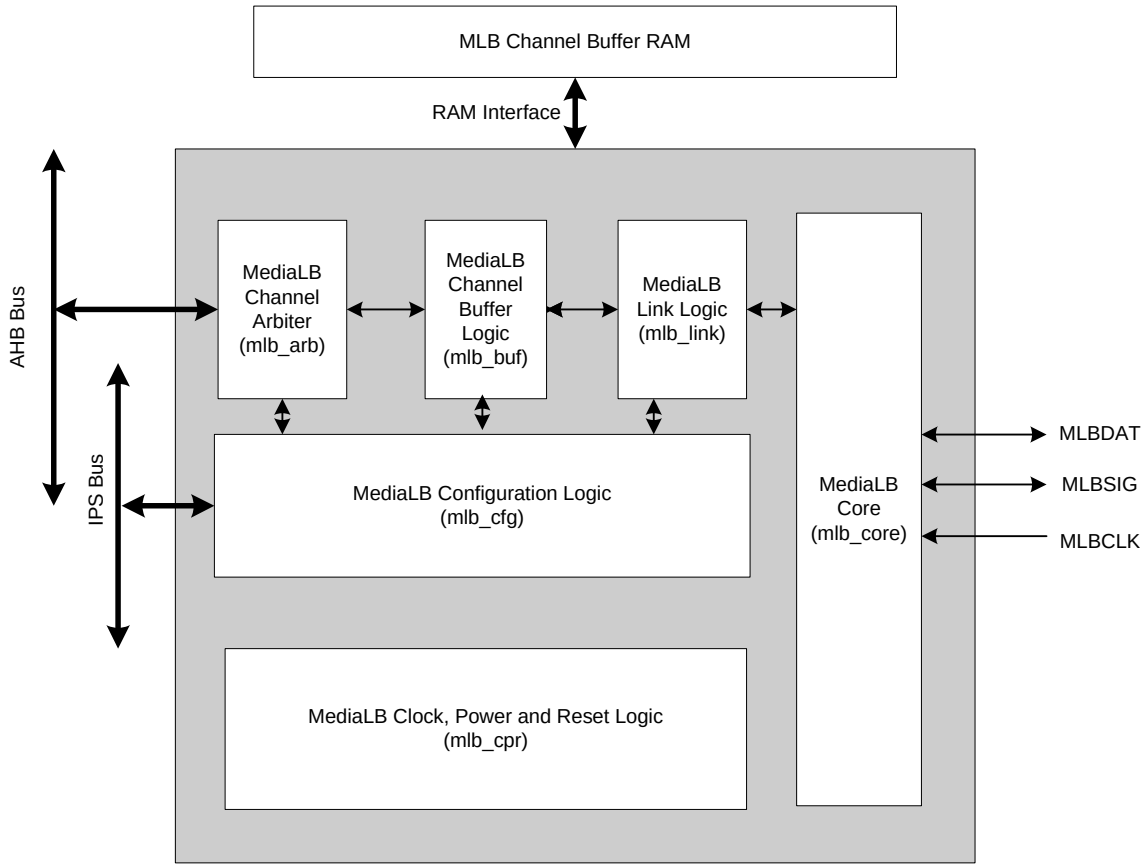

Figure 36-1. MLB Top-level Block Diagram

36.1.1 Features

- Support for up to 16 logical channels and 31 physical channels running at a maximum speed of 1024 Fs
- Transmission of commands and data and reception of receive status when functioning as the transmitting device associated with a logical channel address
- Reception of commands and data and transmission as receive status responses when functioning as the receiving device associated with a logical channel address
- MediaLB lock detection
- System channel command handling
- Local channel buffer RAM (Single Port RAM) of 2k x 36-bits accessed.

36.1.2 MediaLB Submodules

The MediaLB module design is split into 6 major submodules:

- **MediaLB Core**—The MediaLB Core implements the physical layer of the MediaLB interface. This physical layer performs serial-to-parallel and parallel-to-serial data transformations and MediaLB frame synchronization.

- **MediaLB CPR Logic**—The MediaLB Clocks, Power, and Reset (CPR) Logic implements clock and reset control.
- **MediaLB Link Logic**—The MediaLB Link Logic implements the link layer functionality of the MediaLB interface, including:
  - checking of synchronous, asynchronous, control, and isochronous channel protocol,
  - handling of both RX and TX initiated breaks,
  - generating RX responses to the MediaLB Core,
  - generating TX commands for the MediaLB Core,
  - processing of and responding to the system channel commands,
  - detection of MediaLB bus lock/unlock, and
  - recognition and pipe-lining of logical *ChannelAddresses*.
- **MediaLB Configuration Logic**—The MediaLB Configuration Logic implements the memory space for the Configuration Control Registers and Channel Configuration Registers. These configuration and control registers are used to define various parameters and control the operation of the MediaLB Device.
- **MediaLB Channel Buffer Logic**—The function of the MediaLB Channel Buffer logic block includes:
  - buffering of logical channel data for bus latency issues,
  - multiplexing of logical channel data, and
  - implementation of hardware loop-back mode between logical channel N (RX) and logical channel N+1 (TX) {N=0, 2, 4, 6,...,14}.
- **MediaLB Channel Arbiter**—The MediaLB Channel Arbiter functionality includes:
  - operating as an AHB bus master for DMA accesses to/from system memory,
  - determining priorities of channel DMA requests,
  - granting requests based on round-robin arbitration,
  - routing data and control information between MediaLB logical channels and the AHB bus interface
  - consolidating channel interrupts.

36.1.3 Modes of Operation

36.1.3.1 Normal Mode

The MediaLB Device dictates 2 particular methods for transferring data between logical channels and system memory:

- Ping-Pong Buffering mode
- Circular Buffering mode

The Circular Buffering mode is only used in Synchronous type transfers.

36.1.3.2 Loopback Test Mode

In order to facilitate silicon debug of the MediaLB Device, the design supports the Loopback Test Mode. This mode allows testing of the MediaLB pads, physical layer, link layer, channel protocol, and local channel buffer. When the DCCR.LBM bit is set, a data path is enabled which allows RX data from Channel *N* to be sent out as TX data on Channel *N*+1 {*N*=0, 2, 4, 6,... 14}.

Figure 36-2 illustrates the Loopback Test Mode data path.

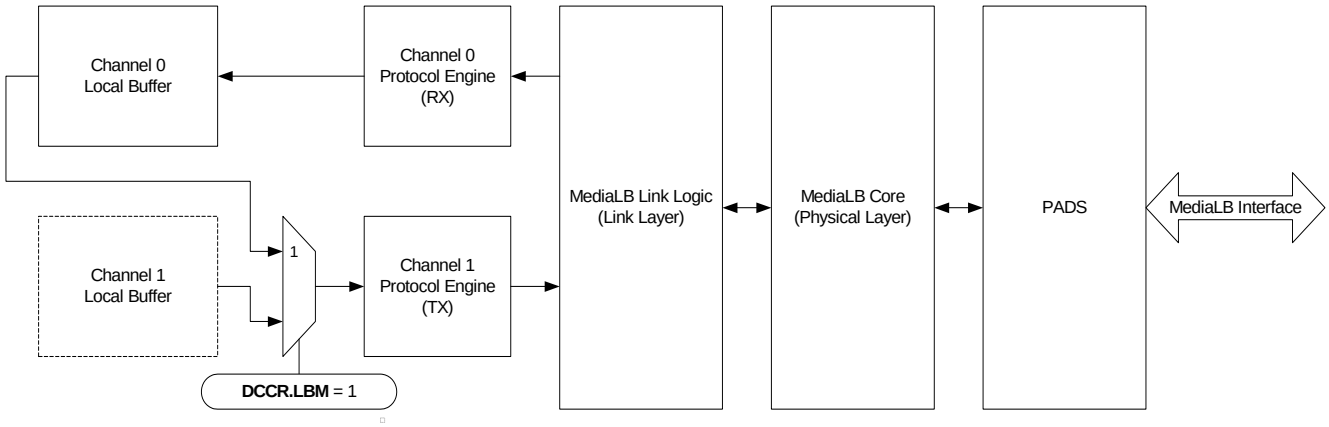

Figure 36-2. Loopback Test Mode Data Path

For Loopback Test Mode operation, software must perform the following steps:

- Set the logical Channel Addresses for Channel *N* and *N*+1. (They cannot be the same address.)
- Enable Channel *N* for receiving synchronous, asynchronous, control, or isochronous data.
- Enable Channel *N*+1 for transmitting the same channel data type as Channel *N*.
- Set the Loopback Mode bit (DCCR.LBM).

Restrictions on the Loopback Test Mode are as follows:

- No protocol errors or breaks are allowed on either the RX or TX channel.
- Isochronous packet lengths must be quadlet multiples.
- Next Buffer Ready bits for Channels *N* and *N*+1 must remain clear (CSCRn.RDY = CSCRn+1.RDY = 0)

36.2 External Signal Description

The MediaLB Device module has three external signals which are summarized in Table 36-1.

Table 36-1. Signal Properties

Name	Function	I/O	Reset	Pull
MLBCLK	MLB Clock	I	In	Down
MLBDAT	MLB Data	I/O	In	Down
MLBSIG	MLB Signal	I/O	In	Down

36.2.1 Detailed Signal Descriptions

Table 36-2. MediaLB Device Interface

Signal	I/O	Description	
MLBCLK	I	MLB Clock.	
		State Meaning	Asserted/Negated—Supports a 256 Fs, 512 Fs or 1024 Fs clock input from the MediaLB controller.
		Timing	Assertion/Negation—Supports maximum frequency of 49.2 MHz for a 48 kHz sample rate.
MLBDAT	I/O	MLB Data	
		State Meaning	Asserted/Negated—MediaLB data for serial receive/transmit channel data.
		Timing	Assertion/Negation—Registered on the falling edge of MLBCLK.
MLBSIG	I/O	MLB Signal	
		State Meaning	Asserted/Negated—MediaLB signal information for serial transmit channel commands, serial receive channel responses, and logical channel address information.
		Timing	Assertion/Negation—Registered on the falling edge of MLBCLK.

36.3 Memory Map and Register Definition

36.3.1 Memory Map

Table 36-3 is the MLB memory map. For the MLB base address, see the system memory map.

Table 36-3. Memory Map

Base Address Offset	Register	Access	Reset Value	Section/Page
General Registers				
0x0000	DCCR—Device Control Configuration Register	R/W[1]	0x0000_0000	36.3.3.1/36-9

[1] Note that R/W registers may contain some read-only or write-only bits.

36.3.2 Register Summary

Figure 36-4 provides a key for register figures and tables.

Table 36-4. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

36.3.3 Registers Descriptions

36.3.3.1 DCCR (Device Control Cfg Register)

The Device Control Cfg Register (DCCR) is used to control basic features of the MediaLB Device module, such as clock rate, pinout, lock status, enable, and application and device addressing.

Offset 0x0000 (DCCR) Access: User read/write

	1531	1430	1329	1228	1127	1026	925	824	723	622	521	420	319	218	117	016

Address 0xBASE_01(DCCR_H) Access: User read/write

Figure 36-3. DCCR (Device Control Cfg Register)

Table 36-5. DCCR Field Description

Field	Description
31 MDE	MediaLB Device Enable. When set, enables the MediaLB Interface based on the other bits in the register. 0 MediaLB Device Disabled 1 MediaLB Device Enabled
30 LBM	Loopback Mode Enable. When set, enables the loop-back testing of the MediaLB bus between logical channel N (RX) and logical channel *N*+1 (TX). {*N*=0, 2, 4, 6,...,14} 0 Loopback Mode Disabled 1 Loopback Mode Enabled
29-28 MCS[1:0]	MediaLB Clock Select. These field must be programmed by system software to reflect the MLBCLK_IN speed. 00 256 Fs: supports 8 quadlets per frame 01 512 Fs: supports 16 quadlets per frame 10 1024 Fs: supports 32 quadlets per frame 11 Reserved
27	Reserved. Should be written as zero for compatibility.
26 MLK	MediaLB Lock. When set, indicates that the MediaLB Port is synchronized to the incoming MediaLB frame. If MLK is clear (unlocked), MLK is set after FRAMESYNC is detected at the same position for three consecutive frames. If MLK is set (locked), MLK is cleared after not receiving FRAMESYNC at the expected time for two consecutive frames. While MLK is set, FRAMESYNC patterns occurring at locations other than the expected one are ignored. 0 MediaLB device is not synchronized to the incoming MediaLB frame. 1 MediaLB device is synchronized to the incoming MediaLB frame.
25	Reserved. Should be written as zero for compatibility.
24 MHRE	MediaLB Hardware Reset Enable. When set, enables hardware to automatically reset the MediaLB physical and link layer logic upon the reception of either a global (SDCR.MDS = 8'h0000) or device specific (SDCR.MDS = DA) MlbReset (FEh) System Command. 0 MediaLB device does not reset on reception of system reset command. 1 MediaLB device is reset on reception of system reset command.
23 MRS	MediaLB Software Reset. When set, resets the MediaLB physical and link layer logic. Hardware clears this bit automatically. 0 MediaLB device is not reset by software. 1 MediaLB device is reset by software.
22-8	Reserved. Should be written as zero for compatibility.
7-0 MDA[8:1]	MediaLB Device Address. Determines the unique DeviceAddress (DA) for the MediaLB Device. DeviceAddresses are used by the system channel MlbScan command. DA[15:0] = {7'h00, MDA[8:1], 1'b0}

36.3.3.2 SSCR (System Status Cfg Register)

The System Status Configuration register (SSCR) allows system software to monitor and control the status of the MediaLB network. SSCR is updated once per frame by hardware during the MediaLB System Channel. Except for the bits associated with MediaLB lock and unlock (SSCR.SDMU and SSCR.SDML), the bits of the SSCR register are not valid until the MediaLB Device is locked to the MediaLB interface. System software must service status events before the start of the next MediaLB frame to prevent the current frame status from being lost.

Figure 36-4. SSCR (System Status Cfg Register)

Table 36-6. SSCR Field Descriptions

Field	Description
31-8	Reserved. Should be written as zero for compatibility.
7 SSRE	System Service Request Enable. System software can set this bit to indicate that this MediaLB Device is present and needs service. An RxStatus DeviceServiceRequest (82h) will be sent in response to a MlbScan System Command from the MediaLB Controller. Hardware clears this bit after the RxStatus is sent. 0 MediaLB device responds to System Scan Command with Device Present (80h). 1 MediaLB device responds to System Scan Command with Device Service Request (82h).
6 SDMU	System Detects MediaLB Unlock. This bit is set to indicate that the MediaLB Device has unlocked from the MediaLB frame. Detecting a MediaLB unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not unlocked from MediaLB frame. 1 MediaLB device has unlocked from MediaLB frame.
5 SDML	System Detects MediaLB Lock. This bit is set to indicate that the MediaLB Device has locked to the MediaLB frame. Detecting a MediaLB lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not locked to MediaLB frame. 1 MediaLB device has locked to MediaLB frame.
4 SDSC	System Detects SubCommand. This bit is set to indicate that the MediaLB Device has received the MlbSubCmd (E6h) System Command. The user-defined software command is stored in the SDCR register. The decoding of this command is left up to software. Detecting MlbSubCmd generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not detected a Sub-command System Command. 1 MediaLB device has detected a Sub-command System Command.
3 SDCS	System Detects Channel Scan. This bit is set to indicate that the MediaLB Device has received the MlbScan (E4h) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MlbScan generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not detected a System Scan Command. 1 MediaLB device has detected a System Scan Command.
2 SDNU	System Detects Network Unlock. This bit is set to indicate that the MediaLB Device has received the MOST_Unlock (E2h) System Command. Detecting MOST_Unlock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not detected an Unlock Command. 1 MediaLB device has detected an Unlock Command.

Table 36-6. SSCR Field Descriptions (Continued)

Field	Description
1 SDNL	System Detects Network Lock. This bit is set to indicate that the MediaLB Device has received the MOST_Lock (E0h) System Command. Detecting MOST_Lock generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software 0 MediaLB device has not detected a Lock Command. 1 MediaLB device has detected a Lock Command.
0 SDR	System Detects Reset. This bit is set to indicate that the MediaLB Device has received the MlbReset (FEh) System Command. The target DeviceAddress is stored in the SDCR register. Detecting MLBReset generates a maskable system interrupt to system software. Once set, this bit is sticky until cleared by software. 0 MediaLB device has not detected a Reset Command. 1 MediaLB device has detected a Reset Command.

36.3.3.3 SDCR (System Data Cfg Register)

The System Data Configuration register (SDCR) allows system software to receive control information from the MediaLB Controller. SDCR is updated once per frame by hardware during the MediaLB System Channel. System software must read SDCR before the start of the next MediaLB frame to prevent the current frame data from being lost.

Figure 36-6. SMCR (System Mask Cfg Register)

Table 36-8. SMCR Field Descriptions

Field	Description
31-7	Reserved. Should be written as zero for compatibility.
6 SMMU	System Masks MediaLB Unlock. When set, this bit masks system interrupts generated when a MediaLB unlock is detected. At reset, MediaLB unlock events are masked (SMMU = 1) 0 MediaLB unlock system interrupt is enabled. 1 MediaLB unlock system interrupt is disabled.
5 SMML	System Masks MediaLB Lock. When set, this bit masks system interrupts generated when MediaLB lock is detected. At reset, MediaLB lock events are masked (SMML = 1). 0 MediaLB lock system interrupt is enabled. 1 MediaLB lock system interrupt is disabled.
4 SMSC	System Masks SubCommand. When set, this bit masks system interrupts for the MlbSubCmd (E6h) System Command. 0 MediaLB SubCommand system interrupt is enabled. 1 MediaLB SubCommand system interrupt is disabled.
3 SMCS	System Masks Channel Scan. When set, this bit masks system interrupts for the MlbScan (E4h) System Command. 0 MediaLB Channel Scan system interrupt is enabled. 1 MediaLB Channel Scan system interrupt is disabled.
2 SMNU	System Masks Network Unlock. When set, this bit masks system interrupts for the MOST_Unlock (E2h) System Command 0 MediaLB Network Unlock system interrupt is enabled. 1 MediaLB Network Unlock system interrupt is disabled.
1 SMNL	System Masks Network Lock. When set, this bit masks system interrupts for the MOST_Lock (E0h) System Command. 0 MediaLB Network Lock system interrupt is enabled. 1 MediaLB Network Lock system interrupt is disabled.
0 SMR	System Masks Reset. When set, this bit masks system interrupts for the MlbReset (FEh) System Command. 0 MediaLB Reset system interrupt is enabled. 1 MediaLB Reset system interrupt is disabled.

36.3.3.5 VCCR (Version Control Configuration Register)

The Version Control Configuration Register (VCCR) allows system software to verify the version of the MediaLB Device.

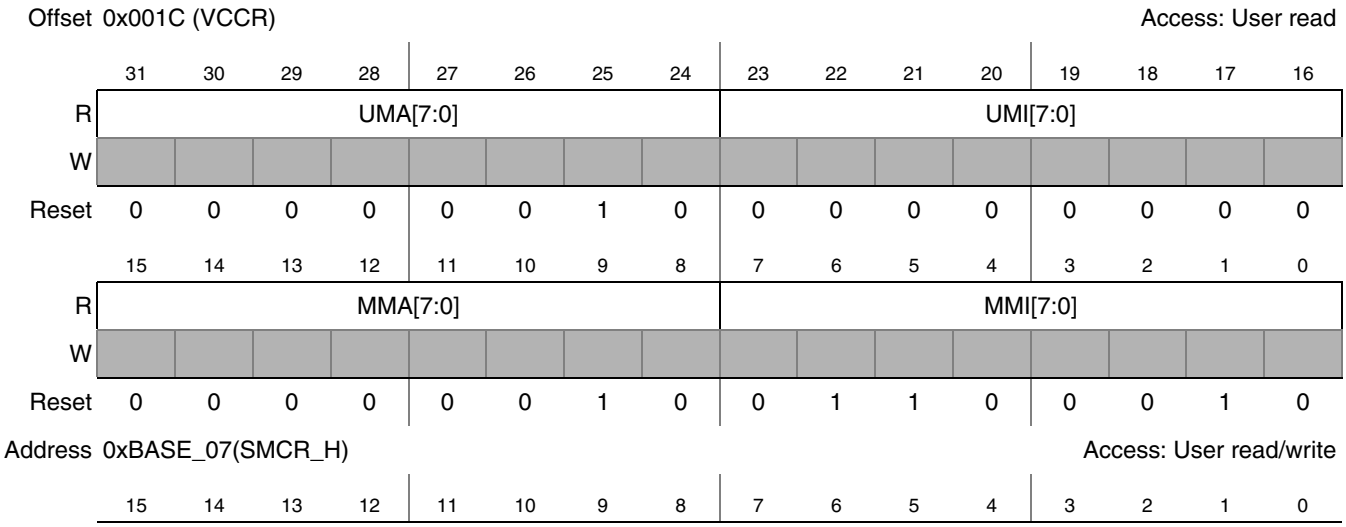

Figure 36-7. VCCR (Version Control Configuration Register)

Table 36-9. VCCR Field Descriptions

Field	Description
31-24 UMA	User Major Revision Code. This field identifies the minor revision of MediaLB Device in MCIMX35. The current major revision code is 0x02.
23-16 UMI	User Minor Revision Code. This field identifies the minor revision of MediaLB Device in MCIMX35.The current minor revision code is 0x00.
15:8 MMA[7:0]	MediaLB Major Revision Code. This field identifies the major revision of the MediaLB Device. The current major revision code is 0x02.
7:0 MMI[7:0]	MediaLB Minor Revision Code. This field identifies the minor revision of the MediaLB Device. The current minor revision code is 0x02.

36.3.3.6 SBCR (Synchronous Base Address Cfg Register)

The Synchronous Base Address Configuration Register (SBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

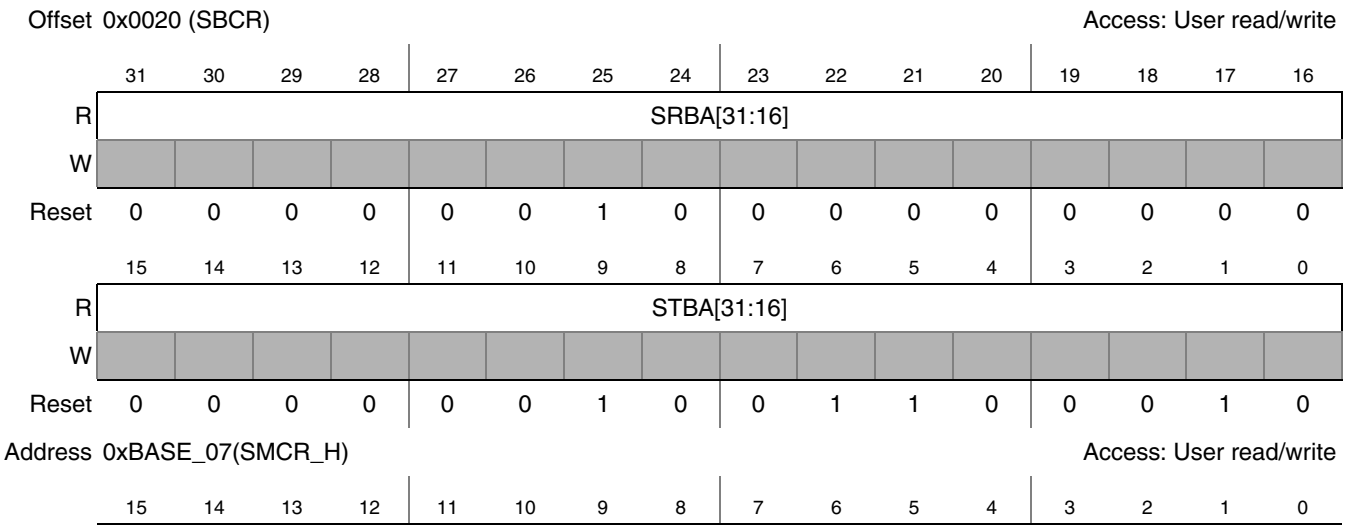

Figure 36-8. SBCR (Synchronous Base Address Cfg Register)

Table 36-10. SBCR Field Descriptions

Field	Description
31-16 SRBA [31:16]	Synchronous Receive Base Address. This base address is shared by all synchronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
23-16 STBA [31:16]	Synchronous Transmit Base Address. This base address is shared by all synchronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

36.3.3.7 ABCR (Asynchronous Base Address Cfg Register)

The Asynchronous Base Address Configuration Register (ABCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

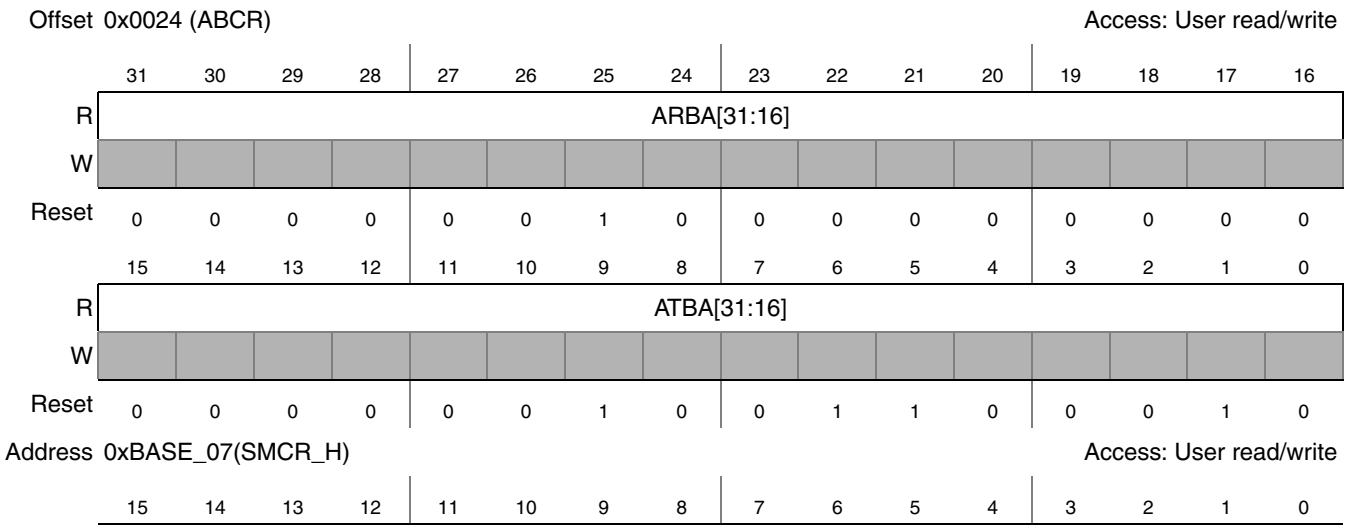

Figure 36-9. ABCR (Asynchronous Base Address Cfg Register)

Table 36-11. ABCR Field Descriptions

Field	Description
31-16 ARBA [31:16]	Asynchronous Receive Base Address. This base address is shared by all asynchronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
23-16 ATBA [31:16]	Asynchronous Transmit Base Address. This base address is shared by all asynchronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

36.3.3.8 CBCR (Control Base Address Cfg Register)

The Control Base Address Configuration Register (CBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

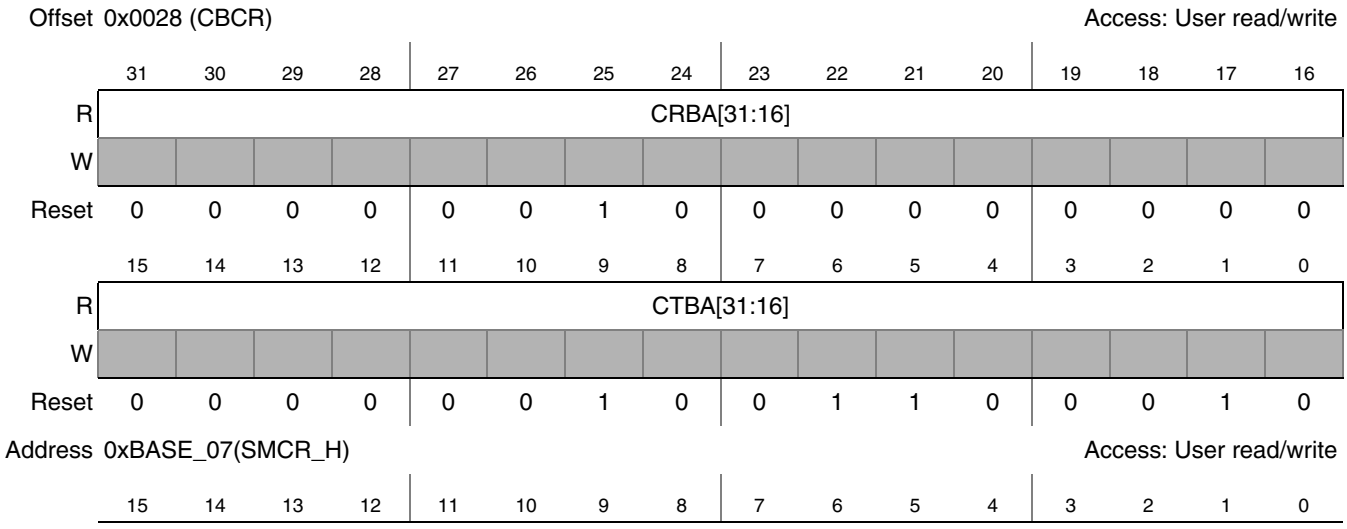

Figure 36-10. CBCR (Control Base Address Cfg Register)

Table 36-12. CBCR Field Descriptions

Field	Description
31-16 CRBA [31:16]	Control Receive Base Address. This base address is shared by all control RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
23-16 CTBA [31:16]	Control Transmit Base Address. This base address is shared by all control TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

36.3.3.9 IBCR (Isochronous Base Address Cfg Register)

The Isochronous Base Address Configuration Register (IBCR) allows system software to define the base address for synchronous RX/TX system memory buffers.

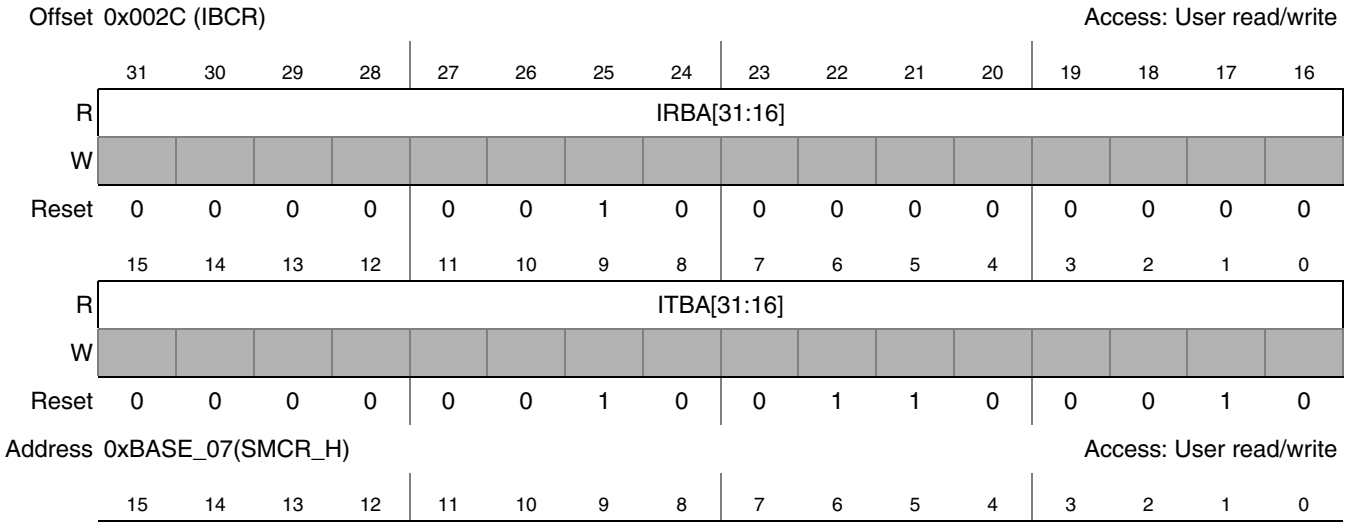

Figure 36-11. IBCR (Isochronous Base Address Cfg Register)

Table 36-13. IBCR Field Descriptions

Field	Description
31-16 IRBA [31:16]	Isochronous Receive Base Address. This base address is shared by all Isochronous RX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.
23-16 ITBA [31:16]	Isochronous Transmit Base Address. This base address is shared by all Isochronous TX channels and defines the upper 16 bits of the 32-bit AHB address for these channels.

36.3.3.10 CICR (Channel Interrupt Cfg Register)

The Channel Interrupt Configuration Register (CICR) reflects the channel interrupt status of the individual MediaLB logical channels. These bits are set by hardware when a channel interrupt is generated. The channel interrupt bits are sticky and can only be reset by software.

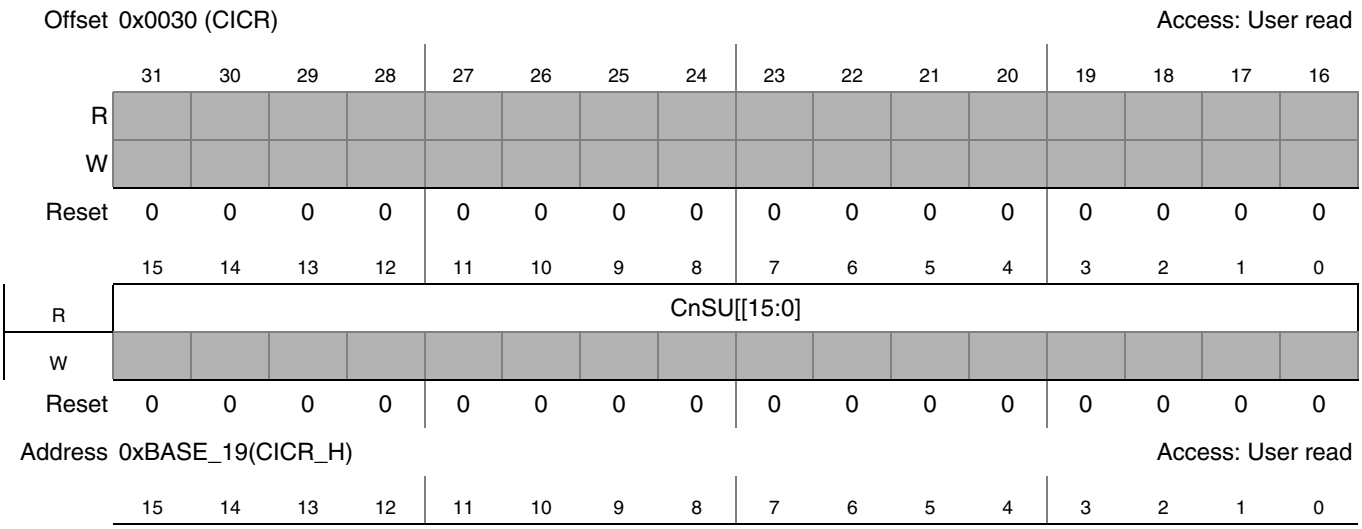

Figure 36-12. CICR (Channel Interrupt Cfg Register)

Table 36-14. Channel Interrupt Configuration Register Field Descriptions

Field	Description
31-16	Reserved. Should be written as zero for compatibility.
15-0 CSU [15:0]	Channel Status Update for Logical Channels 15 through 0. When set, these bits indicate that hardware has generated an interrupt for the appropriate channel. These bits are sticky and can only be cleared by a software write. Writing to the CICR register has no affect. To clear a particular bit in the CICR, software must clear all of the unmasked status bits in the corresponding CSCLRn register. 0 Channel n has not generated an interrupt. 1 Channel n has generated an interrupt.

36.3.3.11 CECRn (Channel *n* Entry Cfg Register)

The Channel *n* Entry Configuration Register (CECR*n*) defines basic attributes about a given logical channel, such as the channel enable, channel type, channel direction, and channel address. The definition of the bit fields in the CECR*n* register vary, depending on the selected channel type.

Table 36-15. CECR Field Description

Field	Description
31 CE	Channel *n* Enable. 0 Channel *n* disabled (default) 1 Channel *n* enabled
30 TR	Channel *n* Transmit Select. 0 Receive (default) 1 Transmit
29-28 CT[1:0]	Channel *n* Type Select. 00 Synchronous (default) 01 Isochronous 10 Asynchronous 11 Control
27 rsvd FSE FCE	For Asynchronous and Control Channels—Reserved For Synchronous Channels—Frame Synchronization Enable. When set, enables Streaming Channel Frame Synchronization for this logical synchronous channel. For Isochronous Channels—Flow Control Enable. When set, allows an isochronous RX channel to generate the ReceiverBusy (0x10) response.
26-25 MDS[1:0]	Channel *n* Mode Select. 00 Ping-pong buffering used 01 Circular buffering used 10, 11Reserved
24-23 rsvd	Reserved. Should be written as zero for compatibility.
22 MLFS	Mask Lost Frame Synchronization. When set, masks *Lost Frame Synchronization* channel interrupts for this logical channel. 0 Enable *Lost Frame Synchronization* channel interrupts for this logical channel 1 Disable *Lost Frame Synchronization* channel interrupts for this logical channel
21 rsvd	Reserved. Should be written as zero for compatibility.
20 MBE	Mask Buffer Error. When set, masks *Buffer Error* channel interrupts for this logical channel. 0 Enable *Buffer Error* channel interrupts for this logical channel 1 Disable *Buffer Error* channel interrupts for this logical channel
19 MBS	Mask Buffer Start. When set, *masks Buffer Start* channel interrupts for this logical channel. 0 Enable *Buffer Start* channel interrupts for this logical channel 1 Disable *Buffer Start* channel interrupts for this logical channel
18 MBD	Mask Buffer End. When set, *masks Buffer End* channel interrupts for this logical channel. 0 Enable *Buffer End* channel interrupts for this logical channel 1 Disable *Buffer End* channel interrupts for this logical channel
17 MDB	Mask Detect Break. When set, masks detect break channel interrupts for this logical channel. At reset, detect break interrupts are masked (this bit is set at reset). This bit is valid for asynchronous and control channels only. 0 Enable detect break channel interrupts for this logical channel 1 Disable detect break channel interrupts for this logical channel

Table 36-15. CECR Field Description

Field	Description
16 MPE	Mask Protocol Error. When set, masks Protocol error channel interrupts for this logical channel. At reset, protocol error interrupts are masked (this bit is set at reset). This bit is valid for all RX channel types and valid for only asynchronous and control TX channels. 0 Enable protocol error channel interrupts for this logical channel 1 Disable protocol error channel interrupts for this logical channel
15 rsvd FSCD IPL[7]	 For Asynchronous and Control channels only—Reserved For Synchronous channels only—Frame Synchronization Channel Disable. When set, disables this logical channel (set **CECHRn.CE** = 0) when *Lost Frame Synchronization* occurs. 0 Do not disable this logical channel when frame synchronization is lost 1 Disable this logical channel when frame synchronization is lost For Isochronous channels only—Isochronous Packet Length bit 7 field Isochronous Packet Length. For Isochronous TX channels, defines the number of packet bytes. The smallest isochronous packet size per frame is 5 bytes (**IPL[7:0]** >= 5). A packet length of 256 bytes can be represented as **IPL[7:0]**=00h. For Isochronous RX channels, software must program **IPL[7:2]** to indicate the expected number of bytes per packet, where **IPL[1:0]** always equals 00.
14-13 rsvd IPL[6:5]	 For Asynchronous, control and synchronous channels only—Reserved For Isochronous channels only—Isochronous Packet Length bit6-bit5 fields
12-8 rsvd FSPC[4:0] IPL[4:0]	 For Asynchronous, Control channels only—Reserved For Synchronous channels only—Frame Synchronization Physical Channels Count bit4-bit0 fields. For Isochronous channels only—Isochronous Packets Length bit4-bit0 fields
7-0 CA[8:1]	Channel Address. These bits determine the *ChannelAddress* associated with this logical channel. This value is matched against the *ChannelAddress* received each physical channel from the MediaLB Controller. There is a *ChannelAddress* match if and only if the *ChannelAddress* recovered from the MediaLB input, *MLBSIG*, equals the *ChannelAddress* defined by: CA[15:0] = {7'h00, CA[8:1], 1'b0}.

36.3.3.12 CSCR*n* (Channel *n* Status Cfg Register)

The Channel n Status Configuration Register (CSCR*n*) reflects the status of the Current Buffer and Previous Buffer for a given logical channel. The definition of the bit fields in the CSCRn register vary dependant on the selected channel type.

Figure 36-14. CSCR (Channel Status Cfg Register)

Table 36-16. CSCR Field Descriptions

Field	Description
31 BM	Buffer Empty. When set, the local channel buffer (for channel n) is empty. This bit is set and cleared by hardware. At reset, the local channel buffer is empty (BM = 1).
30 BF	Buffer Full. When set, the local channel buffer (for channel n) is fill. This bit is set and cleared by hardware.
29-20	Reserved. Should be written as zero for compatibility.
19-18 IVB[1:0]	Isochronous Valid Bytes. These bits are loaded by hardware with the number of valid bytes in the last packet of a broken Isochronous RX channel. Used in conjunction with CCBCRn.BCA, IVB[1:0] can be used by software to determine the final valid byte of the local channel buffer.(Valid for local channel buffers configured for isochronous RX data). 00 Final valid byte = (CCBCRn.BCA - 5) 01 Final valid byte = (CCBCRn.BCA - 4) 10 Final valid byte = (CCBCRn.BCA - 3) 11 Final valid byte = (CCBCRn.BCA - 2)
17 GIRB GB	For isochronous RX data—Generate Isochronous Receive Break. When set, this bit causes hardware to terminate the current packet, flush the local channel buffer, clear the RDY bit, and load IVB[1:0]. This bit is set by system software and cleared by hardware. For asynchronous and control data—Generate Break. When the local channel buffer is configured for TX data, the setting of this bit causes hardware to send the AsyncBreak (26h) or ControlBreak (36h) command and stop the transfer. When the local channel buffer is configured for RX data, the setting of this bit causes hardware to send the MediaLB RxStatus ReceiverBreak (70h) and stop the transfer. This bit is set by system software and cleared by hardware.
16 RDY	Next Buffer Ready. System software should set this bit when all the registers, data, and program memory variables are setup and ready to transmit or receive data. For TX data, the system memory buffer should also be filled. For ping-pong buffering mode, hardware clears this bit after the buffer begins to be processed. For circular buffering mode, software should clear this bit only when buffer processing needs to halted.
15-12	Reserved. Should be written as zero for compatibility.
11 PBS	Previous Buffer Start. When set, this bit indicates the first quadlet of the *Previous Buffer* has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.
10 PBD	Previous Buffer Done. When set, this bit indicates that the last quadlet of the *Previous Buffer* has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.
9 PBDB	Previous Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, *ReceiverBreak* (70h), or an RX channel has detected a transmitter break command, *ControlBreak* (36h) or *AsyncBreak* (26h), while processing the *Previous Buffer*. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types
8 PBPE	Previous Buffer Protocol Error. When set, this bit indicates that either a TX channel has detected an RxStatus of *ReceiverProtocolError* (72h), a RX channel has detected an invalid command for this channel type, or an additional *AsyncStart* (20h) or *ControlStart* (30h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channels and valid for only asynchronous and control TX channels.
7	Reserved. Should be written as zero for compatibility.

Table 36-16. CSCR Field Descriptions (Continued)

Field	Description
6 LFS	Lost Frame Synchronization. When set, this bit indicates that the logical channel has lost synchronization with the MediaLB frame. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous channels only.
5 ABE	AHB Bus Error. When set, this bit indicates that an AHB bus error has been detected. The setting of this bit generates a non-maskable channel interrupt to system software.
4 BE	Buffer Error. When set, this bit indicates that either a TX channel has detected a buffer underflow (e.g. attempted to pop data from an empty buffer), or an RX channel has detected a buffer overflow (e.g. attempted to push data onto a full buffer). The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for synchronous RX/TX and isochronous RX (**CECRn.FCE** = 0) channels only.
3 CBS	Current Buffer Start. When set, this bit indicates that the DMA controller has started processing the *Current Buffer*. This bit is set after the contents of CNBCRn have been loaded into CCBCRn, the **CSCRn.RDY** bit has been cleared (for ping-pong buffering), and hardware is available to accept the next buffer. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.
2 CBD	Current Buffer Done. When set, this bit indicates that the last quadlet from the last packet (in the *Current Buffer*) has been successfully transmitted or received. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all channel types.
1 CBDB	Current Buffer Detect Break. When set, this bit indicates that either a TX channel has detected a receiver break response, *ReceiverBreak* (70h), or an RX channel has detected a transmitter break command, *ControlBreak* (36h) or *AsyncBreak* (26h), while processing the *Current Buffer*. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for asynchronous and control channels only.
0 CBPE	Current Buffer Protocol Error. This bit indicates that either a TX channel has detected an RxStatus of *ReceiverProtocolError* (72h), an RX channel has detected an invalid command for a given channel type, or an additional *ControlStart* (30h) or *AsyncStart* (20h) command has been received while in the middle of a packet. The setting of this bit generates a maskable channel interrupt to system software. This bit is valid for all RX channel types and valid for only asynchronous and control TX channels.

36.3.3.13 CCBCR*n* (Channel *n* Current Buffer Cfg Register)

The Channel *n* Current Buffer Configuration Register (CCBCR*n*) allows system software to monitor the address pointer and buffer length of the *Current Buffer* in system memory for the logical channel.

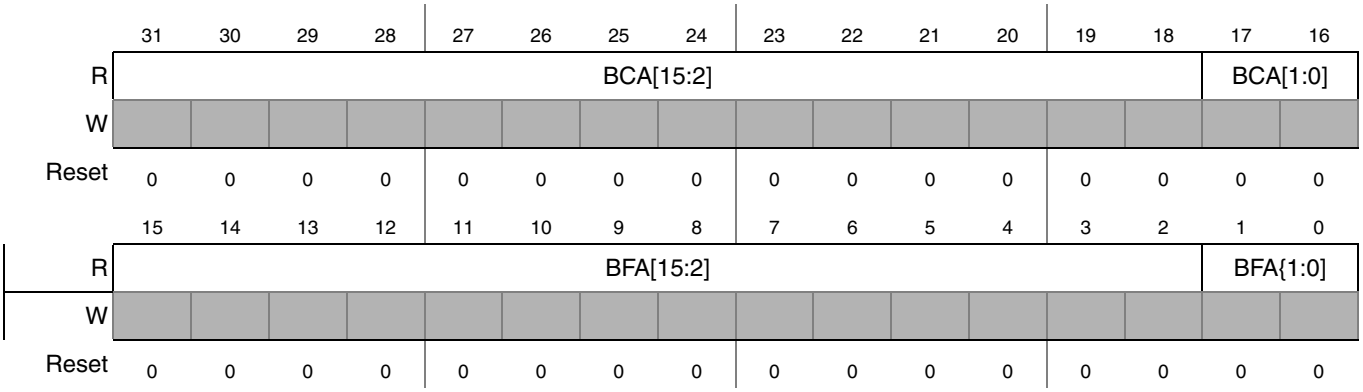

Figure 36-15. CCBCR*n* (Channel n Current Buffer Cfg Register)

Table 36-17. CCBCR Field Descriptions

Field	Description
31-18 BCA[15:2]	Buffer Current Address. The BCA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the *Current Buffer* in system memory. The **BCA[15:2]** bits are loaded from **CNBCRn.BSA[15:2]** when the *Next Buffer* is ready for processing. This *Current Buffer* address pointer should always be quadlet aligned (e.g. **BCA[1:0]** equals 2'b00). During the processing of the *Current Buffer*, the BCA field marks which quadlet of the buffer is currently being processed.
17-16 BCA[1:0]	For Synchronous, Asynchronous, and Control Channels—Hard-wired to 00 For Isochronous Channels—Buffer Current Address bits 1:0
15-2 BFA[15:2]	Buffer Final Address. The BFA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the *Current Buffer* in system memory. The **BFA[15:2]** bits are loaded from **CNBCRn.BEA[15:2]** when the *Next Buffer* is read for processing. This *Current Buffer* address pointer, except when associated with isochronous channels, should always be quadlet aligned (e.g. **BFA[1:0]** equals 2'b00). During the processing of the *Current Buffer*, the point at which the BCA field becomes equal to (or greater than) the BFA field indicates that the processing of the *Current Buffer* will end upon successful completion of the current quadlet (for isochronous and synchronous channels) or upon successful completion of the current packet (for asynchronous and control channels). It is the responsibility of system software to ensure the system memory buffers (for RX asynchronous and control channels) can accommodate overflow in the size of the largest packet supported. Additionally, single-packet buffering can be used by simply programming **CNBCRn.BSA[15:2]** = **CNBCRn.BEA[15:2]**
1-0 BFA[1:0]	For Synchronous, Asynchronous, and Control Channels—Hard-wired to 00 For Isochronous Channels—Buffer Final Address bits 1:0

36.3.3.14 CNBCR*n* (Channel *n* Next Buffer Cfg Register)

The Channel n Next Buffer Configuration Register (CNBCR*n*) allows system software to set the start and end addresses of the *Next Buffer* in system memory for the logical channel.

Figure 36-16. CNBCR (Channel n Current Buffer Cfg Register)

Table 36-18. CNBCR Field Descriptions

Field	Description
31-16 BSA[15:0]	Buffer Start Address. The BSA field defines a 16-bit address pointer, which identifies the lower half of the beginning address of the *Next Buffer* in system memory. After system software detects that **CSCRn.RDY** has been cleared by hardware (for ping-pong buffering), the beginning address of the *Next Buffer* may be loaded into **BSA[15:2]**. System software should then set **CSCRn.RDY**. Once processing of the *Current Buffer* for the logical channel is complete, the **BSA[15:2]** field is loaded into the **CCBCRn.BCA[15:2]** field and processing of the next buffer can begin. This *Next Buffer* address pointer must always be quadlet aligned (e.g. **BSA[1:0]** must be written as 2'b00).
15-0 BEA[15:0]	Buffer End Address. The BEA field defines a 16-bit address pointer, which identifies the lower half of the ending address of the *Next Buffer* in system memory. After system software detects that **CSCRn.RDY** has been cleared by hardware (for ping-pong buffering), the ending address of the *Next Buffer* may be loaded into **BEA[15:2]**. System software should then set **CSCRn.RDY**. Once processing of the *Current Buffer* for the logical channel is complete, the **BEA[15:2]** field is loaded into the **CCBCRn.BFA[15:2]** field and processing of the next buffer can begin. The **BEA[15:2]** bits are loaded into **CCBCRn.BFA[15:2]** when the *Current Buffer* is finished being processed. This *Next Buffer* address pointer, except when associated with isochronous channels, should always be quadlet aligned (e.g. **BEA[1:0]** defaults to 2'b00)

36.3.3.15 LCBCR*n* (Local Channel *n* Buffer Cfg Register)

The Local Channel *n* Buffer Configuration Register (LCBCR*n*) allows software to optimize use of the Local Channel Buffer RAM. This register should only be written by software while the logical channel is disabled (e.g. CECR3.CE clear disables Channel 3; therefore software may write LCBCR3). Writing to this register while the corresponding logical channel is enabled may result in unexpected behavior.

TH[9:0]	Buffer Threshold. The impact of the bit field can be ignored in MCIMX35

Table 36-19. LCBCR Field Descriptions (Continued)

Field	Description
BD[8:0]	Buffer Depth. This field defines the depth of the local channel buffer space in the local buffer RAM. At reset, the **LCBCR.BD[6:0]** field is loaded with 128 quadlets or 1Fh. 00hDepth = 4 quadlets 01hDepth = 8 quadlets 02hDepth = 12 quadlets ... 7FhDepth = 512 quadlets
SA[12:0]	Buffer Start Address. This field defines the starting address of the channel buffer space in the local buffer RAM. At reset, the **LCBCR.SA[9:0]** field is loaded with the channel number multiplied by 32 (for channel number multiplied by 128 quadlets). 000hStart Address = 0 quadlets 001hStart Address = 4 quadlets 002hStart Address = 8 quadlets ... 3FFhStart Address = 2044 quadlets

36.4 Functional Description

36.4.1 Local Channel Buffer RAM

A single-port RAM is used to implement the memory space for local channel buffering. The size of the RAM is 2k x 36-bits (1 quadlet of data; 4-bit tag). The initial start address, depth and threshold values for logical channel buffer RAM are determined by parameters RAM_SADDR, BUF_DEPTH and BUF_THRESHOLD. See Table 36-20 for parameters that indicate the start address, depth and threshold reset values. After reset, the start address, depth, and threshold values for the logical channels buffered in the RAM are controlled via the LCBCRn registers, the initial values can be overwritten by software.

Table 36-20. Local Channel Buffer RAM Parameters

Logical Channel	RAM_SADDR	BUF_DEPTH	BUF_THRESHOLD
0	0	16	2
1	16	16	2
2	32	144	128
3	176	144	128
4	320	144	128
5	464	144	128

13	1616	144	128
14	1760	144	128
15	1904	144	128

See Figure 36-18 for more information on using the CBCHR*n* and CBCLR*n* registers to configure the local RAM buffer.

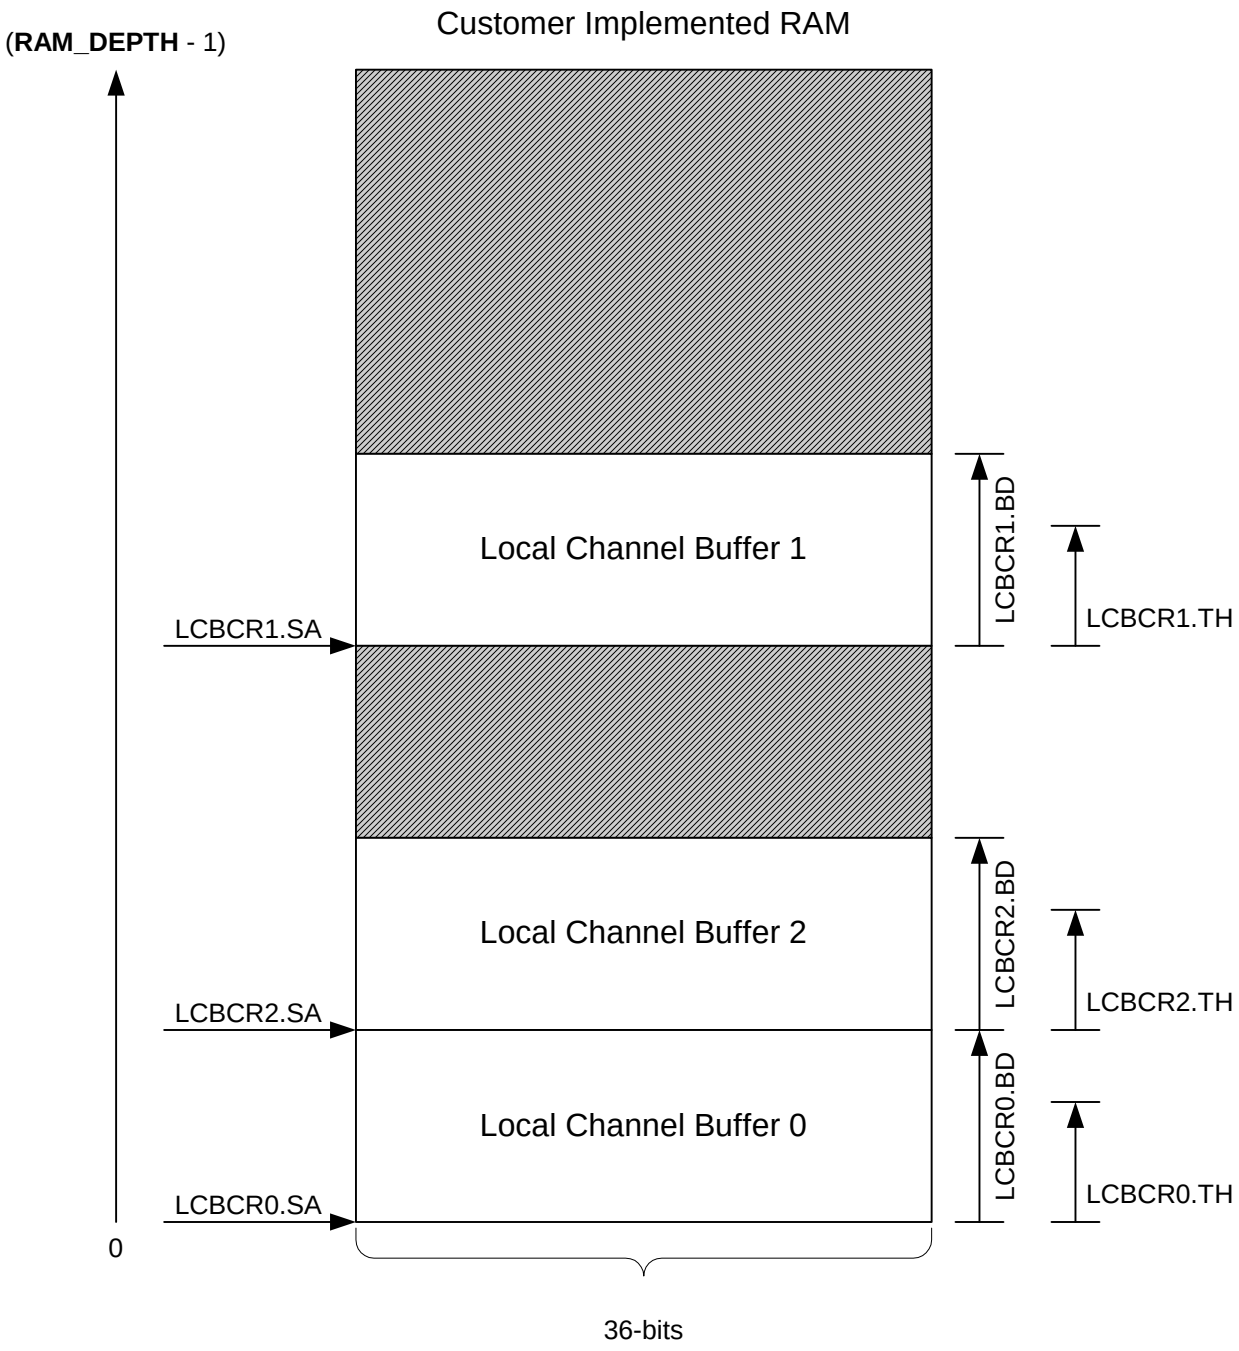

Figure 36-18. Programming Example for CBCHR*n* and CBCLR*n*

36.4.2 Modes of Operation

36.4.2.1 Ping-Pong Buffering

The ping-pong buffering mode dictates a particular method used for transferring data between hardware channels and system memory. When the logical channels of MediaLB Device are configured in this mode, the CCBCR*n* and CNBCR*n* registers are used to configure and monitor the system memory Current Buffer and Next Buffer, respectively.

Channels operate in ping-pong buffering mode when CECRn.MDS[1:0]=00. The Current Buffer and Next Buffer are independent system memory buffers, which allow hardware to support the ping-pong buffering. Each is addressed using two16-bit address pointers, as follows:

- Buffer Start Address (CNBCRn.BSA)—defines the beginning address of the Next Buffer in system memory
- Buffer End Address (CNBCRn.BEA)—determines the end of the Next Buffer in system memory
- Buffer Current Address (CCBCRn.BCA)—defines the beginning of the Current Buffer in system memory
- Buffer Final Address (CCBCRn.BFA)—defines the end of the Current Buffer in system memory

36.4.2.1.1 Asynchronous and Control Packet Handling

The Current Buffer and Next Buffer can be configured for either multi-packet or single-packet buffering, when receiving and transmitting asynchronous and control packet data. Multi-packet buffering allows the system to reduce the interrupt load at the expense of larger system memory buffers. Single-packet buffering allows system memory buffer size to be reduced at the expense of increasing the interrupt rate.

An example of multi-packet buffering for asynchronous and control channels is provided in Figure 36-19.

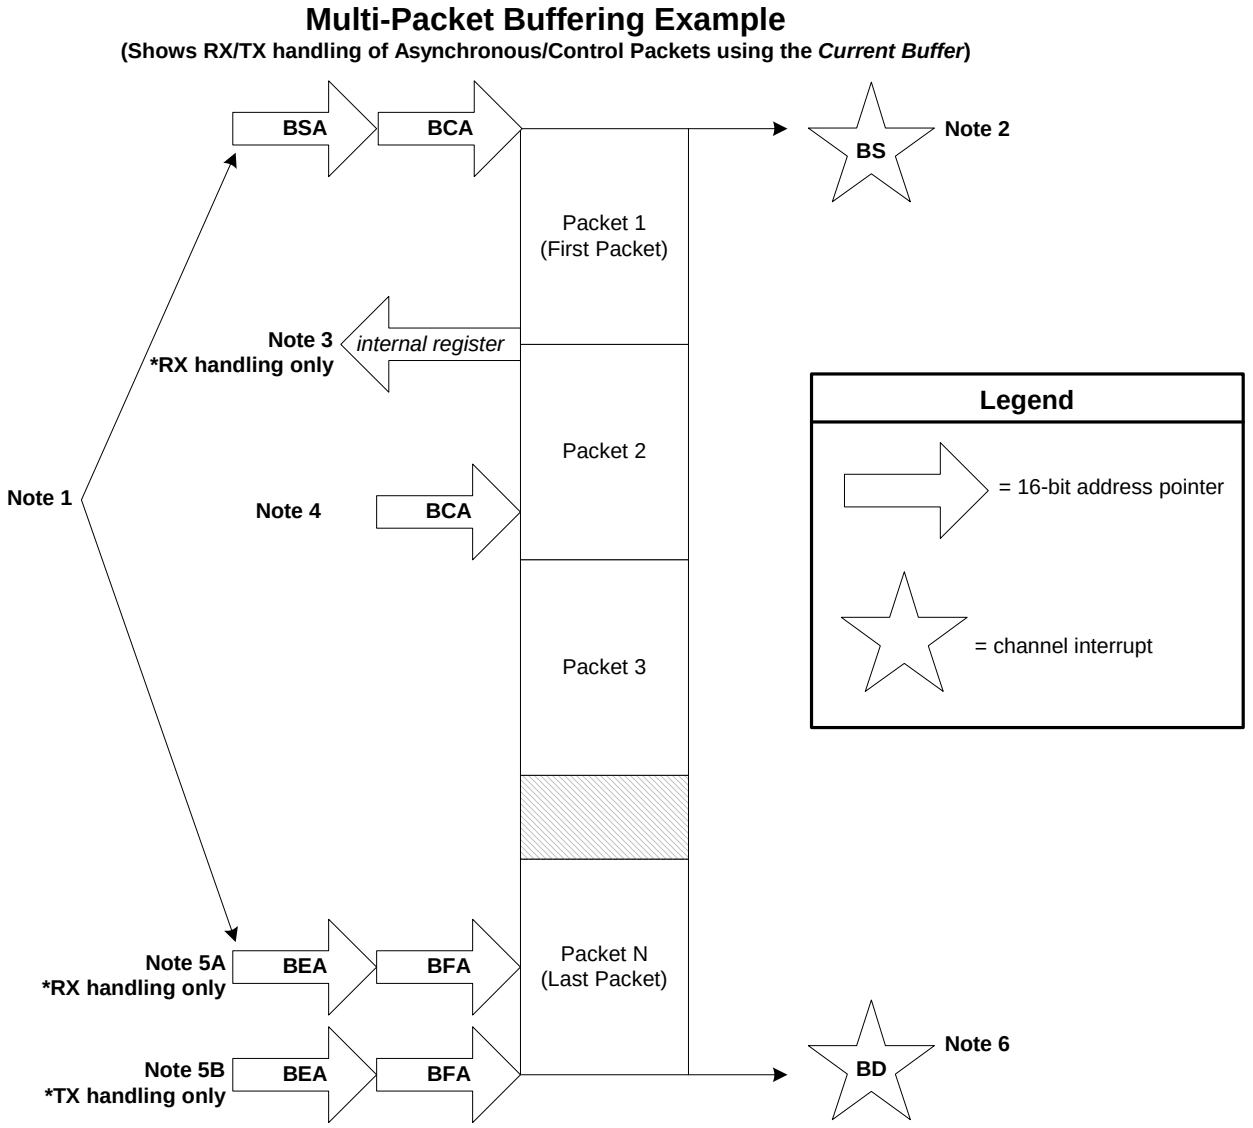

Figure 36-19. Asynchronous/Control Packet Buffering Example

Packet Reception

When multi-packet buffering is used for receiving asynchronous or control data packets, buffer processing should be handled in the following manner:

- At the start of buffer processing, the beginning of the Next Buffer becomes the beginning of the Current Buffer, as CNBCRn.BSA is loaded into CCBCRn.BCA. Additionally, the end of the Next Buffer becomes the end of the Current Buffer, as CNBCRn.BEA is loaded into CCBCRn.BFA.
- A *Buffer Start* interrupt is generated (CSCRn.STS[3] set), which informs software that hardware has updated CCBCRn, cleared the local channel CSCRn.RDY bit, and is available to accept the next buffer. Software may then prepare the Next Buffer by writing: CNBCRn.BSA, CNBCRn.BEA, and CSCRn.RDY.

- The CCBCRn.BCA field is loaded into an internal hardware register (not visible to system software) at the start of each incoming asynchronous or control RX packet. If the packet is later aborted (caused by *AsyncBreak*, *ControlBreak*, *ReceiverBreak*, or *ReceiverProtocolError*), CCBCRn.BCA is restored with the address pointer in the internal hardware register. The next packet then overwrites the aborted RX packet, as aborted RX packets are not stored in system memory.
- During the processing of the Current Buffer, CCBCRn.BCA continues to mark which quadlet of the asynchronous or control RX packet is currently being processed.
- Software is unable to predict the buffer length for asynchronous and control RX channels, since the length of each RX packet is defined by the packet header (PML) and extracted by hardware as the packet is received. As a result, there is a possibility that the last packet in the Current Buffer may extend beyond CCBCRn.BFA. System memory must accommodate this by allowing the buffers to overflow by the worst-case packet length.
- A *Buffer Done* interrupt is generated (CSCRn.STS[2] set) when the last quadlet from the last packet (in the Current Buffer) has been successfully received. Software may then begin processing the buffer.
- When the DMA Controller encounters an asynchronous or control packet that is broken (or has an error), CCBCRn.BCA is reloaded with the start address of the *last* packet and the broken packet is overwritten. This mechanism ensures that system software can always calculate the address of the *next* packet start address within system memory.

Single-packet buffering of asynchronous and control RX packets should be handled in the same manner described for multi-packet buffering, with the exception that the beginning and end address of the Next Buffer should be set to the same address (e.g. CNBCRn.BSA = CNBCRn.BEA).

Packet Transmission

When multi-packet buffering is used for transmitting asynchronous or control data packets, buffer processing should be handled in the following manner:

- At the start of buffer processing, the beginning of the Next Buffer becomes the beginning of the Current Buffer, as CNBCRn.BSA is loaded into CCBCRn.BCA. Additionally, the end of the Next Buffer becomes the end of the Current Buffer, as CNBCRn.BEA is loaded into CCBCRn.BFA.
- A *Buffer Start* interrupt is generated (CSCRn.STS[3] set), which informs software that hardware has updated CCBCRn, cleared the local channel CSCRn.RDY bit, and is available to accept the next buffer. Software may then prepare the Next Buffer by writing: CNBCRn.BSA, CNBCRn.BEA, and CSCRn.RDY.
- During the processing of the Current Buffer, CCBCRn.BCA continues to mark which quadlet of the asynchronous or control TX packet is currently being processed.
- System software can determine the exact buffer length for TX channels. As a result, the last packet in the Current Buffer should coincide with CCBCRn.BFA.
- A *Buffer Done* interrupt is generated (CSCRn.STS[2] set) when the last quadlet from the last packet (in the Current Buffer) has been successfully transmitted.

Single-packet buffering of asynchronous and control TX packets should be handled in the same manner described for multi-packet buffering.

36.4.2.1.2 Isochronous and Synchronous Data Handling

Reception and transmission of isochronous and synchronous data should be handled in the following manner:

- At the start of buffer processing, the beginning of the Next Buffer becomes the beginning of the Current Buffer, as CNBCRn.BSA is loaded into CCBCRn.BCA. Additionally, the end of the Next Buffer becomes the end of the Current Buffer, as CNBCRn.BEA is loaded into CCBCRn.BFA.
- A *Buffer Start* interrupt is generated (CSCRn.STS[3] set), which informs software that hardware has updated CCBCRn, cleared the local channel CSCRn.RDY bit, and is available to accept the next buffer. Software may then prepare the Next Buffer by writing: CNBCRn.BSA, CNBCRn.BEA, and CSCRn.RDY.
- During the processing of the Current Buffer, CCBCRn.BCA continues to mark which quadlet of the isochronous or synchronous data is currently being processed.
- A *Buffer Done* interrupt is generated (CSCRn.STS[2] set) when the last quadlet in the Current Buffer has been successfully transmitted/received.

An example of buffer processing for isochronous and synchronous channels is provided in Figure 36-20.

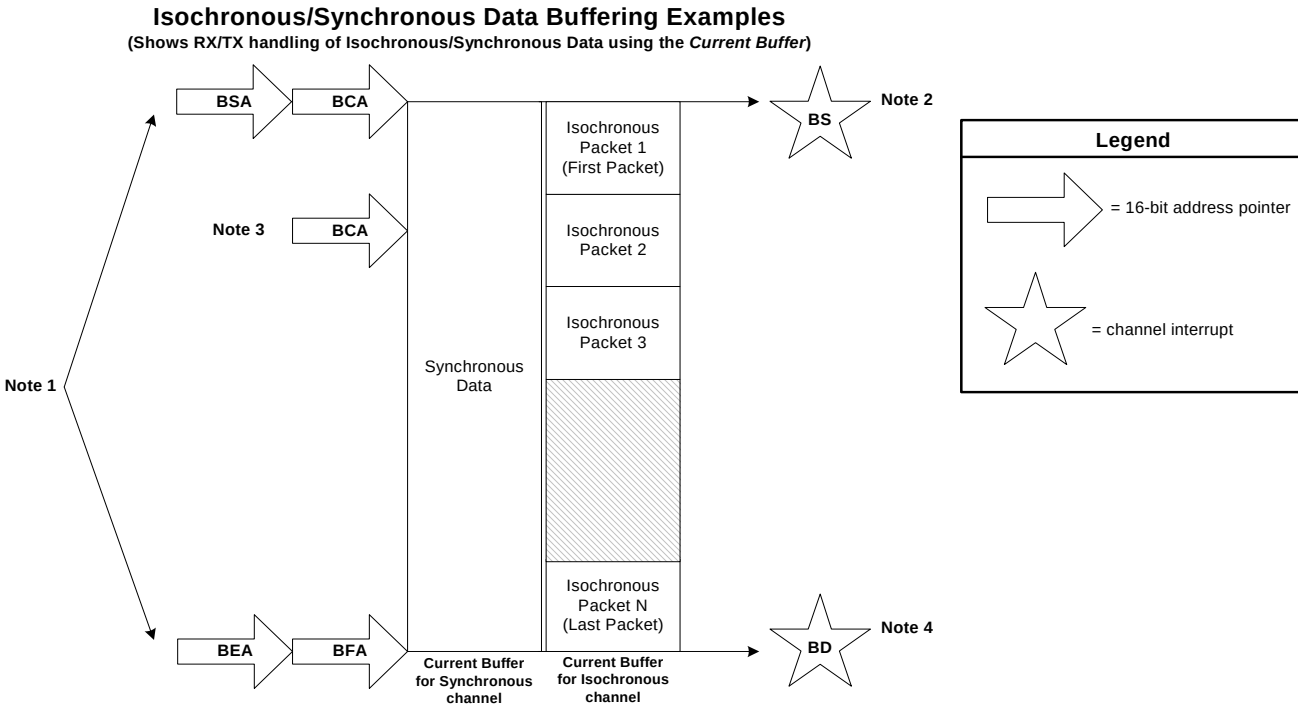

Figure 36-20. Isochronous/Synchronous Data Buffering Examples

For reception or transmission of isochronous data, single-packet and multi-packet buffering is handled in the same manner. Since isochronous channels have a fixed packet length (determined by CECRn.IPL), software should set the system memory buffer length as an even multiple of CECRn.IPL for multi-packet buffering and equal to CECRn.IPL for single-packet buffering. It is assumed that all isochronous packets in the system are of the same length, with the minimum supported length being 5 bytes.

For reception or transmission of synchronous data, the concept of multi-packet or single-packet buffering is not applicable since synchronous data has no packet format. As a result, CCBCRn.BFA will always indicate the end address of the Current Buffer for synchronous channels.

36.4.2.2 Circular Buffering

Logical channels can be programmed to operate in circular buffering mode by programming CECRn.MDS[1:0]=01. It is recommended that circular buffering be used with synchronous channels only (CECRn.CT[1:0]=00). Logical channels configured for transmitting or receiving other types of data (e.g. asynchronous, control, or isochronous) should not be in circular buffering mode.

In contrast to with ping-pong buffering mode, this mode effectively uses a single, circular system memory buffer to process channel data. Software must program the beginning and ending address of the circular buffer in the CNBCRn.BSA and CNBCRn.BEA fields. For proper operation, software must not change the addresses in CNBCRn.BSA and CNBCRn.BEA once buffer processing has started.

While processing the circular buffer, the CSCRn.RDY bit is not automatically cleared by hardware, as it is in ping-pong buffering mode. For circular buffer, the CSCRn.RDY bit can only be cleared by software through the IP Bus interface. Once CNBCRn.BSA and CNBCRn.BEA are initially loaded, software should set the CSCRn.RDY bit to initiate buffer processing. This bit may be cleared by software, as needed, to halt the buffer processing.

System design must ensure synchronous data is loaded into the circular buffer at the same rate at which it is unloaded.

An example of the circular buffering for synchronous channels is provided in Figure 36-21.

Synchronous Data Circular Buffering Example

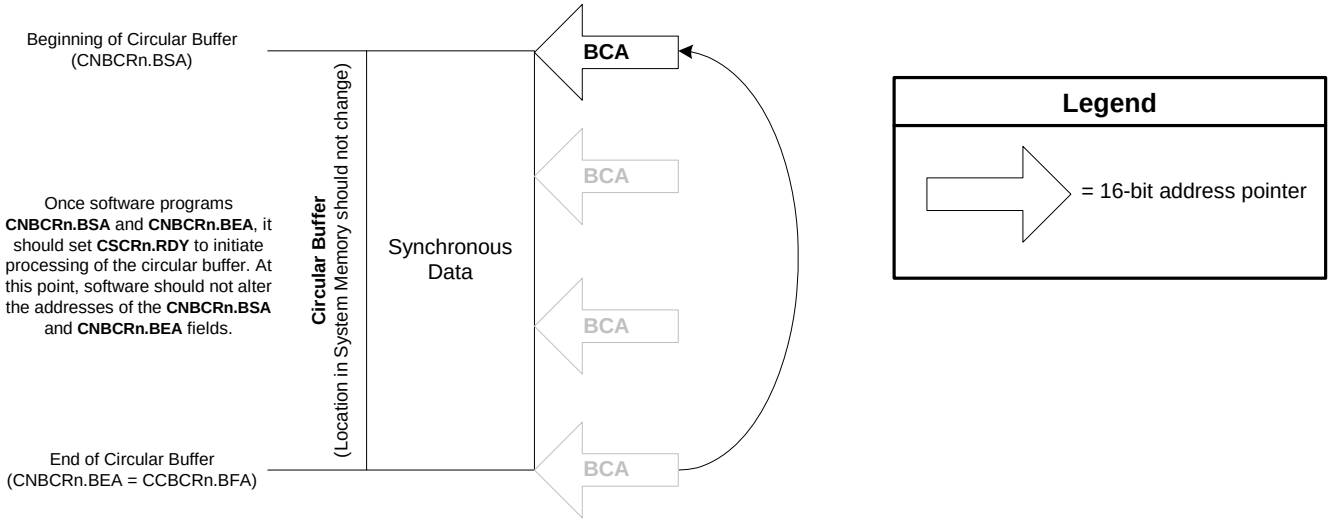

Figure 36-21. Circular Buffering of Synchronous Data

Synchronous data using circular buffering should be handled in the following manner:

- Before buffer processing can begin, software must define the beginning address (CNBCRn.BSA) and ending address of the circular buffer (CNBCRn.BEA). Once the circular buffer beginning and ending addresses are defined, software must set the CSCRn.RDY bit to initiate buffer processing.
- At the start of buffer processing, the beginning address of the circular buffer (CNBCRn.BSA) is loaded into CCBCRn.BCA. Additionally, the ending address of the circular buffer (CNBCRn.BEA) is loaded into CCBCRn.BFA.
- During the processing of the circular buffer, CCBCRn.BCA is updated to indicate which quadlet of the synchronous data is currently being processed.
- Once the end of the buffer is reached and CCBCRn.BCA = CCBCRn.BFA, the CCBCRn.BCA field is reloaded to point to the beginning address of the circular buffer (CNBCRn.BSA).
- The CSCRn.RDY bit remains set during the processing of the circular buffer. Software may clear this bit, as needed, to halt buffer processing.

36.4.3 Streaming Channel Frame Synchronization

Certain types of streaming applications will require data to be synchronous with the MediaLB frame, including: stereo, 5.1 audio, and Generic Synchronous Packet Format (GSPF) DTCP. The MediaLB Device Streaming Channel Frame Synchronization feature provides this option.

For example, 24-bit stereo channels require two MediaLB physical channels (PC) to transmit left (0xLLLLLn) and right (0xRRRRRn) speaker data. Assuming the MediaLB Controller allocates PC1 and PC2 to this stereo channel, the data would be synchronized to the MediaLB frame as shown in Table 36-21.

Frame	PC0	PC1	PC2	PC3	PC4	PC5	PC6	PC7
n=0		0xLLLLL0RR	0xRRR0xxxx					
n=1		0xLLLLL1RR	0xRRR1xxxx					
n=2		0xLLLLL2RR	0xRRR2xxxx					
n=3		0xLLLLL3RR	0xRRR3xxxx					

Table 36-21. Example of 24-bit Stereo Data Synchronous to 256 Fs MediaLB Frame

Without frame synchronization, the MediaLB Device may begin transmitting or receiving data that is not aligned with the MediaLB frame. Misalignment, as depicted in Table 36-22, may result in data corruption.

Frame	PC0	PC1	PC2	PC3	PC4	PC5	PC6	PC7
n=0			0xLLLLL0RR					
n=1		0xRRR0xxxx	0xLLLLL1RR					
n=2		0xRRR1xxxx	0xLLLLL2RR					
n=3		0xRRR2xxxx	0xLLLLL3RR					

Table 36-22. Example of 24-bit stereo data asynchronous to 256Fs MediaLB frame

The MediaLB Device supports Streaming Channel Frame Synchronization as a programmable option for each logical channel configured for synchronous dataflow. System software can enable the frame synchronization feature for a synchronous logical channel by setting CECRn.FSE. When enabled, the synchronous logical channel begins transmitting and receiving data only at a MediaLB frame boundary.

When the loss of MediaLB frame synchronization occurs, the MediaLB Device detects it and optionally notifies system software via a maskable channel interrupt. In order to use this option, system software is responsible for the following actions:

- Program CECRn.FSPC[4:0] with the expected number of physical channels per frame for the logical channel;
- Unmask the CSCRn.STS[6] bit by setting CECRn.MASK[6] to 0.

A channel interrupt is generated when the actual number of physical channels detected during a MediaLB frame does not match the expected value. An additional channel interrupt is generated if the local channel buffer overflows (for RX channels) or underflows (for TX channels).

Additionally, software may instruct the MediaLB Device to automatically disable a logical channel when MediaLB frame synchronization is lost. To enable this feature, software must set CSCRn.FSCD, which causes hardware to automatically clear the Channel Enable bit (CECRn.CE) when synchronization is lost.

Frame synchronization is not supported for asynchronous, control, or isochronous channels.

Chapter 37
Memory Stick Host Controller (MSHC)

37.1 Introduction

The memory stick host controller (MSHC) is placed in between the AIPS/AHB bus and the Sony Memory Stick/Pro to support data transfer between the chip and the Memory Stick/Pro.

The MSHC top level block diagram with input and output signals is shown in Figure 37-1.

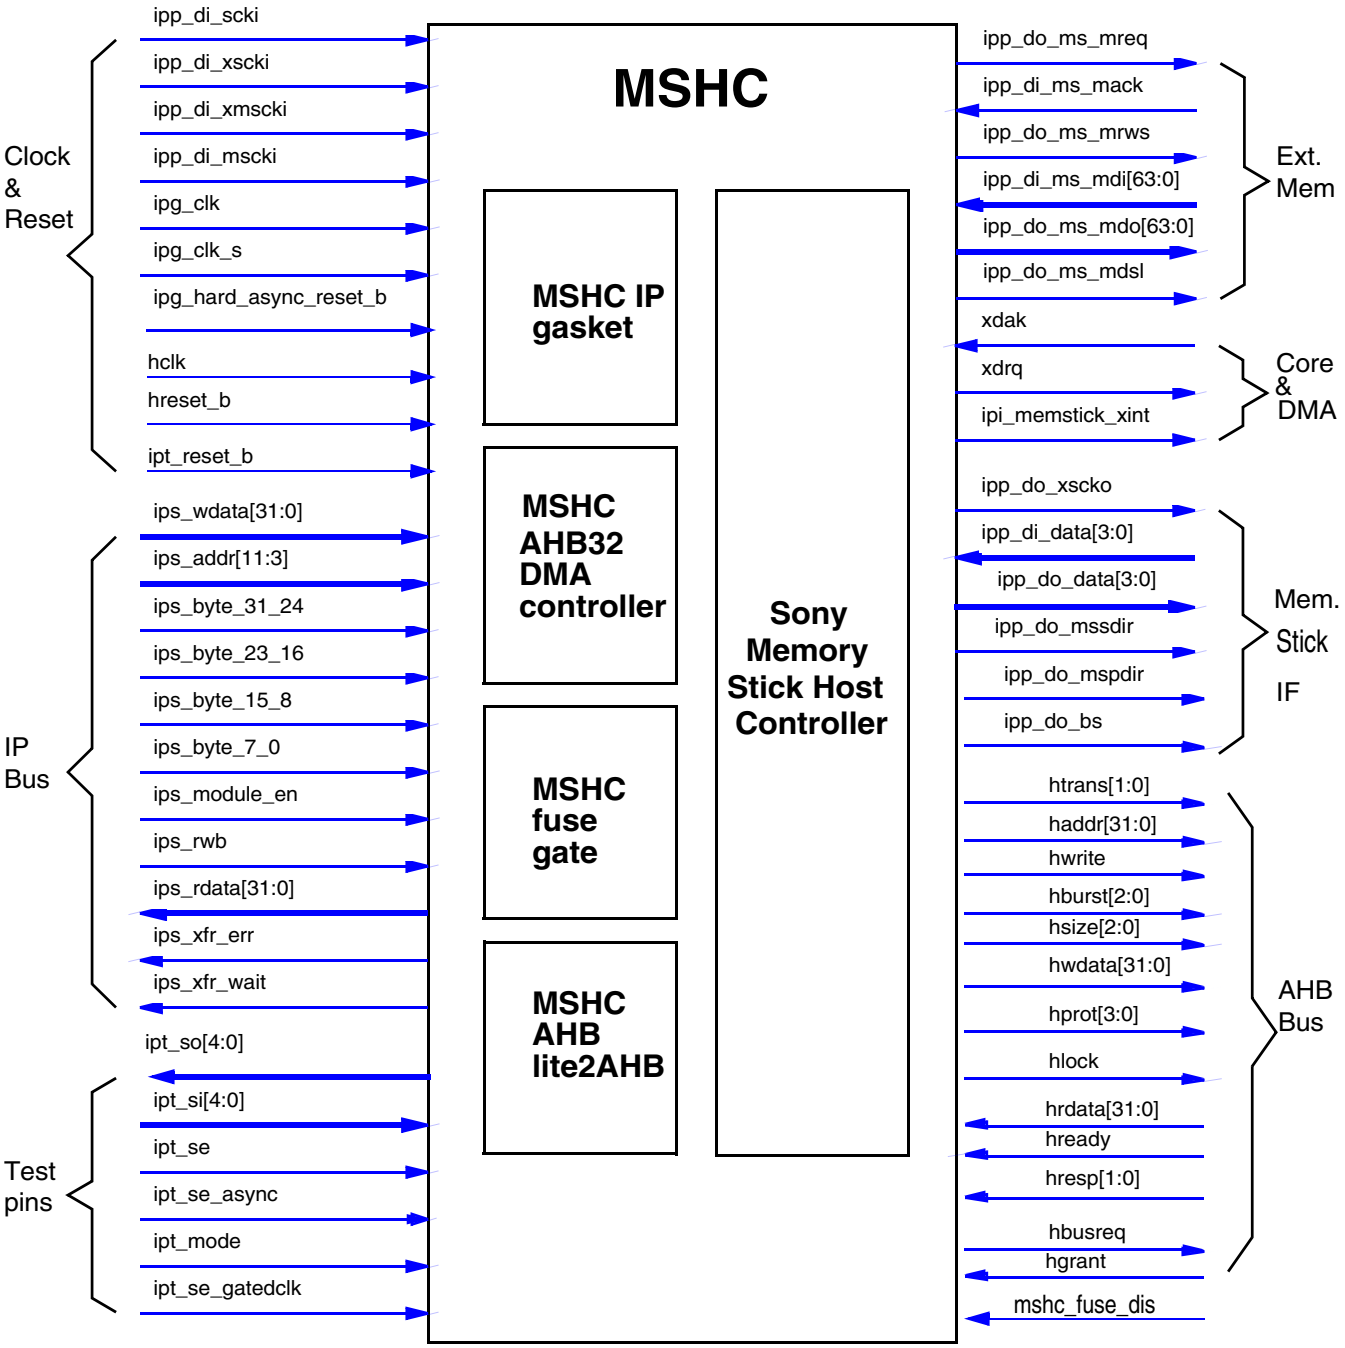

Figure 37-1. Memory Stick Host Controller Block Diagram

37.1.1 Overview

The memory stick host controller consists of five submodules: the MSHC IP gasket, the Sony memory stick host controller (SMSC), the MSHC fuse gate module, the MSHC embedded AHB DMA controller

and a gasket to connect AHB-lite bus to AHB. The SMSC module, which is the actual memory stick host controller, is compatible with Sony Memory Stick Ver 1.x and Memory Stick PRO. The IP gasket connects the AIPS IP bus to the SMSC interface to allow IP bustransfers. The fuse gate module is to disable the MSHC functions when the control fuse is blown. The MSHC embedded AHB DMA controller is for DMA transfers through AHB bus.

This document describes the MSHC IP gasket, fuse gating and embedded AHB DMA controller modules in detail.

37.1.2 Features

The MSHC includes the following features:

- A gasket between IP bus and SMSC
  - IP interface transfer functionality as slave
  - Interrupts for transfer errors, or wait timeout
  - Timeout function for abnormal transfer wait states
  - Fixed 32-bit data bus
  - Little-endian to IP data bus and big-endian to SMSC data bus
- SMSC to communicate to the Sony memory stick
  - Registers structured in 64-bit format
  - FIFO (4 x 64-bit)
  - Interrupt after Memory Stick/Pro communication completes
  - DMA in dual address mode
- An embedded DMA controller through AHB bus
  - DMA transfer through AHB interface as master
  - Fixed burst length as INCR8
  - Word alignment transfer size
- All functions controlled by fuse
- Test mode and DFT implementation

37.1.3 Modes of Operation

The MSHC has a reduced IP bus interface and supports the IP bus read/write by ARM or data transfer by DMA module in the chip.

The MSHC also has AHB interface and an embedded DMA controller. It allows the MSHC can transfer data by embedded DMA controller as a bus master through AHB bus. User can select one of above ways for data transfer by configure system register bit (EDMA_EN).

A transfer can be initiated by the chip DMA module or embedded DMA controller or the host in response to a MSHC DMA request. The MSHC is set to dual address mode for DMA transfers. In dual address

mode, when the MSHC requests a transfer with the DMA request, the chip DMA module or embedded DMA controller initiates a transfer to the MSHC.

37.2 External Signal Description

The MSHC IO ports are listed in Table 37-1.

Table 37-1. Signal Properties

Name	Function	I/O	Reset	Pull Up
MSHC_CLK	MSHC clock output to MS/Pro.	O	0	—
MSHC_BS	MSHC bus status.	O	0	—
MSHC_DATA0	MSHC data output to MS/Pro.	I/O	0	Pull Down
MSHC_DATA1	MSHC data output to MSPro (for parallel mode only).	I/O	0	Pull Down
MSHC_DATA2	MSHC data output to MSPro (for parallel mode only).	I/O	0	Pull Down
MSHC_DATA3	MSHC data output to MSPro (for parallel mode only).	I/O	0	Pull Down

37.2.1 Detailed Signal Descriptions

Detail signal descriptions are shown in Table 37-2.

Table 37-2. Detailed Signal Descriptions

Signal	I/O	Description
MSHC_CLK	O	This signal is the clock output to MS/Pro. This clock is gated when nothing transfering between MSHC and MS/Pro. The maximum frequency of this clock is 20MHz in serial mode and 40MHz in parallel mode.
MSHC_BS	O	This signal is the bus status output to MS/Pro. It can be used for both serial and parallel transfers with the MS/Pro.
MSHC_DATA0	I/O	This signal is the data transfer line[0] between MSHC and MS/Pro. It can be used for both serial and parallel mode.
MSHC_DATA1	I/O	This signal is the data transfer line[1] between MSHC and MSPro. It is for parallel mode only.
MSHC_DATA2	I/O	This signal is the data transfer line[2] between MSHC and MSPro. It is for parallel mode only.
MSHC_DATA3	I/O	This signal is the data transfer line[3] between MSHC and MSPro. It is for parallel mode only.

37.3 Memory Map and Register Definition

37.3.1 Memory Map

Table 37-3 shows the memory map for the MSHC module.

37.3.2 Register Summary

Table 37-3. MSHC Memory Map

Address	Register	Access	Reset Value	Section/Page
General Registers				
0x0000 (CMDR)	Command register	R/W	0x0000_0000	37.3.3.1/37-7
0x0008 (DATR)	Data register	R/W	0x004C_004C	37.3.3.2/37-8
0x0010 (STAR)	Status register	R/W	0x0000_2010	37.3.3.3/37-9
0x0018 (SYSR)	System register	R/W	0x0000_5544	37.3.3.4/37-12
0x0020 (DSAR)	Embedded DMA start address register	R/W	0x0000_0000	37.3.3.5/37-14

Figure 37-2 and Table 37-4 serve as a key for the register summary and register conventions.

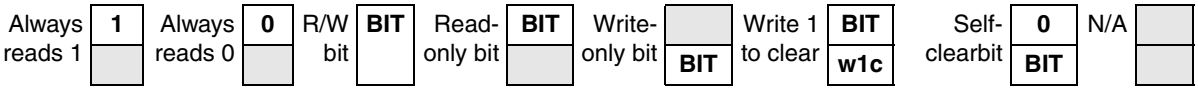

Figure 37-2. Key to Register Fields

Table 37-4. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.

Table 37-4. Register Conventions (Continued)

Convention	Description
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 37-5 shows the format for a register summary table.

37.3.3 Register Descriptions

This section provides detailed register descriptions of MSHC registers.

37.3.3.1 MSHC Command Register (CMDR)

The command register contains the transfer protocol command (TPC), transfer data size and bus time-out value. It must be set before starting a transfer.

Figure 37-3 shows the command register. Table 37-6 shows the register's field descriptions.

Offset 0x0000 (CMDR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 37-3. MSHC Command Register Diagram

Table 37-6. MSHC Command Register Field Descriptions

Field	Description
31-24	Reserved, should be cleared.
23-16 TOVW [7:0]	Time out value for wait. This is a decrement time-out counter if long wait states are encountered. Once the MSHC FIFO becomes full/empty while the bus has more data to be written/read, it asserts the wait state on bus until the FIFO is available. When the counter reaches zero, the wait state of bus is deasserted and an interrupt is generated. When the TOVW[7:0] is set to zero, it does not produce wait states if the FIFO is full or empty, but generates an interrupt. If the interrupt enable bits (INTEN_WFUL and INTEN_REMP in the system register) are disabled, the timeout counter is set to infinity. Once the wait state is entered, it stays in wait until either the bus timeout or the FIFO becomes available for transfer. 00000000 0 wait state is asserted on IP bus. 00000001 1 wait state is asserted on IP bus. ..... 11111111 255 wait states is asserted on IP bus.
15-8 DSZ [7:0] 1-0 DSZ [9:8]	Data Size. The DSZ[7:0] together with DSZ[9:8] designate the transmit/receive data length (total 10 bits). The length can be set from 1 byte to 1024 bytes (1024 bytes corresponds to DSZ = 0). DSZ[9:0]: 0000000000 Data length is 1024 bytes. 0000000001 Data length is 1 byte. 0000000010 Data length is 2 bytes. ..... 1111111111 Data length is 1023 bytes.

Table 37-6. MSHC Command Register Field Descriptions (Continued)

Field	Description
7-4 TPC [3:0]	Transfer protocol code. This designates the TPC (4 bits). 0010 Encoding 2. READ_LONG_DATA -Transfer from MS/Pro data buffer(512 bytes). 0011 Encoding 3. READ_SHORT_DATA -Transfer from MS/Pro data buffer(32~256 bytes). 0100 Encoding 4. READ_REG - Read MS/Pro register. 0111 Encoding 7. GET_INT - Read MS/Pro INT register. 1000 Encoding 8. SET_RW_REG_ADRS - MS/Pro address setting of READ_REG or WRITE_REG. 1001 Encoding 9. EX_SET_CMD - Set MS/Pro CMD and access area. 1011 Encoding B. WRITE_REG - Write to MS/Pro register. 1100 Encoding C. WRITE_SHORT_DATA - Transfer to MS/Pro data buffer(32~256 bytes). 1101 Encoding D. WRITE_LONG_DATA - Transfer to MS/Pro data buffer(512 bytes). 1110 Encoding E. SET_CMD - Set MS/Pro CMD. all others reserved.
3	Reserved, should be cleared.
2 DSL	Data Select. This designates the data to be communicated with the Memory Stick/Pro. 0 Data is transmitted to and received from the Memory Stick/Pro using the internal FIFO. 1 Data is transmitted to and received from the Memory Stick/Pro using an external memory. (Not supported)

37.3.3.2 MSHC Data Register (DATR)

The data register is used to access the 4 x 64-bit internal FIFO. It takes eight 32-bit transfers to fill or empty the FIFO.

Figure 37-4 shows the data register diagram. Table 37-7 shows the register's field descriptions.

Offset 0x0008 (DATR) Access: User read/write

Table 37-7. MSHC Data Register Field Descriptions

Field	Description
31-24 DATA [7:0] 23-16 DATA [15:8] 15-8 DATA [23:16] 7-0 DATA [31:24]	FIFO Data Buffer. DATA[31:0] This register is used to access the internal FIFO. The minimum read or write FIFO access unit is 8 bytes (even when the data is less than 8 bytes). The data is transmitted to and received from the Memory Stick/Pro with MSB first. When the data is less than 8 bytes, the lower bytes are invalid data. During communication with the Memory Stick/Pro, before accessing FIFO the user should check that the status register bit DRQ=1.

37.3.3.3 MSHC Status Register (STAR)

The status register reflects MSHC status, such as FIFO status, ready flag for transfers, CRC error flag and so on. The host needs to read this register in order to start and manage the transfer.

Figure 37-5 shows the status register diagram.Table 37-8 shows the register's field descriptions.

Offset 0x0010 (STAR) Access: User read/write

Figure 37-5. MSHC Status Register Diagram

Table 37-8. MSHC Status Register Field Descriptions

Field	Description
31-24	Reserved, should be cleared.
23 IDA	Illegal Data Access. This bit is asserted if a transfer is not 32-bit. It is always readable and can be cleared (if the interrupt enable bit INTEN_IDA in the system register is enabled) by writing 1 to this bit. Any illegal data access always asserts IDA, but does not generate an interrupt if the interrupt enable bit INTEN_IDA in the system register is disabled. 0 legal data access (32-bit). 1 Illegal data access.

Table 37-8. MSHC Status Register Field Descriptions (Continued)

Field	Description
22 IXFR	Illegal Transfer. This bit is asserted if a data transfer direction is not consistent with the FIFO data direction (FDIR in the system register). It is always readable and can be cleared (if the interrupt enable bit INTEN_IXFR in the system register is enabled) by writing 1 to this bit. Any illegal data transfer always asserts IXFR, but does not generate an interrupt if the interrupt enable bit INTEN_IXFR in the system register is disabled. 0 legal Transfer. 1 Illegal Transfer.
21-20	Reserved, should be cleared.
19 WFUL	Write to FIFO when Full. This bit is asserted if the FIFO is full and the current write transfer is not finished. It is always readable and can be cleared (if the interrupt enable bit INTEN_WFUL in the system register is set) by writing 1 to this bit. The set time of this bit is different depending on whether INTEN_WFUL is enabled and the value of TOVW[7:0]. If INTEN_WFUL is disabled, WFUL is set without the timeout delay when writing to a full FIFO. This bit also be used to generate bus wait state as well as the interrupt. 0 No data write transfer while the FIFO is full. 1 A data write transfer is attempted while the FIFO is full.
18 REMP	Read from FIFO when Empty. This bit is asserted if the FIFO is empty and the current read transfer is not finished. It is always readable and can be cleared (if the interrupt enable bit INTEN_REMP in the system register is set) by writing 1 to this bit. The version number read after a reset also asserts REMP as the FIFO is empty at this time. The set time of this bit is different depending on whether INTEN_REMP is enabled and the value of TOVW[7:0]. If INTEN_REMP is disabled REMP is set without the timeout delay when reading from an empty FIFO. This bit also be used to generate bus wait state as well as the interrupt. 0 No data read transfer while the FIFO is empty. 1 A data read transfer is attempted while the FIFO is empty.
17 HRESP_ ERR	Hresp Error. This bit is set when there is a hresp error (hresp=01) during data transfer on AHB bus. It can be cleared by writing 1 to this bit. 0 There is no hresp error. 1 There is an hresp error.
16–4	Reserved, should be cleared.
13 EMP	FIFO Empty. This bit is set when FIFO is empty. This is cleared to 1 by writing system register bit FCLR = 1. 0 FIFO contains data. 1 FIFO is empty.
12 FUL	FIFO Full. This bit is set when FIFO is full. This is cleared to 0 by writing system register bit FCLR = 1. 0 FIFO has empty space. 1 FIFO is full.
11 CED	MSPro Command End. In parallel interface mode, this bit is reflected by the CED bit in the status register of MSPro card at the same time as MSINT. In serial interface mode, this is always 0. This bit is cleared to 0 by writing to the command register. 0 Command not end. 1 Command end.
10 ERR	MSPro Error. In parallel interface mode, this bit is reflected by the ERR bit in the status register of MSPro card at the same time as MSINT. In serial interface mode this is always 0. This is cleared to 0 by writing to the command register. 0 No error. 1 MSPro error.

Table 37-8. MSHC Status Register Field Descriptions (Continued)

Field	Description
9 BRQ	MSPro Data Buffer Request. In parallel interface mode, this bit is reflected by the BREQ bit in the status register of MSPro card at the same time as MSINT. In serial interface mode this is always 0. This is cleared to 0 by writing to the command register. 0 No request. 1 Data buffer request.
8 CNK	MSPro Command No Acknowledge. In parallel interface mode, this bit is reflected by the CMDNK bit in the status register of MSPro card at the same time as MSINT. In serial interface mode this is always 0. This is cleared to 0 by writing to the command register. 0 Command has acknowledge. 1 Command has not acknowledge.
7	Reserved, should be cleared
6 DRQ	DMA Request. This bit indicates the DMA request. 0 No DMA request. 1 There is a DMA request.
5 MSINT	MS/Pro I/F Interrupt This bit is set when an interrupt request is received from the Memory Stick/Pro card. When an interrupt request is generated by another interrupt factor, the system register bit INTCLR can be set to 1 to clear the interrupt and then the MSINT interrupt is generated. In parallel interface mode, the contents of the interrupt from the Memory Stick/Pro card are reflected to CED, ERR, BRQ and CNK. This is cleared to 0 by writing to the command register. 0 Interrupt request not received from the Memory Stick/Pro. 1 Interrupt request received from the Memory Stick/Pro.
4 RDY	Ready This bit is set when the protocol ends. If some error occurs during protocol execution, the error state is reflected to the CRC and TOE bits at the same time that RDY goes to 1. This is cleared to 0 by writing to the command register. 0 Command receive disabled due to communication with the Memory Stick/Pro. 1 Command receive enabled or protocol ended.
3-2	Reserved, should be cleared.
1 CRC	CRC Error. When a CRC error occurs, CRC goes to 1 when the protocol ends. This is cleared to 0 by writing to the command register. 0 No Error. 1 A CRC error occurred during data receive.
0 TOE	Time Out Error When the busy state is returned continuously from the Memory Stick/Pro for a number of times exceeding the number of clocks set by BSY, the protocol is ended as a Memory Stick/Pro side operation error, and TOE goes to 1. This is cleared to 0 by write to the command register. 0 No Error. 1 A RDY time out error occurred in the handshake state during communication with the MS/Pro.

37.3.3.4 MSHC System Register (SYSR)

The system register has user commands and options that are required for transfer and communication with the MS/Pro. This register must be set before starting a transfer and should not be changed during the communication with the MS/Pro.

Figure 37-6 shows the system register diagram. Table 37-9 shows the register's field descriptions.

Offset 0x0018 (SYSR) Access: User read/write

Figure 37-6. MSHC System Register Diagram

Table 37-9. MSHC System Register Field Descriptions

Field	Description
31-24	Reserved, should be cleared.
23 INTEN_IDA	Illegal Data Access Interrupt Enable. 0 Disable the interrupt for an illegal data access. 1 Enable the interrupt for an illegal data access.
22 INTEN_IXFR	Illegal Transfer Interrupt Enable. 0 Disable the interrupt for an illegal data transfer. 1 Enable the interrupt for an illegal data transfer.
21-20	Reserved, should be cleared.
19 INTEN_WFUL	Interrupt Enable for a write transfer to FIFO with full. If it is set to one it enables the interrupt and the wait state timeout function. 0 Disable the interrupt. 1 Enable the interrupt.
18 INTEN_REMP	Interrupt Enable for a read transfer from FIFO with empty. If it is set to one it enables the interrupt and the wait state timeout function. 0 Disable the interrupt. 1 Enable the interrupt.
17 INTEN_HRESP_ERR	Interrupt Enable for hresponse error. If it is set to one it will enable the interrupt. 0 Disable the interrupt. 1 Enable the interrupt.
16 EDMA_EN	Embedded DMA Enable. This bit should be set if data need to be transferred through AHB bus by the embedded DMA controller. This bit should be cleared if data need to be transferred through IP bus by DMA module. 0 Disable the embedded DMA controller. 1 Enable the embedded DMA controller.

Table 37-9. MSHC System Register Field Descriptions (Continued)

Field	Description
15 DAM	DMA Access Mode. This bit indicates the DMA access mode. In single address mode, the FIFO is accessed using XDAK. In dual address mode, the FIFO is accessed using ADRS and XRD/XWR. The MSHC is fixed to use dual address mode. 0 Sets DMA access to dual address mode. 1 Sets DMA access to single address mode. (Not supported)
14 DRM	DMA Request Mode. This bit indicates the DMA request mode. In edge mode, XDRQ is deasserted after FIFO is accessed. For a continuous request, XDRQ is asserted again after two cycles. In level mode, XDRQ is not deasserted, and remains asserted. 0 Sets the DMA data request to level mode. 1 Sets the DMA data request to edge mode.
13 DRQSL	DRQ Select. When DRQSL = 1, an interrupt is generated when a data request occurs. When DRQSL = 0, an interrupt is not generated when a data request occurs. However, the DRQ bit of the status register changes regardless of the DRQSL setting. 0 Interrupt disabled. 1 Interrupt enabled.
12 REI	Rise Edge Input. This bit indicates the latch edge for the input data from MS/Pro. This setting cannot be changed during protocol execution. When setting the parallel interface mode, set REI = 0. 0 Input data is latched at the falling edge of MSHC_CLK. 1 Input data is latched at the rising edge of MSHC_CLK.
11 REO	Rise Edge Output. This bit indicates the synchronized edge of output data to MS/Pro. This setting cannot be changed during protocol execution. This bit is used when not fixed hold time by the side of the Memory Stick/Pro in parallel communication. 0 Output data to MS/Pro are synchronized with the falling edge of MSHC_CLK. 1 Output data to MS/Pro are synchronized with the rising edge of MSHC_CLK.
10-8 BSY [2:0]	Busy Count. This sets the RDY timeout time for the Memory Stick/Pro. The BSY wait time until the RDY signal is output from the Memory Stick/Pro is set to the BSY setting value x4 MSHC_CLK. However, timeout detection is not performed when BSY = 0. When performing wake-up for Memory Stick Ver. 1.x, the RDY signal from the Memory Stick is extended compared to normal operation, so set BSY = 0 and start the protocol. This setting cannot be changed during protocol execution. 000 0. (Disable timeout function for RDY.) 001 1. 010 2. 011 3. 100 4. 101 5. 110 6. 111 7.
7 RST	Sync Reset. When RST = 1 is written, internal sync reset (initialization of the internal registers and operating sequence) is performed. RST is cleared to 0 after the internal reset is completed. 0 No sync reset. 1 Assert the sync reset.
6 SRAC	Serial Access Mode. This bit indicates the transfer mode. 0 Parallel interface mode. 1 Serial interface mode.

Table 37-9. MSHC System Register Field Descriptions (Continued)

Field	Description
5 INTEN	Interrupt Enable. Interrupt request output is enabled by setting INTEN = 1. 0 Interrupt request output disabled. 1 Interrupt request output enabled.
4 NOCRC	No CRC. When NOCRC = 1, the write protocol is executed without adding the CRC data (16 bits) to the end of the transmit data. During the read protocol, the CRC check is performed like normal regardless of the NOCRC value. Normally set to 0. 0 CRC output on. 1 CRC output off.
3 INTCLR	INT Clear. Interrupt is deasserted by setting INTCLR=1. INTCLR is cleared to 0 after interrupt is deasserted. 0 Do not clear interrupt. 1 Clear interrupt.
2 MSIEN	MS/Pro Interrupt Enable. Interrupt request received from the Memory Stick/Pro is enabled by setting MSIEN = 1. When MSIEN is set to 0, the status register bit MSINT does not change and the interrupt request is not output. 0 Interrupt request received from Memory Stick is disabled. 1 Interrupt request received from Memory Stick is enabled.
1 FCLR	FIFO Clear. The FIFO data is initialized by setting FCLR = 1. FCLR is cleared to 0 after the FIFO is initialized. 0 Do not clear FIFO. 1 Clear FIFO.
0 FDIR	FIFO Direction. This bit indicates the direction of data transfer. The TPC[3] value is reflected when the protocol starts. 0 Sets the FIFO direction to receive (ARM <- FIFO <- MS/Pro). 1 Sets the FIFO direction to transmit (ARM -> FIFO -> MS/Pro).

37.3.3.5 MSHC Embedded DMA Start Address Register (DSAR)

This register is used to indicate the start address for DMA transfer by the embedded DMA controller through AHB bus. This register is not used when using DMA module in chip to transfer data through IP bus.

Figure 37-7 shows the data register diagram.Table 37-10 shows the register's field descriptions.

Offset 0x0020 (DSAR) Access: User read/write

Figure 37-7. MSHC Embedded DMA Start Address Register Diagram

Table 37-10. MSHC Embedded DMA Start Address Register Field Descriptions

Field	Description
31-2 EDMA_ START_ ADRS	Embedded DMA Start Address. In transfer mode (from system memory to MSHC FIFO), this register contains the source address where the embedded DMA controller gets the data to transmit to MS/Pro. In receive mode (from MSHC FIFO to system memory), this register contains the destination address where stores the data read from the MS/Pro card.
1-0	Reserved. The DMA start address should be word alignment. So the EDMA_START_ADRS[1:0] is ignored while writing and always get zero while reading.

37.4 Functional Description

37.4.1 Reset

The MSHC uses one asynchronous reset and one synchronous reset to reset internal registers.

The asynchronous reset is the IP bus hardware asynchronous reset that is active low while the synchronous reset is a soft reset from the MSHC system register RST bit that is active high. Once the soft reset is asserted, it automatically clears the RST bit in the system register after initializing all internal registers. During the soft reset period the behavior of any IP Bus transactions is undefined.

37.4.2 Clocks

MSHC has several clocks, as shown in Figure 37-8. MSHC Clock Structure."

All the input clocks are connected to sub-modules through gating logic and muxing logic. The MSHC also has one inverted clock output.

In normal operation, XSCKI is an inverted version of SCKI and MSCKI is an inverted version of XMSCKI.

HCKI in the SMSC is the main clock for most of the internal registers and the FIFO. The MS/Pro has a slower clock speed and is asynchronous to HCKI, so XSCKO is generated by the SMSC and is output to provide the MS/Pro clock.

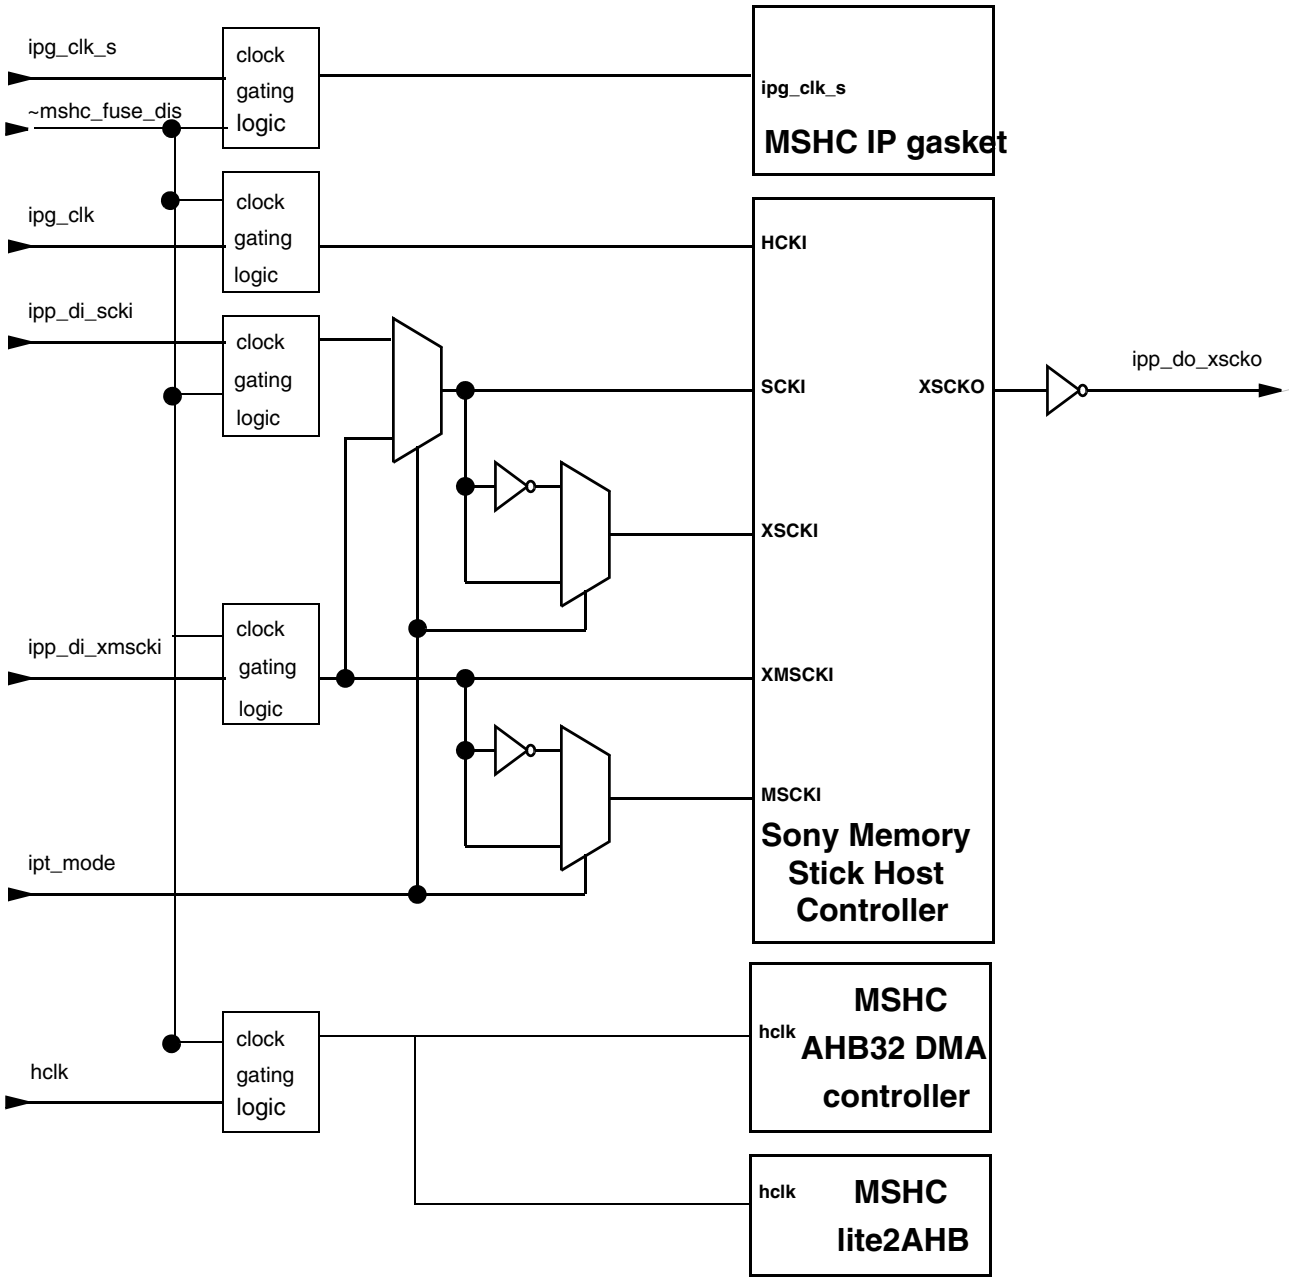

Figure 37-8. MSHC Clock Structure

37.4.3 Interrupts

When the system register bit INTEN = 1, interrupt request output is enabled.

Interrupt Factors:

- End of communication with the Memory Stick/Pro. An interrupt request is generated when status register bit RDY changes from 0 to 1.

- Data transfer request. An interrupt request is generated when status register bit DRQ changes from 0 to 1 while the system register bit DRQSL = 1.
- INT received from the Memory Stick/Pro. An interrupt request is generated when status register bit MSINT changes from 0 to 1 while the system register bit MSIEN = 1. However, when an interrupt request is generated by an interrupt factor other than MSINT, the interrupt request received from the Memory Stick is cued, the other interrupt is cleared, then the interrupt request is generated from the Memory Stick/Pro.
- Illegal data access. An interrupt is generated when status register bit IDA changes from 0 to 1 while the system register bit INTEN_IDA = 1.
- Illegal transfer. An interrupt is generated when status register bit IXFR changes from 0 to 1 while the system register bit INTEN_IXFR = 1.
- Write to FIFO when full. An interrupt is generated when status register bit WFUL changes from 0 to 1 while the system register bit INTEN_WFUL = 1.
- Read from FIFO when empty. An interrupt is generated when status register bit REMP changes from 0 to 1 while the system register bit INTEN_REMP = 1.
- Hresp Error. An interrupt is generated when status register bit HRESP_ERR is 1 while the system register bit INTEN_HRESP_ERR = 1.

Interrupt Clear:

The first three interrupt requests can be cleared by setting the system register bit INTCLR = 1. However, when an interrupt request is generated by a data transfer request (DRQ) while the system register bit DRQSL is set to 1, the interrupt request can also be cleared by writing or reading the FIFO.

The other four interrupt requests (IDA, IXFR, WFULL, REMP) can be cleared by writing 1 to the individual status bit when the corresponding interrupt enable bit is set in the system register.

37.4.4 SMSC (Sony Memory Stick Controller)

The SMSC module, which is the actual memory stick host controller, is compatible with Sony Memory Stick Ver 1.x and Memory Stick PRO. All details regarding the SMSC module can be found separately in ‘Memory Stick/Memory Stick PRO Host Controller IP Specification 1.3’.

37.4.5 IP Gasket

The IP gasket connects the AIPS IP bus to the SMSC interface to allow IP bus transfers.

37.4.5.1 IP bus transfer

The IP bus may perform a single data transfer or multiple data transfers (back-to-back transfers). The SMSC requires the write enable or the read enable low for one clock cycle.

37.4.5.1.1 Basic Read/Write Transfer

Figure 37-9 shows the basic timing for IP bus and the SMSC interface.

These first two write or read transfers have no wait state and take only one clock cycle for each transfer. The gasket generates no wait states prior to a transfer involved with command register access, status register access, system register access or embedded DMA start address register access.

There are two further transfer timings in cycles 8-9 (write transfer) and in cycles 11-12 (read transfer). In these cases the gasket request one more cycle prior to each transfer, and so it takes two cycles to complete the transfer. A two cycle transfer is used for data register access.

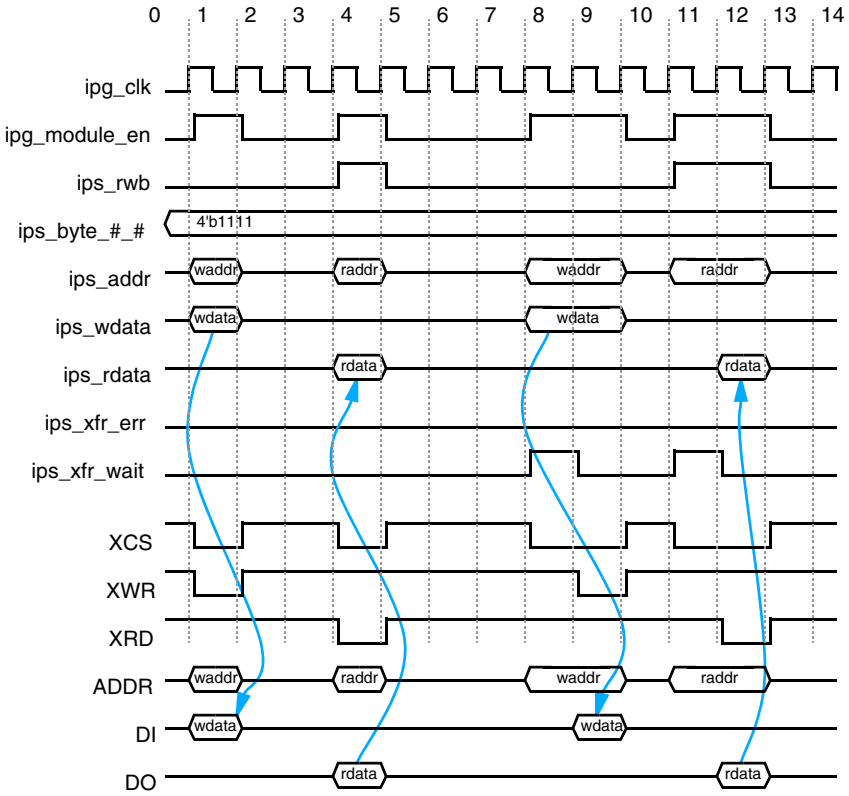

Figure 37-9. Basic IP Bus Read/Write Timing Diagram

37.4.5.1.2 Back-to-Back Transfer

The Figure 37-10 shows the back-to-back timing for IP bus and the SMSC interface.

In the timing diagram there are three write transfers (cycles 1–6) and two read transfers (cycles 8–11).

The IP bus sends back-to-back transfers and the gasket inserts one cycle wait states for each data transfer. This allows the SMSC read/write signal to be asserted for one clock cycle.

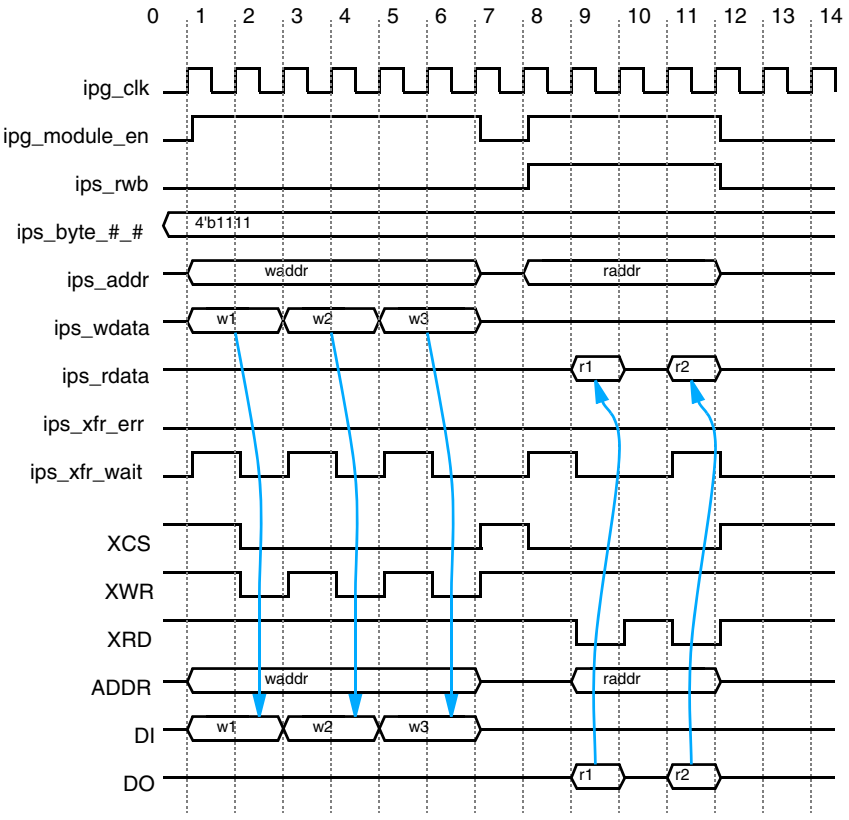

Figure 37-10. Back-to-Back IP Bus Write/Read Timing Diagram

37.4.5.2 Transfer Error

When the gasket detects a transfer error, it generates an interrupt. The transfer error interrupt is an optional feature that can be enabled in system register.

Two transfer error conditions are:

- Illegal data access
- Illegal transfer

The data access error indicates that the transfer is not 32-bit. The gasket checks all four byte enable signals and if any one of these becomes zero during a transfer the gasket sets the interrupt status bit (IDA) and generates the interrupt.

The illegal transfer error shows whether the data transfer direction is correct. The system register includes the FIFO data direction bit (FDIR) that must be set before the transfer is started. If this bit is set to one, the data direction is to MSHC. Then the next IP bus transfer must be a write. If the data direction and data transfer direction are not consistent, the gasket updates the interrupt status bit, IXFR, to one and generates the interrupt. Note that this error condition is applied only to transfers to the data register.

37.4.5.3 Transfer Wait condition

In normal transfers, a wait state may be inserted for one clock cycle for each 32-bit transfer, because of the read/write timing requirements for the SMSC.

If the transfer initiator ensures a maximum transfer burst to fill the SMSC FIFO, there are no multiple wait cycles. If it performs a large transfer burst to the MSHC, the SMSC FIFO is full due to the slow transfer speed between the SMSC and the MS/Pro. In this case, the gasket inserts wait states until the FIFO is available for further transfers, that is, one space in the FIFO is available. At this time the gasket ends the wait state and resume the next transfer. The behavior is similar for read transfers when the FIFO is empty.

There are two conditions for multiple cycles of wait states:

- Write transfers with the SMSC FIFO full
- Read transfers with the SMSC FIFO empty

Exceptional operations can also cause a long wait state. For instance, if one 32-bit data write transfer is performed with the SMSC FIFO empty, the empty flag remains set. Thus, if the following transfer is a read operation it is not processed due to the asserted state of the FIFO empty flag. Therefore the gasket stays in a wait state as long as the read transfer request remains pending on the IP bus. A minimum of two 32-bit write transfers are required to deassert the empty flag. The transfer initiator must make sure that a minimum of two write transfers are made in order to read back the data written to the FIFO.

Another unexpected long wait state may happen if the communication between the MSHC and the MS/Pro is abnormally terminated. To prevent this behavior, the gasket provides a wait timeout function, with which a timeout value can be used to disable the wait state and generate an interrupt if the transfer wait state goes for too long. This option is available when the interrupt enable bits, INTEN_WFUL and INTEN_REMP, are enabled.

The timeout counter has no functionality if the INTEN_WFUL and INTEN_REMP interrupts are disabled. In this case the transfer initiator is responsible for disabling the module to end a long wait state.

37.4.6 Fuse Gate Module

The fuse gate module disables the MSHC functions when the control fuse is blown. If the fuse is blown, all clocks to MSHC are disabled. Once the fuse is blown, MSHC can never work again.

37.4.7 Embedded AHB DMA Controller

The MSHC embedded AHB DMA controller is for DMA transfers through AHB bus.

To reduce the loading of IP bus and DMA module in chip, an embedded DMA controller is included in MSHC. This embedded DMA controller acts as a master on 32-bit AHB bus when data is transferring.

To use this embedded DMA controller, besides the common configurations for gasket and SMSC, user need to set EDMA_EN bit in the system register to enable this embedded DMA controller and provides source/destination address to EDMA_START_ADRS in embedded DMA start address register.

When EDMA_EN is set, the DMA request is sent to the embedded DMA controller and data is transferred through AHB bus. Meanwhile, the DRM bit in the system register should be cleared to set DMA request to level mode. When the embedded DMA controller is reading/writing FIFO, the SMSC data register can not be accessed through IP bus (write option has no effect and return zero for read option).

When EDMA_EN is cleared, the DMA request is sent to the chip DMA module and data is transferred through IP bus. The DRM bit in SMSC system register should be set.

EDMA_START_ADRS is the DMA transfer address for system memory. In transfer mode (data from system memory to MSHC FIFO), this register sets the source address where the embedded DMA controller gets the data. In receive mode (data from MSHC FIFO to system memory), this register sets the destination address to store the data read from the Memory Stick/Pro card.

The embedded AHB DMA controller only issues INCR8 fixed burst length transfer (8 words). For transfer sizes which are not integer multiples of 8 words, the last round of transfer are the real transfer sizes. For example, if the transfer size is 10 words, the embedded DMA controller issues two bursts: the first one is INCR8 (8 words) and the second one is INCR with real burst length (2 words).

37.4.8 Communication with the Memory Stick (Serial Mode)

An example of communication with the Memory Stick is shown below.

This example shows the case when TPC SET_CMD transmit is executed.

1. Set system register bit FDIR to set the FIFO direction.
2. Write the command data to the FIFO.
3. Write the TPC and the data transfer size to the command register and start the protocol.
4. The ARM waits for the protocol end interrupt. After the protocol ends, an interrupt is output from the host controller. The ARM receives this interrupt, then sets system register bit INTCLR to clear the interrupt.
5. Read the status register to confirm that communication with the Memory Stick ended normally.
6. The ARM waits for the INT interrupt from the Memory Stick. After INT generation from the Memory Stick, an interrupt is output from the host controller. The ARM receives this interrupt, then sets system register bit INTCLR to clear the interrupt.
7. Read the status register to confirm INT generation from the Memory Stick.

37.4.9 Parallel Mode Setting Procedure

1. Identify the Memory Stick media and confirm that it is a Memory Stick PRO. For Memory Stick media identification, see *Memory Stick Standard Format Specifications,* ver.1.x, Appendix D; or *Memory Stick Standard Format Specifications,* ver.2.0, Application Notes 1.3, Media Identification Process.
2. Set the Memory Stick Pro card to parallel mode by TPC (clear SRAC bit in system parameter register of Memory Stick Pro card).
3. Write SRAC = 0 and REI = 0 to the system register of MSHC.

Note that communication with the Memory Stick is not possible if the host controller is set to parallel interface mode first.

Chapter 38
ARM1136 Platform

38.1 Introduction to the ARM1136 Platform

The ARM1136 platform satisfies the CPU complex requirements for single core modems and application processors. This chapter includes the following:

- An overview of the modules within the platform
- The bus interfaces provided
- A brief functional description of each module within the platform

Figure 38-1 shows a block diagram of the ARM1136 platform.

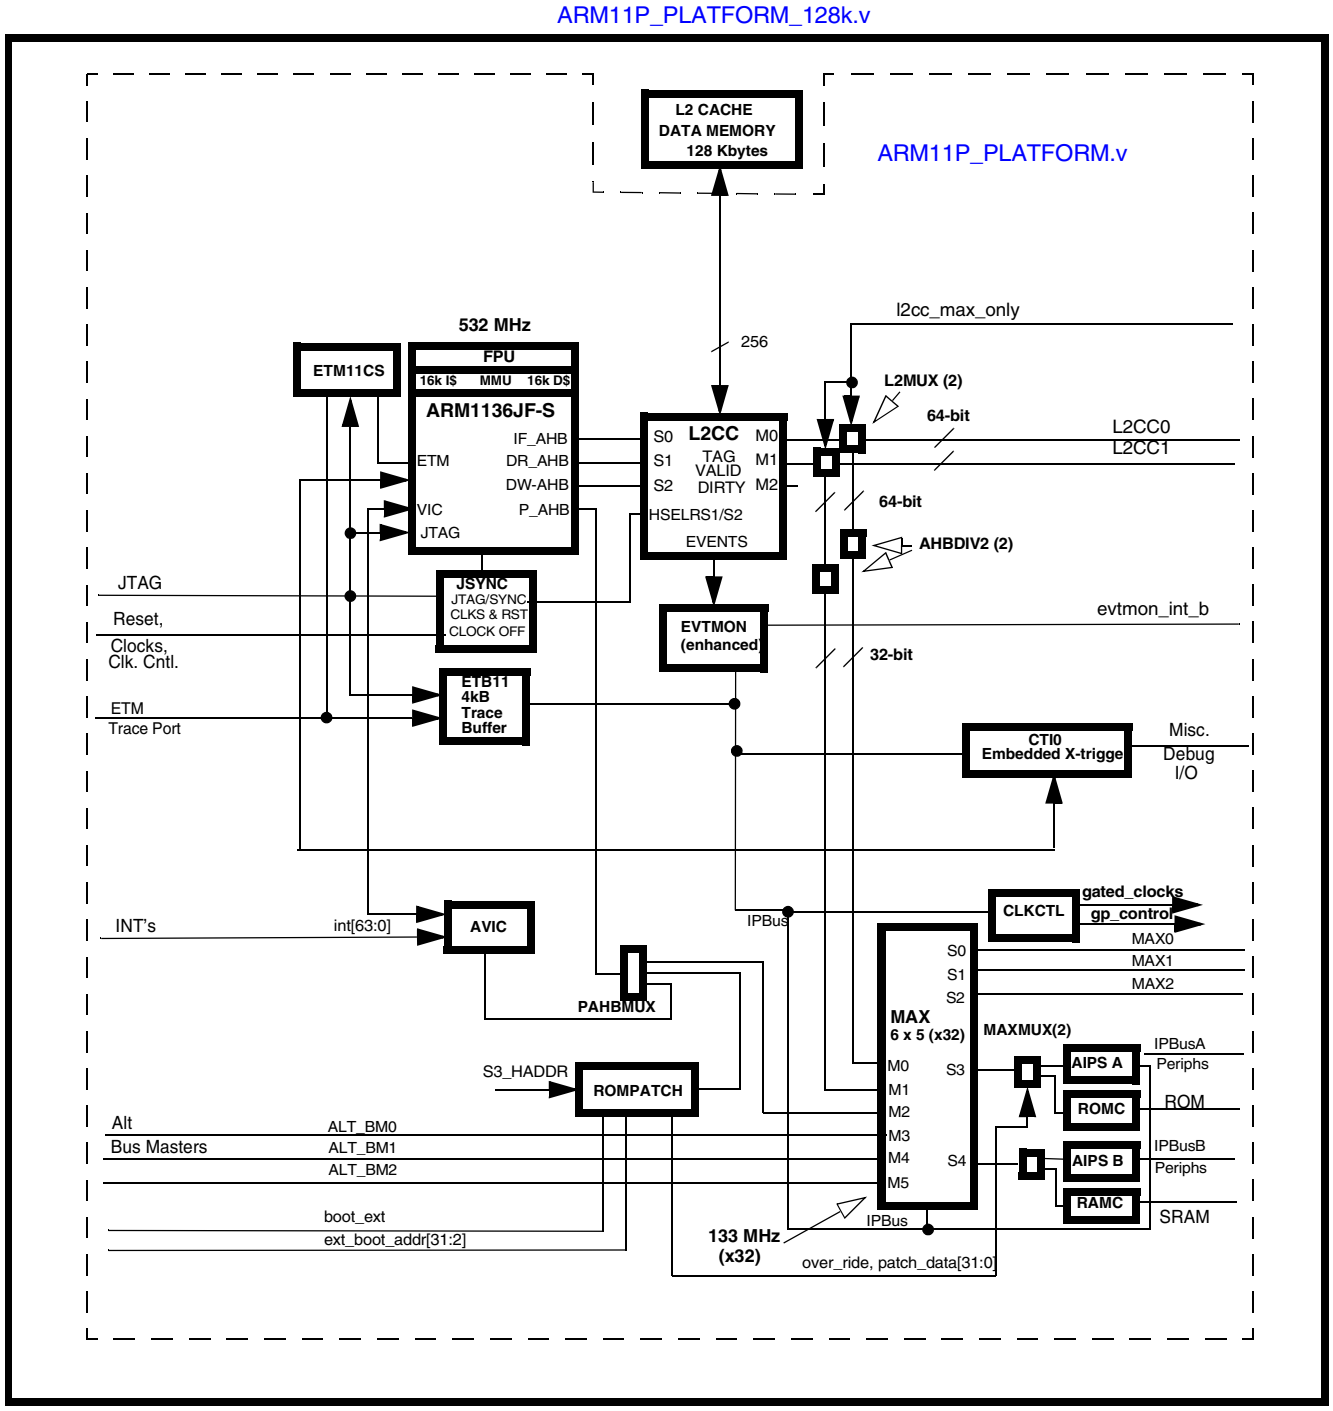

Figure 38-1. ARM1136 Platform Diagram

38.2 The ARM1136JF-S Processor

This section presents a brief overview of the ARM1136JF-S processor.

The core of the ARM1136 platform is the ARM1136JF-S processor, referred to in this document as “the ARM1136.” The ARM1136 incorporates an integer unit that implements the ARM v6 architecture. It supports the ARM and Thumb instruction sets, Jazelle technology enables the direct execution of Java bytecodes, and a range of SIMD DSP instructions that operate on 16-bit or 8-bit data values in 32-bit registers. With the exception of memories related to the caches and MMU, the ARM1136 is a fully synthesizable design.

38.2.1 Features

The ARM1136JF-S processor feature list includes the following:

- Integer unit with Embedded ICE logic
- Eight-stage pipeline
- Branch-prediction with return stack
- Low interrupt-latency mode
- External coprocessor interface
- Instruction and data MMUs, managed using micro-TLB structures backed by a unified main TLB
- Instruction and data caches including a non-blocking data cache with hit-under-miss methodology
- Caches are virtually indexed and physically addressed
- 64-bit interface to both caches
- Write buffer (bypassable)
- AMBA L2 interface supporting multiprocessor implementations
- JTAG-based debug
- Floating-point coprocessor

A block diagram of the ARM1136JF-S is shown in Figure 38-2.

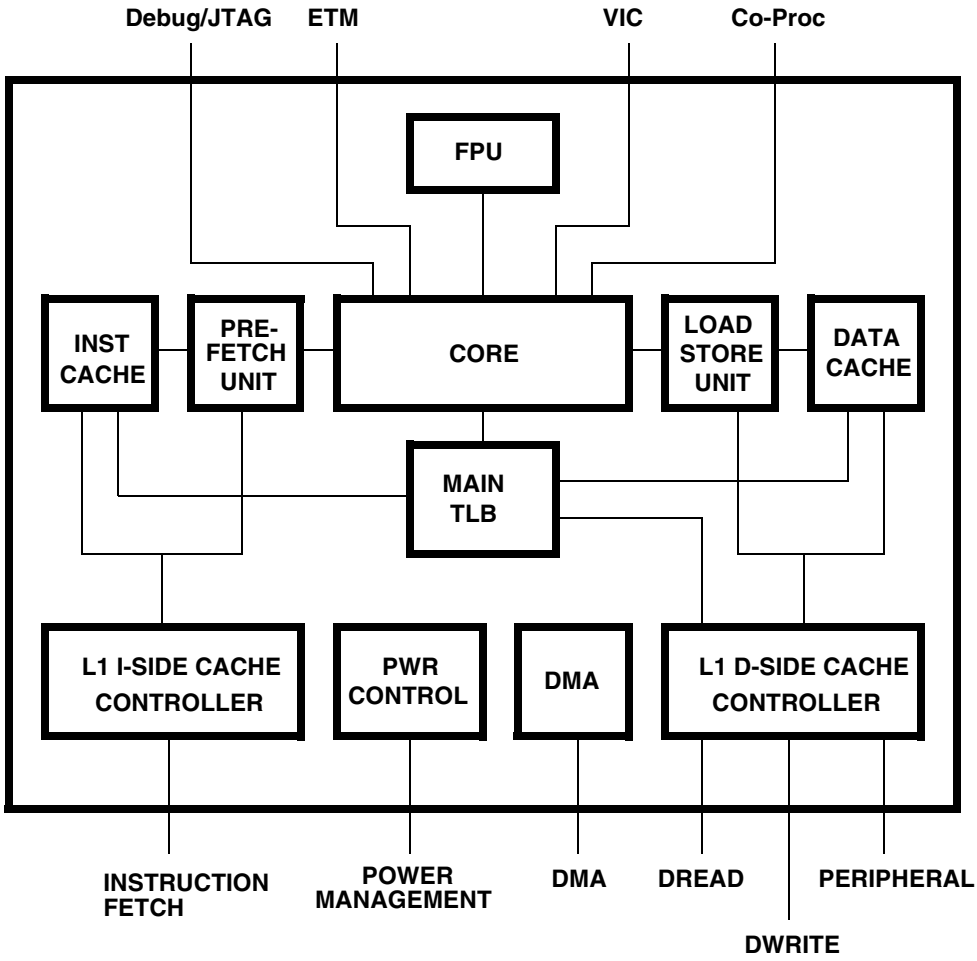

Figure 38-2. The ARM1136JF-S Block Diagram

38.3 ARM1136 Interfaces

This section provides short descriptions of the main interfaces to the ARM1136 processor.

38.3.1 Debug and JTAG

This interface provides connection to external tools for the development of application software, operating systems, and hardware. The ARM1136 JTAG interface must be synchronized externally to the processor's CLK domain as with previous ARM cores. The JTAG synchronization is done internal to the ARM1136 platform by the JSYNC module. See Section 38.7.26, "JTAG Synchronization Module (JSYNC)."

38.3.2 Embedded Trace Macrocell

The Embedded Trace Macrocell (ETM) interface provides connection to the ETM11 real-time trace hardware.

38.3.3 Vectored Interrupt Controller

The vectored interrupt controller (VIC) port is provided to support vectored interrupts. An external interrupt controller supplies the starting address (vector address) of the interrupt handler corresponding to the highest priority interrupt request.

38.3.4 Coprocessor Interface

The ARM1136 coprocessor interface supports the connection of external coprocessors. The ARM instruction set supports the connection of sixteen coprocessors, numbered 0–15, to an ARM processor. In the ARM1136 processor, the following coprocessor numbers are reserved:

- CP10—VFP Control (Floating Point Unit)
- CP11—VFP Control (Floating Point Unit)
- CP14—Debug and ETM Control
- CP15—System Control

Coprocessors CP0-9, CP12, and CP13 are available for the user's own external coprocessors.

NOTE

The coprocessor interface is not ported out of the ARM1136 platform. See Section 38.7.4, "Coprocessor Interface (COP)," for more information.

38.3.5 Level-two Memory Interface

The ARM1136 level-two (L2) memory interface exists to provide a high-bandwidth interface to L2 caches, on-chip RAM, peripherals, and interfaces to external memory. It provides a high-bandwidth mechanism for filling the caches on a cache miss. The ARM1136 processor L2 interconnect system uses 64-bit wide generic AMBA 2.v6 (AHB-Lite) interfaces:

- Instruction-fetch interface
- Data-read interface
- Data-write interface

Another interface is a 32-bit AHB-Lite interface to peripherals:

- Peripheral interface

All ARM1136 AHB interfaces are AMBA 2.0, v6 extended compatible (2.v6).

The L2 bus interfaces are shown in Figure 38-3.

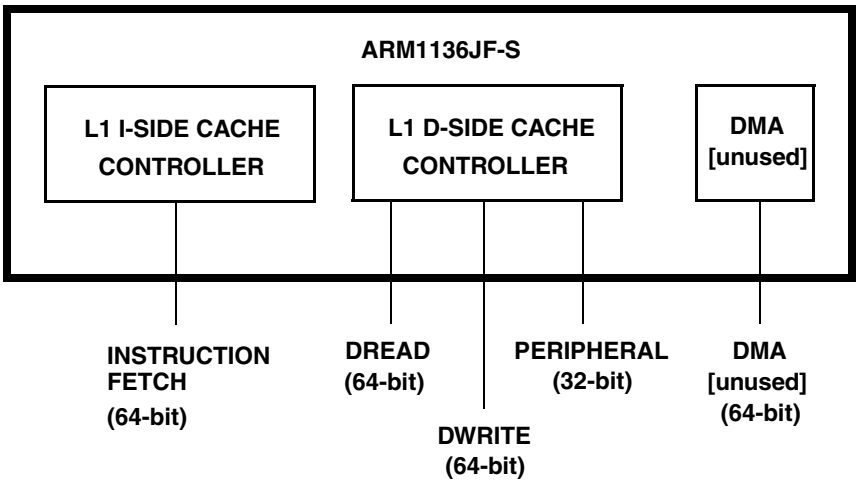

Figure 38-3. L2 Interfaces

38.3.5.1 Instruction-Fetch Interface

The instruction-fetch interface is a read-only interface that services the instruction cache on cache misses, including the fetching of instructions for the prefetch unit of instructions that are held in memory marked as non-cacheable. The interface is optimized for cache linefills rather than individual requests.

38.3.5.2 Data-Read Interface

The data-read interface performs reads and swap writes. It services the data cache on cache misses, handles translation lookaside buffer (TLB) misses on hardware page-table walks, and reads uncacheable locations. While cache-miss handling is important, the latency between outstanding uncacheable loads is minimized. The same address never appears on the data-read interface and the data-write interface simultaneously.

38.3.5.3 Data-Write Interface

The data-write interface is a write-only interface that services the writes out of the write buffer. Multiple writes can be queued as part of this interface.

38.3.5.4 Peripheral Interface

The peripheral interface is an AHB-Lite interface that services peripheral devices. The peripheral bus is a single-master bus with the ARM1136's peripheral interface being the only master. In the ARM1136 processor, this interface is intended for peripherals that are private to the ARM1136 core, such as the vectored interrupt controller or a watchdog timer.

Accesses to regions of memory that are marked as device and non-shared are routed to the peripheral interface in preference to the data-read or data-write interface. The peripheral port memory remap register enables memory regions to be remapped to the peripheral interface.

38.4 Overview of Platform Submodules

The platform consists of the ARM1136JF-S processor, an L2 cache controller (L2CC), L2 cache memory, an L1 and L2 event monitor (EVTMON), two AMBA bus downsizers (AHBDIV2), a 6x5 multi-layer AHB 2.v6 crossbar switch (MAX), an SRAM controller (RAMC), two AHB to IP-Bus interface gaskets (AIPS), a ROM controller (ROMC), an ARM1136 vectored interrupt controller (AVIC), a clock control module (CLKCTL), a ROMPATCH module, and a JTAG synchronization module (JSYNC). In addition, the L2MUX, PAHBMUX and MAXMUX modules handle AHB infrastructure support.

In addition, the ARM1136 platform contains the Embedded Trace Kit (ETK) from ARM. The ETK modules consist of the ETM, the Embedded Trace Buffer (ETB), and the Cross Trigger Interface (CTI) module.

The other debug improvement is that the event monitor has two additional counters. This allows simultaneous monitoring of additional L2CC events. The event monitor counters have also been made writable, which allows for more frequent interrupts from the EVTMON.

38.5 Overview of Platform Bus Interfaces

This section describes the major bus interfaces of the ARM1136 platform. All AHB buses on the ARM1136 platform are AHB-Lite 2.v6 compatible.

Brief functional descriptions of each module within the platform are discussed in Section 38.4, “Overview of Platform Submodules.”

38.5.1 L2CC AHB Interfaces

The ARM1136, via L2CC master ports M0 and M1, communicates directly to the ARM1136 platform I/O through two 133 MHz 64-bit AHB-Lite 2.v6 buses. These AHBs are labeled L2CC0 and L2CC1 on Figure 38-1. Each L2CC master port, M0 and M1, also feeds a bus divider (AHBDIV2), and then connects to MAX ports M0 and M1, respectively. The AHBDIV2 module translates the 64-bit data AHB accesses into 32-bit data accesses allowing the ARM1136 to communicate through the MAX module, which is configured to support a 32-bit data path. A configuration input, **l2cc_max_only**, is provided to disable the 64-bit direct connect buses and route all L2CC master transactions through the MAX.

38.5.2 MAX AHB Interfaces

Three slave ports of the MAX module (S0, S1, and S2) connect directly to the ARM1136 platform I/O via 133 MHz 32-bit AHB-Lite 2.v6 buses. These AHBs are labelled MAX0, MAX1, and MAX2 on Figure 38-1.

38.5.2.1 Alternate Bus Master Interfaces

Three 32-bit AHB-Lite 2.v6 interfaces are provided for alternate bus masters to connect directly to MAX master ports M3, M4, and M5 and thereby enable access to external ports (MAX0,1,2), ROM, SRAM, and peripherals (AIPS A, AIPS B). To support the connection of AHB2.0 compatible alternate bus masters, the

platform contains AHB2.v6 byte strobe generation logic on all alternate bus master ports. See Section 38.7.14, “AHB2.v6 Byte Strobe Generation Logic.”

38.5.3 IP-Bus v3.1

Slave ports S3 and S4 of the MAX are connected to AHB <-> IP-Bus peripheral interface gaskets (AIPS A and AIPS B). The two IP-Bus interfaces are v3.1 compatible.

38.5.4 Peripheral AHB Bus

The ARM1136 peripheral bus, or “P_AHB”, is a 32-bit AHB-Lite 2.v6 bus which connects the ARM1136 to the platform’s AHB slaves via the MAXMUX. These connections allow the ARM1136 to access its vectored interrupt controller (AVIC), the ROMPATCH registers, as well as MAX port M2. Thus, all peripherals residing behind both AIPS modules (including the ETB and ECT modules) are accessible via the ARM1136’s P_AHB.

The peripheral port (P_AHB) is accessed by memory locations whose MMU page table attributes are programmed as Non-Shared Device. To save MMU page tables, a region of memory can be programmed as Non-Shared Device by writing to the Peripheral Port Memory Remap Register (PPMRR) in the ARM1136 CPU. This register is programmed with the peripheral region’s base address and size.

38.6 ARM1136 Platform Submodules

The submodules of the ARM1136 platform are listed in the following sections along with short functional descriptions. See Figure 38-1 for the major bus interconnections of each module within the platform.

38.7 Configuration of ARM1136JF-S in the ARM1136 Platform

The ARM1136 was discussed in Section 38.2, “The ARM1136JF-S Processor.” The information presented in this section focuses on the ARM1136JF-S implementation within the ARM1136 platform. See the *ARM1136JF-S Technical Reference Manual* for more detailed information.

38.7.1 Vector Floating Point CoProcessor

The ARM1136JF-S processor comes bundled with a vector floating point unit (VFP11) that is fully compatible with the *ANSI/IEEE Std 754-1985, IEEE Standard for Binary Floating-Point Arithmetic*. The VFP11 coprocessor supports all addressing modes described in section C5 of the *ARM Architecture Reference Manual*.

The VFP11 is optimized for high data transfer bandwidth through 64-bit split load and store buses. Divide and square root operations run in parallel with other arithmetic operations to reduce the impact of long-latency operations. In addition to full IEEE 754 support, near IEEE 754 compatibility is provided in RunFast mode without support code assistance.

The VFP11 coprocessor provides full support of single-precision and double-precision add, subtract, multiply, divide, multiply with accumulate and square root operations. Conversions between floating-point data formats and ARM integer word format are provided, with special operations to perform the

conversion in round-toward-zero mode for high level language support. Throughput and latency cycle counts for some commonly used VFP11 instructions are shown in Table 38-1.

Table 38-1. VFP11 Instruction Throughput and Latency Cycle Counts

Instructions	Single-Precision Throughput/Latency	Double-Precision Throughput/Latency
FABS, FNEG, FCVT, FCPY	1 5	1 5
FCMP, FCMPE, FCMPZ, FCMPEZ	1 5	1 5
FADD, FSUB	1 9	1 9
FMUL, FNMUL	1 9	1 9
FMAC, FNMAC, FMSC, FNMSC	1 9	2 10
FDIV, FSQRT	15 19	29 33

The VFP11 coprocessor is integrated with the ARM1136 CPU through a dedicated VFP coprocessor interface and uses coprocessor ID number 10 for single-precision instructions and coprocessor ID number 11 for double-precision instructions. In some cases, such as mixed-precision instructions, the coprocessor ID represents the destination precision. In the ARM1136 platform, which contains the VFP11 coprocessor, these coprocessor ID numbers must not be used by another coprocessor.

Access to the VFP11 coprocessor is controlled by the ARM1136 Coprocessor Access Control Register. The coprocessor access rights must be configured correctly before any VFP11 instructions may be executed. See the *VFP11 Technical Reference Manual* for detailed information.

38.7.2 ARM1136 Instruction and Data Caches (L1)

The ARM1136 is configured with a 16-Kbyte instruction cache and a 16-Kbyte data cache. Each cache is implemented as four-way set associative and each is both virtually indexed and physically addressed. Both the instruction cache and data cache are capable of providing two words per cycle for all requesting sources. The number of cache ways is fixed at four. The line-length is not configurable and is fixed at eight words per line.

See the *ARM1136EJ-S Technical Reference Manual* for more detailed information.

38.7.3 L2 Interface (IF_AHB, DR_AHB, DW_AHB)

The three 64-bit L2 interfaces, instruction fetch, data read, and data write, are connected directly to the tightly coupled L2 cache controller.

38.7.4 Coprocessor Interface (COP)

This interface is not ported to the top level of the ARM1136 platform.

38.7.5 Vectored Interrupt Controller Interface

The vectored interrupt controller (VIC) interface of the ARM1136 is connected directly to the ARM1136 vectored interrupt controller (AVIC) module. The AVIC module is accessed by the ARM1136 via its P_AHB bus and the MAXMUX module. See Section 38.7.21, "ARM1136 Vectored Interrupt Controller (AVIC)," for more detail.

NOTE

The AVIC module used on the ARM1136 platform is not the VIC module supplied by ARM. The AVIC module is one designed by Freescale to support the vectored interrupt interface (VIC) on the ARM1136.

38.7.6 JTAG Interface

The JTAG interface on the ARM1136 and the ETK11 modules are connected to the platform's JSYNC module. The JSYNC module performs the standard ARM JTAG synchronization logic. The JSYNC module also contains some miscellaneous debug related logic in addition to JTAG and power-on-reset control. See Section 38.7.26, "JTAG Synchronization Module (JSYNC)," for more detail. Finally the JSYNC provides clock gating for all CPU domain peripherals.

38.7.7 Level Two Cache Controller (L2CC)

This section will focus on the use and configuration of the L2CC within the ARM1136 platform. First, the general features of the L2CC will be listed.

See ARM's *L2 Cache Controller (L2CC) Engineering Specification* for more detail.

38.7.7.1 L2CC Configuration on the ARM1136 Platform

The ARM1136 platform Level 2 Cache Controller (L2CC) is optimized to sit between the ARM1136 (L1) and main memory (L3, or the external EMI). The L2 cache is a unified, physically indexed, physically tagged 8-way cache. The replacement algorithm can be locked on a way basis, allowing the associativity to be reduced from 8 way down to 1 way (direct mapped), and the locked ways to be used as physically mapped memory. The L2CC does not have snooping hardware to maintain coherency between caches, so coherency must be maintained in via software.

The L2 cache size supported by the ARM1136 platform is 128 Kbytes. A 256-bit data path is implemented to the L2 data arrays. The L2 cache latency is 8 clocks on hits assuming a single cycle RAM access. However, the actual latency of the L2 data RAMs on the ARM1136 platform is 2 clocks (one wait-state), and therefore the range on the ARM1136 platform is predicted to be 9–10 clocks. The L2 tag, valid, and dirty RAMs are zero wait-state compiled memories.

All slave and master ports of the L2CC are 64-bit AHB-Lite 2.v6 compatible.

38.7.8 L2CC Performance

The L2CC on the ARM1136 platform implement zero wait-state tag, valid and dirty memory arrays. These memories will reside inside the common ARM1136 platform module. The L2 data memories will reside

outside of the common ARM1136 platform and use one-wait state for both reads and writes. The total access time to the first word of read data is calculated to be 11 or 12 clocks. This number will increase from the ARM1136 perspective due to L1 pipeline delays. Table 38-2 shows the ARM1136 platform's L2CC access times for a 4 word burst read hit from the perspective of the ARM1136 L2 interface AHBs. These are best case access times, as there are other scenarios when access times on L2 hits could be longer (concurrent requests for example).

Table 38-2. L2CC Burst Read Access Time

Burst of 4	Access Time in Clock Cycles
1st 64 bits of burst	11
2nd 64 bits of burst	12
3rd 64 bits of burst	13
4th 64 bits of burst	14

See ARM's *L2 Cache Controller (L2CC) Engineering Specification* for more detailed information on the L2CC design and the L2CC programmer's model.

38.7.8.1 L2 Initialization

In order to cache instructions/data into the L2CC, the cache must first be configured and invalidated. The way size, associativity, and cache memory latencies are specified using the **Auxiliary Control register**. Then the cache is invalidated using the **Invalidate By Way Cache Maintenance Operations register**.

Next, it is recommended that user initialize the MMU. Next, the L2CC is enabled by writing to the **L2 Control register** before the MMU is enabled.

38.7.8.2 Example of Configuring the ARM11P L2CC

The ARM1136 Platform memory map places the L2 registers at the base address of **0x3000_0000**. The registers are listed and described in the L2 Cache Controller Technical Reference Manual.

The L2CC is configured using the **L2 Auxiliary Control register** located address: **0x3000_0104**. For this example, this register is set to: **0x0003_0009**. This value corresponds to the following configuration:

- 128k cache size (16k way size)
- 8-way associativity
- Event Monitor Bus disabled
- 1 clk latency (0 wait state) TAG/VALID and DIRTY memories.
- 2 clk latency (1 wait state) DATA memory for Read and Write.

NOTE

The L2CC must be disabled when accessing internal registers.

NOTE

Writes to any of the L2CC registers should be preceded by an explicit cache-sync request. This is especially important when the cache is enabled and changes to how the cache allocates new cache-lines are to be made, such as, cache lockdown and change of debug control attributes.

38.7.8.3 Invalidating the L2CC Cache Memory

The cache memory is invalidated using the Cache Invalidate by Way Maintenance Operations register. This register uses the Format C way-based background operation. Writing 0x0000_00FF to this register, located at address: 0x3000_077C, will invalidate the entire L2 cache. Note that the cache way-based maintenance operations, and specifically the Invalidate by Way operation, run as background tasks. This requires polling the register to determine when the operation is complete. The Cache Invalidate by Way Maintenance Operations register will go to zero (each bit clearing as the corresponding way completes).

38.7.9 L2CC Event Monitor (EVTMON)

The L2CC design provides a number of L2 cache event monitoring output signals as shown in Table 38-3. These signals are routed from the L2CC to the L2CC's Event Monitor (EVTMON) module, which contains a control register, a status register, and event counters. The event counters have been made writable to allow the EVTMON to assert its interrupt more frequently. This can be accomplished by writing a non-zero value to the counter each time the EVTMON interrupt is serviced. Access to EVTMON registers will be provided via an IP-Bus connection (see Section 38.7.20.2, "AIPS A Peripheral Support"). The **evtmon_interrupt** output signal is generated based upon enabling various L2CC events. This signal will be brought out to the top-level of the ARM1136 platform in order to provide flexible interrupt assignment and muxing at the SoC level. Although some of the events monitored by the EVTMON module are used for L2 operational profiling (cache requests, hits, etc.), some of the event signals monitored are necessary to resolve error conditions not signaled on the ARM1136/L2CC AHB interfaces (**bwabt** for example).

Table 38-3. L2CC Event Monitoring Signals

Signal	Type	Notes
BWABT	Output	Buffered Write Abort
CO	Output	Castout of a line from the L2 cache
DRHIT	Output	Data read hit
DRREQ	Output	Data read request
DWHIT	Output	Data write hit
DWREQ	Output	Data write request
IRHIT	Output	Instruction read hit
IRREQ	Output	Instruction read request
WA	Output	Write allocate (write caused a linefill to the L2 cache)

38.7.10 Performance Monitor for Level 1 Cache

ARM Platform has a submodule included in the Event Monitor. It is a level 1 cache performance monitor. This is modeled after the L1 performance monitor which is provided with the ARM core (and is also available to the user). The L1 Performance Monitor allows the user to simultaneously count events such as L1 cache misses, TLB misses, pipeline stalls and other related features. This enables system developers to profile the performance of their system. All registers and counters are memory mapped.

38.7.11 Level Two AHB Mux (L2MUX)

The 64-bit L2CC master ports M0 and M1 are routed directly to the top-level of the ARM1136 platform. Additionally, the 64-bit L2CC master ports M0 and M1 are each connected to an AHBDIV2 module before connecting to the MAX module. The AHBDIV2 modules will downsize the 64-bit L2CC data paths to the 32-bit data path of the MAX. There will be two Level Two AHB Mux (L2MUX) modules instantiated, one for each L2CC master (one for M0 and one for M1), to handle the AHB infrastructure. Each L2MUX will perform address decoding (HSEL generation) to select either the EMI or AHBDIV2 as the target of the requested transaction. The **l2cc_max_only** input (intended to be tied off at the SoC level) will feed into the HSEL logic in the L2MUX. When asserted, **l2cc_max_only** will cause all transactions from the L2CC master ports to be routed only to the MAX. Each L2MUX will also perform the HRDATA muxing and HREADY generation back to the L2CC master port.

38.7.12 AHB Downsizer (AHBDIV2)

The purpose of the AHBDIV2 module is to translate the L2CC master ports' 64-bit data AHB accesses into a 32-bit data AHB access for the MAX. In order to alleviate a critical timing path in the 133 MHz **per_clk** domain, a wait-state is taken on transactions destined for the MAX which immediately follow a previous access to the L2CC0/1 direct connect ports. This wait-state is not observed on designs which chose not to utilize the direct connect ports (**l2cc_max_only**=1).

38.7.13 Multi-Layer 6 X 5 AHB Crossbar Switch (MAX)

The L2CC master ports, the off-platform alternate bus masters, and the ARM1136's P_AHB arbitrates memory and peripherals via a 6X5 Multi-Layer AHB Crossbar switch (a 6x5 MAX). The MAX port connections for the ARM1136 platform are shown in Table 38-4.

Table 38-4. MAX Port Connections

MAX Port Name	AHB Function	ARM1136 Platform Connection
M0	Slave	L2CC Master M0 (through an AHBDIV2)
M1	Slave	L2CC Master M1 (through an AHBDIV2)
M2	Slave	P_AHB
M3	Slave	ALT_BM0
M4	Slave	ALT_BM1
M5	Slave	ALT_BM2

Table 38-4. MAX Port Connections (Continued)

MAX Port Name	AHB Function	ARM1136 Platform Connection
S0	Master	Off Platform AHB-Lite 2.v6
S1	Master	Off Platform AHB-Lite 2.v6
S2	Master	Off Platform AHB-Lite 2.v6
S3	Master	AIPS A and ROMC (ROM Controller)
S4	Master	AIPS B and RAMC (RAM Controller)

NOTE:

In the MAX specification, and on the MAX symbol used on the block diagrams in this document, MAX “master” ports (M0, M1, etc.) are connected to AHB masters. MAX “slave” ports (S0, S1, etc.) are connected to AHB slaves. This convention is the opposite of the L2CC naming convention. L2CC master ports M0 and M1 are true AHB bus masters.

The design of the MAX allows for concurrent transactions to proceed from any slave port to any master port. That is, it is possible for five MAX slave ports to be active at the same time as a result of five independent master requests. If a particular slave port is simultaneously requested by more than one master port, arbitration logic exists in the MAX to allow the higher priority master port to be granted access to the slave, while stalling the other requestor(s) until that transaction has completed. The slave port arbitration schemes supported are fixed, programmable fixed, round-robin, and programmable default parking.

In addition, the MAX contains AHB2.v6 byte strobe generation logic on all alternate bus master ports. This enables AHB2.0 compatible bus masters to be directly connected to the ARM1136 platform’s alternate bus master ports. See Section 38.7.14, “AHB2.v6 Byte Strobe Generation Logic.”

38.7.13.1 MAX AHB Configuration

The MAX on the ARM1136 platform is configured as 6x5 and supports a 32-bit data bus. All master and slave ports are AHB-Lite 2.v6 compatible. All master and slave ports are required to run at the same HCLK frequency (**per_clk**). The maximum frequency of the MAX on the ARM1136 platform is 133 MHz. Slave devices residing on the alternate bus master ports will not be supported.

38.7.13.2 MAX Configuration Registers

The MAX has configuration and control registers accessible via the IP-Bus (AIPS A, on-platform slot #1). Programmable registers exist to control arbitration schemes, bus parking, as well as other crossbar bus switch functionality. A write-block sticky bit is implemented for those applications where it is desirable to prevent changes to the MAX registers after boot.

See the ARM1136 *Multi-Layer AHB Crossbar Switch (MAX) Specification* for more detail.

38.7.14 AHB2.v6 Byte Strobe Generation Logic

All of the ARM1136 platform's AHB interfaces are AHB2.v6 compatible. To support direct connection of AHB2.0 masters to the alternate bus master ports of the platform, the MAX contains logic to generate the byte strobes required by AHB2.v6.

38.7.15 MAX AHB MUX (MAXMUX)

There are two instantiations of the MAXMUX module on the ARM1136 platform. The first instantiation resides on MAX master port M3 and handles the AHB infrastructure for the AIPS A and ROMC modules. In addition, the MAXMUX supports the ROMPATCH over-ride feature for ROM patches. The second MAXMUX instantiation resides on MAX master port M4. It handles the AHB infrastructure for AIPS B and RAMC. Each MAXMUX has a timeout monitor, which is discussed in the next section.

38.7.16 Peripheral Bus Timeout Monitors

The ARM1136 platform's MAX module returns an AHB hresp=ERROR termination status on attempted accesses to undefined regions of memory. Likewise, the AIPS module returns an AHB hresp=ERROR termination status on attempted accesses to unpopulated regions of the peripheral space. The memory controllers (RAMC and ROMC) are, by design, either zero or one wait-state responders. However, the danger still exists that peripherals residing on the AIPS module's (2) IP-Buses could hang up and not properly terminate an access. This could happen even though they may have been programmed in the AIPS module's configuration registers as being populated and enabled. Therefore, the ARM1136 platform supports AHB bus timeout monitors on each AIPS AHB interface. The timeout monitors are implemented in each instantiation of the MAXMUX module. The timeout interval for both modules are set by the **bmon_timeout[1:0]** inputs which should be statically tied off at integration time. The timeout monitors both share a single enable bit in the general purpose register of the CLKCTL module. When the timeout monitors are enabled, an AHB access to either of the AIPS modules that does not terminate within the time it takes for the bus monitor counter to reach zero will be terminated by the timeout monitor in the MAXMUX module. The timeout monitor terminates a "hung" access by forcing an hresp=ERROR and hready termination. The bus timeout clock counts for the **bmon_timeout[1:0]** encodings are shown in Table 38-5.

Table 38-5. Bus Monitor Timeout Interval

bmon_timeout[1:0]	Timeout Interval
00	31 clocks
01	127 clocks
10	511 clocks
11	2047 clocks

NOTE

The ARM1136 platform does not include timeout monitors for MAX ports S0, S1, or S2. Timeout monitors also do not exist for L2CC0 and L2CC1.

38.7.17 ROM Controller (ROMC)

The ARM platform's ROM controller (ROMC) shares MAX master port S3 with the AIPSA module. The ROMC interface is AHB-Lite 2.v6 compatible. The **rom_connect** input on the ARM1136 platform must be tied high if ROM exists on the ROMC interface. The ROMC module supports ROM sizes between 16 Kbytes and 4 Mbytes, in 1-Kbyte increments, by strapping the **rom_size[11:0]** inputs appropriately. Any actual ROM size smaller than 16 Kbytes is not fully supported as it is treated as a 16-Kbyte ROM.

38.7.17.1 ROM Wait State Control

Internal ROM accesses from the ARM1136 and/or the L2CC have significantly better timing than external ROM accesses (via alternate bus masters). For this reason, the platform has two ROM related wait-state control inputs. The **rom_wait_arm11** input should be tied high at integration time if a wait state is required to make read data timing on ROM accesses from the ARM1136 (or L2CC). A separate input, **rom_wait_alt_mstr**, is provided to control ROM wait-states for alternate bus masters. Typically, **rom_wait_arm11** could be tied low (ARM1136 accesses ROM at zero wait-states) while **rom_wait_alt_mstr** could be tied high (more difficult timing on alternate bus masters may require a wait-state on ROM accesses). The implementation uses the **hmaster** encodings to identify the ARM1136/L2CC as the access requester, and is optimized for critical ARM1136 zero-wait state ROM timing.

38.7.17.2 ROM Addressing

The first 16 Kbytes of ROM (secure ROM) is always mapped starting at 0x0000_0000. Supported ROM sizes are from 16 Kbytes to 4 Mbytes, sized in 1-Kbyte increments, based on the **rom_size** inputs. ROM sizes smaller than 16 Kbytes are aliased throughout this 16-Kbyte region. Any ROM larger than 16 Kbytes has the remainder of its space mapped starting at 0x0040_4000 (4 Mbytes + 16-Kbyte boundary). ROM sizes 16 Kbytes and above will not be aliased.

NOTE

The ARM1136 MMU should be used to secure ROM space as desired.

NOTE

The 16 Kbytes of secure ROM space occupying a separate 4-Mbyte space is done to keep the non-secured memory in a different page table. The 16-Kbyte "hole" at the start of the is to keep the addressing of the ROM simple. This makes it easier to meet timing than if the starting address were translated at 0x0040_0000 (it is the same physical ROM used for the 16-Kbyte secure ROM and the remainder of ROM which starts at the 4 Mbyte+16 Kbyte boundary.)

38.7.18 SRAM Controller (RAMC)

The SRAM controller (RAMC) shares MAX port S4 with the AIPSB module. The ram_connect input on the ARM1136 platform must be tied high if RAM exists on the RAMC RAM interface. The RAMC module supports a minimum of 1 Kbyte of RAM and a maximum of 1 Mbyte. Non power-of-two sizes between 1 Kbyte and 1 Mbyte are supported by strapping the ram_size[9:0] inputs, which correspond to

HADDR[19:10]. RAMC address space starts at 0x1000_0000 and ascends to a maximum of 0x100F_FFFF (1MB). RAMC space is aliased between 0x1000_0000 and 0x1FFF_FFFF (a 256-Mbyte region) based on the ram_size inputs.

38.7.18.1 SRAM Wait State Control

Internal RAM accesses from the ARM1136 and/or the L2CC have significantly better timing than external RAM accesses (via alternate bus masters). For this reason, the platform has two RAM related wait-state control inputs. The **ram_read_wait_arm11** input should be tied high at integration time if a wait state is required to make read data timing on RAM accesses from the ARM1136 (or L2CC). A separate input, **ram_wait_alt_mstr**, is provided to control RAM wait-states for alternate bus masters. Typically, **ram_read_wait_arm11** could be tied low (ARM1136 accesses RAM at zero wait-states) while **ram_wait_alt_mstr** could be tied high (more difficult timing for alternate bus masters requires a wait-state on RAM accesses). The solution uses the **hmaster** encodings to identify the ARM1136/L2CC as the access requester, and is optimized for critical ARM1136 zero-wait state RAM timing.

NOTE

The RAM interface timing supports C90LP2 compiled memories up to TBD Kbytes with zero wait-states. It is anticipated that SRAM sizes above TBD Kbytes will require **ram_read_wait_arm11** to be tied high. However, since the actual memory does not reside on the ARM1136 platform, timing closure should be reached at the SoC level before assuming the correct polarity of the **ram_readwait_arm11** tie-off.

All RAM write accesses are zero wait-state. The RAM interface supports single clock-edge non late-write style compiled memories, and implements an internal write buffer to mimic the late-write capability for improved performance. Both polarities of RAM control signals are provided to support Freescale and non-Freescale RAM solutions. The RAMC module also supports a single outstanding AHB 2.v6 exclusive access.

38.7.19 ROM Patch Module (ROMPATCH)

The ROM patch module (ROMPATCH) is used to patch errant ROM code. The registers of the ROMPATCH are programmed by the ARM1136 over the P_AHB. However, the ROM only patches accesses to the ROMC (not accesses to AIPS A, which shares MAX master port S3 with the ROMC module). The ROMPATCH module can be used to patch source code or data tables. The module supports 16 patches. The ROMPATCH module also supports external booting by over-riding the reset vector fetch.

38.7.20 AHB <-> IP-Bus Interface (AIPS)

There are two AIPS modules instantiated in the ARM1136 platform (AIPS A and AIPS B). The AIPS module design supports many configuration options so that it may be reused across multiple systems. This section begins with a short description of the generic AIPS module, followed by specific implementation details of the two AIPS instantiations used in the ARM1136 platform.

38.7.20.1 AIPS Configuration on ARM1136 Platform

This section describes the configuration of both AIPS modules (AIPS A and AIPS B) used within the ARM1136 platform.

- The attributes common to both AIPS modules used in the ARM1136 platform are as follows:
- 32-bit data path.
- Write buffering is disabled.
- Memory map option #1 is used.
- The AIPS_DLY_CYCLE parameter is disabled. No additional one-cycle delay is incurred on initiating reads or buffered writes.
- Support for hmaster ID's 8-15 is enabled

A list of all configuration options for both AIPS modules within the ARM1136 Platform are shown in Table 38-9. The **aips_byte_config[1:0]** inputs support little endian (LE) and big endian word-invariant (BE32) modes.

Table 38-6. aips_byte_config Encoding

aips_byte_config[1:0]	Mode
00	BE8
01	LE
10	Reserved
11	BE32

- When the ARM1136 processor is operating in BE8 mode, the AIPS modules function the same as in LE mode. Software is responsible for any necessary peripheral data alignment requirements in BE8 mode. The **aips_byte_config[1:0]** signals will be tied as follows:
  - **aips*_byte_config[1]** = **cfg_bigend**; (from ARM1136JF-S)
  - **aipsa_byte_config[0]** = **clkctl_gp_ctrl[9]**; (from CLKCTL general purpose reg, reset to "1")
  - **aipsb_byte_config[0]** = **clkctl_gp_ctrl[10]**; (from CLKCTL general purpose reg, reset to "1")

NOTE

Connection of aips*_byte_config[0] on AIPSA and AIPSB to the CLKCTL module's general purpose control register is for flexibility only in case of a possible peripheral endian related bug. The default setting ("1") is the intended use.

- 64-bit data accesses and data accesses which cross a 32-bit boundary are terminated with an error: no module select is asserted.
- Although the AIPS modules on the ARM1136 platform are designed for a 32-bit operation on the IP-Bus side, they support connection of 8 and 16-bit peripherals. However, the AIPS does not support accesses of a larger size than the peripherals maximum width. For example, a 16-bit access to an 8-bit peripheral is not supported by the AIPS. Likewise, a 32-bit access to a 16-bit peripheral is not supported. The AIPS responds with **hresp**=Error for unsupported accesses.

- The Master Privilege Register (MPR) configuration of the AIPS allows the ARM1136JF-S processor to be the default “trusted” master out of reset. All other masters will be non-trusted. The ARM1136 processor can re-program the MPR at any time after reset.
- Table 38-7 shows the default (out-of-reset) privilege configuration of the ARM1136JF-S processor (trusted).

The ARM1136JF-S addresses peripherals using the P_AHB. The peripheral port (P_AHB) is accessed by memory locations whose MMU page table attributes are programmed as Non-Shared Device. To save MMU page tables, a region of memory can be programmed as Non-Shared Device by writing to the Peripheral Port Memory Remap Register (PPMRR) in the ARM1136 CPU. This register is programmed with the peripheral region’s base address and size.

NOTE

For programming PPMRR, see Section 38.9.2, “Peripheral Port Remap Register.” Table 38-7 shows the default (out-of-reset) privilege configuration for all bus masters other than the ARM1136 processor (non-trusted).

Table 38-7. AIPS MPR Reset Configuration for Trusted Master (ARM1136)

Default (Out of Reset) ARM1136JF-S Trusted Master Privileges (hmaster = 4’h1)
Master buffered writes: No buffered writes
Master trusted for reads: Yes—trusted
Master trusted for writes: Yes—trusted
Master privilege level: Supervisor accesses are not downgraded to user accesses

Table 38-8. AIPS MPR Reset Configuration of Non-Trusted Masters

Default (Out of Reset) Non-Trusted Master Privileges (hmaster!= 4’h1)
Master buffered writes: No buffered writes
Master trusted for reads: No—not trusted
Master trusted for writes: No—not trusted
Master privilege level: Supervisor accesses are downgraded to user accesses

NOTE

Legacy AIPI peripherals having a standard 4 Kbyte address space may be aliased throughout the 16-Kbyte standard address space of the AIPS.

Table 38-9. ARM1136P AIPS Configuration

AIPS Parameter	Integration Value	
	AIPSA	AIPSB
DATA_PORT_WIDTH	32	32
AIPS_NO_BUFFERING	1	1
AIPS_MEMMAP	1	1
AIPS_DLY_CYCLE	0	0
MSTR_8_15_PRESENT	1	1
OPACR16_31_PRESENT	0	1
AIPS_REG_XFR_ERR	0	0
ARM11PLAT_TIMEOUT_FIX	1	1
PACR1_PRESENT - PACR6_PRESENT	1	0
PACR7_PRESENT - PACR31_PRESENT	0	0
PACR1_SIZE - PACR31_SIZE	32	32
AIPS Tie Off	**Integration value**	
	AIPSA	**AIPSB**
Reset Configuration - aips_rstcfg	0x0000000007000000	0x0000000007000000
Disable multicycle access - aips_disable_macc	1	1

The number of external peripherals each AIPS module supports is discussed in the following sections. External peripherals should be chosen to reside on AIPS A or AIPS B based on concurrent use case analysis.

See the *AIPS Block Guide V1.1* for more detail.

38.7.20.2 AIPS A Peripheral Support

AIPS A shares the MAX output port S3 with the ROM controller (ROMC). AIPS A is configured to support 16 standard (16 Kbyte) external peripherals, as well as the two global external module enables (31- and 32-Mbyte). AIPS A will also support 6 on-platform peripherals as shown in Table 38-10.

Table 38-10. On-Platform IP-Bus Peripherals (AIPS “A”)

On-Platform Peripheral	AIPS “A” On-Platform Slot
MAX Configuration Registers	1
EVTMON[1]	2
CLKCTL (General Purpose Registers)	3
ETB registers[1]	4

Table 38-10. On-Platform IP-Bus Peripherals (AIPS “A”) (Continued)

On-Platform Peripheral	AIPS “A” On-Platform Slot
ETB Memory[1]	5
ECT[1]	6

[1] Reads of these registers by an alternate bus master while the ARM1136 platform is powered down will return 32’hFFFFFFFF with no wait states and no error response.

38.7.20.3 AIPS B Peripheral Support

AIPS B shares MAX output port S4 with the RAM controller (RAMC). AIPS B is configured to support 32 standard external peripherals, as well as the two global external module enables. AIPS B does not support any on-platform peripherals.

38.7.20.4 Peripheral Summary

Table 38-11. is a summary of the total ARM1136 platform internal (on platform) and external (off platform) peripherals which are supported.

Table 38-11. Summary of ARM1136 Platform Peripheral Support

AIPS Module	# of On Platform Peripherals	# of Off Platform Standard Peripherals (16 Kbyte)	# of Off Platform Global Module Enables (31 Mbyte, 32 Mbyte)
AIPS A	6	16	2
AIPS B	None	32	2
Total	6	48	4

38.7.21 ARM1136 Vectored Interrupt Controller (AVIC)

NOTE

The VIC module is designed by FreeScale and not the VIC provided by ARM Limited.

The ARM1136 Vectored Interrupt Controller (AVIC) hardware exists to prioritize interrupts and to supply the interrupt vector address of the highest priority interrupt to the ARM1136 core automatically via an interrupt sideband bus (the ARM1136 “VIC” interface). The AVIC module has an AHB-Lite interface, and is programmed via the ARM1136’s peripheral AHB bus (P_AHB). The AVIC contains a 63x30 register array to store the vector table.

Synchronization of the VIC interface to the ARM1136 takes place in the ARM1136 itself. This is why the INTSYNCEN and IRQADDRVSYCNEN inputs on the ARM1136 are tied low.

NOTE

The ARM1136 TRM states that the synchronizers in the ARM1136 are bypassed when INTSYNCEN and IRQADDRVSYNCEN are asserted. This is not intuitively obvious from the signal names (one would normally consider synchronization to take place when the signals are asserted since the signals have the SYNCEN suffix attached). The AVIC interface to the ARM1136 is shown in Figure 38-4.

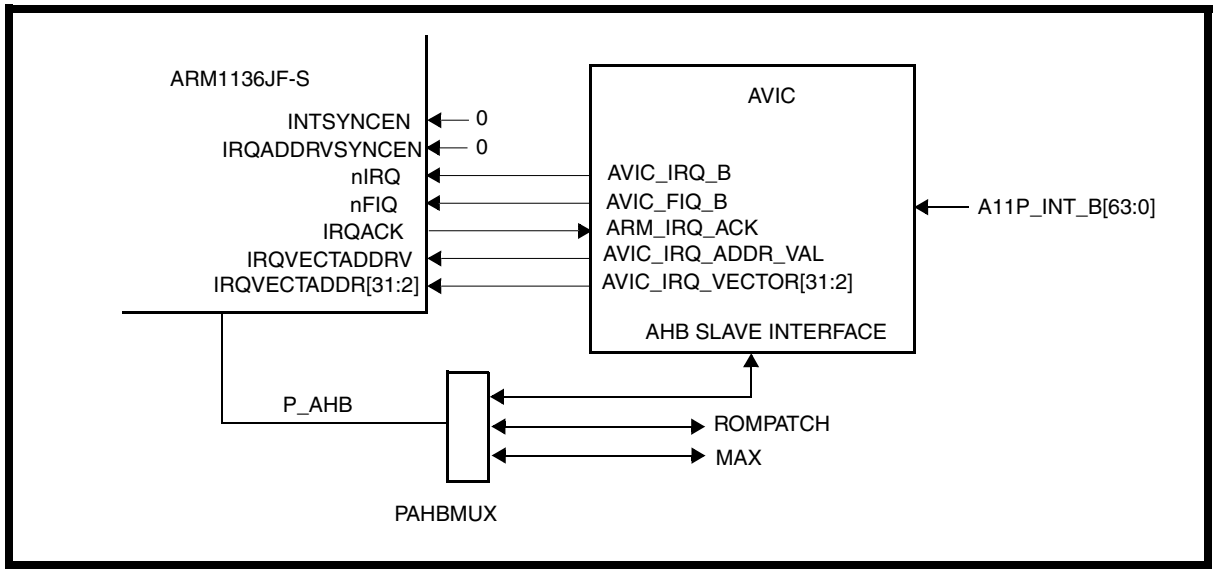

Figure 38-4. The AVIC Module Connected to the ARM1136

38.7.22 Platform Interrupts

The ARM1136 platform interrupt signals are summarized in Table 38-12.

Table 38-12. Summary of ARM1136 Platform Interrupt Support

Signal	Type	Description
a11p_int_b[63:0]	Input	The 64 interrupts routed to the AVIC module.
evtmon_interrupt_b	Output	The L2CC Event Monitor Interrupt
pmu_irq_b	Output	The ARM1136's System Metrics Module Interrupt
ect_irq_b[1:0]	Output	The Cross Trigger's Interrupts

At the SoC level, the four interrupt outputs shown in Table 38-12 must be connected directly or indirectly (shared) to one or more of the **a11p_int_b[63:0]** inputs.

38.7.23 P_AHB Mux (PAHBMUX)

Similar to the L2MUX, the P_AHB Mux (PAHBMUX) module handles the AHB infrastructure for slaves residing on the ARM1136's peripheral AHB (P_AHB). Slaves on the ARM1136's P_AHB include the

AVIC, ROMPATCH, and MAX modules. The PAHBMUX performs address decoding (HSEL generation) for these slaves as well as read data muxing and hready generation.

See the *ARM1136 platform AHB MUXES Specification* for more detail.

38.7.24 Clock Control Module (CLKCTL)

The Clock Control Module (CLKCTL) module performs module level clock gating and provides reset synchronization for peripherals in the peripheral power domain. The CLKCTL module is also a 32-bit peripheral connected to AIPS A's on platform peripheral bus. The IP-Bus slave interface allows access to a general purpose control register and a general purpose status register. The signal interface for the general purpose registers is shown in Figure 38-5. Four of the general purpose control outputs, **clkctl_gp_ctrl[3:0],** are ported to the top-level of the ARM1136 platform. The upper twelve bits, **clkctl_gp_ctrl[15:4]**, are used internally and are not brought to the top-level. All of the general purpose status signals, **clkctl_gp_stat[7:0]**, are ported to the top-level of the ARM1136 platform.

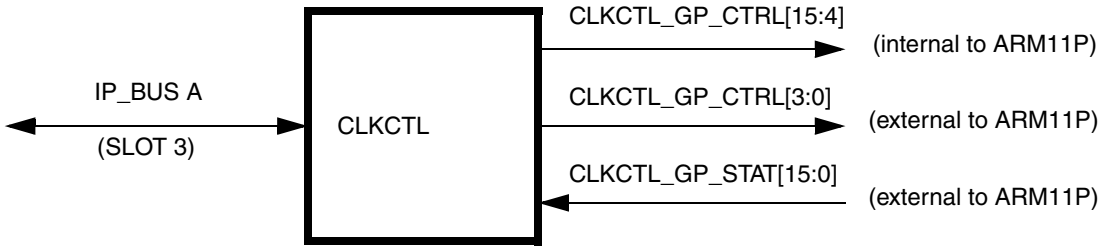

Figure 38-5. CLKCTL General Purpose Register Interface

38.7.25 CLKCTL Registers

The CLKCTL module is connected to IPBus A, slot 3 as a 32-bit peripheral. The registers residing in the CLKCTL module are shown in Table 38-13.

Table 38-13. CLKCTL Registers

AIPSA_ADDR[3:0]	Register Name	Register Definition	Width
5'h00	GP_CTRL	General Purpose Control Register	[15:0]
5'h04	GP_SER	Set Enable Register	[15:0]
5'h08	GP_CER	Clear Enable Register	[15:0]
5'h0C	GP_STAT	General Purpose Status Register	[15:0]
5'h10	L2_MEM_VAL	L2 Data Memory VAL Settings	[11:0]
5'h14	DBG_CTRL1T	Debug Control Register 1	[31:0]
5'h20	PLAT_ID	Platform version ID	[31:8]

38.7.25.1 GP_CTRL, GP_SER, and GP_CER Registers

The GP_CTRL register is a write-read register. All bits in the GP_CTRL are cleared on reset. All bits of the GP_CTRL register may be written concurrently by writing directly to the GP_CTRL register. However, to simplify software (prevent the need for a read-modify-write), a single bit may be set in the GP_CTRL register by writing a one to the relative bit location in the Set Enable Register (GP_SER). Similarly, writing a one to the relative bit location in the Clear Enable Register (GP_CER) clears the associated GP_CTRL bit. Reading the GP_SER or GP_CER registers will return all zeros.

Table 38-14 shows the functions of all bits in the CLKCTL module's general purpose control register.

Table 38-14. CLKCTL General Purpose Control Bit (GP_CTRL) Usage

GP_CTRL Register Bit	Reset Value	Description
[3:0]	0	Driven off-platform for use at SoC level.
[4]	0	When set, will enable the peripheral bus timeout monitors.See 38.7.16/38-15.
[5]	0	When set, this bit will enable clocks to the CTI module. Clocks to the CTI module are automatically issued when a debugger is connected (dbgen asserted). However, if it is desirable to enable cross trigger entry into debug mode prior to connecting a debugger, this bit must be set, and the **disable_trace** input must be negated. This bit should not be set in a non-debug mode environment.
[6]	0	When set, this bit will enable the clocks to the ETB. Clocks to ETB are automatically issued when a debugger is connected (**dbgen** asserted). However if system wants to use the ETB trace buffer as a general purpose memory, this bit must be set, and the **disable_trace** input must be negated. This bit should not be set in a non-debug mode environment if the ETB memory is not going to be used.
[7]	0	When set, enables few core signals (htransi, htransr, htransw, hransp and vfpabusy), to propagate through the platform boundary flip-flop. It also allows **a11p_clk_off** to assert (to allow the SOC to shut off **arm_clk** to the platform) even when the ARM1136 platform debug sticky bit is set, which would normally prevent the **a11p_clk_off** from asserting since **arm_clk** must run for debug activity to occur.
[8]	0	When set, this bit will enable module level clock gating of the L2CC. When low, module level clock gating of the L2CC is disabled.
[9]	1	Connected to AIPS A's aips_byte_config[0] input. The default setting ("1") is the intended use. This control bit is for flexibility only in case of a possible peripheral endian related bug. See 38.7.20.1/38-18.
[10]	1	Connected to AIPS B's aips_byte_config[0] input. The default setting ("1") is the intended use. This control bit is for flexibility only in case of a possible peripheral endian related bug. See 38.7.20.1/38-18.
[11]	0	Not Used

Table 38-14. CLKCTL General Purpose Control Bit (GP_CTRL) Usage (Continued)

GP_CTRL Register Bit	Reset Value	Description
[12]	1	This register bit enables the a11p_clk_off signal in the JSYNC
[15:13]	001	Not Used

38.7.25.2 GP_STAT Register

The GP_STAT register is read only. All bits are cleared on reset. Reading the GP_STAT register while reset is negated will return the values on the ARM1136 platform's **clkctl_gp_stat[15:0]** inputs.

38.7.25.3 L2_MEM_VAL Register

The L2_MEM_VAL register enables the user to modify the default value of the L2 data memory's "VAL" settings. The L2_MEM_VAL register is reset to the values on the **l2_rval_rst[3:0]**, **l2_rval2_rst[3:0]**, and **l2_wval_rst[3:0]** inputs. Subsequent to system reset, this register may be written to change the VAL settings driven to the L2 data memory. The register's bit assignments are shown in Table 38-15.

Table 38-15. L2_MEM_VAL Register Bit Assignments

L2_MEM_VAL Bit	Reset Value	Description
[3:0]	l2_rval_rst[3:0]	These bits are reset to the value of the l2_rval_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's RVAL inputs. After reset, these bit may be written by the user to modify the reset value.
[7:4]	l2_rval2_rst[3:0]	These bits are reset to the value of the l2_rval2_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's RVAL2 inputs. After reset, these bit may be written by the user to modify the reset value.
[11:8]	l2_wval_rst[3:0]	These bits are reset to the value of the l2_wval_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's WVAL inputs. After reset, these bit may be written by the user to modify the reset value.
[12]	l2_val_offset_rst	Controls the VAL_OFFSET parameter in the level 2 cache RAM.
[31:11]	Unimplemented	Unspecified.

38.7.25.4 Debug Control Register

The DBG_CTRL1 register, shown in Table 38-16 is a read-write register. All bits are cleared on reset. This register can be written and read in supervisor mode only. Reads in user mode return all zeroes.

Table 38-16. CLKCTL Debug Control Bit (DBG_CTRL1) Usage

DBG_CTRL Register Bit	Reset Value	Description
[4:0]	0	Not Used
TOMS [5]	0	Controls trigger output multiplexors in the ECTCTI wrapper.

Table 38-16. CLKCTL Debug Control Bit (DBG_CTRL1) Usage

DBG_CTRL Register Bit	Reset Value	Description
[6:7]	0	Not Used
TOMS [11:8]	0	Controls trigger output multiplexors in the ECTCTI wrapper.
TIMS [13:12]	0	Controls trigger input multiplexors in the ECTCTI wrapper.
[15:14]	0	Not Used
TIMS [19:16]	0	Controls trigger input multiplexors in the ECTCTI wrapper.
[23:20]	0	Not Used
EPS [24]	0	ETM11 ext_etm_extin3 Pulse Select
[32:25]	0	Not Used

38.7.25.5 Platform ID Register

The PLAT_ID register, shown in Table 38-17, is read only. All bits are set to an appropriate ID value on reset. Reading the PLAT_ID register while reset is negated returns the values programmed into that particular version of the ARM1136 platform.

Table 38-17. CLKCTL Platform ID (PLAT_ID) Usage

PLAT_ID Register Bit	Reset Value	Description
[7:0]	0000_0000	Not Used
ECO[15:8]	0000_0000	Enumerates ECO changes to the platform
MINOR[23:16]	0000_0000	Enumerates minor changes (bug fixes, I/O changes) to the platform
IMPL[27:24]	0000	Enumerates implementation changes to the platform
SPEC[31:28]	0101	Enumerates major changes (module or architectural) to the platform

38.7.26 JTAG Synchronization Module (JSYNC)

The JTAG Synchronization Module (JSYNC) will synchronize the external JTAG interface to the ARM1136's clock (**arm_clk**). The inputs and outputs of the synchronization circuit will be connected to the JTAG interface on the ARM1136, ETM11, and ETB11 modules. The standard ARM1136 JTAG synchronization circuit will be used. The JSYNC module will also perform any synchronization requirements for CPU domain resets. In addition, the JSYNC module will monitor the ARM1136's DR and DW AHB HADDR[31:28] bits in order to decode the HSELRS1 and HSELRS2 inputs to the L2CC module. These inputs will assert on accesses to the L2CC configuration registers.

The JSYNC also does clock gating for modules in the CPU power domain. Finally the JSYNC block contains a sticky bit that is set whenever the JTAG state machine leaves test logic reset or a debug request is asserted. This sticky bit is cleared with power-on reset or JTAG test. When the sticky bit is set,

a11p_clk_off will not assert when in standbywfi mode unless CLKCTL **gp_ctrl[7]** in clock control module is set.

38.7.27 ARM1136JF-S Embedded Trace Macrocell (ETM11)

The Embedded Trace Module (ETM11) is directly connected to the ARM1136's ETM interface and provides real time trace debug capability. ETM11 is capable of both instruction and data tracing. ETM11 provides a trace protocol that is an integral part of the ARM Real Time Debug solution (*RealView*). Real time tracing is controlled by specifying a set of triggering and filtering resources which include address and data comparators, counters, and sequencers. Figure 38-6 shows the main functional blocks and external interfaces of the ETM11 module.

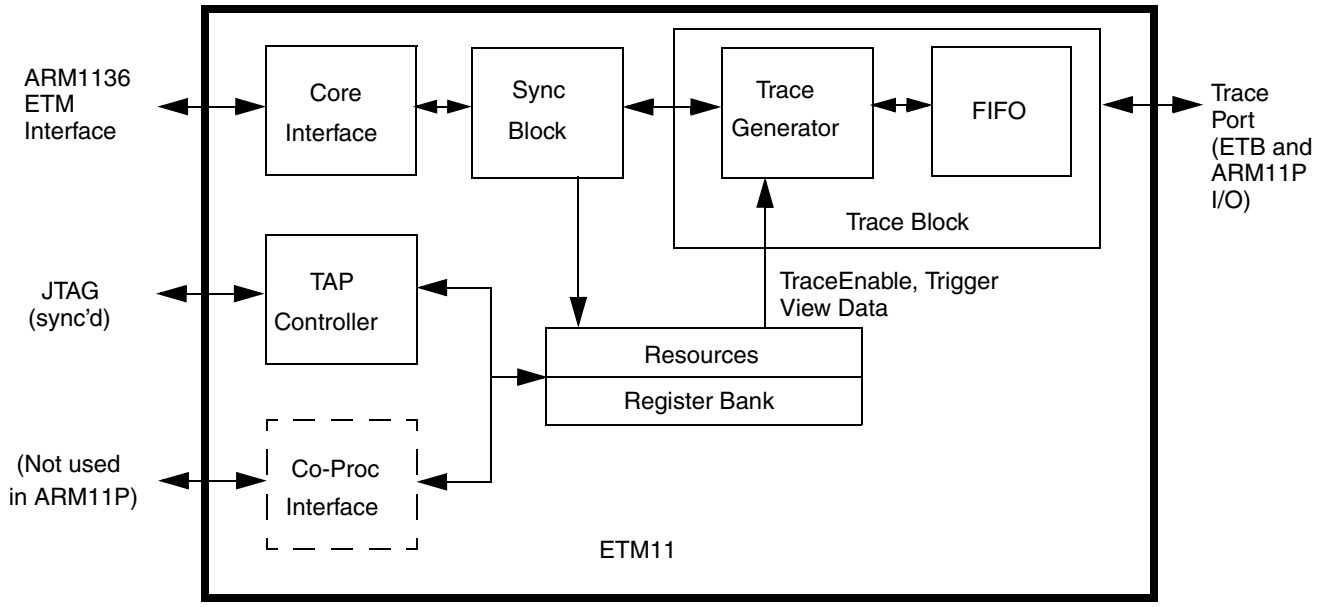

Figure 38-6. ETM11 Functional Block Diagram

The ETM11 is delivered with a fixed FIFO size (69 bytes) optimized for use with the Embedded Trace Buffer (ETB). The trace data packet width is selectable at 4/8/16/24/32 using the ETM control register. ETM11 supports two data comparators and 4 pairs of address comparators.

Trace port timing is a critical issue and the way in which ARM Ltd. named the port modes is not intuitive. The ETM11 supports only 3 modes: dynamic, 1:2 and 1:4. Dynamic is used for on-chip trace (ETB11). 1:2 and 1:4 modes refer to the traceport data to ARM_CLK ratio, not the ARM_CLK to TRACECLK ratio. The 1:2 mode corresponds to a 1:4 clock ratio; the 1:4 mode corresponds to a 1:8 clock ratio.

The system metrics module within ARM1136 can be used to count events, such as cache hits for example, and indicate such events on the ARM1136's **eventus[19:0]** outputs. The ETM11 can then be configured to monitor these events and use them as additional trace filters. Alternately, the ARM1136 system metrics unit can count the two ETM11 outputs as additional inputs.

See ARM's *ETM11 Technical Reference Manual* and *Embedded Trace Macrocell Architecture Specification* for more detailed information.

38.7.28 Embedded Trace Buffer (ETB11)

The ETB11 module, or Embedded Trace Buffer, stores trace data from the trace port of the ETM11 module. The buffered data can then be accessed via the JTAG interface or through the ETB11's slave interface on the IP-bus. Providing an on-chip buffer alleviates the pin count, bandwidth, and pad design requirements associated with sending trace data to a debugger directly through package pins in a real-time fashion. The ETB11 is designed with a standard compiled RAM interface. The ARM1136 platform has implemented a 4-Kbyte compiled memory for the trace buffer. The 4-Kbyte buffer can be used by the system as a general purpose memory, however the clocks must be manually enabled if the platform is not in debug mode. To simplify Endian issues, the ETB module only supports 32-bit accesses to the 4-Kbyte buffer. The access time of the ETB memory over the IP-bus is 7 per_clks for both writes and reads. The 4-Kbyte ETB memory begins at address 32'h43F1_4000. Figure 38-7 shows a simplified block diagram of the main functional blocks and external interfaces of the ETB11 module.

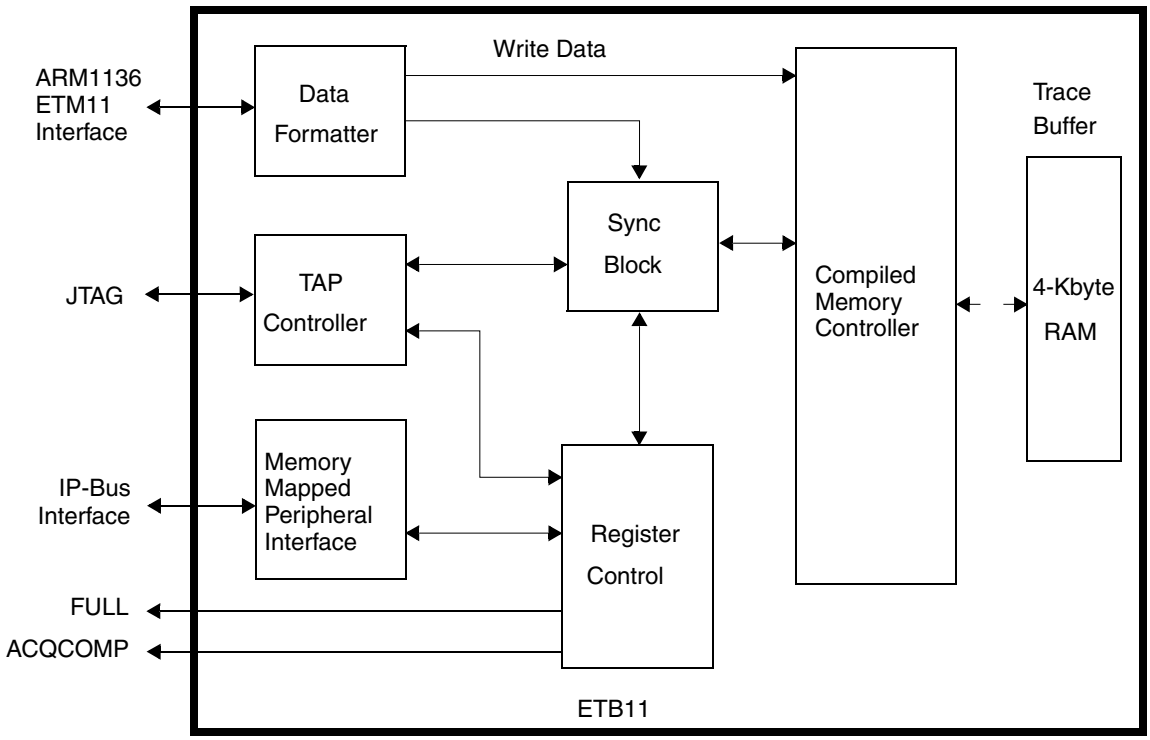

Figure 38-7. ETB11 Functional Block Diagram

See ARM's *ETB11 Technical Reference Manual* for more detailed information.

38.7.29 Embedded Cross-Trigger (ECT)

The ECT module, or Embedded Cross-Trigger, passes debug events from one processor to another. For example, the ECT can be programmed to allow communication of debug state information from one core to another so that program execution on both processors can be stopped at the same time. The ECT module contains two main components: the CTI (Cross Trigger Interface) unit provides a common programmers model for use by the debug tools, controls the trigger sources, and interfaces to the CTM component. The CTM (Cross Trigger Matrix) combines the trigger requests from the CTI's and broadcasts them to all other CTI's as triggers, enabling one CPU to trigger with another. Figure 38-8 shows a simplified block diagram of the main functional blocks and external interfaces of the ECT module.

38.7.30 ECT Implementation in the ARM1136 Platform

For SoC partitioning reasons, only a single CTI of the ECT module (CTI0) will be instantiated on the platform, as shown in blue shade in Figure 38-8. The full ECT design is shown for completeness and to understand how the ARM1136 platform communicates cross-trigger information with other processors.

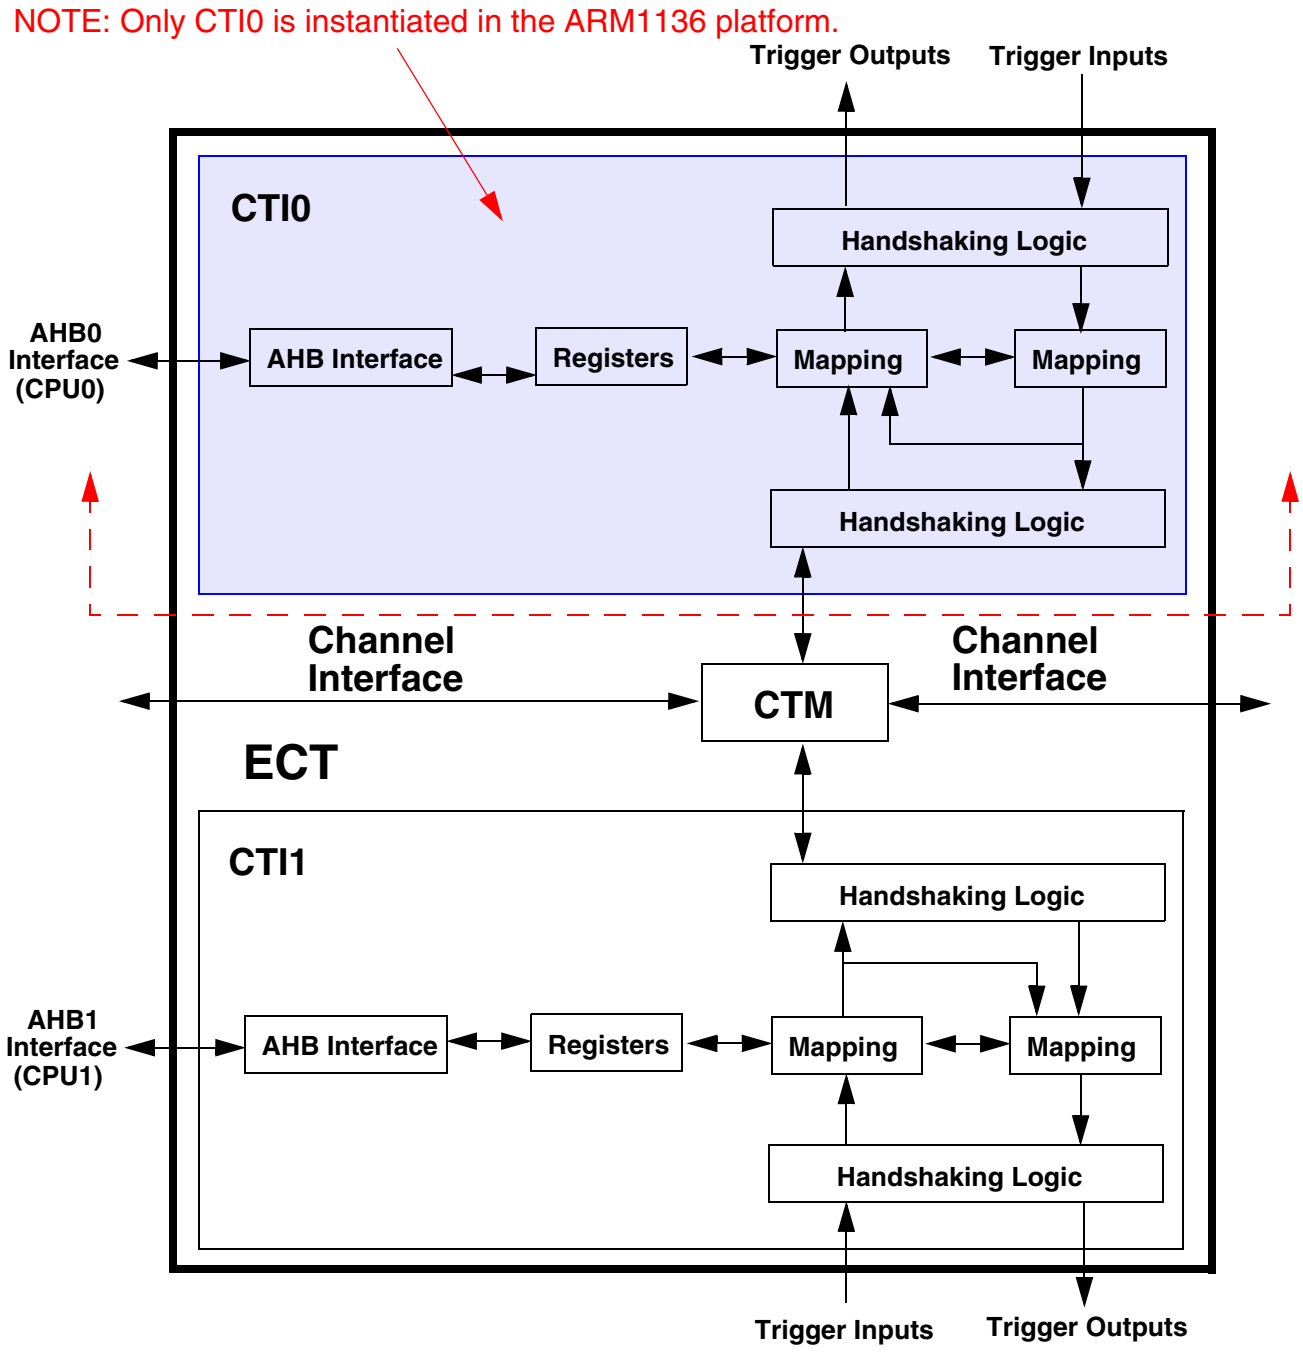

Figure 38-8. ECT Functional Block Diagram

See ARM's *ECT Technical Reference Manual* for more detailed information.

38.7.31 Common Platform Design Hierarchy

The first two levels of the ARM11 platform hierarchy, called the **arm11p_platform.v**, is shown in Figure 38-9.

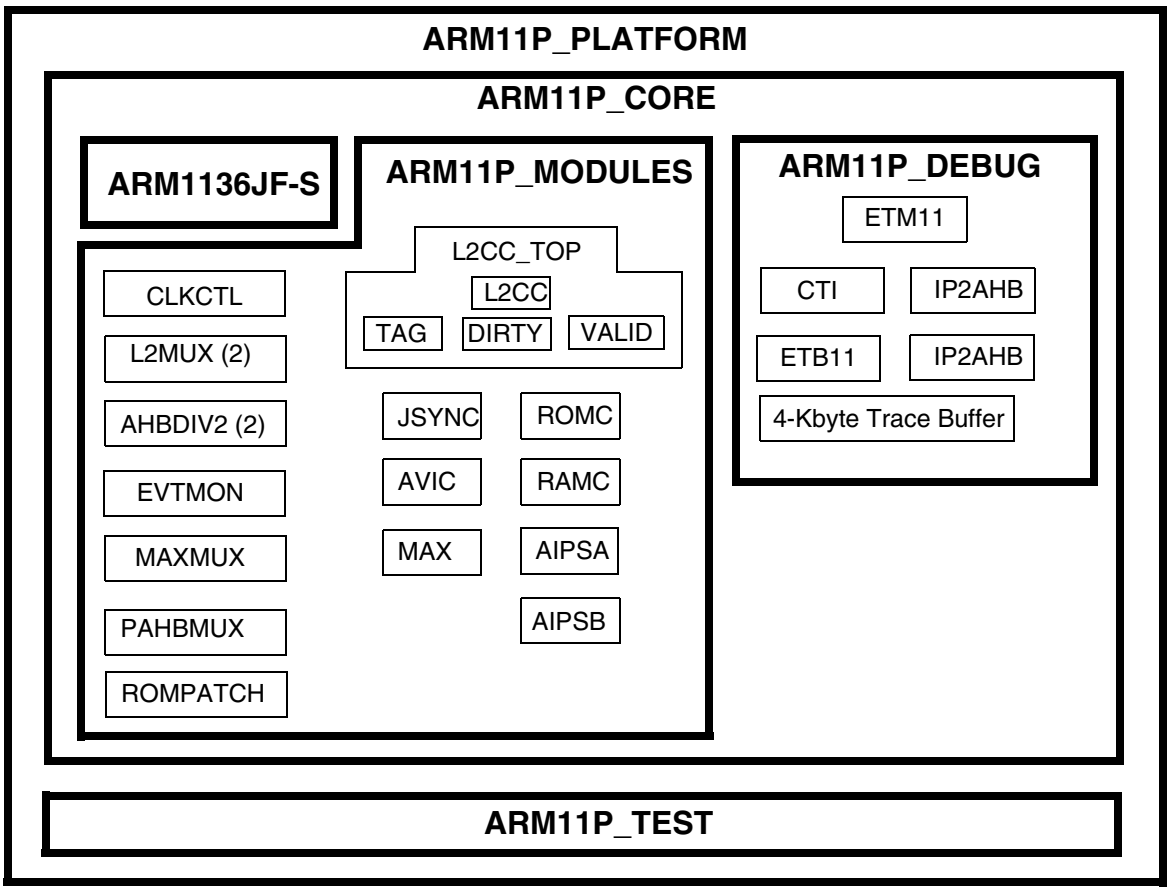

Figure 38-9. Common Platform: arm11p_platform.v Hierarchy

38.7.32 ARM11P_PLATFORM_128K.v

The common **arm11p_platform.v** will be combined with the 128-Kbyte L2 cache data arrays to form the **arm11p_platform_128k.v** deliverable shown in Figure 38-10.

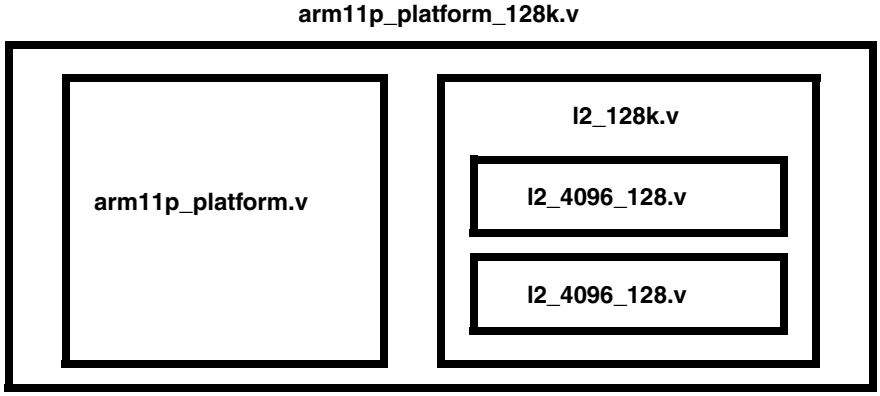

Figure 38-10. The arm11_platform_128k.v Hierarchy

38.8 Security Summary

The ARM1136 platform works in conjunction with a variety of components and mechanisms, some of which are external to the platform, to address security concerns. These are summarized here:

- ARM1136JF-S MMU
- AIPS Peripheral Access Control Registers
- AHB hmaster[3:0] Encoding
- disable_trace input to halt external instruction and data tracing via ETM11
- Secure JTAG (external to platform)
- Security Controller Module (SCC) - external to platform

38.9 System Memory Map

This section provides the ARM1136 platform memory map.

38.9.1 ARM1136 Platform Memory Map

The ARM1136 platform address decoding needs to be very fast in order to meet the aggressive performance goals. Table 38-18 shows a high level view of the platform's memory map. Only the top four address bits are needed for **hsel** decoding.

Table 38-18. ARM1136 Platform High Level Address Map

Addr[31:28]	Size	Usage
0000	256 Mbytes	ROM
0001	256 Mbytes	RAM

Table 38-18. ARM1136 Platform High Level Address Map (Continued)

Addr[31:28]	Size	Usage
0010	256 Mbytes	MAX S0
0011	256 Mbytes	L2CC Configuration Registers
0100	256 Mbytes	AIPS A
0101	256 Mbytes	AIPS B
0110	256 Mbytes	ROMPATCH, AVIC
0111	256 Mbytes	MAX S2
1xxx	2 Gbytes	MAXS1 or L2CC(0 or 1)[1]

[1]If the **l2cc_max_only** input is low, accesses to this region can be steered to either L2CC0 or L2CC1, depending on L2CC internal functionality. If the **l2cc_max_only** input is high, accesses to this region will be steered to the MAX, and NOTE 1. above is applicable.

The detailed memory map is shown in Table 38-19.

Table 38-19. ARM1136 Platform Detailed Memory Map

Address Range	Size	Destination
0x0000_0000 - 0x000F_FFFF	1 Mbytes	ROMC (16 Kbyte Secure ROM[1])
0x0010_0000 - 0x0FFF_FFFF	255 Mbytes	ROMC (transfer error based on ROM_SIZE[2])
0x1000_0000 - 0x1FFF_FFFF	256 Mbytes	RAMC (Aliased based on RAM_SIZE)
0x2000_0000 -0x 2FFF_FFFF	256 Mbytes	MAX S0
0x3000_0000 - 0x3FFF_FFFF	256 Mbytes	L2CC Configuration Registers[3]
0x4000_0000 - 0x41FF_FFFF	32 Mbytes	AIPS A Off platform global module enable #0
0x4200_0000 - 0x43EF_FFFF	31 Mbytes	AIPS A Off platform global module enable #1
0x43F0_0000 - 0x43F0_3FFF	16 Kbytes	AIPS A Control Registers (on platform slot 0)
0x43F0_4000 - 0x43F0_7FFF	16 Kbytes	AIPS A - MAX Registers (on platform slot 1)
0x43F0_8000 - 0x43F0_BFFF	16 Kbytes	AIPS A - EVTMON (on platform slot 2)
0x43F0_C000 - 0x43F0_FFFF	16 Kbytes	AIPS A - CLKCTL (on platform slot 3)
0x43F1_0000 - 0x43F1_3FFF	16 Kbytes	AIPS A - ETB Registers (on platform slot 4)
0x43F1_4000 - 0x43F1_7FFF	16 Kbytes	AIPS A - ETB Memory (on platform slot 5)
0x43F1_8000 - 0x43F1_BFFF	16 Kbytes	AIPS A - ECT CTI0 (on platform slot 6)
0x43F1_C000 - 0x43F2_BFFF	64 Kbytes	Reserved
0x43F2_C000 - 0x43F7_FFFF	336 Kbytes	**Reserved** (AIPS A Unused on platform slots[31:11])
0x43F8_0000 - 0x43FB_FFFF	256 Kbytes	AIPS A Off platform slots [15:0]
0x43FC_0000 -0x43FF_FFFF	256 Kbytes	**Reserved** (Unused AIPS A Off Platform Slots**)**
0x4400_0000 - 0x4FFF_FFFF	192 Mbytes	**Reserved** (Aliased AIPS A Space)
0x5000_0000 - 0x51FF_FFFF	32 Mbytes	AIPS B Off platform global module enable #0

Table 38-19. ARM1136 Platform Detailed Memory Map (Continued)

Address Range	Size	Destination
0x5200_0000 - 0x53EF_FFFF	31 Mbytes	AIPS B Off platform global module enable #1
0x53F0_0000 - 0x53F0_3FFF	16 Kbytes	AIPS B Control Registers (on platform slot 0)
0x53F0_4000 - 0x53F7_FFFF	496 Kbytes	**Reserved** (AIPS B on platform slots [31:1])
0x53F8_0000 - 0x53FF_FFFF	512 Kbytes	AIPS B Off platform slots [31:0]
0x5400_0000 - 0x5FFF_FFFF	192 Mbytes	**Reserved** (Aliased AIPS B Space)
0x6000_0000 - 0x67FF_FFFF	128 Mbytes	ROMPATCH (Aliased throughout the 128-Mbyte region)[4]
0x6800_0000 - 0x6FFF_FFFF	128 Mbytes	AVIC (Aliased throughout the 128-Mbyte region)[5]
0x7000_0000 - 0x7FFF_FFFF	256 Mbytes	MAX S2
0x8000_0000 - 0xFFFF_FFFF	2 Gbytes	MAX S1 or L2CC(0 or 1)[6]

1 A transfer error is asserted on accesses above 0x0000_03FFF.

2 A transfer error is asserted on accesses above the hardware configured size (ROM_SIZE) of the ROM. A transfer error is also asserted between 0x0010_0000 and 0x0040_3FFF.

3 For Alternate Bus Master this area is reserved

4 For Alternate Bus Master this area is reserved

5 For Alternate Bus Master this area is reserved

6 If the **l2cc_max_only** input is low, accesses to this region can be steered to either L2CC0 or L2CC1, depending on L2CC internal functionality. If the **l2cc_max_only** input is high, accesses to this region will be steered to the MAX, and NOTE 1. above is applicable.

38.9.2 Peripheral Port Remap Register

The PPMRR in the ARM1136 CPU, could be programmed to 0x4000_0014 or 0x4000_0015 for the ARM1136 platform. These values corresponds to a base address of 0x4000_0000 with total peripheral region of 512 Mbytes and 1 Gbyte, respectively.

With a 512-Mbyte region separate peripheral page table entries will be needed for the AVIC and ROMPATCH modules as it falls outside of the 0x4000_0000-5FFF_FFFF region defined by the PPMRR=0x4000_0014.

With 1-Gbyte region, 0x4000_0000 - 0x7FFF_FFFF address space will be available for Peripheral Port, which will incorporate ALL peripheral space with the drawback of encompassing MAX port S2 as well. This would work quite well if a peripheral of some sort were residing on MAX port S2. However, it would be a problem if memory was connected to MAX port S2, and it was desirable for it to be cacheable.

Designers should be aware that the L2CC registers are addressed over the L2 interface, not the Peripheral AHB.

38.10 Clocks

The ARM11 platform is divided into 2 clock domains: **arm_clk** and **per_clk**, as shown in Figure 38-11. The ARM11, L2CC, EVTMON, ETM11, ETB11, ECT, and JSYNC modules will run on **arm_clk**, as

shown in red. The rest of the ARM11 platform, including the ARM11 P_AHB and master side of the L2CC, will run at the **per_clk** frequency, as shown in green.

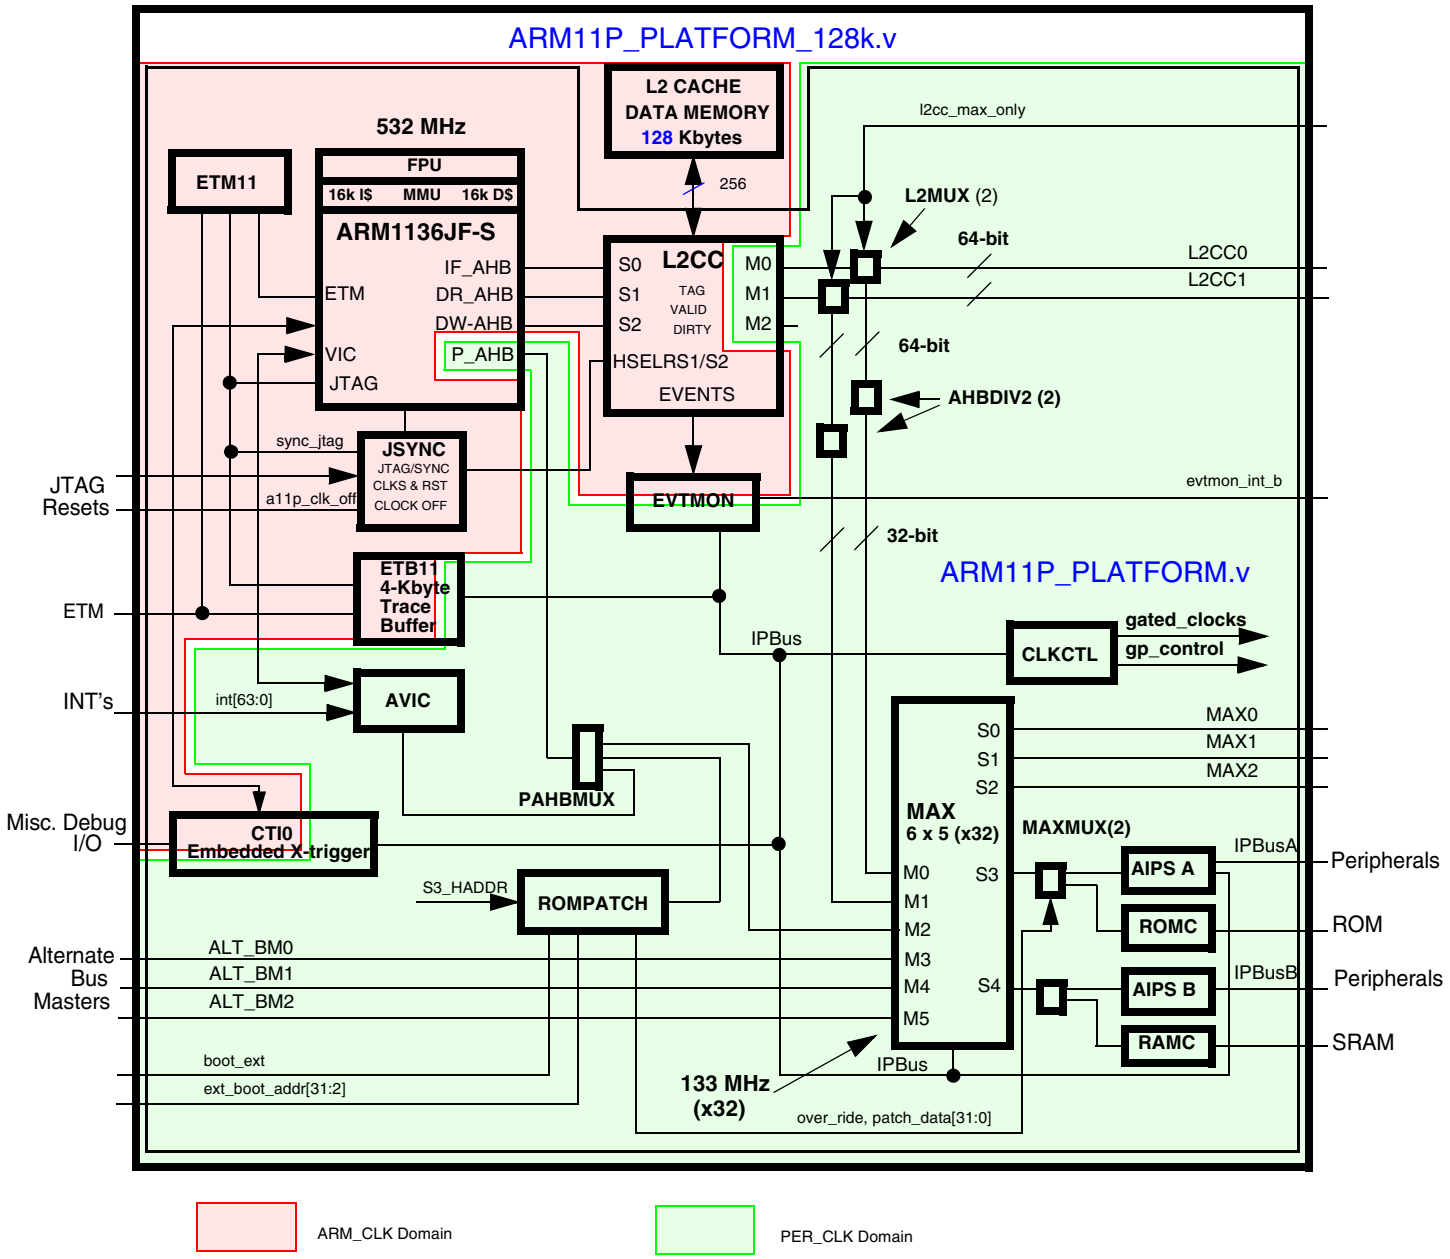

Figure 38-11. ARM11 Platform Clock Domains

38.10.1 Clocking Strategy

The clocking strategy of the ARM11 platform can be summarized by the following bullets:

- The ARM11 platform, in conjunction with an external Clock Control Module (CCM), will support dynamic clock frequency scaling.

- The ARM11 platform will receive two clocks from the CCM: **arm_clk** and **per_clk**.
- The frequencies of **arm_clk** and **per_clk** may be the same, or integer multiples of one another. In all cases, the **arm_clk** and **per_clk** clocks will be rising edge aligned.
- The L2CC slave interface and L2CC memory interface will always run in a 1:1 ratio with respect to **arm_clk**. The L2CC master interface will always run at the **per_clk** frequency.
- Two-level clock gating will be employed.
  - Module level clock gating will be used when possible. A specific module's **per_clk** will be gated off at the top-level by the CLKCTL module when the module is not in use. **arm_clk** gating will be performed by the JSYNC module.
  - Register level clock gating will be used throughout the platform via power compiler.
- Clocks may be turned off for various low-power use cases by an external clock control module.

38.10.2 ARM1136 Power Down Procedures

See the *ARM1136 Technical Reference Manual* chapter 10.

Chapter 39
NAND Flash Controller (NFC)

This chapter describes the NAND Flash controller (NFC) module implemented on this device, and provides information on the following topics:

39.1 Overview

The NFC provides the system’s interface to standard NAND Flash devices, and hides the complexities of accessing the NAND Flash. It provides a glueless interface to 8-bit and 16-bit NAND Flash parts, with page sizes of 512 bytes, 2 Kbytes or 4 Kbytes.

Figure 39-1 shows a block diagram of the NFC, which is composed of various control logic units and a 4.5-Kbyte internal RAM buffer.

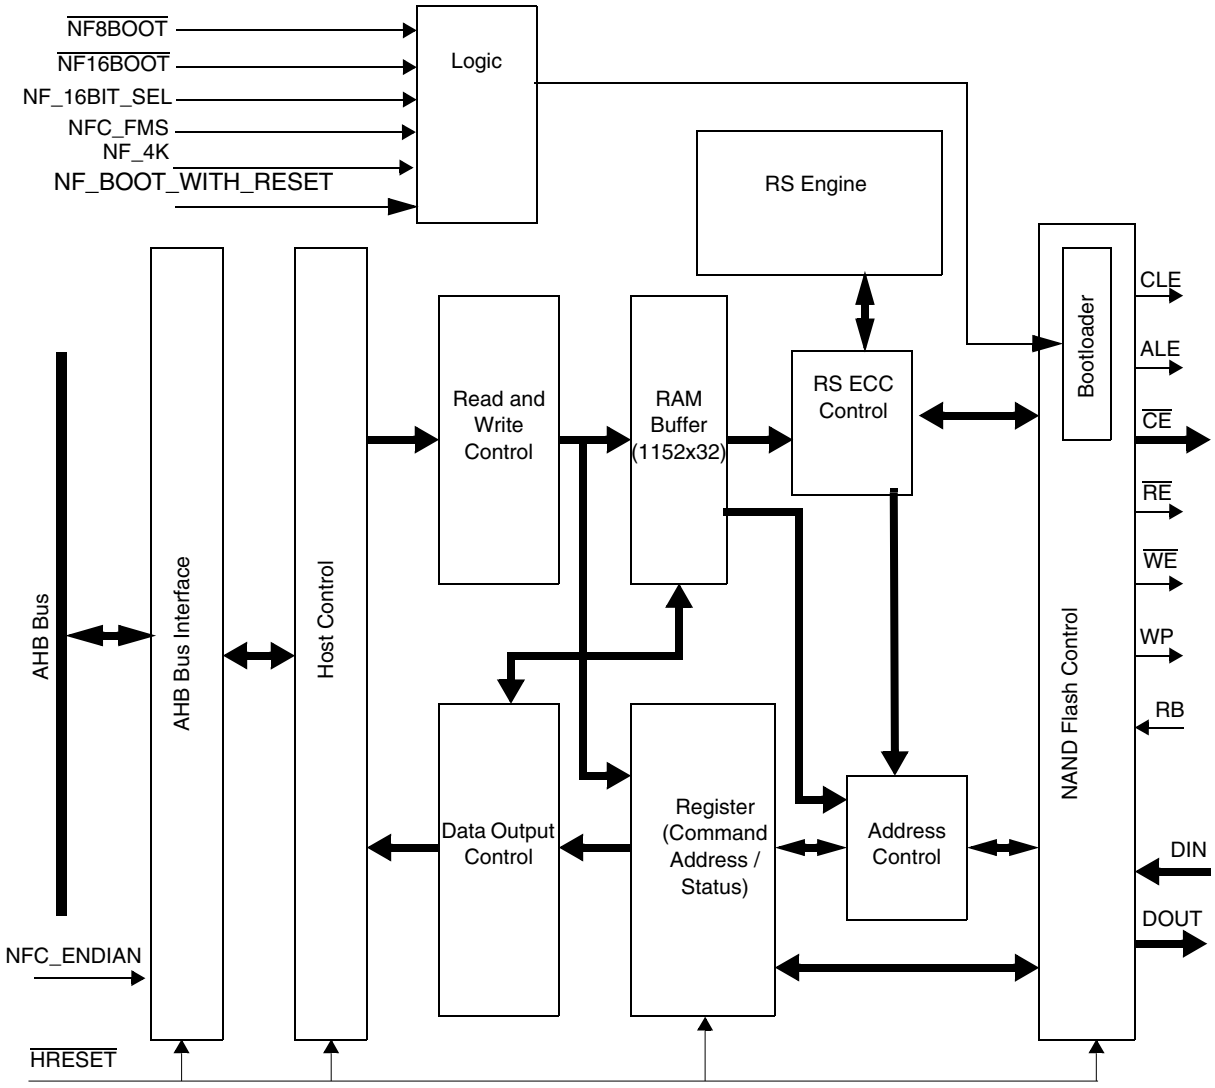

Figure 39-1. NAND Flash Controller Block Diagram

39.1.1 Features

The NAND Flash controller (NFC) includes the following features:

- x8/x16 (pin-configurable) NAND Flash interface
- Internal RAM buffer (4 Kbytes + 512 bytes)
  - Can be configured as Boot RAM
  - Operates as a buffer during normal operation
  - Registers and internal RAM buffer are memory-mapped to the same AHB region
- Manual interface with NAND Flash devices

  - Supports all NAND Flash products of up to 64-Kbyte blocks (for instance, NFC supports single-level cell (SLC) NAND Flash devices with 512 bytes per page, 16 Kbytes per block, and memory size up to 8 Gbits)
  - Supports SLC NAND Flash devices with 2 Kbytes per page, 128 Kbytes per block, and memory size up to 64 Gbits
  - Supports multi-level cell (MLC) NAND Flash devices with 4 Kbytes per page, 512 Kbytes per block, and memory size up to 256 Gbits
- Supports MLC NAND with two options for Reed-Solomon error correction (configurable):
  - Corrects four 9-bit symbol errors in 528 bytes (512 main bytes + 16 bytes spare)
  - Corrects eight 9-bit symbol errors in 538 bytes (512 main bytes + 26 bytes spare)
- Advanced high-performance bus (AHB) host interface:
  - Supports read and write bursts
  - Supports 16-bit or 32-bit bus transfers
- Supports DMA requests for page read, section read and other read operations.
- Supports error correction (ECC) mode and ECC mode bypass
- Supports multiple reset (reset of NFC and NAND Flash device)
- Internal boot code loader during power-up provides advanced data protection (can be enabled or disabled)
  - Data protection
  - RAM buffer write-protect mode provides write protection for the lower 2 Kbytes of RAM buffer) (see Section 39.4.3.6, “Controller Status and Result of Flash Operation Register 2 (ECC_STATUS_RESULT2)”).
  - Write-protect mode for NAND Flash devices provides block-based write protection of NAND Flash
- Automatic write protection for RAM buffer and NAND Flash during power-up, in addition to run-time write protection modes for both the RAM buffer and the NAND Flash device.
- Handshaking feature: INT pin indicates ready/busy status of NFC
- Special arbitration logic enables sharing of I/O pins with other memory controllers

39.1.2 Modes of Operation

The NFC has several modes of operation that correspond to different boot, page size, and I/O bus width configurations. The mode of operation is determined by five input signals: NFC_FMS, NF_4K, NF8BOOT, NF16BOOT, NF_16BIT_SEL. See Section 39.5.2, “Modes of Operation,” for more details.

39.2 External Signal Description

This section describes the NFC external signals.

39.2.1 Overview of Signals

The following signals shown in Table 39-1 are used to configure and control the NFC and its attached Flash device.

Table 39-1. NFC Signal Properties

Name	Abbreviation	Function	I/O	Reset
HCLK_IN	—	AHB clock.	I	enable
$\overline{\text{HRESET}}$	—	WARM reset (active low)	I	0
$\overline{\text{IPI\_INT\_NFC}}$	—	NAND Flash controller interrupt	O	1
IPP_FLASH_CLK	—	Clock for the Flash side	I	enable
IPP_NFC_ALE_OUT	ALE#	Flash address latch enable	O	0
IPP_NFC_CE*n*_OUT	CE#	Flash #*n* chip enable (*n* = 0,1,2,3)	O	1
IPP_NFC_CLE_OUT	CLE#	Flash command latch enable	O	0
IPP_NFC_RB_IN	RB	Flash ready/busy	I	1
IPP_NFC_RE_OUT	RE#	Flash read enable	O	1
IPP_NFC_READ_DATA_IN [15:0]	—	NFC data input from the NAND Flash	I	
IPP_NFC_WE_OUT	WE#	Flash write enable	O	1
IPP_NFC_WP_OUT	WP#	Flash write protect	O	1
IPP_NFC_WRITE_DATA_OUT [15:0]	—	NFC data output towards the NAND Flash	O	0000
$\overline{\text{IPP\_RESET}}$	—	Power on reset for booting	I	1
NF_16BIT_SEL	—	Use 8 or 16-bits NAND Flash	I	0
$\overline{\text{NF8BOOT}}$	—	Boot from 8-bit NAND Flash	I	1
NFC_FMS	—	Flash memory select (512-byte / 2-Kbyte page)	I	0
NF_4K	—	Flash device is a 4-Kbyte page device	I	0
$\overline{\text{NF16BOOT}}$	—	Boot from 16-bit NAND Flash	I	1
NF_BOOT_WITH_RESET	—	Perform reset command before boot sequence	I	—

39.2.2 Detailed Signal Descriptions

Table 39-2 gives detailed descriptions of the NFC external signals.

Table 39-2. NFC Detailed Signal Descriptions

Signal (Signal Abbreviation)	I/O	Description
HCLK_IN	I	AHB clock input. This is the clock signal for the NFC, which arrives from the AHB side. Its frequency can be up to 133 MHz.
$\overline{\text{HRESET}}$		Warm reset. This signal produces a warm reset, causing the NFC and the NAND Flash device to cease current operation, and set all internal registers to their default state. See Figure 39-2 for a timing diagram of the reset operation. The AHB bus interface is connected directly to this signal, and will cause a reset immediately when this line goes to low state. Warm reset has no effect on the contents of main/spare area buffers.
$\overline{\text{IPI\_INT\_NFC}}$	O	NFC interrupt. This output is the NFC interrupt, and is asserted to low when an NFC event takes place. In addition, it is asserted to low when any of the following occur: • NAND Flash command input • NAND Flash address input • NAND Flash data input • NAND Flash data output The signal returns to high when basic operation and boot loading is done, or when a warm or hot reset is released.
IPP_FLASH_CLK		This clock signal controls the NAND Flash controller's state machine when interfacing with a NAND Flash device. Maximum supported clock frequency is 50 MHz.
IPP_NFC_ALE_OUT (ALE#)	O	Flash address latch enable. The ALE# output controls the activating path for addresses sent to the address register of NAND Flash (NAND_FLASH_ADD). When active high, addresses are latched into the NAND FC address register of NAND Flash through the I/O ports on the rising edge of the WE# signal.
IPP_NFC_CE*n*_OUT(*n* = 0…3) (CE#)	O	Flash #*n* chip enable (*n* = 0…3). This signal indicates the NAND Flash selection. When the NAND Flash device is in the Busy state, or when the NAND Flash device is accessed, this signal is low.
IPP_NFC_CLE_OUT (CLE#)	O	Flash command latch enable. The CLE# output controls the activating path for commands sent to the command register of NAND Flash (NAND_Flash_CMD). When active high, commands are latched into the command register of NAND Flash through the I/O ports on the rising edge of the IPP_NFC_WE_OUT (WE#) signal.
IPP_NFC_RB_IN (RB)	I	Flash ready/busy. This signal indicates the status of the NAND Flash operation. When low, it indicates that a program, erase, or random read operation of NAND Flash is in process. Upon completion of the process, this signal returns to high state. This signal is connected to an open drain output, via a 100 KΩ pull-up resistor that is outside the external NAND Flash memory device.
IPP_NFC_READ_DATA_IN[15:0]	I	The AHB host uses this 16-bit signal to read data from registers or from internal memory.
IPP_NFC_RE_OUT (RE#)	O	Flash read enable. This output is the NAND Flash device serial data output control. When active, this signal drives the data from the NAND Flash device onto the NAND Flash I/O bus, allowing the NFC to read the data. When reading a burst from the NAND Flash device, this signal increments the NAND Flash internal column address counter by one.

Table 39-2. NFC Detailed Signal Descriptions (Continued)

Signal (Signal Abbreviation)	I/O	Description
IPP_NFC_WE_OUT (WE#)	O	Flash write enable.This output controls writes to the NAND Flash I/O port, thus allowing the NAND Flash device to read data. Commands, address and data are latched on the rising edge of this signal.
IPP_NFC_WP_OUT (WP#)	O	Flash write protect. This signal provides inadvertent program/erase protection during power transitions and is automatically controlled by NFC. This pin status is only active (held low) during power-up.
IPP_NFC_WRITE_DATA_OUT [15:0]	O	The AHB host uses this 16-bit signal to write data to registers or to internal memory.
IPP_RESET_B	I	This input is the power on reset (POR) signal in the NFC. When asserted, a POR takes place.
$\overline{\text{NF8BOOT}}$, $\overline{\text{NF16BOOT}}$, NF_16BIT_SEL		The $\overline{\text{NF8BOOT}}$ and $\overline{\text{NF16BOOT}}$ are boot signals that determine whether the chip will boot from the NAND Flash device. They are also used to control the external bus width of the NAND Flash (8 bit or 16 bit). If either of the boot inputs is asserted (that is, either $\overline{\text{NF8BOOT}}$ or $\overline{\text{NF16BOOT}}$ is low) at System Power-On reset (IPP_RESET_B rising edge), a 4-Kbyte boot code is copied from the NAND Flash device to the RAM buffer. If neither of the two boot signals are asserted, then the input signal NF_16BIT_SEL is read to help determine the operating mode of the NFC. See Section 39.5.2, “Modes of Operation” for more details. **Note:** The boot signals should remain at the same value before and after the boot process.
NF_BOOT_WITH_RESET	I	Perform a reset command (0xFF), before automatic boot load.
NFC_FMS, NF_4K	I	Flash memory select. The NFC_FMS and NF_4K signals indicates the size of the NAND Flash page (512 bytes, 2 Kbytes, or 4Kbytes). 00 NAND Flash page size is 512 bytes. 10 NAND Flash page size is 2 Kbytes. 01 NAND Flash page size is 4 Kbytes. 11 NAND Flash page size is 4 Kbytes.

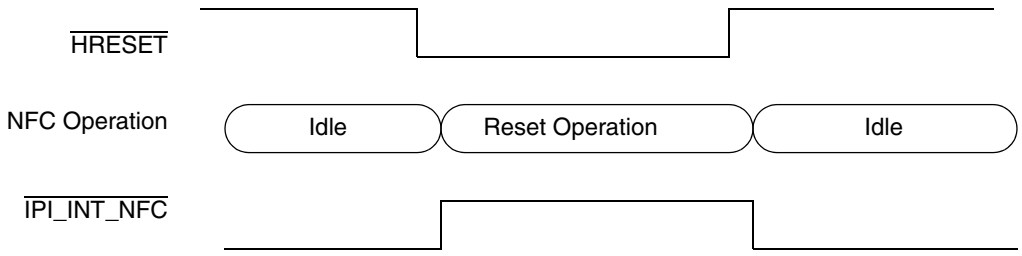

Figure 39-2. Reset Operation Timing

39.3 NFC Buffer Memory Space

Table 39-3 shows the organization of the buffer memory space in the NFC.

Table 39-3. Data (Buffer) Organization in Memory

Address	Use	Access
0x0000–0x01FE	Main area buffer 0	R/W
0x0200–0x03FE	Main area buffer 1	R/W
0x0400–0x05FE	Main area buffer 2	R/W
0x0600–0x07FE	Main area buffer 3	R/W
0x0800–0x09FE	Main area buffer 4	R/W
0x0A00–0x0BFE	Main area buffer 5	R/W
0x0C00–0x0DFE	Main area buffer 6	R/W
0x0E00–0x0FFE	Main area buffer 7	R/W
0x1000–0x103E	Spare area buffer 0	R/W
0x1040–0x107E	Spare area buffer 1	R/W
0x1080–0x10BE	Spare area buffer 2	R/W
0x10C0–0x10FE	Spare area buffer 3	R/W
0x1100–0x113E	Spare area buffer 4	R/W
0x1140–0x117E	Spare area buffer 5	R/W
0x1180–0x11BE	Spare area buffer 6	R/W
0x11C0–0x11FE	Spare area buffer 7	R/W
0x1200–0x1BFE	Reserved	—
0x1E00–0x1E1C	Registers	R/W

39.3.1 Main and Spare Area Buffers

The main area buffer is a general data block. The spare area buffer is used for a variety of functions, including error correction. All spare area buffers 0–7 have the same organization, which is shown in Table 39-4. The host can use all of the spare area except for the area occupied by the ECC code: so for example, the AHB host can write data to a reserved area of the spare area buffer during a program operation.

Table 39-4. Spare Area Buffer Organization

Spare Buffer Base Address Offset	F	E	D	C	B	A	9	8	7	6	5	4	3	2	1	0
0x1000	2nd logical sector number (LSN)								1st logical sector number (LSN)							
0x1002	1st wrap count (WC)[1]								3rd logical sector number (LSN)							
0x1004	Bad block information (BI)								2nd wrap count (WC)[1]							

Table 39-4. Spare Area Buffer Organization (Continued)

Spare Buffer Base Address Offset	F	E	D	C	B	A	9	8	7	6	5	4	3	2	1	0
0x1006	RS ECC code for main and spare area data (1st)								Reserved							
0x1008	RS ECC code for main and spare area data (3rd)								RS ECC code for main and spare area data (2nd)							
0x100A	RS ECC code for main and spare area data (5th)								RS ECC code for main and spare area data (4th)							
0x100C	RS ECC code for main and spare area data (7th)								RS ECC code for main and spare area data (6th)							
0x100E	RS ECC code for main and spare area data (9th)								RS ECC code for main and spare area data (8th)							
0x1010	RS ECC code for main and spare area data (11th)								RS ECC code for main and spare area data (10th)							
0x1012	RS ECC code for main and spare area data (13th)								RS ECC code for main and spare area data (12th)							
0x1014	RS ECC code for main and spare area data (15th)								RS ECC code for main and spare area data (14th)							
0x1016	RS ECC code for main and spare area data (17th)								RS ECC code for main and spare area data (16th)							
0x1018	Reserved								RS ECC code for main and spare area data (18th)							
0x101A–0x103E	Reserved															

[1] Wrap count and other bytes have the same wrap count information, and are used as error correction for wrap count itself.

39.4 Memory Map and Register Definitions

This section includes the module memory map and detailed descriptions of all registers. For the base address of a particular module instantiation, see the system memory map.

39.4.1 Memory Map

Table 39-5 shows the NFC memory map.

Table 39-5. NFC Module Register Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x1E00	Reserved	—	—	—
0x1E02	Reserved	—	—	—
0x1E04 (RAM_BUFFER_ADDRESS)	RAM buffer address register	R/W	0x0000_0000	39.4.3.1/39-12
0x1E06 (NAND_FLASH_ADDR)	NAND Flash address register	R/W	0x0000_0000	39.4.3.2/39-13
0x1E08 (NAND_FLASH_CMD)	NAND Flash command register	R/W	0x0000_0000	39.4.3.3/39-13
0x1E0A (NFC_CONFIGURATION)	NFC internal buffer lock control register	R/W	0x0000_0001	39.4.3.4/39-14
0x1E0C (ECC_STATUS_RESULT1)	RS ECC status register 1	Read-only	0x0000_0000	39.4.3.5/39-14
0x1E0E (ECC_STATUS_RESULT2)	RS ECC status register 2	Read-only	0x0000_0000	39.4.3.6/39-15
0x1E10 (SPAS)	Spare only size register	R/W	0x0000_0000	39.4.3.7/39-16
0x1E12 (NF_WR_PROT)	NAND Flash write protection register	R/W	0x0000_0002	39.4.3.8/39-16
0x1E14	Reserved	—	—	—

39.4.2 Register Summary

Figure 39-3 shows the key to the register fields and Table 39-6 shows the register figure conventions.

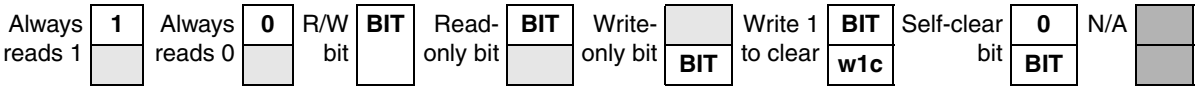

Figure 39-3. Key to Register Fields

Table 39-6. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 39-7 shows the NFC register summary.

39.4.3 Register Descriptions

39.4.3.1 RAM Buffer Address Register (RAM_BUFFER_ADDRESS)

RBA specifies which part of the RAM buffer is transferred to/from Flash memory. The bit assignments for the register are shown in Figure 39-4 and the field descriptions are shown in Table 39-10.

Offset 0x1E04 (RAM_BUFFER_ADDRESS) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	ACTIVE_CS		0	RBA		
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-4. RAM Buffer Address Register

Table 39-8. RAM Buffer Address Field Descriptions

Field	Description
15–6	Reserved, read as 0
5–4 ACTIVE_CS	Active chip select. Defines the chip-select line to be asserted during any NAND operation. For example, if ACTIVE_CS is set to 0b01, then all NFC operations are executed to chip select 1 (ipp_nfc_ce1_out) 00 - chip select 0 is active 01 - chip select 1 is active 10 - chip select 2 is active 11- chip select 3 is active

Table 39-8. RAM Buffer Address Field Descriptions

Field	Description
3	Reserved, read as 0
2–0 RBA	RAM buffer address. Specifies the RAM buffer number to use for data transfers to or from the NAND Flash device. 0000 1st internal RAM buffer 0001 2nd internal RAM buffer 0010 3rd internal RAM buffer 0011 4th internal RAM buffer 0100 5th internal RAM buffer 0101 6th internal RAM buffer 0110 7th internal RAM buffer 0111 8th internal RAM buffer

39.4.3.2 NAND Flash Address Register (NAND_FLASH_ADDR)

The NAND Flash address (NAND_FLASH_ADDR) register is a read-write register containing the address of the NAND Flash device that will be read, programmed or erased. The address in the NAND_FLASH_ADD register is written to the Flash device. The bit assignments for the register are shown in Figure 39-5 and the field descriptions are shown in Table 39-9.

Offset 0x1E06 (NAND_FLASH_ADDR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-5. NAND Flash Address Register

Table 39-9. NAND Flash Address Register Field Description

Field	Description
15–0 ADDR	NAND Flash address. NAND Flash address which will be read, programmed or erased. This address is written to the NAND Flash device.

39.4.3.3 NAND Flash Command Register (NAND_FLASH_CMD)

The bit assignments for the register are shown in Figure 39-6 and the field descriptions are shown in Table 39-10.

Offset 0x1E08 (NAND_FLASH_CMD) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMD															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-6. NAND_FLASH_CMD Register

Table 39-10. NAND_FLASH_CMD REGISTER Field Description

Field	Description
15–0 CMD	NAND Flash command. This field contains the CMD that is written to the NAND Flash device.

39.4.3.4 NFC Internal Buffer Lock Control Register (NFC_CONFIGURATION)

The bit assignments for the register are shown in Figure 39-7 and the field descriptions are shown in Table 39-11.

Offset 0x1E0A (NFC_CONFIGURATION) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	BLS

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 39-7. NFC_CONFIGURATION Register

Table 39-11. NFC_CONFIGURATION Register Field Descriptions

Field	Description
15–2	Reserved
1–0 BLS	Buffer lock set. This field specifies the buffer lock status of first four sections of the internal buffer. The other four sections are always unlocked.(for more details see section Section 39.6.4, “Write Protection Operation”) 00 Locked 01 Locked (default) 10 Unlocked 11 Locked

39.4.3.5 Controller Status and Result of Flash Operation Register 1 (ECC_STATUS_RESULT1)

The fields in this register shows the number of symbol errors for the first four sections of 528/538 bytes of data (including 512 bytes of main data plus 16/26 bytes of spare data, depending on the setting of the ECC_MODE bit in the NAND_FLASH_CONFIG1 register) as a result of the RS ECC check. The bit assignments for the register are shown in Figure 39-8 and the field descriptions are shown in Table 39-12.

Offset 0x1E0C (ECC_STATUS_RESULT1) Access: User read-only

Figure 39-8. ECC_STATUS_RESULT1 Register

Table 39-12. ECC_STATUS_RESULT1 Register Field Descriptions

Field	Description
15–12 11–8 7–4 3–0 NOSER*n* (*n* = 4,3,2,1)	Number of symbol errors for *n*'th section of the internal RAM (528 or 538 bytes, depending on the setting of the ECC_MODE bit in the NAND_FLASH_CONFIG1 register). These fields shows the number of symbols with errors in 512 bytes main data plus 16/26 bytes spare data (528/538 bytes total) as a result of the RS ECC check upon read. For the entire 528/538 bytes the number of correctable symbols is 4/8, depending on ECC_MODE. 0000 No error 0001–1000Indicates the number of symbol errors (correctable error) 1111 Unknown number of errors (uncorrectable error) Others Reserved

39.4.3.6 Controller Status and Result of Flash Operation Register 2 (ECC_STATUS_RESULT2)

The fields in this register shows the number of symbol errors for the last four data sections of 528/538 bytes (including 512 bytes of main data plus 16/26 bytes of spare data, depending on the setting of the ECC_MODE bit in the NAND_FLASH_CONFIG1 register) as a result of the RS ECC check. Figure 39-9 shows the bit assignments for the register, and Table 39-13 shows the field descriptions.

Offset 0x1E0E (ECC_STATUS_RESULT2) Access: User read-only

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 39-9. ECC_STATUS_RESULT2 Register

Table 1. ECC_STATUS_RESULT2 Field Descriptions

Field	Description
15–12 11–8 7–4 3–0 NOSER*n* (*n* = 8,7,6,5)	Number of symbol errors for *n*'th section of the internal RAM (528 or 538 bytes, depending on the setting of the ECC_MODE bit in the NAND_FLASH_CONFIG1 register). These fields shows the number of symbols with errors in 512 bytes main data plus 16/26 bytes spare data (528/538 bytes total) as a result of the RS ECC check upon read. For the entire 528/538 bytes the number of correctable symbols is 4/8, depending on ECC_MODE. 0000 No error 0001–1000Indicates the number of symbol errors (if errors are correctable) 1111 Unknown number of errors (uncorrectable error) Others Reserved

39.4.3.7 Spare Area Size Register (SPAS)

This register specifies the total size (in 16-bit half-words) for the spare area of the NAND device.The bit assignments for the register are shown in Figure 39-10, and the field descriptions are shown in Table 39-13.

Offset 0x1E10 (SPAS) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	SPAS							
W																
RESET	0	0	0	0	0	0	0	0	0	1	1	0	1	1	0	1

Figure 39-10. Spare Area Size Register

Table 39-13. Spare Area Size Register Description

Field	Description
15–8	Reserved
7–0 SPAS	Spare area size. This field specifies the total size (in 16-bit half-words) of the spare area for the NAND device. The size refers to a full page: for example, SPAS should be set to 64 for a 2 Kbyte SLC device.

39.4.3.8 NAND Flash Write Protection Register (NF_WR_PROT)

This register specifies the protection command (LOCK, UNLOCK, or LOCK TIGHT) performed by the NFC.The bit assignments for the register are shown in Figure 39-11, and the field descriptions are shown in Table 39-14.

Offset 0x1E12 (NF_WR_PROT) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	WPC		
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Figure 39-11. NAND Flash Write Protection Register

Table 39-14. NAND Flash Write Protection Register Field Descriptions

Field	Description
15–3	Reserved
2–0 WPC	Write protection command. This command field specifies the write-protect operation that the NFC performs. The command is performed on the protection mechanism of the chip-select that is configured in the ACTIVE_CS field. For example, if ACTIVE_CS = 0b01, then writing to WPC will change the state of LTS1, US1 and LS1. 100 Unlock NAND Flash blocks according to the block address range specified in the UNLOCK_START_BLK_ADD*n* and UNLOCK_END_BLK_ADD*n* registers, where *n* refers to the value of ACTIVE_CS. 010 Lock all NAND Flash blocks 001 Lock-tight locked blocks (see also Section 39.6.4, “Write Protection Operation”)

39.4.3.9 NAND Flash Write Protection Status Register (NAND_FLASH_WR_PR_ST)

This register is a status register which reads the NAND Flash write protection status (lock, unlock or lock tight) for each of the four chip selects. The write protection mechanism is the same for each chip select. The bit assignments for the register are shown in Figure 39-12 and the field descriptions are shown in Table 39-15.

Offset 0x1E18 (NAND_FLASH_WR_PR_ST) Access: User read-only

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	US3	LS3	LTS3	US2	LS2	LTS2	US1	LS1	LTS1	US0	LS0	LTS0
W																
RESET	0	0	0	0	0	1	0	0	1	0	0	1	0	0	1	0

Figure 39-12. NAND_FLASH_WR_PR_ST Register

Table 39-16 shows the write protect modes associated with different US*n*, LS*n*, and LTS*n* settings.

Table 39-15. NAND_FLASH_WR_PR_ST Register Field Descriptions

Field	Description
15–12	Reserved
11 US3	Unlocked status. This bit indicates whether there are any unlocked blocks in the NAND Flash that is connected to chip select 3. This bit is updated every time a command is issued to the NAND Flash. 0 There are no unlocked blocks in NAND Flash 1 There are unlocked block(s) in NAND Flash
10 LS3	Locked status. This bit indicates whether there are any locked blocks in the NAND Flash that is connected to chip select 3. This bit is updated every time a command is issued to the NAND Flash. 0 There are no locked blocks in NAND Flash 1 There are locked block(s) in NAND Flash

Table 39-15. NAND_FLASH_WR_PR_ST Register Field Descriptions (Continued)

Field	Description
9 LTS3	Lock-tight status: Indicates if any of the locked block(s) of the NAND connected to chip select 3 is (are) have a lock-tight status. This bit is updated every time a command is issued to the NAND Flash. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
8 US2	Unlocked status. This bit indicates whether there are any unlocked blocks in the NAND Flash that is connected to chip select 2. This bit is updated every time a command is issued to the NAND Flash. 0 There are no unlocked blocks in NAND Flash 1 There are unlocked block(s) in NAND Flash
7 LS2	Locked status. This bit indicates whether there are any locked blocks in the NAND Flash that is connected to chip select 2. This bit is updated every time a command is issued to the NAND Flash. 0 There are no locked blocks in NAND Flash 1 There are locked block(s) in NAND Flash
6 LTS2	Lock-tight status: Indicates if any of the locked block(s) of the NAND connected to chip select 2 is (are) have a lock-tight status. This bit is updated every time a command is issued to the NAND Flash. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
5 US1	Unlocked status. This bit indicates whether there are any unlocked blocks in the NAND Flash that is connected to chip select 1. This bit is updated every time a command is issued to the NAND Flash. 0 There are no unlocked blocks in NAND Flash 1 There are unlocked block(s) in NAND Flash
4 LS1	Locked status. This bit indicates whether there are any locked blocks in the NAND Flash that is connected to chip select 1. This bit is updated every time a command is issued to the NAND Flash. 0 There are no locked blocks in NAND Flash 1 There are locked block(s) in NAND Flash
3 LTS1	Lock-tight status: Indicates if any of the locked block(s) of the NAND connected to chip select 1is (are) have a lock-tight status. This bit is updated every time a command is issued to the NAND Flash. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight
2 US0	Unlocked status. This bit indicates whether there are any unlocked blocks in the NAND Flash that is connected to chip select 0. This bit is updated every time a command is issued to the NAND Flash. 0 There are no unlocked blocks in NAND Flash 1 There are unlocked block(s) in NAND Flash

Table 39-15. NAND_FLASH_WR_PR_ST Register Field Descriptions (Continued)

Field	Description
1 LS0	Locked status. This bit indicates whether there are any locked blocks in the NAND Flash that is connected to chip select 0. This bit is updated every time a command is issued to the NAND Flash. 0 There are no locked blocks in NAND Flash 1 There are locked block(s) in NAND Flash
0 LTS0	Lock-tight status: Indicates if any of the locked block(s) of the NAND connected to chip select 0 is (are) have a lock-tight status. This bit is updated every time a command is issued to the NAND Flash. 0 Locked block(s) is (are) not lock-tight 1 Locked block(s) is (are) lock-tight

Table 39-16. Write Protect Modes

State	Status Bit Settings (US, LS, LTS)
Lock—All blocks are locked.	010
Unlock-lock—There are both locked and unlocked blocks.	110
Unlock-lockt—There are unlocked blocks. Cannot change to another state	101
Lockt—All blocks are locked, and cannot change to another state	001

39.4.3.10 NAND Flash Operation Configuration Register (NAND_FLASH_CONFIG1)

This register is a configuration register for the NAND Flash device to control the ECC enable or disable, mask interrupt. The bit assignments for the register are shown in Figure 39-13 and the field descriptions are shown in Table 39-17

Offset 0x1E1A (NAND_FLASH_CONFIG1) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	FP_INT	PPB		SYM	NF_CE	NFC_RST	NF_BIG	INT_MSK	ECC_EN	SP_EN	DMA_MODE	ECC_MODE
W																
RESET	0	0	0	0	1	1	0	0	0	0	0	0	1	0	1	0

Figure 39-13. NAND_FLASH_CONFIG1 Register

Table 39-17. NAND_FLASH_CONFIG1 Register Field Descriptions

Field	Description
15–11	Reserved
11 FP_INT	Full page interrupt. By default NFC generates an interrupt (during program,/read) after each section of 512 bytes (plus accompanied spare bytes). If this bit is set, then the interrupt will be generated only after the whole page was read/programmed. This bit affects the interrupt only during read or program of a full page. 0 - NFC generates interrupt after each section of 512 bytes plus 16/26 spare bytes (default) 1 - NFC generates interrupt only after the entire read/program operation is complete.
10-9 PPB	Pages per block. Indicates how many pages are in each block of the NAND Flash. 00 - 32 pages per block 01 - 64 pages per block 10 - 128 pages per block 11 - 256 pages per block
8 SYM	1 Enable one Flash clock cycle per access of RE# and WE#, (symmetric mode). 0 Enable two Flash clock cycles per access of RE# and WE#, (asymmetric mode). See timing diagrams in Section 39.6.3, “Symmetric Mode—One Flash Clock Cycle per Input or Output Data Cycle.”
7 NF_CE	NAND Flash force CE. Setting this bit to 1 forces the CE# signal to the NAND Flash device to 0. This bit allows a greater range of support for new NAND Flash devices. 0 CE# signal operates normally 1 CE# signal is forced to 0
6 NFC_RST	NFC reset. This bit resets the NFC state machine. This bit should be used when issuing reset command to the NAND Flash device during operation. This bit is self-cleared, and resets also NF_BIG, INT_MSK and SP_EN. 0 Do not reset the NFC state machine 1 Reset the NFC state machine
5 NF_BIG	NAND Flash big-endian mode. This bit enables big-endian mode when writing from internal RAM to the NAND Flash device or reading from NAND Flash device to internal RAM. 0 Little-endian mode 1 Big-endian mode
4 INT_MSK	Mask interrupt bit. This bit enables the interrupt by masking or not masking the interrupt bit. 0 Mask interrupt is disabled (interrupt enabled) 1 Mask interrupt is enabled (interrupt disabled)
3 ECC_EN	ECC operation enable. This bit determines whether ECC operation is executed or bypassed 0 ECC operation is bypassed 1 ECC operation is executed
2 SP_EN	NAND Flash spare enable. This bit determines whether host reads/writes are to NAND Flash spare data only or NAND Flash main and spare data. This feature is supported only with memories with 1/2K page size. Note: There is no ECC in this mode of operation. 0 NAND Flash main and spare data is enabled 1 NAND Flash spare only data is enabled

Table 39-17. NAND_FLASH_CONFIG1 Register Field Descriptions (Continued)

Field	Description
1 DMA_MODE	This bit defines the DMA_REQ signal mode of operation during a page read. DMA_REQ can be asserted after every section of the page is read (main + relevant part of the spare), or only at the end of the page read. Other read operations that assert dma_req are not affected by this bit, 0 — DMA_REQ is asserted after each section is read out. 1 — DMA_REQ is asserted only at the end of a page read.
0 ECC_MODE	This bit selects the ECC capabilities. Error correction mechanism can fix 4-symbol errors or 8-symbol errors. In 4-bit ECC mode, the NFC uses 16 bytes of spare area for every 512 bytes section of the NAND device (7 bytes for user-specific application and 9 bytes for the ECC). In 8-bit ECC mode, the NFC uses 26 bytes of spare area for every 512 bytes section of the nand device (7 bytes for user-specific application, 18 bytes for the ECC and 1 reserved byte). To use 8-symbol ECC mode, you must have a NAND device that has at least 26 bytes of spare area for every 512 B main section. 0 — 8-symbol error correction (reset value). 1 — 4-symbol error correction

39.4.3.11 NAND Flash Operation Configuration 2 (NAND_FLASH_CONFIG2)

This register controls the NAND Flash signals (CLE, ALE, WE, RE, CE) and sets the interrupt after command completion. The bit assignments for the register are shown in Figure 39-14 and the field descriptions are shown in Table 39-18.

Offset 0x1E1C (NAND_FLASH_CONFIG2) Access: User read-write

Figure 39-14. NAND_FLASH_CONFIG2 Register

Table 39-18. NAND_FLASH_CONFIG2 Register Field Descriptions

Field	Description
15 INT	Interrupt. This field determines the state of the interrupt output of the NAND Flash controller. It is set by the controller when a basic operation is done. It can also be written to by the host. 0 Basic operation or boot loading is still running 1 Basic operation or boot loading is done. **Note:** This bit resets to 0, but soon after power-up it will change to 1. When booting from NAND Flash, the INT bit will change from 0 to 1 after the boot code has been transferred. For more information, see Section 39.5.2, "Modes of Operation."
14–6	Reserved
5–3 FDO	NAND Flash data output. This bit enables NAND Flash data output. The bit is automatically cleared when the operation is completed. 001 One page data out[1] 010 NAND Flash ID data out 100 NAND Flash status register data out **Note:** Only one of the bit fields (FCMD/FADD/FDI/FDO) can be set at any given time.

Table 39-18. NAND_FLASH_CONFIG2 Register Field Descriptions (Continued)

Field	Description
2 FDI	NAND Flash data input. This field enables NAND Flash data input.The bit is automatically cleared when the operation is completed. 0 No NAND Flash data input operation 1 Enable NAND Flash data input operation **Note:** Only one of the bit fields (FCMD/FADD/FDI/FDO) can be set at any given time.
1 FADD	NAND Flash address input. This field enables NAND Flash address input. The bit is automatically cleared when the operation is completed. 0 No NAND Flash address input operation 1 Enable NAND Flash address input operation **Note:** Only one of the bit fields (FCMD/FADD/FDI/FDO) can be set at any given time.
0 FCMD	NAND Flash command input. This field enables the NAND Flash command input. The bit is automatically cleared when the operation is completed. 0 No NAND Flash command input operation 1 Allow NAND Flash command input operation **Note:** Only one of the bit fields (FCMD/FADD/FDI/FDO) can be set at any given time.

[1] Page size is determined by SP_EN register bit (main + spare or spare only).

39.4.3.12 Address to Unlock in Write Protection Mode—Start for Chip Select *n* (UNLOCK_START_BLK_ADD*n*, *n* = 0,1,2,3)

These registers contains the starting address of block memory in the NAND Flash that is unlocked in write protection mode for chip select *n* (*n* = 0,1,2,3). The bit assignments for the registers are shown in Figure 39-15 and the field descriptions are shown in Table 39-19.

Offset 0x1E20 (UNLOCK_START_BLK_ADD0)
0x1E24 (UNLOCK_START_BLK_ADD1)

39.5 Functional Description

This section provides the functional description for the NAND Flash controller.

39.5.1 Overview

The operation of the NFC begins by the AHB host initiating a read from the NAND Flash device by configuring the controller and then waiting for an interrupt from the NFC. When it receives the interrupt, the NFC inputs a page from the NAND Flash device, and upon completion, generates an interrupt to the AHB host.

When the AHB host receives this interrupt, it reads the content from the internal RAM buffer of the NFC. To complete the operation the AHB host checks the status of the operation by reading the NFC status registers.

The 4-Kbyte RAM buffer is used as the boot RAM during a cold reset (if the system is configured for a boot to be carried out from the NAND Flash device). After the boot procedure completes, the RAM is available as buffer RAM.

In addition, the NAND Flash controller provides an x16 bit and x32 bit interface to the AHB bus on the chip side, and an x8/x16 interface to the NAND Flash device on the external data bus.

39.5.2 Modes of Operation

The NAND FLASH Controller operating modes are described in this section.

The operating mode is determined by five input lines: NFC_FMS, NF_4K, $\overline{\text{NF8BOOT}}$, $\overline{\text{NF16BOOT}}$, NF_16BIT_SEL, as shown in Table 39-21.

The IC can boot from a NAND Flash device if exactly one of the two signals $\overline{\text{NF8BOOT}}$ or $\overline{\text{NF16BOOT}}$ must be low. If both signals are high, a boot from the NAND Flash device does not occur. If both signals are low, the situation is undefined.

The page size of the NAND Flash is determined by the values of NFC_FMS and NF_4K. The NAND Flash is 512 bytes if both NFC_FMS and NF_4K are low, 2 Kbyte if NFC_FMS is high and NF_4K is low, and 4 Kbyte if NFC_FMS is low and NF_4K is high. See the signal description for more information.

When booting from a NAND Flash device, the bus width used corresponds to which of the signals $\overline{\text{NF8BOOT}}$ or $\overline{\text{NF16BOOT}}$ is asserted (low). When not booting from the NAND Flash device, the bus width is determined by the value of the NF_16BIT_SEL signal (0 = 8-bit bus, 1 = 16-bit bus).

Table 39-21. NAND FLASH Controller Operating Modes

NFC_FMS	NF_4K	$\overline{\text{NF8BOOT}}$	$\overline{\text{NF16BOOT}}$	NF_16BIT_SEL	Function
0	0	1	1	0	Do not boot from NAND Flash. NAND Flash is configured to 8-bits I/O bus width and page size is 512 bytes
0	0	1	1	1	Do not boot from NAND Flash. NAND Flash is configured to 16-bits I/O bus width and page size is 512 bytes.
1	0	1	1	0	Do not boot from NAND Flash. NAND Flash is configured to 8-bits I/O bus width and page size 2KB
1	0	1	1	1	Do not boot from NAND Flash. NAND Flash is configured to 16-bits I/O bus width and page size 2KB
0	1	1	1	0	Do not boot from NAND Flash. NAND Flash is configured to 8-bits I/O bus width and page size 4KB
0	1	1	1	1	Do not boot from NAND Flash. NAND Flash is configured to 16-bits I/O bus width and page size 4KB
X	1	1	0	X	Boot from x16 NAND Flash. NAND Flash is configured to 16-bits I/O bus width and page size 4 Kbytes + 218 bytes spare.
X	1	0	1	X	Boot from x8 NAND Flash. NAND Flash is configured to 8-bits I/O bus width and page size 4 Kbyte + 218 bytes spare.
X	X	0	0	X	Not defined (do not use this setting)

39.5.3 Booting From a NAND Flash Device

A Boot from the NAND Flash device only occurs if one of the boot inputs is asserted ($\overline{\text{NF8BOOT}}$ or $\overline{\text{NF16BOOT}}$ is low) at system power-on reset ($\overline{\text{IPP\_RESET}}$ rising edge).

Boot from a NAND Flash device proceeds as follows:

1. The boot loader copies 1 page of 4 Kbytes main data + 218 bytes spare data from the NAND Flash to the NFC internal RAM buffer.
2. There are 5 address latch cycles during the bootloader. This is hard-coded and cannot be modified.
3. There is a read confirm command after the address cycles (0x30)
   - ECC is always calculated for each 512-byte section separately, and not for the whole 4-Kbyte page. Therefore, each 512 bytes of data in the NAND Flash is follow by 26 bytes of spare data (repeated 8 times for the entire 4-Kbyte page).
4. After exiting from reset state, the host reads the code from the NFC's internal RAM buffer.

Figure 39-17 shows boot mode operation from a NAND Flash device.

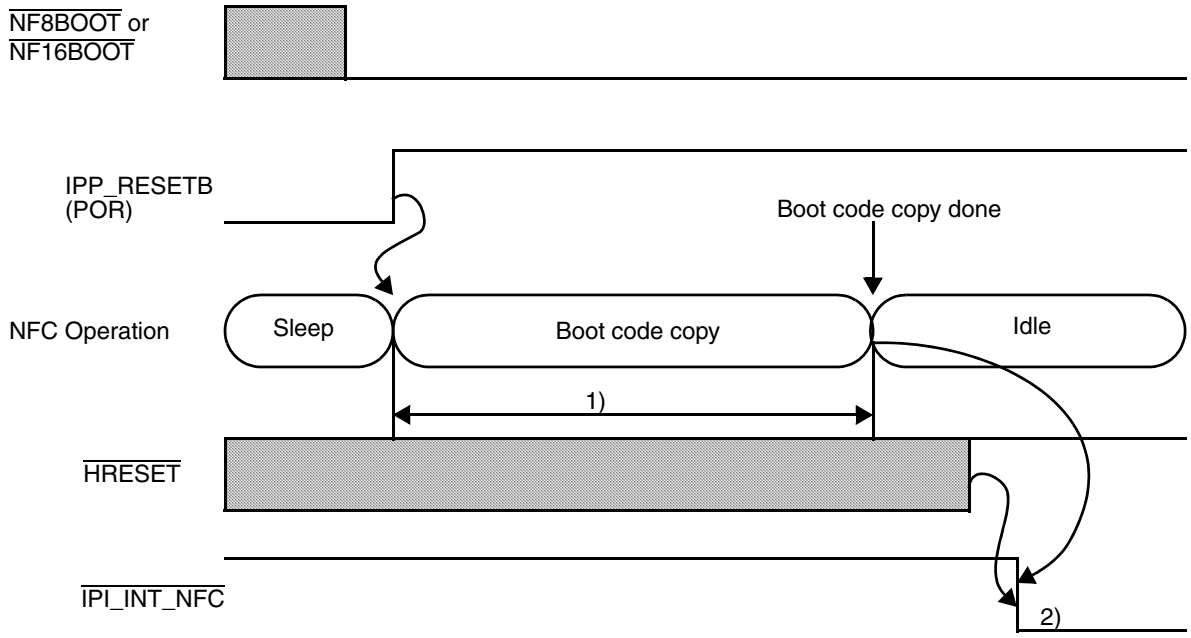

Figure 39-17. Boot Mode Operation

NOTE

The time it takes the boot copy to load 4 Kbytes is dependent on the NAND device and the frequency of Flash clock. The host must not read the boot code in the RAM buffer (4 Kbytes) until after the boot code copy is completed.

The interrupt signal ($\overline{\text{IPI\_INT\_NFC}}$) goes high to low when the boot code copy is completed, and upon the $\overline{\text{HRESET}}$ rising edge. If $\overline{\text{HRESET}}$ goes low to high before the boot code copy is done, the interrupt signal ($\overline{\text{IPI\_INT\_NFC}}$) goes from high to low as soon as the boot code copy is completed.

The interrupt can be relevant for cases of secured boot (booting from ROM and then enabling the NFC boot).

39.5.4 NAND Flash Control Submodule

The NAND Flash control submodule generates the following control signals:

- CE# (Flash chip enable)
- RE# (Read enable for read operations)
- WE# (Flash write enable)
- CLE# (Flash command latch enable)
- ALE# (Flash address latch enable).

The submodule also monitors the RB (Flash ready/busy indication) signal to check if the NAND Flash is in the middle of an operation.

The ratio of IPP_FLASH_CLK to HCLK frequency is required to be an integer greater than or equal to 2. IPP_FLASH_CLK and HCLK must be synchronous.

The boot loader is part of the NAND Flash control submodule.

For NAND Flash programming or read operations, the RAM buffer address (RBA) field in the RAM_BUFFER_ADDRESS register is set according to page size as follows:

- 512-byte page:

  Every page is written to 512 bytes in the NFC internal RAM buffer. The RBA is chosen to indicate which 512 bytes the page is written to/read from. After the program/read operation is done, RBA remains unchanged.
- 2-Kbyte page:

  In this case, the NFC programs/reads to/from 4 sections of the internal RAM. Legal values of RBA are 0b0000 or 0b0100. After the program/read operation is done, the RBA automatically increments to the next legal value (0b0000 changes to 0b0100, and vice versa)
- 4-Kbyte page:

  In this case, the NFC programs/reads to/from the entire internal RAM. The only legal value of RBA is 0b0000.

The error correcting code (ECC) is always calculated separately for each 512-byte section. See Section 39.5.6, “Reed-Solomon Error Correcting Code Engine (ECC Engine),” for more details.

Figure 39-18, Figure 39-19, and Figure 39-20 show timing diagrams for NAND Flash read, program, and erase operations.

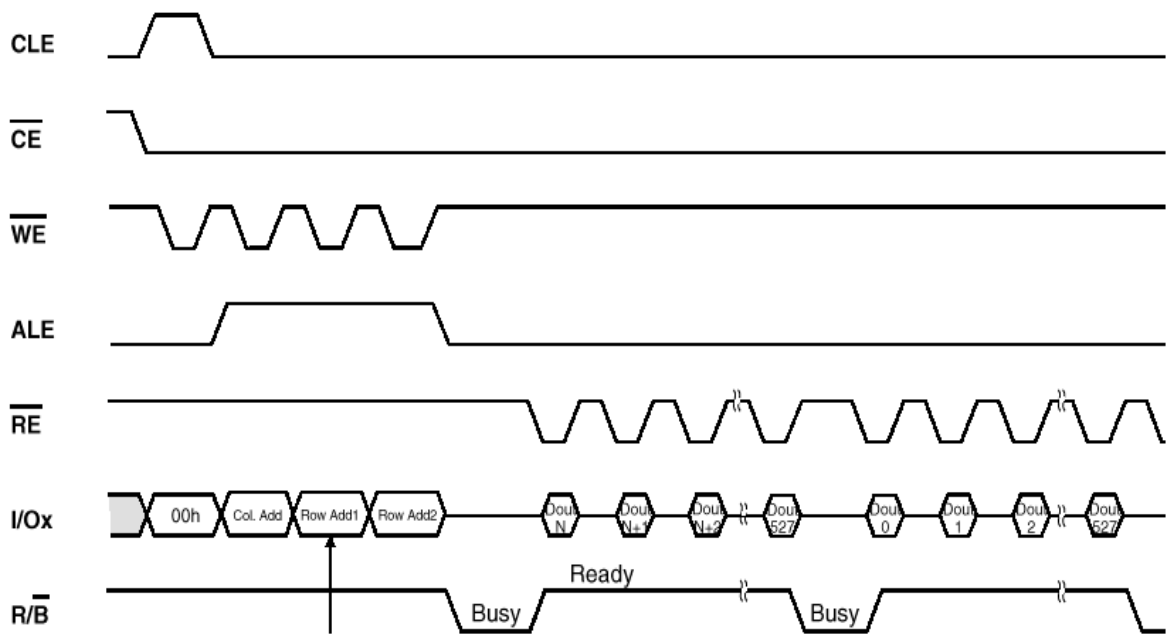

Figure 39-18. Read Operation

Note: ALE can be asserted and negated separately for each address phase.

PAGE PROGRAM OPERATION

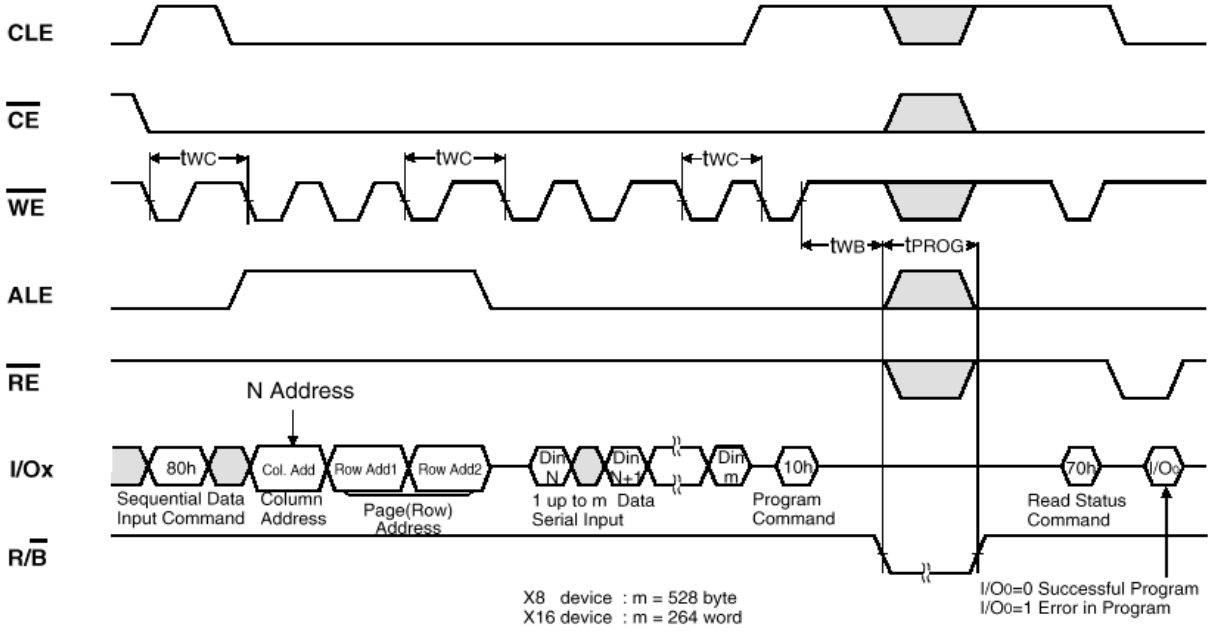

Figure 39-19. Program Operation

BLOCK ERASE OPERATION (ERASE ONE BLOCK)

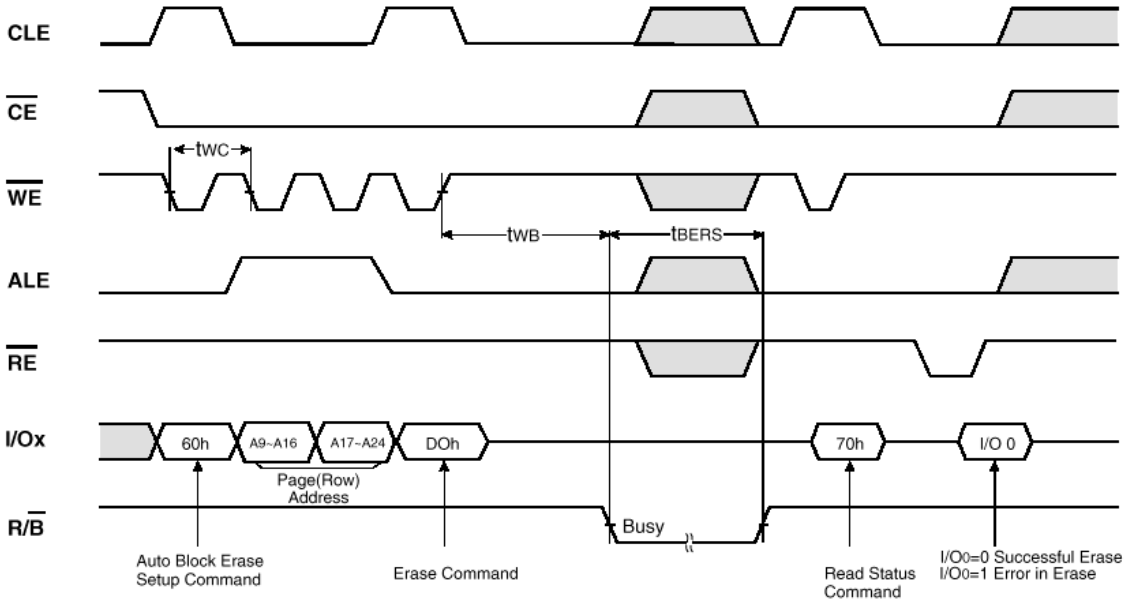

Figure 39-20. Erase Operation

39.5.5 DMA Request Operation

DMA request signal triggers in the following cases:

- After reading a page from the NAND Flash (based on DMA_MODE-bit configuration).
- After read ID operation.
- After reading spare only area.

When asserted, the NFC asserts the DMA_REQ signal for 8 Flash clock cycles, and then it is negated automatically.

39.5.6 Reed-Solomon Error Correcting Code Engine (ECC Engine)

The error correcting code (ECC) engine inside NFC can correct 4 or 8 erroneous 9-bit symbols, depending on the ECC_MODE configuration bit:

- When ECC_MODE = 0, NFC detects and correct up to 8 9-bit symbols per 538 bytes of data (512 bytes main data + 26 bytes spare data). This mode can only be used with devices with sufficient spare area (at least 26 bytes per section).
- When ECC_MODE = 1, NFC detects and correct up to 4 9-bit symbols per 528 bytes of data (512 bytes main data + 16 bytes spare data).

When the NFC accesses the NAND Flash device for a program operation, it generates ECC codes of 9/18 bytes (these bytes will override the corresponding spare area data that is written in the internal RAM). When the NFC accesses the NAND Flash device for a read operation, it performs a RS detection algorithm, which indicates how many symbol errors were detected and corrected.

The ECC code is updated by the NFC automatically. After a read operation, the host can determine the number of errors per 528/538 bytes by reading the status registers ECC_STATUS_RESULT*n*. During a program operation the RS ECC bytes are written to the NAND Flash device, but not to the internal RAM. The host can obtain the ECC from the NAND Flash device spare area.

The ECC is always calculated per 512 bytes. If memory with 2-Kbyte (or 4-Kbyte) page size is used, the ECC is calculated 4 (or 8) times, respectively. NAND Flash with larger page sizes is filled with repeated writes of 512 bytes data followed by spare data:

512 bytes main + spare bytes + 512 bytes main + spare bytes + 512 bytes main + spare bytes + ...

The ECC operation can be bypassed using ECC_EN bit in CONFIG1 register.

The NAND Flash device programming operation proceeds as follows:

1. Write a page of data to the internal RAM.
2. Set RBA (RAM_BUFFER_ADDRESS register) to point to the section in which the data is in.
3. Configure the command and address sequence for program operation.
4. Program one page of data by writing 1 to the FDI bit in NAND_FLASH_CONFIG2 register (the RS ECC code will override the corresponding spare area bytes).

Read sequence:

1. Set RBA to point to the section in which you want the data to be written in the internal RAM.

2. Configure the command and address sequence for read operation.
3. Read 1 page by writing 1 to the FDO field in the NAND_FLASH_CONFIG2 register (the RS algorithm will automatically fix correctable symbol errors).

39.5.7 Address Control Module

The address control module is responsible for address control and generation. The module has the following functions:

- Defines the RAM buffer address generation (RAM buffer address for data in/ data out).
- Generates and takes into account the lock state sequence (see Section 39.6.4, “Write Protection Operation”) and therefore contains the Flash memory lock address comparator, and RAM buffer lock address comparator which are used to determine if this area is protected or not.
- Generates the RAM buffer address for boot load.

39.5.8 RAM Buffer (SRAM)

The internal RAM buffer is a 4608 byte (4.5 Kbyte) single-port RAM buffer which is a synchronous high-performance design. This memory has 1152 32-bit words, from which 1024 words are used for the main buffer and the remaining 128 words are allotted to a spare area that is used for error correction and other applications.

The NFC logically divides the RAM into 8 sections of 512 bytes for main data and 64 bytes for spare data. When reading (or programming) the NAND device, the NFC writes the main data from the NAND device into the main section, and the spare data from the NAND device into the spare section. If the NAND device spare-area is less then 64 bytes per 512 bytes of main data, then, the NFC’s spare-section in the RAM will not be fully utilized, and some data in the spare section will not be valid.

For example, a NAND device with 2 Kbytes of main area and 64 bytes of spare area has 16 bytes of spare area per 512 bytes of main area. In this case, the first 16 bytes of spare area will be located in spare section 1, the next 16 bytes in spare section 2, and so on.)

If a NAND device is used in which the spare area size is not evenly divisible by the number of main sections, then this remainder is located at the last spare section. For example, if a NAND device is used with a 4-Kbyte page and 218 bytes of spare area (27.25 bytes of spare area for each 512 bytes of main area), then the NFC has 26 bytes per section (the largest even number less than 27.25). The remaining 10 bytes of spare area will be added the last spare section, so that the last spare section has 36 bytes.

This memory is used as a boot RAM memory during boot from the NAND Flash device, and as a buffer during normal operation.

39.5.9 Read and Write Control

The read and write control block contains a connection to the internal bus (which is connected to the Internal RAM buffer and the registers).

It is also responsible for RAM buffer Control and Register Control, RAM buffer Lock Control and Address and Data latches.

39.5.10 Data Output Control

This module defines the data output of 16-bits to the internal bus which is driven to the AHB interface. It includes RAM buffer data output, register data output and RAM buffer synchronization for the read mode pipeline.

39.5.11 Host Control

This module defines host control which is connected to the AHB interface though the internal bus. It detects the chip enable signals, controls the reset and output enable signals, and generates the $\overline{\text{SRAM\_WE}}$ signal.

39.5.12 AHB Bus Interface

The AHB bus interface is an adapter between ABMA AHB bus and the internal bus. 16-bit and 32-bit AHB bus widths are supported for both burst and non-burst operation. The internal bus width is 32 bits.

39.5.12.1 Big/Little-Endian Operation

The AHB bus interface supports both big- and little-endian data types. The NFC_ENDIAN pin controls the endian mode. Only the AHB side is controlled by the NFC_ENDIAN pin.

The endianness between the internal RAM and external NAND Flash devices is controlled by the NFC_BIG bit in CONFIG1 register.

39.5.12.2 Burst Access Support

When a data transaction from the AHB is a burst it will create a synchronous burst on the internal bus. Table 39-22 lists NFC supported access burst types.

Table 39-22. NAND Flash Burst Access Support

HBURST	BURST TYPE	SUPPORTED	Description
000	SINGLE	Yes	Single transfer
001	INCR	Yes	Incrementing burst
010	WRAP4	No	4-beat wrapping burst
011	INCR4	Yes	4-beat incrementing burst
100	WRAP8	No	8-beat wrapping burst
101	INCR8	Yes	8-beat incrementing burst
110	WRAP16	No	16-beat wrapping burst
111	INCR16	Yes	16-beat incrementing burst

NOTE

NFC supports bursts of 16/32-bit words only. Bursts of byte words (8-bits) are not supported.

39.5.13 I/O Pin Sharing

The NAND Flash controller has logic that allows it to share I/O pins with signals of another memory controller. For example, the 16 I/O signals of the NAND Flash controller share I/O pins with the data signals of the WEIM when interfacing to the PSRAM.

The arbitration between the NFC and the other memory has hard priority favoring the other memory. When another memory requests the bus, the NFC halts its operation as soon as possible, and the other memory is granted access to the pins. The only NFC operations that do not halt in the middle are short operations such as command, address phase or spare-area access. This priority-based arbitration mechanism can cause long delays in NFC accesses when the I/O bus is shared with another memory that is accessed frequently.

39.6 Initialization/Application Information

This section describes how to operate the NFC using its registers and its interrupts, and covers the following topics:

- Section 39.6.1, “Normal Operation,” provides instructions on to operate a NAND Flash device using the NFC.
- Section 39.6.2, “ECC Operation,” describes the NFC’s error-correction operations.
- Section 39.6.3, “Symmetric Mode—One Flash Clock Cycle per Input or Output Data Cycle,” describes symmetric mode, which accommodates lower NAND Flash frequencies.
- Section 39.6.4, “Write Protection Operation,” describes write protection, which is used when the programmer wishes to protect part of the NAND Flash device memory from being written except in certain cases. There are two levels of protection: software (for frequently-changed memory locations), and hardware (for memory locations whose contents are rarely changed).

39.6.1 Normal Operation

Normal operations are composed of fundamental building block operations, in addition to specific operations, as shown in Figure 39-21 through Figure 39-26.

39.6.1.1 Fundamental Building Block Operations

39.6.1.1.1 Preset Operation

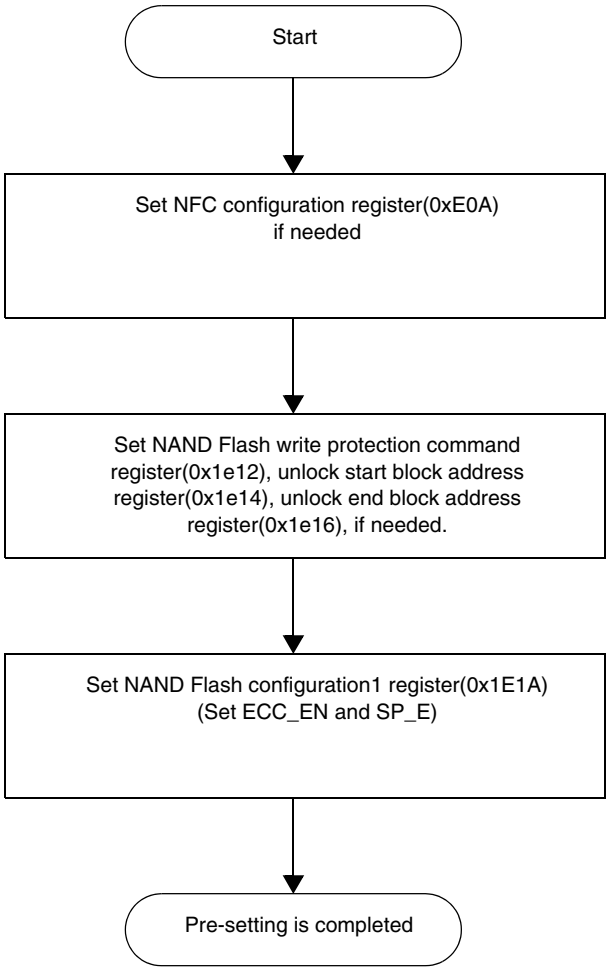

Figure 39-21. Flow Chart of Preset Operation

39.6.1.5 Program NAND Flash Data Operation

Figure 39-32 shows program NAND Flash data operation.

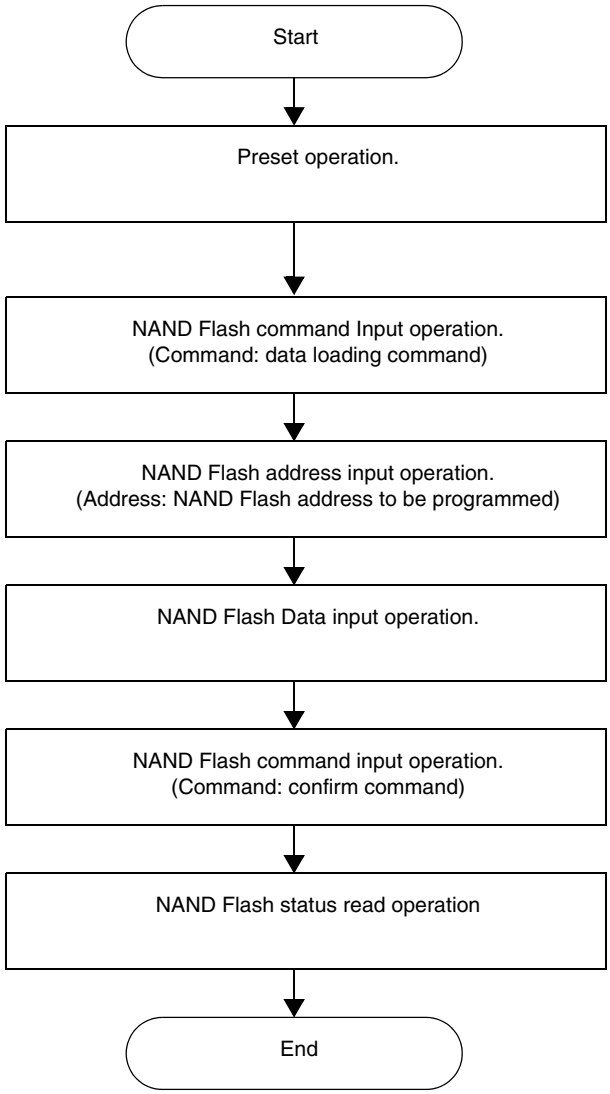

Figure 39-32. Flow Chart of Program NAND Flash Data Operation

39.6.1.6 Erase NAND Flash Data Operation

Figure 39-33 shows erase NAND Flash data operation.

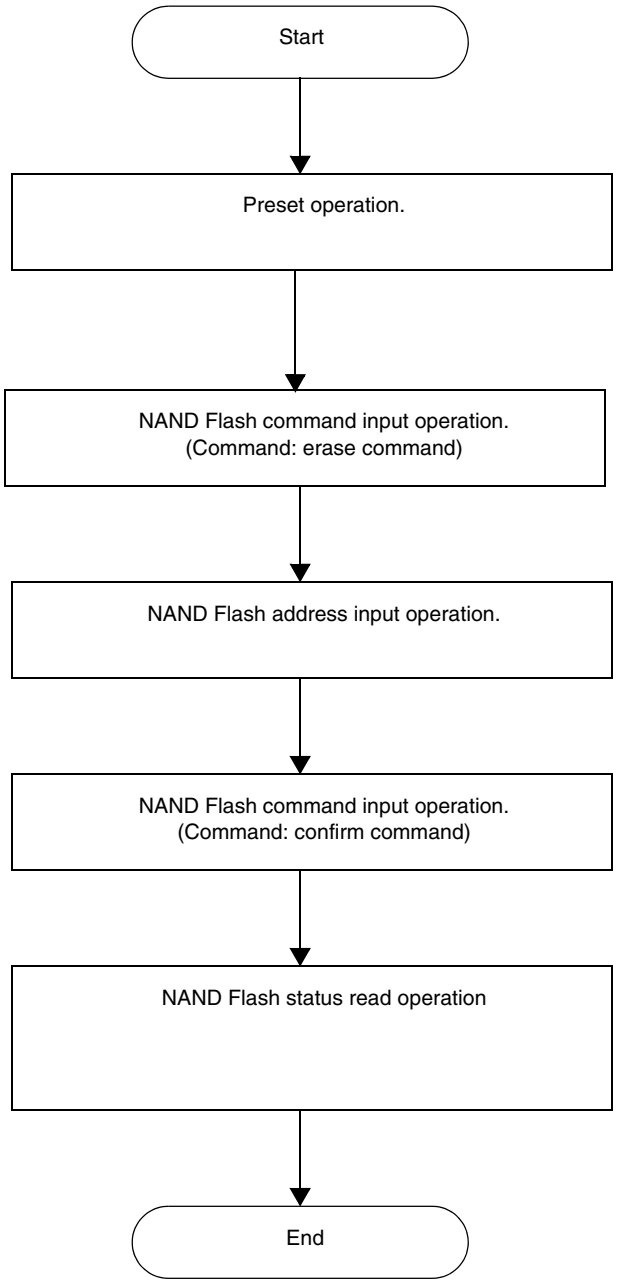

Figure 39-33. Flow Chart of Erase NAND Flash Operation

39.6.1.7 HOT Reset (Controller and NAND Flash Reset)

A reset causes the NFC and the NAND Flash device to cease their current operation, and causes the internal registers to revert to their default state.

Figure 39-34 shows reset operation.

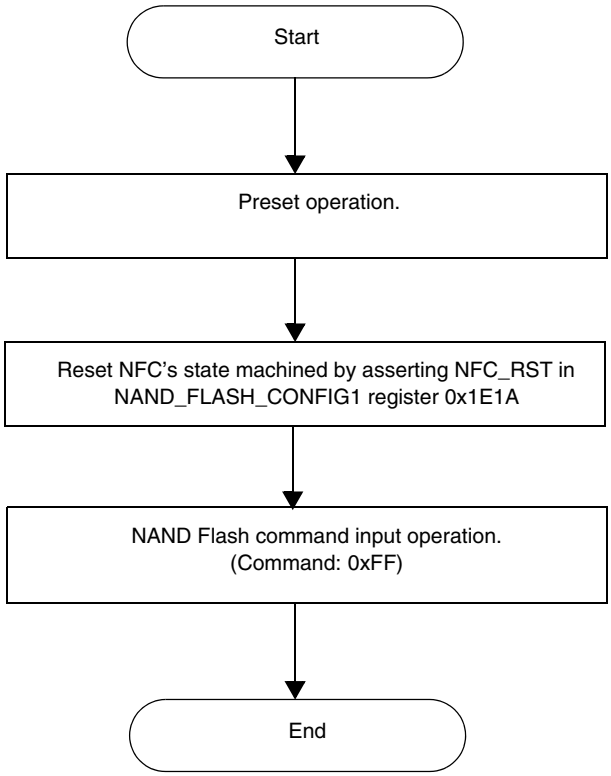

Figure 39-34. Flow Chart of Reset Operation

39.6.2 ECC Operation

39.6.2.1 ECC Normal Operation

When the NFC accesses the NAND Flash device for program operation, it generates ECC code (9/18 bytes for each 528/538 bytes). Since the generated ECC code is not updated to the internal buffer RAM, but is updated to the NAND Flash spare area immediately upon program operation, the host can read the generated ECC code only from the NAND Flash spare area.

When the NFC accesses the NAND Flash device for a read operation, it reads the ECC code, detects the number of errors and their position and corrects up to four/eight symbols (9-bits each) if applicable. Table 39-23 shows the ECC code assignment of the NAND Flash spare area. This ECC code is updated by NFC automatically. After the read operation, the host can determine whether there are errors or not by reading the ECC_STATUS_RESULT*n* registers.

39.6.2.2 ECC Bypass

In ECC bypass operation, the spare area is copied from NFC internal RAM buffer to the NAND Flash device during program operation. During read operations the ECC detect-fix mechanism does not work, and the status register is not updated.

Table 39-23. ECC Code/Result Readability

Operation	Read Operation		Program Operation		
	ECC Code from Spare Area Buffer	ECC Status Register	ECC Code from Spare Area Buffer	ECC Status Register	ECC Content in NAND Flash Device
ECC operation	ECC code copied from NAND Flash device spare area	Valid	Invalid (old data[1])	—	ECC code generated by the NFC
ECC bypass	User data copied from NAND Flash device spare area	not Valid	Invalid (old data)	—	Data from spare area of NFC's internal RAM

1 The ECC code in the spare buffer is not updated during program operations, so the ECC code in the spare area buffer is obsolete.

39.6.2.3 ECC Operation

In order to generate ECC and carry out the correction by the NFC,

- Program with ECC operation / Read with ECC operation

In order to generate ECC by the NFC and carry out the correction by the host,

- Program with ECC operation / Read without ECC operation

39.6.3 Symmetric Mode—One Flash Clock Cycle per Input or Output Data Cycle

In the NFC's default state, two Flash clock cycles are used for each access of RE# or WE#. By setting the SYM bit in CONFIG1 register, the WE# and RE# periods during read or program change to one Flash clock cycle instead of two. In this way, lower Flash clock frequencies can be accommodated. The SYM bit also changes the RE# duty cycle to be about 50% during read operation.

In symmetric mode (SYM = 1) the data is latched into NFC on the falling edge of RE#. In default mode (SYM = 0), the data is latched on rising edge of RE#.

Figure 39-36, Figure 39-38, and Figure 39-37, and Figure 39-35 show timing diagrams for input/output operations with different SYM bit settings.

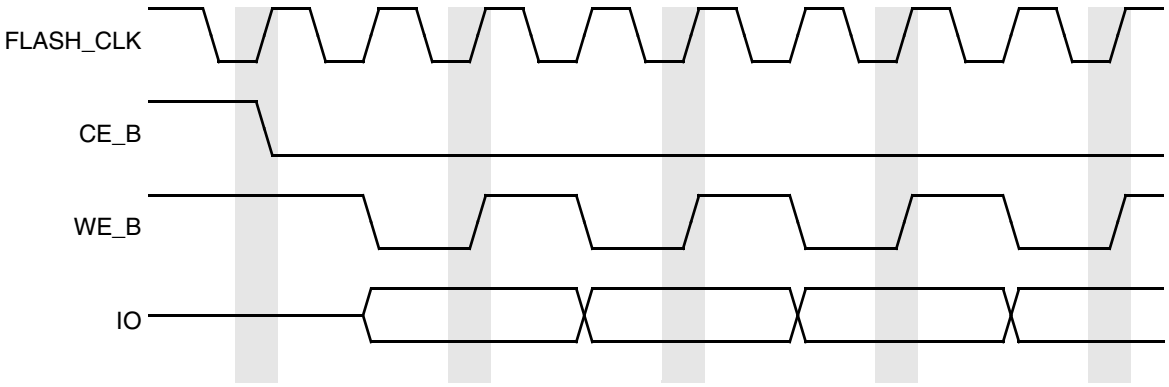

Figure 39-35. Two Flash Clock Cycles per Data Input (SYM bit =0)

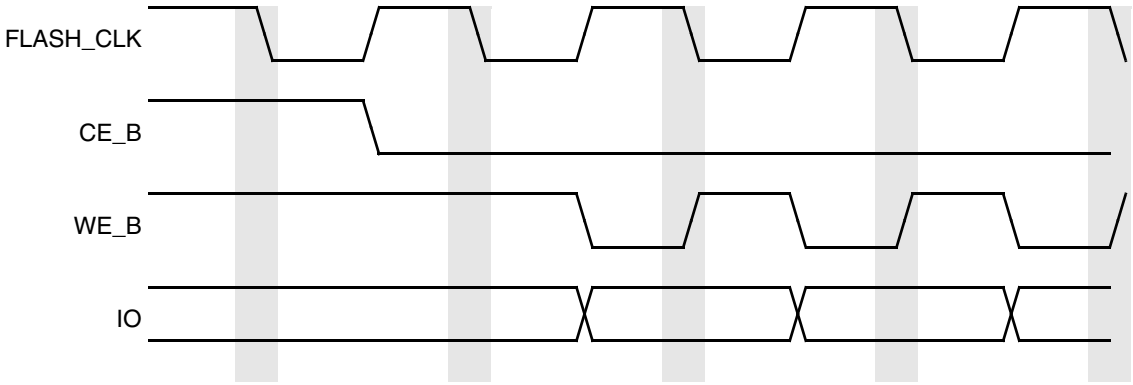

Figure 39-36. One Flash Clock Cycle per Data Input (SYM bit =1)

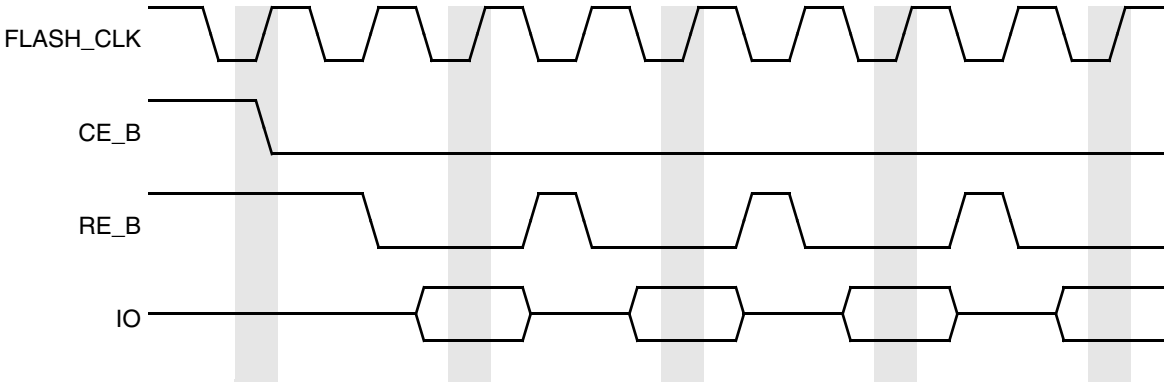

Figure 39-37. Two Flash Clock Cycles per Data Output (SYM bit =0)

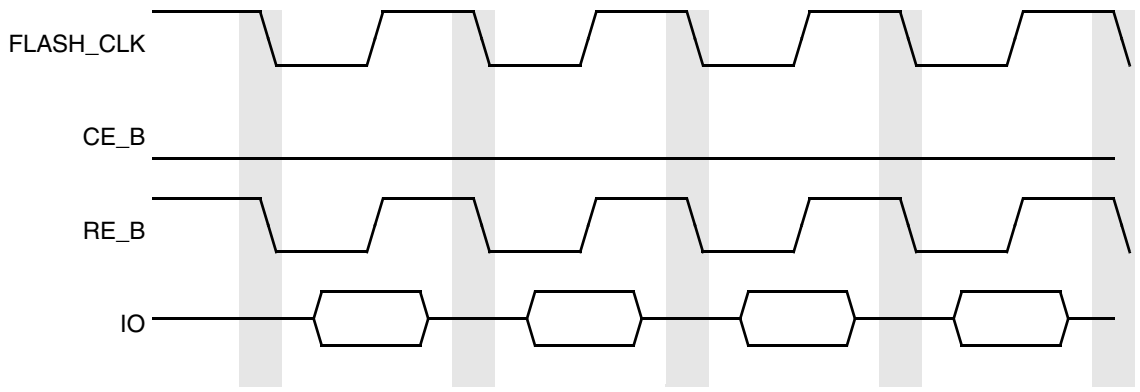

Figure 39-38. One Flash Clock Cycle per Data Output (SYM bit =1)

39.6.4 Write Protection Operation

The NFC offers software and hardware write-protection features. Both are described in this section.

39.6.4.1 Write Protection for RAM Buffer (LSB 2 Kbytes)

The NFC offers a software write protection feature for the first 2 Kbytes (+ accompanied spare area data) of the RAM buffer, which protects RAM buffer data. This write protection is carried out by setting the WPC bit of the NF_WR_PROT register.

The default state is locked state, and the first 2 Kbytes go to this state after a cold or warm reset.

Write protection availability for main/spare memory regions in the RAM buffer is described on Table 39-24. Figure 39-39 shows a state diagram of RAM buffer write protection.

Table 39-24. Write Protection for Main/Spare RAM Buffer

Main area	Spare area	
1st section of RAM buffer	1st section of RAM buffer	Write Protection Available
2nd section of RAM buffer	2nd section of RAM buffer	
3rd section of RAM buffer	3rd section of RAM buffer	
4th section of RAM buffer	4th section of RAM buffer	
5th section of RAM buffer	5th section of RAM buffer	Write Protection not available
6th section of RAM buffer	6th section of RAM buffer	
7th section of RAM buffer	7th section of RAM buffer	
8th section of RAM buffer	8th section of RAM buffer	

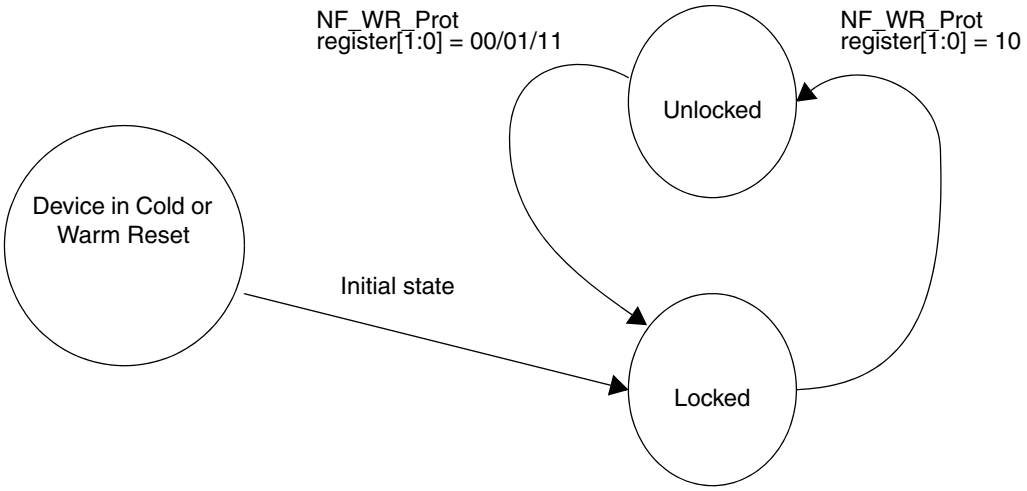

Figure 39-39. State Diagram of RAM Buffer Write Protection

39.6.4.2 Write Protection Modes

The NFC offers both hardware and software write protection options for the NAND Flash device. The software write protection feature is used by executing the LOCK BLOCK command or LOCK-TIGHT BLOCK command. The hardware write protection feature is used by executing a cold or warm reset. The WP# signal is asserted only upon POR.

39.6.4.3 Write Protection Commands

There are two write protection states: locked and lock-tight.

- Locked state means that memory block in question is write-protected (cannot be written to), but the UNLOCK command can unlock it. This is useful for frequently-changed memory blocks.
- Lock-tight state is a higher level of protection, and means that the memory block in question is write protected, but the UNLOCK command cannot unlock it. This is useful for memory blocks whose contents are rarely changed.

The followings summarizes the locking functionality.

- All blocks power up in a locked state except block zero. The UNLOCK command can unlock these blocks.
- The LOCK-TIGHT BLOCK command locks blocks so that they cannot be unlocked.
- Lock-tight state can be changed to locked state only when cold or warm reset is executed.
- Writing to the unlock start/end address registers (UNLOCK_START_BLK_ADD and UNLOCK_END_BLK_ADD) while the NFC is in the lock-tight state does not affect the unlock address.

39.6.4.4 Write Protection Status

The current write protection status of the NFC can be read in NAND Flash write protection status register (NAND_FLASH_WR_PR_ST). The unlock status, lock status, and lock-tight status bits (US*n*, LS*n*, and LTS*n*) are not cleared by hot reset. These write protection status bits are updated only when a command is issued to the NAND device.

Figure 39-40 shows a state diagram for the write protection of the NFC.

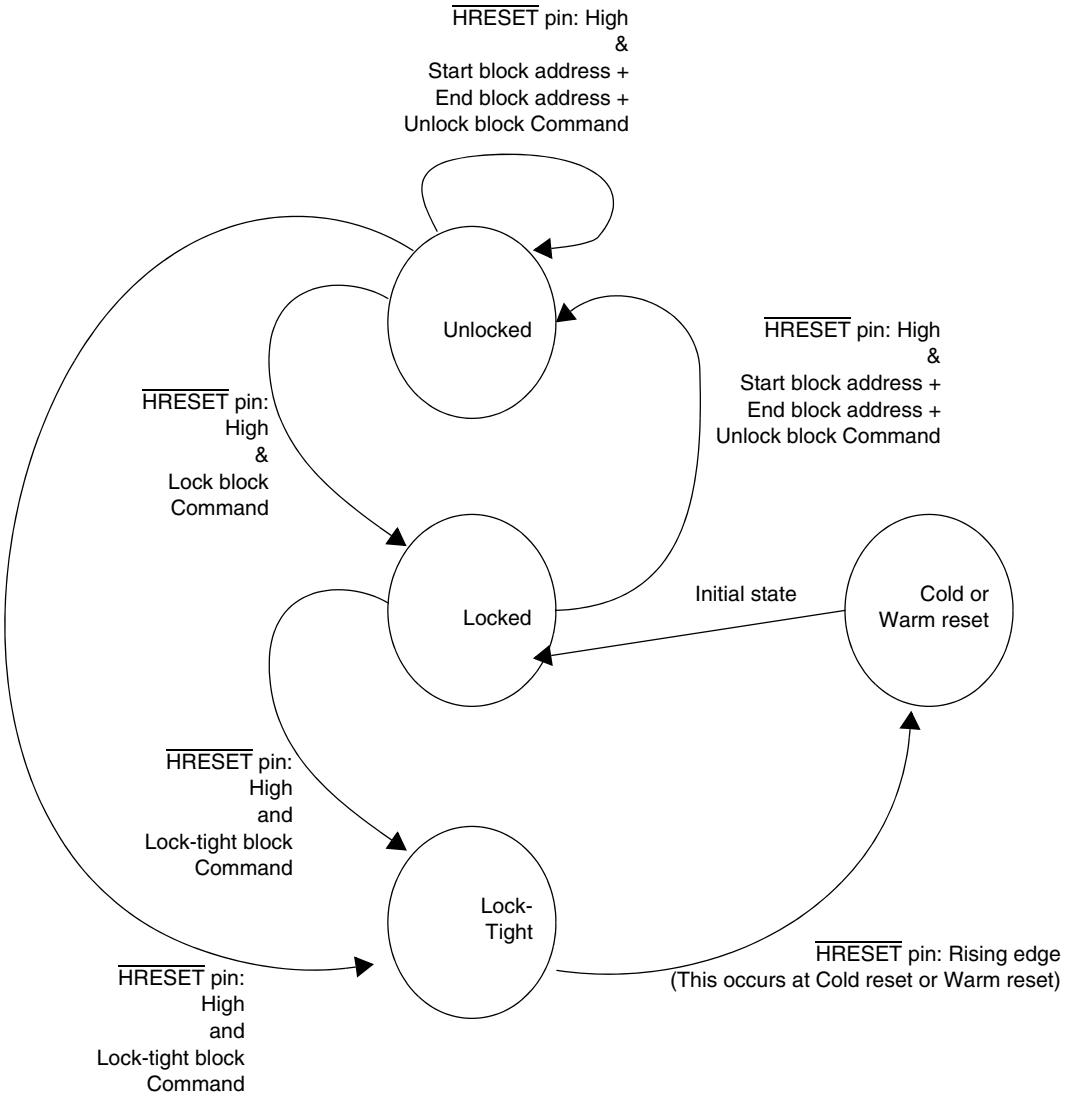

Figure 39-40. State diagram of NAND Flash Write Protection

39.6.4.4.1 Lock Sequence

The following describes the lock sequence:

1. Command sequence: LOCK BLOCK command (0x02)
2. All blocks default to locked after initial cold reset or warm reset.

3. Locking some of the blocks is not available; all memory blocks are locked upon reset except block zero.
4. Unlocked memory blocks can be locked by using the LOCK BLOCK command. The status of a locked memory block can be changed to unlocked or lock-tight using the appropriate software commands.

39.6.4.4.2 Unlock Sequence

The following describes the unlock sequence:

1. Command sequence: start block address + end block address + UNLOCK BLOCK command (0x04)
2. Unlocked blocks can be programmed or erased
3. The status of an unlocked block can be changed to locked or lock-tight using the appropriate software commands
4. Only one consecutive area can be released to unlocked state from locked state; Unlocking of nonconsecutive blocks is not available.

39.6.4.4.3 Lock-tight Sequence

The following describes the “lock-tight” sequence:

1. Only locked blocks can be “locked-tight” by the LOCK-TIGHT BLOCK command.
2. Command sequence: LOCK-TIGHT BLOCK command (0x01)
3. Lock-tight blocks revert to the locked state at cold/warm reset.

39.6.5 Memory Configuration Examples

The following figures show memory connections for various bit widths. An 8-bit configuration example is shown in Figure 39-41 and a 16-bit configuration example is shown in Figure 39-42.

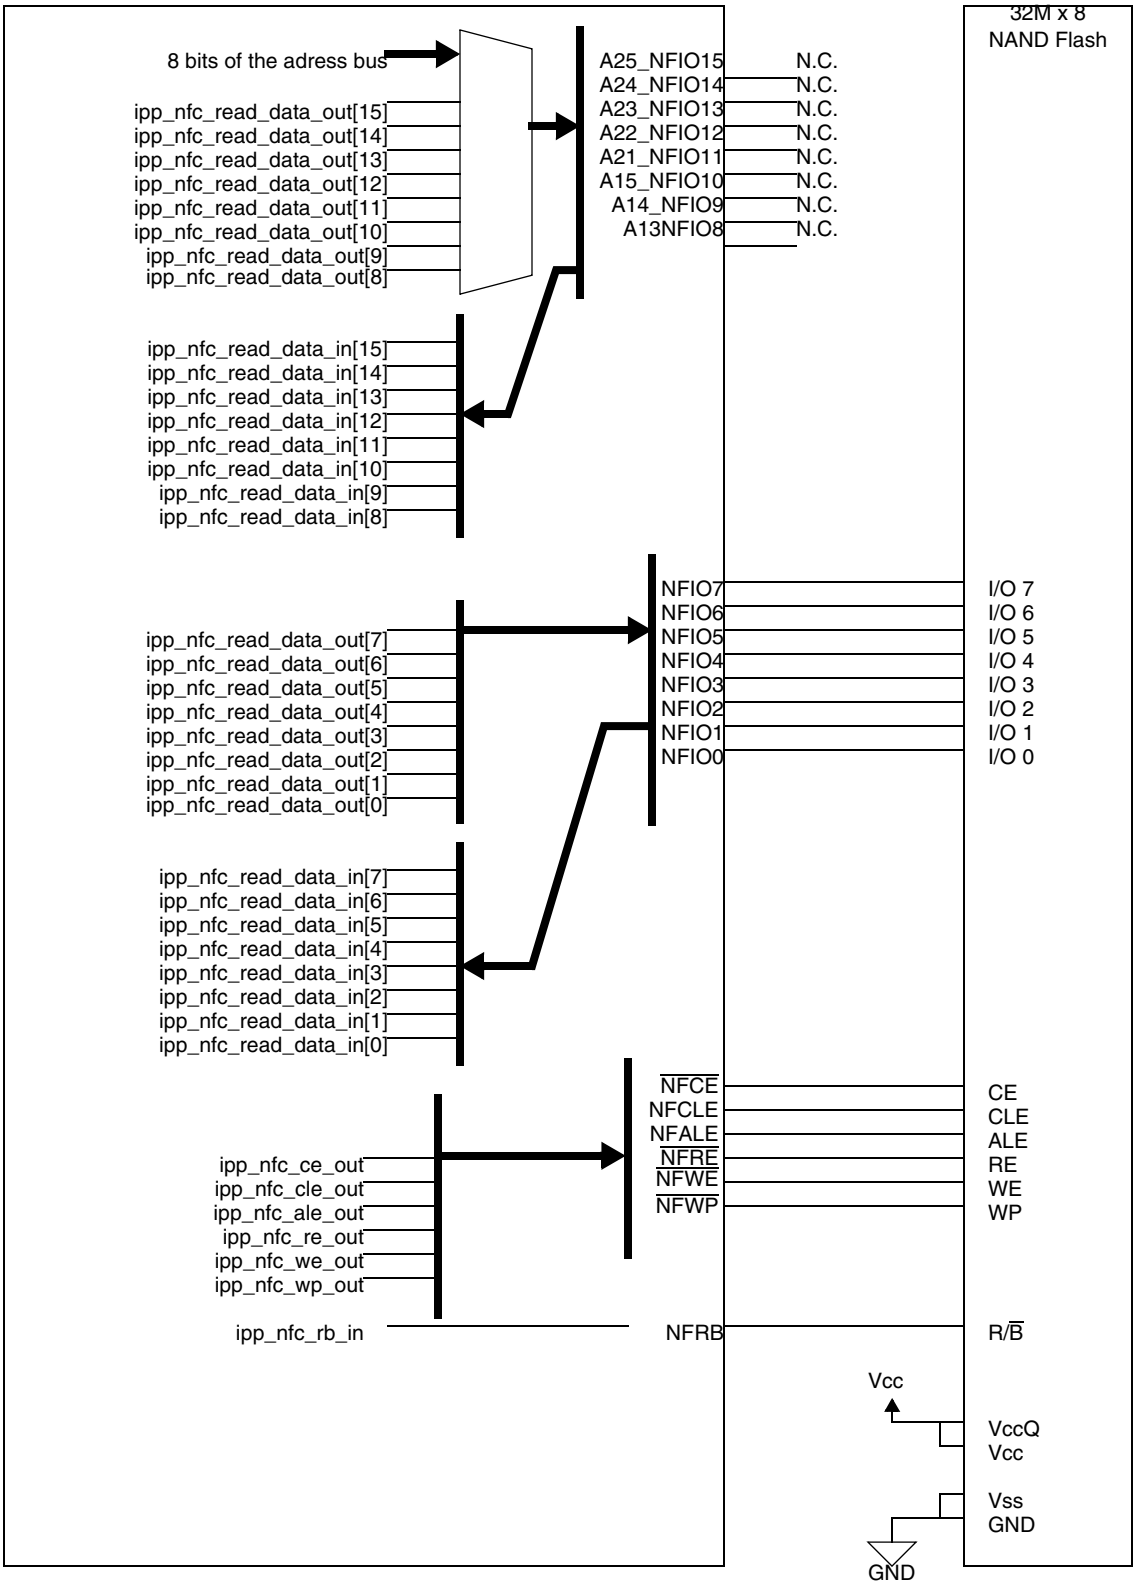

Figure 39-41. 256 Mbit (32 M x 8-bit) NAND Flash Connection Diagram

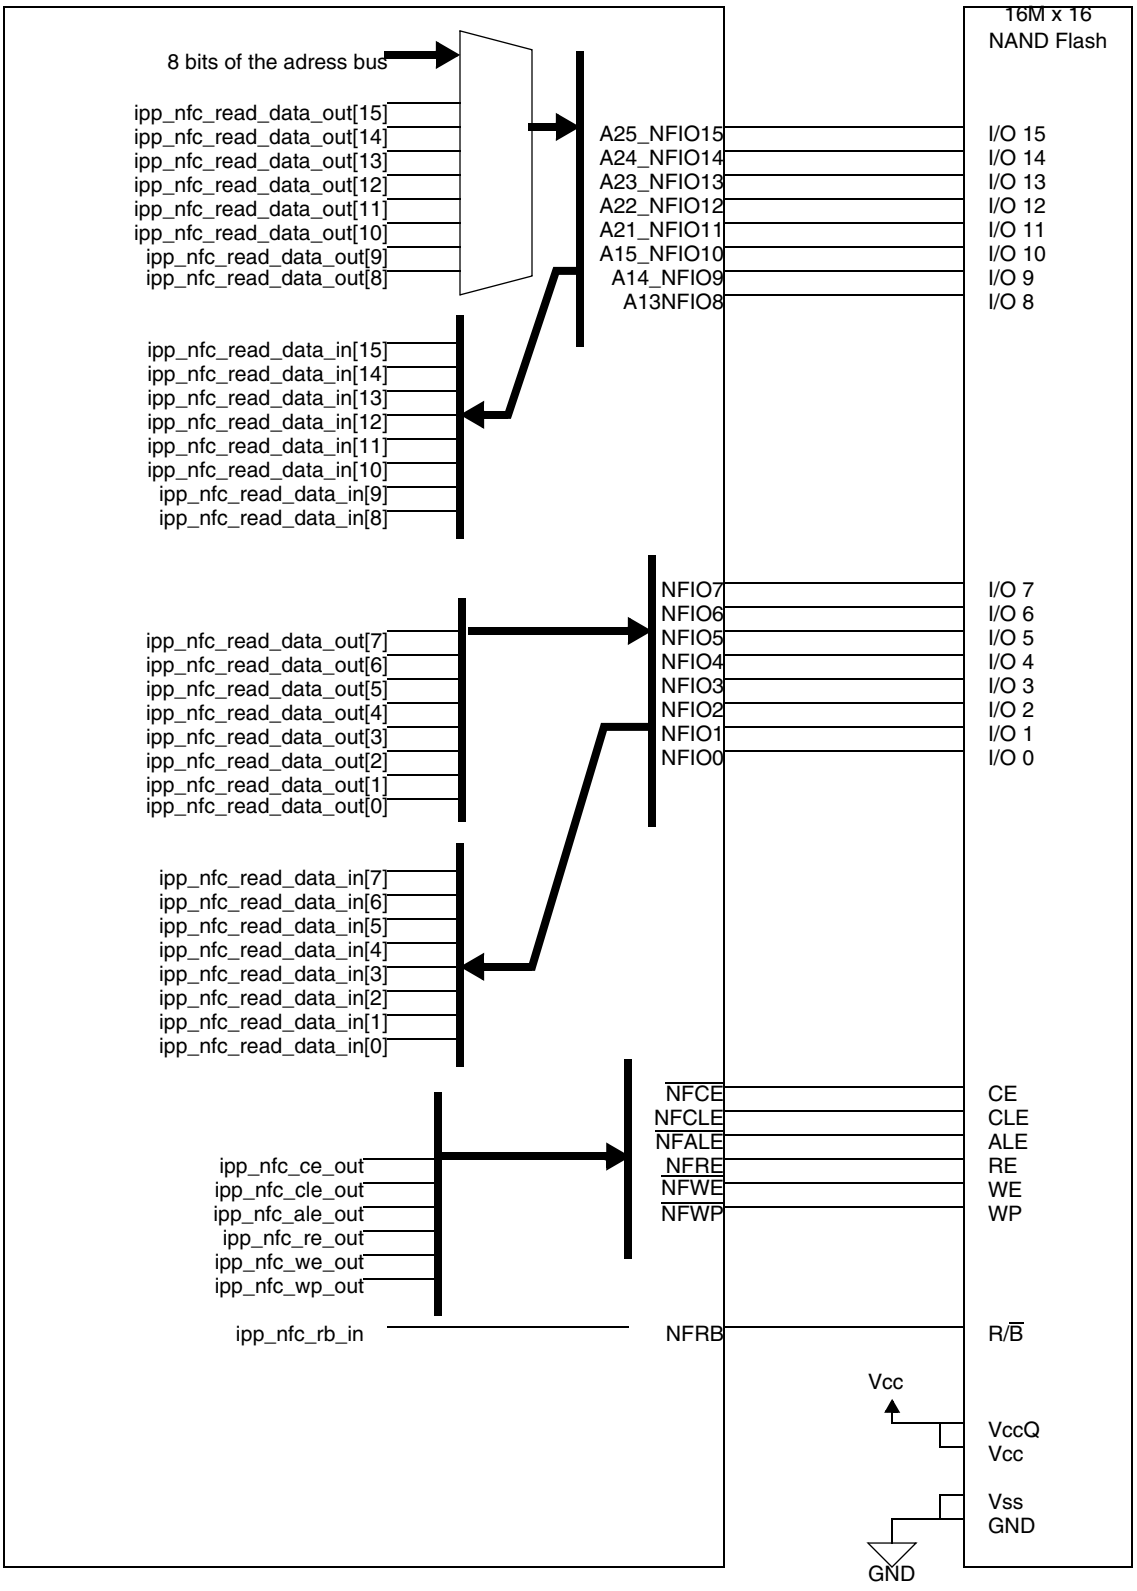

Figure 39-42. 256 Mbit (16 M x 16-bit) NAND Flash Connection Diagram

39.6.6 Verified NAND models.

The following part number models have been verified and are guaranteed to be supported by the NFC:

- k9f1g08u0m
- k9f1g16u0m
- k9f5608q0c
- k9f5616q0c
- tc58nyg0d9bxgj5
- tc58nvg4d1dtg00

NOTE

The NFC controller can support high-speed NAND Flash by supplying higher frequencies to the Flash clock input.

Chapter 40
Pulse-Width Modulator (PWM)

The pulse-width modulator (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images; it can also generate tones. It uses 16-bit resolution and a 4 × 16 data FIFO to generate sound.

40.1 Overview

This section presents an overview of the PWM. Figure 40-1 gives the PWM block diagram.

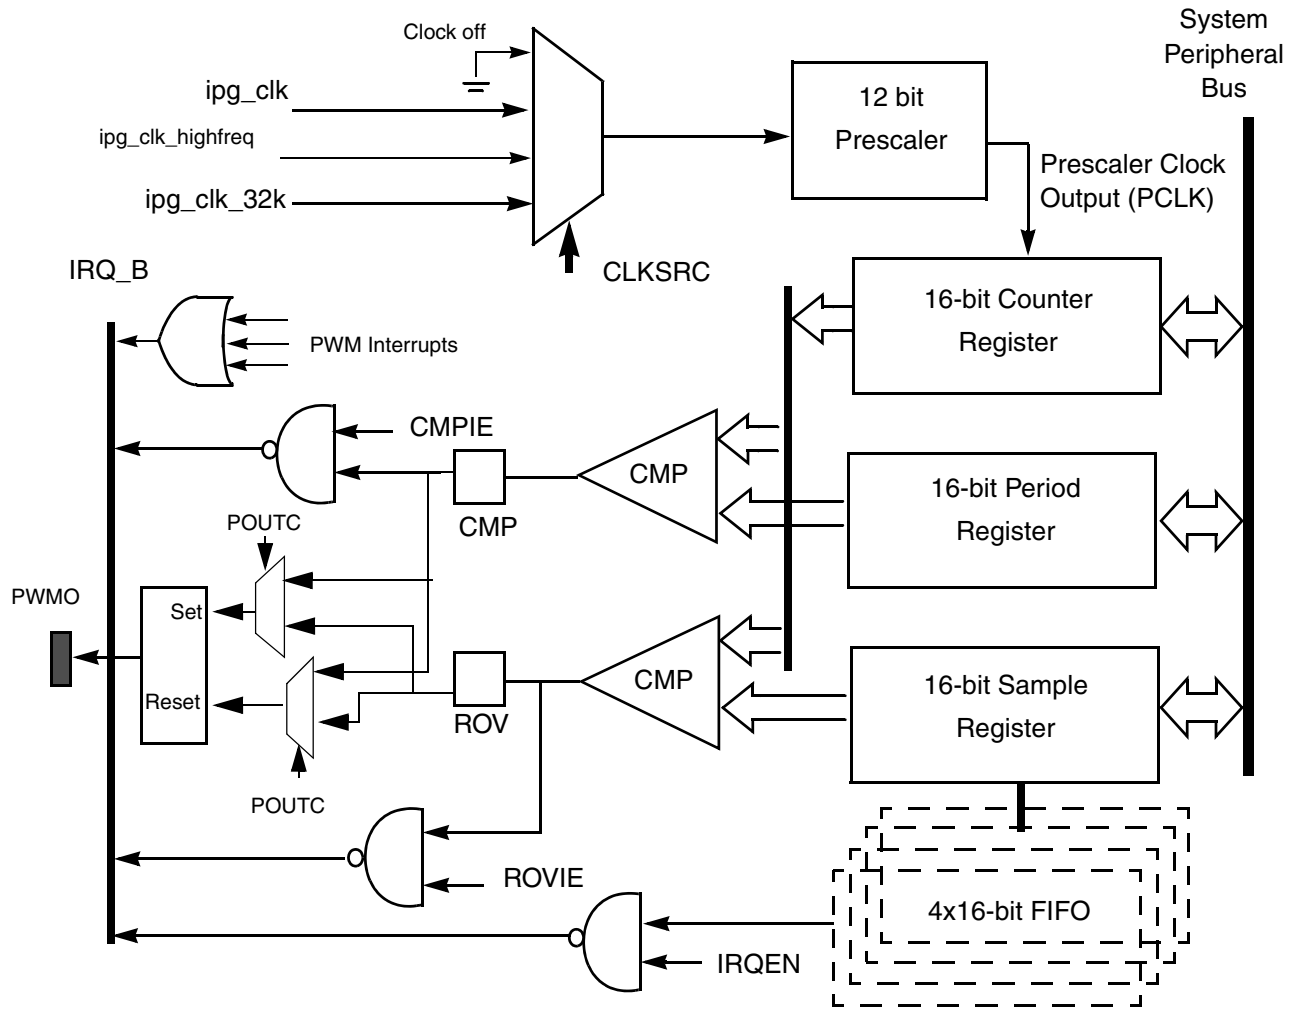

Figure 40-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4×16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power and debug modes
- Interrupts at compare and rollover

40.2 Signal Description

The PWM follows the IP Bus protocol for interfacing with the processor core. It does not have any interface signals with any other module inside the chip except for clock and reset inputs from the clock module and interrupt signals to the processor interrupt handler. There is a single output signal going outside the chip boundary.

40.2.1 External Signals

PWM has a single output signal to the chip boundary named ipp_do_pwmo.

Table 40-1 describes the external signals.

Table 40-1. External Signals

Name	Direction	Function	Reset State	Pull up
ipp_do_pwmo	Output	This is the functional output of the PWM. The modulated signal of the module is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the PWM. The smallest period can be two ipg_clk clock periods with duty cycle of 50%	0	—

40.3 Memory Map and Register Definition

The PWM module includes six user-accessible registers. Section 40.3.2, “Register Descriptions,” provides the detailed descriptions for all of the PWM registers.

The PWM memory map is shown in Table 40-2.

Table 40-2. PWM Memory Map

Offset	Register	Access	Reset Value	Section/Page
0xBASE_00 (PWMCR)	PWM Control Register (PWMCR)	R/W	0x0000_0000	40.3.2.1/40-5
0xBASE_04 (PWMSR)	PWM Status Register (PWMSR)	R/W	0x0000_0008	40.3.2.2/40-7
0xBASE_08 (PWMIR)	PWM Interrupt Register (PWMIR)	R/W	0x0000_0000	40.3.2.3/40-8
0xBASE_0C (PWMSAR)	PWM Sample Register (PWMSAR)	R/W	0x0000_0000	40.3.2.4/40-9
0xBASE_10 (PWMPR)	PWM Period Register (PWMPR)	R/W	0x0000_FFFE	40.3.2.5/40-10
0xBASE_14 (PWMCNR)	PWM Counter Register (PWMCNR)	R	0x0000_0000	40.3.2.6/40-11

40.3.1 Register Summary

Figure 40-2 shows the key to the register fields, and Table 40-3 shows the register figure conventions.

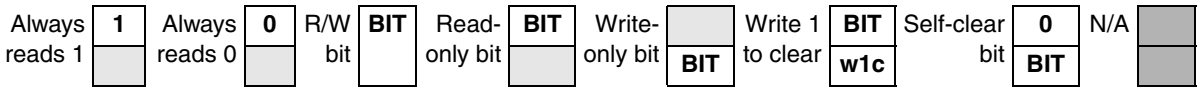

Figure 40-2. Key to Register Fields

Table 40-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 40-4 shows the PWM register summary.

40.3.2 Register Descriptions

This section contains the detailed register descriptions for the PWM registers.

40.3.2.1 PWM Control Register (PWMCR)

The PWM control register (PWMCR) is used to configure the operating settings of the PWM. It contains the prescaler for the clock division.

0xBASE_00 (PWMCR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 40-3. PWM Control Register (PWMCR)

Table 40-5. PWMCR Field Descriptions

Field	Description
31–28 Reserved	Reserved. These reserved bits are always read as zero.
27–26	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32 bit IP-Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k

Table 40-5. PWMCR Field Descriptions (Continued)

Field	Description
15 –4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 ... 0xFFF Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the module is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times
0 EN	PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins. 0 PWM disabled 1 PWM enabled

40.3.2.2 PWM Status Register (PWMSR)

The PWM status register (PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. FE, ROV, and CMP bits are associated to FIFO-Empty, Roll-over, and Compare interrupts, respectively.

0xBASE_04 (PWMSR) Access: User read-write

Figure 40-4. PWM Status Register (PWMSR)

Table 40-6. PWMSR Field Descriptions

Field	Description
31–7 Reserved	Reserved. These reserved bits are always read as zero.
6 FWE	FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full. 0 FIFO write error not occurred 1 FIFO write error occurred
5 CMP	Compare Status. This bit shows that a compare event has occurred. 0 Compare event not occurred 1 Compare event occurred
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
2–0 FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

40.3.2.3 PWM Interrupt Register (PWMIR)

The PWM Interrupt register (PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

0xBASE_08 (PWMIR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40-7. PWMIR Field Descriptions

Field	Description
31–3 Reserved	Reserved. These reserved bits are always read as zero.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt. 0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

40.3.2.4 PWM Sample Register (PWMSAR)

The PWM sample register (PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written and read when the PWM is disabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the ipp_pwm_pwmo output signal being always low/high (POUTC =00 it will be low and POUTC = 01 it will be high), and hence no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be reset/set depending on POUTC value.

0xBASE_0C (PWMSAR) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–16 Reserved	These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

40.3.2.5 PWM Period Register (PWMPR)

The PWM period register (PWMPR) determines the period of the PWM output signal (PWMO) in terms of the prescaler clock output (PCLK). After the counter value matches PERIOD + 1, the counter is reset to start another period. The frequencies of PWMO and PCLK are related by the following equation:

$$f_{PWMO} = f_{PCLK} / (PERIOD + 2) \qquad \textit{Eqn. 40-1}$$

A value of zero in the PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWMPR results in the counter being reset to zero and the start of a new count period.

0xBASE_10 (PWMPR) Access: User read-write

Field	Description
31–16 Reserved	These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

40.4 Functional Description

The following sections detail the PWM operation and function.

40.4.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the [Value in Period register] + 1. After this match occurs the Counter is reset to 0x0000.

At the beginning of a count period cycle, the PWMO pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWMO signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers begin cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

40.4.1.1 Clocks

The clock that feeds the prescaler can be selected from:

- **High-frequency Clock** (ipg_clk_highfreq) pat_ref or CKIH

  This is a high frequency clock provided by the clock module (CM). This clock is supposed to be on in the low-power mode when the ipg_clk is turned off. Thus the PWM can be run on this clock in the low-power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in the normal functional mode and switch to the unsynchronized version in the low-power mode.
- **Low-frequency Reference Clock** (ipg_clk_32k) CKIL

  This is the 32 KHz low-frequency reference clock which is provided by the CM. This clock is supposed to be on in the low-power mode when ipg_clk is turned off. Thus PWM can be run on this clock in the low-power mode. The CCM is expected to provide this clock after synchronizing it to ahb_clk in the normal functional mode and switch to the unsynchronized version in the low-power mode.
- **Global Functional Clock** (ipg_clk)

  This clock is supposed to be on in normal operations. In low-power modes it can be switched off.

The clock input source is determined by the CLKSRC field of the PWM control register. **The CLKSRC value should only be changed when the PWM is disabled.**

A change in the value of the PRESCALER field of the control register is immediately reflected in the output clock frequency.

40.4.1.2 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The byte order can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write in the sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written into when the PWM is disabled. The FIFOAV field shows how many data words are currently contained in the FIFO and if it can be written into.

A read on the sample register yields the current FIFO value being used or will be used by the PWM for generation on the output signal. Therefore a write and a subsequent read on the sample register may result in different values being obtained.

40.4.1.3 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PERIOD + 1 and resumes counting thereafter. This event is referred to as a rollover. When PERIOD = 0x0000, the counter is reset after count reaches 0x0001. Therefore PERIOD = 0xFFFF or 0xFFFE results in the counter value being reset after count till 0xFFFF. During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

40.4.1.4 Low-Power Mode Behavior

In low-power modes if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced depending on whether the control bit for that mode is set. In the absence of the clock itself or if the corresponding low-power bit in the control register is 0, the counter is reset and resumes counting when it exits the low-power mode.

40.4.1.5 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

Chapter 41 Real Time Clock (RTC)

See Figure 41-1 for a block diagram of the functional organization of the real time clock (RTC) block. The block consists of the following sub-blocks:

- Prescaler
- Time-of-day (TOD) clock counter
- Alarm
- Sampling timer
- Minute stopwatch
- Associated control and bus interface hardware

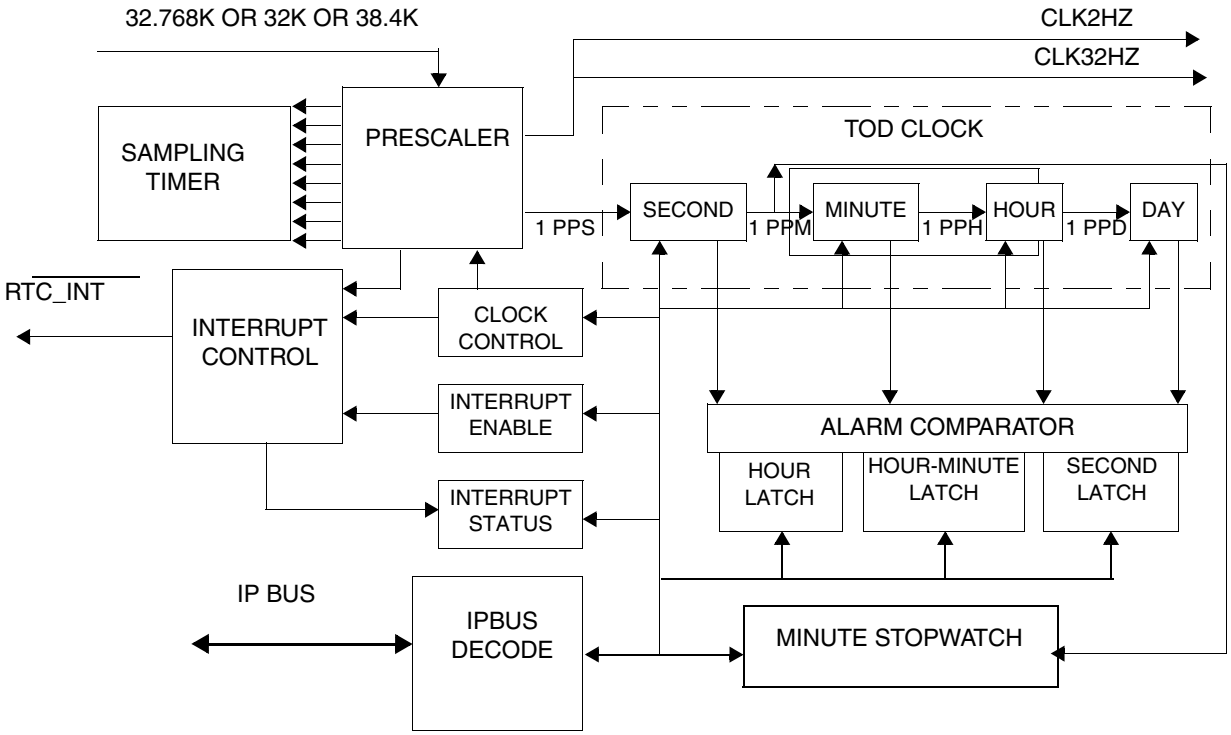

Figure 41-1. Real Time Clock Block Diagram

41.1 Overview

This section discusses how to operate and program the real-time clock (RTC) module that maintains the system clock, provides stopwatch, alarm, and interrupt functions, and supports the features described in Section 41.1.1, “Features.”

41.1.1 Features

The RTC module includes the following features:

- Full clock—days, hours, minutes, seconds
- Minute countdown timer with interrupt
- Programmable daily alarm with interrupt
- Sampling timer with interrupt
- Once-per-day, once-per-hour, once-per-minute, and once-per-second interrupts

41.1.2 Modes of Operation

The prescaler converts the incoming crystal reference clock to a 1 Hz signal which is used to increment the seconds, minutes, hours, and days TOD counters. The alarm functions, when enabled, generate RTC interrupts when the TOD settings reach programmed values. The sampling timer generates fixed-frequency interrupts, and the minute stopwatch allows for efficient interrupts on minute boundaries.

- Prescaler and counter

  The prescaler divides the reference clock down to 1 Hz. The reference frequency is 32 kHz by default (optional at 32.768 kHz or 38.4 kHz).
- The counter portion of the RTC module consists of four groups of counters that are physically located in three registers:
  - The 6-bit seconds counter is located in the SECONDS register
  - The 6-bit minutes counter and the 5-bit hours counter are located in the HOURMIN register
  - The 16-bit day counter is located in the DAYR register
- Alarm

  There are three alarm registers that mirror the three counter registers. An alarm is set by accessing the real-time clock alarm registers (ALRM_HM, ALRM_SEC, and DAYALARM) and loading the exact time that the alarm should generate an interrupt. When the TOD clock value and the alarm value coincide, an interrupt occurs.
- Sampling timer

  The sampling timer is designed to support application software. The sampling timer generates a periodic interrupt with the frequency specified by the SAMx bits of the RTCIENR register. This timer can be used for digitizer sampling, keyboard debouncing, or communication polling. The sampling timer operates only if the real-time clock is enabled. See Table 41-15 for the list of the interrupt frequencies of the sampling timer for the possible reference clocks.
- Minute stopwatch

  The minute stopwatch performs a countdown with a one minute resolution. It can be used to generate an interrupt on a minute boundary.

41.2 External Signal Description

The RTC has no external signals.

41.2.1 Overview

There are no signals connected off the chip.

41.3 Memory Map and Register Definition

The RTC module has ten registers. Section 41.3.3, “Register Descriptions” on page 41-6 provides the detailed descriptions for all of the RTC registers.

41.3.1 Memory Map

Table 41-2 shows the RTC memory map.

Table 41-2. RTC Register Memory Map

Address	Register	Access	Reset Values	Section/Page
0x53FD_8000 (HOURMIN)	RTC Hours and Minutes Counter Register (HOURMIN)	R/W	0x0000_– – – –	41.3.3.1/41-6

41.3.2 Register Summary

Figure 41-2 shows the key to the register fields and Table 41-3 shows the register figure conventions.

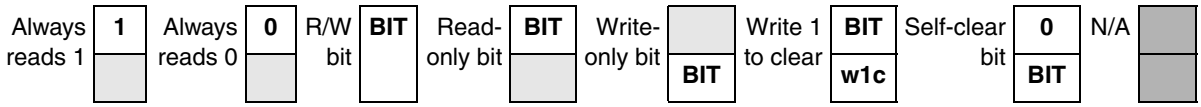

Figure 41-2. Key to Register Fields

Table 41-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 41-4 shows the RTC register summary.

41.3.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

41.3.3.1 RTC Hours and Minutes Counter Register (HOURMIN)

The real-time clock hours and minutes counter register (HOURMIN) is used to program the hours and minutes for the TOD clock. It can be read or written at any time. After a write, the time changes to the new value. This register cannot be reset since the real-time clock is always enabled at reset.

See Figure 41-3 for illustration of valid bits in the hours and minutes counter register and Table 41-5 for description of the bit fields.

0x53FD_8000 (HOURMIN) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 41-3. RTC Hours and Minutes Counter Register

Table 41-5. RTC Hours and Minutes Counter Register Field Descriptions

Field	Description
31–13	Reserved
12–8 HOUR	Hour setting indicates the current hour that can be set to any value between 0 and 23. 00000 Current hour is 0 00001 Current hour is 1 .... 10111 Current hour is 23. Indicates the current hour that can be set to any value between 0 and 23.
7–5	Reserved
5–0 MINUTES	Minutes setting indicates the current minutes that can be set to any value between 0 and 59. 000000 Current minute is 0 000001 Current minute is 1 .... 111011 Current minute is 59

The HOURS and MINUTES are not affected by any of the hardware or software reset, so their RESET values are “unknown”.

41.3.3.2 RTC Seconds Counter Register (SECONDS)

The real-time clock seconds register (SECONDS) is used to program the seconds for the TOD clock. It can be read or written at any time. After a write, the time changes to the new value. This register cannot be reset since the real-time clock is always enabled at reset.

See Figure 41-4 for illustration of valid bits in the RTC seconds counter register and Table 41-6 for description of the bit fields.

0x53FD_8004 (SECONDS) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

5–0 SECONDS	Seconds setting indicates the current seconds that can be set to any value between 0 and 59. 000000 Current second is 0 000001 Current second is 1 .... 111011 Current second is 59

The SECONDS are not affected by any of the hardware or software reset, so their RESET values are “unknown”.

41.3.3.3 RTC Hours and Minutes Alarm Register (ALRM_HM)

The real-time clock hours and minutes alarm (ALRM_HM) register is used to configure the hours and minutes setting for the alarm. The alarm settings can be read or written at any time.

See Figure 41-5 for illustration of valid bits in the RTC hours and minutes alarm register and Table 41-7 for description of the bit fields.

0x53FD_8008 (ALRM_HM) Access: User read/write

41.3.3.4 RTC Seconds Alarm Register (ALRM_SEC)

The real-time clock seconds alarm (ALRM_SEC) register is used to configure the seconds setting for the alarm. The alarm settings can be read or written at any time.

See Figure 41-6 for illustration of valid bits in the RTC seconds alarm register and Table 41-8 for description of the bit fields.

41.3.3.5 RTC Control Register (RTCCTL)

The real-time clock control (RTCCTL) register is used to enable the real-time clock module and specify the reference frequency information for the prescaler.

See Figure 41-7 for illustration of valid bits in the RTC control register and Table 41-9 for description of the bit fields.

0x53FD_8010 (RTCCTL) Access: User read/write

RESET	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Figure 41-7. RTC Control Register

Table 41-9. RTC Control Register Field Descriptions

Field	Description
31–8	Reserved
7 EN	Enables/Disables the real-time clock. The software reset bit (SWR) has no effect on this bit. Bit description 0 Disable the real-time clock 1 Enable the real-time clock
6–5 XTL	Crystal Selection. Selects the proper input crystal frequency. It is important to set these bits correctly or the real-time clock will be inaccurate. 00 input crystal frequency is 32.768 kHz 01 input crystal frequency is 32 kHz (recommended) 10 input crystal frequency is 38.4 kHz 11 input crystal frequency is 32.768 kHz
4–2	Reserved
1 GEN	GEN — IPG_CLK gating enable. Decides whether to enable or disable the ipg_clk gating. Upon reset the ipg_clk gating is enabled. 0 Enable ipg_clk gating 1 Disable ipg_clk gating
0 SWR	Software reset. Resets the module to its default state. However, a software reset will have no effect on the RTC enable (EN) bit. 0 No effect 1 Reset the module to its default state
Note: The reference frequency for the real-time clock counter is 32 kHz. It comes from the clock controller module, where the 24-Mhz clock is divided by 750 to generate a 32-kHz clock.	

41.3.3.6 RTC Interrupt Status Register (RTCISR)

The real-time clock interrupt status register (RTCISR) indicates the status of the various real-time clock interrupts. When an event of the types included in this register occurs, then the bit will be set in this register regardless of its corresponding interrupt enable bit.These bits are cleared by writing a value of 1, which also clears the interrupt. Interrupts may occur while the system clock is idle or in sleep mode. Every interrupt status bit is independent of each other.

See Figure 41-8 for illustration of valid bits in the RTC interrupt status register and Table 41-10 for description of the bit fields.

0x53FD_8014 (RTCISR) Access: User read/write

Figure 41-8. RTC Interrupt Status Register

Table 41-10. RTC Interrupt Status Register Field Descriptions

Field	Description
31–16	Reserved
15 SAM7	Sampling Timer Interrupt Flag at SAM7 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 512, 500, or 600 Hz depending on different input clock. 0 No SAM7 interrupt occurred. 1 A SAM7 interrupt occurred.
14 SAM6	Sampling Timer Interrupt Flag at SAM6 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 256, 250, or 300 Hz depending on different input clock. 0 No SAM6 interrupt occurred. 1 A SAM6 interrupt occurred.
13 SAM5	Sampling Timer Interrupt Flag at SAM5 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 128, 125, or 150 Hz depending on different input clock. 0 No SAM5 interrupt occurred. 1 A SAM5 interrupt occurred.
12 SAM4	Sampling Timer Interrupt Flag at SAM4 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 64, 62.5, or 75 Hz depending on different input clock. 0 No SAM4 interrupt occurred. 1 A SAM4 interrupt occurred.
11 SAM3	Sampling Timer Interrupt Flag at SAM3 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 32, 31.25, or 37.5 Hz depending on different input clock. 0 No SAM3 interrupt occurred. 1 A SAM3 interrupt occurred.
10 SAM2	Sampling Timer Interrupt Flag at SAM2 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 16, 15.625, or 18.75 Hz depending on different input clock. 0 No SAM2 interrupt occurred. 1 A SAM2 interrupt occurred.

Table 41-10. RTC Interrupt Status Register Field Descriptions (Continued)

Field	Description
9 SAM1	Sampling Timer Interrupt Flag at SAM1 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 8, 7.8125, or 9.375 Hz depending on different input clock. 0 No SAM1 interrupt occurred. 1 A SAM1 interrupt occurred.
8 SAM0	Sampling Timer Interrupt Flag at SAM0 Frequency. Indicates that an interrupt has occurred. If enabled, this bit is periodically set at a rate of 4, 3.90625, or 4.6875 Hz depending on different input clock. 0 No SAM0 interrupt occurred. 1 A SAM0 interrupt occurred.
7 2 Hz	2 Hz Flag. Indicates that an interrupt has occurred. If enabled, this bit is set at every 2 Hz frequency. 0 No 2 Hz interrupt occurred. 1 A 2 Hz interrupt has occurred.
6	Reserved
5 HR	Hour Flag. Indicates that the hour counter has increment. If enabled, this bit is set on every increment of the hour counter in the time-of-day clock. 0 No 1-hour interrupt occurred. 1 A 1-hour interrupt has occurred.
4 1 Hz	1 Hz Flag. Indicates that the second counter has increment. If enabled, this bit is set on every increment of the second counter of the time-of-day clock. 0 No 1 Hz interrupt occurred. 1 A 1 Hz interrupt has occurred.
3 DAY	Day Flag. indicates that the day counter has increment. If enabled, this bit is set on every increment of the day counter of the time-of-day clock. 0 No 24-hour rollover interrupt occurred. 1 A 24-hour rollover interrupt has occurred.
2 ALM	Alarm Flag. Indicates that the real-time clock matches the value in the alarm registers. The alarm will reoccur every 65536 days. For a single alarm, clear the interrupt enable for this bit in the interrupt service routine. 0 No alarm interrupt occurred. 1 An alarm interrupt has occurred.
1 MIN	Minute Flag. Indicates that the minute counter has increment. If enabled, this bit is set on every increment of the minute counter in the time-of-day clock. 0 No 1-minute interrupt occurred. 1 A 1-minute interrupt has occurred.
0 SW	Stopwatch Flag. Indicates that the stopwatch countdown timed out. 0 The stopwatch did not time out. 1 The stopwatch timed out.

41.3.3.7 RTC Interrupt Enable Register (RTCIENR)

The real-time clock interrupt enable register (RTCIENR) is used to enable/disable the various real-time clock interrupts. Masking an interrupt bit has no effect on its corresponding status bit. Every interrupt enable bit is independent of each other.

See Figure 41-9 for illustration of valid bits in the RTC interrupt enable register and Table 41-11 for description of the bit fields.

8 SAM0	Sampling Timer Interrupt Flag at SAM0 Interrupt. Enables/Disables the real-time sampling timer interrupt 0. 0 The SAM0 interrupt is disabled. 1 The SAM0 interrupt is enabled.

Table 41-11. RTC Interrupt Enable Register Field Descriptions (Continued)

Field	Description
7 2 Hz	2 Hz Interrupt Enable. Enables/Disables an interrupt at a 2 Hz rate. 0 The 2-Hz interrupt is disabled. 1 The 2-Hz interrupt is enabled.
6	Reserved
5 HR	Hour Interrupt Enable. Enables/Disables an interrupt whenever the hour counter of the real-time clock increments. 0 The 1-hour interrupt id disabled. 1 The 1-hour interrupt is enabled.
4 1HZ	1 Hz Interrupt Enable. Enables/Disables an interrupt whenever the second counter of the real-time clock increments. 0 The 1-Hz interrupt is disabled. 1 The 1-Hz interrupt is enabled.
3 DAY	Day Interrupt Enable. Enables/Disables an interrupt whenever the hours counter rolls over from 23 to 0. (midnight rollover) 0 The 24-hour interrupt is disabled. 1 The 24-hour interrupt is enabled.
2 ALM	Alarm Interrupt Enable. Enables/Disables the alarm interrupt. 0 The alarm interrupt is disabled. 1 The alarm interrupt is enabled.
1 MIN	Minute Interrupt Enable. Enables/Disables an interrupt whenever the minute counter of the real-time clock increments. 0 The 1-minute interrupt is disabled. 1 The 1-minute interrupt is enabled.
0 SW	Stopwatch Interrupt Enable. Enables/Disables the stopwatch interrupt. **Note:** The stopwatch counts down and remains at decimal -1 until it is reprogrammed. If this bit is enabled with -1 (decimal) in the STPWCH register, an interrupt will be posted on the next minute tick. 0 Stopwatch interrupt is disabled. 1 Stopwatch interrupt is enabled.

41.3.3.8 RTC Stopwatch Minutes Register (STPWCH)

The stopwatch minutes (STPWCH) register contains the current stopwatch countdown value. When the minute counter of the TOD clock increments, the value in this register decrements.

See Figure 41-10 for illustration of valid bits in the stopwatch minutes counter register and Table 41-12 for description of the bit fields.

0x53FD_801C (STPWCH) Access: User read/write

Figure 41-10. RTC Stopwatch Minutes Register

Table 41-12. RTC Stopwatch Minutes Register Field Descriptions

Field	Description
31–6	Reserved
5-0 CNT	Stopwatch Count. Contains the stopwatch countdown value. **Note:** The stopwatch counter is decremented by the minute (MIN) tick output from the real-time clock, so the average tolerance of the count is 0.5 minute. For better accuracy, enable the stopwatch by polling the MIN bit of the RTCISR register or by polling the minute interrupt service routine. 000000 stopwatch countdown value is 0 000001 stopwatch countdown value is 1 .... 111111 stopwatch countdown value is 63

41.3.3.9 RTC Days Counter Register (DAYR)

The real-time clock days counter register (DAYR) is used to program the day for the TOD clock. When the HOUR field of the HOURMIN register rolls over from 23 to 00, the day counter increments. It can be read or written at any time. After a write, the time changes to the new value. This register cannot be reset since the real-time clock is always enabled at reset.

See Figure 41-11 for illustration of valid bits in the counter register and Table 41-13 for description of the bit fields.

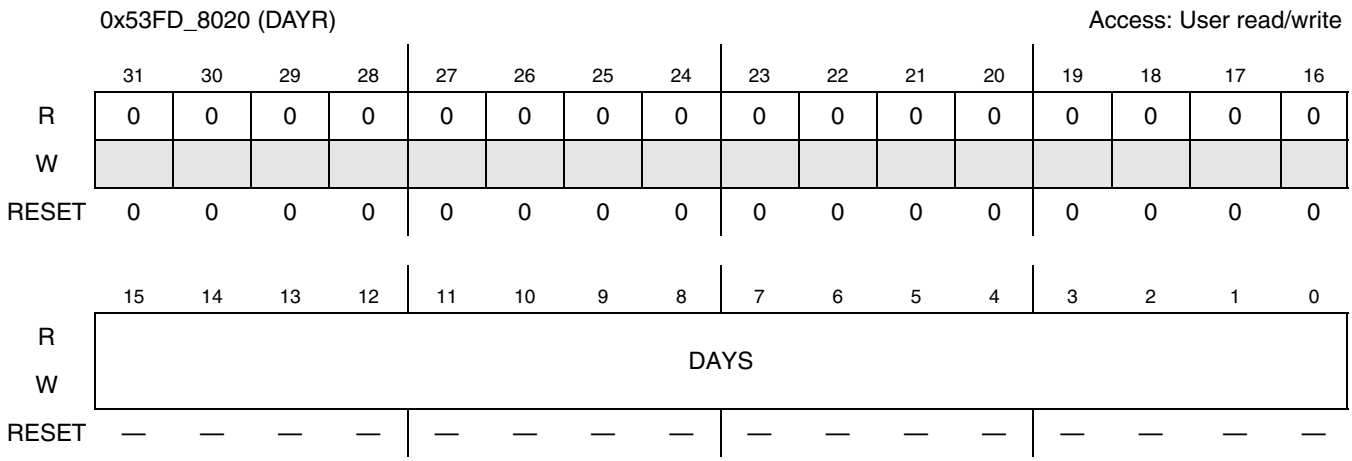

Figure 41-11. RTC Days Counter Register

Table 41-13. RTC Days Counter Register Field Descriptions

Field	Description
31–16	Reserved
15–0 DAYS	Day Setting. Indicates the current day count, can be set to any values between 0 and 65535. 0x0000 current day count is 0 0x0001 current day count is 1 .... 0xFFFF current day count is 65535

The DAYS are not affected by any of the hardware or software reset, so their RESET values are “unknown”.

41.3.3.10 RTC Day Alarm Register (DAYALARM)

The real-time clock day alarm (DAYALARM) register is used to configure the day for the alarm. The alarm settings can be read or written at any time.

See Figure 41-12 for illustration of valid bits in the RTC day alarm register and Table 41-14 for description of the bit fields.

Figure 41-12. RTC Day Alarm Register

Table 41-14. RTC Day Alarm Register Field Descriptions

Field	Description
31–16	Reserved
15–0 DAYSAL	Day Setting of the Alarm. Indicates the current day setting of the alarm. It can be set to any value between 0 and 65535. 0x0000 current day setting of alarm is 0 0x0001 current day setting of alarm is 1 .... 0xFFFF current day setting of alarm is 65535

41.4 Functional Description

The prescaler converts the incoming crystal reference clock to a 1-Hz signal which is used to increment the seconds, minutes, hours, and days TOD counters. The alarm functions, when enabled, generate RTC interrupts when the TOD settings reach programmed values. The sampling timer generates fixed-frequency interrupts, and the minute stopwatch allows for efficient interrupts on minute boundaries.

41.4.1 Prescaler and Counter

The prescaler divides the reference clock down to 1 Hz. The reference frequency is 32 kHz by default (optional at 32.768 kHz or 38.4 kHz). The prescaler stages are tapped to support the sampling timer.

The counter portion of the RTC module consists of four groups of counters that are physically located in three registers:

- The 6-bit seconds counter is located in the SECONDS register.
- The 6-bit minutes counter and the 5-bit hours counter are located in the HOURMIN register.
- The 16-bit day counter is located in the DAYR register.

These counters cover a 24-hour clock over 65536 days. All three registers can be read or written at any time.

Interrupts signal when each of the four counters increments, and can be used to indicate when a counter rolls over. For example, each tick of the seconds counter causes the 1-Hz interrupt flag to be set. When the seconds counter rolls from 59 to 00, the minute counter increments and the MIN interrupt flag is set. The same is true for the minute counter with the HR signal, and the hour counter with the DAY signal.

41.4.2 Alarm

There are three alarm registers that mirror the three counter registers:

- ALRM_HM
- ALRM_SEC
- DAYALARM

An alarm is set by accessing the three real-time clock alarm registers and loading the exact time that the alarm should generate an interrupt. When the TOD clock value and the alarm value coincide, if the ALM bit in the real-time clock interrupt enable register (RTCIENR) is set, an interrupt occurs.

NOTE

If the alarm is not disabled, it will reoccur every 65536 days. If a single alarm is desired, the alarm function must be disabled through the RTC interrupt enable register (RTCIENR).

41.4.3 Sampling Timer

The sampling timer is designed to support application software. The sampling timer generates a periodic interrupt with the frequency specified by the SAMx bits of the RTCIENR register. This timer can be used for digitizer sampling, keyboard debouncing, or communication polling. The sampling timer operates only if the real-time clock is enabled. See Table 41-15 for the list of the interrupt frequencies of the sampling timer for the possible reference clocks.

Multiple SAMx bits may be set in the RTC interrupt enable register (RTCIENR). The corresponding bits in the RTC interrupt status register (RTCISR) will be set at the noted frequencies.

Table 41-15. Sampling Timer Frequencies

Sampling Frequency	32.768-kHz Reference Clock	32-kHz Reference Clock (Default Source)	38.4-kHz Reference Clock
SAM7	512 Hz	500 Hz	600 Hz
SAM6	256 Hz	250 Hz	300 Hz
SAM5	128 Hz	125 Hz	150 Hz
SAM4	64 Hz	62.5 Hz	75 Hz
SAM3	32Hz	31.25 Hz	37.5 Hz
SAM2	16 Hz	15.625 Hz	18.75 Hz
SAM1	8 Hz	7.8125 Hz	9.375 Hz
SAM0	4 Hz	3.90625 Hz	4.6875 Hz

41.4.4 Minute Stopwatch

The minute stopwatch performs a countdown with a one minute resolution. It can be used to generate an interrupt on a minute boundary. For example, to turn off the LCD controller after five minutes of inactivity, program a value of 0x04 into the stopwatch count (CNT) field of the stopwatch minutes (STPWCH) register. At each minute, the value in the stopwatch is decremented. When the stopwatch value reaches -1, the interrupt occurs. The value of the register does not change until it is reprogrammed.

NOTE

The actual delay includes the seconds from setting the stopwatch to the next minute tick.

Chapter 42
Smart Direct Memory Access (SDMA) Controller

42.1 Introduction

The smart direct memory access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by offloading the CPU in dynamic data routing.

NOTE

In this document, “AP” refers to interfaces to the ARM (Applications Processor) core.

42.1.1 Overview

Figure 42-1 shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units,the CRC unit, and the scheduler.

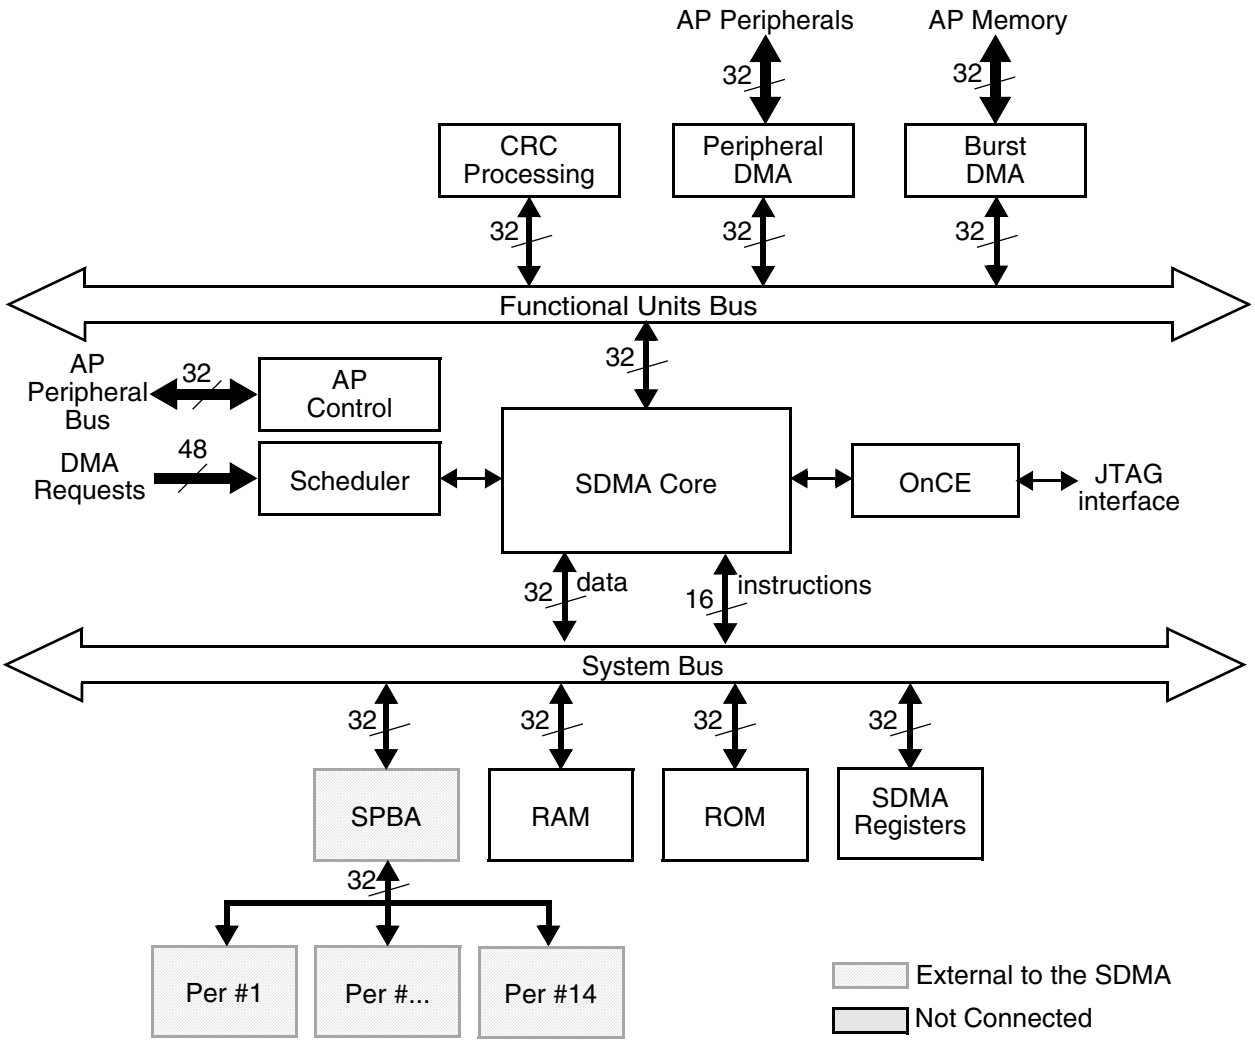

Figure 42-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in Section 42.11.5.1, “Instruction Memory Map” and Section 42.11.5.2, “Data Memory Map”).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the AP. Every channel contains a corresponding channel script located in RAM and/or ROM that can

be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to “conditionally yield” the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two `yield` instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (`yieldge`), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the “Channel Pending (EP)” register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The AP Control module contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This module also contains all other control registers that the AP can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The “receive register full” and “transmit register empty” signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

42.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)

  - Misaligned data-transfer support
  - Uni-directional and bi-directional flows (copy mode)
  - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping and CRC calculations
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the AP DMA units
    - 1:2 ratio with maximum of SDMA core running at AP Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and AP DMA clocks are set to the AP Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the AP
- The SDMA RISC engine (arithmetic and logic operations, plus CRC acceleration), which is referred to as the “SDMA core.”
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.
- The peripheral DMA unit that is hooked-up to the AP Crossbar Switch to service AP peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

42.2 Functional Description

Figure 42-2 shows the SDMA topology, and is composed of the following components:

- SDMA Core (Section 42.3, “SDMA Core”)
- SDMA Scheduler (Section 42.4, “Scheduler”)
- Functional Units:
  - CRC (Section 42.5.1, “CRC Calculation Unit”)
  - Burst DMA (Section 42.5.2, “Burst DMA Unit”)
  - Peripheral DMA (Section 42.5.3, “Peripheral DMA Unit”)
- AP Control for AP control register access.

- Internal RAM and ROM Memory (Section 42.11, “SDMA Programming Model)
- OnCE debug Port (Section 42.17, “The OnCE Controller”)

The functional unit bus provides access by the SDMA core to the CRC hardware accelerator and the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

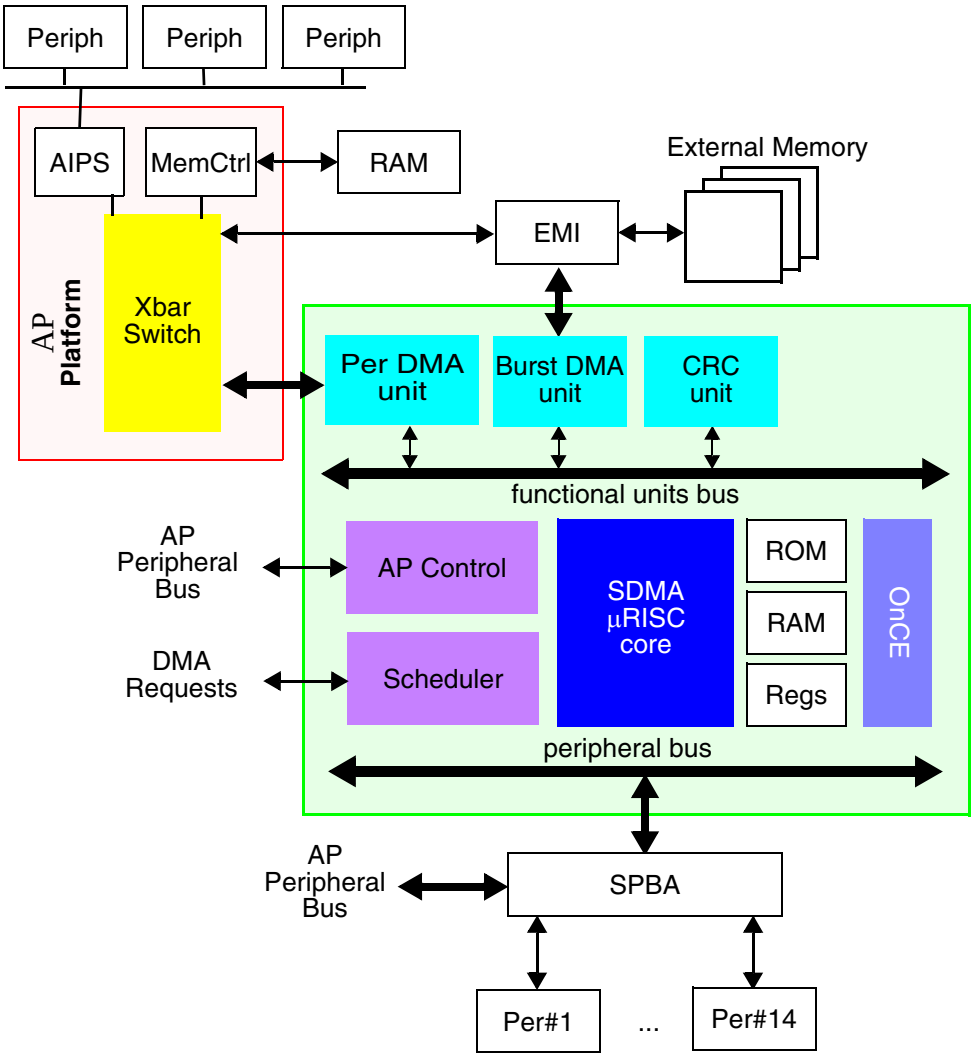

Figure 42-2. SDMA Connections

42.3 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing. The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

42.3.1 SDMA Core Structure

Figure 42-3 shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

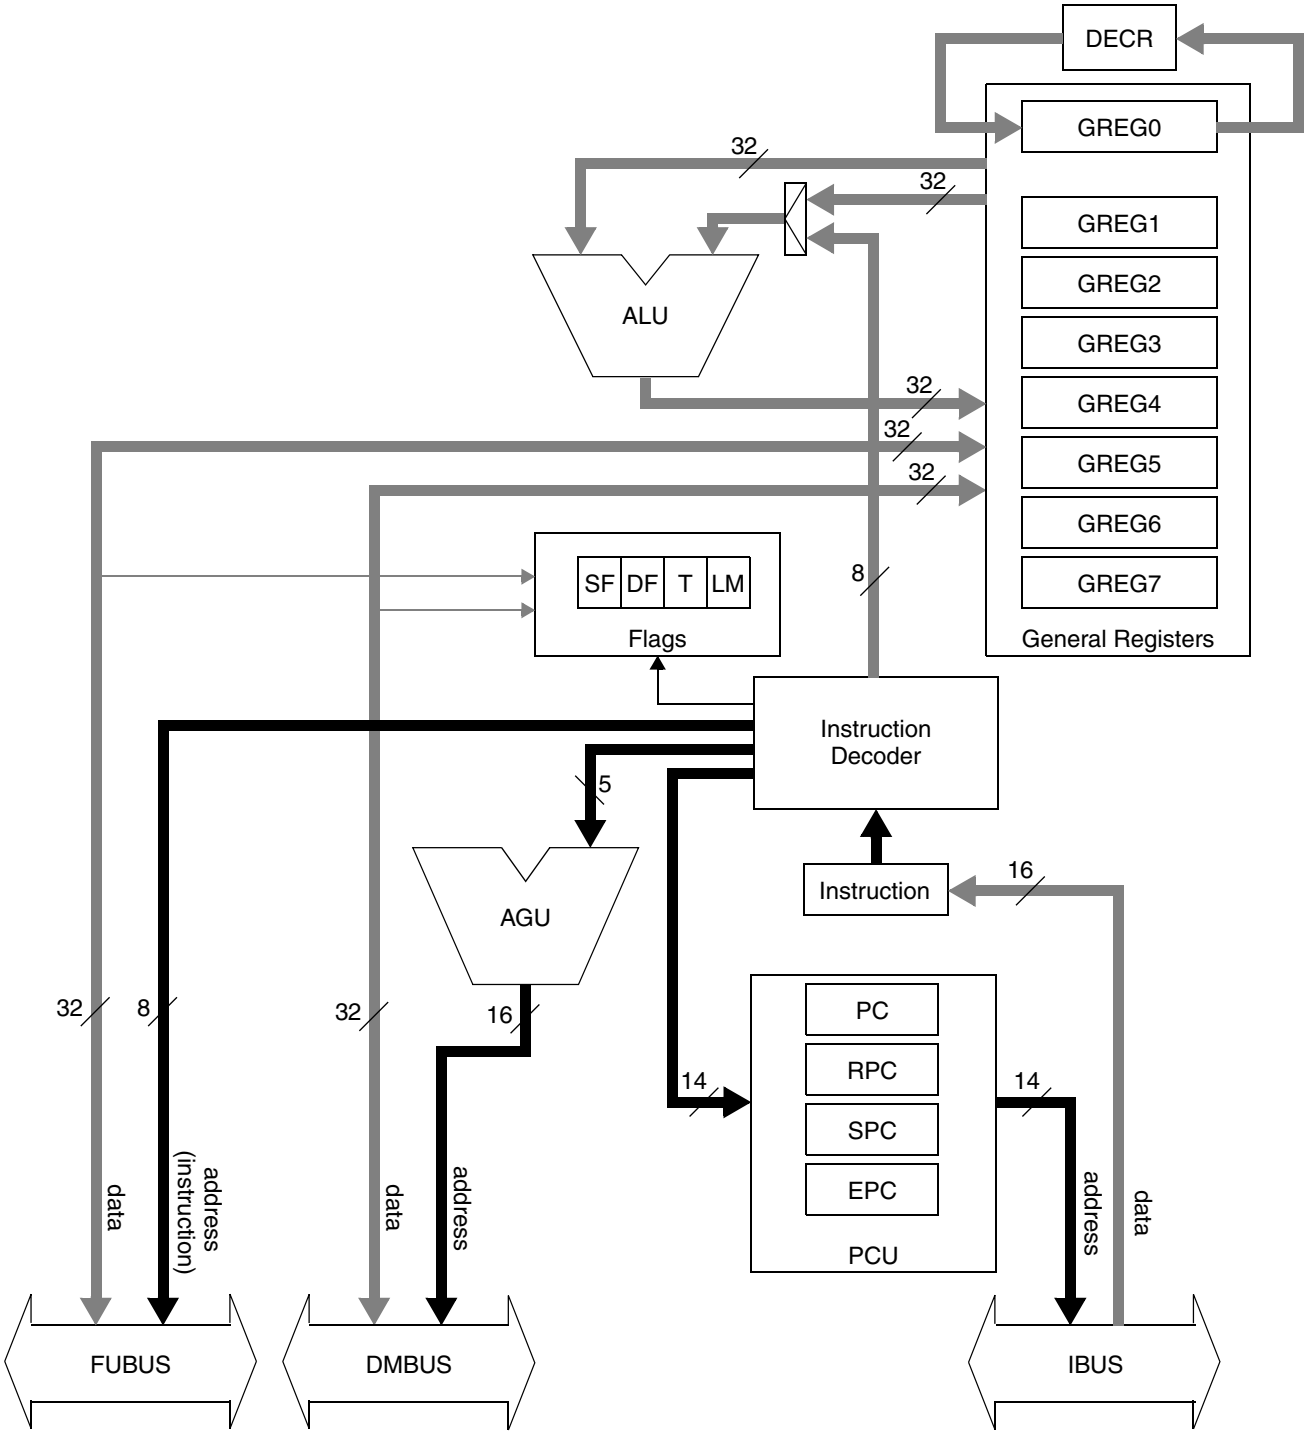

Figure 42-3. SDMA Core

- The Program Control Unit (PCU) is described in Section 42.3.2, “Program Control Unit (PCU).” It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA core instruction register prior to their decoding. The PCU contains the following registers:

  - The Program Counter (PC) contains the address of the current instruction.
  - The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
  - The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
  - End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
  - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs or CRC via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
  - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in Figure 42-3.
  - The flags reflect the status of operations:
    - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
    - LM is set when the core is executing instructions inside a hardware loop.
    - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: `mov R0,R0`).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).
- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

42.3.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA. It

contains the PC, RPC, SPC, and EPC registers that are described in Section 42.3.1, “SDMA Core Structure.”

42.3.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. `standard`—Most of the instructions belong to this category, and always last 1 cycle.
2. `ldf`/`stf`—These are respectively the load and store instructions that access the functional units. They last 1+n cycles where n is the number of wait-states of the targeted functional unit.
3. `ld`/`st`—These are the load and store instructions that access the memory and peripherals. They last 1+n cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. `branch`—These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. `loop`-modified load or store—The hardware `loop` instruction modifies the potential behavior of any load or store inside the `loop` (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the `ld`/`st`/`ldf`/`stf` original execution delay). Although there is usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.
6. `done`—The `done`, `yield`, or `yieldge` instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in Section 42.4.4, “Context Switching”).

42.3.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see Section 42.18.8.4, “Real-Time Debug Outputs”) or the OnCE status register (see Section 42.17.4.9, “OnCE Status Register (OSTAT)”).

The PCU state is a four-bit field that can take the values shown in Table 42-1. Figure 42-4 shows the possible state transitions and the corresponding conditions.

Table 42-1. PCU States

Value	State	Description
0	Program	The is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).

Table 42-1. PCU States (continued)

Value	State	Description
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	he SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Section 42.10.3.22, “Channel 0 Boot Address (CHN0ADDR)”).
15	Restore	The context switch FSM is restoring the next channel context.

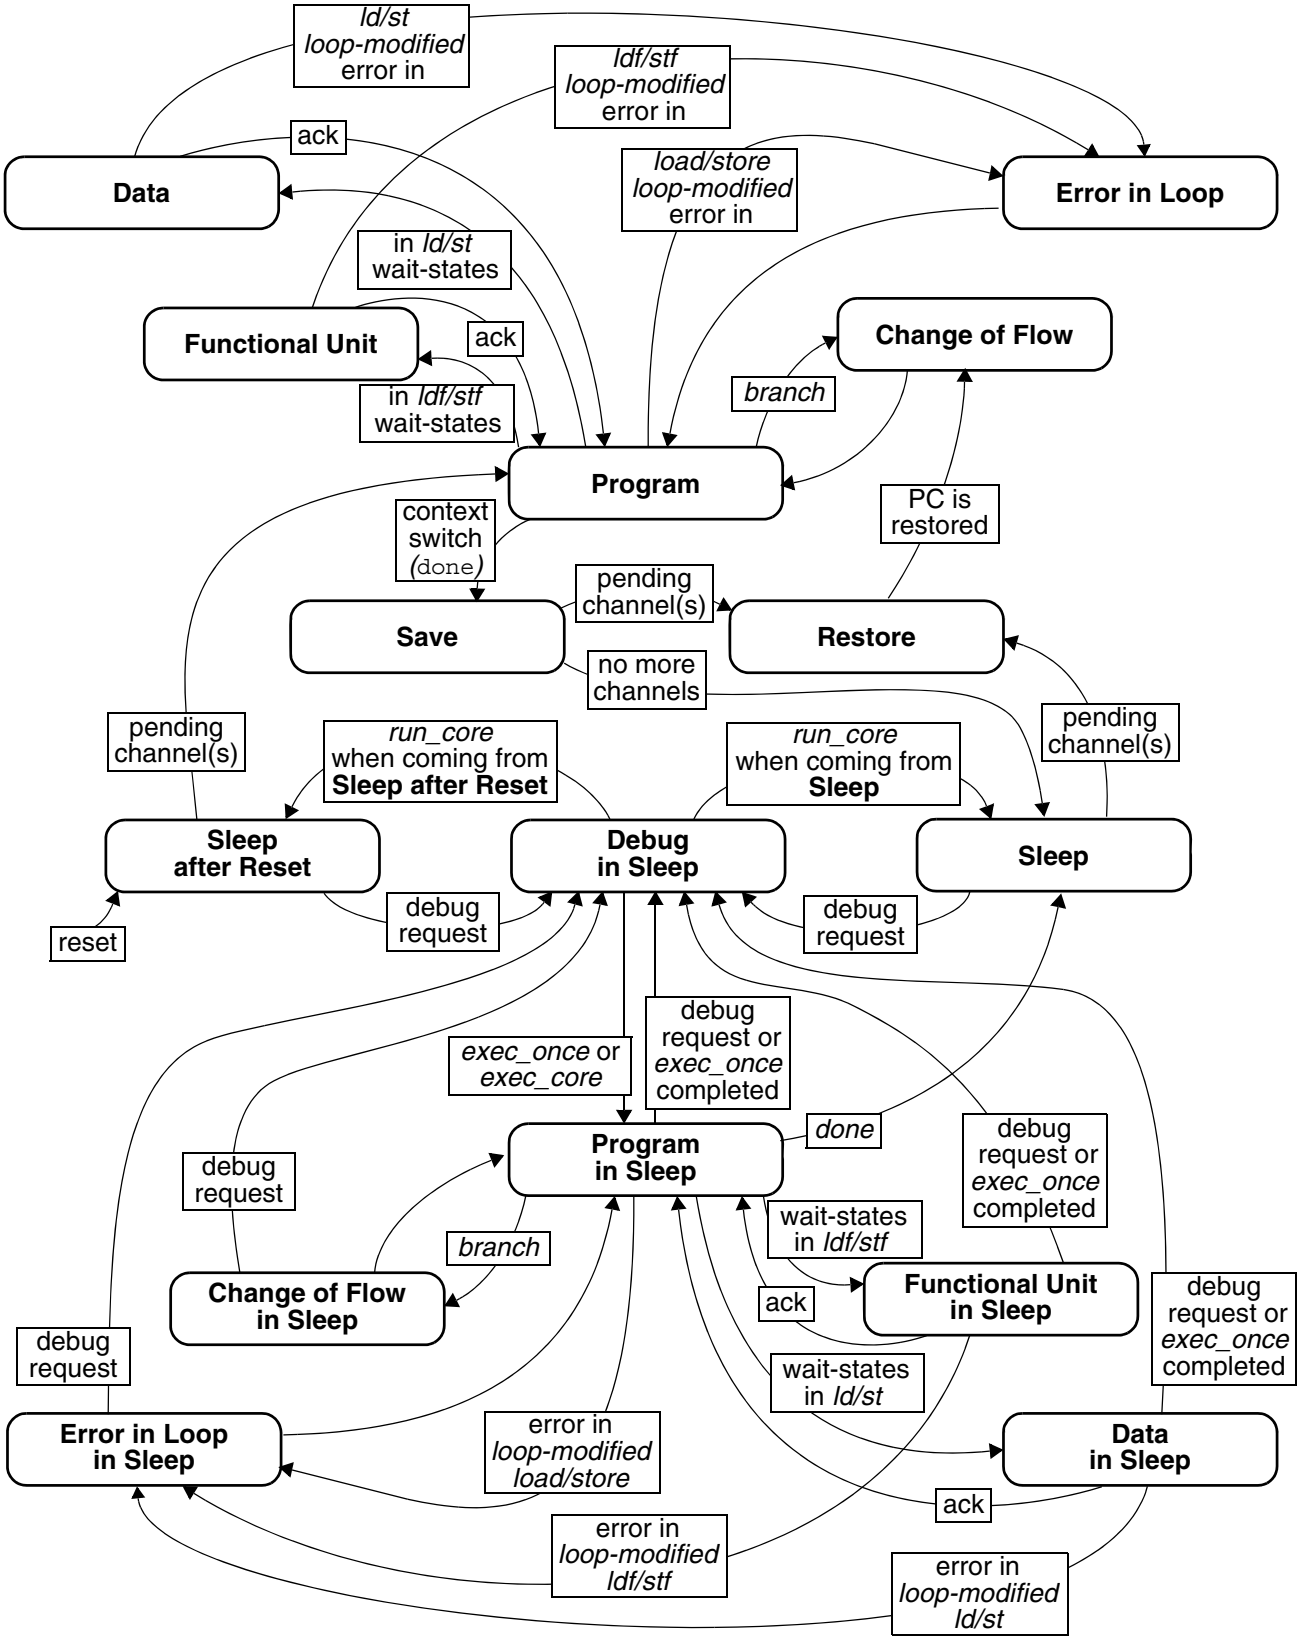

Figure 42-4. PCU State Diagram

42.3.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write. Program and data memory is further described in Section 42.11.5, “Address Space.”

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

42.4 Scheduler

All channel scheduling hardware is included in the Scheduler.

42.4.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority. The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service
- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

42.4.2 Channels and DMA Requests

42.4.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional. The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the AP software.

42.4.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

42.4.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels). The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event. Every channel also has a three-bit register that indicates its priority.

42.4.3 Scheduler Functional Description

Section 42.4.3.1, “Scheduler Overview” describes the behavior of the SDMA scheduler—from the channel enabling conditions to the highest priority pending channel selection.

42.4.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the AP to control its behavior. Figure 42-5 shows a functional overview. The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

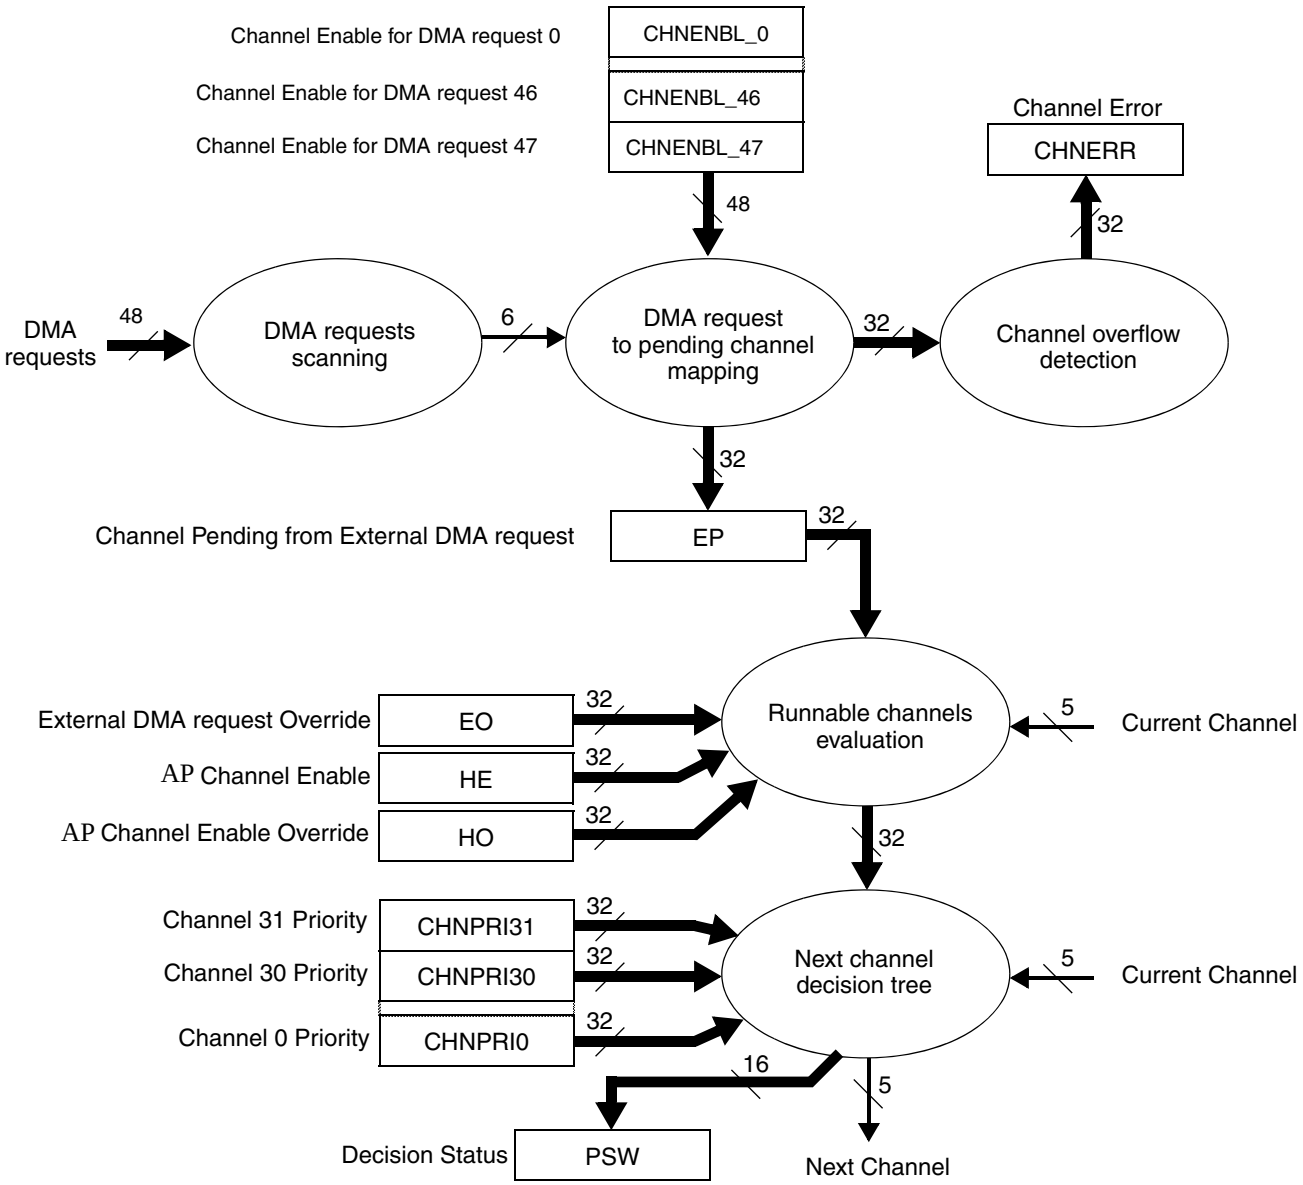

Figure 42-5. SDMA Hardware Scheduler

42.4.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage. The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

Figure 42-6 shows examples of valid DMA requests.

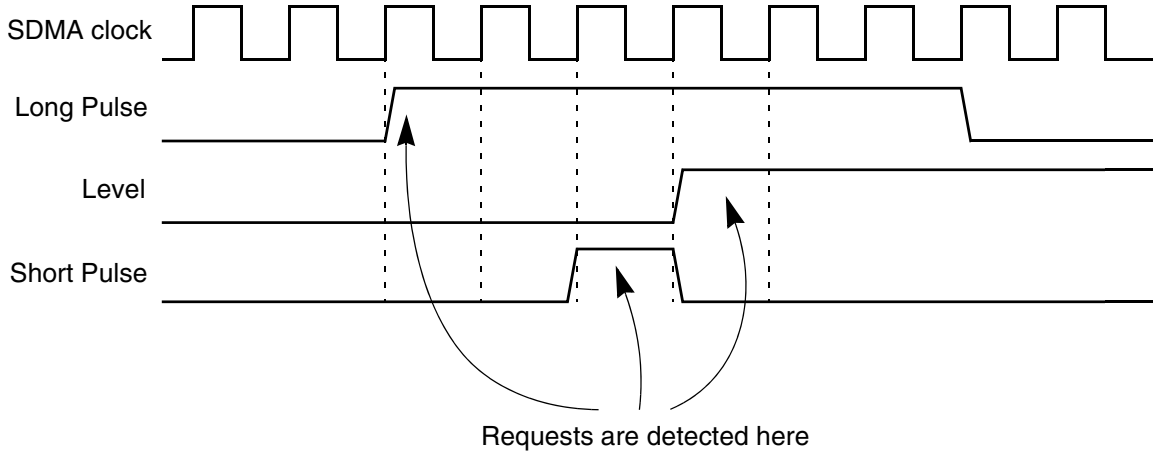

Figure 42-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

42.4.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated. This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by Equation 42-1:

$$EP = EP \text{ or } CHNENBLn \qquad \textit{Eqn. 42-1}$$

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. Table 42-2 illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

Table 42-2. Channel Enable RAM Programming Example

DMA Request Number	Channel (31 … 0)
0	1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1
1	0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

42.4.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition. This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the AP when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

42.4.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable. Registers EO, DO, HO and HE, are controlled by the AP. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The i^{th} channel is runnable if (and only if) the condition below is true:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i]) ***Eqn. 42-2***

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i]) ***Eqn. 42-3***

The registers in these equations are controlled as follows:

- AP (host) channel enable flag HE[i] may be set or cleared by the AP with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

  Typical usage is for the AP to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.
- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The AP channel override flag HO[i] may be set or cleared by the AP. When set, it enables the i^{th} channel to run without the involvement of the AP.

  Typical usage is for the AP to set this flag for channels that do not need AP supervision such as channels that are controlled by DMA request events (EP).
- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the AP. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a `done` or `notify` instruction. The `done` instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the `notify` instruction does not. The `done` and `notify` instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 42-3. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the `done` or `notify` instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the `done` or `notify` instructions

42.4.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities. It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a `yield`, `yieldge`, or `done` instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority. The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a `yield`, not a `yieldge`), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a `yield`(`ge`) or a `done` instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the Table 42-4. The grayed cells in Table 42-4 correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 42-4. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
`yield` (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the AP)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the AP)
`yieldge` (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next[1]
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the AP)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the AP)

Table 42-4. Channel Switching Decision with a yield, yield(ge), or done (continued)

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
done (done >1)	Not runnable	Not runnable	none	none[2]
	Runnable	Not runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next[1]
	Runnable	Runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)

1 Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes

2 Current channel context is saved and SDMA enters IDLE mode

3 Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in Section 42.4.3.8, “Scheduler Pipeline Timing Diagram.”

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since 24 > 13.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a `yieldge`; it is preempted by channel 29. After a period, channel 29 runs a `yieldge`; it is then preempted by channel 23 which is the selected channel, because channel 29 is the current channel. Later, channel 23 runs a `yieldge` and is preempted by channel 29. Channels 23 and 29 will go on switching after every `yieldge` until one of them terminates. It is only at that point that channel 7 becomes eligible again.
- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a `yield` instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a `yield` and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number 11 < 18).

42.4.3.7 Scheduler State Diagram

The Figure 42-7 summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in Section 42.4.3.8, “Scheduler Pipeline Timing Diagram.”

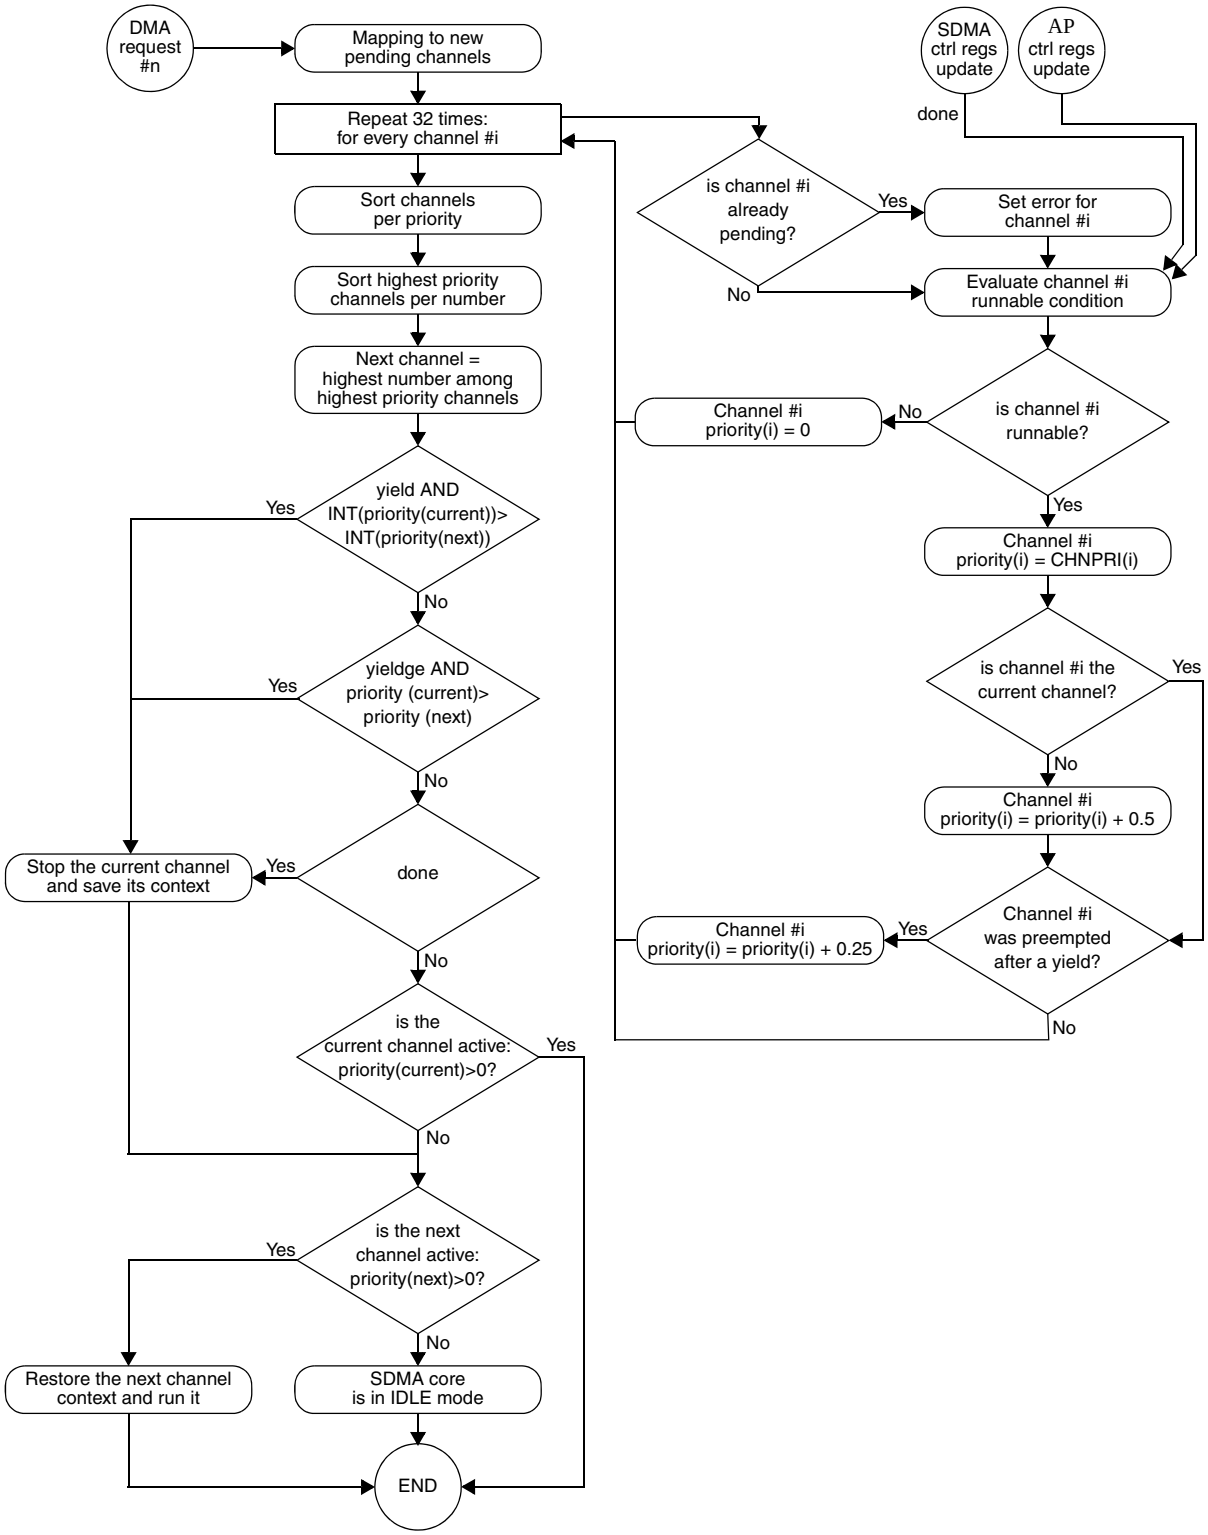

Figure 42-7. Scheduler State Diagram

42.4.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate. Figure 42-8 shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

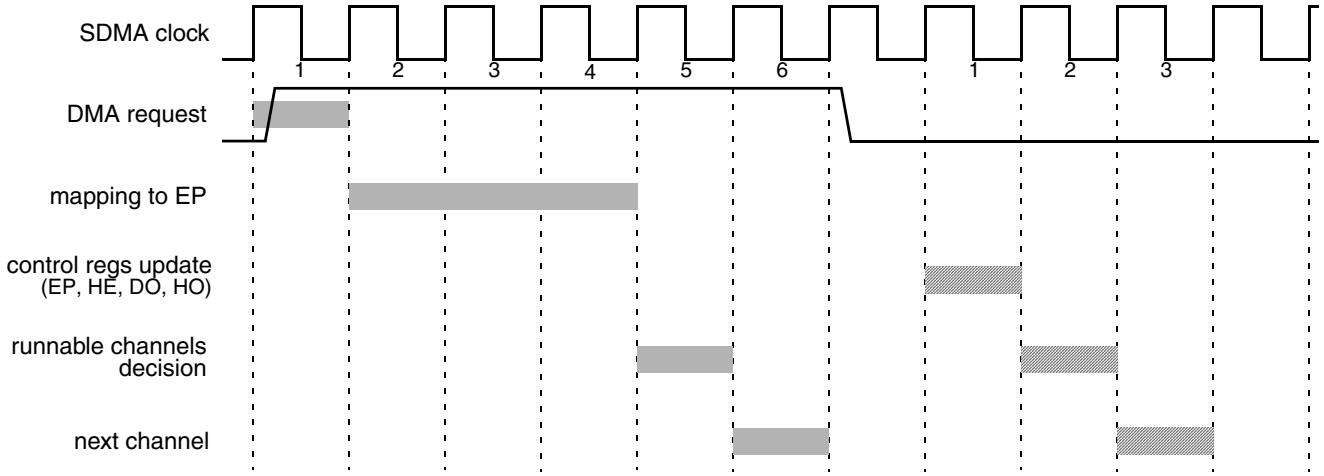

Figure 42-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the AP with a write access through the corresponding control port on their respective peripheral bus).

42.4.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. See the respective chapters for this information.

42.4.3.10 Examples: How to Start a Channel

A channel can be started when Equation 42-2 is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by AP software:
   - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in Table 42-3.
   - AP software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting Equation 42-2 true.
2. To start a channel triggered by DMA request event.
   - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in Table 42-3.

— The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes Equation 42-2 true.

42.4.4 Context Switching

On execution of a `done` or `yield`(`ge`) instruction, the current channel may be changed either because it has finished (which necessarily happens when the `done` instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the `yield`(`ge`) is executed).

Upon a channel change the SDMA goes through a context switch procedure. When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in Section 42.11.4, "Context Switching." and Table 42-41 on page 42-73. There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

42.4.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the AP in the CONFIG control register. The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)—which leaves very few registers to save when the switch is decided—resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore

phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.

- In a “static” context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootload channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

42.4.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the AP.

The context switch procedure is as follows:

1. Load the current context’s spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

   On a `done` or `yield(ge)` that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.
3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

   As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

   Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a `done` or `yield(ge)` instruction. That means the current channel cannot be modified by the AP, even if it is no more runnable or if its priority is modified.

   The AP can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a `done` instruction. That feature should only be used to stop the SDMA in emergency cases.
4. Load the context base-address of the new channel.

   In “static” mode, all the registers are restored. In either “dynamic” modes, only the PCU registers are restored.

   The new channel is running. In “static” mode, no more activity regarding context restoring or saving is performed. In either “dynamic” modes, the registers are restored in the background every time an access to the context RAM is possible, and priority is given to restoring the registers that

are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In “dynamic” and “dynamic with no loop” modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In “dynamic” and “dynamic with no loop” modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In “dynamic power” and “static” modes, the contents of the context RAM remain unchanged until the channel terminates with a `done` or gets preempted.

42.4.4.3 Context Map in Memory

See Section 42.11.4, “Context Switching.”

42.5 Functional Units

The functional units are small systems that are used by the SDMA core to perform complex calculations like the CRC unit, or to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units’ registers via the FUBUS. This is done with the `ldf` and `stf` instructions.

The following sections provide introductions to the available functional units. Section 42.16, “Functional Units Programming Model” provides descriptions the functional units’ behaviors.

42.5.1 CRC Calculation Unit

The Cyclic Redundancy Check (CRC) unit can perform CRC calculation. A single byte of data can be processed every cycle, but up to four bytes can be simultaneously loaded.

The CRC unit supports the following set of polynomials:

```
CRC32:   X^32+X^26+X^23+X^22+X^16+X^12+X^11+X^10+X^8+X^7+X^5+X^4+X^2+X+1
CRC16:   X^16+X^15+X^2+1
CCITT16: X^16+X^12+X^5+1
IS136:   X^12+X^10+X^8+X^5+X^4+X^3+1
CRC10:   X^10+X^9+X^5+X^4+X+1
CRC8:    X^8+X^2+X+1
parity:  X^8+1
```

42.5.1.1 CRC Structure

Figure 42-9 describes the overall structure of the CRC unit and introduces its registers that are accessible by the SDMA core via the FUBUS.

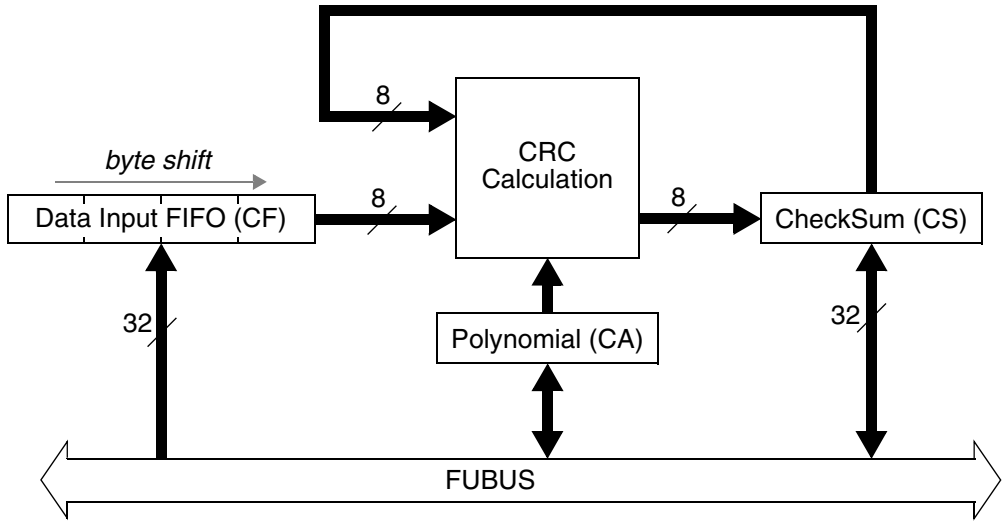

Figure 42-9. CRC Structure

42.5.1.2 CRC Data Processing

CRC processing requires the following three stages:

1. The preliminary initialization stage consists of selecting the desired polynomial, and storing the initialization pattern into the checksum register.
2. Data processing itself, which comes to feeding incoming bytes to the CRC input FIFO — bytes can be written one at a time (8-bit write access from the SDMA core), by pairs (16-bit write), or groups of four (32-bit write). One byte is processed every cycle: Any subsequent access may stall the SDMA core until completion of the previous calculation.
3. The CRC result (or checksum) can be retrieved at any time, but all data must be processed before it is made available.

42.5.1.3 CRC Registers

The CRC enables reading and writing to three register addresses, which trigger the operations described in Section 42.5.1.2, "CRC Data Processing." The following are the three registers:

- *CA (CRC algorithm)*—The CA selects the desired polynomial. Reading and writing this register correspond to retrieving and changing the polynomial.
- *CS (CRC checksum)*—Writing to this register initializes the checksum accumulator, and reading this register yields the result from the CRC calculation (the result width depends on the polynomial size).
- *CF (CRC FIFO)*—Writing to this register loads the data into the input FIFO and triggers the CRC calculation process. It is not possible to read this register.

42.5.1.4 CRC Summary

Every operation mentioned in Section 42.5.1.3, "CRC Registers" takes time to be executed by the CRC unit. When the CRC receives a command, it immediately acknowledges the SDMA core provided it is not

busy completing a previous operation. Therefore, wait-states are inserted by the CRC when a command succeeds another command that is not yet competed. Table 42-5 lists the number of cycles that the CRC takes to execute every possible command. When an operation lasts one cycle, it means the CRC is able to process another command in the next clock cycle (for example, no wait-state is inserted by the CRC because of the former operation that is processing).

Table 42-5. CRC Processing Summary

Operation	Command	Delay	Comments
Set the polynomial	Write CA	1	
Retrieve the polynomial	Read CA	1	
Initialize the checksum	Write CS	1	
Retrieve the checksum	Read CS	1	
Store 1 byte to process	Write CF	1	
Store 2 bytes to process	Write CF	2	CRC is busy for 1 cycle
Store 4 bytes to process	Write CF	4	CRC is busy for 3 cycles

42.5.2 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the AP memory. It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the AP memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the AP memory at once or twice the SDMA core frequency
- Copy data from one AP memory location to another AP memory location at the AP bus speed, which provides a very high throughput
- Control the method for addressing the AP memory (automatic increment of addresses or frozen addresses—the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the AP memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the AP memory. Or, it forces a flush when a data transfer must terminate.

  In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the AP memory.

  In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the AP memory. This error status is retrieved by a later access to the burst DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the AP memory is caught.

- Handle address alignment issues between the AP memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding AP address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the AP memory space.

This unit structure and registers are described in Section 42.5.2.1, "Burst DMA Structure" and Section 42.5.2.2, "Burst DMA Registers."

42.5.2.1 Burst DMA Structure

The burst DMA is depicted in Figure 42-10. It is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

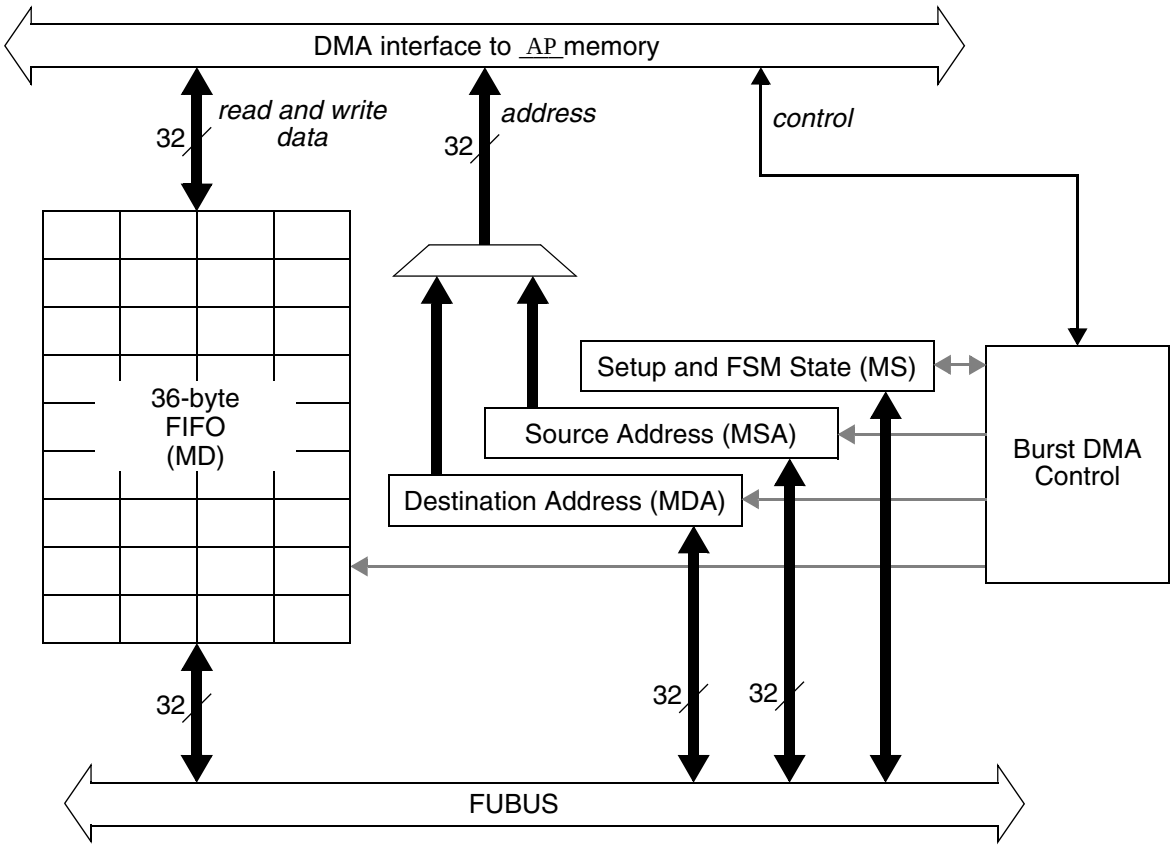

Figure 42-10. Burst DMA Structure

42.5.2.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) — Holds the source byte address in the AP memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.

- MDA (Memory Destination Address) — Holds the destination byte address in the AP memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- MD (Memory Data) — Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the AP memory).

  When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the AP memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to AP memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

  Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the AP memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the AP memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to AP memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.
- MS (Memory Setup) — Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

42.5.2.3 Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both. Every case requires a different procedure, as listed in the following sections:

42.5.2.3.1 Data Retrieval from the AP Memory

The following steps retrieve data from AP memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from AP memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

42.5.2.3.2 Storing Data Into the AP Memory

The following steps store data from AP memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).

- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the AP memory and the error status of the transfer is available in the DF flag.

42.5.2.3.3 Transferring Data Between Two AP Memory Locations

The following steps copy data between two AP memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

42.5.3 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the AP memory. Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the AP peripherals or memory at once or twice the SDMA core frequency
- Data copy from one AP memory location to another AP memory location at memory bus speed, improving throughput
- Control of the method for addressing the AP memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the AP memory. In prefetch mode, the peripheral DMA automatically fetches another data—without waiting for the SDMA core to request it—when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the AP memory.

  In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the AP memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the AP memory has been caught.

This unit structure and registers are described in Section 42.5.3.1, “Peripheral DMA Structure” and Section 42.5.3.2, “Peripheral DMA Registers.”

42.5.3.1 Peripheral DMA Structure

The peripheral DMA is shown in Figure 42-11. It is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

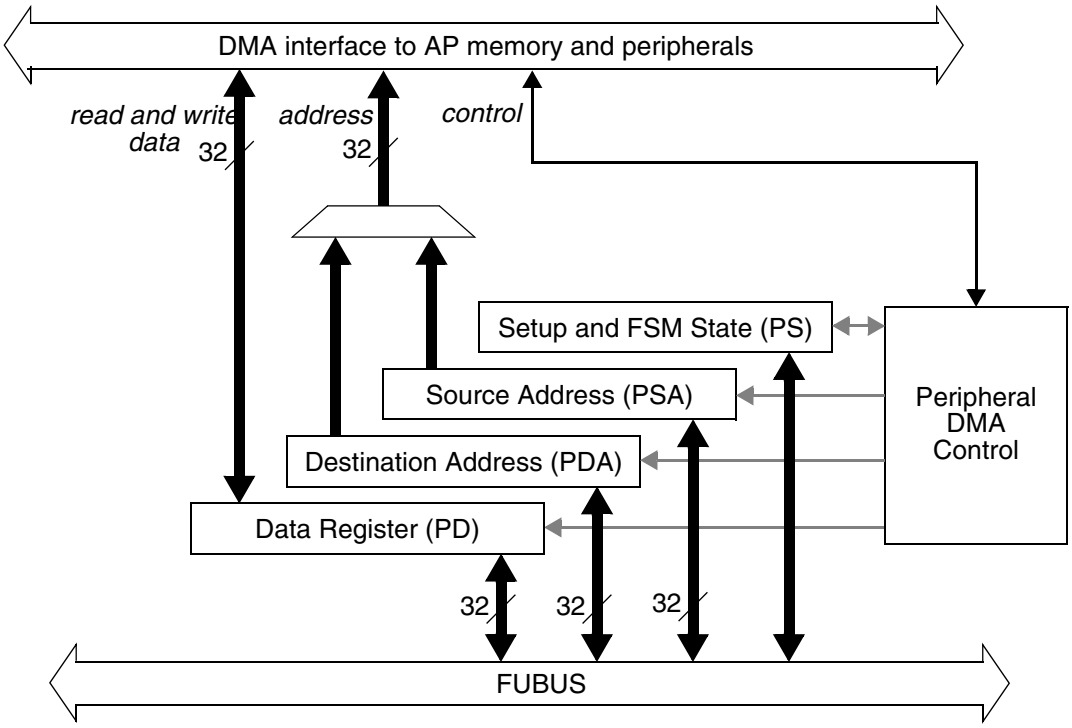

Figure 42-11. Peripheral DMA structure

42.5.3.2 Peripheral DMA Registers

According to Figure 42-11, the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD (Peripheral Data)* is the DMA 32-bit data register.
- *PSA (Peripheral Source Address)* holds the source byte address in the AP memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.
- *PDA (Peripheral Destination Address)* holds the destination byte address in the AP memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

42.5.3.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both. Every case requires a different procedure, as described in Section 42.5.3.3.1, "Data Retrieval from the AP Memory or Peripheral," Section 42.5.3.3.2, "Storing Data into the AP Memory or Peripheral," and Section 42.5.3.3.3, "Transferring Data Between Two AP Memory Locations."

42.5.3.3.1 Data Retrieval from the AP Memory or Peripheral

The following steps retrieve data from AP memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the `ldf PD` instruction as many times as needed. If an error occurs during the fetch from the AP memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

42.5.3.3.2 Storing Data into the AP Memory or Peripheral

The following steps store data to AP memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.
- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the AP memory or peripheral, and the error status of the transfer is available in the DF flag.

42.5.3.3.3 Transferring Data Between Two AP Memory Locations

The following steps copy data between two AP memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

42.6 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The AP loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in Section 42.6.1, “Locked Mode.”

There is no SDMA Privilege signal associated with the Peripheral DMA interface.

42.6.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM. After initial RAM contents are uploaded, AP software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a ‘1’, the SDMA is “locked” until reset.

The LOCK bit can be read in the SDMA’s internal memory map in the LOCK register (see Section 42.12.3.20/42-98). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation.

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SREST_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under AP control from being used to gain access to SDMA internal memory. If AP control of the OnCE is enabled before setting the LOCK bit, the AP can use the ONCE for debug purpose after LOCK is set.

42.7 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions. See Figure 42-4 for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a `SoftBkpt` instruction from the channel script or receive a debug request. When either happens, the SDMA enters its “Classical” *Debug* state, which is described in Section 42.16.4, “OnCE and Real-Time Debug.”

- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the `exec_core` instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a `SoftBkpt` is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. Table 42-6 summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in Section 42.16.4, "OnCE and Real-Time Debug."

Table 42-6. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
`exec_once`	`exec_once` <instruction> SDMA executes the <instruction> and returns to the *Debug* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	`exec_once` <instruction> SDMA executes the <instruction> and returns to the *Debug in Sleep* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
`run_core`	`run_core` <instruction> SDMA executes the <instruction>, leaves the *Debug* state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	`run_core` <instruction> SDMA executes the <instruction> and returns to its *Sleep* or *Sleep after Reset* initial state. This command must not be used with an instruction that modifies the PC value.
`exec_core`	`exec_core` <instruction> It is similar to `run_core` except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the *Debug* state and starts executing instructions from this new PC value.	`exec_core` <instruction> If the previous state was *Sleep after Reset*, the SDMA returns to this state, and Chn0Addr value overrides the PC value. Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

NOTE

The feature `exec_core` in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC value. The SDMA will be ready to boot at the Chn0Addr address.

42.8 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller module and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA. Root clock control is available from the SoC clock controller module.

There are numerous clock sources that are used in the SDMA. They belong to one of twopossible clock domains listed in Table 42-7, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the AP/SDMA clock domain, all clocks must come from the same PLL. The AP DMA interfaces (peripheral DMA and burst DMA) receive their clock from the AP DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the AP DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum AP DMA frequency, the SDMA core clock is tied to the AP peripheral clock frequency.

The AP Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 42-7. Clocking Scheme

Clock Domain	Source Clock	Comments
AP	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-modules.
	AP DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	AP peripheral	Connection to the AP peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than $1/8^{th}$ of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

42.8.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

42.8.1.1 Coarse Clock Gating

Every sub-module clock comes from one of the five available sources, and is gated with the sub-module specific enabling condition. Table 42-8 displays the sub-module clocks and their source. It also indicates the relationships that may exist between different sub-modules clock enables.

Table 42-8. Sub-Modules Clocks

Sub-Module	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-module clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-module clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-module clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-module clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the AP modifies the channel running conditions.	None
AP Control	SDMA Main Core & AP peripheral	The AP peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on SDMA main clock; it is active when the AP or the SDMA modifies the contents of one of these registers.	None
CRC	SDMA Main Core	The CRC clock is based on SDMA main clock and is only active during data processing.	Disabled when Core sub-module clock is disabled
Burst DMA	SDMA Main Core & AP DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the AP DMA clock and drives registers that are connected to the AP DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	Disabled when Core sub-module clock is disabled
Peripheral DMA	SDMA Main Core & AP DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the AP DMA clock and drives registers that are connected to the AP DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-module clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the AP peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. See Section 42.17.5.2, "Synchronization Implementation."	When enabled, all other clocks are systematically on (clock gating is off)

42.8.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis. Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

42.8.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG. The following Table describes these modes, and shows how to switch from one mode to another.

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are

Table 42-9. Power Modes

Power Mode	Sub-modules								Comments
	Core	Memories	Scheduler	AP Control	CRC	Burst DMA	Peripheral DMA	OnCE	
SLEEP	off[1]	off	wait[2]	wait	off	off	off	off	Set when the PCU state is either *Sleep* or *Sleep after Reset* and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on[3]	wait	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: *Program*, *Data*, *Change of Flow*, *Error in Loop*, *Debug*, *Functional Unit*, *Save*, or *Restore*.
DEBUG	on	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either *clk_gating_off* pin high or ONCE_ENB[0] set).

1 *off*: no clock

2 *wait*: only clocked when accessed or stimulated

3 *on*: clock is always running

described in Section 42.8.1.3.1, “SLEEP Mode.”

42.8.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode. However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.

- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in Section 42.8.1.4, "Stop Mode Response."

42.8.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

42.8.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA:

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

42.8.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode. If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMAs clocks can be turned off.

42.8.2 Reset

After reset (either received from the reset module or a software reset required by the AP), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated. Activating a channel can be done by the AP after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

42.9 Initialization Information

42.9.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents. The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The AP will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the AP first creates some channel control blocks (CCB) and buffer descriptors (BD) in AP memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (MC0PTR) to the address of the first control block. The HSTART, HOSTOVR and EVTOVR registers are then configured according to Equation 42-2 on page 42-18 to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (CHN0ADDR) in the program memory. The reset value of CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (MC0PTR) to determine the location of the Channel Control Block (CCB) in AP memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its AP Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the CHN0ADDR register in the AP programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

42.9.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters passed in the buffer descriptor or. All these items must be initialized before the script is allowed to execute. Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the AP by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The AP selects which trigger conditions that must occur for the channel to start by configuring the CHNENBL, HOSTOVR and EVTOVR registers. The trigger events include AP setting HE (HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can becomes active according to its priority compared with other runnable channels when the selected trigger(s) cause Equation 42-2 on page 42-18 to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script.

42.9.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and CHNENBLn registers have unpredictable contents after this reset.
- Initialize CHNENBLn registers to map DMA request events to desired channels.
- Configure CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the CONFIG register to select DMA to SDMA core clock ratio.
- Set up channel control blocks and buffer descriptors in AP to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used.
- Configure MC0PTR register with base address of AP Channel Control Block base address.
- Initialize CHNENBLn registers to map DMA request events to associated channel. Reference Section 42.4.3.3, “Mapping DMA Requests to Pending Channels.”
- Configure CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure HOSTOVR (HO) and EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference Section 42.4.3.5, “Runnable Channels Evaluation.”
- Set bit 0 of the HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_INTR register, or by optional interrupt to the AP.
- Set the LOCK bit in the SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scrips can now be run by enabling the selected software or hardware trigger event according to Equation 42-2 on page 42-18.

42.10 AP Memory Map and Control Register Definitions

The AP controls the SDMA by means of several interface registers. Those registers are described in the current section.

42.10.1 AP Memory Map

The following table provides the memory map for the AP control SDMA registers.

Table 42-10. AP Memory Map

Offset	Register	Access	Reset Value	Section/Page
General Registers				
AP_BASE+000 (MC0PTR)	AP (MCU) Channel 0 Pointer	R/W	0x0000_0000	42.10.3.2/42-48

Table 42-10. AP Memory Map (continued)

Offset	Register	Access	Reset Value	Section/Page
AP_BASE+004 (INTR)	Channel Interrupts	R/W	0x0000_0000	42.10.3.2/42-48

42.10.2 Register Summary

The following definitions serve as a key for the AP control SDMA register summary.

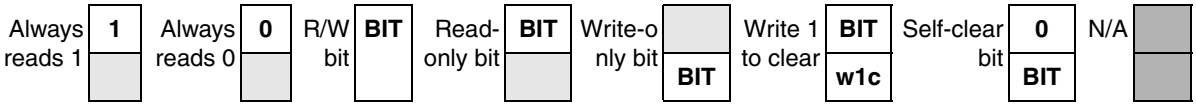

Figure 42-12. Key to Register Fields

Table 42-11 provides a key for register figures.

Table 42-11. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.

Table 42-11. Register Figure Conventions (continued)

Convention	Description
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

All registers are clocked with the SDMA clock (which means the AP must ensure that the SDMA clock is running when it wants to access any register).

42.10.3 Register Descriptions

The following sections provide figures and detailed field descriptions of the SDMA registers.

42.10.3.1 AP Channel 0 Pointer (MC0PTR)

The following table presents the register; Table 42-13 provides its field descriptions.

AP_BASE+000 (MC0PTR) Access: User Read/Write
Wait State: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	MC0PTR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MC0PTR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-13. AP Channel 0 Pointer (MC0PTR)

Table 42-13. MC0PTR Field Descriptions

Field	Description
31–0 MC0PTR	Channel 0 Pointer contains the 32-bit address, in AP memory, of channel 0 control block (the boot channel). The AP has a read/write access and the SDMA has a read-only access.

42.10.3.2 Channel Interrupts (INTR)

Figure 42-14 presents the register; Table 42-14 provides its field descriptions.

AP_BASE+004 (INTR)
Wait State: 0

Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-14. Channel Interrupts (INTR) Register

Table 42-14. INTR Field Descriptions

Field	Description
31–0 HI[31:0]	The AP Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the AP. This register is a “write-ones” register to the AP. When the AP sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding done instruction is executed.

42.10.3.3 Channel Stop/Channel Status (STOP_STAT)

Figure 42-15 presents the register; Table 42-15 provides its field descriptions.

AP_BASE+008
(STOP_STAT)

Figure 42-15. Channel Stop/Channel Status (STOP_STAT) Register

Table 42-15. STOP_STAT Field Descriptions

Field	Description
31–0 HE	This 32-bit register gives access to the AP Enable bits. There is one bit for every channel. This register is a “write-ones” register to the AP. When the AP writes 1 in bit i of this register, it clears the HE[i] and HSTART[i] bits. Reading this register yields the current state of the HE[i] bits.

42.10.3.4 Channel Start (HSTART)

Figure 42-16 presents the register; Table 42-16 provides its field descriptions.

AP_BASE+00C (HSTART) Access: User Read/Write

Figure 42-16. Channel Start (HSTART) Register

Table 42-16. HSTART Field Descriptions

Field	Description
31–0 HSTART/HE	The HSTART/HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the AP to trigger a channel a second time before the first trigger is processed. • This register is a “write-ones” register to the AP. Neither HSTART[i] bit can be set while the corresponding HE[i] bit is cleared. • When the AP tries to set the HSTART[i] bit by writing a one (if the corresponding HE[i] bit is clear), the bit in the HSTART[i] register will remain cleared and the HE[i] bit will be set. • If the corresponding HE[i] bit was already set, the HSTART[i] bit will be set. The next time the SDMA channel *i* attempts to clear the HE[i] bit by means of a done instruction, the bit in the HSTART[i] register will be cleared and the HE[i] bit will take the old value of the HSTART[i] bit. • Reading this register yields the current state of the HSTART[i] bits. This mechanism enables the AP to pipeline two HSTART commands per channel.

42.10.3.5 Channel Event Override (EVTOVR)

Figure 42-17 presents the register; Table 42-17 provides its field descriptions.

Figure 42-20. Channel Event Pending (EVTPEND) Register

Table 42-20. EVTPEND Field Descriptions

Field	Description
31–0 EP	The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the AP to determine what channels are pending after the reception of a DMA request. • Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. • The EP[i] bit may be cleared by the done instruction when running the channel *i* script. This a “write-ones” mechanism: Writing a ‘0’ does not clear the corresponding bit.

42.10.3.9 Reset Register (RESET)

Figure 42-21 presents the register; Table 42-21 provides its field descriptions.

AP_BASE+024 (RESET) Access: User Read-Only

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-21. Reset Register

Table 42-21. RESET Field Descriptions

Field	Description
31–2	Reserved
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a done instruction. This enables the AP to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

42.10.3.10 DMA Request Error Register (EVTERR)

Figure 42-22 presents the register; Table 42-22 provides its field descriptions.

AP_BASE+028 (EVTERR) Access: User Read-Only

Figure 42-22. DMA Request Error (EVTERR) Register

Table 42-22. EVTERR Field Descriptions

Field	Description
31–0 CHNERR	This register is used by the SDMA to warn the AP when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel. • An interrupt is sent to the AP if the corresponding channel bit is set in the INTRMASK register. • This is a “write-ones” register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the AP or during SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the AP tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

42.10.3.11 Channel AP Interrupt Mask Flags (INTRMASK)

Figure 42-24. Schedule Status (PSW) Register

Table 42-24. PSW Field Descriptions

Field	Description
31–16	Reserved
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1–7 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1–7 Active channel priority
3–0 CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA.In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

42.10.3.13 DMA Request Error Register for Debug (EVTERRDBG)

Figure 42-25 presents the register; Table 42-25 provides its field descriptions.

AP_BASE+034
(EVTERRDBG)
Wait State: 0

Access: User Read-Only

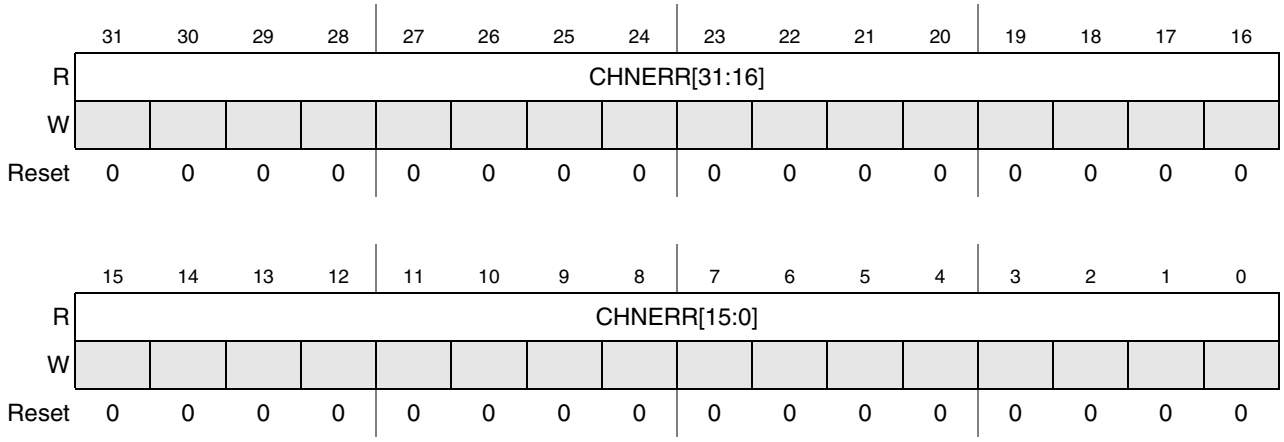

Figure 42-25. DMA Request Error for Debug (EVTERRDBG) Register

Table 42-25. EVTERRDBG Field Descriptions

Field	Description
31–0 CHNERR	This register is the same as EVTERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The AP OnCE may check this register value without modifying it.

42.10.3.14 Configuration Register (CONFIG)

Figure 42-26 presents the register; Table 42-26 provides its field descriptions.

AP_BASE+038 (CONFIG)
Wait State: 0

Access: User Read/Write

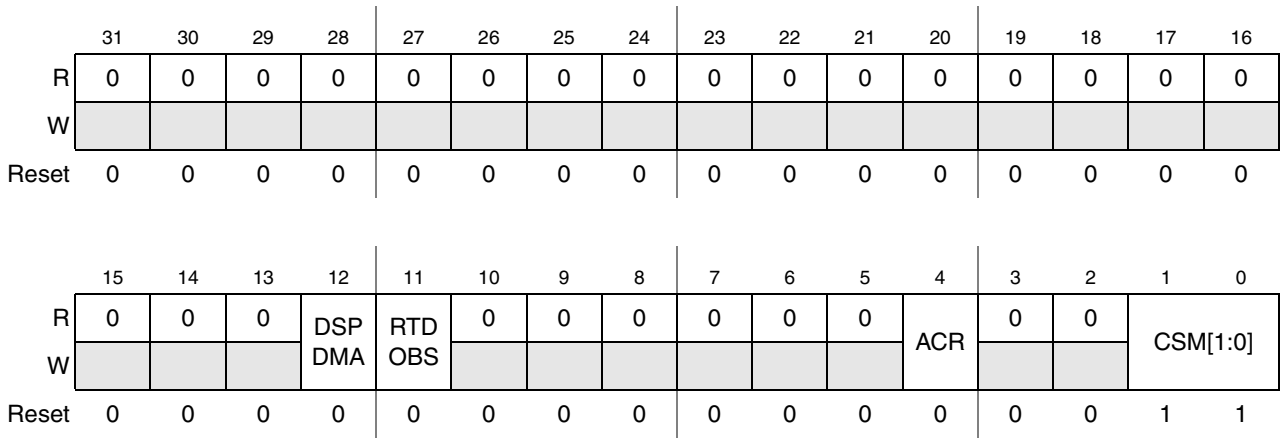

Figure 42-26. Configuration Register (CONFIG)

Table 42-26. CONFIG Register Field Descriptions

Field	Description
31–13	Reserved
12 DSPDMA	This bit's function is reserved and **should be configured as zero**. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–6	Reserved
4 ACR	AP DMA / SDMA Core Clock Ratio. Selects the clock ratio between AP DMA interfaces (burst DMAand peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 AP DMA interface frequency equals twice core frequency 1 AP DMA interface frequency equals core frequency
3–2	Reserved
1–0 CSM	Selects the Context Switch Mode. The AP has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase. NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used. 0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic

42.10.3.15 SDMA Lock Register (SDMA_LOCK)

Figure 42-27 presents the register; Table 42-27 provides its field descriptions.

AP_BASE+03C
(SDMA_LOCK)
Wait State: 0

Figure 42-27. SDMA LOCK(SDMA_LOCK) Register

Table 42-27. ONCE_ENB Field Descriptions

Field	Description
31–2	Reserved
1 SRESET_LOCK_CLR	The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit. 0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.
0 LOCK	The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under MCU control. The LOCK bit is set: • The SDMA_LOCK, ONCE_ENB,CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. • SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register on page 42-98 to determine if certain operations are allowed, such as up-loading new scripts. Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set. 0 LOCK disengaged. 1 LOCK enabled.

42.10.3.16 OnCE Enable (ONCE_ENB)

Figure 42-28 presents the register; Table 42-28 provides its field descriptions.

AP_BASE+040 (ONCE_ENB) Access: User Read/Write

Figure 42-31. OnCE Status Register (ONCE_STAT)

Table 42-31. ONCE_STAT Field Descriptions

Field	Description
31–16	Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows: • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the RISC engine idle state). The “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the AP peripheral interface. 0 The JTAG interface controls the OnCE. 1 The AP peripheral interface controls the OnCE.

Table 42-31. ONCE_STAT Field Descriptions (continued)

Field	Description
6–3	Reserved
2–0 ECDR	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits. EDR[0] 1 matched addra_cond EDR[1] 1 matched addrb_cond EDR[2] 1 matched data_cond

42.10.3.20 OnCE Command Register (ONCE_CMD)

Figure 42-34. Channel 0 Boot Address (CHN0ADDR) Register

Table 42-34. CHN0ADDR Register Field Descriptions

Field	Description
31–15	Reserved
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set.
13–0 CHN0ADDR	This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80). The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

42.10.3.23 DMA Requests (EVT_MIRROR)

Wait State: 1

Access: User Read/Write

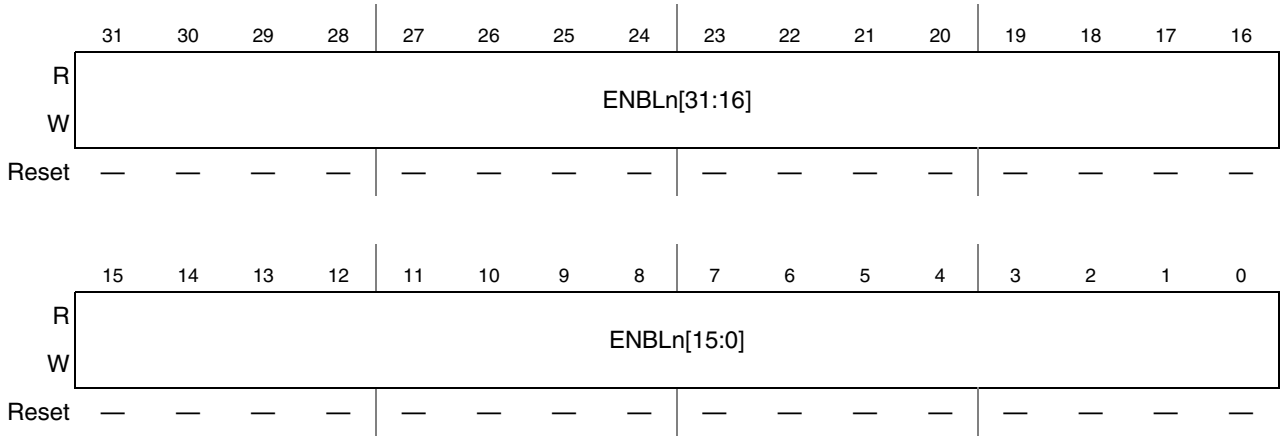

Figure 42-40. Channel Enable RAM (CHNENBLn) Register

[1] for n = 0 to 47

Table 42-40. CHNENBLn Field Descriptions

Field	Description
31–0 ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number *n*. If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request *n* is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the AP to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

42.11 SDMA Programming Model

The following section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the AP memory maps. The AP processor has no access to any hardware resource described, except when those resources are described in Section "AP Memory Map and Control Register Definitions."

42.11.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time. This chapter lists the components of every channel state.

42.11.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the `loop` instruction, but otherwise can be used for any purpose.

42.11.3 Functional Unit State

Each channel context has some state that is part of the functional units. The specific allocation of this state is part of the functional unit definition that is described in Section 42.16.1, "Burst DMA Unit," Section 42.16.2, "Peripheral DMA Unit." This state must be saved/restored on context switches.

42.11.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction. A low order bit of zero selects the most significant half of the word.[1]

42.11.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.
- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (`CLRF` and `loop`). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.

  Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

  The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the `loop` instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.
- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the `loop` instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch Greg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

1. For example, big-Endian.

42.11.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions. Instructions are available to transfer its contents to and from a general register.

42.11.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the `loop` instruction to the location immediately following it.

42.11.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the `loop` instruction to the location of the next instruction after the loop.

42.11.4 Context Switching

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units. The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode (Section 42.4.4, “Context Switching”), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a `done` or `yield(ge)` instruction, SDMA goes into “real” context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel *i* is *CONTEXT_BASE* + 24**i* or *CONTEXT_BASE* + *32***i* where CONTEXT_BASE equals 0x0800. Table 42-41 presents the layout of a channel context in memory:

42.11.5 Address Space

The SDMA has four internal buses, as follows:

- The Instruction bus reads instructions from the memory. Its address map is described in Section 42.11.5.1, “Instruction Memory Map.”

- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in Section 42.11.5.2, "Data Memory Map."
- The Functional Units bus (FUBUS) accesses the burst DMA, peripheral DMA, and CRC internal registers. The addressing mechanism is further detailed in Section 42.16, "Functional Units Programming Model."
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

42.11.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location. Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a `jmp` to handle routines.

Table 42-42. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Module Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	—	0	4-Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	—	0	8-Kbyte internal RAM with channels context and user data/routines.

42.11.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA. This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the AP)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

The SDMA can perform only 32-bit access to shared peripheral registers. For this device, shared peripherals registers are aliased as if byte addressed. This is a consequence of connections through the SPBA shared peripheral bus outside of the SDMA. The result is that although address space 4 Kwords (16KB) is allocated for each peripheral, only the first 4 Kbytes of the peripheral's register space can accessed. For example, the shared peripheral register at address 0x3000 is mapped also to addresses 0x3001, 0x3002, 0x3003. A read or write access to any of any of these 4 addresses will respond as if the access was to address 0x3000.

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GReg*n*). The mapping between the general purpose register contents and the address bus is given in Table 42-43:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Table 42-43. GReg*n* to DMBUS Address Mapping

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 42-44. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbytes	4-Kbyte internal ROM with boot code and standard routines

RAM	0x0800 → 0x0FFF	8 Kbytes	8-Kbyte internal RAM with channels contexts and user data/routines
per1	0x1000 → 0x1FFF	16 Kbytes	*peripheral 1* memory space (4-Kbyte address space)
per2	0x2000 → 0x2FFF	16 Kbytes	*peripheral 2* memory space (4-Kbyte address space)
per3	0x3000 → 0x3FFF	16 Kbytes	*peripheral 3* memory space (4-Kbyte address space)
per4	0x4000 → 0x4FFF	16 Kbytes	*peripheral 4* memory space (4-Kbyte address space)
per5	0x5000 → 0x5FFF	16 Kbytes	*peripheral 5* memory space (4-Kbyte address space)
per6	0x6000 → 0x6FFF	16 Kbytes	*peripheral 6* memory space (4-Kbyte address space)

Table 42-44. SDMA Data Memory Space (continued)

Device	SDMA Address (Hex)	Size	Description
Registers	0x7000 → 0x7FFF	16 Kbytes	Memory mapped registers
per7	0x8000 → 0x8FFF	16 Kbytes	*peripheral 7* memory space (4-Kbyte peripheral address space)
per8	0x9000 → 0x9FFF	16 Kbytes	*peripheral 8* memory space (4-Kbyte peripheral address space)
per9	0xA000 → 0xAFFF	16 Kbytes	*peripheral 9* memory space (4-Kbyte peripheral address space)
per10	0xB000 → 0xBFFF	16 Kbytes	*peripheral 10* memory space (4-Kbyte address space)
per11	0xC000 → 0xCFFF	16 Kbytes	*peripheral 11* memory space (4-Kbyte address space)
per12	0xD000 → 0xDFFF	16 Kbytes	*peripheral 12* memory space (4-Kbyte address space)
per13	0xE000 → 0xEFFF	16 Kbytes	*peripheral 13* memory space (4-Kbyte address space)
per14	0xF000 → 0xFFFF	16 Kbytes	*peripheral 14* memory space (4-Kbyte address space)

42.12 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, see the respective chapters.

42.12.1 SDMA Internal (Core) Registers Memory Map

Table 42-45. SDMA Internal Registers Memory Map

Offset	Register	Access	Reset Value	Section/Page
General Registers				
0x7000 (MC0PTR)	AP (MCU) Channel 0 Pointer	R	0x0000_0000	42.12.3.1/42-82

42.12.2 Register Summary

The following definitions serve as a key for the SDMA internal register summary.

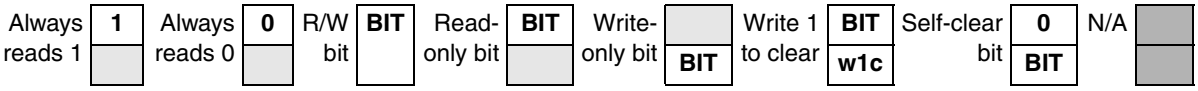

Figure 42-41. Key to Register Fields

Table 42-46 provides a key for register figures.

Table 42-46. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.

Table 42-46. Register Figure Conventions (continued)

Convention	Description
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Note: for n = 0 to 31

Table 42-47 presents a summary of the SDMA internal (core) registers.

42.12.3 SDMA Core Register Descriptions

The SDMA core has access to several memory mapped registers through its internal data bus. They are described in the following sections.

42.12.3.1 AP (MCU) Channel 0 Pointer (MC0PTR)

The following table shows the register; Table 42-48 provides its field descriptions.

0x7000 (MC0PTR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MC0PTR[31:16]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MC0PTR[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-42. AP (MCU) Channel 0 Pointer (MC0PTR) Register

Table 42-48. MC0PTR Field Descriptions

Field	Description
31–0 MC0PTR	Contains the address—in the AP memory space—of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

42.12.3.2 Current Channel Pointer (CCPTR)

Figure 42-43 shows the register; Table 42-49 provides its field descriptions.

0x7002 (CCPTR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CCPTR[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-43. Current Channel Pointer (CCPTR) Register

Table 42-49. CCPTR Field Descriptions

Field	Description
31–16	Reserved
15–0 CCPTR	Contains the start address of the context data for the current channel: Its value is *CONTEXT_BASE* + 24**CCR* or *CONTEXT_BASE* + 32**CCR* where CONTEXT_BASE = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Section 42.10.3.22, “Channel 0 Boot Address (CHN0ADDR).”

42.12.3.3 Current Channel Register (CCR)

Figure 42-44 shows the register; Table 42-50 provides its field descriptions.

0x7003 (CCR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	CCR[4:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-44. Current Channel Register (CCR)

Table 42-50. CCR Field Descriptions

Field	Description
31–5	Reserved
4–0 CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

42.12.3.4 Highest Pending Channel Register (NCR)

Figure 42-45 shows the register; Table 42-51 provides its field descriptions.

0x7004 (NCR) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EVENTS[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 42-46. External DMA Requests Mirror (EVENTS)

Table 42-52. EVENTS Field Descriptions

Field	Description
31–0 EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the AP programmed.

42.12.3.6 Current Channel Priority (CCPRI)

Figure 42-47 shows the register; Table 42-53 provides its field descriptions.

0x7006 (CCPRI) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 42-50. OnCE Event Cell Control Register (ECTL)

Table 42-56. ECTL Field Descriptions

Field	Description
31–14	Reserved
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin. 0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before a debug request is sent. After every event detection, the counter is decreased. When the counter reaches the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter. 0 Counter is disabled. 1 Counter is enabled.
11–10 ECTC[1:0]	The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation. 00 address ONLY 01 data ONLY 10 address AND data 11 address OR data
9–8 DTC[1:0]	The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values. 00 equal 01 not equal 10 greater than 11 less than

Table 42-56. ECTL Field Descriptions (continued)

Field	Description
7–6 ATC[1:0]	The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows. 00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved
5–4 ABTC[1:0]	The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition. 00 equal 01 not equal 10 greater than 11 less than
3–2 AATC[1:0]	The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition. 00 equal 01 not equal 10 greater than 11 less than
1–0 ATS[1:0]	The access type select bits define the memory access type required on the SDMA memory bus. 00 read ONLY 01 write ONLY 10 read or write 11 —

42.12.3.10 OnCE Event Address Register A (EAA)

Figure 42-51 shows the register; Table 42-57 provides its field descriptions.

15–0 EAB	Event Cell Address Register B computes an address B condition. It is cleared on a JTAG reset.

42.12.3.12 OnCE Event Cell Address Mask (EAM)

Figure 42-53 shows the register; Table 42-59 provides its field descriptions.

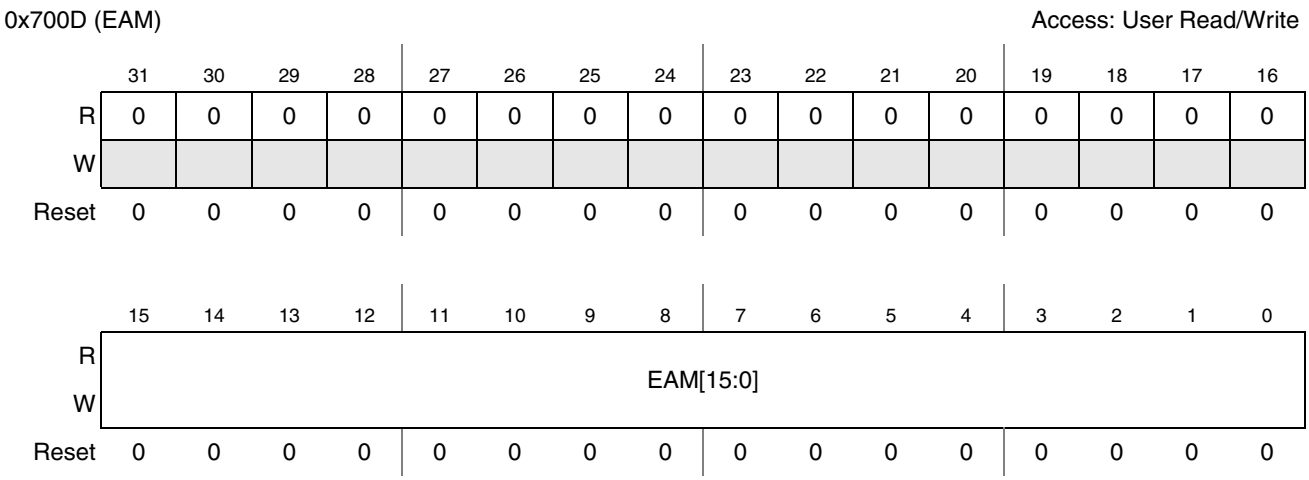

Figure 42-53. OnCE Event Cell Address Mask (EAM)

Table 42-59. EAM Field Descriptions

Field	Description
31–16	Reserved
15–0 EAM	The Event Cell Address Mask contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before performing the address comparison. **Note:** There is a common address mask value for both address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The register is cleared on a JTAG reset.

42.12.3.13 OnCE Event Cell Data Register (ED)

Figure 42-54 shows the register; Table 42-60 provides its field descriptions.

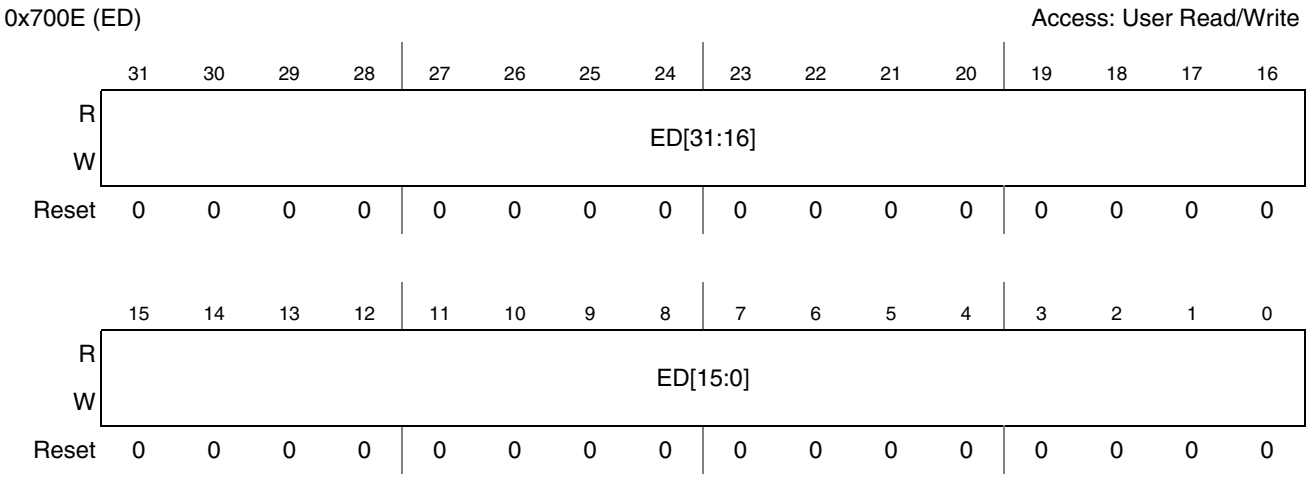

Figure 42-54. OnCE Event Cell Data (ED) Register

Table 42-60. ED Field Descriptions

Field	Description
31–0 ED	The event cell data register contains a user defined data value. This data value is an input for the data comparator which generates the data condition. It is cleared on a JTAG reset.

42.12.3.14 OnCE Event Cell Data Mask (EDM)

Figure 42-55 shows the register; Table 42-61 provides its field descriptions.

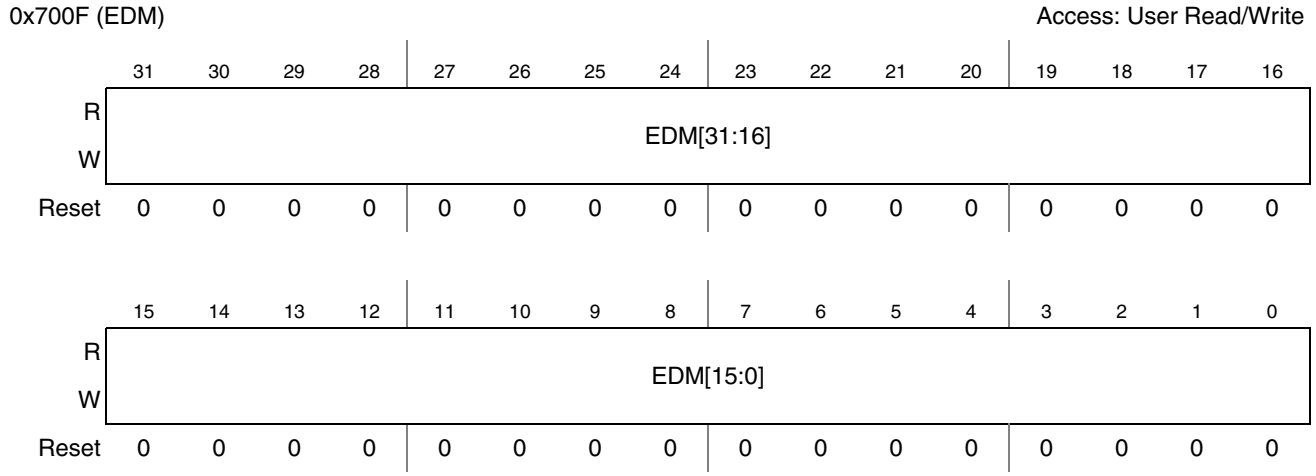

Figure 42-55. OnCE Event Cell Data Mask (EDM) Register

Table 42-61. EDM Field Descriptions

Field	Description
31–0 EDM	The event cell data mask register contains the user-defined data mask value. • This mask is applied to the data value latched from the memory bus before performing the data comparison. • Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. • The data mask is cleared on a JTAG reset.

42.12.3.15 OnCE Real-Time Buffer (RTB)

Figure 42-58. OnCE Status (OSTAT) Register

Table 42-64. OSTAT Field Descriptions

Field	Description
31–16	Reserved
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the RISC engine idle state). The “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.

Table 42-64. OSTAT Field Descriptions (continued)

Field	Description
7 MST	This flag is raised when the OnCE is controlled from the AP peripheral interface. 0 JTAG interface controls the OnCE. 1 AP peripheral interface controls the OnCE.
2–0 ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: EDR[0] 1 matched addressA condition EDR[1] 1 matched addressB condition EDR[2] 1 matched data condition The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits.

42.12.3.18 Channel 0 Boot Address (MCHN0ADDR)

Figure 42-59 shows the register; Table 42-65 provides its field descriptions.

Table 42-65. MCHN0ADDR Field Descriptions

Field	Description
31–15	Reserved

Table 42-65. MCHN0ADDR Field Descriptions (continued)

Field	Description
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
13–0 CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the AP; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

42.12.3.19 ENDIAN Mode Status Register (ENDIANESS)

Figure 42-60 shows the register; Table 42-66 provides its field descriptions.

0x701D (ENDIANESS) Access: User Read-Only

Figure 42-65. Current Channel Privilege (PRIV) Register

Table 42-71. PRIV Field Descriptions

Field	Description
31–1	Reserved
0 BPPRIV	The BPPRIV bit indicates if the current channel has privilege to access BP memory. This bit is only updated when SDMA enters a context restore state based on the value of DE at the time. Thus, if DE is cleared while the channel is running, the privilege is retained until the next channel switch to allow any remaining DMA activity for that channel to complete. 0 - Current Channel does not have privilege to access BP memory 1 - Current Channel has privilege to access BP memory

42.13 SDMA Peripheral Registers

See the respective peripherals' chapters more information.

42.14 SDMA Initialization

This section provides a quick description of several initialization procedures.

42.14.1 Hardware Reset

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content. The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

42.14.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register—detailed in Section 42.10.3.14, "Configuration Register (CONFIG)"—to determine the AP DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see Section 42.10.3.27, "Channel Enable RAM (CHNENBLn)").
3. Program the channel control registers—Channel Event Override (EVTOVR), Channel BP Override (DSPOVR), Channel BP Override (HOSTOVR), and Channel Event Pending (EVTPEND)—according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in MOT-SFS-IAPI-SAS-001 (version 0.04)).
5. Trigger channel 0 with the Channel Start (HSTART) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

42.14.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the Configuration Register (CONFIG), Channel Enable RAM (CHNENBLn), Channel Event Override (EVTOVR), Channel BP Override (DSPOVR), Channel AP Override (HOSTOVR), and Channel Event Pending (EVTPEND).
2. Use the OnCE (either via its JTAG interface or its AP control registers) to download any code in the SDMA RAM. Section 42.18.5.4, "Accessing the Memory" describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in Channel 0 Boot Address (CHN0ADDR). (This register default address points to the standard boot script.)

42.14.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute. Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The AP manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the AP via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the AP can enable any channel that becomes active and begins fetching and executing instructions from its script.

42.15 Instruction Description

This section provides a quick description of several initialization procedures. The following sections introduce the instruction of the SDMA. Instruction set details are available in Section •, "RESERVEDRESERVEDSection 42.16.2.6, "Peripheral DMA Read (ldf)—Read Mode" for Peripheral DMA."

42.15.1 Scheduling Instructions

The following are scheduling instructions:

- `done`—The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The `done` 5 has a special usage reserved for debug, as explained in Section 42.15.17, "Debug Instructions."
- `yield`—These instructions are special cases of the `done` instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.

- yieldge—These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- notify—The notify instruction affects the scheduling bits, but does not cause rescheduling.

42.15.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied. Otherwise, control passes to the next sequential instruction.

- BF—Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- BT—Branch if True. The branch is taken if the T bit in the processor status is one (true).
- BSF—Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- BDF—Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

42.15.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer. Absolute transfers have a 14-bit address field that replaces the current PC.

- JMP—Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- JSR—Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- JMPR—Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- JSRR—Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

42.15.4 Subroutine Return Instructions

The following are subroutine return instructions:

- RET—Return from Subroutine. The RET restores the contents of RPC to PC.
- LDRPC—Load from RPC to Register. THe LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

42.15.5 Loop Instruction

The following is a loop instruction:

LOOP—Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

42.15.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF—Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s—This moves data from GReg[s] to GReg[r].
- LDI r,immediate—This loads GReg[r] with a zero-extended immediate value.

42.15.7 Logic Instructions

The following are logic instructions:

- XOR r,s—This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORI r,immediate—This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- OR r,s—This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORI r,immediate—This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDN r,s—This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNI r,immediate—This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- AND r,s—This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDI r,immediate—This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

42.15.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s—This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate—This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- SUB r,s—This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBI r,immediate—This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

42.15.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- `CMPEQ r,s`—This sets T when registers `GReg[r]` and `GReg[s]` are equal.
- `CMPEQI r,immediate`—This sets T when register `GReg[r]` and the zero-extended immediate value are equal.
- `CMPLT r,s`—This sets T when register `GReg[r]` is less than and not equal to `GReg[s]`. The comparison is signed.
- `CMPHS r,s`—This sets T when register `GReg[r]` is greater than or equal to `GReg[s]`. The comparison is signed.

42.15.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- `TST r,s`—This performs an `and` between `GReg[r]` and `GReg[s]`, and sets T if the result is not zero.
- `TSTI r,immediate`—This performs an `and` between `GReg[r]` and a zero-extended immediate value, and sets `T` if the result is not zero.

42.15.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3, b_2, b_1, b_0.

- `RORB r`—The rotate right byte. The result is b_0, b_3, b_2, b_1.
- `REVB r`—The reverse bytes in word. The result is b_0, b_1, b_2, b_3.
- `REVBLO r`—The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1.

42.15.12 Bit Shift Instructions

The following are bit shift instructions:

- `ROR1 r`—The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- `LSR1 r`—The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- `ASR1 r`—The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- `LSL1 r`—The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

42.15.13 Bit Manipulation Instructions

- `BCLRI r,n`—The bit clear is immediate; clears bit number *i* in register *r*.
- `BSETI r,n`—The bit set is immediate; sets bit number *i* in register *r*.
- `BTSTI r,n`—The bit test is immediate; tests bit number *i* in register *r* (T becomes equal to the selected register bit).

42.15.14 SDMA Memory Access Instructions

All memory accesses are 32 bits. Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s. All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault. What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- `LD r,(b,d)`—The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- `ST r,(b,d)`—The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

42.15.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus. Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See Section 42.16, “Functional Units Programming Model.”

There are two functional unit instructions, as follows:

- `LDF r,fub`—The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- `STF r,fub`—The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

42.15.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the Illegal Instruction Trap Address (ILLINSTADDR) register (the default value is 0x0001).

ILLEGAL—Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

42.15.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT—The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug module only.
- done 5—This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in Section 42.18.5.2, "Saving the Context."
- CpShReg—This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in Section 42.18.5.3, "Restoring the Context."

42.16 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus. Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in Table 42-72. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 42-72. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit	MSA	Memory Source Address Register	42.16.1.1/42-109
	MDA	Memory Source Address Register	42.16.1.2/42-109
	MD	Memory Data Buffer Register	42.16.1.3/42-110 (Write) 42.16.1.5/42-112 (Read) 42.16.1.6/42-114
	MS	Memory State Register	42.16.1.4/42-110
Peripheral DMA Unit	PSA	Peripheral Source Address Register	42.16.2.1/42-123
	PDA	Peripheral Source Address Register	42.16.2.2/42-123
	PD	Peripheral Data Buffer Register	42.16.2.3/42-124 (Write) 42.16.2.5/42-126 (Read) 42.16.2.6/42-128
	PS	Peripheral State Register	42.16.2.4/42-124

Table 42-72. Functional Unit Registers (continued)

Functional Unit	Register	Register Name	Section/Page
CRC Unit	CA	Polynomial Register	42.16.3.1/42-133
	CS	Accumulator Register	42.16.3.2/42-134

More information regarding the functional units can be found in Section 42.5.1, "CRC Calculation Unit,", Section 42.5.3, "Peripheral DMA Unit," and Section 42.5.2, "Burst DMA Unit".

42.16.1 Burst DMA Unit

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus. There are four registers associated with the burst DMA unit, a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS).
The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

42.16.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EMI memory associated with the next read data transfer. It has byte granularity.

Reading the register with the `ldf` instruction has no side effects, and gives the address value in the EMI memory of the next data that is read by the SDMA during an `ldf MD` instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen—In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)—In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

42.16.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EMI memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the `ldf` instruction has no side effects. It gives the address value in the EMI memory where the next SDMA data (`stf r,MD` instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen—In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)—The MDA register is incremented by the number of bytes transferred during write cycles.

42.16.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO. This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode). The MD register is in write mode after a writing in MDA or after an `stf MD` instruction. In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EMI controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EMI (reading or writing), no immediate error is possible because the module manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EMI memory mapping. The only potential error, in this mode, would be the error sent back by the EMI controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Section 42.16.1.10, “Error Management.”

42.16.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	spriv	stype	0	0	dpriv	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

Figure 42-66. MS Structure

Table 42-73. MS Field Descriptions

Field	Description
31–22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen—MSA is not modified. 1 Incremented—MSA is incremented by the number of transferred bytes during read access.
19–18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen—MDA is not modified. 1 Incremented—MDA is incremented by the number of transferred bytes during write access.
15–12	Reserved
11 y	Conditional Yielding selector. When selected, the `yield`/`yieldge` instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by `stf MD` instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value.DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an `ldf MD` instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode

Table 42-73. MS Field Descriptions (continued)

Field	Description
9–8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7–6	Reserved
5–0 n	Number of bytes in the MD FIFO.

42.16.1.5 Burst DMA Write (stf)

When received from a `stf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

Figure 42-67. STF Code Bits

Table 42-74. STF Code Bit Field Descriptions

Field	Description
7–6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3–2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS

Table 42-74. STF Code Bit Field Descriptions (continued)

Field	Description
1–0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in Table 42-75 (unused bits should always be cleared).

Table 42-75. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSA|FR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDA|FR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MD|SZ0|FL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MD|SZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MD|SZ8|FL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MD|SZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MD|SZ16|FL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MD|SZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MD|SZ32|FL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MD|CPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)

Table 42-75. Burst DMA STF Instruction List (continued)

Binary	Assembly	Comments
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MS|SZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as `clref` MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the `stf r,MD` instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an `ldf` from MS before terminating a channel in order to check the final error status. (The `ldf` from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every `stf MD` instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

42.16.1.6 Burst DMA Read (ldf)

When received from an `ldf` instruction, the function code bits are interpreted as follows, depending on the addressed register:

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

Figure 42-68. LDF Code Bits

Table 42-76. LDF Code Bit Field Descriptions (continued)

Field	Description
3–2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1–0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table 42-77 lists the possible write instructions (unused bits should always be cleared).

Table 42-77. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an `ldf` MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MD|SZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MD|SZ8|PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MD|SZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MD|SZ16|PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MD|SZ32	32-bit (word) read
00_1_0_10_11	ldf r,MD|SZ32|PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

42.16.1.7 Prefetch/Flush and Auto-Flush Management

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed. When the RISC core requires a prefetch (p = 1) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32’nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an `stf MD|SZ8` is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an `stf MD|SZ16` is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an `stf MD|SZ32` is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.

  Therefore, if an `stf MD|SZ32` is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (`stf`) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, `stf MD|SZ8`. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.
- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EMI controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush—which occurs only at the beginning of a misaligned write transfer—no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

42.16.1.8 Data Alignment and Endianness

42.16.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). Table 42-78 shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 42-78. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1

Table 42-78. FIFO Read Configuration (continued)

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

42.16.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size. The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. Table 42-79 shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 42-79. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??

11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an `ldf` MD is executed after `stf` MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a `stf MD|SZ0|FL` instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

42.16.1.8.3 Endianness

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian. Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

42.16.1.9 Copy Mode

A mechanism is available to perform fast AP-to-AP transfers. Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag). It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an `stf MD|CPY` is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)—given by the SDMA general register (4 LSB)—is also limited to eight. The following

SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Example 42-1. Burst DMA copy mode example

```
        ldi r0,@src
        stf r0,MSA                  // Source address setup
        ldi r1,@dst
        stf r1,MSA                  // Destination address setup
        ldi r0,0x64                 // data transfer counter
        ldi r1,0x8
MAIN_XFER:
        cmphs r0,r1                 // Is r0 >= 0x8
        bf LAST_XFER                // If not, jump to last transfer label
        stf r1,MD|CPY               // Copy 8 words from MSA to MDA address.
        subi r0,0x8                 // Decrement counter
        jmp MAIN_XFER               // return to main transfer loop
LAST_XFER:
        stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then `r0` equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

42.16.1.10 Error Management

Another point to consider is the management of errors. Because the DMA immediately sends an acknowledge to the RISC core (except for the `stf MS|SZ0|FLS` instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access. This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the `ldf` copy or `stf` copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2’b11 (error read burst). It is possible to read MS (“n” field) to know how much valid data remains in MD and when MD is empty (after `ldf` instructions). The next read MD instruction sets the MS error flag to 2’b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In “error read burst” mode, writing MDA, MSA, or MD, or starting a copy transfer by a `stf MD|COPY` instruction will cancel the error mode. Table 42-80 shows when an immediate error is sent back according to the executed instruction.

Table 42-80. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (IU IPF) stf rn, MDA stf rn,MD|COPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the `stf MD|COPY`, a copy loop is executed.
stf rn, MS	NO	MS is updated.

ldf rn, MS
ldf rn, MSA
ldf rn, MDA
	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 42-81. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an `stf MS|SZ0` instruction.

ldf rn, MS
ldf rn, MSA
ldf rn, MDA
	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, MD	Yes	Whatever the DMA direction (read or write), an `ldf rn` triggers an immediate error.

42.16.1.11 Conditional Yielding

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Example 42-2. Hardware Loop

```
loop
load Rn,source  // can be ldf or ld
<computation>   // can be done through functional units
store Rn,dest   // can be st or stf
done 0          // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes—conditional or always-true—for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

42.16.2 Peripheral DMA Unit

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the AP platform. Its goal is to perform data transfers between any modules connected to the DMA bus of this platform. These modules are either peripherals or memories. The peripheral DMA could be seen as the AP DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the AP and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode—When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode—When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.

- Decremented mode—In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

42.16.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity. It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an `ldf MD` instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all `ldf MD` instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (`stf PSA|SZ32|I`), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the `stf PSA` instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

42.16.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity. It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an `stf MD` instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the `stf PDA` instruction and may also generate an error in case of incorrect programming.

42.16.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data. The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an `ldf` instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag—part of PS—is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

42.16.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. Although all PS fields can be written by an `stf` instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

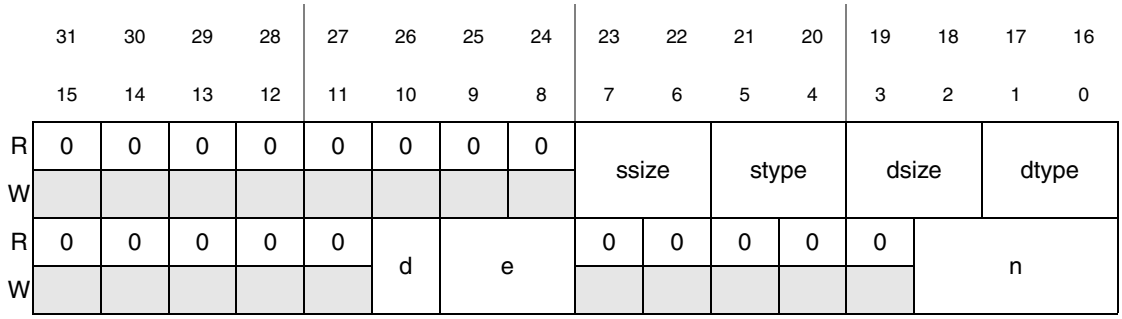

Figure 42-69. PS Structure

Table 42-82. PS Field Descriptions

Field	Description
31–24	Reserved
23–22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21–20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
19–18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17–16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
15–11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by `stf PD` instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an `ldf PD` instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9–8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 Error read
7–3	Reserved
2–0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

42.16.2.5 Peripheral DMA Write (stf)—Write Mode

When written by an `stf` instruction, the function code bits are interpreted as follows:

Register	7	6	5	4	3	2	1	0
PSA	s		p	ar	am		sz	
PDA								
PD			pdsel					
PS			pssel					

Figure 42-70. STF Code Bits

Table 42-83. STF Code Bits Field Descriptions

Field	Description
7–6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3–2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen—Address registers are not modified after the transfer. 01 Incremented—Address registers are incremented by the number of transferred bytes. 10 Decremented—Address registers are decremented by the number of transferred bytes. 11 Updated—PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1–0 sz	Transfer Size 00 *reserved* 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5–0 pdsel	PD access selector 001000 is the only valid option
5–0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible `stf` instructions, Table 42-84 provides only a short list of all the possible write instructions:

Table 42-84. Peripheral DMA STF Instruction List

Binary	Assembly	Comments
11_00_00_01 11_00_00_10 11_00_00_11	stf Rn, PSA|SZ8 |F stf Rn, PSA|SZ16|F stf Rn, PSA|SZ32|F	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is frozen.
11_10_00_01 11_10_00_10 11_10_00_11	stf Rn,PSA|SZ8 |F|PF stf Rn,PSA |SZ16|F|PF stf Rn,PSA |SZ32|F|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • 1, 2, or 4 bytes are *fetched* from the peripheral source. • Source address is frozen.
11_00_01_01 11_00_01_10 11_00_01_11	stf Rn, PSA|SZ8 |I stf Rn, PSA|SZ16|I stf Rn, PSA|SZ32|I	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1,2 or 4 after read PD.
11_10_01_01 11_10_01_10 11_10_01_11	stf Rn, PSA|SZ8 |I|PF stf Rn, PSA|SZ16|I|PF stf Rn, PSA|SZ32|I|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1, 2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_10_01 11_00_10_10 11_00_10_11	stf Rn, PSA|SZ8 |D stf Rn, PSA|SZ16|D stf Rn, PSA|SZ32|D	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA—1,2, or 4 after read PD.
11_10_10_01 11_10_10_10 11_10_10_11	stf Rn, PSA|SZ8 |D|PF stf Rn, PSA|SZ16|D|PF stf Rn, PSA|SZ32|D|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA—1,2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_11_01 11_00_11_10 11_00_11_11	stf Rn, PSA|SZ8 |U stf Rn, PSA|SZ16 |U stf Rn, PSA|SZ32 |U	• *Update* source pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost.
11_10_11_01 11_10_11_10 11_10_11_11	stf Rn, PSA|SZ8 |PF|U stf Rn, PSA|SZ16 |PF|U stf Rn, PSA|SZ32 |PF|U	• *Update* source pointer, which becomes a pointer to a target accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost. • 1, 2, or 4 bytes are *fetched* from the memory source.
11_01_00_01 11_01_00_10 11_01_00_11	stf Rn, PDA|SZ8 |F stf Rn, PDA|SZ16|F stf Rn, PDA|SZ32|F	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is frozen.

11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDA|SZ8 |D stf Rn, PDA|SZ16|D stf Rn, PDA|SZ32|D	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA—1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDA|SZ8 |U stf Rn, PDA|SZ16 |U stf Rn, PDA|SZ32 |U	• *Update* destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PDA value is not modified by Rn • bytes present in PD are lost
11_00_10_00	stf Rn, PD	• Write “dsize” bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	• Write status register
11_00_11_00	stf Rn,clrefPS	• Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

42.16.2.6 Peripheral DMA Read (ldf)—Read Mode

When received from an `ldf` instruction, the function code bits are interpreted as follows.

<table>
<tr><th>Register</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>PSA</td><td colspan="2" rowspan="4">s</td><td></td><td rowspan="2">ar</td><td rowspan="3">a</td><td></td><td></td><td></td></tr>
<tr><td>PDA</td><td></td><td></td><td></td><td></td></tr>
<tr><td>PD</td><td>p</td><td>cpy</td><td></td><td></td><td></td></tr>
<tr><td>PS</td><td colspan="5">pssel</td></tr>
</table>

Figure 42-71. LDF Code Bits

Table 42-85. LDF Code Bits Descriptions

Field	Description
7–6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5–0 pssel	PS access selector 111111 is the only valid option to read PS

Table 42-86 provides a list of supported `ldf` instructions.

Table 42-86. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PD|PF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PD|COPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are *not* the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

42.16.2.7 Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers. Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for

transfers that involve two targets of the same data path width. Since copy mode is invoked with an `ldf` instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

42.16.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

42.16.2.8.1 Immediate Errors

Table 42-87 lists all incorrect DMA register setups.

Table 42-87. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSA|SZ16|F stf Rn, PSA|SZ16|I stf Rn, PDA|SZ16|F stf Rn, PDA|SZ16|I	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSA|SZ32|F stf Rn, PSA|SZ32|I stf Rn, PDA|SZ32|F stf Rn, PDA|SZ32|I	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]–PDA[1:0]	**DMA instruction**	**Comments**
0x01 0x10 0x11	stf Rn, PSA|SZ32|U stf Rn, PDA|SZ32|U	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSA|SZ16|U stf Rn, PDA|SZ16|U	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	**Comments**	
stf Rn,PD ldf Rn,PD	If PDA size (dsize) has never been set up before an `stf PD` instruction (dsize=0) If PSA size (ssize) has never been set up before an `ldf PD` instruction (ssize=0)	
ldf Rn,PD|CPY	Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.	

42.16.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an `ldf PD` or `stf PD` instruction would be the error of the previous DMA cycle. Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral). When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: Read Error (First Phase), Write Error and Read Error (Second Phase), and Copy Mode Errors handling.

42.16.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next `ldf PD` instruction and writing PSA, PDA, or PD will cancel the error flag. The module returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. Table 42-88 details which instructions can be executed in this mode.

Table 42-88. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn,PDICOPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the `ldf PD|COPY`, a copy loop is executed.
stf rn, PS	NO	PS is updated.

ldf rn, PS
ldf rn, PSA
ldf rn, PDA
	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

42.16.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in Read Error (First Phase), when an `ldf PD` is executed while the module is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, `stf` instructions may raise an immediate error, and `ldf` instructions will not (as detailed in Table 42-89).

Table 42-89. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an `stf PS` instruction.

ldf rn, PS
ldf rn, PSA
ldf rn, PDA
	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).

ldf rn, PD	YES	Whatever the DMA direction (read or write), an `ldf rn, PD` instruction will show an immediate error.

42.16.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in Read Error (First Phase) on page 42-131 and Write Error and Read Error (Second Phase) on page 42-131: It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an `ldf` instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another `ldf` instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual `stf PD` instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual `stf PD` instruction.

42.16.2.8.6 Error Check Example

Example 42-3 illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first `bdf` instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the `ldf PS` instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an `ldf` command sets the SF flag and any error returned on an `stf` instruction sets the DF flag. This can create a situation as shown in Example 42-3 where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an `ldf` instruction.

Example 42-3. Peripheral DMA Error Check

```
clrf    0               // Clear SF and DF flags
stf     R4, PD          // Write data to memory
bdf     error_routine   // Check for immediate error from write to PD.
ldf     r3, PS          // Read PS (PS value in R3 can be ignored)
bsf     error_routine   // Check for bus error from “stf R4,PD”
                        // SF is set because it is a ldf instruction, even though
                        // the original error was a destination fault
```

42.16.2.9 Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a `stf PD` instruction—assuming PDA is correctly programmed—it is automatically flushed to the destination. An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

42.16.3 CRC Unit

The Cyclic Redundancy Check (CRC) unit is connected to the SDMA core via the FUBUS. This unit can perform a CRC calculation for a set of given polynomials from degree 8 to 32.

When all CRC unit registers are loaded, the unit can process one byte of data every clock cycle. When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses.

Two 32-bit registers comprise the unit:

- The CRC algorithm CA that describes the polynomial
- The CRC checksum CS to accumulate the data after each processing

42.16.3.1 Polynomial Register (CA)

This register defines the CRC algorithm currently used in the calculation, and the management of data ordering to/from the data register CS. Before starting any CRC calculation, it must be loaded with the chosen polynomial reference number and data ordering mode as indicated in Figure 42-72 and Table 42-90.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
R	0	0	0	0	0	0	0	0	0	0	0	ri	ro	p		
W																

Figure 42-72. CA Structure

Table 42-90. CA Descriptions

Field	Description
31–5	Reserved
4 ri	Reverse bit order of data in 0 Must be used when the peripheral receives bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral receives bytes as bit streams in MSB-first order (MMC case).

Table 42-90. CA Descriptions (continued)

Field	Description
3 ro	Reverse bit order of data out 0 Must be used when the peripheral transmits bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral transmits bytes as bit streams in MSB-first order (MMC case).
2–0 p	Polynomial selection 000 CRC32 ($X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^{8}+X^{7}+X^{5}+X^{4}+X^{2}+X+1$) 001 CRC16 ($X^{16}+X^{15}+X^{2}+1$) 010 CCITT16 ($X^{16}+X^{12}+X^{5}+1$) 011 IS136 ($X^{12}+X^{10}+X^{8}+X^{5}+X^{4}+X^{3}+1$) 100 CRC10 ($X^{10}+X^{9}+X^{5}+X^{4}+X+1$) 101 CRC8 ($X^{8}+X^{2}+X+1$) 110 Parity ($X^{8}+1$) 111 Reserved

42.16.3.2 Accumulator Register (CS)

The accumulator register accumulates the division remainder during the CRC processing.

When writing the accumulator register (process bit is not set) if the *ro* bit is set, the write data has its order reversed whatever the data length (the length is specified by the selected polynomial).

When computing new CRC (writing CS and process bit set) if the *ri* bit is set in CA, any byte of write data will have its bit order reversed before storage and calculation. In the first byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on. In the second byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on, which means in the write data, bit 15 is replaced by bit 8, bit 14 will replaced by bit 9, and so on.

If the *ro* bit is set in CA, any read data will have its bit order reversed whatever the data length. If the valid data length is 16 bits, bit 15 is replaced by bit 0, bit 14 is replaced by bit 1, and so on.

When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses. The CRC is computed in four clock cycles when performing a 32-bit access, in two clock cycles when performing a 16-bit access, and in one clock cycle when performing an 8-bit access. In all cases, an immediate acknowledge is sent back to the SDMA. A wait state is inserted if the SDMA tries to perform a new access before the end of the computation.

When performing a multi-bit access, the first byte used to compute the CRC is the most significant byte of the valid data.

42.16.3.3 Write Instruction (stf)

Table 42-91 shows the `stf` instructions.

Table 42-91. Stf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	Write polynomial encoded in the General Register (CA)
1	0	0	0	0	1	0	0	Write accumulator register (right-aligned)

Table 42-91. Stf Instructions for CRC (continued)

Byte Command								Description
1	0	0	1	0	1	0	0	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	0	1	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	1	0	Compute the CRC with the new incoming halfword (b1 b2) The bytes are used in the following order: b1 and b0.
1	0	0	1	0	1	1	1	Compute the CRC with the new incoming word (b3 b2 b1 b0) The bytes are used in the following order: b3, b2, b1, and b0.

42.16.3.4 Read Instruction (ldf)

Table 42-92 shows the `ldf` instructions.

Table 42-92. Ldf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	read the polynomial register encoded
1	0	0	0	0	1	0	0	read the accumulator register, right aligned

42.16.3.5 Operating Mode

The following is the operating mode example:

- Load the polynomial register to select the algorithm and preset the accumulator, if required.
- Data is right-aligned in the general register.
- Input data is fed byte-by-byte into the accumulator through `stf` instructions.
- When all data is fed into the CRC unit, the CRC checksum is read with `ldf ca, sz`.

Example 42-4. 16-bit CCITT CRC with P(X) = $X^{16}+X^{12}+X^5+1$

```
.equ rL,0         // GReg[0] = rL; loop count register
.equ rA,1         // GReg[1] = rA; CCITT16 polynomial
.equ rP,2         // GReg[2] = rP; initial CRC value
.equ rT,3         // GReg[3] = rT; transferred byte register
.equ aT,4         // GReg[4] = aT; transferred byte address
                  // (MMC DAT_RX - $A003)
.equ CA,8         // CRC unit CA register
.equ CS,9         // CRC unit CS register
ldi rA,2          // init register with CCITT16 polynomial
stf rA,CA         // updates the selected polynomial
ldi rP,$ff        // initializes register with $000000ff
stf rP,CS,0       // presets the accumulator with $000000ff
ldi aT,$A0        // initializes aT with $A003: aT = $000000A0
revblo aT         // initializes aT with $A003: aT = $0000A000
ori aT,$03        // initializes aT with $A003: aT = $0000A003
ldi rL,200        // expects to read 200 bytes from MMC DAT_RX
loop 2            // executes 200 times the next 2 instructions
ld rT,(aT,0)      // loads next byte from MMC DAT_RX
stf rT,CS,1       // process checksum with new incoming byte
ldf rT,CS         // read the final checksum at the end
```

42.16.4 OnCE and Real-Time Debug

The On-Chip Emulation module (OnCE) is the debug interface to the SDMA. It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

42.16.4.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the AP Control interface when the OnCE is controlled by the AP, as described in Section 42.18, "Using the OnCE."

42.16.4.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core. A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see Section 42.12.3, "SDMA Core Register Descriptions"): You can modify them through a regular memory access or the AP control interface.

42.16.4.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

42.16.4.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode. No hardware step execution mode is implemented in the OnCE module, but this feature may be implemented at the software level with this instruction.

42.16.4.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status. Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

42.17 The OnCE Controller

The OnCE controller receives commands from the AP or from the JTAG controller. Each command is interpreted before being sent to the core.

42.17.1 OnCE Commands

A small set of commands supports the communication between the OnCE module and the external world. This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE module. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: Table 42-93 presents their formats.

Table 42-93. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TAP controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE module. The nature of the associated data field is clearly identified. The `dmov` command is followed by a 32-bit data value (which is a data value for the SDMA); the `exec_once` and the `exec_core` commands are followed by a 16-bit data value (which is an instruction for the SDMA); the `rstatus` command is followed by a 16-bit control value (which is the content of the OnCE status register); the `rbuffer` command is followed by a 32-bit data value. The `debug_rqst` and the `run_core` commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

42.17.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one AP access to the OnCE is provided.

42.17.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal. It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compatible with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the AP access is enabled.

42.17.2.2 Using the AP

The AP access to the OnCE is not the standard access, but it is required if the JTAG is not available. For example, if the SDMA ROM is out of use on a chip in production, and the AP needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an AP access to the OnCE.

To drive the OnCE, the AP uses some registers contained in the AP Control module of the SDMA. These registers are accessed through the AP peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the AP Control module is listed below:

- ONCE_ENB register (1 bit, read/write)—This 1-bit register enables the AP access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.
- ONCE_CMD register (4 bits, read/write)—This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing “0001” in this register, a `dmov` command is executed.

NOTE

On the AP side, the `rstatus` and `bypass` commands are not supported. This register is reset on a JTAG reset.

- ONCE_DATA register (32 bits, read/write)—This 32-bit register is connected to the SDMA data register. This register is used when executing a `dmov` or `rbuffer` command.

NOTE

Before requesting a `dmov` command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- ONCE_INSTR register (16 bits, read/write)—This 16-bit register is connected to the SDMA instruction register. This register is used when executing an `exec_core` or an `exec_once` command.

NOTE

Before requesting an `exec_core` or an `exec_once` command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)—A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the AP controls the OnCE, therefore no register is defined in the AP Control module to access the bypass register.

42.17.2.3 Conflicts Between the JTAG and the AP Accesses

When AP access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the module is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a `dmov` command from debug mode (with neither 0xffffffff nor 0x0 as `dmov` value: 0x5a5a5a5a is good).
- Execute another `dmov` command (the value here is not important).

  The returned value from the latter `dmov` command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

42.17.3 Executing a Command from the OnCE

All the commands defined in Section 42.17.1, “OnCE Commands” can be accessed through the JTAG. The AP can access all these commands except the `rstatus` command. On the AP side, the OnCE status is directly accessed by reading the ONCE_STAT register.

42.17.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: `rstatus` and `rbuffer`. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: `dmov`, `run_core`, `exec_core`, `exec_once`, and `debug_rqst`. These commands are core status dependent, as follows:

- During user mode only the `debug_rqst` is taken into account.
- During debug mode, all these commands are taken into account except the `debug_rqst`. For example, an `exec_once` command requested while not in debug mode has no effect.

42.17.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is send after decoding the `update_dr` state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the AP side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the AP side: After writing ‘010’ in the ONCE_CMD register, the OnCE controller asks the SDMA to execute the instruction contained in the ONCE_INSTR register. The instruction involved should be available in the ONCE_INSTR register before the beginning of the execution.

42.17.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- `rstatus` command execution—The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the capture_dr state, and shifted out after 16 TCK clock cycles in the shift_dr state. The `rstatus` command is not supported on the AP side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.
- `dmov` command execution—The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register GReg[1].

  If the JTAG is used, the content of GReg1 is captured in the SDMA data register during the capture_dr state, then it is shifted out after 32 TCK clock cycles in the shift_dr state. During the update_dr state, GReg1 is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the AP side, the data values contained in GReg1 and the SDMA data register are exchanged

after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- `exec_once` command execution—The `exec_once` command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.

  Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises `done/yield/yiedge` (except `done` 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions.

  No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the `rstatus` OnCE command, monitoring the debug_mode pin, or checking the Section 42.10.3.19, "OnCE Status Register (ONCE_STAT)" register via the AP control interface.

  NOTE

  Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

  If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- `run_core` command execution—The `run_core` command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in Section 42.18.5.3, "Restoring the Context."

  If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the core is rerun when detecting a write access to the ONCE_CMD register.

- `exec_core` command execution—The `exec_core` command resumes program execution from any address. The 16-bit instruction provided with the `exec_core` overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an `exec_core` command, the SDMA leaves debug mode. The `exec_core` command is usually used with a `jmp` instruction.

  If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the SDMA reruns when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a `jump to address 0x100` instruction.

- `debug_rqst` command execution—The `debug_rqst` command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug

request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the AP side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.

- `rbuffer` command execution—The `rbuffer` command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the AP side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.
- `bypass` command execution—This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

42.17.4 Registers Descriptions

See Section 42.12.3, “SDMA Core Register Descriptions” and Section “AP Memory Map and Control Register Definitions” for detailed information on each register.

42.17.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request. This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

42.17.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers—the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

42.17.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

42.17.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition. The event cell data register is cleared on a JTAG reset.

42.17.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data. Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

42.17.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode. See Section 42.18.8.2, “Real Time Buffer” for more details.

42.17.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions. The event cell control register is cleared on a JTAG reset. See also Section 42.18.6, “OnCE Event Detection Unit” for more details.

42.17.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer. See Section 42.18.8.1, “Trace Buffer” for more details.

42.17.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register. See Section 42.10.3.19, “OnCE Status Register (ONCE_STAT)” for detailed description of the individual fields in the OSTAT register.

Figure 42-73 shows the OSTAT structure.

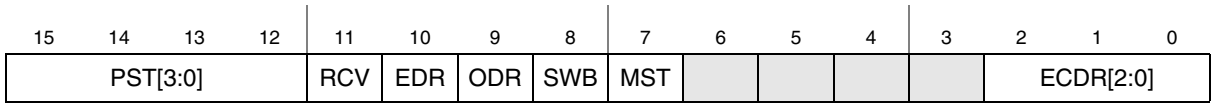

Figure 42-73. OnCE Status Register (OnCE)

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the AP control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an `rstatus` command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the AP access. Executing the `rstatus` command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the `exec_once` command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

42.17.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

42.17.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see Figure 42-74) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, TCK < CLK/8, limitation guarantees that all operations are performed as expected.

42.17.5.2 Synchronization Implementation

Figure 42-74 shows the synchronization mechanism. Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to `yield` the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

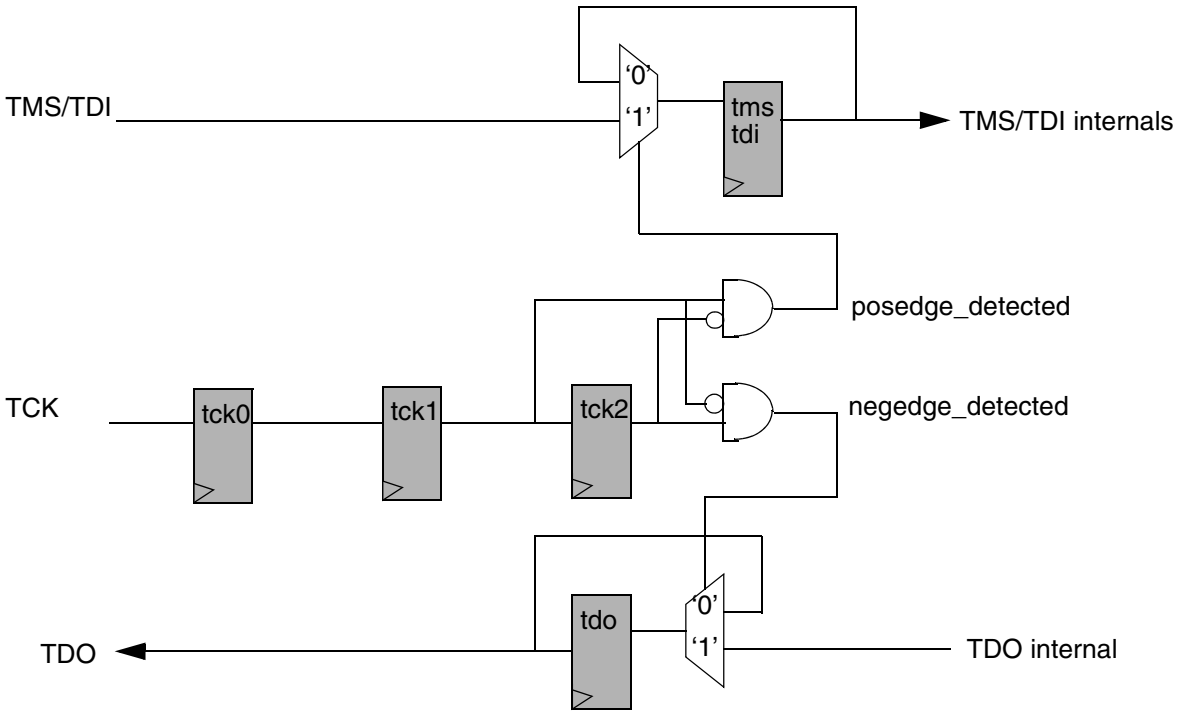

Figure 42-74. OnCE Synchronization Layer

Figure 42-75 shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

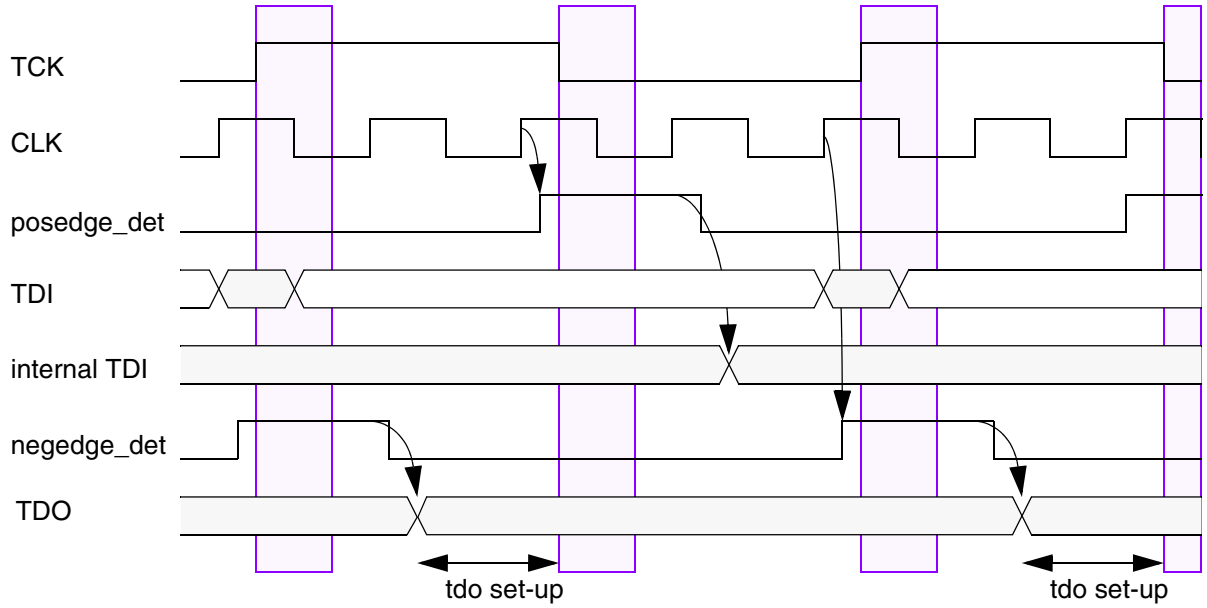

Figure 42-75. Synchronization Timings

42.17.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

42.18 Using the OnCE

This section provides the elements necessary to run the OnCE module during a debug process. In addition to the basic set of commands described in Section 42.17.1, "OnCE Commands," more complex commands can be built to meet users' requirements.

42.18.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed. This is the case for instance when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the clk_gating_off input.
- For the AP access, the SDMA clock gating is automatically turned off when the AP access is enabled (see Section 42.10.3.16, "OnCE Enable (ONCE_ENB)").

42.18.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA. It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA. Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

42.18.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch. The request is ignored when the core is already in debug mode. See Figure 42-4, which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

42.18.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see Section 42.18.1, “Activating Clocks in Debug Mode”). The debug request line should be not be maintained high when the SDMA is in debug mode.

The `debug_rqst` command (from the OnCE command set) is not supported during system reset.

42.18.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

   The `debug_rqst` command can be sent by the JTAG access or by an access on the AP side (if the AP access is enabled).

42.18.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

42.18.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus. See Section 42.18.6, “OnCE Event Detection Unit” for more details.

42.18.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution. Some instructions are not supported by the `exec_once` command: `done/yield/yiedge` (except `done` 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

42.18.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the AP and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);    // executing my_command with a data field
my_command(-);             // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an AP access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in);// returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

42.18.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus(); // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-); // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

42.18.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags. Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

Example 42-5 shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Example 42-5. Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-);              // the value exported is the content of GReg[1]
exec_once("mov GReg1,GReg0");      // puts the content of GReg[0] into GReg[1]
GReg0_data = dmov(-);              // the value exported is the content of GReg[0]
exec_once("mov GReg1, GReg2");     // puts the content of GReg[2] into GReg[1]
GReg2_data = dmov(-);              // the value exported is the content of GReg[2]
exec_once("mov GReg1, GReg3");     // puts the content of GReg[3] into GReg[1]
GReg3_data = dmov(-);              // the value exported is the content of GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a `done 5`, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5");      // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Example 42-6. Exporting the Context

```
dmov(ctx_base_addr);                // loading GReg[1] with the channel context base address
exec_once("ld GReg0,(GReg1,0)");    // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)");   // get SPC-EPC into GReg1
Loop_data = dmov(-);                // read back the value of Loop registers
exec_once("mov GReg1, GReg0");      // puts the PC info into GReg1
PC_data = dmov(-);                  // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

42.18.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE. Example 42-7 shows how it is possible to modify the current channel context:

Example 42-7. Modifying the Current Channel Context

```
dmov(Loop_data);                    // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1");      // copy to GReg[0]
dmov(PC_data);                      // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1");      // copy to GReg[2]
dmov(ctx_base_addr);                // put channel context base address into GReg[1]
exec_once("st GReg0, (GReg1,1)");   // restore Loop context
exec_once("st GReg2, (GReg1,0)");   // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg");      // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

Example 42-8 shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Example 42-8. Restoring the General Register Context

```
dmov(GReg3_data);          // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1");// restore GReg[3]
dmov(GReg2_data);          // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1");// restore GReg[2]
dmov(GReg0_data);          // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1");// restore GReg[0]
dmov(GReg1_data);          // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a `mov` instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a `mov` to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The `cpShReg` instruction is meant to provide a means for changing these register contents via the context memory.

42.18.5.4 Accessing the Memory

In the following example, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:      dmov(target_addr);                // put the target address in GReg[1]
                 exec_once("ld GReg1,(GReg1,0)");  // execute the load instruction
                 res_data = dmov(-);               // exports the result data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:     dmov(target_addr);                // puts the target address in GReg[1]
                 exec_once("mov GReg0,GReg1");     // puts the target address in GReg[0]
                 dmov(target_data);                // puts the target data in GReg[1]
                 exec_once("st GReg1,(GReg0,0)");  // performs the store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

42.18.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA. Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);              // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a `jump` instruction.

```
exec_core(“jmp start_addr”);// rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

42.18.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

Example 42-9 shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

Example 42-9. READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);      // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the “bkpt_addr”
instr_save = READ(bkpt_addr/2);     // save the instruction before overwriting
STORE(“bkpt instruction”,bkpt_addr/2);// store the bkpt instruction in memory
exec_core(“jmp run_addr”);          // rerun the SDMA
rstatus(-);                         // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);      // restore the instruction overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

42.18.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

42.18.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers. A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true. See Figure 42-76.

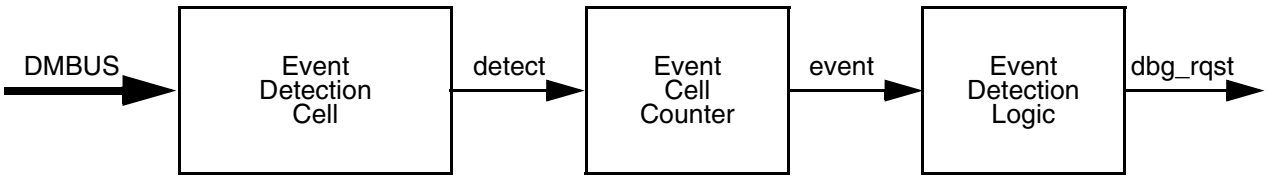

Figure 42-76. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic module that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

Figure 42-77 shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

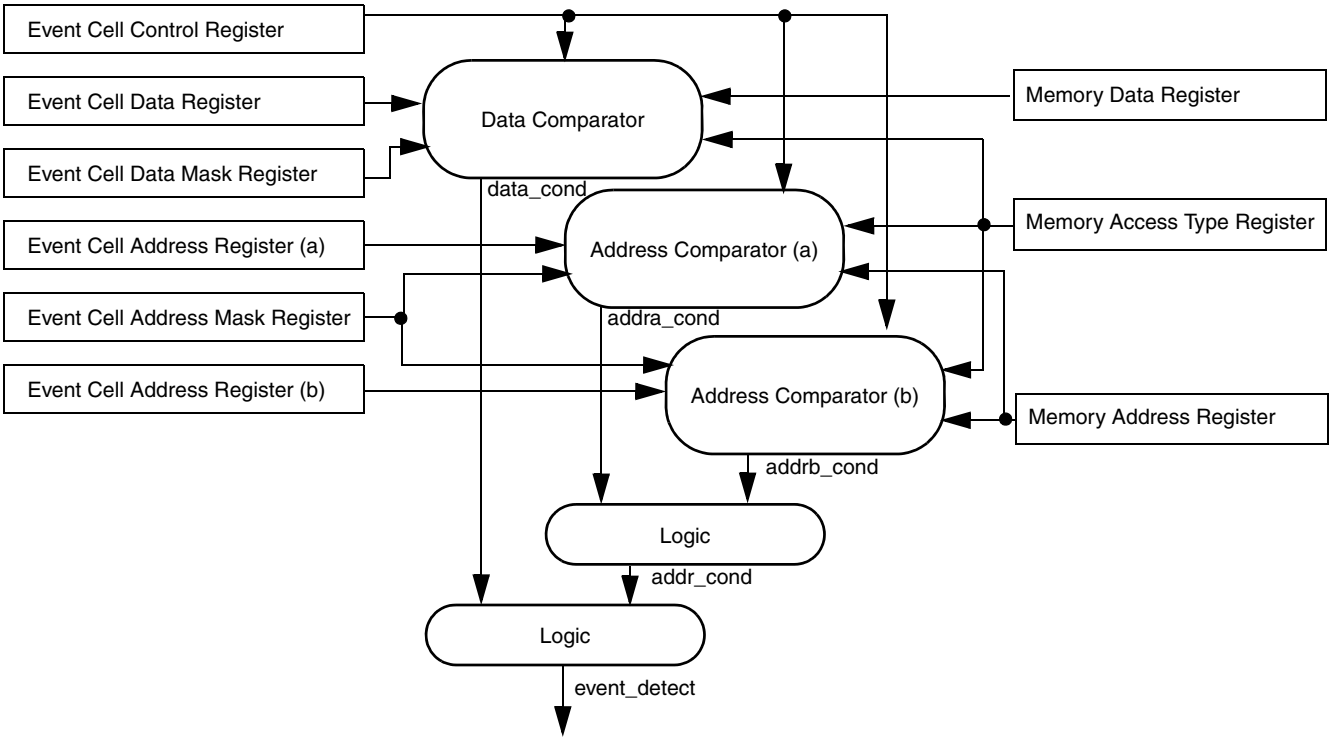

Figure 42-77. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

42.18.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

42.18.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE. When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port clk_gating_off. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

This clk_gating_off input is controlled by a control bit in the System JTAG Controller. See the System JTAG Controller chapter for more information.

When the OnCE is accessed through the AP Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see Section 42.10.3.16, “OnCE Enable

(ONCE_ENB)") is set. A write access to this register is possible even when the OnCE clock is not running. If the AP access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

42.18.7.2 Resets

The OnCE reset is different from the SDMA main reset. The OnCE reset is connected to the TRST_B pin.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

42.18.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution. The content of this register may be exported through JTAG ports without stopping the core.

42.18.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution. Figure 42-78 shows an overview of the Trace Buffer.

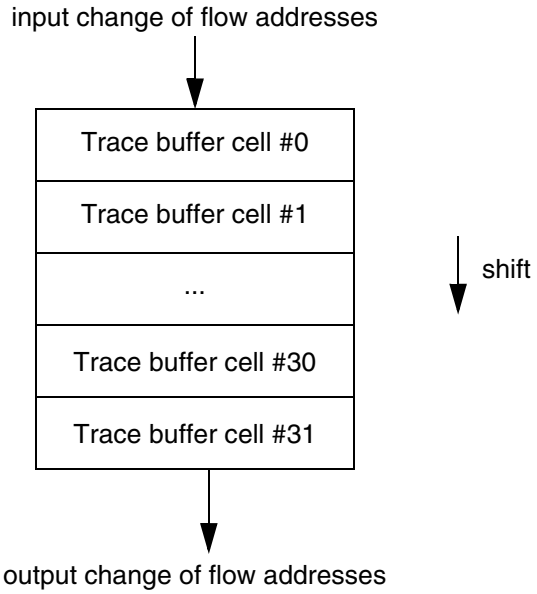

Figure 42-78. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a

valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is a follows:

```
exec_once(“mov r1, TB”);          // stores the oldest change-of-flow in GReg1
dmov(-);                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

42.18.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE. Executing ar `rbuffer` command (see Section 42.17, “The OnCE Controller” for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

42.18.8.3 Emulation Pin

The debug_matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

42.18.8.4 Real-Time Debug Outputs

Table 42-94 shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 42-94. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	The core_state bits reflect the state of the SDMA core. • The “Program” state is the usual instruction execution cycle. • The “Data” state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The “Change of Flow” state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The “Change of Flow in Loop” state is used when an error causes a hardware loop exit. • The “Debug” state means the SDMA is in debug mode. • The “Functional Unit” state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In “Sleep” modes, no script is running (this is the core idle state); the “after Reset” is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The “in Sleep” states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the “Sleep after Reset” state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel
debug_yield	Pulse that is active when a `yield` (`done` 0) or a `yieldge` (`done` 1) instruction is executed. 0 - 1 `yield`/`yieldge` executed
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode 1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.

Table 42-94. Real-Time Debug Output Pins (continued)

Pin	Description
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (`ld`, `st`, `ldf`, or `stf` instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, “no access” is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register 18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected

Table 42-94. Real-Time Debug Output Pins (continued)

Pin	Description
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register (1) and (2) (XTRIG_CONF1 and XTRIG_CONF2) (as described in Section "AP Memory Map and Control Register Definitions"). The following two parameters are available for every line: • CNF—Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]—Gives the number of the DMA request or channel to monitor

The matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the Configuration Register (CONFIG) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

Total 24 Registers

SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units. The AP memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See Table 42-95 for the summary.

Table 42-95. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
AP External Memory ↔ AP External Memory		3	Copy mode Script example, see Section 42.16.1.9, "Copy Mode" and Section 42.18.9.1, "External Memory to External Memory."
AP Peripheral ↔ AP Peripheral	3		Copy mode if same data path width Script example, see Section 42.18.9.2, "Peripheral to Peripheral Transfer."
AP External Memory ↔ AP Peripheral	3	3	Data transit through SDMA Script example, see Section 42.18.9.3, "Transfer Between Peripheral and External Memory."
AP External Memory ↔ AP Internal Memory		3	Copy mode Script example, see Section 42.18.9.4, "Transfer Between External Memory and Internal Memory."
AP Internal Memory ↔ AP Internal Memory		3	Copy mode Script example, see Section 42.18.9.4.1, "Internal Memory to Internal Memory."
AP Internal memory ↔ AP Peripheral	3		Data transit through SDMA Script example, see Section 42.18.9.4.2, "Transfer Between Peripheral and Internal Memory."

NOTE

These scripts are provided as examples of how to use DMA modules to perform required data transfers: They are not "official" programs.

42.18.9.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory. For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register. The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Example 42-10. Data Moves in External Memory

```
1         stf r1,MSA                  // Source address setup
2         stf r2,MDA                  // Destination address setup
3         ldi r0,0x64                 // 64 words must be transferred from MSA to MDA
4         ldi r1,0x8
MAIN_XFER:
5         cmphs r0,r1                 // Is r0 >= 0x8
6         bf LAST_XFER                // If not, jump to last transfer label
7         stf r1,MD|CPY               // Copy 8 words from MSA to MDA address.
8         subi r0,0x8                 // Decrement counter
9         jmp MAIN_XFER               // return to main transfer loop
```

```
LAST_XFER:
10       stf r0,MD|CPY              // perform last transfer
```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), `r1` always equals 8, so burst lengths are 8 words. On the last `ldf |CPY` instruction (10), `r1` equals the reminder of `r0` divided by 8; therefore, the length of bursts triggered in copy mode equal `r1` value, which is between 1 and 7.

42.18.9.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used. It is programmed in copy mode, so no data will transmit through the SDMA general register used in the `ldf` instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

42.18.9.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Example 42-11. Same Data Path Width for Source and Destination

```
//SETUP SECTION
1        stf r1, PSA|SZ16|F         //r1=0x1002 Source address register setup
2        stf r2, PDA|SZ16|F         //r2=0x2006 Destination address register setup
3        bdf ERROR_ADDR_SETUP
4        ldi r0,0xa                 //loop counter is 10
//MAIN LOOP TRANFER
copy_loop:
5        loop 2,0
6          ldf r7,PD|CPY            //Reads 1 half-word from src and writes to dest.
7          yield
8        bdf ERROR_DURING_XFER

ERROR_ADDR_SETUP:
//correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware `loop` instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute he next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction `ldf` is a multi-cycle instruction.

42.18.9.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag. Example 42-12 shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Example 42-12. Different Data Path Width for Source and Destination

```
//SETUP SECTION
1        stf r1, PSA|SZ32|F|PF      //r1=0x1000 and prefetch data
2        stf r2, PDA|SZ16|F         //r2=0x2006
3        bdf ERROR_ADDR_SETUP
4        ldi r0,0xa                 //loop counter is 10
//MAIN LOOP TRANFER
main_loop_xfer_16_16:
5        loop 6,0
6          ldf r7,PD                //copy 32-bit of PD in r7
7          stf r7,PD                //store 16 LSB of r7 in PD and a flush is executed
8          rorb r7
9          rorb r7                  //16 MSB --> 16 LSB
10         stf r7,PD                //store 16 LSB of r6 in PD and a flush.
11         yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the `ldf` will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

42.18.9.3 Transfer Between Peripheral and External Memory

42.18.9.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA. The code for transferring 100 word from word peripheral to the external memory would be as follows:

Example 42-13. Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1        stf r1, PSA|SZ16|F|PF      //r1=0x1000 and prefetch 32-bit data
2        stf r2, MDA                //r2=0x2000, setup burst DMA destination address
3        bdf ERROR_ADDR_SETUP
4        ldi r0,0x64                //loop counter is 100
5
//MAIN LOOP TRANFER
6        loop 3,0
7          ldf r1,PD|PF             // read 32 bits of PD and initiate a new read access.
8          stf r1,MD|32             // store 32 bits of r1 in the MD fifo.
9          yield
10       ldf r1,PD                  // last word data is read
11       stf r1,MD|32|FL            // to flush all remaining bytes of MD
```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. Figure 42-79 and Figure 42-80 show how the peripheral DMA and burst DMA work in parallel.

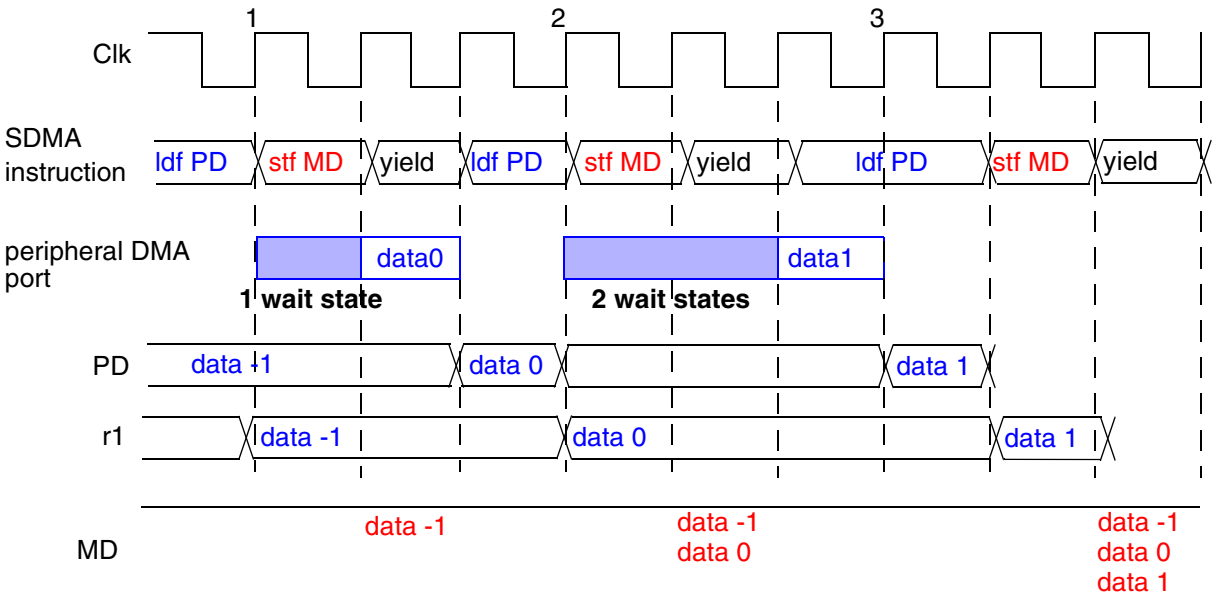

Figure 42-79. Peripheral to External Memory Example (1)

As seen in Figure 42-79, the read access triggered by the `ldf PD` instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the `ldf` instruction, which lasts two cycles. Figure 42-80 shows an example of when MD FIFO is full with data.

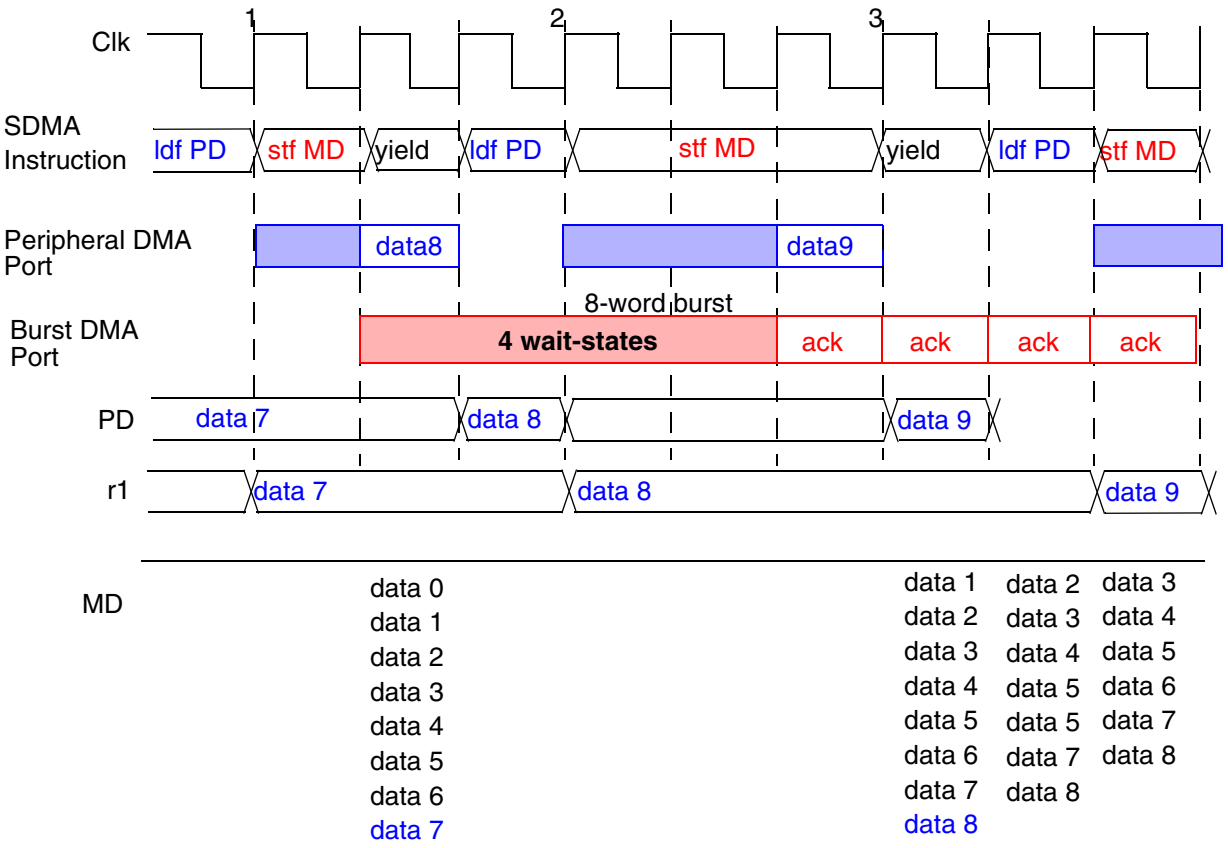

Figure 42-80. Peripheral to External Memory Example (2)

In Figure 42-80, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction `stf` because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the `stf MD` instruction lasts one cycle.

42.18.9.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA. The code for transferring 100 word from external memory to a word peripheral would be as follows:

Example 42-14. External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1        stf r1, MSA|PF    //r1=0x1000 and starts a 8-word read burst
2        stf r2, PDA|SZ32|P//r2=0x2010, setup peripheral DMA destination address
3        bdf ERROR_ADDR_SETUP
4        ldi r0,0x64       //loop counter is 100

//MAIN LOOP TRANFER
6        loop 3,0
7          ldf r1,MD|32|PF // read 32 bits of MD and initiate a new read access
                           // if MD is empty after this reading.
```

```
8          stf r1,PD       // store 32 bits of r1 in the PD.
9          yield

10       ldf r1,MD|32      // last word data is read
11       stf r1,PD         // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

42.18.9.4 Transfer Between External Memory and Internal Memory

Since the internal memory (AP RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in Section 42.18.9.3, “Transfer Between Peripheral and External Memory” can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

42.18.9.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in Section 42.18.9.2, “Peripheral to Peripheral Transfer” can be reused with a different programming of the peripheral DMA address registers.

42.18.9.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode. The SDMA script is very similar to the one described in Section 42.18.9.2, “Peripheral to Peripheral Transfer,” except for the peripheral DMA address registers programming.

Chapter 43
Sony/Philips Digital Interface (SPDIF)

43.1 Introduction

The Sony/Philips Digital Interface (SPDIF) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

Figure 43-1 shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and data interface.

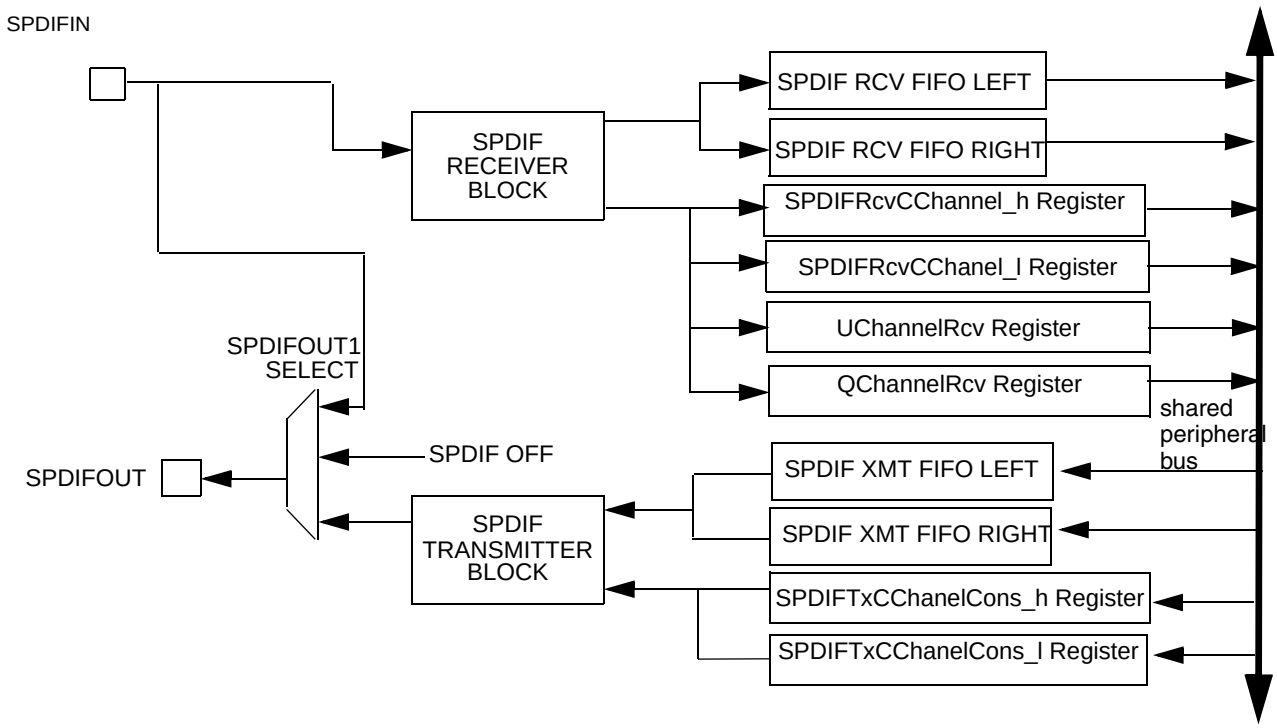

Figure 43-1. SPDIF Transceiver Data Interface Block Diagram

43.1.1 Overview

The SPDIF is composed of two parts: an SPDIF receiver and SPDIF transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in a 16-word-deep FIFO. The channel status and user bits are also extracted from each frame and placed in the corresponding

registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The channel status bits are also provided via the corresponding registers. The SPDIF transmitter generates an SPDIF output bit-stream in the biphase mark format (IEC958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC958 biphase bit stream is generated on both edges of the SPDIF transmit clock. The SPDIF transmit clock is generated by the SPDIF internal clock-generation module and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF receive clock. Both the transmit clock and the receive clock are sent to the ASRC. Figure 43-2 shows the clock structure of the SPDIF transceiver.

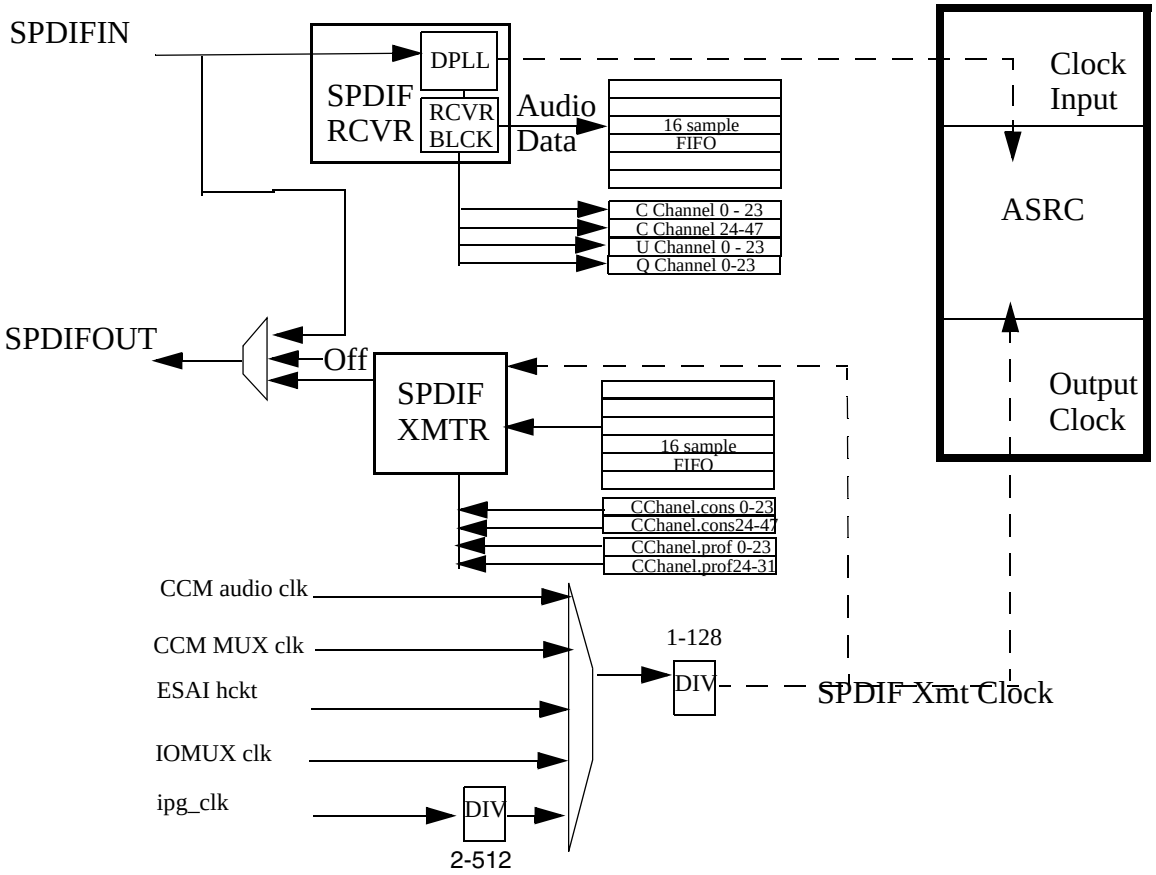

Figure 43-2. SPDIF Transceiver Clock Diagram

43.2 External Signal Description

Table 43-1. Signal Properties

Signal Name	Signal Type	Description
SPDIFIN	Input	SPDIF input line 1 IEC958 data in biphase mark format.
SPDIFOUT	Output	SPDIF output line 1 IEC958 data in biphase mark format (consumer C channel).

43.3 Memory Map and Register Definition

43.3.1 Memory Map

Table 43-2 is the module memory map. For the base address of a particular module instantiation, see the system memory map.

Table 43-2. SPDIF Register Map

Base Address Offset	Access	Name (Name Abbreviation)	Description	Size Bits	Valid Bits	Reset Value
0x0000	R/W	SPDIFConfig (SCR)	SPDIF configuration register	24	[23:0]	0x00_0400

43.3.2.4 Interrupt Registers

The interrupt registers include InterruptEn (SIE), InterruptStat (SIS) and InterruptClear (SIC).

1. The InterruptEn register (SIE) provides control over the enabling of interrupts.
2. The InterruptStat (SIS) register is a read only register providing status on interrupt operation.
3. The InterruptClear (SIC) register is a write only register and is used to clear interrupts.

Field	Description
23–20	Reserved
19–11 SYSCLK_DF	System clock divider factor, 2–512. 0 No clock signal 1 Divider factor is 2 2 Divider factor is 3 ... 511divider factor is 512
10–8 TxClk_Source	000 CCM audio clk input, 001 CCM Mux clk input, 010 ESAI HCKT input, 011 IOMUX clk input, 100 MLBCLK input, 101 Frequency divided ipg_clk input, 110 Ground input, no clock 111 Ground input, no clock
7	Reserved, return zero when read
6–0 TxClk_DF	Divider factor (1-128) 0 Divider factor is 1 1 Divider factor is 2 ... 127 Divider factor is 128

43.4 Functional Description

43.4.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in a 16-deep FIFO. The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers. The input data is sent via a 6-deep FIFO to the memory-mapped data registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception
- Channel Status bits Reception
- User Channel bits Reception
- Validity Flag Reception
- SPDIF Receiver Exception support
- SPDIF Lock Detection

43.4.1.1 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register is set, and the SPDIF Lock output pin SPLOCK is asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 kHz input sampling frequency, the average pulse rate = 128 x 44.1 kHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

43.4.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided via the SPDIFTxLeft and SPDIFTxRight registers. Clocking for the SPDIF transmitter is from either the CCM audio clk, CCM Mux clk, ESAI HCKT, IOMUX clk, or the system clock. A multiplexer is used to choose the clock source. The SPDIF transmitter clock source can be divided down as needed using the Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC958 biphase mark format, consisting of audio data and channel status.

Chapter 44
Secure JTAG Controller (SJC)

44.1 Introduction

The IEEE 1149.1 JTAG test access port (TAP) supports IEEE 1149.1 v2001 standard features, provides access to OnCE and ICE of each core, and includes debug features to improve controllability and observability of the cores for debug purposes.

The secure JTAG controller provides debug and test control with maximum security, and provides a flexible architecture for future derivatives or future multicore architecture. JTAG pins can be multiplexed to the PCS bus connector ($\overline{\text{TRST}}$/TCK/TDI/TDO/TMS)—see Chapter 4, "External Signals and Pin Multiplexing",” for more details.

44.1.1 Overview

The secure JTAG controller provides the following capabilities:

1. Supports JTAG IEEE1149.1 mandatory instructions, as described in Section 44.5.4.3, “EXTEST Instruction,” Section 44.5.4.2, “SAMPLE/PRELOAD Instruction,” and Section 44.5.4.5, “BYPASS Instruction.”
2. Supports JTAG IEEE 1149.1 optional instructions, as described in Section 44.5.4.1, “ID_CODE Instruction,” and Section 44.5.4.4, “HIGHZ Instruction.”
3. Provides access to each OnCE/ICE TAP controller independently, to control a target system (see section Section 44.2, “Modes of Operation”).
4. Provides access to the ExtraDebug logic (see Section 44.5.4.6, “ENABLE_ExtraDebug Instruction”).
5. The secure JTAG controller operates at maximum 1/8 the slowest frequency of the accessed OnCE/ICE. For example, in normal operation (with no core in low-power mode), the SJC frequency will be 1/8 of the SDMA frequency, if this core is present in the TDI-TDO chain (serially connected with other cores or stand-alone). The User also needs to take into account the 25 MHz frequency limitation on the CE bus.
6. Mode to support stand-alone core debuggers (see Section 44.2, “Modes of Operation”).
7. Multicore daisy-chained mode (default) to support multicore debuggers (see Section 44.2, “Modes of Operation”).

NOTE

Depending on SoC tool needs, RTCK may be supported. See the pins chapter for more information. RTCK (adaptive clocking methodology) may be supported in ARM-compatible mode only, allowing external tools to adapt TCK frequency automatically even when the ARM frequency is changing. Note that RTCK may no longer be used when the ARM core is chained with other TAPs, as these cores may run at slower frequency than the ARM core. This clock does not come from secure JTAG controller, but is generated from the ARM core platform. Synchronization is maintained with the help of RTCK, since the off-chip device does not progress to the next TCK edge until after an RTCK edge is received.

44.2 Modes of Operation

The secure JTAG controller (SJC) modes are controlled through both the TAP select register (TSR) and sjc_mode input port. The sjc_mode port selects between two connection modes of SoC TAPs:

- Negating sjc_mode (default) causes all TAPs (SJC, SDMA, and ARM) to be connected in the TDI-TDO chain. This is referred to as daisy-chain mode.
- Asserting sjc_mode connects only the SJC TAP to the TDI-TDO chain.

IEEE1149.1-compatible mode is enabled by changing the input signal **sjc_mod**, as shown in Table 44-1 below.

Table 44-1. Mode Selection via sjc_mod Signal

sjc_mod	Name	Description
0	Daisy chain ALL	For common software debug (High speed, production)
1	SJC only	IEEE 1149.1 JTAG compatible mode -

The “Connect SDMA” bit (TAP select register) controls the SDMA TAP bypass:

- When the bit is cleared (default), SDMA TAP is bypassed with a single D-FF during Shift-Dr path.
- When the bit is set to 1, the SDMA TAP is connected in the chain.

The TAP Selection Block (TSB) enables simple integration of IP blocks which have embedded TAPs, and has the following features:

- Enables connection of multiple TAPs within a single SoC.
- Identifies the SJC TAP as the master TAP that controls the boundary chain (for IEEE 1149.1 standard compliance).
- Follows the state of SJC TAP. When the Test-Logic-Reset (TLR) state is reached, all TAPs are reset.

NOTE

When configuring the TAP controllers, the user is responsible to ensure that all TAPs in the chain comply with TCK clock frequency requirements, as well as the required ratios between the TCK clock frequency and the frequencies of the cores to which the TAPs refer.

44.3 TAP Selection Block (TSB)

As described in Section 44.2, “Modes of Operation,” the secure JTAG controller can access cores in different modes selected through the TAP selection block.

44.3.1 Mode Selection via Software

Conceptually, the TAP select register (TSR) is a data register which is accessed through the “Access TSR” IR instruction of the SJC TAP.

The TAP select register is only allowed to change during the update-DR state of the TSB JTAG state machine. This prevents a TAP that is being selected from losing synchronization with the TSB state machine as the TSB state machine returns to run-test-idle. An associated shift register for the TAP select register is loaded into the TAP select register during the update-DR state (see Figure 44-1). The shift register captures the state of the TAP select register when in the Capture-DR state for visibility of the contents of the TAP select register. See Chapter 44.5.4.9, “TAP Select Instruction” for more information.

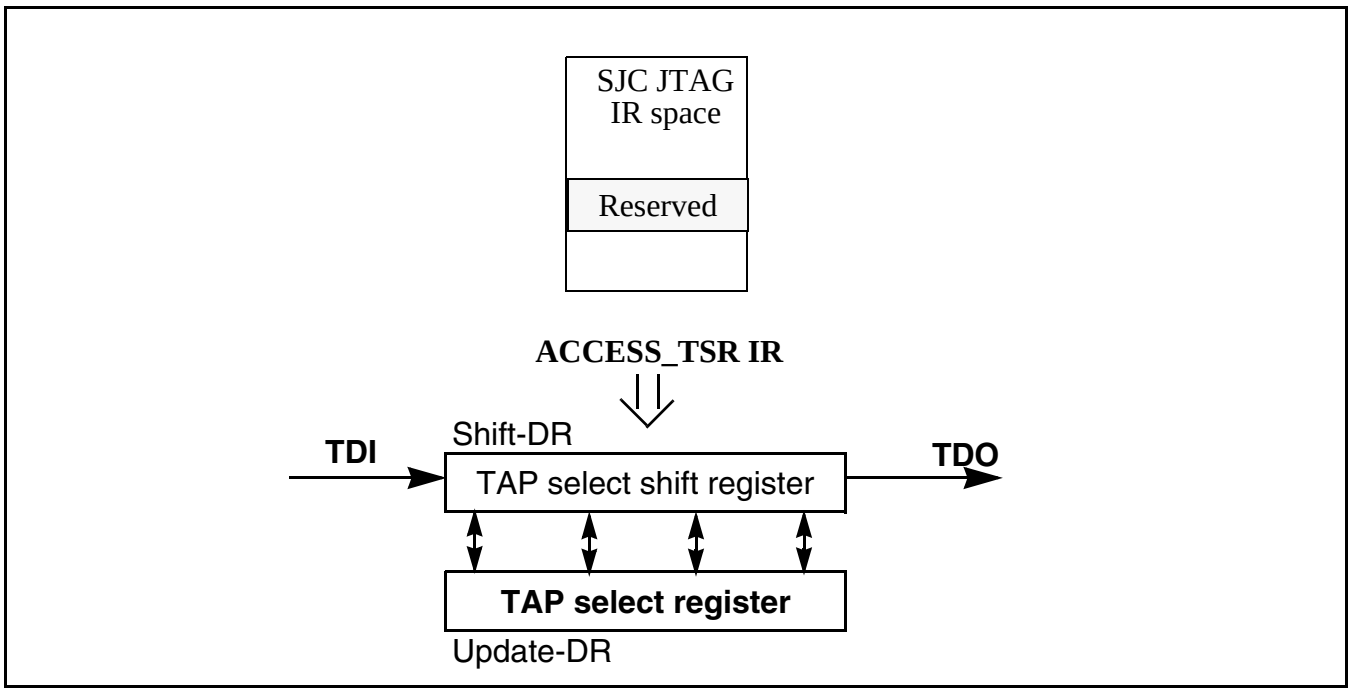

Figure 44-1. Using Reserved IR to Access TAP Select Register

44.4 External Signal Description

44.4.1 Overview

[The SJC provides test and debug control with a minimum pin count.

Table 44-2 describes SJC external signals.

Table 44-2. SJC External Signal Properties

Signal Name	Port	Signal Function	Reset State	Pull up
POR_B	POR_B	POR reset input. This input can arrive from either pad of IC or from IC's internal logic, e.g. Clock Controller.	0	-
TCK	TCK	Test Clock (TCK): used to synchronize the test logic and includes an internal pullup resistor	0	-
TDI	TDI	Test Data Input (TDI): serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK and includes an internal pullup resistor	1	Active
TDO	TDO	Test Data Output (TDO): serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK	-	-
TDO_EN	TDO_EN	Test Data Output Enable (TDO_EN). This signal enables tri-state buffer which output is connected to TDO pad and input connected to IC internal SJC generated TDO signal. Whenever TDO_EN is negated TDO will be tri-stated.	-	-
TMS	TMS	Test Mode Select (TMS): used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK and includes an internal pullup resistor	1	Active
TRST_B	TRST_B	Test Reset (TRST): used to asynchronously initialize the test controller. The TRST pin has an internal pullup resistor	1	Active
SJC_MOD	SJC_MOD	secure JTAG controller mode selection. This pin is sampled at TRST reset to determine two possible modes for the TAP connection configuration.	11	Active
DE_IN_B	DE_IN_B	SoC debug request/acknowledge pins. These pins are used to propagate a debug request to the core(s) after programming of the SoC JTAG, they can also reflect debug acknowledge from the cores.	1	Active
DE_B_OE	DE_B_OE			

44.4.2 TAP Controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. The state machine is shown in Figure 44-2. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal. For a description of the TAP controller states, see the IEEE 1149.1 document.

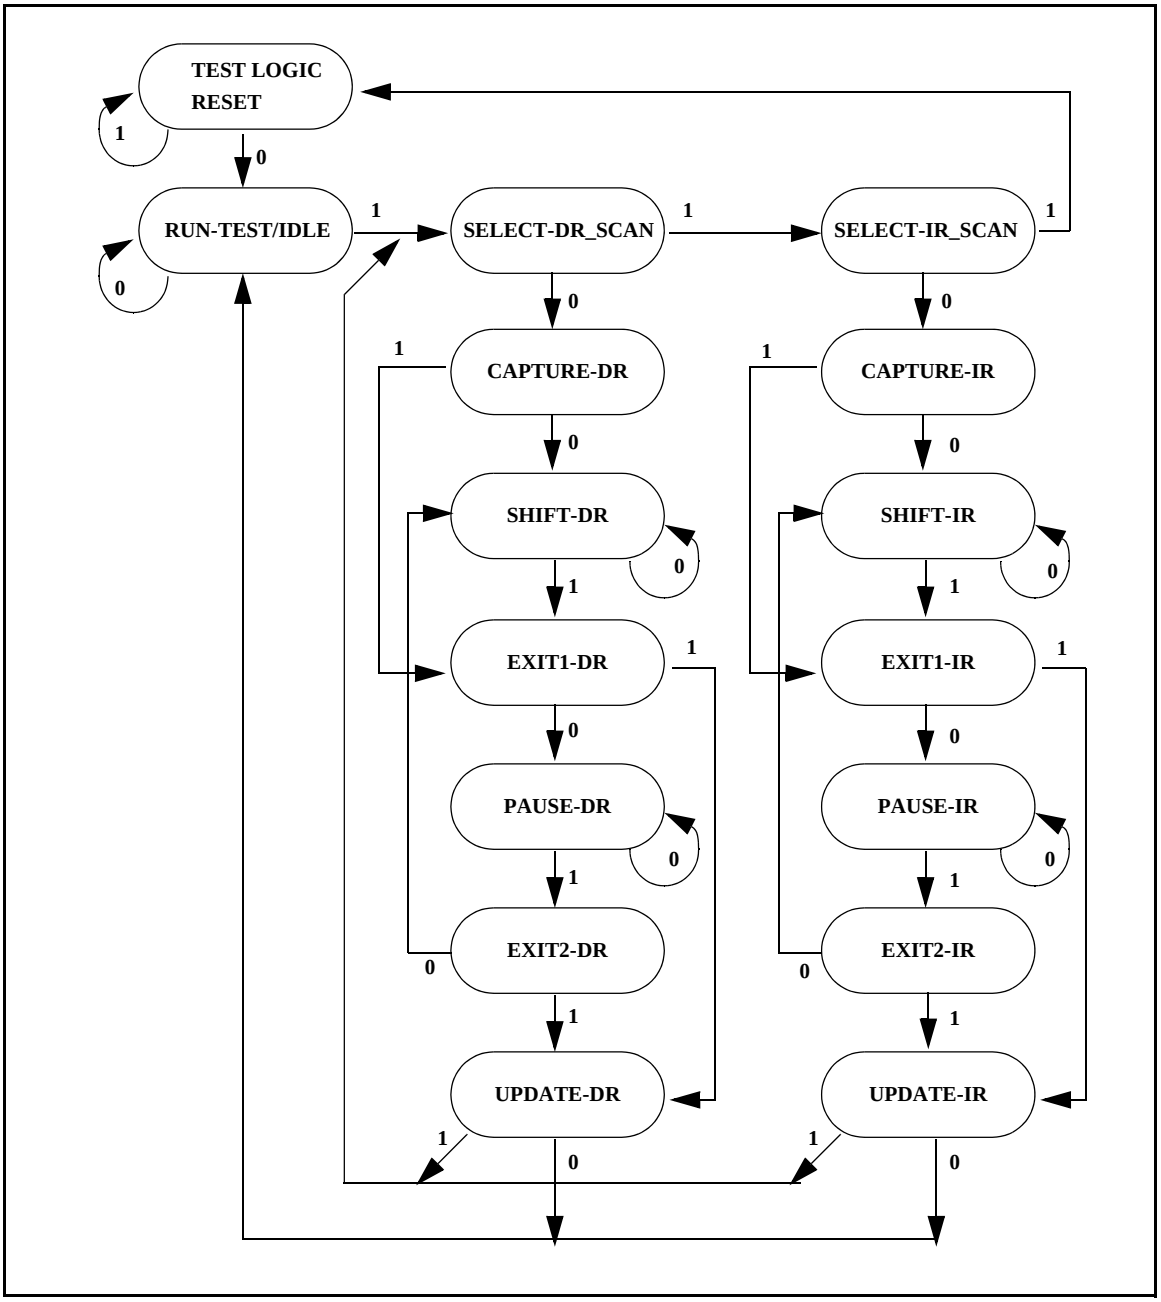

Figure 44-2. TAP Controller State Machine

The change of the JTAG state machine occurs on the rising edge of TCK. TMS and TDI changes on the falling edge of TCK. Also TDO changes on the falling edge of TCK following entry into the Shift_DR or Shift_IR states (TDO_EN is the enable of the tristate buffer driving TDO output).

The Figure 44-3 shows the timings of the SJC signals.

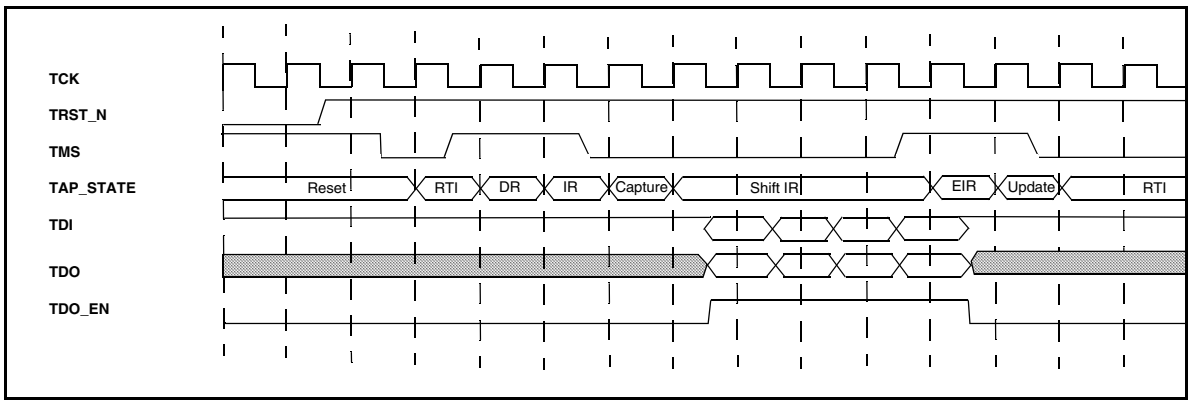

Figure 44-3. SJC Signals Timing Diagram

44.5 SoC JTAG

This section assumes the SoC JTAG is accessed (either in standalone or daisy chained) through appropriate TSB configuration.

44.5.1 Register Summary

Table 44-3 is the JTAG register summary. The registers in Table 44-3 are accessed using the ExtraDebug register. See section Section 44.5.2, “Accessing ExtraDebug Registers,” for more information.

The base address for the addresses in Table 44-3 is necessary for automatic tests generation of the JTAG design. This variable is equal to 0 for the JTAG module.

KEY:

Always Reads One	Always Reads Zero	Read/ Write Bit	Read-Only Bit	Write-Only Bit	Write 1 to Clear	Self-Clear Bit	N/A
1	0	bit	bit	bit	bit	0

44.5.2 Accessing ExtraDebug Registers

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) comprising a 32 bit data field (max length, see ExtraDebug register description), a 5 bit address field and read/write bit. The write actually takes place when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read will take place on the next path through DR at the Capture-DR state, the data will be shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported: command converter software will shift in 0s so the TAP will decode a write to the CSR (read-only register) which won't have any effect on the circuit.

The number of shift depends on the width of the accessed register as explained in the following diagrams.

First a write access (one path through Select-DR-Scan):

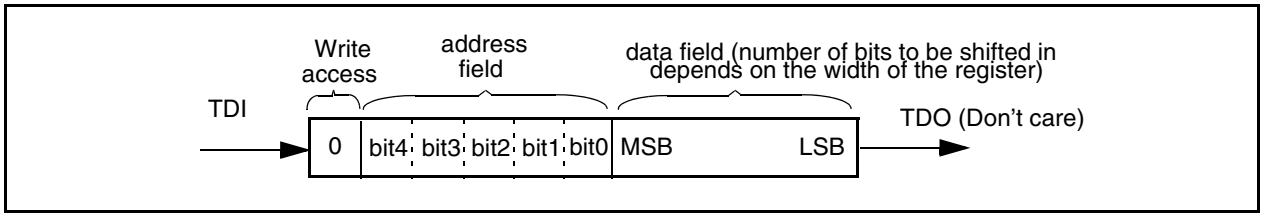

Figure 44-4. TDI/TDO on Write Access

Then a read access (requires two paths through JTAG DR Scan path):

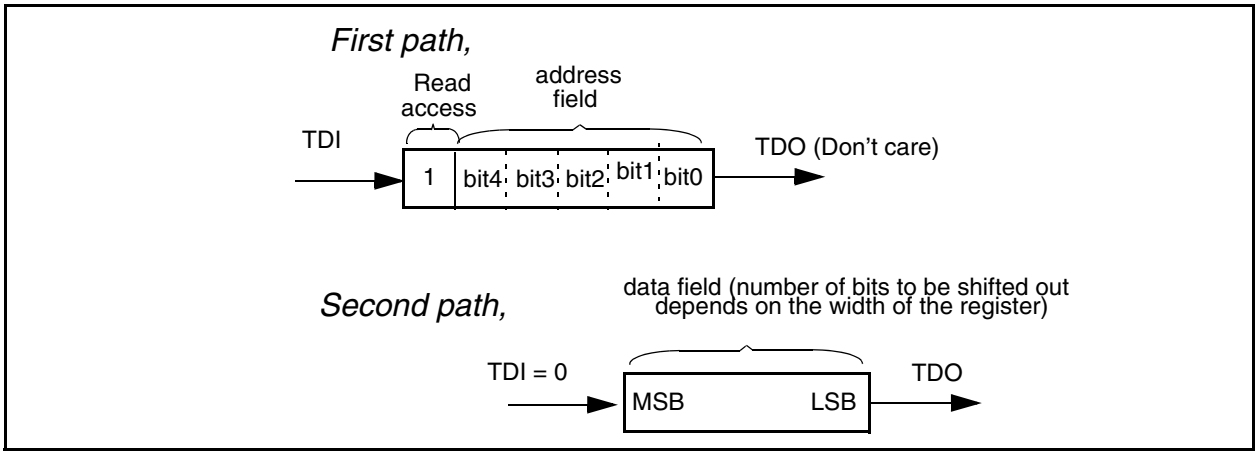

Figure 44-5. TDI/TDO on Read Access

Example: Write value 0b1010_1100 to Debug Control Register (address=0b00110).

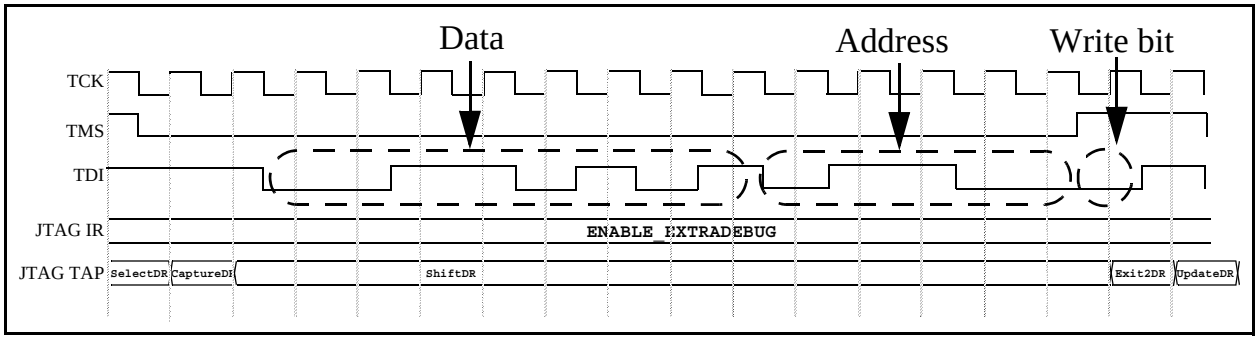

Figure 44-6. Example: Write Access to DCR

The secure JTAG controller registers have different levels of security (see Section 44.6.3, "JTAG Security Modes"):

- **Secured**: accessible only in modes 2 (supposed correct response entered), mode 3 and mode 4.
- **Unsecured** (accessible in all modes)

This information is displayed in the detailed register description below. In the "Note" rows the letter "s" means a secured bit and "u" an unsecured bit.

44.5.2.1 General-Purpose Unsecured Status Register 1 (GPUSR1)

The general-purpose unsecured status register 1 is a read-only register used to check the status of the different cores and of the PLL. The rest of its bits are for general-purpose use.

GPUSR1 — **General Purpose Unsecured Status Register 1** — **Offset 0x0000**

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16

Note:	S	S	S	S	S	S	S	S	S	S	S	S	S	S	S	S

Figure 44-7. Debug Control Register

Table 44-6. Debug Control Register (DCR) Description

Name	Description	Settings
DCR Bits 31-4	Reserved	—
debug_obs Bits 3	**Debug observability —** This bit controls propagation of the system debug signal from Embedded Cross Trigger Block (ECT) to DE_B pin (for example, it can propagate a debug acknowledge signal).	0 - Disable propagation of system debug to DE_B pin 1- Enable propagation of system debug to DE_B pin
DE_to_SDMA Bits 1	**SDMA debug request input propagation —** This bit controls propagation of the debug request to the SDMA.	0 - Disable propagation of debug request to SDMA 1- Enable propagation of debug request to SDMA
DE_to_core] Bits 0	**ARM debug request input propagation —** This bit controls propagation of the debug request to the core.	0 - Disable propagation of debug request to ARM 1- Enable propagation of debug request to ARM

The DE_B pin is dedicated for debug requests (input)/system debug (output), $\overline{DE}$, and bidirectional open drain (including an internal pull-up device).

The main function of the embedded cross trigger (ECT) is to pass debug events from one core to another. For example, the ECT can be programmed to pass debug requests from one IP's debug request to ARM, so that ARM enters debug mode when the debug request is generated. ECT system_debug is connected to the SJC, and can be programmed for observability on the $\overline{DE}$ pin.

Bits 2:0 of the DCR define the propagation of external debug request to each core. Bit 3 controls propagation of the system debug signal from the ECT on $\overline{DE}$.

For security reasons, output and input propagation control bits are cleared after reset, so that a user is not be able to put the cores in debug mode through $\overline{DE}$ without any JTAG access.

According to the values of those bits, the user can:

1. Get the three cores or only two of them to enter debug mode from an external command controller.
2. Acknowledge entrance in debug mode from one core, two cores, or all three cores. Note that if two debug acknowledges arrive at the same time from two different cores, the user may see only see one low pulse on $\overline{DE}$. This has to be defined in the embedded cross trigger integration and programming.

If one core enters debug, it can force the other ones to enter debug also if the I/O connection scheme supports it. A debug acknowledge propagates to the other cores debug request lines. Normally this is handled by the ECT.

The configuration after reset prevents propagation of debug requests/acknowledges to/from the cores.

44.5.2.4 Security Status Register (SSR)

This register is used to reflect IC security status and is accessible in all the security modes. The assumption is that the information contained in this register does not pose any security breach for the system.

SSR	Security Status Register															Offset 0x0005
	BIT 31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16

GPCCR Bits 31-3	General Purpose Clocks Control Register	
SWRES Bit 2	**SW reset**	
ACLKOFFDIS Bit 1	**Disable/prevent ARM clock/power shutdown**	
SCLKR Bit 0	**SDMA Clock ON Register** - This bit will force the clock on of the SDMA	0 - SDMA clock is not forced ON. 1 - Force SDMA clock ON

Bit 0 of GPCCR controls SDMA clocks invocation. When out of reset, the SDMA is in sleep mode with no SDMA clock running. Unlike events, debug requests does not wake SDMA if it is in sleep mode. The debug request is be recognized by the SDMA when it exits sleep mode upon reception of an event. To be able to enter debug mode even if no event is triggered, the SDMA clock on (SCLKR) bit needs to be set to 1 prior to sending the debug request (the bit is cleared at reset).

44.5.2.6 General Purpose Unsecured Control Registers 1–2 (GPUCR1–2)

These registers are used to configure IEEE 1149.1 JTAG for special test or debug modes. These registers are not secured, and are accessible in all JTAG security modes. The bits of these registers are directly connected to SJC outputs.

44.5.2.7 General Purpose Secured Control Register (GPSCR) (Secured)

This register is used to configure IEEE 1149.1 JTAG for special test or debug modes. This register is secured, and only accessible in secure JTAG modes #3, #4 and #2 with response entered. The register bits are directly connected to SJC outputs.

Table 44-11. General Purpose Secured Control Register Description

Name	Description
GPSCR Bits 31-0	**General Purpose Control Register**.

44.5.3 Boundary Scan Register

The boundary scan register (BSR) in the JTAG implementation contains bits for all device signal and clock pins and associated control signals. All SoC bidirectional pins have a single register bit in the boundary scan register for pin data, and are controlled by an associated control bit in the boundary scan register. To obtain a BSDL file, contact Freescale.

44.5.4 SoC JTAG Instruction Register

The SoC JTAG instruction register, shown in Figure 44-10, is 5 bits wide.

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	IDCODE
0	0	0	0	1	SAMPLE/PRELOAD

0	1	1	0	1	Security Enter response
.....					Rsvd.
1	1	1	1	1	BYPASS

Figure 44-10. JTAG Instruction Register

The instruction register is reset to 0b00000 in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01 in the least significant bits as required by the standard, the most significant bits are loaded with the values 00, leading to a capture value of 0b00001.

44.5.4.1 ID_CODE Instruction

Selects the ID register, and the system logic controls the I/O pins. This instruction is provided as a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP. The following table shows the ID register configuration.

IDCODE				ID Configuration Register												
	BIT 31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16

Name	Description	Settings
Version Information Bits 31-28	Version information number - This number is incremented for each metal fix of the IC.	Bits [31:28] - 0000 (for initial SoC, 0001 for first metal fix, etc. See “System Integration” chapter for details on specific SOC.
Customer Part Number Bits 27-12	**Customer Part Number —** The Customer Part Number consists of two parts: Bits [27-22] - Freescale Design Center Number Bits [21:12] - A sequence number divided into two parts: Bits [21-17] - Core Number (SoC project) Bits [16-12] - Chip Derivative Number	See “System Integration” chapter for details on specific SOC. (for zzzzzz, yyyyy,x defaults).
Manufacturer Identity Bits 11-1	**Manufacturer Identity —** Freescale’s Manufacturer Identity code.	Bits [11:1] - 00000001110
Bit 0	Tied to logic 1.	1

NOTE

The IDCODE value is programmed by SOC integration of the SJC module.

One application of the ID register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. As more components emerge which conform to the IEEE 1149.1 standard, it is desirable to allow for a system diagnostic controller unit to blindly interrogate a board design in order to determine the type of each component in each location. This information is also available for factory process monitoring and for failure mode analysis of assembled boards.

Once the IDCODE instruction is decoded, it will select the ID register which is a 32 Bit data register. Since the bypass register loads a logic 0 at the start of a scan cycle, whereas the ID register loads a logic 1 into its least significant bit, examination of the first bit of data shifted out of a component during a test data scan sequence immediate following exit from Test-Logic-Reset controller state will show whether such a register is included in the design. When the IDCODE instruction is selected, the operation of the test logic has no effect on the operation of the on-chip system logic as required by the IEEE 1149.1 standard.

44.5.4.2 SAMPLE/PRELOAD Instruction

Selects the boundary scan register and the system logic controls the I/O pins. The SAMPLE/PRELOAD instruction provides two separate functions:

1. First, it provides a means to obtain a snapshot of system data and control signals. The snapshot occurs on the rising edge of TCK in the capture-DR controller state. The data can be observed by shifting it transparently through the boundary scan register.
2. The second function of SAMPLE/PRELOAD is to initialize the boundary scan register output cells prior to selection of EXTEST. This initialization ensures that known data will appear on the outputs when entering the EXTEST instruction.

NOTE

Because there is no internal synchronization between the JTAG clock (TCK) and the system clock (CLK), the user must provide some form of external synchronization to achieve meaningful results.

For more details on the function and use of SAMPLE/PRELOAD, see the IEEE Std. 1149.1™ specification.

44.5.4.3 EXTEST Instruction

Selects the boundary scan register, and the 1149.1 test logic has control of the I/O pins.

By using the TAP controller, the register is capable of:

1. Scanning user-defined values into the output buffers,
2. Capturing values presented to input pins
3. Controlling the direction of bidirectional pins,
4. Controlling the output drive of tri-statable output pins.

For more details on the function and use of EXTEST, see IEEE 1149.1.

The EXTEST instruction also asserts internal reset for the cores to force a predictable internal state while performing external boundary scan operations.

44.5.4.4 HIGHZ Instruction

All output drivers, including the two-state drivers, are turned off (i.e., high impedance). The instruction selects the bypass register. In this mode, all internal pull-up resistors on all the pins (except for the TMS TDI TCK $\overline{\text{TRST}}$ pins) will be disabled. This “disabling” functionality is not built into SJC, but should be implemented by some logic in the SOC/IO Pads.

For more details on the function and use of HIGHZ, see IEEE 1149.1.

The HIGHZ instruction also asserts internal reset for the cores to force a predictable internal state while performing external boundary scan operations.

44.5.4.5 BYPASS Instruction

Selects the single Bit bypass register and the system logic controls the I/O pins. This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register. This instruction is used to enhance test efficiency when a component other than the SoC Core based device becomes the device under test.

When the bypass register is selected by the current instruction, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register will always be a logic zero.

For more details on the function and use of BYPASS, see IEEE 1149.1.

44.5.4.6 ENABLE_ExtraDebug Instruction

The TDI and TDO pins are connected directly to the ExtraDebug registers, the secure JTAG controller TAP controller remaining connected to TDI and TMS. The ExtraDebug shift register consists of 38 bits (maximum) comprising a 32 bits data field (maximum length, see 44.5.2, "Accessing ExtraDebug Registers"), a 5 bits address field and read/write bit. On a register read, the data field doesn't need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug Address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

44.5.4.7 ENTER_DEBUG Instruction

Generates a debug request to the three cores "simultaneously" (or "Pseudo simultaneously" as the Cores run at different frequencies), the TDI and TDO are connected to the Instruction Register. After the acknowledgment of the Debug Mode is received (can be checked by reading the Core Status Register part of the ExtraDebug logic), the user can perform system debug functions on the three Cores.

NOTE

In case the user needs only one of the cores in Debug Mode, he should not issue the ENTER_DEBUG instruction but rather access the preferred core and issue a debug request only to this core.

The user need to be careful to shift another IR value (like IDCODE) before trying to get the Cores out of debug as the debug request signals to the Cores stay asserted until IR is no longer equals to ENTER_DEBUG.

The user need to check that cores are in debug mode (watching debug acknowledge signal) before leaving ENTER_DEBUG instruction, otherwise debug request might not have been seen by the core.

44.5.4.8 Serial Access Instruction - Reserved for Test

This instruction is not intended for Customer use, reserved for manufacturing test (allow to access to SOC modules serially through TDI/TDO (shift DR)).

44.5.4.9 TAP Select Instruction

By means of “TAP select” instruction a user can access TAP select register and by controlling its only bit “SDMA Bypass”, control whether SDMA TAP will be bypassed or not.

TAP select Register

	BIT 0
	Connect SDMA
TYPE	rw
RESET	0
Note:	

Table 44-13. TAP select Register Description

Name	Description	Settings
SDMA Bypass Bits 0	Connect SDMA — control whether SDMA TAP will be bypassed or not.	• When negated (should be the default state), SDMA TAP is bypassed with a single D-FF. • When asserted SDMA TAP is connected inside the chain.

44.6 Security

44.6.1 Introduction

JTAG manipulation is one of the known hackers’ ways of executing unauthorized program code, getting control over the OS and run code in privileged modes.

The SJC provides debug access to several hardware blocks, including the ARM processor and the system bus. This allows for program control and manipulation as well as visibility into system peripherals and memory. The ETM and NEXUS interfaces allow bus transactions to be traced. Together these tools provide the hacker all the access needed to completely comprise the system. Means must be provided to block any malicious JTAG access.

The SJC provides a way of regulating the JTAG access.

There are four different JTAG security modes:

- Mode #1: No Debug - Maximum Security. All security sensitive JTAG features are permanently blocked.
- Mode #2: Secure JTAG - High security. JTAG use is regulated by secret key based authentication mechanism.
- Mode #3: JTAG Enabled - Low security. JTAG always enabled.

- Mode #4: SCC JTAG - No Security. The SCC forced to remain in its secure state during JTAG operation.Parts in this mode are to be used only under tight control, for secure operation debug.

The JTAG security modes are configured using fuses. There are two kinds of fuses: eFuse and laser fuse. Laser fuses can be burned only before chip packaging while eFuses can be burned after packaging, just by applying electrical signals.

NOTE

Fuse burning is an irreversible process. Once the fuse is burned (eFuse or laser fuse), it is impossible to change the fuse back to the un-burned state.

44.6.2 Fuses Programming

44.6.2.1 Laser Fuses Technology

When laser fuses technology is used the sought fuses configuration is obtained at fabrication stage and cannot be changed later.

44.6.2.2 Electric Fuses (eFuse) Technology

For eFuse technology and programing description, see the IC Identification Module (IIM) block guide.

44.6.3 JTAG Security Modes

JTAG can be in one of four JTAG security modes. The specific security mode is determined by the SJC fuses configuration[1].

44.6.3.1 Mode #1: No Debug - Maximum Security

“No Debug” JTAG security mode provides the highest security level. In this mode, all JTAG features are disabled except for:

- Scan.
- Boundary Scan.
- MBIST, all modes except for debug modes which enable controlled memory contents output.
- PLL BIST.
- BIST monitor mode[2].
- PLL bypass[3]
- Visibility of the following status bits: power mode - normal, standby, stop, shutdown, etc.

These features do not reduce the security level of the product, and they allows to perform important tests and board connectivity checks.

1. Physical location of the fuses is not in the SJC.
2. Allowing routing to external pins BIST pass/fail/invoke information
3. Bypass ARM or/and USB PLL.

NOTE

If external boot is done (enabled by a corresponding fuse and requested) then it is possible to use all JTAG features even if “No Debug” JTAG security mode is chosen, as described in Chapter 44.6.7, “External Boot Fuse”

44.6.3.2 Mode #2: Secure JTAG - High Security

The Secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is being checked. Only authorized debug devices (i.e. devices having the right response) will be able to access the JTAG, unauthorized JTAG access attempts will be denied. The intent of this mode is to allow “return field” testing. When a secured JTAG device is being returned for debugging, this mode will allow authorized re-activation of the JTAG.

44.6.3.2.1 Challenge/Response Mechanism in Secure JTAG Mode

When SJC is in Secure JTAG mode the authentication process is as follows:

- Shift “Output Challenge” instruction to IR.
- Passing through “Capture-DR” state of System JTAG Controller and by performing Shift-DR operations Challenge code can be accessed from TDO.
- Shift “Enter Response” instruction to IR. By performing Shift-DR operations enter Response code value through TDI. At Update-DR state entered Response code will be compared with the correct one.

There are two modes that SJC supports for generating the challenge - response pair:

1. Fixed challenge—response pair. Each part has its individual challenge - response pair which is determined at manufacturing time, and will not change later on. The SJC will compare the user’s response to the expected response.

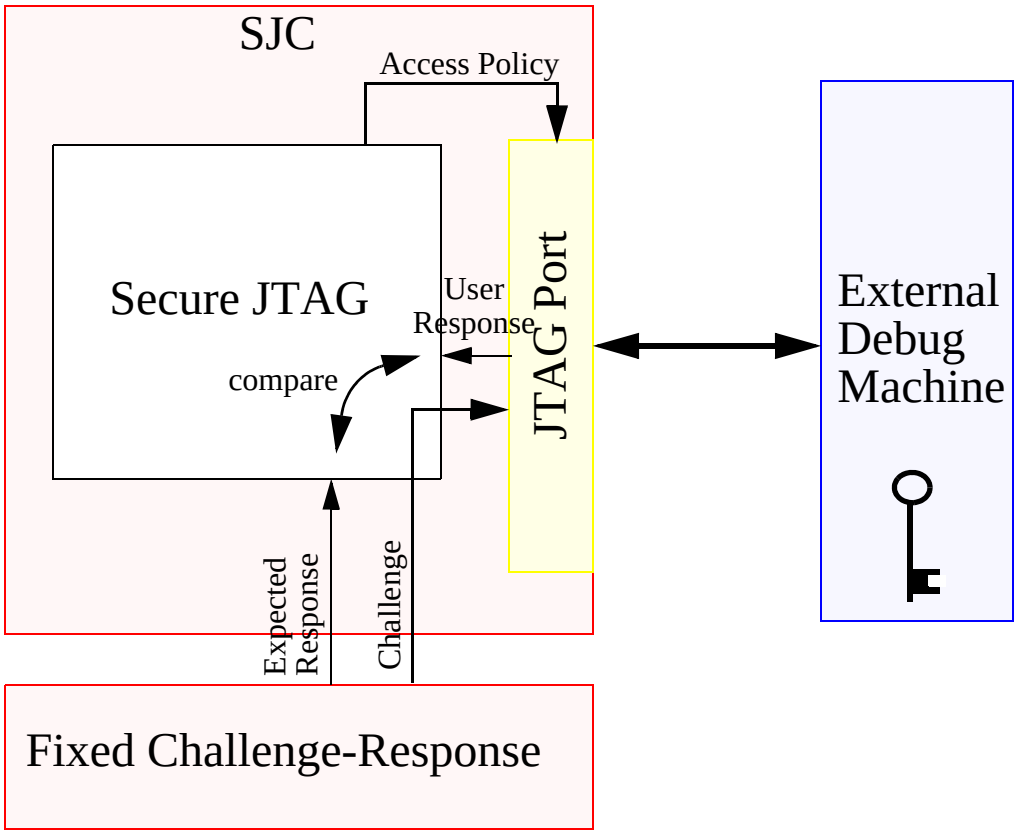

Figure 44-12. Mode #2 - Secure JTAG with Fixed Challenge-Response Pair

2. Random challenge - response pair. In this mode, a random challenge will be generated by a separate module, and the response will be checked inside this challenge-response module, too.

The SJC module can be configured to either mode via the ext_check_select input signal, depending on the alternative that is implemented for a chip.

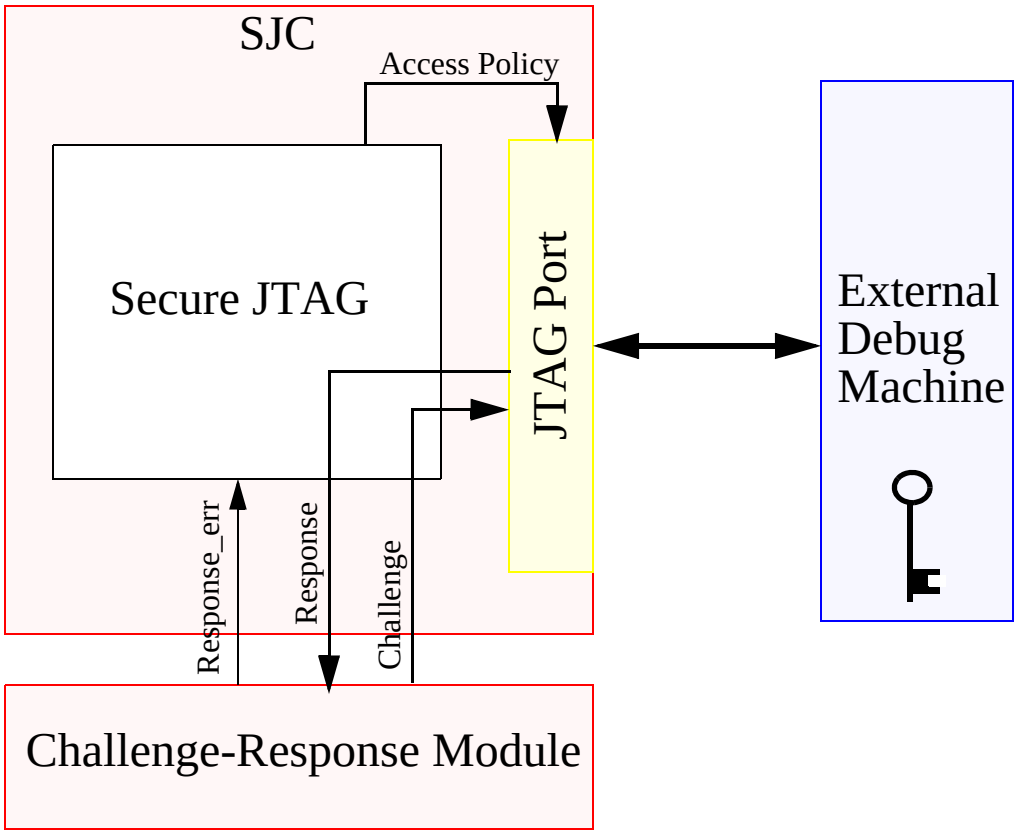

Figure 44-13. Mode #2 - Secure JTAG with Random Challenge-Response

44.6.3.3 Mode #3: JTAG Enabled - Low Security

In the “JTAG Enabled” JTAG security mode, all JTAG features are enabled.

44.6.3.4 Mode #4: SCC JTAG - No Security

In all JTAG secure modes but Mode #4 (SCC JTAG) the Secure monitor of the SCC will transit into non-secure or failure state whenever JTAG is activated (assert of jtag_active signal). This security feature reduces the SCC debug capabilities. In order to debug the SCC, it should remain in secure state even when JTAG is activated. When Mode #4 is configured, the SCC will be forced to remain in its secure state during JTAG operation. This, of course, eliminates all security abilities of the SCC.

44.6.4 Bypass Secure JTAG

By burning a specific fuse it is possible to bypass the “Secure JTAG” mode, i.e. to change a device state from “Secure JTAG” mode (#2) to “JTAG enabled” mode (#3). In all other security modes (#1, #3, and #4), this “bypass secure JTAG” eFuse has no effect.

This fuse allows to permanently open up the JTAG access for field return parts, without the need to pass via the challenge-response mechanism after each reset, or use software enabling on JTAG. If the part should go back into the field, a second fuse, “re-enable secure JTAG”, can be burned, and the device is reverted back to “secure JTAG” mode (#2). This “re-enable secure JTAG” fuse can also be used to disable the “bypass secure JTAG” feature, in case this might pose a security risk.

The “bypass secure JTAG” fuse poses a potential security risk, and burning this fuse is thus strongly restricted:

- Burning is not possible via external pins.
- Burning is only possible, after successfully passing the challenge-response test, even in the case of an external boot. This is true independent of whether the burning is initiated via software, or via JTAG/ICE.

The “re-enable secure JTAG” fuse can be burned without any security restrictions, as it never lowers the security level.

44.6.5 Software-Enabled JTAG

To increase the flexibility of the SJC, an option to enable the JTAG via software is added and is available only in Secure JTAG mode. This feature can be permanently blocked by burning the dedicated eFuse. By writing to SW_*JTAG_EN* bit in the system control module (IIM), the JTAG will be opened, regardless of its security mode. It is the responsibility of the HAB (High Assurance Boot) software to assert or negate this bit. The *JTAG_SW_LOCK* bit of the system control (IIM) makes sure that only the HAB will be able to set the SW_*JTAG_EN* bit. When *JTAG_SW_LOCK* sets, no future change of SW_*JTAG_EN* is possible, unless after asserting POR (power-on-reset). The HAB sets the *JTAG_SW_LOCK* bit before transferring control to the application code. It is also automatically set whenever the device transitions into a non-secure state. Through this means, the HAB ensures that only it may modify SW_*JTAG_EN*. The *JTAG_SW_LOCK* is write only, and sticky bit. It can only be cleared through POR.

The S/W JTAG enable allows JTAG enabling without activating the challenge-Response mechanism (which requires JTAG access tool enhancement or special H/W). The JTAG S/W enable doesn’t allow debug in case of boot or memory fault as it requires reset before entering debug.

NOTE

The S/W enabled JTAG feature reduces the overall security level of the system as it relies on S/W protections. If this feature is not required, it is strongly recommended to burn a dedicated eFuse which disables this feature.

44.6.6 ETM Kill Trace

The kill trace signal disables any output from the ETM module. The ETM can be accessed via JTAG port and by direct software address. When JTAG port access is blocked the kill trace signal is active, and the trace module’s output is blocked. This action is intended to block any attempt to break into the system via ETM software configuration. When active, the kill trace signal prevents trace output even in case where it can be activated via chip pin.

The “kill trace” feature needs to be activated by burning a dedicated eFuse. If the fuse is left intact, “kill trace” will never be activated as seen in Figure 44-14.

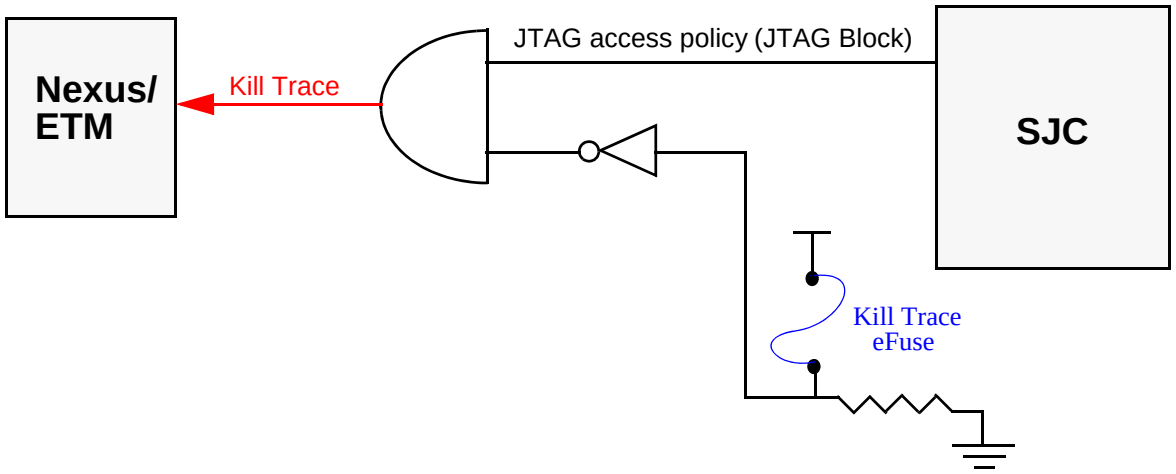

Figure 44-14. Kill Trace eFuse

The kill trace signal is asserted when the ipt_enable_kill_trace_fuse is burned and the ipt_secur_block signal in SJC is asserted, which in turn occurs when at least one of the following is true:

- “iim_fuses_latched” signal come from IIM to Secure JTAG is not asserted which tells that Secure JTAG can’t consider fuses values to be valid
- Mode #2 (Secure JTAG) and no code has been entered
- Mode #2 (Secure JTAG) with burned “Bypass” and “Re-enable” fuses
- Mode #2 (Secure JTAG) with incorrect response entered
- Mode #1 (No debug)
- “trst_b” signal is active
- POR has not ever been asserted

44.6.7 External Boot Fuse

External boot can be a security hazard. Using external boot, it is possible to run any code without having it passes the authentication checks. However, sometimes, external boot is required in debug processes. The purpose of the external boot eFuse is to disable the external boot feature. When burned (intact if laser fuse is used instead of eFuse), no external boot is possible. If external boot enabled (by the fuse, and configured via boot mode pins, all JTAG features are enabled for all JTAG security modes.

44.7 Functional Description

44.7.1 Cores Static Debug

The SJC interfaces with cores on the same die: an ARM core with ETM real-time trace interface, and an SDMA RISC machine.

A SoC JTAG TAP controller fully compatible with the IEEE1149.1a-2001 IEEE Standard Test Access Port and Boundary Scan Architecture specification is implemented at the top level.

The core has an integrated JTAG interface and a TAP controller to manage its own ICE. Also it can access an embedded trace ETM interface, see ARM core and ETM Technical reference guide for more information.

The SDMA has a TAP controller to manage its own OnCE but is a JTAG free core, see SDMA OnCE specification for more information.

While the JTAG port provides board test capability, the OnCE and ICE ports provide emulation and debug capability to the user. The JTAG port conforms to the IEEE1149.1a-2001 IEEE Standard Test Access Port and Boundary Scan Architecture specification defined by the Join Test Action Group (JTAG). The TAP (test access port) uses a boundary scan technique to test the interconnections between integrated circuits after they are assembled onto a printed circuit board. Boundary scan allows a tester to observe and control signal levels at each component pin through a shift register placed next to each pin. This is important for testing continuity and determining if pins are stuck at a one or zero level.

The OnCE and ICE provide a mean of interacting with the cores and their peripherals non-intrusively so that a user may examine registers, memories to facilitate hardware and software development.

44.7.2 Reset Mechanism

In real applications, initialization is performed by the analog internal POR. On the tester, initialization is performed through $\overline{\text{TRST}}$ and RESET_IN.

NOTE

- Asserting $\overline{\text{TRST}}$ in any scan mode will reset the TCR. The test mode configuration is lost, and the default TAP is selected.
- The SMC generates an IEEE reset signal to the CCM when in one of the IEEE modes HIGHZ or EXTEST. This signal generate a system reset to the cores until exit from one of these modes.
- The TAP Selection Block generates Once/ICE reset (either $\overline{\text{TRST}}$ if implemented or other) when its TAP state reaches Test-Logic-Reset (meaning that TAP accessed has also reached Test-Logic-Reset).
- When the secure JTAG controller is in scan mode, reset lines are controlled from RESET_IN for manufacturing test purposes.

44.8 Initialization/Application Information

WARNING

The control afforded by the output enable signals using the boundary scan register and the EXTEST instruction requires a compatible circuit-board test environment to avoid configurations that are destructive to the device. The user is responsible to avoid situations in which the secure JTAG controller output drivers are enabled into actively driven networks.

There are two constraints related to the JTAG interface:

- Ensure that the JTAG test logic is kept transparent to the system logic by forcing TAP into the Test-Logic-Reset controller state. During power-up, SJC's internal TRST is asserted as IC's POR is asserted, which forces the TAP controller into this state. After that, if TMS either remains unconnected or is connected to VCC, then the TAP controller cannot leave the Test-Logic-Reset state, regardless of the state of TCK.
- DE_B is an IO pin with pullup, and care must be taken with the direction when driving this signal.

Chapter 45
Shared Peripheral Bus Arbiter (SPBA)

45.1 Introduction

The shared peripheral bus arbiter (SPBA) is a three-to-one IP line interface (IP-Bus) arbiter, with a resource locking mechanism. The masters can access up-to thirty one shared peripherals through the SPBA.

Figure 45-1 shows the SPBA block diagram and details of the out-of-band signals routing.

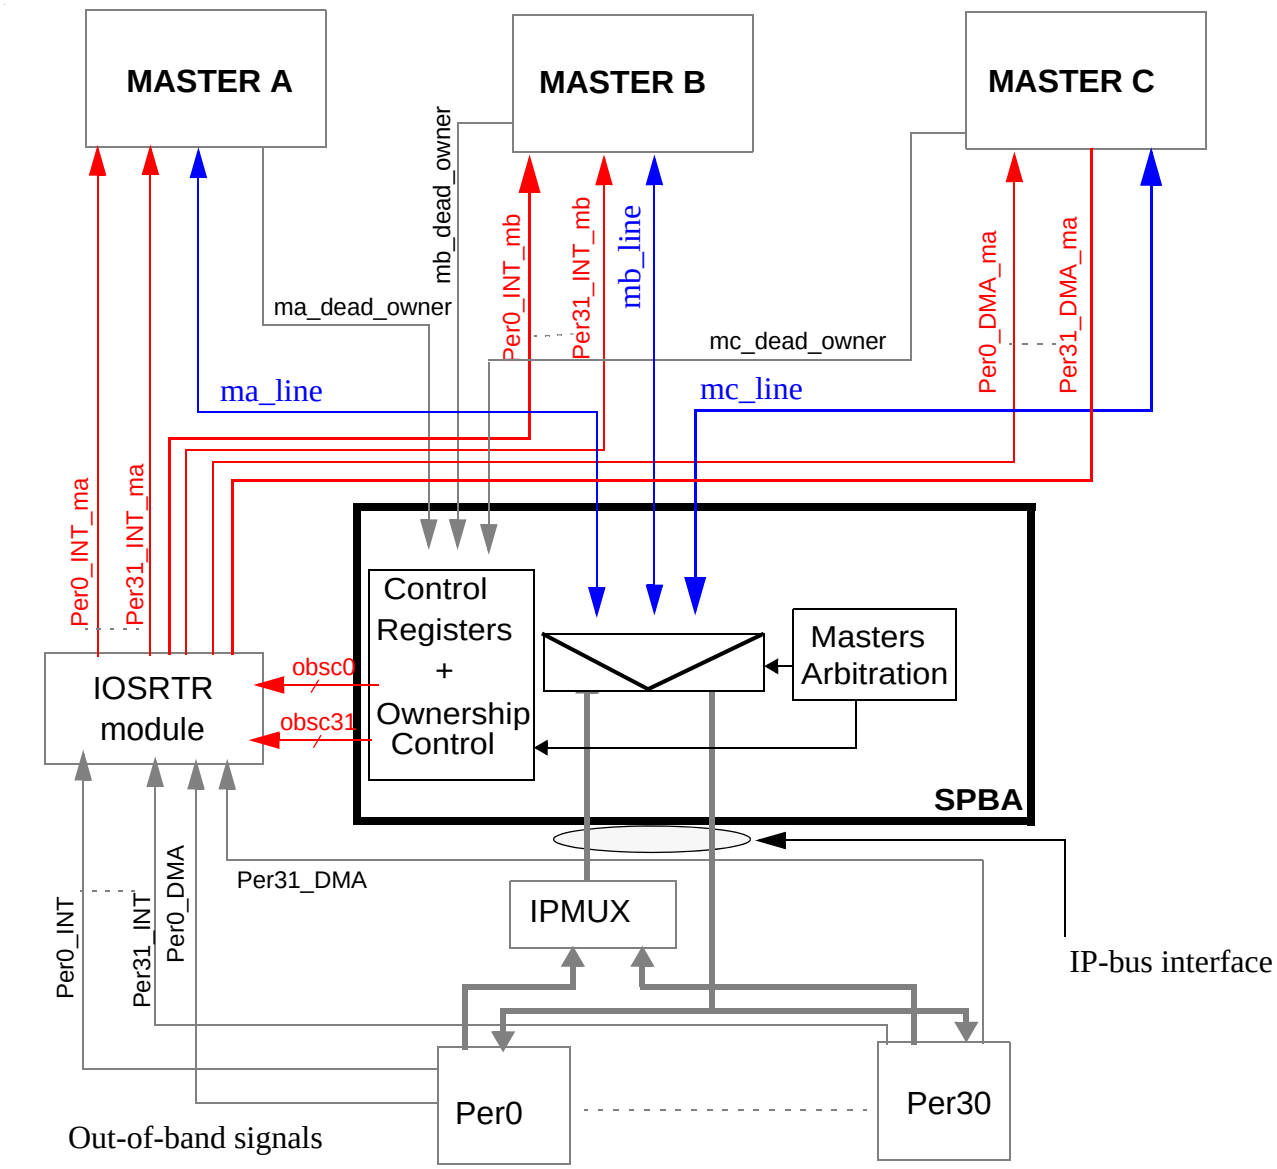

Figure 45-1. SPBA Block Diagram

45.2 Overview

The shared peripheral bus arbiter (SPBA) is a three-to-one IP interface (IP-Bus) arbiter. Three masters arbitrate for shared peripherals access through the SPBA.

The SPBA functions include the following:

- The IP bus line switches a master to one peripheral.
- The Masters arbiter arbitrates between the three masters to solve concurrent access or restricted access to peripherals.
- The Control Registers and Ownership Control, including a set of registers that are reachable through software, permits the access scheme definition to each peripheral (Resource Ownership and Access Control).

The SPBA generates signals usable for the external steering logic of interrupts and DMA signals.

45.3 Features

The SPBA includes the following features:

- Three IP bus masters arbitration, master A, master B and master C,
- Support for DMA masters.
- 32 bits data,
- Supports up to 31 shared peripherals, each consuming 16 Kilobytes of address space,
- SPBA can be considered as the 32th peripheral, used for resource ownership and access control mechanism to the 31 peripherals,
- Provides 31 sets of Out of Band Steering Control (obsc) signals to the off-module steering logic,
- Operating frequency up to 67 MHz,
- clocks: ipg_clk, ipg_clk_s.

45.4 Modes of Operation

SPBA behavior is transparent when accessing a peripheral, and it can distinguish different modes of operation:

- **Reset/Abort:**

  The SPBA has a hardware reset which initialize all registers, arbitration and PRR (peripherals rights registers).

  Additionally, an abort signal input is provided allowing each master to abort their current access and release their ownership (in case of master reset sequence,...).
- **Functional:**

  Once a master request is granted, its IP-Bus signals are steering to the requested peripheral.
- **Standby:**

  No clock needed. The SPBA needs clocks only during: access to the PRRs, arbitration and abort phases. It generates two clock enable signals indicating when the clocks must be provided.
- **Configuration:**

  This is the phase where a master is accessing the SPBA PRRs. Indeed, SPBA memory mapped registers are seen as a shared peripheral.

45.5 Memory Map/Register Definition

The following section describes the memory maps and detailed descriptions of all registers which are accessible to the end user within and through SPBA.

45.5.1 Memory Map

From a master side, the absolute address of one peripheral memory map registers is accessible by setting the **<master>_ips_addr[24:0]**:

- **<master>_ips_addr[24:19]** to the SPBA master base address (defined by top level parameters SPBA_<MASTER>_BASE_ADDR),
- **<master>_ips_addr[18:14]** to one of the 32 IPS peripherals (including SPBA). See Table 45-2.
- **<master>_ips_addr[13:0]** to one of the 16-Kbyte memory-mapped registers (16 Kbytes only if accessing to a shared peripheral, not the same for SPBA PRR access)

Table 45-2 describes the absolute memory mapped address range for each IPS peripheral accessible through the SPBA for one master. (This does not include the **<master>_ips_addr[24:19]** bits.)

Table 45-2. Peripherals Absolute Address

Peripheral	<master>_ips_addr[18:0] Start Address	<master>_ips_addr[18:0] End Address [1]
Peripheral 0	{5'b0_0000, 14'b00_0000_0000_0000}	{5'b0_0000, 14'b11_1111_1111_1111}
Peripheral 1	{5'b0_0001, 14'b00_0000_0000_0000}	{5'b0_0001, 14'b11_1111_1111_1111}
Peripheral 2	{5'b0_0010, 14'b00_0000_0000_0000}	{5'b0_0010, 14'b11_1111_1111_1111}
Peripheral 3	{5'b0_0011, 14'b00_0000_0000_0000}	{5'b0_0011, 14'b11_1111_1111_1111}
Peripheral 4	{5'b0_0100, 14'b00_0000_0000_0000}	{5'b0_0100, 14'b11_1111_1111_1111}
Peripheral 5	{5'b0_0101, 14'b00_0000_0000_0000}	{5'b0_0101, 14'b11_1111_1111_1111}
Peripheral 6	{5'b0_0110, 14'b00_0000_0000_0000}	{5'b0_0110, 14'b11_1111_1111_1111}
Peripheral 7	{5'b0_0111, 14'b00_0000_0000_0000}	{5'b0_0111, 14'b11_1111_1111_1111}
Peripheral 8	{5'b0_1000, 14'b00_0000_0000_0000}	{5'b0_1000, 14'b11_1111_1111_1111}
Peripheral 9	{5'b0_1001, 14'b00_0000_0000_0000}	{5'b0_1001, 14'b11_1111_1111_1111}
Peripheral 10	{5'b0_1010, 14'b00_0000_0000_0000}	{5'b0_1010, 14'b11_1111_1111_1111}
Peripheral 11	{5'b0_1011, 14'b00_0000_0000_0000}	{5'b0_1011, 14'b11_1111_1111_1111}
Peripheral 12	{5'b0_1100, 14'b00_0000_0000_0000}	{5'b0_1100, 14'b11_1111_1111_1111}
Peripheral 13	{5'b0_1101, 14'b00_0000_0000_0000}	{5'b0_1101, 14'b11_1111_1111_1111}
Peripheral 14	{5'b0_1110, 14'b00_0000_0000_0000}	{5'b0_1110, 14'b11_1111_1111_1111}
Peripheral 15	{5'b0_1111, 14'b00_0000_0000_0000}	{5'b0_1111, 14'b11_1111_1111_1111}
Peripheral 16	{5'b1_0000, 14'b00_0000_0000_0000}	{5'b1_0000, 14'b11_1111_1111_1111}
Peripheral 17	{5'b1_0001, 14'b00_0000_0000_0000}	{5'b1_0001, 14'b11_1111_1111_1111}
Peripheral 18	{5'b1_0010, 14'b00_0000_0000_0000}	{5'b1_0010, 14'b11_1111_1111_1111}
Peripheral 19	{5'b1_0011, 14'b00_0000_0000_0000}	{5'b1_0011, 14'b11_1111_1111_1111}
Peripheral 20	{5'b1_0100, 14'b00_0000_0000_0000}	{5'b1_0100, 14'b11_1111_1111_1111}
Peripheral 21	{5'b1_0101, 14'b00_0000_0000_0000}	{5'b1_0101, 14'b11_1111_1111_1111}

Peripheral 31	{5'b1_1111, 14'b00_0000_0000_0000}	{5'b1_1111, 14'b11_1111_1111_1111}

[1] One of these peripherals must be defined as the SPBA. The end address range given is not valid for SPBA internal registers. If **<master>_ips_addr[13:0]** is greater than the last PRR location, the SPBA returns a transfer error to the master (see Table 45-4).

45.5.2 SPBA Register Definition

The SPBA control registers (a.k.a Peripheral Right Registers) are mapped as a virtual shared peripheral using by default the **sips_module_en[15]** (or another one using verilog parameter during integration phase) which must not be used for shared IPs.

SPBA can support up to 31 shared peripherals. Each of them has its own Peripheral Right Register (PRR) accessible within the SPBA memory mapped registers, and consists of the **Requesting Master Owner**, the **Resource Owner ID** and the **Resource Access Right** fields (using verilog parameters it can be defined which peripheral is present or not, and so if the corresponding PRR exists or not).

Table 45-3. SPBA PRR Register Summary

Name		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRRn[1] address = ($BASE[2] + n*4)	R	RMOn														ROIn	
	W																
	R														RARn		
	W																

[1] For n=0 to 31

[2] $BASE = {6'bSPBA_<MASTER>_BASE_ADDR, 5'bx_xxxx, 14'b00_0000_0000_0000}, where 5'bx_xxxx are <master>_ips_addr[18:14] reserved for SPBA registers access.

Table 45-4 details the value of **<master>_ips_addr[13:0]** for master access any of the shared PRR.

Table 45-4. PRR Addresses

Peripheral Rights Registers (SPBA Control Registers)	<master>_ips_addr[13:0] [1]	Comment

[1]for n=0 to 31
[2]$BASE = {6'bSPBA_M**X**_BASE_ADDR, 5'bx_xxxx, 14'b00_0000_0000_0000}, where 5'bx_xxxx are the bit [18:14] of master address bus reserved for SPBA access

Figure 45-2. Peripheral Right Register Diagram

RMOn[1:0] — Requesting Master Owner

This 2-bit register field indicates if the corresponding resource is owned by the requesting master or not. This register is reset to 2'b0 if ROI[1:0] = 2'b0.

Table 45-5. RMOn Values

Value	Meaning
00	resource un-owned
10	resource owned by another master
11	resource owned by requesting master

ROIn[1:0] — Resource Owner ID

This 2-bits register field indicates which master (one at a time) can access to the PRR for rights modification. This is a Read-Only register.

Table 45-6. ROIn Values

Value	Meaning
00	un-owned resource
01	resource owned by master A port

Table 45-6. ROIn Values (Continued)

Value	Meaning
10	resource owned by master B port
11	resource owned by master C port

After reset, ROI bits are cleared (“00” -> un-owned resource).
A master performing a write access to the an un-owned PRR will get its ID automatically written into ROI, while modifying RAR bits.
It can then read back the RMO, RAR, ROI bits to make sure RMO returns the right value, ROI bits contain its ID and RAR bits are correctly asserted.
Then no other master (whom ID is different from the one stored in ROI) will be able to modify RAR fields.
Owner master of a peripheral can assert its dead_owner signal, or write 3’b0 in the RAR to release the ownership (ROI[1:0] reset to 2’b0).

RARn[2:0] — Resource Access Right

This 3-bit register field indicates which master can access to the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).

RARn[0] — Control and Status bit for master A which is connected to port MA,
1 = access to peripheral is granted.
0 = access to peripheral is not allowed.

RARn[1] — Control and Status bit for master B which is connected to port MB,
1 = access to peripheral is granted.
0 = access to peripheral is not allowed.

RARn[2] — Control and Status bit for master C which is connected to port MC,
1 = access to peripheral is granted.
0 = access to peripheral is not allowed.

After reset all RAR registers are set to value 1. So by default all masters have access granted to all the shared peripherals. This is verified until one master modify this default value.

45.7 Functional Description

The following section intends to describe the main features of the SPBA module.

45.7.1 Masters Arbitration

The arbitration mechanism determines which port will control the master port, based on a simple round-robin arbitration scheme.

We can distinguish between different cases:

- Only one master request per different access. So the master is switched to the shared peripheral bus, without arbitration. Figure 45-3 shows the MB request on the global module enable signal, served without wait state.
- If two masters simultaneously access to SPBA, then the last granted master is held-off, using **<master>_ips_xfr_wait** output signal (default value is high). When the master is granted **sips_xfr_wait** from shared IPS peripheral is connected to <master>_ips_xfr_wait outputs.
- If three masters simultaneously access to SPBA, then the last two granted masters are held-off, using their <master>_ips_xfr_wait signal. Figure 45-4 shows the case when the last two accesses granted are MA then MB, and how the requests are used even if they are in the same cycle.
- After reset, at the first multiple access, no master has been granted, thus, the priority is static: Master A (MA), Master B (MB) and last Master C (MC) port.
- No master request. No more master switch to shared peripherals.

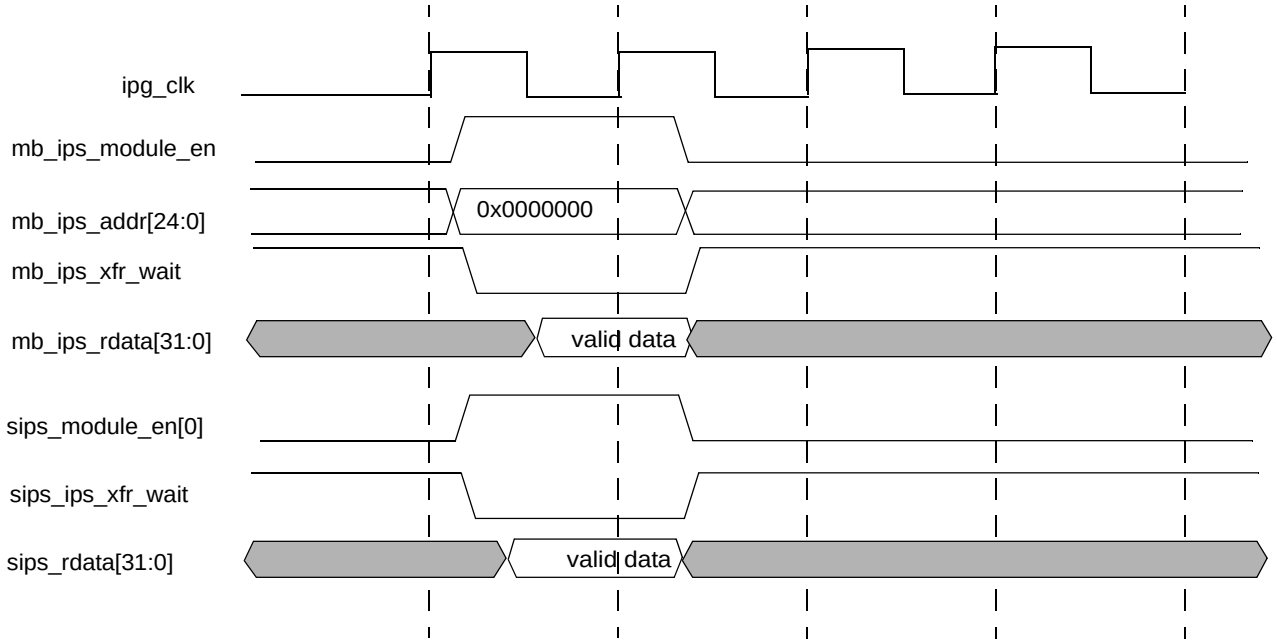

Figure 45-3. Example of One Master Request: No SPBA Arbitration;

Figure 45-4 assumes MA and MB have been the last two masters already granted in the previous transfers (MA then MB).

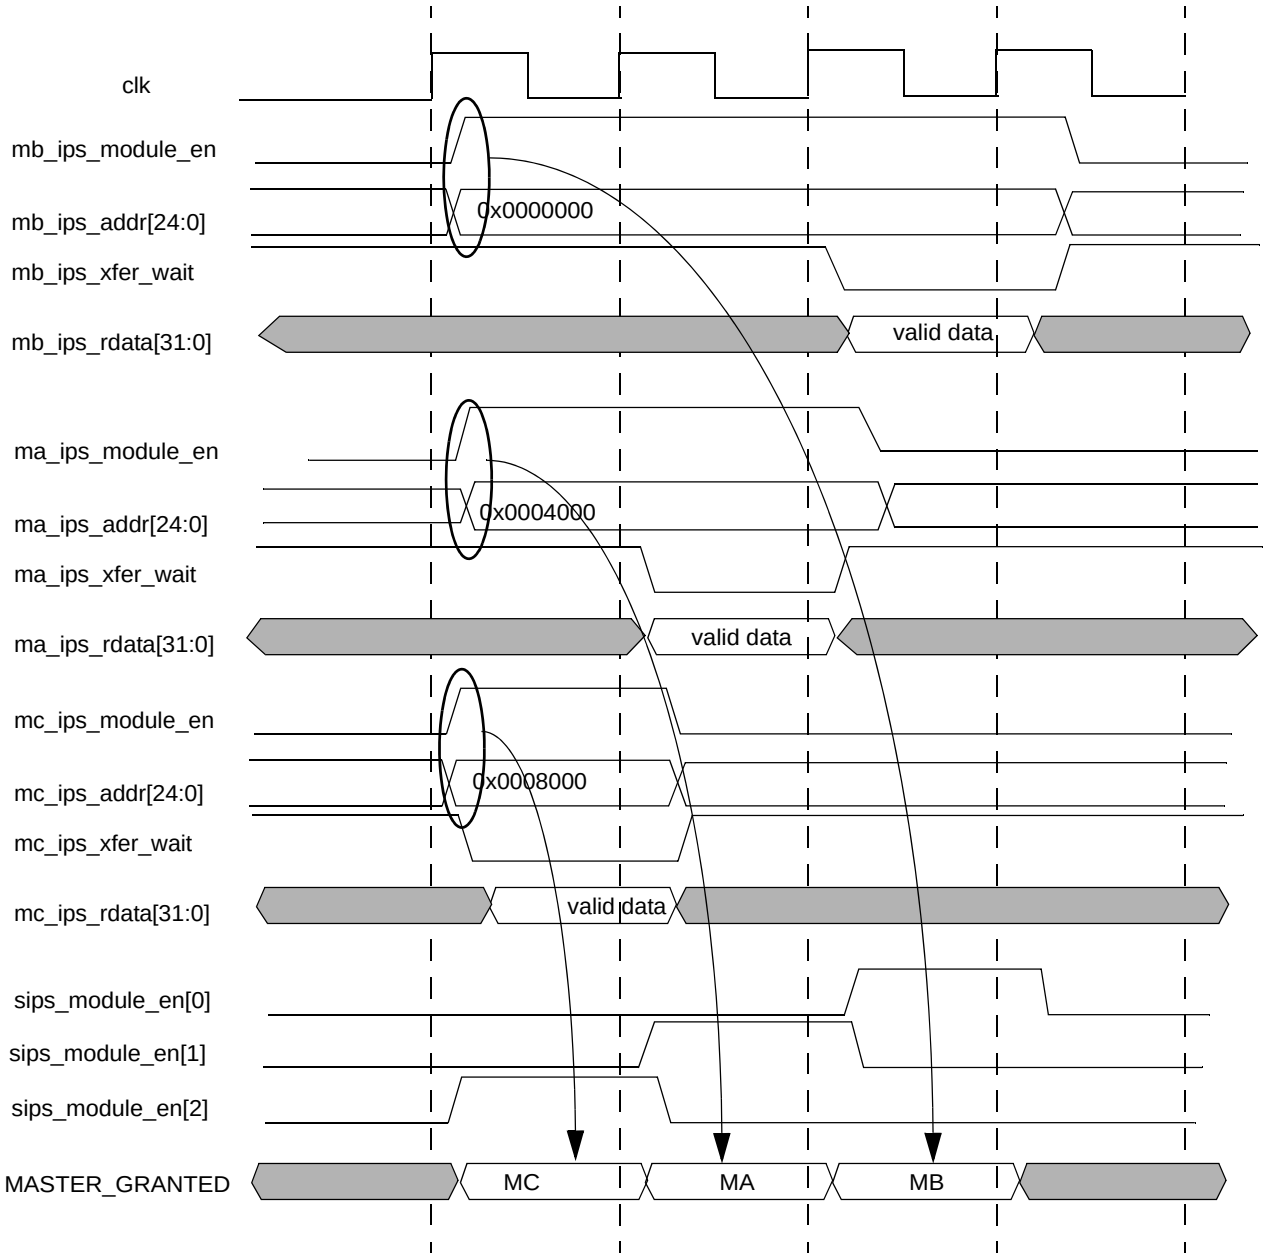

Figure 45-4. Example of Three Master Requests: Masters Already Granted are “Waited”;

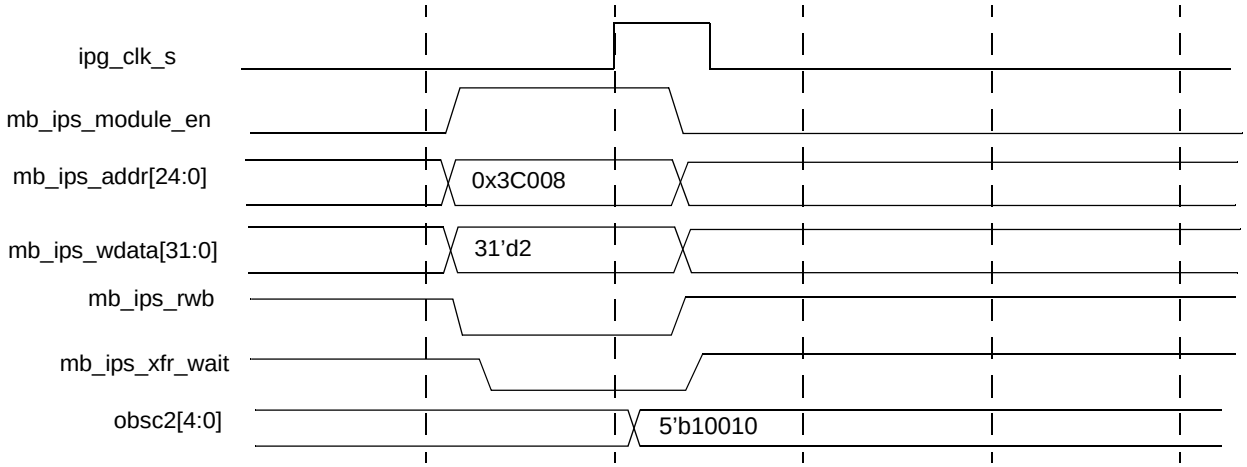
45.8 Resource Ownership Control

The Resource Ownership Control controls accesses to the shared peripherals and determines steering of out-of-band signals.

45.8.1 Access Control

45.8.1.1 Peripheral Access

The peripheral access (a.k.a resource access) of the requesting master is given by the corresponding RAR bit of the Peripheral Right Register. It determines if the master has access privilege to the resource. Any attempted access to a resource by a requesting master whose access privilege bit is not set (in the PRR), is terminated with a bus error (**<master>_ips_xfr_err** is asserted by SPBA logic).
The master which owns the resource can lock the peripheral for itself and/or grant other masters access to the peripheral by setting the appropriate bit(s) in the RAR field.



Master B is taking ownership of peripheral 2 by writing 3'b010 in the SPBA peripheral 2 right register (rar field)
This ownership can be checked on obsc2 output as roi2[1:0] = 2'b10 and rar2[2:0] = 3'b010
(obsc2[4:0] = {roi2[1], roi2[0], rar2[2], rar2[1], rar2[0]})

Figure 45-5. Example of One Master B Gaining Ownership of Peripheral 2

45.8.1.2 Peripheral Right Register Access

The ROI bits of the Peripheral Right Register (PRR) determine which master is allowed to make write access to PRR. The identification of the requesting master is compared to the ROI bits of the Peripheral Right Register to determine if the master has ownership of the corresponding register. Any attempted write access to a Peripheral Right Register (PRR) already owned by another master is ignored.

45.8.2 Owner Election

When the peripheral is not owned by any master (i.e ROI=”00”, such as after coming out of reset), the first master to perform successfully a write to the RAR bits of the PRR is granted ownership of the peripheral and its associated PRR.

After writing to the PRR (i.e. RAR bit(s)), the master must read it back to make sure that it was actually granted ownership.

If the RMO field is 2’b11, then the ownership claim is successful. If RMO is 2’b10, then another master claimed ownership before this master was able to complete its write.

This resolves the case in which two or more masters attempt to write the PRR at the same time; only the first master will be granted ownership. However all masters must read the PRR to determine if this case occurred, and if so, whether they were the first master which was actually granted ownership. See Section 45.5.2, “SPBA Register Definition” for more detail on the fields of the PRR.

NOTE

A master that has been granted ownership of the PRR does not automatically have the right access to the peripheral; it must still set its own RAR bits in the PRR to access the peripheral.

45.8.3 Ending Ownership

Ownership may be voluntarily ended by the owning master, or automatically upon assertion of a master-specific dead_owner signal. The former is appropriate for software-controlled yielding of ownership. The latter is appropriate for automatic yielding of ownership when the owner has gone into reset.

45.8.3.1 Hardware Controlled Ownership Ending

When a master gets reset, it clears the ROI bits of the PRRs owned by the corresponding master. When the owner is dead (i.e. owner is in reset), all peripherals previously owned by that master must be changed to the un-owned state.

NOTE

It is the programmer’s responsibility to make sure the peripherals are placed in an appropriate state before ending ownership.

45.8.3.2 Software Controlled Ownership Ending

The ROI bits will be automatically cleared when the master which owns the PRR access right clears (write) the RAR bits. (See Table 45-6.) The master then ends the ownership of the PRR.

45.8.4 The Unowned State

During the time when the peripheral is un-owned (that is, the ROI field contains all 0’s), all masters have full access to it (RAR bits can then be modified by a master if ROI[1:0] = 2’b0). In such cases it is necessary for software to ensure any necessary coherency in the resource, there is no hardware protection.

Chapter 46
Synchronous Serial Interface (SSI)

This chapter presents the synchronous serial interface (SSI) and discusses the architecture, programming model, operating modes, and initialization of SSI.

See Figure 46-1 for an illustration of the SSI block diagram. It consists of control registers to set up the port, status register, separate transmit and receive circuits with FIFO registers, and separate serial clock and frame sync generation for the transmit and receive sections. The second set of Tx and Rx FIFOs, replicates the logic used for the first set of FIFOs.

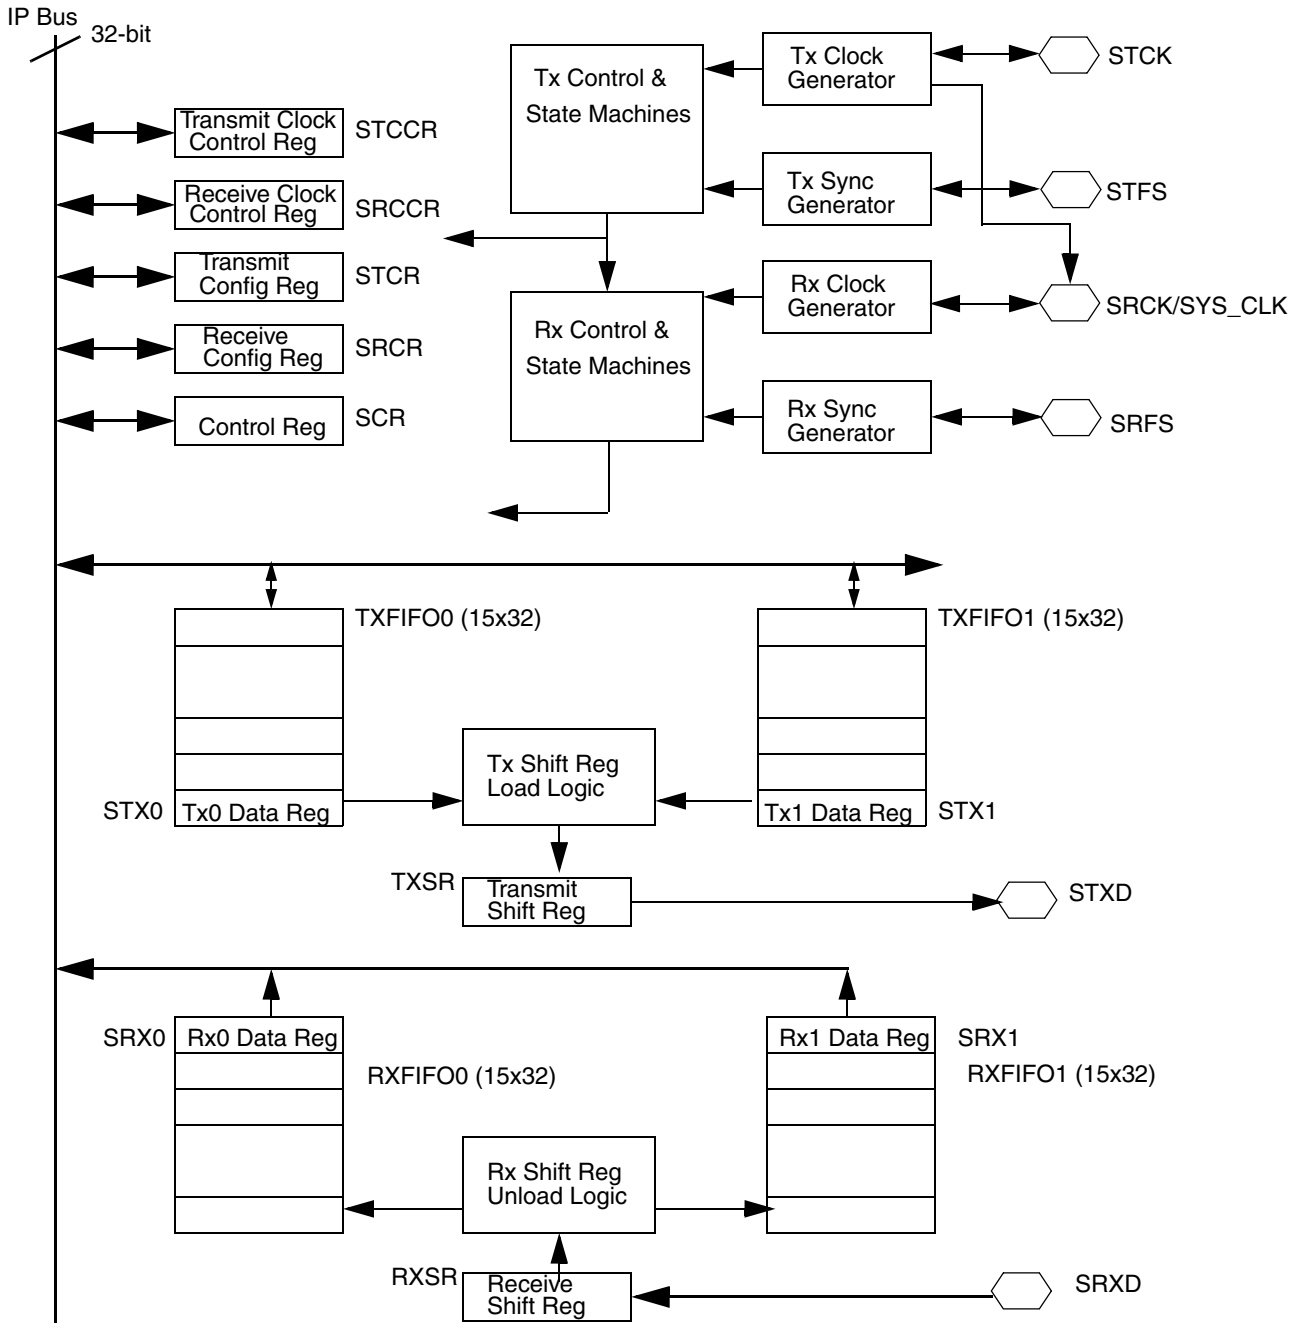


Figure 46-1. SSI Block Diagram

46.1 Overview

The SSI is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices. These serial devices can be standard CODer-DECoder (CODECs), Digital Signal Processors (DSPs), microprocessors, peripherals, and popular industry audio CODECs that implement the inter-IC sound bus standard (I^2S) and Intel AC97 standard.

SSI is typically used to transfer samples in a periodic manner. The SSI consists of independent transmitter and receiver sections with independent clock generation and frame synchronization.

46.1.1 Features

The SSI includes the following features:

- Independent (asynchronous) or shared (synchronous) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Normal mode operation using frame sync
- Network mode operation allowing multiple devices to share the port with as many as thirty-two time slots
- Gated Clock mode operation requiring no frame sync
- 2 sets of Transmit and Receive FIFOs. Each of the four FIFOs is 15x32 bits. The two sets of Tx/Rx FIFOs can be used in Network mode to provide 2 independent channels for transmission and reception
- Programmable data interface modes such like I2S, LSB, MSB aligned
- Programmable word length (8, 10, 12, 16, 18, 20, 22 or 24 bits)
- Program options for frame sync and clock generation
- Programmable I2S modes (Master, Slave or Normal). Oversampling clock, ccm_ssi_clk available as output from SRCK in I2S Master mode
- AC97 support
- Completely separate clock and frame sync selections for the receive and transmit sections. In AC97 standard, the clock is taken from an external source and frame sync is generated internally.
- External ccm_ssi_clk input for use in I2S Master mode. Programmable oversampling clock (ccm_ssi_clk) of the sampling frequency available as output in master mode at SRCK, when operated in sync mode.
- Programmable internal clock divider
- Time Slot Mask Registers for reduced CPU overhead (for Tx and Rx both)
- SSI power-down feature
- Programmable wait states for CPU accesses
- IP Interface for register accesses, compatible to SRS 3.0.2 standard

46.1.2 Modes of Operation

SSI has the following basic operating modes.

- Normal mode
  - — Asynchronous protocol
  - — Synchronous protocol
- Network mode
  - — Asynchronous protocol

  - Synchronous protocol
- Gated Clock mode
  - Synchronous protocol only

These modes can be programmed by several bits in the SSI control registers. See Table 46-1 for the list of SSI operating modes and some of the typical applications in which they can be used:

Table 46-1. SSI Operating Modes

TX, RX Sections	Serial Clock	Mode	Typical Application
Asynchronous	Continuous	Normal	Multiple synchronous CODECs
Asynchronous	Continuous	Network	TDM CODEC or DSP networks
Synchronous	Continuous	Normal	Multiple synchronous CODECs
Synchronous	Continuous	Network	TDM CODEC or DSP network
Synchronous	Gated	Normal	SPI-type devices; DSP to MCU

The transmit and receive sections of the SSI can be synchronous or asynchronous. In Synchronous mode, the transmitter and the receiver use a common clock and frame synchronization signal. Masking of slots for Transmit and Receive section can differ in synchronous mode. Also the shifting of data in independent and for receive section depends on RXBIT0 and RSHFD bits in SRCR register. In Asynchronous mode, the transmitter and receiver each has its own clock and frame synchronization signals.

Normal or Network mode can be selected. In Normal mode, the SSI functions with one data word of I/O per frame. In Network mode, any number from two to thirty-two data words of I/O per frame can be used. Network mode is typically used in star time division multiplex networks with other processors or CODECs, allowing interface to time division multiplexed networks without additional logic. Gated clock mode option can be selected in Normal synchronous mode only. During Gated-mode the clock is not-continuous and runs only during data-transmission. These distinctions result in the basic operating modes that allow the SSI to communicate with a wide variety of devices.

The SSI supports both Normal and Network modes, and these can be selected independently of whether the transmitter and receiver are synchronous or asynchronous. Typically these protocols are used in a periodic manner, where data is transferred at regular intervals, such as at the sampling rate of an external CODEC. Both modes use the concept of a frame. The beginning of the frame is marked with a frame sync when programmed with continuous clock. The frame sync occurs at a periodic interval. The length of the frame is determined by the DC[4:0] bits in either the SRCCR or STCCR register, depending on whether data is being transmitted or received. The number of words transferred per frame depends on the mode of the SSI.

In Normal mode, one data word is transferred per frame. In Network mode, the frame is divided into anywhere between two and thirty-two time slots, where in each time slot one data word can optionally be transferred.

Apart from the above basic modes of operation, SSI supports the following modes which require some specific programming.

- I2S mode

- AC97 mode
  - AC97 Fixed mode
  - AC97 Variable mode

In (non-I2S) slave modes (external frame sync), the programmed word length setting of the SSI should be equal to the word length setting of the master. In I2S slave mode, the programmed word length setting of the SSI can be lesser than or equal to the word length setting of the I2S master (external CODEC).

In slave modes, the programmed frame length setting (DC bits) of the SSI can be lesser than or equal to the frame length setting of the master (external CODEC).

The following sections provide detailed descriptions of the above modes.

46.1.2.1 Normal Mode

Normal mode is the simplest mode of the SSI. It is used to transfer data in one time slot per frame. A time slot is a unit of data and the WL[3:0] bits define the number of bits in a time slot. In Continuous Clock mode, a frame sync occurs at the beginning of each frame. The length of the frame is determined by the following factors:

- The period of the Serial Bit Clock (DIV2, PSR, PM[7:0] bits for internal clock or the frequency of the external clock on the STCK port)
- The number of bits per time slot (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

If Normal mode is configured with more than one time slot per frame, data is transferred only in the first time slot. No data is transferred in subsequent time slots. In Normal mode, DC[4:0] values corresponding to more than a single time slot in a frame, only results in lengthening of the frame.

46.1.2.1.1 Normal Mode Transmit

The conditions for data transmission from the SSI in Normal mode are:

- SSI Enabled (SSIEN = 1)
- Write data to Transmit Data Register (STX)
- Transmitter Enabled (TE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

When the above conditions occur in Normal mode, the next data word is transferred into the Transmit Shift Register (TXSR) from the Transmit Data Register 0 (STX0), or from the Transmit FIFO 0 Register, if transmit FIFO 0 is enabled. The new data word is transmitted on arrival of frame-sync preceded by clocks in continuous clock mode. In gated external mode, data word in transmitted on arrival of frame-sync. In gated-internal mode, data word is transmitted whenever data is available in Tx-FIFO.

If Transmit FIFO 0 is not enabled and the transmit data register empty enable (TDE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the word in SSI_STX0 is shifted to Transmit Shift (TXSR) register for shifting.

If Transmit FIFO 0 is enabled and the transmit fifo full enable (TFF0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the number of empty slots in Transmit Fifo 0 exceed or are equal to the selected threshold value i.e. Transmit Fifo 0 Watermark (TFWM0) value. If transmit FIFO 0 is enabled and filled with data, 15 data words can be transferred before the core must write new data to the STX0 register.

The STXD port is disabled except during the data transmission period. For a continuous clock, the optional frame sync output and clock outputs are not disabled, even if both receiver and transmitter are disabled.

46.1.2.1.2 Normal Mode Receive

The conditions for data reception from the SSI are:

- SSI enabled (SSIEN = 1)
- Receiver enabled (RE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

With the above conditions in Normal mode with a continuous clock, each time the frame sync signal is generated (or detected) a data word is clocked in. With the above conditions and a gated clock, each time the clock begins, a data word is clocked in.

If Receive FIFO 0 is not enabled and Receive Interrupt enable (RIE) and Received Data 0 Ready enable (RDR0_EN) bits are set, receive interrupt occurs when received data word is transferred from the Receive Shift Register (RXSR) to the Receive Data Register 0 (SRX0) thus setting the Receive Data Ready 0 (RDR0) flag.

If Receive FIFO 0 is enabled, and Receive Interrupt enable (RIE) and Received Fifo 0 full enable (RDR0_EN) bits are set, receive interrupt occurs when the received data word is transferred to the Receive FIFO 0 and Receive FIFO 0 reaches the selected threshold and results in Receive FIFO Full 0 (RFF0) flag to get set.

The core program has to read the data from the Receive Data Register 0 (SRX0) (in case Receive FIFO0 is disabled) before a new data word is transferred from the Receive Shift Register (RXSR), otherwise the Receive Overrun Error 0 (ROE0) bit is set. If receive FIFO 0 is enabled, the Receive Overrun Error 0 (ROE0) bit is set when the Receive FIFO 0 data level reaches the selected threshold and a new data word is ready to be transferred to the Receive FIFO 0.

See Figure 46-2 for illustration of transmitter and receiver timing for an 8-bit word in the first time slot in Normal mode, continuous clock with a late word length frame sync. The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and at the end of the time slot, this data is transferred to the Rx Data Register.

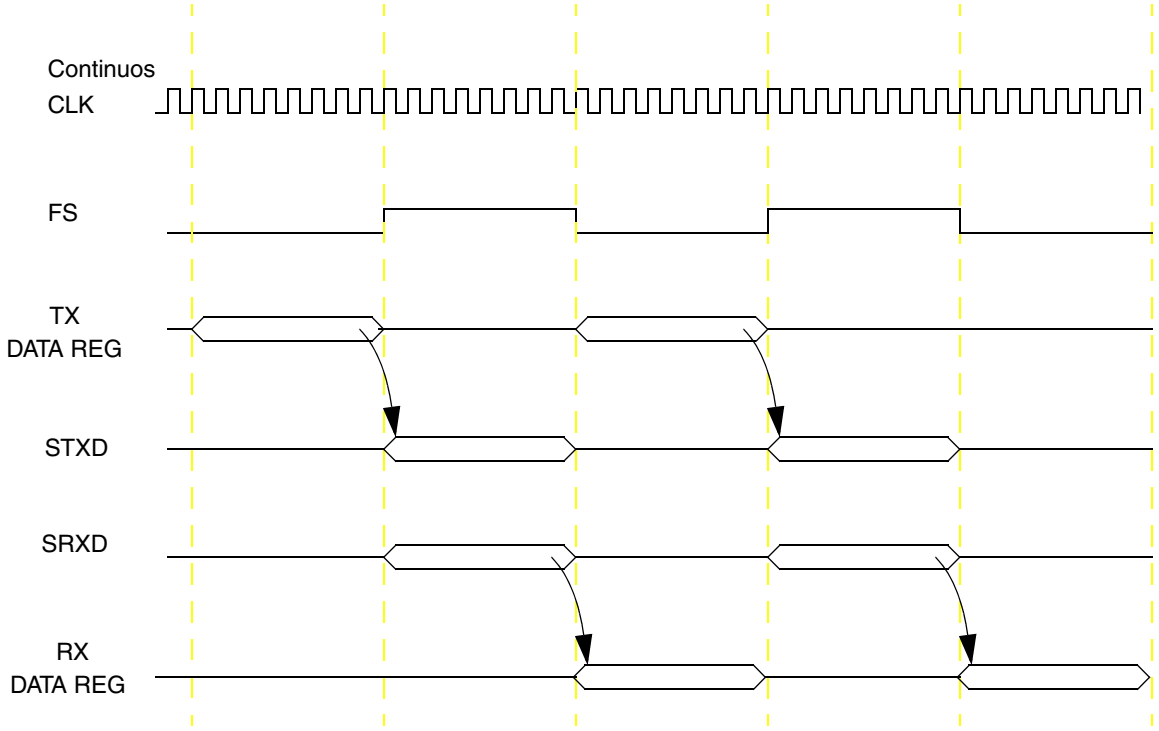

Figure 46-2. Normal Mode Timing—Continuous Clock

Figure 46-3 shows a similar case for internal (SSI generates clock) gated clock mode and Figure 46-4 shows a case for external (SSI receives clock) gated clock mode.

NOTE

A pull-down resistor is required in the gated clock case because the clock port is disabled between transmissions.

The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and at the end of the time slot, this data is transferred to the Rx Data Register. In case of Internal Gated clock mode, the Tx Data line and clock output port are put in the high-impedance state at the end of transmission of the last bit (at the completion of the complete clock cycle), whereas, in External Gated clock mode, the Tx Data line is tri-stated at the last inactive edge of the incoming bit clock (during the last bit in a data word).

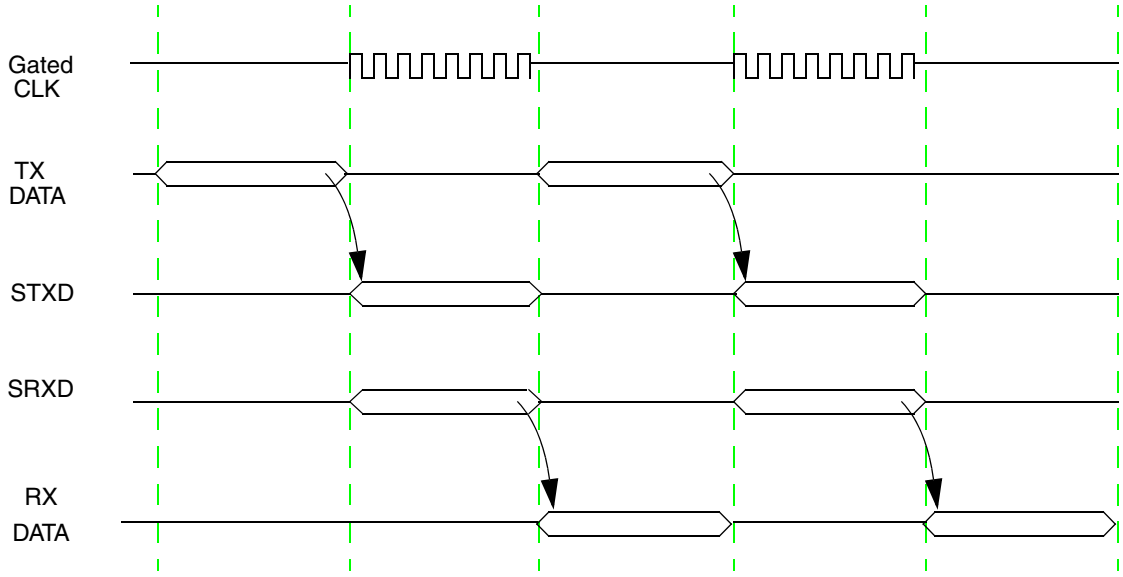

Figure 46-3. Normal Mode Timing—Internal Gated Clock

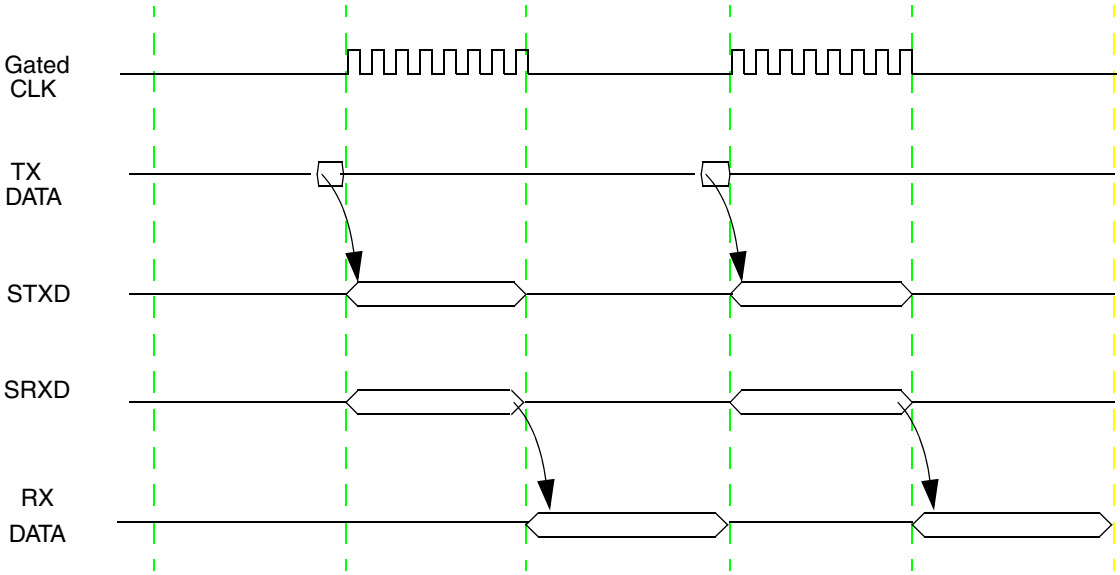

Figure 46-4. Normal Mode Timing—External Gated Clock

46.1.2.2 Network Mode

Network mode is used for creating a Time Division Multiplexed (TDM) network, such as a TDM CODEC network or a network of DSPs. In Continuous Clock mode, a frame sync occurs at the beginning of each frame. In this mode, the frame is divided into more than one time slot. During each time slot, one data word can be transferred. Each time slot is then assigned to an appropriate CODEC or DSP on the network. The DSP can be a master device that controls its own private network, or a slave device that is connected to an existing TDM network and occupies a few time slots.

The frame sync signal indicates the beginning of a new data frame. Each data frame is divided into time slots and transmission and/or reception of one data word can occur in each time slot (rather than in just the frame sync time slot as in Normal mode). The frame rate dividers, controlled by the DC[4:0] bits, select two to thirty-two time slots per frame. The length of the frame is determined by the following factors:

- The period of the serial bit clock (PSR, PM[7:0] bits for internal clock, or the frequency of the external clock on the STCK port)
- The number of bits per sample (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

In Network mode, data can be transmitted in any time slot. The distinction of the Network mode is that each time slot is identified with respect to the frame sync (data word time). This time slot identification allows the option of transmitting data during the time slot by writing to the STX registers or ignoring the time slot as determined by STMSK register bits. The receiver is treated in the same manner and received data is only transferred to the receive data register/fifo if the corresponding time slot is enabled (through SRMSK).

By utilizing the STMSK and SRMSK registers, software only has to service the SSI during valid time slots. This eliminates any overhead associated with unused time slots. See Section 46.3.3.20, “SSI Transmit Time Slot Mask Register (STMSK),” and Section 46.3.3.21, “SSI Receive Time Slot Mask Register (SRMSK),” for more information on STMSK and SRMSK.

In the Two-Channel mode of operation, the second set of Transmit and Receive FIFOs and Data Registers are used to create two separate channels. These channels are completely independent, with a their own set of Core interrupts and DMA requests, which are identical to the ones available for the default channel. In this mode, data is transmitted/received in enabled time slots alternately from/to FIFO 0 and FIFO 1, starting from FIFO 0. The first data word is taken from FIFO 0 and transmitted in the first enabled time slot and subsequently, data is loaded from FIFO 1 and FIFO 0 alternately and transmitted. Similarly, the first received data is sent to FIFO 0 and subsequent data is sent to FIFO 1 and FIFO 0 alternately. Time slots can be selected through the Transmit and Receive Time Slot Mask registers (STMSK and SRMSK). For using this mode of operation, the TCH_EN bit (SCR[8]) needs to be set.

46.1.2.2.1 Network Mode Transmit

The transmit portion of SSI is enabled when the SSIEN and the TE bits in the SCR are both set. However, for continuous clock, when the TE bit is set, the transmitter is enabled only after detection of a new frame sync (transmission starts from the next frame boundary).

Normal start-up sequence for transmission is to perform the following:

1. Enable Network Mode.
2. Enable SSI
3. Write the data to be transmitted to the STX register. This clears the TDE flag
4. Set the TE bit to enable the transmitter on the next frame boundary (for continuous clock case).
5. Enable transmit interrupts.

(Alternatively, the programmer may decide not to transmit in a time slot by configuring the STMSK.) TDE flag is cleared as data is shifted from STX register to TXSR, but the STXD port remains disabled during

the time slots. When the next frame sync is detected or generated (continuous clock), the data word in TXSR and is shifted out (transmitted). When the STX register is empty, the TDE bit is set, which causes a transmitter interrupt (in case the FIFO is disabled) to be sent if the TIE bit is set. Software can poll the TDE bit or use interrupts to reload the STX register with new data for the next time slot. Failing to reload the STX register before the TXSR is finished shifting (empty) causes a transmitter underrun and the TUE error bit is set. In case the FIFO is enabled, the TFE flag is set in accordance with the watermark setting and this flag causes the transmitter interrupt to occur.

The operation of clearing the TE bit disables the transmitter after completion of transmission of the current frame. Setting the TE bit enables transmission from the next frame. During that time the STXD port is disabled. The TE bit should be cleared after the TDE bit is set to ensure that all pending data is transmitted.

To summarize, the Network mode transmitter generates interrupts every enabled time slot (when FIFO is disabled) and requires the core program to respond to each enabled time slot. These responses from the core are one of the following:

- Write data in data register to enable transmission in the next time slot.
- Configure the time slot register to disable transmission in the next time slot (unless time slot is already masked by STMSK register bit).
- Do nothing—transmit underrun occurs at the beginning of the next time slot and the previous data is re-transmitted.

In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected (TDE1 is low by default).

46.1.2.2.2 Network Mode Receive

The receiver portion of the SSI is enabled when both the SSIEN and the RE bits in the SCR are set. However, the receive enable only takes place during that time slot if RE is enabled before the second to last bit of the word. If the RE bit is cleared, the receiver is disabled at the end of the current frame. SSI is capable of finding the start of the next frame automatically. When the word is completely received, it is transferred to the SRX register, which sets the RDR bit (Receive Data Ready). Setting the RDR bit causes a receive interrupt to occur if the receiver interrupt is enabled (the RIE bit is set) and (Receive data ready enable) RDR_EN bit is set. The second data word (second time slot in the frame), begins shifting in immediately after the transfer of the first data word to the SRX register. The core program has to read the data from the Receive Data Register (which clears RDR) before the second data word is completely received (ready to transfer to RX data register) or a receive overrun error occurs (the ROE bit is set).

An interrupt can occur after the reception of each enabled data word or the programmer can poll the RDR flag. The core program response can be one of the following:

- Read RX and use the data.
- Read RX and ignore the data.
- Do nothing—the receiver overrun exception occurs at the end of the current time slot.

NOTE

For a continuous clock, the optional frame sync output and clock output signals are not affected, even if the transmitter or receiver is disabled. TE and RE do not disable the bit clock or the frame sync generation. To disable the bit clock and the frame sync generation, the SSIEN bit in the SCR can be cleared or TFR_CLK_DIS/RFR_CLK_DIS bits can be set, or the port control logic external to the SSI (for example, in the IOMUX) can be re configured.

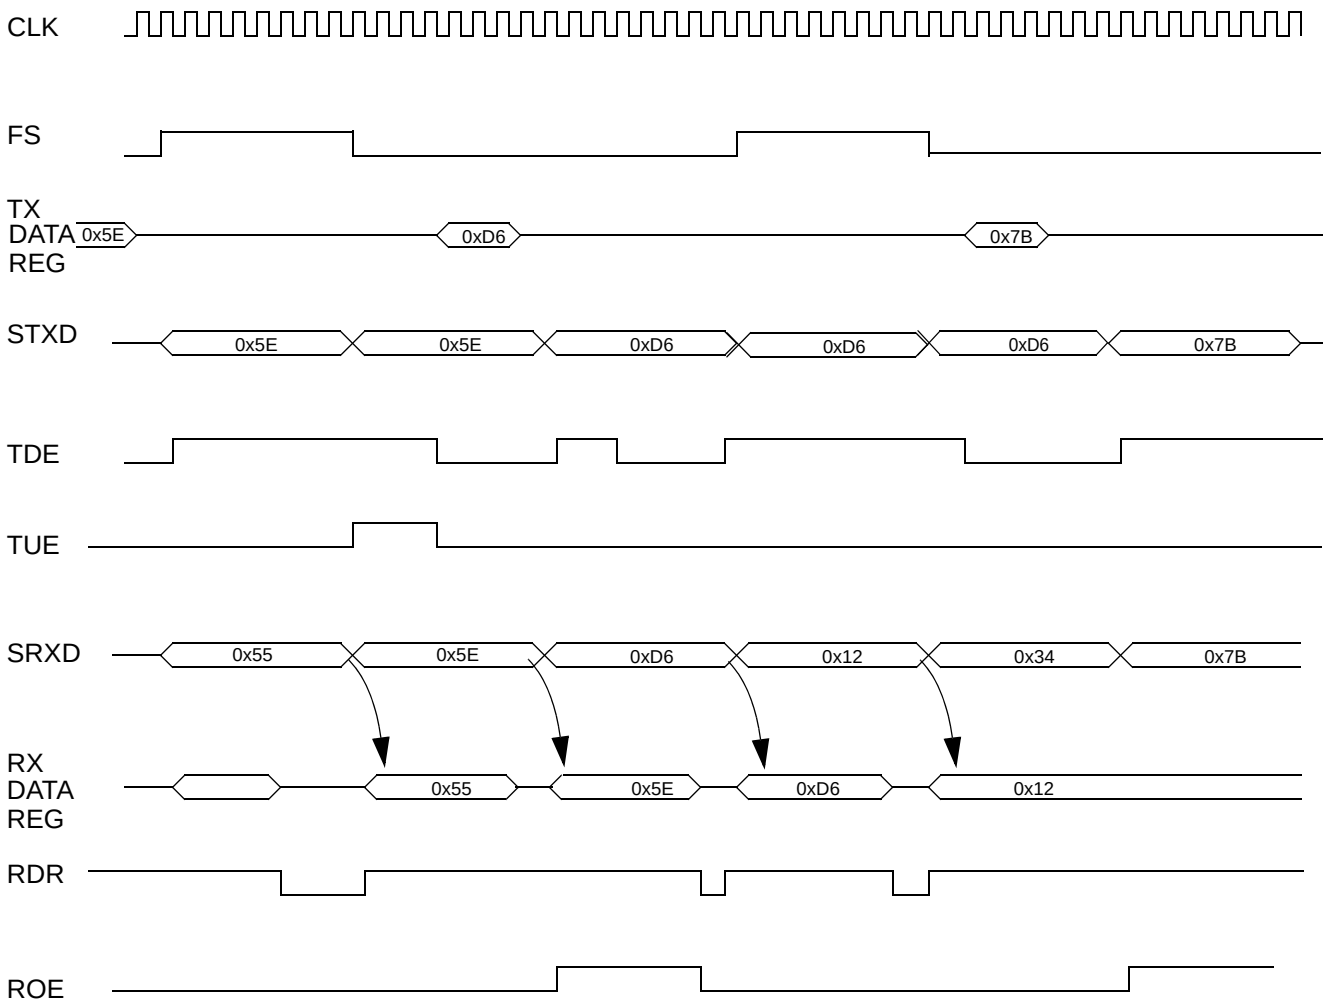
In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected.

The transmitter and receiver timing for an 8-bit word with continuous clock, FIFO disabled, three words per frame sync in Network mode is shown in Figure 46-5, “Network Mode Timing—Continuous Clock.”

NOTE

The transmitter repeats the value 0x5E because of an underrun condition

For the receive section, data received on the SRXD pin gets transferred to the Rx Data register at the end of each time slot. If the FIFO is disabled, the RDR flag gets set and causes a receiver interrupt if RE, RIE and RDR_EN bits are set. If the FIFO is enabled, then the RFF flag is used for interrupt generation (this flag is set in accordance with the watermark settings). Here all time slots are enabled. The receive data ready flag is set after reception of the first data (0x55). Since the flag is not cleared (Rx Data Register is not read by core), the Receive Overrun Error (ROE) flag is set on reception of the next data (0x5E). ROE flag is cleared on writing ‘1’ to the corresponding interrupt status bit in SSI Status Register.



Note: Processor must write ‘1’ to the corresponding TUE/ROE Interrupt status bit in SISR to clear TUE/ROE Interrupt.

Figure 46-5. Network Mode Timing—Continuous Clock

46.1.2.3 Gated Clock Mode

Gated Clock mode is often used to hook up to SPI-type interfaces on Micro controller Units (MCUs) or external peripheral chips. In Gated Clock mode, the presence of the clock indicates that valid data is on the STXD or SRXD ports. For this reason, no frame sync is needed in this mode. Once transmission of data has completed, the clock is pulled to the inactive state. Gated clocks are allowed for both the transmit and receive sections with either internal or external clock in Normal mode. Gated clocks are not allowed in Network mode. See Table 46-5, “Clock Pin Configurations,” for SSI configuration for gated-mode operation.

The clock runs when the TE bit and/or the RE bit are appropriately enabled. For the case of internally generated clock, all internal bit clocks, word clocks, and frame clocks continue to operate. When a valid

time slot occurs (such as the first time slot in Normal mode), the internal bit clock is enabled onto the appropriate clock port. This allows data to be transferred out in periodic intervals in Gated Clock mode. With an external clock, the SSI waits for a clock signal to be received. Once the clock begins, valid data is shifted in. Care should be taken to clear all DC bits (0x00000) when SSI is used in Gated mode. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of AISR register are not generated.

For Gated clock operated in external clock mode, a proper clock signalling must be applied to the SSI STCK in order for it to function properly. When TSCKP is 0, CLK_IST value should be 1. When TSCKP is 1, CLK_IST value should be 0. If the SSI uses rising edge transition to clock data (TSCKP=0) and the falling edge transition to latch data (RSCKP=0), the clock must be in an active low state when idle. If the SSI uses falling edge transition to clock data (TSCKP=1) and the rising edge transition to latch data (RSCKP=1), the clock must be in a active high state when idle. Figure 46-6, through Figure 46-9 illustrate the different edge clocking/latching.

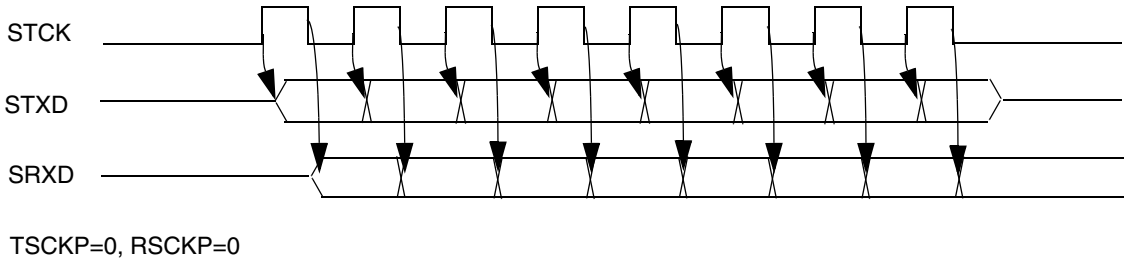


Figure 46-6. Internal Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

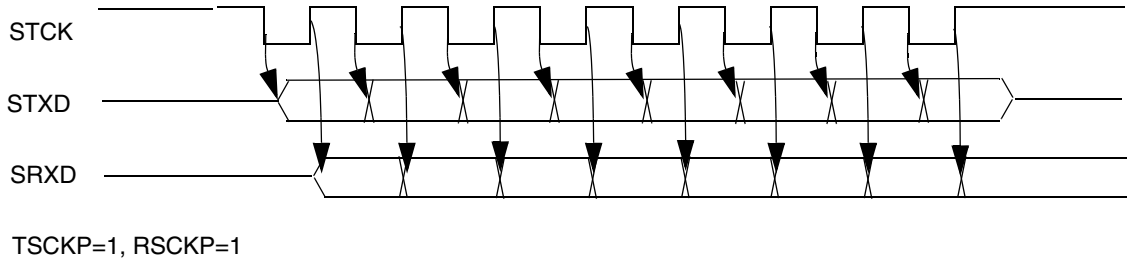

Figure 46-7. Internal Gated Mode Timing - Falling Edge Clocking / Rising Edge Latching

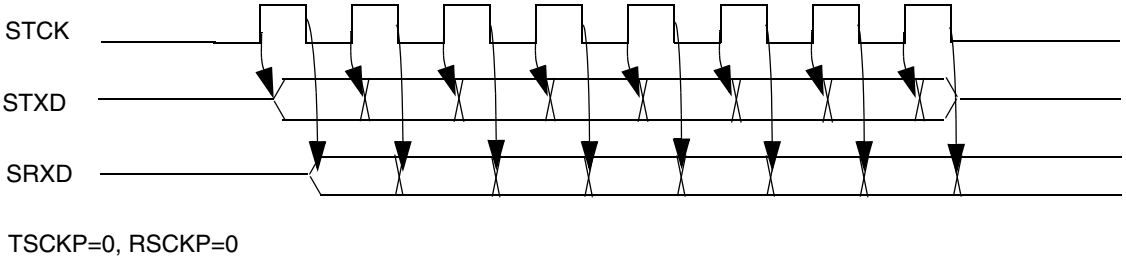

Figure 46-8. External Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

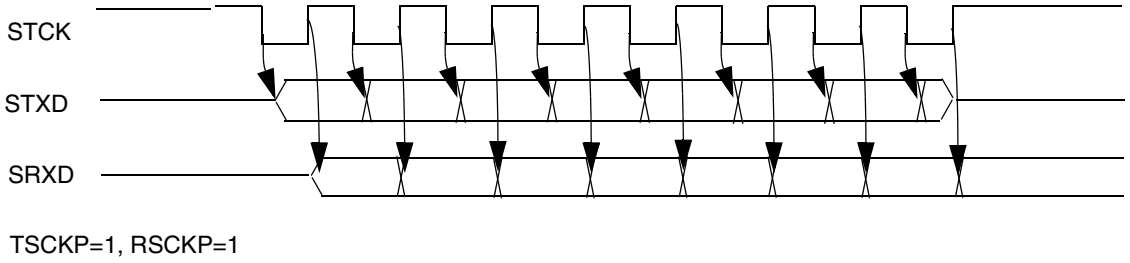

Figure 46-9. External Gated Mode Timing - Falling Edge clocking / Rising Edge Latching

NOTE

- The bit clock ports must be kept free of timing glitches. If a single glitch occurs, all ensuing transfers will be out of synchronization.
- In case of External Gated Mode, even though the Tx Data line is put in the high-impedance state at the last non-active edge of the bit clock, the round trip delay should be sufficient to take care of hold time requirements at the external receiver.

46.1.2.4 I2S Mode

The SSI is compatible with the I^2S bus specification from Philips Semiconductors (February 1986, Revised June 5, 1996). See Figure 46-10 on "I^2S Mode Timing - Serial Clock, Frame Sync and Serial Data" for an illustration of the basic I2S protocol timing.

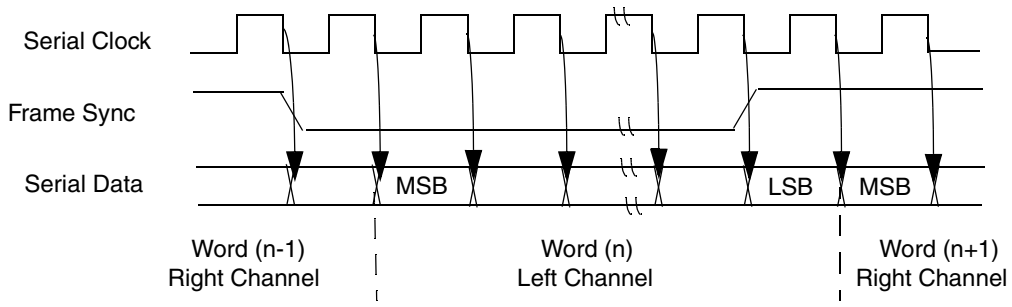

Figure 46-10. I2S Mode Timing - Serial Clock, Frame Sync and Serial Data

Select I^2S mode using the options listed in Table 46-2.

Table 46-2. I^2S Mode Selection

I^2S_MODE[1]	I2S_MODE[0]	Mode Type
0	0	Normal mode
0	1	I2S master mode
1	0	I2S slave mode
1	1	Normal mode

In normal mode operation, no register bits are forced to any particular state internally and the user can program the SSI to work in any operating condition.

When I2S modes are entered (I2S master (01) or I2S slave (10)), the following settings are recommended:

- Sync mode (SCR[4] =1)
- Tx shift direction: MSB transmitted first (STCR[4]=0)
- Rx shift direction: MSB received first (SRCR[4]=0)
- Tx data clocked at falling edge of the clock (STCR[3]=1)
- Rx data latched at rising edge of the clock (SRCR[3]=1)
- Tx frame sync active low (STCR[2]=1)
- Rx frame sync active low (SRCR[2]=1)
- Tx frame sync initiated one bit before data is transmitted (STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SRCR[0]=1)
- TX Frame Rate should be 2 i.e. (STCCR[12:8] = 1)
- RX Frame Rate should be 2 i.e. (SRCCR[12:8] = 1)

In I^2S master mode(SCR[6:5]=01), the following additional settings are recommended:

- TXDIR bit (STCR[5]) set to 1 to select internal generated bit clock
- TFDIR bit (STCR[6]) set to 1 to select internal generated frame sync

In I^2S master mode(SCR[6:5]=01), the following settings are internally overridden by the hardware:

- Network mode is selected (SCR[3]=1)
- Tx frame sync length set to one-word-long-frame (STCR[1]=0)
- Rx frame sync length set to one-word-long-frame (SRCR[1]=0)
- Tx shifting w.r.t. bit 0 of TXSR (STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SRCR[9]=1)

The user needs to set the following control bits to configure the bit clock and frame sync:

- PM (STCCR[7:0])
- PSR (STCCR[17])
- DIV2(STCCR[18]
- WL (STCCR[16:13]
- DC (STCCR[12:8])

The word length is fixed to 32 in I^2S Master mode and the WL bits determine the number of bits that will contain valid data (out of the 32 transmitted/received bits in each channel). The fixing of word duration as 32 simplifies the relation between oversampling clock (ccm_ssi_clk) and Frame Sync (ccm_ssi_clk becomes an integer multiple of Frame Sync).

In I^2S slave mode(SCR[6:5]=10), the following additional settings are recommended:

- TXDIR bit(STCR[5]) set to 0 to select external generated bit clock
- TFDIR bit(STCR[6]) set to 0 to select external generated frame sync

In I^2S slave mode(SCR[6:5]=10), the following settings are internally overridden by the hardware:

- Normal mode is selected (SCR[3]=0)
- Tx frame sync length set to one-bit-long-frame (STCR[1]=1)
- Rx frame sync length set to one-bit-long-frame (SRCR[1]=1)
- Tx shifting w.r.t. bit 0 of TXSR (STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SRCR[9]=1)

The user needs to set the following control bits to configure the data transmission:

- WL (STCCR[16:13])
- DC (STCCR[12:8])

The word length is variable in I^2S slave mode and the WL bits determine the number of bits that will contain valid data. The actual word length is determined by the external CODEC. The external I^2S Master still sends frame sync according to the I^2S protocol (early, word wide and active low), the SSI internally operates so that each frame sync transition is the start of a new frame (the WL bits determine the number of bits to be transmitted/received). After one data word has been transferred, the SSI waits for the next frame sync transition to start operation in the next time slot. Transmit (STMSK) and receive (SRMSK) mask bits should not be used in I^2S Slave mode of operation. Masking is supported only for network mode of operation.

46.1.2.5 AC97 Mode

In AC97 mode of operation, the SSI transmits a 16-bit Tag Slot at the start of a frame and the rest of the slots (in that frame) are all 20-bits wide. The same sequence is followed while receiving data. See the AC97 specification for details regarding transmit and receive sequences and data formats.

Note that the SSI only has one RxDATA pin so the SSI can only support one codec. Secondary codecs are not supported.

When AC97 mode is enabled, the following settings are internally overridden by the hardware. The programmed register values are not changed by entering AC97 mode but they no longer apply to the module’s operation. Writing to the programmed register fields will update their values; these updates can be seen by reading back the register fields. However, these settings will not take effect until AC97 mode is turned off.

The register bits within the bracket are the equivalent settings:

- Sync mode is entered (SCR[4] =1)
- Network mode is selected (SCR[3]=1)
- Tx shift direction is MSB transmitted first (STCR[4]=0)
- Rx shift direction is MSB received first (SRCR[4]=0)
- Tx data is clocked at rising edge of the clock (STCR[3]=0)
- Rx data is latched at falling edge of the clock (SRCR[3]=0)
- Tx frame sync is active high (STCR[2]=0)
- Rx frame sync is active high (SRCR[2]=0)

- Tx frame sync length is one-word-long-frame (STCR[1]=0)
- Rx frame sync length is one-word-long-frame (SRCR[1]=0)
- Tx frame sync initiated one bit before data is transmitted (STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SRCR[0]=1)
- Tx shifting w.r.t. bit 0 of TXSR (STCR[9]=1)
- Rx shifting w.r.t. bit 0 of RXSR (SRCR[9]=1)
- Tx FIFO is enabled (STCR[7]=1)
- Rx FIFO is enabled (SRCR[7]=1)
- TFDIR bit (STCR[6]) is forced to 1 internally to select internal generated frame sync
- TXDIR bit (STCR[5]) is forced to 0 internally to select external generated bit clock

Any alteration of these bits individually will not affect the operational conditions of the SSI unless AC97 mode is deselected.

Hence, the only control bits needed to be set by the user to configure the data transmission/reception are the WL (STCCR[16:13]) and DC (STCCR[12:8]) bits. In AC97 mode, the WL bits can only legally take the values corresponding to 16-bit (truncated data) or 20-bit time slots. In case WL bits are set to select 16-bit time slots, the SSI pads the transmit data (four least significant bits) with zeros and while receiving, stores only the most significant 16 bits in the Rx FIFO.

Follow the sequence for programming the SSI to work in AC97 mode:

1. Program the WL bits to a value corresponding to either 16 or 20 bits. The WL bit setting is only for the data portion of the AC97 frame (Slots #3 through #12). The Tag slot (Slot #0) is always 16 bits wide and the Command Address and Command Data slots (Slots #1 and #2) are always 20 bits wide.
2. Select the number of time slots by programming the DC bits. For AC97 operation, DC bits should be set to a value of ‘0xC’, resulting in 13 time slots per frame.
3. Write data to be transmitted, in Tx FIFO 0 (through Tx Data Register 0) and Tx FIFO 1 while using Two-Channel Mode (TCH_EN = 1).
4. Program the FV, TIF, RD, WR and FRDIV bits in SACNT register
5. Update the contents of SACADD, SACDAT and SATAG (for Fixed mode only) registers
6. Enable the AC97 mode of operation (AC97EN bit in SACNT register)

Once the SSI starts transmitting and receiving data (after being configured in AC97 mode), the programmer needs to service the interrupts, as and when they are raised (updates to command address/data or tag registers, reading of received data and writing more data for transmission). Further details regarding fixed and variable mode implementation are provided in the following sections.

While using AC97 in Two-Channel Mode (TCH_EN=1), it is recommended that the received tag is not stored in the Rx FIFO (TIF=0). In case the programmer needs to update the SATAG register and also issue a RD/WR command (in a single frame), it is recommended that the SATAG register be updated prior to issuing a RD/WR command.

46.1.2.5.1 AC97 Fixed Mode (SACNT[1]=0)

In fixed mode of operation, SSI transmits in accordance with the AC97 Frame Rate Divider bits (i.e. FRDIV in SACNT) which decides the number of frames for which the SSI should be idle, after operating for one frame.

In a valid frame, TAG Value (written by Core) will be transmitted in Slot #0, Command Address will be transmitted in Slot #1 in case of RD/WR Command, and Command Data will be transmitted in Slot #2 in case of a WR Command. The data from TX-FIFO is transmitted in Slot #3 - Slot #12 depending on the valid slots indicated by the TAG value.

While receiving, bit 15 of the TAG Value (Slot #0) is checked to see if the CODEC is ready. If this bit is set, the frame is received. The received TAG provides the information about Slots containing valid data. The the corresponding TAG bit is valid, the Command Address (Slot #1) and Command Data (Slot #2) values are stored in the corresponding registers. The received data (Slot #3 - Slot #12) is then stored in the Rx-FIFO (for valid slots).

46.1.2.5.2 AC97 Variable Mode (SACNT[1]=1)

In Variable Mode, the transmit slots which should contain data in the current frame are determined by SLOTREQ bits received in the previous frame. While receiving, if the CODEC is ready, the frame is received and the SLOTREQ bits (contained in Slot #1) are stored for scheduling transmission in the next frame.

The SACCST, SACCEN and SACCDIS registers helps in determining which transmit slots are active. This information is used to ensure that SSI does not transmit data for powered-down/inactive channels.

46.1.2.6 External Frame and Clock Operation

When applying external frame sync and clock signals to SSI, there should be at least 4-bit clock cycles between the enabling of the transmit or receive section and the rising edge of the corresponding frame sync signal. The transition of STFS or SRFS should be synchronized with the rising edge of external clock signal, STCK or SRCK.

46.1.2.7 Data Alignment Formats Supported

The SSI supports three data formats in order to provide flexibility with handling data. These formats dictate how data is written to (and read from) the data registers. Therefore, data can appear in different places in STX0/1 and SRX0/1 based on the data format and the number of bits per word. Independent data formats are supported for both the transmitter and receiver (that is, the transmitter and receiver can use different data formats).

The supported data formats are:

- MSB alignment
- LSB alignment
  - Zero-extended (receive data only)
  - Sign-extended (receive data only)

With MSB alignment, the most significant byte is bits 31 through 24 of the data register if the word length is larger than or equal to 16 bits. If the word length is less than 16 bits and MSB alignment is chosen, the most significant byte is bits 15 through 8. With LSB alignment, the least significant byte is bits 7 through 0. Data alignment is controlled by the TXBIT0 bit in the STCR and the RXBIT0 bit in the SRCR. See Table 46-3 for the bit assignment for all the data formats supported by the SSI.

Table 46-3. Data Alignment

Format	Bit Number																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8-bit LSB Aligned																									7	6	5	4	3	2	1	0
8-bit MSB Aligned																	7	6	5	4	3	2	1	0								
10-bit LSB Aligned																							9	8	7	6	5	4	3	2	1	0
10-bit MSB Aligned																	9	8	7	6	5	4	3	2	1	0						
12-bit LSB Aligned																					11	10	9	8	7	6	5	4	3	2	1	0
12-bit MSB Aligned																	11	10	9	8	7	6	5	4	3	2	1	0				
16-bit LSB Aligned																	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
16-bit MSB Aligned	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
18-bit LSB Aligned															17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
18-bit MSB Aligned	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
20-bit LSB Aligned													19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
20-bit MSB Aligned	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0												
22-bit LSB Aligned											21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
22-bit MSB Aligned	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0										
24-bit LSB Aligned									23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
24-bit MSB Aligned	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								

In addition, receive data can either be zero-extended or sign-extended if LSB alignment is selected. With zero-extension, all bits above the most significant bit are 0's. This format is useful when data is stored in a pure integer format. With sign-extension, all bits above the most

significant bit. This format is useful when data is stored in a fixed-point integer format (which implies fractional values). Receive data extension is controlled by the RXEXT bit in the SRCR. Transmit data used with LSB alignment has no concept of sign/zero-extension. Unused bits above the most significant bit are simply ignored.

When configured in I2S or AC97 mode, the SSI forces the selection of LSB alignment. However, RXEXT still permits a choice between zero-extension and sign-extension.

See Section 46.3.3.10, "SSI Transmit Configuration Register (STCR)," and Section 46.3.3.11, "SSI Receive Configuration Register (SRCR)," for more details on the relevant bits in the STCR and SRCR registers.

46.2 External Signal Description

46.2.1 Overview

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) module or directly as well. See the AUDMUX chapter for programming details of various multiplexing options.

Table 46-4. Signal Properties

Name	Port	I/O	Function	Reset State	Pull up
SRCK	—	I/O	Serial Receive Clock	0	Passive
SRFS	—	I/O	Serial Receive Frame Sync	0	Passive
SRXD	—	I	Serial Receive Data	—	—
STCK	—	I/O	Serial Transmit Clock	0	Passive
STFS	—	I/O	Serial Transmit Frame Sync	0	Passive
STXD	—	O	Serial Transmit Data	0	Passive

46.2.2 Detailed Signal Descriptions

46.2.2.1 SRCK—Serial Receive Clock

The SRCK port can be used as either an input or an output. This clock signal is used by the receiver in asynchronous mode and is always continuos. During synchronous mode, the STCK port is used instead for clocking in data. In SSI synchronous modes, this port can be used as an output port for the oversampling clock, (ccm_ssi_clk) e.g. In I^2S master mode, this port can be used to output ccm_ssi_clk to external CODEC.

46.2.2.2 SRFS—Serial Receive Frame Sync

The SRFS port can be used as either an input or an output. The frame sync is used by the receiver to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur

one bit before the transfer of data or right at the transfer of data. If SRFS is configured as input, the external device should drive SRFS during rising edge of STCK or SRCK.

46.2.2.3 SRXD—Serial Receive Data

The SRXD port is an input and is used to bring serial data into the Receive Data Shift Register.

46.2.2.4 STCK—Serial Transmit Clock

The STCK port can be used as either an input or an output. This clock signal is used by the transmitter and can be either continuous or gated. During Gated Clock mode, data on the STCK port is valid only during the transmission of data, otherwise it is pulled to the inactive state. In Synchronous mode, this port is used by both the transmit and receive sections.

46.2.2.5 STFS—Serial Transmit Frame Sync

The STFS port can be used as either an input or an output. The frame sync is used by the transmitter to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. In Synchronous mode, this port is used by both the transmit and receive sections. In Gated Clock mode, frame sync signals are not used. If STFS is configured as input, the external device should drive STFS during rising edge of STCK if TSCKP is +ve edge triggered. The external device should drive STFS during falling edge of STCK if TSCKP is -ve edge triggered.

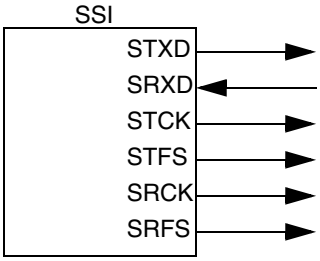
46.2.2.6 STXD—Serial Transmit Data

The STXD port is an output and transmits data from the Serial Transmit Shift Register. The STXD port is an output port when data is being transmitted and is disabled between data word transmissions and on the trailing edge of the bit clock after the last bit of a word is transmitted.

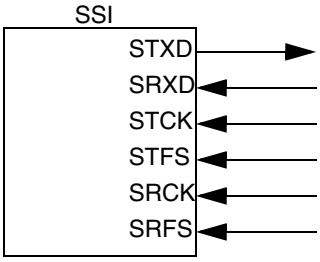
Figure 46-11, Asynchronous (SYN=0) SSI Configurations—Continuous Clock," and Figure 46-12, "Synchronous SSI Configurations—Continuous and Gated Clock," show the main SSI configurations. These ports support all transmit and receive functions with continuous or gated clock as shown.

NOTE

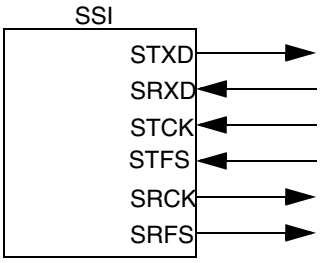
Gated clock implementations do not require the use of the frame sync ports (STFS and SRFS).



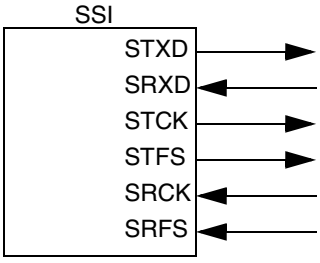
SSI Internal Continuous Clock for TX/RX (RXDIR=1,TXDIR=1,RFDIR=1,TFDIR=1,SYN=0)



SSI External Continuous Clock for TX/RX (RXDIR=0,TXDIR=0,RFDIR=0,TFDIR=0,SYN=0)



SSI Internal Continuous Clock for RX (RXDIR=1, TXDIR=0,RFDIR=1,TFDIR=0, SYN=0)
SSI External Continuous Clock for TX



SSI Internal Continuous Clock for TX (RXDIR=0, TXDIR=1, RFDIR=0, TFDIR=1, SYN=0)
SSI EXternal Continuous Clock for RX

0xBASE_48 (STMSK)	SSI Transmit Time Slot Mask Register	R/W	0x0000_0000	46.3.3.20/46-64
0xBASE_4C (SRMSK)	SSI Receive Time Slot Mask Register	R/W	0x0000_0000	46.3.3.21/46-65
0xBASE_50 (SACCST)	SSI AC97 Channel Status Register	R	0x0000_0000	46.3.3.22/46-66
0xBASE_54 (SACCEN)	SSI AC97 Channel Enable Register	W	0x0000_0000	46.3.3.23/46-67
0xBASE_58 (SACCDIS)	SSI AC97 Channel Disable Register	W	0x0000_0000	46.3.3.24/46-68

[1]SSI Test Register is intended for debugging purposes only and is not visible to the end user.
[2]SSI Option Register intended for internal use only and is not visible to the end user.

46.3.2 Register Summary

Figure 46-14 shows the key to the register fields and Table 46-8 shows the register figure conventions.

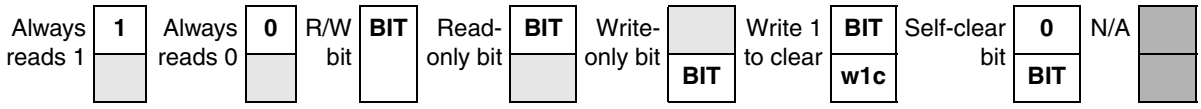

Figure 46-14. Key to Register Fields

Table 46-8. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.

Table 46-8. Register Figure Conventions (Continued)

Convention	Description
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 46-9 shows the SSI register summary.

Figure 46-16. SSI1 Transmit Data Register

Table 46-10. SSI Transmit Data Register Field Descriptions

Field	Description
31–0 STX0 STX1	SSI Transmit Data. These bits store the data to be transmitted by the SSI. These are implemented as the first word of their respective Tx FIFOs. Data written to these registers is transferred to the Transmit Shift Register (TXSR), when shifting of the previous data is complete. If both FIFOs are in use, data is alternately transferred from STX0 and STX1, to TXSR. Multiple writes to the STX registers will not result in the previous data being over-written by the subsequent data. STX1 can only be used in Two-Channel mode of operation. Protection from over-writing is present irrespective of whether the transmitter is enabled or not. Example 1: If Tx FIFO0 is in use and user writes Data1...Data16 to STX0, Data16 will not over-write Data1. Data1...Data15 are stored in the FIFO while Data16 is discarded. Example 2: If Tx FIFO0 is not in use and user writes Data1, Data2 to STX0, then Data2 will not over-write Data1 and will be discarded.

NOTE

Enable SSI (SSIEN=1) before writing to SSI Transmit Data Registers.

46.3.3.2 SSI Transmit FIFO 0 & 1 Registers

The SSI Transmit FIFO registers are 15x32-bit registers. These registers are not directly accessible by the end user. Transmit Shift Register (TXSR) receives its values from these FIFO registers. Transmitted data is first-in-first-out. When the Transmit Interrupt Enable (TIE) bit in the SIER and either of the Transmit FIFO Empty Enable (TFE0 or 1) bits in the SIER are set, the core is interrupted whenever the number of empty slots exceed or are equal to the selected threshold value of corresponding Tx-FIFO.

46.3.3.3 SSI Transmit Shift Register (TXSR)

The SSI Transmit Shift Register (TXSR) is a 24-bit shift register that contains the data being transmitted. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted out to the Serial Transmit Data (STXD) port by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted out to the STXD port by the selected (internal/external) gated clock. The Word Length control bits (WL[3:0]) in the STCCR (described in SSI Transmit and Receive Clock Control Registers) determine the number of bits to be shifted out of the TXSR before it is considered empty and can be written to again. This word length can be 8, 10, 12, 16, 18, 20, 22 or 24 bits. The data to be transmitted occupies the most significant portion of the shift register if TXBIT0 is ‘0’, otherwise it occupies the least significant portion. The unused portion of the register is ignored. Data is always shifted out of this register with the Most Significant Bit (MSB) first when the SHFD bit of the STCR is cleared. If this bit is set, the Least Significant Bit (LSB) is shifted out first. Figure 46-17 through Figure 46-20 show the transmitter loading and shifting operation. The figures show the working for some WL values, the same can be extended for other values.

Figure 46-22. SSI1 Receive Data Register

Table 46-11. SSI_1 Receive Data Register Field Descriptions

Field	Description
31–0 SRX0 SRX1	SSI Receive Data. These bits store the data received by the SSI. These are implemented as the first word of their respective Rx FIFOs. These bits receive data from the RXSR depending on the mode of operation. In case both FIFOs are in use, data is transferred to each data register alternately. SRX1 can only be used in Two-Channel mode of operation.

46.3.3.5 SSI Receive FIFO 0 & 1 Registers

The SSI Receive FIFO Registers are 15x32-bit registers. These registers are not directly accessible by the end user (except in SSI test mode). They always accepts data from the Receive Shift Register (RXSR). The core is interrupted when the data level in either of the SSI Receive FIFOs reaches the selected threshold, if the associated interrupt is enabled.

46.3.3.6 SSI Receive Shift Register (RXSR)

The SSI Receive Shift Register (RXSR) is a 24-bit, shift register that receives incoming data from the serial receive data SRXD port. This register is not directly accessible by the end user. When a continuous clock is used, data is shifted in by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted in by the selected (internal/external) gated clock. Data is assumed to be received MSB first if the SHFD bit of the SRCR is cleared. If this bit is set, the data is received LSB first. Data is transferred to the appropriate SSI Receive Data Register (SRX0/1) or Receive FIFOs (if the receive FIFO is enabled and the corresponding SRX is full) after 8, 10, 12, 16, 18, 20, 22 or 24 bits have been shifted in depending on the WL[3:0] control bits. For receiving less than 24 bits of data, LSB bits are appended with zero. The following figures show the receiver loading and shifting operation. The figures show the working for some WL values, the same can be extended for other values.

46.3.3.7 SSI Control Register (SCR)

The SSI Control Register (SCR) is a 10-bit register used to set up the SSI. SSI reset is controlled by bit 0 in the SCR. SSI operating modes are also selected in this register (except AC97 mode which is selected in SACNT register).

See Figure 46-27 for illustration of valid bits in SSI Control Register and Table 46-12 for description of the bit fields in the register.

Figure 46-27. SSI Control Register

Table 46-12. SSI Control Register Field Descriptions

Field	Description
31-13	Reserved
12 SYNC_TX_FS	SYNC_FS_TX bit provides a safe window for TE to be visible to the internal circuit which is just after FS occurrence. When SYNC_TX_FS is set, TE(SCR[1]) gets latched on FS occurrence & latched TE is used to enable/disable SSI transmitter. TE needs setup of 2 bit-clock cycles before occurrence of FS. If TE is changed within 2 bit-clock cycles of FS occurrence, there is high probability that TE will be latched on next FS. Note : With TFR_CLK_DIS feature on, TE is used directly to enable transmitter in following cases (i) Sync mode & Rx disabled (ii) Async Mode. Latched-TE is used to disable the transmitter. This bit has no relevance in gated mode and AC97 mode. 0 - TE not latched with FS occurrence & used directly for transmitter enable/disable. 1 - TE latched with FS occurrence & latched-TE used for transmitter enable/disable.
11 RFR_CLK_DIS	Receive Frame Clock Disable. This bit provide option to keep the Frame-sync and Clock enabled or disabled after current receive frame, in which receiver is disabled by clearing RE bit. Writing to this bit has effect only when RE is disabled. 0 Continue Frame-sync/Clock generation after current frame during which RE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where receiver is already disabled in current or previous frames.

Table 46-12. SSI Control Register Field Descriptions (Continued)

Field	Description
10 TFR_CLK_DIS	Transmit Frame Clock Disable. This bit provide option to keep the Frame-sync and Clock enabled or disabled after current transmit frame, in which transmitter is disabled by clearing TE bit. Writing to this bit has effect only when SSI is enabled TE is disabled. 0 Continue Frame-sync/Clock generation after current frame during which TE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received. 1 Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where transmitter is already disabled in current or previous frames.
9 CLK_IST	Clock Idle State. This bit controls the idle state of the transmit clock port during SSI internal gated mode. Note: When Clock idle state is '1' the clock polarity should always be negedge triggered and when Clock idle = '0' the clock polarity should always be positive edge triggered. 0 Clock idle state is '0'. 1 Clock idle state is '1'.
8 TCH_EN	Two-Channel Operation Enable. This bit allows SSI to operate in the two-channel mode.In this mode while receiving, the RXSR transfers data to SRX0 and SRX1 alternately and while transmitting, data is alternately transferred from STX0 and STX1 to TXSR. For an even number of slots, Two-Channel Operation can be enabled to optimize usage of both FIFOs or disabled as in the case of odd number of active slots. This feature is especially useful in I2S mode, where data for Left Speaker can be placed in Tx-FIFO0 and for Right speaker in Tx-FIFO1. 0 Two-channel mode disabled. 1 Two-channel mode enabled.
7 SYS_CLK_EN	System Clock (Oversampling Clock) Enable. When set, this bit allows the SSI to output the (ccm_ssi_clk) at the SRCK port, provided that synchronous mode, and transmit internal clock mode are set. The relationship between bit clock and ccm_ssi_clk is determined by DIV2, PSR, and PM bits. This feature is especially useful in I2S Master mode to output oversampling clock on SRCK port. 0 ccm_ssi_clk not output on SRCK port. 1 ccm_ssi_clk output on SRCK port.
6–5 I2S MODE[1:0]	I2S Mode Select. These bits allow the SSI to operate in Normal, I2S Master or I2S Slave mode. See Section 46.1.2.4 for a detailed description of I2S Mode of operation. See Table 46-2 ("Mode Selection") for details regarding settings.
4 SYN	Synchronous Mode. This bit controls whether SSI is in synchronous mode or not. In synchronous mode, the transmit and receive sections of SSI share a common clock port (STCK) and frame sync port (STFS). 0 Asynchronous mode selected. 1 Synchronous mode selected.
3 NET	Network Mode. This bit controls whether SSI is in network mode or not. 0 Network mode not selected. 1 Network mode selected.
2 RE	Receive Enable. This control bit enables the receive section of the SSI. When this bit is enabled, data reception starts with the arrival of the next frame sync. If data is being received when this bit is cleared, data reception continues until the end of the current frame and then stops. If this bit is set again before the second to last bit of the last time slot in the current frame, then reception continues without interruption. RE should not be toggled in the same frame. 0 Receive section disabled. 1 Receive section enabled.

Table 46-12. SSI Control Register Field Descriptions (Continued)

Field	Description
1 TE	Transmit Enable. This control bit enables the transmit section of the SSI. It enables the transfer of the contents of the STX registers to the TXSR and also enables the internal transmit clock. The transmit section is enabled when this bit is set and a frame boundary is detected. When this bit is cleared, the transmitter continues to send data until the end of the current frame and then stops. Data can be written to the STX registers with the TE bit cleared (the corresponding TDE bit will be cleared). If the TE bit is cleared and then set again before the second to last bit of the last time slot in the current frame, data transmission continues without interruption. The normal transmit enable sequence is to write data to the STX register(s) and then set the TE bit. The normal disable sequence is to clear the TE and TIE bits after the TDE bit is set. In gated clock mode, clearing the TE bit results in the clock stopping after the data currently in TXSR has shifted out. When the TE bit is set, the clock starts immediately (for internal gated clock mode). TE should not be toggled in the same frame. After enabling/disabling transmission, SSI expects 4 setup clock cycles before arrival of frame-sync for frame-sync to be accepted by SSI. In case of fewer clock cycles, there is high probability of the frame-sync to get missed. Note: If continuos clock is not provided, SSI expects 6 clock cycles before arrival of frame-sync for frame-sync to be accepted by SSI. 0 Transmit section disabled. 1 Transmit section enabled.
0 SSIEN	SSIEN — SSI Enable This bit is used to enable/disable the SSI. When disabled, all SSI status bits are preset to the same state produced by the power-on reset, all control bits are unaffected, the contents of Tx and Rx FIFOs are cleared. When SSI is disabled, all internal clocks are disabled (except register access clock). 0 SSI is disabled. 1 SSI is enabled.

46.3.3.8 SSI Interrupt Status Register (SISR)

The SSI Interrupt Status Register (SISR) is used to monitor the SSI. This register is used by the core to interrogate the status of the SSI. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of AISR register are not generated. The status bits are described in the following table.

NOTE

- SSI Status flags are valid when SSI is enabled.
- See Section 46.4.3, “Receive Interrupt Enable Bit Description,” and Section 46.4.4, “Transmit Interrupt Enable Bit Description,” for interrupt source mapping.
- All the flags in the SISR are updated after the first bit of the next SSI word has completed transmission or reception. Certain status bits (ROE0/1 and TUE0/1) are cleared by writing 1 to the corresponding interrupt status bit in SISR.

See Figure 46-28 for illustration of valid bits in SSI Interrupt Register and Table 46-13 for description of the bit fields in the register.

Figure 46-28. SSI Interrupt Status Register

Table 46-13. SSI Interrupt Status Register Field Descriptions

Field	Description
31–19	Reserved
24 RFRC	Receive Frame Complete. This flag is set at the end of the frame during which Receiver is disabled. If Receive Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Receive Frame & Clock are disabled. See description of RFR_CLK_DIS (add cross reference) bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled. 0 End of Frame not reached 1 End of frame reached after disabling RE or disabling RFR_CLK_DIS, when receiver is already disabled.
23 TFRC	Transmit Frame Complete. This flag is set at the end of the frame during which Transmitter is disabled. If Transmit Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Transmit Frame & Clock are disabled. See description of TFR_CLK_DIS (add cross reference) bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled. 0 End of Frame not reached 1 End of frame reached after disabling TE or disabling TFR_CLK_DIS, when transmitter is already disabled.
18 CMDAU	Command Address Register Updated. This bit causes the Command Address Updated interrupt (when CMDAU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Address. This bit is cleared on reading the SACADD register. 0 No change in SACADD register. 1 SACADD register updated with different value.
17 CMDDU	Command Data Register Updated. This bit causes the Command Data Updated interrupt (when CMDDU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Data. This bit is cleared on reading the SACDAT register. 0 No change in SACDAT register. 1 SACDAT register updated with different value.

Table 46-13. SSI Interrupt Status Register Field Descriptions (Continued)

Field	Description
16 RXT	Receive Tag Updated. This status bit is set each time there is a difference in the previous and current value of the received tag. It causes the Receive Tag Interrupt (if RXT_EN bit is set). This bit is cleared on reading the SATAG register. 0 No change in SATAG register. 1 SATAG register updated with different value.
15 RDR1	Receive Data Ready 1. This flag bit is set when SRX1 or Rx FIFO 1 is loaded with a new value and Two-Channel mode is selected. RDR1 is cleared when the Core reads the SRX1 register. If Rx FIFO 1 is enabled, RDR1 is cleared when the FIFO is empty. If RIE and RDR1_EN are set, a Receive Data 1 interrupt request is issued on setting of RDR1 bit in case Rx FIFO1 is disabled, if the FIFO is enabled, the interrupt is issued on RFF1 assertion. The RDR1 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
14 RDR0	Receive Data Ready 0. This flag bit is set when SRX0 or Rx FIFO 0 is loaded with a new value. RDR0 is cleared when the Core reads the SRX0 register. If Rx FIFO 0 is enabled, RDR0 is cleared when the FIFO is empty. If RIE and RDR0_EN are set, a Receive Data 0 interrupt request is issued on setting of RDR0 bit in case Rx FIFO0 is disabled, if the FIFO is enabled, the interrupt is issued on RFF0 assertion. The RDR0 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
13 TDE1	Transmit Data Register Empty 1. This flag is set whenever data is transferred to TXSR from STX1 register and Two-Channel mode is selected. If Tx FIFO1 is enabled, this occurs when there is at least one empty slot in STX1 or Tx FIFO1. If Tx FIFO1 is not enabled, this occurs when the contents of STX1 are transferred to TXSR. The TDE1 bit is cleared when the Core writes to STX1. If TIE and TDE1_EN are set, an SSI Transmit Data 1 interrupt request is issued on setting of TDE1 bit. The TDE1 bit is cleared by POR and SSI reset. 0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
12 TDE0	Transmit Data Register Empty 0. This flag is set whenever data is transferred to TXSR from STX0 register. If Tx FIFO 0 is enabled, this occurs when there is at least one empty slot in STX0 or Tx FIFO 0. If Tx FIFO 0 is not enabled, this occurs when the contents of STX0 are transferred to TXSR. The TDE0 bit is cleared when the Core writes to STX0. If TIE and TDE0_EN are set, an SSI Transmit Data 0 interrupt request is issued on setting of TDE0 bit. The TDE0 bit is cleared by POR and SSI reset. 0 Data available for transmission. 1 Data needs to be written by the Core for transmission.
11 ROE1	Receiver Overrun Error 1. This flag is set when the RXSR is filled and ready to transfer to SRX1 register or to Rx FIFO 1 (when enabled) and these are already full and Two-Channel mode is selected. If Rx FIFO 1 is enabled, this is indicated by RFF1 flag, else this is indicated by the RDR1 flag. The RXSR is not transferred in this case. The ROE1 flag causes an interrupt if RIE and ROE1_EN are set. The ROE1 bit is cleared by POR and SSI reset. It is also cleared by writing ‘1’ to this bit. Clearing the RE bit does not affect the ROE1 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.

Table 46-13. SSI Interrupt Status Register Field Descriptions (Continued)

Field	Description
10 ROE0	Receiver Overrun Error 0. This flag is set when the RXSR is filled and ready to transfer to SRX0 register or to Rx FIFO 0 (when enabled) and these are already full. If Rx FIFO 0 is enabled, this is indicated by RFF0 flag, else this is indicated by the RDR0 flag. The RXSR is not transferred in this case. The ROE0 flag causes an interrupt if RIE and ROE0_EN are set. The ROE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE0 bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
9 TUE1	Transmitter Underrun Error 1. This flag is set when the TXSR is empty (no data to be transmitted), the TDE1 flag is set, a transmit time slot occurs and the SSI is in Two-Channel mode. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE1 flag causes an interrupt if TIE and TUE1_EN are set. The TUE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
8 TUE0	Transmitter Underrun Error 0. This flag is set when the TXSR is empty (no data to be transmitted), the TDE0 flag is set and a transmit time slot occurs. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set). The TUE0 flag causes an interrupt if TIE and TUE0_EN are set. The TUE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. 0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.
7 TFS	Transmit Frame Sync. This flag indicates the occurrence of transmit frame sync. Data written to the STX registers during the time slot when the TFS flag is set, is sent during the second time slot (in Network mode) or in the next first time slot (in Normal mode). In Network mode, the TFS bit is set during transmission of the first time slot of the frame and is then cleared when starting transmission of the next time slot. In Normal mode, this bit is high for the first time slot. This flag causes an interrupt if TIE and TFS_EN are set. The TFS bit is cleared by POR and SSI reset. 0 No Occurrence of Transmit frame sync. 1 Transmit frame sync occurred during transmission of last word written to STX registers.
6 RFS	Receive Frame Sync. This flag indicates the occurrence of receive frame sync. In Network mode, the RFS bit is set when the first slot of the frame is being received. It is cleared when the next slot begins to be received. In Normal mode, this bit is always high. This flag causes an interrupt if RIE and RFS_EN are set. The RFS bit is cleared by POR and SSI reset. 0 No Occurrence of Receive frame sync. 1 Receive frame sync occurred during reception of next word in SRX registers.
5 TLS	Transmit Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last time slot of the frame. TLS is set at the start of the last transmit time slot and causes the SSI to issue an interrupt (if TIE and TLS_EN are set). TLS is not generated when frame rate is 1 in normal mode of operation. TLS is cleared when the SISR is read with this bit set. The TLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last transmit time slot of frame.

Table 46-13. SSI Interrupt Status Register Field Descriptions (Continued)

Field	Description
4 RLS	Receive Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last receive time slot of the frame. RLS is set at the end of the last time slot and causes the SSI to issue an interrupt (if RIE and RLS_EN are set). RLS is cleared when the SISR is read with this bit set. The RLS bit is cleared by POR and SSI reset. 0 Current time slot is not last time slot of frame. 1 Current time slot is the last receive time slot of frame.
3 RFF1	Receive FIFO Full 1. This flag is set when Rx FIFO1 is enabled, the data level in Rx FIFO1 reaches the selected Rx FIFO WaterMark 1 (RFWM1) threshold and the SSI is in Two-Channel mode. The setting of RFF1 only causes an interrupt when RIE and RFF1_EN are set, Rx FIFO1 is enabled and the Two-Channel mode is selected. RFF1 is automatically cleared when the amount of data in Rx FIFO1 falls below the threshold. The RFF1 bit is cleared by POR and SSI reset. When Rx FIFO1 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read. 0 Space available in Receive FIFO1. 1 Receive FIFO1 is full.
2 RFF0	Receive FIFO Full 0. This flag is set when Rx FIFO0 is enabled and the data level in Rx FIFO0 reaches the selected Rx FIFO WaterMark 0 (RFWM0) threshold. The setting of RFF0 only causes an interrupt when RIE and RFF0_EN are set and Rx FIFO0 is enabled. RFF0 is automatically cleared when the amount of data in Rx FIFO0 falls below the threshold. The RFF0 bit is cleared by POR and SSI reset. When Rx FIFO0 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read. 0 Space available in Receive FIFO0. 1 Receive FIFO0 is full.
1 TFE1	Transmit FIFO Empty 1. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 1 (TFWM1) threshold and the Two-Channel mode is selected. The setting of TFE1 only causes an interrupt when TIE and TFE1_EN are set, Tx FIFO1 is enabled and Two-Channel mode is selected. The TFE1 bit is automatically cleared when the data level in Tx FIFO1 becomes more than the amount specified by the watermark bits. The TFE1 bit is set by POR and SSI reset. 0 Transmit FIFO1 has data for transmission. 1 Transmit FIFO1 is empty.
0 TFE0	Transmit FIFO Empty 0. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 0 (TFWM0) threshold. The setting of TFE0 only causes an interrupt when TIE and TFE0_EN are set and Tx FIFO0 is enabled. The TFE0 bit is automatically cleared when the data level in Tx FIFO0 becomes more than the amount specified by the watermark bits. The TFE0 bit is set by POR and SSI reset. 0 Transmit FIFO0 has data for transmission. 1 Transmit FIFO0 is empty.

46.3.3.9 SSI Interrupt Enable Register (SIER)

The SSI Interrupt Enable Register (SIER) is a 25-bit register used to set up the SSI interrupts and DMA requests. See Figure 46-29 for illustration of valid bits in SSI Interrupt Enable Register and Table 46-14 for description of the bit fields in the register.

Figure 46-29. SSI Interrupt Enable Register

Table 46-14. SSI Interrupt Enable Register Field Descriptions

Field	Description
31–23	Reserved
24-23 Enable Bits	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
22 RDMAE	Receive DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the RFF0/1 bits in the SISR are set and if the corresponding RFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding RDR bit is set. 0 SSI Receiver DMA requests disabled. 1 SSI Receiver DMA requests enabled.
21 RIE	Receive Interrupt Enable. This control bit allows the SSI to issue receiver related interrupts to the Core. See Section 46.4.3 for a detailed description of this bit. 0 SSI Receiver Interrupt requests disabled. 1 SSI Receiver Interrupt requests enabled.
20 TDMAE	Transmit DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the TFE0/1 bits in the SISR are set and if the corresponding TFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding TDE bit is set. 0 SSI Transmitter DMA requests disabled. 1 SSI Transmitter DMA requests enabled.

Table 46-14. SSI Interrupt Enable Register Field Descriptions (Continued)

Field	Description
19 TIE	Transmit Interrupt Enable. This control bit allows the SSI to issue transmitter data related interrupts to the Core. See Section 46.4.4 for a detailed description of this bit. 0 SSI Transmitter Interrupt requests disabled. 1 SSI Transmitter Interrupt requests enabled.
18–0 Enable Bits	Enable Bit. Each bit controls whether the corresponding status bit in SISR can issue an interrupt to the Core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.

46.3.3.10 SSI Transmit Configuration Register (STCR)

The SSI Transmit Configuration Register (STCR) is a read/write control registers used to direct the transmit operation of the SSI. STCR controls the direction of the bit clock and frame sync ports, STCK and STFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all STCR bits. However, SSI reset does not affect the STCR bits. The STCR bits are described in the following paragraphs. See Table 46-7 for the programming model of the SSI. The SSI Control Register (SCR) must first be set to enable interrupts. Next, the SSI interrupt bit in the Interrupt Enable Register (SIER) must be set to enable the interrupt. Finally, the interrupt can be enabled from within the SSI.

See Figure 46-30 for illustration of valid bits in SSI Transmit Configuration Register and Table 46-15 for description of the bit fields in the register.

0xBASE_1C (STCR) Access: User read/write

Figure 46-30. SSI Transmit Configuration Register

Table 46-15. SSI Transmit Configuration Register Field Descriptions

Field	Description
31–10	Reserved
9 TXBIT0	Transmit Bit 0. This control bit allows SSI to transmit the data word from bit position 0 or 15/31 in the transmit shift register. The shifting data direction can be MSB or LSB first, controlled by the TSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of transmit shift register (MSB aligned). 1 Shifting with respect to bit 0 of transmit shift register (LSB aligned).
8 TFEN1	Transmit FIFO Enable 1. This bit enables transmit FIFO 1. When enabled, the FIFO allows 15 samples to be transmitted by the SSI (per channel) (a 9th sample can be shifting out) before TDE1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 1 disabled. 1 Transmit FIFO 1 enabled.
7 TFEN0	Transmit FIFO Enable 0. This bit enables transmit FIFO 0. When enabled, the FIFO allows 15 samples to be transmitted by the SSI per channel (a 9th sample can be shifting out) before TDE0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 0 disabled. 1 Transmit FIFO 0 enabled.
6 TFDIR	Transmit Frame Direction. This bit controls the direction and source of the transmit frame sync signal. Internally generated frame sync signal is sent out through the STFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 TXDIR	Transmit Clock Direction. This bit controls the direction and source of the clock signal used to clock the TXSR. Internally generated clock is output through the STCK port. External clock is taken from this port. See Table 46-5 for details of clock pin configurations 0 Transmit Clock is external. 1 Transmit Clock generated internally.
4 TSHFD	Transmit Shift Direction. This bit controls whether the MSB or LSB will be transmitted first in a sample. **Note:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (TSHFD cleared). 0 Data transmitted MSB first. 1 Data transmitted LSB first.
3 TSCKP	Transmit Clock Polarity. This bit controls which bit clock edge is used to clock out data for the transmit section. 0 Data clocked out on rising edge of bit clock. 1 Data clocked out on falling edge of bit clock. Note: TSCKP is 0 CLK_IST = 0; TSCKP is 1CLK_IST = 1
2 TFSI	Transmit Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the transmit section of SSI. 0 Transmit frame sync is active high. 1 Transmit frame sync is active low.

Table 46-15. SSI Transmit Configuration Register Field Descriptions (Continued)

Field	Description
1 TFSL	Transmit Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the transmit section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Transmit frame sync is one-word long. 1 Transmit frame sync is one-clock-bit long.
0 TEFS	Transmit Early Frame Sync. This bit controls when the frame sync is initiated for the transmit section. The frame sync signal is deasserted after one bit-for-bit length frame sync and after one word-for-word length frame sync. In case of synchronous operation, the frame sync can also be initiated on receiving the first bit of data. 0 Transmit frame sync initiated as the first bit of data is transmitted. 1 Transmit frame sync is initiated one bit before the data is transmitted.

46.3.3.11 SSI Receive Configuration Register (SRCR)

The SSI Receive Configuration Register (SRCR) is a read/write control registers used to direct the receive operation of the SSI. SRCR controls the direction of the bit clock and frame sync ports, SRCK and SRFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SRCR bits. However, SSI reset does not affect the SRCR bits. See Figure 46-31 for illustration of valid bits in SSI Receive Configuration Register and Table 46-16 for description of the bit fields in the register.

Figure 46-31. SSI Receive Configuration Register

Table 46-16. SSI Receive Configuration Register Field Descriptions

Field	Description
31–11	Reserved
10 RXEXT	Receive Data Extension. This control bit allows SSI to store the received data word in sign extended form. This bit affects data storage only in case received data is LSB aligned (SRCR[9]=1) 0 Sign extension turned off. 1 Sign extension turned on.

Table 46-16. SSI Receive Configuration Register Field Descriptions (Continued)

Field	Description
9 RXBIT0	Receive Bit 0. This control bit allows SSI to receive the data word at bit position 0 or 15/31 in the receive shift register. The shifting data direction can be MSB or LSB first, controlled by the RSHFD bit. 0 Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of receive shift register (MSB aligned). 1 Shifting with respect to bit 0 of receive shift register (LSB aligned).
8 RFEN1	Receive FIFO Enable 1. This bit enables receive FIFO 1. When enabled, the FIFO allows 15 samples to be received by the SSI per channel (a 16th sample can be shifting in) before RDR1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 1 disabled. 1 Receive FIFO 1 enabled.
7 RFEN0	Receive FIFO Enable 0. This bit enables receive FIFO 0. When enabled, the FIFO allows 15 samples to be received by the SSI (per channel) (a 16th sample can be shifting in) before RDR0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 0 disabled. 1 Receive FIFO 0 enabled.
6 RFDIR	Receive Frame Direction. This bit controls the direction and source of the receive frame sync signal. Internally generated frame sync signal is sent out through the SRFS port and external frame sync is taken from the same port. 0 Frame Sync is external. 1 Frame Sync generated internally.
5 RXDIR	Receive Clock Direction. This bit controls the direction and source of the clock signal used to clock the RXSR. Internally generated clock is output through the SRCK port. External clock is taken from this port. See Table 46-5 for details on clock pin configurations. 0 Receive Clock is external. 1 Receive Clock generated internally.
4 RSHFD	Receive Shift Direction. This bit controls whether the MSB or LSB will be received first in a sample. **Note:** The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (RSHFD cleared). 0 Data received MSB first. 1 Data received LSB first.
3 RSCKP	Receive Clock Polarity. This bit controls which bit clock edge is used to latch in data for the receive section. 0 Data latched on rising edge of bit clock. 1 Data latched on falling edge of bit clock.
2 RFSI	Receive Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the receive section of SSI. 0 Receive frame sync is active high. 1 Receive frame sync is active low.

Table 46-16. SSI Receive Configuration Register Field Descriptions (Continued)

Field	Description
1 RFSL	Receive Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the receive section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0]. 0 Receive frame sync is one-word long. 1 Receive frame sync is one-clock-bit long.
0 REFS	Receive Early Frame Sync. This bit controls when the frame sync is initiated for the receive section. The frame sync is disabled after one bit-for-bit length frame sync and after one word-for-word length frame sync. 0 Receive frame sync initiated as the first bit of data is received. 1 Receive frame sync is initiated one bit before the data is received.

46.3.3.12 SSI Transmit and Receive Clock Control Registers (STCCR & SRCCR)

The SSI Transmit and Receive Control (STCCR and SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock and Reset Module (CRM) can source the SSI clock (ccm_ssi_clk) from multiple sources and perform fractional division to support commonly used audio bit rates. The CRM can maintain the ccm_ssi_clk frequency at a constant rate even in cases where the ipg_clk frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The STCCR register is dedicated to the transmit section, and the SRCCR register is dedicated to the receive section except in Synchronous mode, in which the STCCR register controls both the receive and transmit sections. Power-on reset clears all STCCR and SRCCR bits. SSI reset does not affect the STCCR and SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the STCCR and SRCCR registers are the same, the contents of these two registers can be programmed differently.

See Figure 46-32 for illustration of valid bits in SSI Transmit Clock Control Register and Table 46-17 for description of the bit fields for both SSI Transmit and Receive Clock Control registers.

Figure 46-33. SSI Receive Clock Control Register

Table 46-17. SSI Transmit and Receive Clock Control Register Field Descriptions

Field	Description
31–19	Reserved
18 DIV2	Divide By 2. This bit controls a divide-by-two divider in series with the rest of the prescalers. 0 Divider bypassed. 1 Divider used to divide clock by 2.
17 PSR	Prescaler Range. This bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. It extends the range of the prescaler for those cases where a slower bit clock is required. 0 Prescaler bypassed. 1 Prescaler used to divide clock by 8.
16–13 WL3–WL0	Word Length Control. These bits are used to control the length of the data words being transferred by the SSI. These bits control the Word Length Divider in the Clock Generator. They also control the frame sync pulse length when the FSL bit is cleared. In I2S Master mode, the SSI works with a fixed word length of 32, and the WL bits are used to control the amount of valid data in those 32 bits. See Table 46-18 for details of data word lengths supported by SSI. In AC97 Mode of operation, if word length is set to any value other than 16 bits, it will result in a word length of 20 bits.

Table 46-17. SSI Transmit and Receive Clock Control Register Field Descriptions (Continued)

Field	Description

Table 46-18. SSI Data Length

WL3	WL2	WL1	WL0	Number of Bits/Word	Supported in Implementation
0	0	0	0	2	No
0	0	0	1	4	No
0	0	1	0	6	No
0	0	1	1	8	Yes
0	1	0	0	10	Yes
0	1	0	1	12	Yes

1	1	0	0	26	No
1	1	0	1	28	No
1	1	1	0	30	No
1	1	1	1	32	No

12–8 DC4–DC0	Frame Rate Divider Control. These bits are used to control the divide ratio for the programmable frame rate dividers. The divide ratio works on the word clock. In Normal mode, this ratio determines the word transfer rate. In Network mode, this ratio sets the number of words per frame. The divide ratio ranges from 1 to 32 in Normal mode and from 2 to 32 in Network mode. In Normal mode, a divide ratio of 1 (DC=00000) provides continuous periodic data word transfer. A bit-length frame sync must be used in this case. These bits can be programmed with values ranging from “00000” to “11111” to control the number of words in a frame.
7–0 PM7–PM0	Prescaler Modulus Select. These bits control the prescale divider in the clock generator. This prescaler is used only in Internal Clock mode to divide the internal clock (ccm_ssi_clk). The bit clock output is available at the clock port. A divide ratio from 1 to 256 (PM[7:0] = 0x00 to 0xFF) can be selected. See Section 46.4.2.2 for details regarding settings.

46.3.3.13 SSI FIFO Control/Status Register (SFCSR)

1100	RFF set when more than or equal to 12 data word have been written to the Receive FIFO. Set when RxFIFO = 12,13.....15 data words
1101	RFF set when more than or equal to 13 data word have been written to the Receive FIFO. Set when RxFIFO = 13,14,15data words
1110	RFF set when more than or equal to 14 data word have been written to the Receive FIFO. Set when RxFIFO = 14,15 data words
1111	RFF set when 15 data word have been written to the Receive FIFO (default). Set when RxFIFO = 15 data words

Table 46-20. SSI FIFO Control/Status Register Field Descriptions (Continued)

Field	Description
19–16 TFWM1[3:0]	Transmit FIFO Empty WaterMark 1. These bits control the threshold at which the TFE1 flag will be set. The TFE1 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. See Table 46-22 for details regarding settings for transmit FIFO watermark bits.

Table 46-22. Transmit FIFO WaterMark Bit Description

Bits	Description
0000	Reserved
0001	TFE set when there are more than or equal to 1 empty slots in Transmit FIFO. (default) Transmit FIFO empty is set when TxFIFO <= 14 data.
0010	TFE set when there are more than or equal to 2 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 13 data.
0011	TFE set when there are more than or equal to 3 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 12 data.
0100	TFE set when there are more than or equal to 4 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 11 data.
0101	TFE set when there are more than or equal to 5 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 10 data.
0110	TFE set when there are more than or equal to 6 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 9 data.
0111	TFE set when there are more than or equal to 7 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 8 data.
1000	TFE set when there are more than or equal to 8 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 7 data.
1001	TFE set when there are more than or equal to 9 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 6 data.
1010	TFE set when there are more than or equal to 10 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 5 data.
1011	TFE set when there are more than or equal to 11 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 4 data.
1100	TFE set when there are more than or equal to 12 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 3 data.
1101	TFE set when there are more than or equal to 13 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 2 data.
1110	TFE set when there are more than or equal to 14 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 1 data.
1111	TFE set when there are 15 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO = 0 data.

Table 46-20. SSI FIFO Control/Status Register Field Descriptions (Continued)

Field	Description
15–12 RFCNT0[3:0]	Receive FIFO Counter 0. These bits indicate the number of data words in Receive FIFO 0. See Table 46-19 for details regarding settings for receive FIFO counter bits.
11–8 TFCNT0[3:0]	Transmit FIFO Counter 0. These bits indicate the number of data words in Transmit FIFO 0. See Table 46-20 for details regarding settings for transmit FIFO counter bits.
7–4 RFWM0[3:0]	Receive FIFO Full WaterMark 0. These bits control the threshold at which the RFF0 flag will be set. The RFF0 flag is set whenever the data level in Rx FIFO 0 reaches the selected threshold. See Table 46-21 for details regarding settings for receive FIFO watermark bits.
3–0 TFWM0[3:0]	Transmit FIFO Empty WaterMark 0. These bits control the threshold at which the TFE0 flag will be set. The TFE0 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. See Table 46-22 for details regarding settings for transmit FIFO watermark bits.

Table 46-23 indicates the status of the Transmit FIFO Empty flag, with different settings of the Transmit FIFO WaterMark bits and varying amounts of data in the Tx FIFO.

Table 46-23. Status of Transmit FIFO Empty Flag

Transmit FIFO Watermark (TFWM)	Number of data in Tx-Fifo														
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 46-21. SSI Test Register

Table 46-24. SSI Test Register Field Descriptions

Field	Description
31–16	Reserved
15 TEST	Test Mode. This bit enables the test features of SSI. When set, the RXSTATE and TXSTATE bit values get transferred to the state machine. When in test mode, the user can read the contents of a specific FIFO by writing an appropriate value to the RFCNT0/1 or TFCNT 0/1 bits (in SFCSR). 0 No effect on SSI operation. 1 SSI in Test Mode.
14 RCK2TCK	Receive Clock to Transmit Clock Loop Back. This bit connects SRCK (used as output) to STCK (used as input). 0 No effect on SSI operation. 1 SRCK to STCK loop back enabled.
13 RFS2TFS	Receive Frame to Transmit Frame Loop Back. This bit connects SRFS (used as output) to STFS (used as input). 0 No effect on SSI operation. 1 SRFS to STFS loop back enabled.
12–8 RXSTATE[4:0]	Receiver State Machine Status. These bits indicate the current status of the Receive State Machine.
7 TXD2RXD	Transmit Data to Receive Data Loop Back. This bit connects STXD to SRXD. 0 No effect on SSI operation. 1 STXD to SRXD loop back enabled.
6 TCK2RCK	Transmit Clock to Receive Clock Loop Back. This bit connects STCK (used as output) to SRCK (used as input). 0 No effect on SSI operation. 1 STCK to SRCK loop back enabled.

Table 46-24. SSI Test Register Field Descriptions (Continued)

Field	Description
5 TFS2RFS	Transmit Frame to Receive Frame Loop Back. This bit connects STFS (used as output) to SRFS (used as input). 0 No effect on SSI operation. 1 STFS to SRFS loop back enabled.
4–0 TXSTATE	Transmitter State Machine Status. These bits indicate the current status of the Transmit State Machine.

46.3.3.15 SSI Option Register (SOR)

NOTE

SSI Option Register is designed for debugging purpose only and is not intended for general user access.

See Figure 46-22 for illustration of valid bits in SSI Option Register and Table 46-25 for description of the bit fields for the register.

Figure 46-22. SSI Option Register

Table 46-25. SSI Option Register Field Descriptions

Field	Description
31–7	Reserved
6 CLKOFF	Clock Off. This bit is used to turn off the ipg_clk to further reduce power consumption. 0 No effect on SSI operation. 1 Turn off ipg_clk.
5 RX_CLR	Receiver Clear. This bit flushes the contents of Rx FIFOs. It is always read as cleared (‘0’). 0 No effect on SSI operation. 1 Flush Rx FIFOs.

Table 46-25. SSI Option Register Field Descriptions (Continued)

Field	Description
4 TX_CLR	Transmitter Clear This bit flushes the contents of Tx FIFOs. It is always read as cleared ('0'). 0 No effect on SSI operation. 1 Flush Tx FIFOs. **It is recommended that we flush Tx-FIFOs after re-enabling Transmission.
3 INIT	Initialize. The setting of this bit causes the SSI state machine to reset. 0 No effect on SSI operation. 1 Initialize SSI state machine.
2–1 WAIT[1:0]	Wait. These bits control the number wait states to be added to all transactions between the Core and SSI. The value of these bits ranges from '00' (no wait states) to '11' (three wait states).
0 SYNRST	Frame Sync Reset. This bit automatically resets the accumulation of data in Receive Data Registers (SRX0/1) and Receive FIFOs (RXFIFO 0/1) on the next frame synchronization. 0 Data accumulation not affected. 1 Reset data accumulation on Frame Synchronization.

46.3.3.16 SSI AC97 Control Register (SACNT)

See Figure 46-23 for illustration of valid bits in SSI AC97 Control Register and Table 46-26 for description of the bit fields for the register.

0xBASE_38 (SACNT) Access: User read/write

Figure 46-23. SSI AC97 Control Register

Table 46-26. SSI AC97 Control Register Field Descriptions

Field	Description
31–11	Reserved
10–5 FRDIV[5:0]	Frame Rate Divider. These bits control the frequency of AC97 data transmission/reception. They are programmed with the number of frames for which the SSI should be idle, after operating in one frame. Through these bits, AC97 frequency of operation, from 48 KHz (000000) to 1 KHz (101111) can be achieved. Sample Value: 001010 (10 Decimal) = SSI will operate once every 11 frames.

Table 46-26. SSI AC97 Control Register Field Descriptions (Continued)

Field	Description
4 WR	Write Command. This bit specifies whether the next frame will carry an AC97 Write Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bits (corresponding to Command Address and Command Data slots of the next Tx frame) are automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Write Command. 1 Next frame will have a Write Command.
3 RD	Read Command. This bit specifies whether the next frame will carry an AC97 Read Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bit (corresponding to Command Address slot of the next Tx frame) is automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Read Command. 1 Next frame will have a Read Command.
2 TIF	Tag in FIFO. This bit controls the destination of the information received in AC97 tag slot (Slot #0). 0 Tag info stored in SATAG register. 1 Tag info stored in Rx FIFO 0.
1 FV	Fixed/Variable Operation. This bit selects whether the SSI is in AC97 Fixed mode or AC97 Variable mode. 0 AC97 Fixed Mode. 1 AC97 Variable Mode.
0 AC97EN	AC97 Mode Enable. This bit is used to enable SSI AC97 operation. See Section 46.1.2.5 for details of AC97 operation. 0 AC97 mode disabled. 1 SSI in AC97 mode.

46.3.3.17 SSI AC97 Command Address Register (SACADD)

See Figure 46-24 for illustration of valid bits in SSI AC97 Command Address Register and Table 46-27 for description of the bit fields for the register.

0xBASE_3C (SACADD) Access: User read/write

Figure 46-24. SSI AC97 Command Address Register

Table 46-27. SSI AC97 Command Address Register Field Descriptions

Field	Description
31–19	Reserved
18–0 SACADD	AC97 Command Address. These bits store the Command Address Slot information (bit 19 of the slot is sent in accordance with the Read and Write Command bits in SACNT register). These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Address Slot. If the contents of these bits change due to an update, the CMDAU bit in SISR is set.

46.3.3.18 SSI AC97 Command Data Register (SACDAT)

See Figure 46-25 for illustration of valid bits in SSI AC97 Command Data Register and Table 46-28 for description of the bit fields for the register.

0xBASE_40 (SACDAT) Access: User read/write

Figure 46-25. SSI AC97 Command Data Register

Table 46-28. SSI AC97 Command Data Register

Field	Description
31–20	Reserved
19–0 SACDAT	AC97 Command Data. The outgoing Command Data Slot carries the information contained in these bits. These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Data Slot. If the contents of these bits change due to an update, the CMDDU bit in SISR is set. These bits are transmitted only during AC97 Write Command. During AC97 Read Command, 0x00000 is transmitted in time slot #2.

46.3.3.19 SSI AC97 Tag Register (SATAG)

See Figure 46-26 for illustration of valid bits in SSI AC97 Tag Register and Table 46-29 for description of the bit fields for the register.

0xBASE_44 (SATAG) Access: User read/write

Figure 46-26. SSI AC97 Tag Register

Table 46-29. SSI AC97 Tag Register Field Descriptions

Field	Description
31–16	Reserved
15–0 SATAG	AC97 Tag Value. Writing to this register (by the Core) sets the value of the Tx-Tag in AC97 fixed mode of operation. On a read, the Core gets the Rx-Tag Value received (in the last frame) from the Codec. If TIF bit in SACNT register is set, the TAG value is also stored in Rx-FIFO in addition to SATAG register. When the received Tag value changes, the RXT bit in SISR register is set. Bits SATAG[1:0] convey the Codec -ID. In current implementation only Primary Codecs are supported. Thus writing value 2'b00 to this field is mandatory.

46.3.3.20 SSI Transmit Time Slot Mask Register (STMSK)

See Figure 46-27 for illustration of valid bits in SSI Transmit Time Slot Register and Table 46-30 for description of the bit fields for the register.

0xBASE_48 (STMSK) Access: User read/write

Figure 46-27. SSI Transmit Time Slot Mask Register

Table 46-30. SSI Transmit Time Slot Mask Register Field Descriptions

Field	Description
31–0 STMSK	Transmit Mask. These bits indicate which slot has been masked in the current frame. The Core can write to this register to control the time slots in which the SSI transmits data. Each bit has info corresponding to the respective time slot in the frame. Transmit mask bits should not be used in I2S Slave mode of operation. STMSK register value must be set before enabling Transmission. 0 Valid Time Slot. 1 Time Slot masked (no data transmitted in this time slot).

46.3.3.21 SSI Receive Time Slot Mask Register (SRMSK)

See Figure 46-28 for illustration of valid bits in SSI Receive Time Slot Mask Register and Table 46-31 for description of the bit fields for the register.

0xBASE_4C (SRMSK) Access: User read/write

Figure 46-29. SSI AC97 Channel Status Register

Table 46-32. SSI AC97 Channel Status Register Field Descriptions

Field	Description
9–0 SACCST	AC97 Channel Status. These bits indicate which data slot has been enabled in AC97 variable mode operation. This register is updated in case the core enables/disables a channel through a write to SACCEN/SACCDIS register or the external codec enables a channel by sending a ‘1’ in the corresponding SLOTREQ bit. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). The contents of this register only have relevance while the SSI is operating in AC97 variable mode. Writes to this register result in an error response on the IP interface. 0 Data channel disabled. 1 Data channel enabled.

46.3.3.23 SSI AC97 Channel Enable Register (SACCEN)

See Figure 46-30 for illustration of valid bits in SSI AC97 Channel Enable Register and Table 46-33 for description of the bit fields for the register.

0xBASE_54 (SACCEN) Access: User write

Figure 46-30. SSI AC97 Channel Enable Register

Table 46-33. SSI AC97 Channel Enable Register Field Descriptions

Field	Description
9–0 SACCEN	AC97 Channel Enable. The Core writes a ‘1’ to these bits to enable an AC97 data channel. Writing a ‘0’ has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as ‘0’ by the Core. 0 Write Has no effect. 1 Write Enables the corresponding data channel.

46.3.3.24 SSI AC97 Channel Disable Register (SACCDIS)

See Figure 46-31 for illustration of valid bits in SSI AC97 Channel Disable Register and Table 46-34 for description of the bit fields for the register.

0xBASE_58 (SACCDIS) Access: User write

Figure 46-31. SSI AC97 Channel Disable Register

Table 46-34. SSI AC97 Channel Disable Register Field Descriptions

Field	Description
9–0 SACCDIS	AC97 Channel Disable. The Core writes a ‘1’ to these bits to disable an AC97 data channel. Writing a ‘0’ has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as ‘0’ by the Core. 0 Write Has no effect. 1 Write Disables the corresponding data channel.

46.4 Functional Description

46.4.1 SSI Architecture

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) module or directly as well. The AUDMUX can be configured to connect the SSI module to the chip pads in various ways. See Figure 46-1 for a block diagram of the SSI.

46.4.2 SSI Clocking

The SSI uses the following clocks:

- Bit clock — Used to serially clock the data bits in and out of the SSI port. This clock is either generated internally (from ccm_ssi_clk) or taken from external clock source (through the Tx/Rx clock ports).
- Word clock — Used to count the number of data bits per word (8, 10, 12, 16, 18, 20, 22 or 24 bits). This clock is generated internally from the bit clock.

- Frame clock (Frame Sync) — Used to count the number of words in a frame. This signal can be generated internally from the bit clock, or taken from external source (from the Tx/Rx frame sync ports).
- Sys clock —In master mode, this is an integer multiple of frame clock. This is ccm_ssi_clk. It is used in cases when SSI has to provide the clock.

Care should be taken to ensure that the bit clock frequency (either internally generated by dividing the ccm_ssi_clk or sourced from external device through Tx/Rx clock ports) is never greater than 1/5 of the ipg_clk frequency.

In Normal mode (SCR[6:5]=00), the bit clock, used to serially clock the data, is visible on the Serial Transmit Clock (STCK) and Serial Receive Clock (SRCK) ports. The word clock is an internal clock used to determine when transmission of an 8, 10, 12, 16, 18, 20, 22 or 24 bit word has completed. The word clock in turn then clocks the frame clock, which counts the number of words in the frame. The frame clock can be viewed on the STFS and SRFS frame sync ports, because a frame sync is generated after the correct number of words in the frame have passed. In master and synchronous mode, the unused port SRCK is used as Serial Oversampling Clock (ccm_ssi_clk) enabled by the SCR register bit 15, SYS_CLK_EN. This Serial System Clock is an oversampling clock of the frame sync clock (STFS). In this mode, the word length (WL), Prescaler Range (PSR), Prescaler Modulus (PM) and Frame rate (DC) selects the ratio of ccm_ssi_clk to sampling clock STFS. In case of I2S mode, the oversampling clock ccm_ssi_clk can be made available on this port if the SYS_CLK_EN bit is set. The relationship between the clocks and the dividers is shown in Figure 46-32 (“SSI Clocking”). The bit clock can be received from an SSI clock port or can be generated from the ccm_ssi_clk through a divider, as shown in Figure 46-33 (“SSI Transmit Clock Generator Block Diagram”).

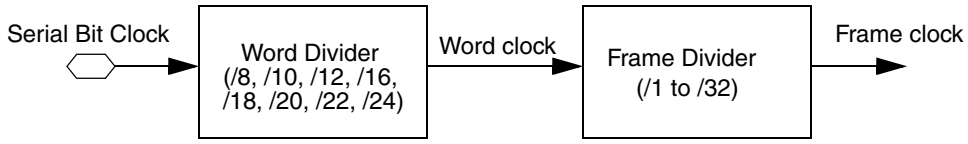

Figure 46-32. SSI Clocking

46.4.2.1 SSI Clock and Frame Sync Generation

Data clock and frame sync signals can be generated internally, or can be obtained from external sources. If internally generated, the SSI clock generator is used to derive bit clock and frame sync signals from the ccm_ssi_clk clock. The SSI clock generator consists of a selectable, fixed prescaler and a programmable prescaler for bit rate clock generation. In Gated Clock mode, the data clock is valid only when data is being transmitted. Otherwise the clock port is pulled to the inactive state. A programmable frame rate divider and a word length divider are used for frame rate sync signal generation.

Figure 46-33 shows a block diagram of the clock generator for the transmit section. The serial bit clock can be internal or external, depending on the Transmit Direction (TXDIR) bit in the SSI Transmit Configuration Register (STCR). The receive section contains an equivalent clock generator circuit.

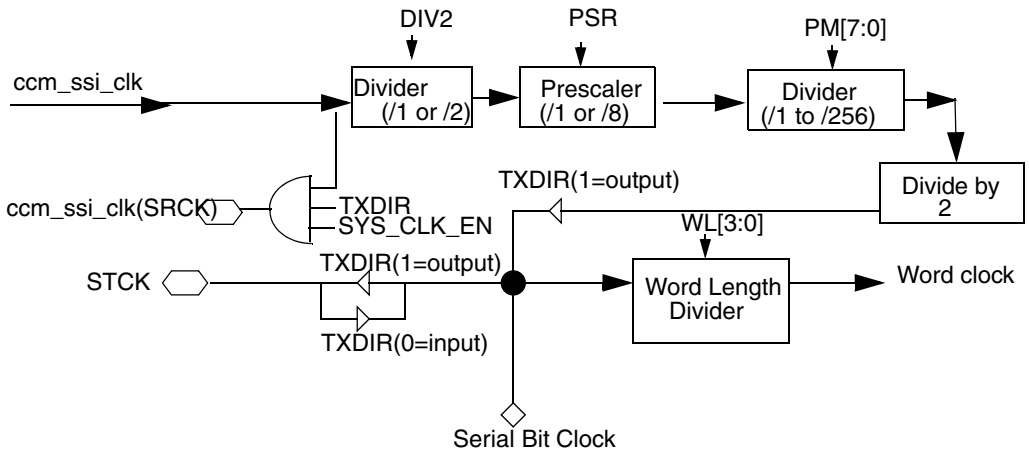

Figure 46-33. SSI Transmit Clock Generator Block Diagram

See Figure 46-34 shows the Frame Sync Generator block for the transmit section. When internally generated, both receive and transmit frame sync are generated from the word clock and are defined by the Frame Rate Divider (DC[4:0]) bits and the Word Length (WL[3:0]) bits of the SSI Transmit Clock Control Register (STCCR). The receive section contains an equivalent circuit for the Frame Sync Generator.

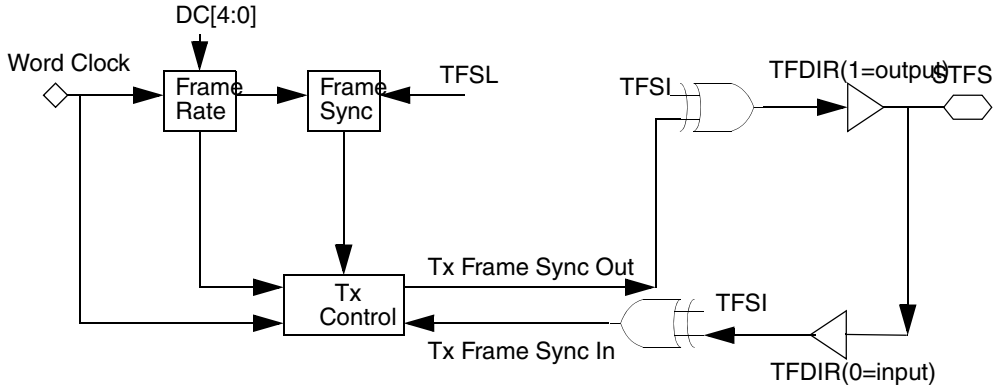

Figure 46-34. SSI Transmit Frame Sync Generator Block Diagram

46.4.2.2 DIV2, PSR and PM Bit Description

The bit clock frequency can be calculated from the SSI Serial System Clock (ccm_ssi_clk) using the equation in Figure 46-35.

NOTE

You must ensure that the bit-clock frequency must be 5 times the ipg_clk frequency. The oversampling clock frequency can go up to ipg_clk frequency. Bits DIV2, PSR and PM should not be all set to zero at the same time.

$$f_{INT\_BIT\_CLK} = f_{ccm\_ssi\_clk} / [(DIV2 + 1) \times (7 \times PSR + 1) \times (PM + 1) \times 2]$$

where PM=PM[7:0]

$$f_{FRAME\_SYN\_CLK} = (f_{INT\_BIT\_CLK}) / [(DC + 1) \times WL]$$

where DC = DC[4:0] and WL = 8, 10, 12, 16, 18, 20, 22, 24

Figure 46-35. SSI Bit Clock Equation

For example, if the SSI oversampling clock (ccm_ssi_clk) is 12.288, in 8-bit word Normal mode with DC[4:0] set to 1 (00001), PM[7:0] set to 47 (0010 1111), the PSR bit cleared, DIV2 bit set to 1, a bit clock rate of 12.288 Mhz / [1 x 4 x 48] = 64 kHz is generated. Since the 8-bit word rate is equal to one (i.e. normal mode), the sampling rate (FS rate) would then be 64 kHz / [1 * 8] = 8 kHz.

In next example, the oversampling clock (ccm_ssi_clk) clock is 11.2896 Mhz. A 16-bit word Network mode with DC[4:0] set to 1 (00001), PM[7:0] set to 3 (0000 0011), the PSR bit is set to 0, DIV2 bit set to 0, and a 11.2896 MHz oversampling clock, a bit clock rate of 11.2896 Mhz / [1 x 2 x 4] = 1.4112 MHz is generated. Since the 16-bit word rate is equal to two, the sampling rate (FS rate) would be 1.4112 MHz / [2 * 16] = 44.1 kHz.

Table 46-35 shows programming examples for the clock dividers in the CRM and the SSI to support various bit clock (STCK) frequencies.

Table 46-35. SSI Bit Clock and Frame Rate as a Function of PSR, PM, and DIV2

Bits/ Word	Words/ Frame	Ideal Frame Rate (kHz)	PLL Freq (Mhz)	SSIDIV (in CRM)	MCLK/ ccm_ssi_clk Freq (Mhz)	DIV 2	PS R	PM	WL	DC	Actual Bit_Clk Freq (kHz) STCK	Target Bit_Clk Freq (kHz) STCK	Error (Hz)

NOTE

Table 46-35 describes how various frame rates can be achieved with the PLL0/1 supplying a frequency of 294.912 MHz and 270.9504 MHz (with WL and DC settings as shown). Using PLL2 requires that these input frequencies be lowered by a factor of 2 (and the dividers be changed accordingly). Using the MRCG allows the input frequency to be lowered by a factor of 4 (provided the dividers are changed accordingly). These clocks are recommended as convenient starting points but the system allows for other input clock frequencies as well.

Table 46-35 below shows programming of the CRM and SSI dividers in order to generate the appropriate oversampling clock and BIT_CLK frequencies for various sampling rates. In these examples, the master mode is selected either by setting I2S master bit (SCR[6:5]=01) or individually programming the SSI in network, synchronous, transmit internal mode (the table specifically illustrates the I2S mode frequencies/sample rates). The oversampling clock is ccm_ssi_clk.

Note that the I2S master mode requires that a word length of 32 bits be used (regardless of the actual data type). Consequently, the fixed I2S frame rate of 64 bits per frame (word length (WL) can be any value) and DC of 1 are assumed.

46.4.3 Receive Interrupt Enable Bit Description

When the RIE and RE bit are set, the processor is interrupted when either of the SSI Receive FIFO Full (RFF0/1) bits in SISR is set (if the corresponding Receive FIFO is enabled). If the Receive FIFO is not enabled, the interrupt is generated when the corresponding SSI Receive Data Ready (RDR0/1) bit in the SISR is set. When the receive FIFO is enabled, a maximum of 15 values are available to be read (15 values per channel in Two-Channel mode). If not enabled, then one value can be read from the SRX register (one each in case of Two-Channel mode). If the RIE bit is cleared, these interrupts are disabled. However, the RFF0/1 and RDR0/1 bits still indicate the receive data register full condition. Reading the SRX registers

clears the RDR bits, thus clearing the pending interrupt. Two receive data interrupts (two per channel in case of Two-Channel mode) are available: receive data with exception status and receive data without exception. Table 46-36 and Table 46-37 show the conditions under which these interrupts are generated.

Table 46-36. SSI Receive Data 1 Interrupts

Interrupt	RIE	ROE0	RFF0/RDR0
Receive Data 1(with Exception Status)	1	1	1
Receive Data 1(without exception)	1	0	1

Table 46-37. SSI Receive Data 0 Interrupts

Interrupt	RIE	ROE1	RFF1/RDR1
Receive Data 0 (with Exception Status)	1	1	1
Receive Data 0 (without exception)	1	0	1

46.4.4 Transmit Interrupt Enable Bit Description

The SSI Transmit Interrupt Enable (TIE) control bit determines whether the processor is interrupted when the SSI transmitter needs to be serviced. When the TIE and TE bits are set, the program controller is interrupted when either of the SSI Transmit FIFO Empty (TFE0/1) flags in SISR are set (if corresponding Transmit FIFO is enabled). If the corresponding Transmit FIFO is not enabled, an interrupt is generated when the corresponding SSI Transmit Data Register Empty (TDE0/1) flag in the SISR is set and Transmit Enable (TE) bit is set.

When Transmit FIFO 0 is enabled, a maximum of 15 values can be written to the SSI (15 per channel in case of Two-Channel mode, using Tx FIFO 1). If not enabled, then one value can be written to the STX0 register (one per channel in case of Two-Channel mode using STX1). When the TIE bit is cleared, all transmit interrupts are disabled. However, the TDE0/1 bits always indicate the corresponding STX register empty condition, even when the transmitter is disabled by the Transmit Enable (TE) bit (in the SCR). Writing data to the STX clears the corresponding TDE bit, thus clearing the interrupt. Two transmit data interrupts are available (four in case of Two-Channel mode, two per channel): transmit data with exception status and transmit data without exceptions. Table 46-38 and Table 46-39 show the conditions under which these interrupts are generated.

Table 46-38. SSI Transmit Data 1 Interrupts

Interrupt	TIE	TUE1	TFE1/TDE1
Transmit Data 1 (with Exception Status)	1	1	1
Transmit Data 1 (without exception)	1	0	1

Table 46-39. SSI Transmit Data 0 Interrupts

Interrupt	TIE	TUE0	TFE0/TDE0
Transmit Data 0 (with Exception Status)	1	1	1
Transmit Data 0 (without exception)	1	0	1

46.4.5 Internal Frame and Clock Shutdown

During transmit/receive operation, disabling TE/RE will ensure that data transmission/reception stops after current frame ends following which TFRC/RFRC Status bits will get set to indicate the Frame Completion State. If TE is disabled 4 clock cycles before the next frame, extra frame generated are invalid frames. TFR_CLK_DIS/RFR_CLK_DIS bit is set in the current or any of the previous frames, SSI will stop driving the STFS/SRFS and STCK/SRCK signals after the current frame ends.

If TFR_CLK_DIS/RFR_CLK_DIS bit is not set, SSI will continue generating STFS/SRFS and STCK/SRCK signals (in case direction is from SSI), which then can be disabled by writing '1' to TFR_CLK_DIS/RFR_CLK_DIS bit. SSI will then stop driving these signals after end of frame is reached following which TFRC/RFRC status bits will get set to indicate the Frame Completion State.

Figure 46-36 is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TE is disabled with TFR_CLK_DIS bit set in current or any of the previous frames.

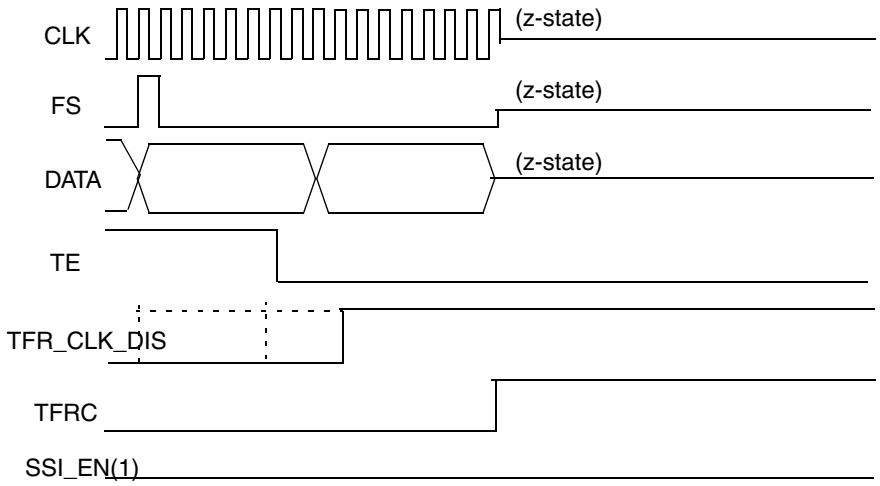

Figure 46-36. TFR_CLK_DIS assertion in current or previous frame as TE disable

Figure 46-37 is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TFR_CLK_DIS bit is set after few frames of disabling TE. TFRC (Transmit Frame Complete) is set at frame boundary after TE is cleared. Once software services this interrupt and sets TFR_CLK_DIS bit later, TFRC bit is again set at next frame boundary.

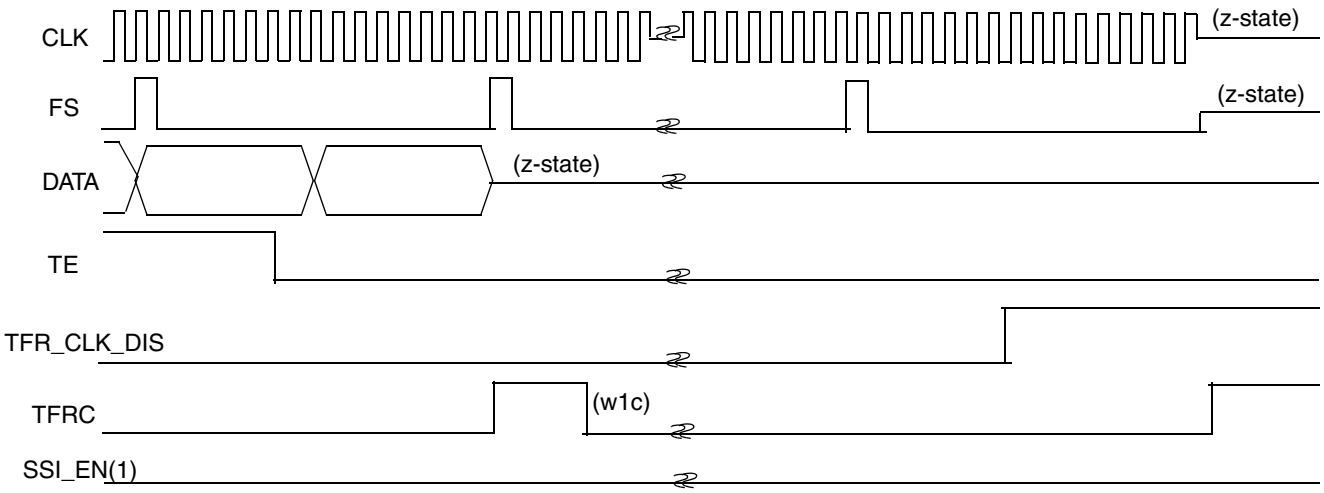

Figure 46-37. TFR_CLK_DIS Assertion in Subsequent Frame after Disabling TE

46.4.6 IP Bus Interface

The SSI has an IP Bus interface compatible with SRS 3.0.2 in order to provide a control and data interface. This interface is used by both the processor and DMA controller.

46.4.6.1 Transfer Lengths Supported

The IP Bus interface of the SSI only supports 32-bit transfers with all SSI registers other than STX0, STX1, SRX0, and SRX1 (that is, the data registers). With the exception of the data registers, using 8-bit and 16-bit transactions could result in undesired behavior but will not result in a transfer bus error. The data registers (STX0, STX1, SRX0, and SRX1) support 8-bit, 16-bit, and 32-bit transfer lengths without restrictions.

46.4.6.2 Transfer Bus Errors

Transfer bus errors are generated upon response to the following:

- Write transfer to a read-only register.
- Read or write access to a register space beyond the last populated register of the SSI in its memory map (up until the end of the allocated memory address range of the SSI).

46.4.6.3 Clock Rate

The IP Bus clock frequency must be at least five times the serial bit clock frequency.

46.5 Initialization/Application Information

The SSI is affected by the following types of reset:

- Power-on Reset—The Power-on reset is generated by asserting the RESET port. The Power-on reset clears the SSIEN bit in SCR, which disables the SSI. All other status and control bits in the SSI are affected as described in SSI Programming Model in Section 46.3.
- SSI Reset—The SSI reset is generated when the SSIEN bit in the SCR is cleared. The SSI status bits are preset to the same state produced by the Power-on reset. The SSI control bits are unaffected. The control bits in the SCR are also unaffected. The SSI reset is useful for selective reset of the SSI without changing the present SSI control bits and without affecting the other peripherals.

The correct sequence to initialize the SSI is as follows:

1. Issue a Power-on or SSI reset (SCR[SSIEN]=0).
2. Disable SSI clocks (ipg_clk, ccm_ssi_clk).
3. Set all control bits for configuring the SSI (see Table 46-40 for the list of “SSI Control Bits Requiring SSI to be Disabled Before Change”).
4. Enable appropriate interrupts/DMA requests through SIER.
5. Set the SCR[SSIEN] bit (=1) to enable the SSI.
6. Enable SSI clocks (ipg_clk, ccm_ssi_clk), as required.
7. In case of AC97 mode, set the SACNT[AC97EN] bit after programming the SATAG register (if needed, for AC97 Fixed mode).
8. In case of AC97 fixed mode, do not program the slot request bits without programming the frame valid bits in SATAG register.
9. In case of gated mode of operation refer Table 46-5.
10. Set SCR[TE/RE] bits.
11. To ensure proper operation of the SSI, use the “Power-on or SSI reset before changing any of the SSI Control” bits listed in Table 46-40).

NOTE

These control bits should not be changed when SSI is enabled

Table 46-40. SSI Control Bits Requiring SSI to be Disabled Before Change

Chapter 47
Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

47.1 Overview

This section briefly introduces the module. The full description of the module is in Section 47.4, "Functional Description."

This section includes a top level diagram that shows the functional organization of the module, including all off-chip signals. Figure 47-1 shows the block diagram.

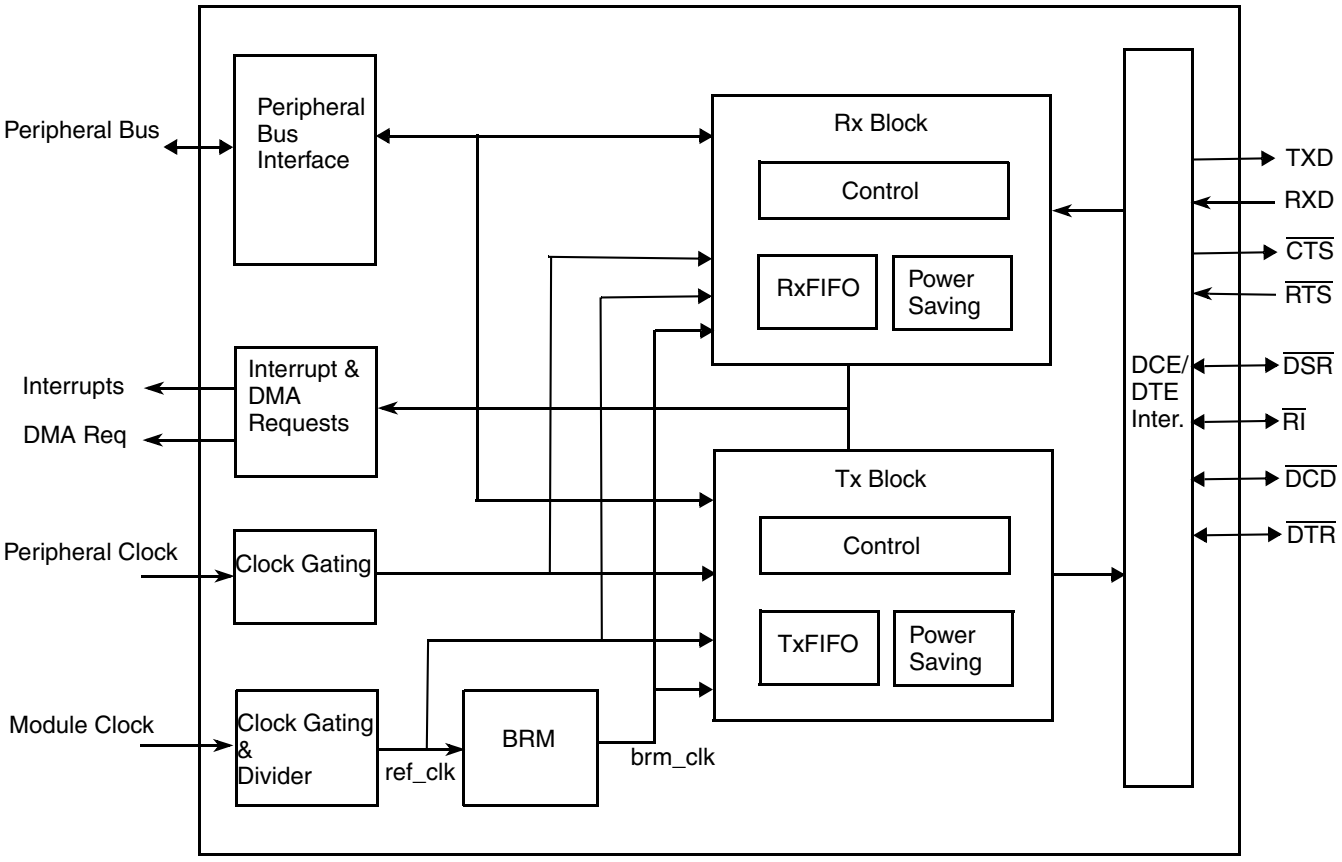

Figure 47-1. UART Block Diagram

47.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible
- 7 or 8 data bits
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send ($\overline{\text{RTS}}$) and clear to send ($\overline{\text{CTS}}$) signals
- Edge-selectable $\overline{\text{RTS}}$ and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s).
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression
- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- DCE/DTE capability
- $\overline{\text{RTS}}$, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE), $\overline{\text{RI}}$ (DTE only), $\overline{\text{DCD}}$ (DTE only), $\overline{\text{DTR}}$ (DCE only) and $\overline{\text{DSR}}$ (DTE only) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset ($\overline{\text{SRST}}$)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

47.1.2 Modes of Operation

The UART includes the following modes of operation:

- Serial RS-232 NRZ format.
- IrDA

47.2 External Signals

Table 47-1 lists conventions for representing signals.

Table 47-1. Module Signal Conventions

Category	Convention	Example(s)
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

[1] Internal signals are for reference only in descriptions of internal module or SoC functionality.

Table 47-2 describes all UART signals that connect off-chip.

47.2.1 Detailed Signal Descriptions

Table 47-2. Off-Chip Module Signals

Signal name	I/O	Active state	Description	Reset state
Serial / IrDA Signals				
RXD	I		Serial / infrared data receive	
TXD	O		Serial/infrared data transmit	High
Modem Control Signals				
$\overline{\text{CTS}}$	O	Low	Clear to send	High
$\overline{\text{RTS}}$	I	Low	Request to send	
$\overline{\text{DSR}}$	I/O	Low	Data set ready	High
$\overline{\text{DCD}}$	I/O	Low	Data carrier detected	High
$\overline{\text{DTR}}$	I/O	Low	Data terminal ready	
$\overline{\text{RI}}$	I/O	Low	Ring indicator	High
Interrupts				
interrupt_uart	O	Low	UART interrupt	High
DMA Requests				
dma_req_rx	O	Low	Receiver DMA request	High
dma_req_tx	O	Low	Transmitter DMA request	High
Clocks				
peripheral_clock	I		Peripheral clock	
module_clock	I		Clock source for the module's logic	
Special Signals				
stop_req	I	High	Module stop mode	
doze_req	I	High	Module doze mode	
debug_req	I	High	Module debug	

47.2.1.1 Serial / IrDA Signals

47.2.1.1.1 RXD — Data Receive

Input asynchronous data receive in Serial and IrDA modes.

47.2.1.1.2 TXD — Data Transmit

Output asynchronous data transmit in Serial and IrDA modes.

47.2.1.2 Modem Control Signals

47.2.1.2.1 $\overline{\text{CTS}}$ — Clear To Send

Output in DCE and DTE mode. This signal informs the remote modem that UART is ready to receive data.

47.2.1.2.2 $\overline{\text{RTS}}$ — Request To Send

Input in DCE and DTE mode. This signal informs UART that remote modem is ready to receive data.

47.2.1.2.3 $\overline{\text{DSR}}$ — Data Set Ready

Input in DTE mode. Indicates to UART that remote modem is operational.

Output in DCE mode. Indicates to remote modem that UART is operational.

47.2.1.2.4 $\overline{\text{DCD}}$ — Data Carrier Detected

Input in DTE mode. Indicates to UART that a good carrier is being received from the remote modem.

Output in DCE mode. Indicates to remote device that a good carrier is being received from the UART.

47.2.1.2.5 $\overline{\text{DTR}}$ — Data Terminal Ready

Input in DCE mode. Indicates to UART (in DCE mode) that remote device (in DTE mode) is operational.

Output in DTE mode. Indicates to remote modem (in DCE mode) that UART (in DTE mode) is operational.

47.2.1.2.6 $\overline{\text{RI}}$ — Ring Indicator

Input in DTE mode. Indicates to UART that remote modem is detecting a ringing tone.

Output in DCE mode. Indicates to remote device that UART is detecting a ringing tone.

47.2.1.3 Interrupt Signals

47.2.1.3.1 $\overline{\textit{interrupt\_uart}}$ — UART Interrupt

Output interrupt request.

47.2.1.4 DMA Request Signals

47.2.1.4.1 $\overline{\textit{dma\_req\_rx}}$ — Receiver DMA Request

Output DMA Request signal for receiver interface.

47.2.1.4.2 $\overline{\textit{dma\_req\_tx}}$ — Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

47.2.1.5 Clock Signals

47.2.1.5.1 *peripheral_clock* — Peripheral Clock

See Section 47.4.2, “Clocks” for more information about *peripheral_clock*.

47.2.1.5.2 *module_clock* — Module Clock

See Section 47.4.2, “Clocks” for more information about *module_clock*.

47.2.1.6 Special Signals

47.2.1.6.1 *stop_req* — Stop Mode

Input stop mode. Indicates UART that MCU is going to enter in Stop Mode and clocks are going to stop running. See Section 47.4.8, “Low Power Modes” for more information about Stop Mode.

47.2.1.6.2 *doze_req* — Doze Mode

Input doze mode. MCU requests UART to switch in doze mode (power saving mode). See Section 47.4.8, “Low Power Modes” for more information about Doze Mode.

47.2.1.6.3 *debug_req* — Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode. See Section 47.4.9, “UART Operation in System Debug State”, for more information about Debug Mode.

47.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

47.3.1 Memory Map

Table 47-3 is the UART memory map.

Table 47-3. UART Memory Map

Offset Address (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (URXD)	UART Receiver Register	R	00– –	47.3.3.1/47-11
0x0004–0x003c	Reserved	—	—	—
0x0040 (UTXD)	UART Transmitter Register	W	00– –	47.3.3.2/47-12

47.3.2 Register Summary

Table 47-5 is the register summary table.

The UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All the memory mapped registers are 32 bits wide, however as the 16 MSB are not used for all of the registers except the ONEMS register:

- For 32-bits write access, the 16 MSB are not taken into account for all of the registers except the ONEMS.
- For 32-bits read access the 16 MSB is read as 0 for all of the registers except the ONEMS.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed in the way of 8-bits, 16-bits or 32-bits.

- For 32-bits write access, the 8 MSB of the ONEMS is not taken into account.
- For 32-bits read access, the 8 MSB of the ONEMS is read as 0.

All registers except the ONEMS described in this section are for 16 LSB. The ONEMS register is for 24 LSB.

Figure 47-2 shows the key to the register fields and Table 47-4 shows the register figure conventions.

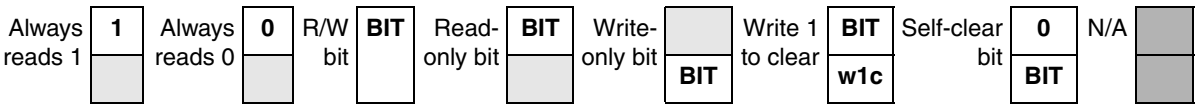

Figure 47-2. Key to Register Fields

Table 47-4. Register Figure Convention

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 47-5 shows the UART register summary.

47.3.3 Register Descriptions

This section provides detailed descriptions of the UART registers.

47.3.3.1 UART Receiver Register (URXD)

See Figure 47-3 for illustration of valid bits in the UART Receiver Register and Table 47-6 for description of the bit fields.

0x0000 (URXD) Access: User read

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 47-3. UART Receiver Register

Table 47-6. UART Receiver Register Field Descriptions

Field	Description
31–16	Reserved
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.

Table 47-6. UART Receiver Register Field Descriptions (Continued)

Field	Description
14 ERR	Error Detect. Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected
13 OVRRUN	Receiver Overrun. This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	Frame Error. Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	BREAK Detect. Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	Parity Error. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8	Reserved
7–0 RX_DATA	Received Data. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.

NOTE

The UART yields a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

47.3.3.2 UART Transmitter Register (UTXD)

See Figure 47-4 for illustration of valid bits in the UART Transmitter Register and Table 47-7 for description of the bit fields.

0x0040 (UTXD) Access: User write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

R	0	0	0	0	0	0	0	0								
W									TX_DATA							
RESET	0	0	0	0	0	0	0	0	—	—	—	—	—	—	—	—

Figure 47-4. UART Transmitter Register

Table 47-7. UART Transmitter Register Field Descriptions

Field	Description
31–16	Reserved
15–8	Reserved
7–0 TX_DATA	Transmit Data. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

NOTE

The UART yields a transfer error on the peripheral bus when core is writing into URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between URXD and UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

47.3.3.3 UART Control Register 1 (UCR1)

See Figure 47-5 for illustration of valid bits in the UART Control Register 1 and Table 47-8 for description of the bit fields.

0x0080 (UCR1) Access: User read/write

Figure 47-5. UART Control Register 1

Table 47-8. UART Control Register 1 Field Descriptions

Field	Description
31–16	Reserved
15 ADEN	Automatic Baud Rate Detection Interrupt Enable. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	Automatic Detection of Baud Rate. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character “A” or “a” (0x61 or 0x41). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	Transmitter Ready Interrupt Enable. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **Note:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	Idle Condition Detected Interrupt Enable. Enables/Disables the IDLE bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt
11–10 ICD	Idle Condition Detect. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames

Table 47-8. UART Control Register 1 Field Descriptions (Continued)

Field	Description
9 RRDYEN	Receiver Ready Interrupt Enable. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	Receive Ready DMA Enable. Enables/Disables the receive DMA request $\overline{dma\_req\_rx}$ when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	Infrared Interface Enable. Enables/Disables the IR interface. See the IR interface description in Section 47.4.7, "Infrared Interface," for more information. 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	Transmitter Empty Interrupt Enable. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. $\overline{interrupt\_uart}$. When negated, the TXFE interrupt is disabled. **Note:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	RTS Delta Interrupt Enable. Enables/Disables the RTSD interrupt. The current status of the $\overline{RTS}$ pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	Send BREAK. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	Transmitter Ready DMA Enable. Enables/Disables the transmit DMA request $\overline{dma\_req\_tx}$ when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the $\overline{dma\_req\_tx}$ is controlled by the TXTL bits. **Note:** A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request
2 ATDMAEN	Aging DMA Timer Enable. Enables/Disables the receive DMA request $\overline{dma\_req\_rx}$ for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request

Table 47-8. UART Control Register 1 Field Descriptions (Continued)

Field	Description
1 DOZE	DOZE. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the CPU executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Section 47.4.8, "Low Power Modes." 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	UART Enable. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

47.3.3.4 UART Control Register 2 (UCR2)

See Figure 47-6 for illustration of valid bits in the UART Control Register 2 and Table 47-9 for description of the bit fields.

0x0084 (UCR2) Access: User read/write

Figure 47-6. UART Control Register 2

Table 47-9. UART Control Register 2 Field Descriptions

Name	Description
31–16	Reserved
15 ESCI	Escape Sequence Interrupt Enable. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	Ignore RTS Pin. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin

Table 47-9. UART Control Register 2 Field Descriptions (Continued)

Name	Description
13 CTSC	CTS Pin Control. Controls the operation of the $\overline{CTS}$ output pin. When CTSC is asserted, the $\overline{CTS}$ output pin is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the $\overline{CTS}$ output pin is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the $\overline{CTS}$ output pin is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the $\overline{CTS}$ pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the $\overline{CTS}$ signal is negated. 0 The $\overline{CTS}$ pin is controlled by the CTS bit 1 The $\overline{CTS}$ pin is controlled by the receiver
12 CTS	Clear to Send. Controls the $\overline{CTS}$ pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The $\overline{CTS}$ pin is high (inactive) 1 The $\overline{CTS}$ pin is low (active)
11 ESCEN	Escape Enable. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10-9 RTEC	Request to Send Edge Control. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 47-23). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	Parity Enable. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	Parity Odd/Even. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity
6 STPB	Stop. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	Word Size. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)
4 RTSEN	Request to Send Interrupt Enable. Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the $\overline{RTS}$ pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (See Table 47-23.) 0 Disable request to send interrupt 1 Enable request to send interrupt

Table 47-9. UART Control Register 2 Field Descriptions (Continued)

Name	Description
3 ATEN	Aging Timer Enable. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	Transmitter Enable. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	Receiver Enable. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 $\overline{\text{SRST}}$	Software Reset. Once the software writes 0 to $\overline{\text{SRST}}$, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts $\overline{\text{SRST}}$. The software can only write 0 to $\overline{\text{SRST}}$. Writing 1 to $\overline{\text{SRST}}$ is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC, URXD, UTXD and UTS[6-3]. 1 No reset

47.3.3.5 UART Control Register 3 (UCR3)

See Figure 47-7 for illustration of valid bits in the UART Control Register 3 and Table 47-10 for description of the bit fields.

Figure 47-7. UART Control Register 3

Table 47-10. UART Control Register 3 Field Descriptions

Name	Description
31–16	Reserved
15–14 DPEC	DTR/DSR Interrupt Edge Control. These bits control the edge of $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) on which an interrupt will be generated. An interrupt will only be generated if the DTREN bit is set. 00 interrupt generated on rising edge 01 interrupt generated on falling edge 1X interrupt generated on either edge
13 DTREN	Data Terminal Ready Interrupt Enable. When this bit is set, it will enable the status bit DTRF (USR2 [13]) (DTR/DSR edge sensitive interrupt) to cause an interrupt. 0 Data Terminal Ready Interrupt Disabled 1 Data Terminal Ready Interrupt Enabled
12 PARERREN	Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt. 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt. 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	Data Set Ready. This bit is used by software to control the DSR/DTR output pin for the modem interface. In DCE mode it applies to $\overline{\text{DSR}}$ and in DTE mode it applies to $\overline{\text{DTR}}$. 0 DSR/ DTR pin is logic zero 1 DSR/ DTR pin is logic one
9 DCD	Data Carrier Detect. In DCE mode this bit is used by software to control the $\overline{\text{DCD}}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit DCDDELT (USR2 (6)) to cause an interrupt. 0 $\overline{\text{DCD}}$ pin is logic zero (DCE mode) 1 $\overline{\text{DCD}}$ pin is logic one (DCE mode) 0 DCDDELT interrupt disabled (DTE mode) 1 DCDDELT interrupt enabled (DTE mode)
8 RI	Ring Indicator. In DCE mode this bit is used by software to control the $\overline{\text{RI}}$ output pin for the modem interface. In DTE mode, when this bit is set, it will enable the status bit RIDELT (USR2 (10)) to cause an interrupt. 0 $\overline{\text{RI}}$ pin is logic zero (DCE mode) 1 $\overline{\text{RI}}$ pin is logic one (DCE mode) 0 RIDELT interrupt disabled (DTE mode) 1 RIDELT interrupt enabled (DTE mode)
7 ADNIMP	Autobaud Detection Not Improved—. Disables new features of autobaud detection (see Section 47.4.5.6.2, “Baud Rate Automatic Detection Protocol Improved,” for more details). 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt ($\overline{\textit{interrupt\_uart}}$). When this bit is enabled and RXDS status bit is set, the interrupt $\overline{\textit{interrupt\_uart}}$ will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt

Table 47-10. UART Control Register 3 Field Descriptions (Continued)

Name	Description
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	Data Terminal Ready Delta Enable. Enables / Disables the asynchronous DTRD interrupt. When DTRDEN is asserted and an edge (rising or falling) is detected on $\overline{\text{DTR}}$ (in DCE mode) or on $\overline{\text{DSR}}$ (in DTE mode), then an interrupt is generated. 0 Disable DTRD interrupt 1 Enable DTRD interrupt
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. **Note:** In this chip, UARTs are used in MUXED mode, so that this bit should always be set. 0 Input pin RXD is not used for serial and IR interfaces 1 Input pin RXD is used for serial and IR interfaces
1 INVT	Inverted Infrared Transmission. Sets the active level for the transmission. When INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 Active low transmission 1 Active high transmission.
0 ACIEN	Autobaud Counter Interrupt Enable. This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

47.3.3.6 UART Control Register 4 (UCR4)

See Figure 47-8 for illustration of valid bits in the UART Control Register 4 and Table 47-11 for description of the bit fields.

Figure 47-8. UART Control Register 4

Table 47-11. UART Control Register 4 Field Descriptions

Name	Description
31–16	Reserved
15–10 CTSTL	CTS Trigger Level. Controls the threshold at which the $\overline{CTS}$ pin is deasserted by the RxFIFO. After the trigger level is reached and the $\overline{CTS}$ pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. 000000 0 characters received 000001 1 characters in the RxFIFO ... ... 100000 32 characters in the RxFIFO (maximum) All Other Settings Reserved
9 INVR	Inverted Infrared Reception. Determines the logic level for the detection. When cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 Active low detection 1 Active high detection
8 ENIRI	Serial Infrared Interrupt Enable. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled
7 WKEN	WAKE Interrupt Enable. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	DMA IDLE Condition Detected Interrupt Enable Enables/Disables the receive DMA request $\overline{dma\_req\_rx}$ for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	IR Special Case. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See Section 47.4.7.3, “InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	Low Power Bypass. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	Transmit Complete Interrupt Enable. Enables/Disables the TXDC bit to generate an interrupt ($\overline{interrupt\_uart}$ = 0) **Note:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	BREAK Condition Detected Interrupt Enable. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt

Table 47-11. UART Control Register 4 Field Descriptions (Continued)

Name	Description
1 OREN	Receiver Overrun Interrupt Enable. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	Receive Data Ready Interrupt Enable. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

47.3.3.7 UART FIFO Control Register (UFCR)

See Figure 47-9 for illustration of valid bits in the UART FIFO Control Register and Table 47-12 for description of the bit fields.

Table 47-12. UART FIFO Control Register Field Descriptions

Name	Description
31–16	Reserved
15–10 TXTL	Transmitter Trigger Level. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... ... 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum) All Other Settings Reserved

Table 47-12. UART FIFO Control Register Field Descriptions (Continued)

Name	Description
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	DCE/DTE mode select. Selects data communication equipment (DCE) or data terminal equipment (DTE) mode. This bit controls the pin direction of the bidirectional modem pins DSR, DCD, DTR and RI. 0 DCE mode selected 1 DTE mode selected
5–0 RXTL	Receiver Trigger Level. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. 000000 0 characters received 000001 RxFIFO has 1 character ... ... 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum) All Other Settings Reserved

47.3.3.8 UART Status Register 1 (USR1)

Figure 47-10. UART Status Register 1

Table 47-13. UART Status Register 1 Field Descriptions

Name	Description
31–16	Reserved
15 PARITYERR	Parity Error Interrupt Flag. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	$\overline{\text{RTS}}$ Pin Status. Indicates the current status of the $\overline{\text{RTS}}$ pin. A “snapshot” of the pin is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0. 0 The $\overline{\text{RTS}}$ pin is high (inactive) 1 The $\overline{\text{RTS}}$ pin is low (active)
13 TRDY	Transmitter Ready Interrupt / DMA Flag. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	RTS Delta. Indicates whether the $\overline{\text{RTS}}$ pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the $\overline{\text{RTS}}$ pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 $\overline{\text{RTS}}$ pin did not change state since last cleared 1 $\overline{\text{RTS}}$ pin changed state (write 1 to clear)
11 ESCF	Escape Sequence Interrupt Flag. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	Frame Error Interrupt Flag. Indicates that a frame error is detected. The $\overline{\textit{interrupt\_uart}}$ interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	Receiver Ready Interrupt / DMA Flag. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in Table 47-12 for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)

Table 47-13. UART Status Register 1 Field Descriptions (Continued)

Name	Description
7 DTRD	DTR Delta. Indicates whether $\overline{\text{DTR}}$ (in DCE mode) or $\overline{\text{DSR}}$ (in DTE mode) pins changed state. DTRD generates a maskable interrupt if DTRDEN (UCR3[3]) is set. Clear DTRD by writing 1 to it. Writing 0 to DTRD has no effect. 0 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin did not change state since last cleared 1 $\overline{\text{DTR}}$ (DCE) or $\overline{\text{DSR}}$ (DTE) pin changed state (write 1 to clear)
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3–0	Reserved

47.3.3.9 UART Status Register 2 (USR2)

See Figure 47-11 for illustration of valid bits in the UART Status Register 2 and Table 47-14 for description of the bit fields.

Figure 47-11. UART Status Register 2

Table 47-14. UART Status Register 2 Field Descriptions

Name	Description
31–16	Reserved
15 ADET	Automatic Baud Rate Detect Complete. Indicates that an “A” or “a” was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII “A” or “a” was not received 1 ASCII “A” or “a” was received (write 1 to clear)
14 TXFE	Transmit Buffer FIFO Empty. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	DTR edge triggered interrupt flag. This bit is asserted, when the programmed edge is detected on the $\overline{\text{DTR}}$ pin (DCE mode). or on $\overline{\text{DSR}}$ (DTE mode). This flag can cause an interrupt if DTREN (UCR3[13]) is enabled. 0 Programmed edge not detected on DTR/DSR 1 Programmed edge detected on DTR/DSR (write 1 to clear)
12 IDLE	Idle Condition. Indicates that an idle condition has existed for more than a programmed amount frame (see Section 47.4.5.1, “Idle Line Detect”). An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	Autobaud Counter Stopped. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See Section , “New Autobaud Counter Stopped bit and Interrupt,” for more details. An interrupt can be flagged on *interrupt_uart* if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	Ring Indicator Delta. This bit is used in DTE mode to indicate that the Ring Indicator input ($\overline{\text{RI}}$) has changed state. This flag can generate an interrupt if RI (UCR3[8]) is enabled. RIDELT is cleared by writing 1 to it. Writing 0 to RIDELT has no effect. 0 Ring Indicator input has not changed state 1 Ring Indicator input has changed state (write 1 to clear)
9 RIIN	Ring Indicator Input. This bit is used in DTE mode to reflect the status if the Ring Indicator input ($\overline{\text{RI}}$). The Ring Indicator input is used to indicate that a ring has occurred. In DCE mode this bit is always zero. 0 Ring Detected 1 No Ring Detected
8 IRINT	Serial Infrared Interrupt Flag. When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	Wake. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)

Table 47-14. UART Status Register 2 Field Descriptions (Continued)

Name	Description
6 DCDDELT	Data Carrier Detect Delta. This bit is used in DTE mode to indicate that the Data Carrier Detect input ($\overline{DCD}$) has changed state. This flag can cause an interrupt if DCD (UCR3[9]) is enabled. When in STOP mode, this bit can be used to wake the processor. In DCE mode this bit is always zero. 0 Data Carrier Detect input has not changed state 1 Data Carrier Detect input has changed state (write 1 to clear)
5 DCDIN	Data Carrier Detect Input. This bit is used in DTE mode reflect the status of the Data Carrier Detect input ($\overline{DCD}$). The Data Carrier Detect input is used to indicate that a carrier signal has been detected. In DCE mode this bit is always zero. 0 Carrier signal Detected 1 No Carrier signal Detected
4 RTSF	RTS Edge Triggered Interrupt Flag. Indicates if a programmed edge is detected on the $\overline{RTS}$ pin. The RTEC bits select the edge that generates an interrupt (see Table 47-23). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on $\overline{RTS}$ 1 Programmed edge detected on $\overline{RTS}$ (write 1 to clear)
3 TXDC	Transmitter Complete. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	BREAK Condition Detected. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	Overrun Error. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect. 0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	Receive Data Ready—Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

47.3.3.10 UART Escape Character Register (UESC)

Table 47-16. UART Escape Timer Register Field Descriptions

Name	Description
31–12	Reserved
11–0 TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Section 47.4.5.7, “Escape Sequence Detection” and Table 47-28 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

47.3.3.12 UART BRM Incremental Register (UBIR)

See Figure 47-14 for illustration of valid bits in the UART BRM Incremental Register and Table 47-17 for description of the bit fields.

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Software reset will reset the register to its reset value.

Figure 47-14. UART BRM Incremental Register

Table 47-17. UART BRM Incremental Register Field Descriptions

Name	Description
31–16	Reserved
15–0 INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Section 47.4.6, “Binary Rate Multiplier (BRM)”). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM ignores this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

1. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priority than hardware when writing this register at the same time.

47.3.3.13 UART BRM Modulator Register (UBMR)

See Figure 47-15 for illustration of valid bits in the UART BRM Modulator Register and Table 47-18 for description of the bit fields.

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[1].

Software reset will reset the register to its reset value.

Name	Description
31–16	Reserved
15–0 BCNT	Baud Rate Count Register. This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

47.3.3.15 UART One Millisecond Register (ONEMS)

Figure 47-17. UART One Millisecond Register

Table 47-20. UART One Millisecond Register Field Descriptions

Name	Description
31–24	Reserved
23–0 ONEMS	One Millisecond Register. This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Figure 47-1) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F(*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Section 47.4.5.7, "Escape Sequence Detection") to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see Section 47.4.7.3, "InfraRed Special Case (IRSC) Bit."

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

47.3.3.16 UART Test Register (UTS)

See Figure 47-18 for illustration of valid bits in the UART Test Register and Table 47-21 for description of the bit fields.

Figure 47-18. UART Test Register

Table 47-21. UART Test Register Field Descriptions

Name	Description
31–14	Reserved
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	$\overline{\text{debug\_enable}}$. This bit controls whether to respond to the *debug_req* input signal. 0 UART will go into debug mode when *debug_req* is HIGH 1 UART will not go into debug mode even if *debug_req* is HIGH
10 LOOPIR	Loop TX and RX for IR Test (LOOPIR). This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	RX_fifo_debug_mode. This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal
8–7	Reserved
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1	Reserved
0 SOFTRST	Software Reset. Indicates the status of the software reset ($\overline{\text{SRST}}$ bit of UCR2). 0 Software reset inactive 1 Software reset active

47.4 Functional Description

This section provides a complete functional description of the module.

47.4.1 Interrupts and DMA Requests

See Table 47-22 for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 47-22. Interrupts and DMA

47.4.2 Clocks

This section describes clocks and special clocking requirements of the UART.

47.4.2.1 Clock requirements

UART module receives two clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Section 47.4.2.3, “Clocking in Low-Power Modes”).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. Off course, they can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M x 16 = 64MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

47.4.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the *module_clock* and logic synthesis results. For example, if SoC can provide the fastest *module_clock* 66.5MHz and the UART synthesis timing is valid under this constraint, the UART can transmit and receive serial data with the max baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2Kbit/s. To support the 115.2Kbit/s, *module_clock* frequency must be higher or equal to 1.8432MHz.

47.4.2.3 Clocking in Low-Power Modes

The UART supports two low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at ‘1’), the UART does not need any clock. In this mode the UART can wake-up the MCU with the asynchronous interrupts (see Section 47.4.8, “Low Power Modes”). An application of this feature is when the system must be waken-up by the arrival of a frame of characters.

- If before entering in Stop mode the software has enabled RTSDEN interrupt, then when RTS will change state (put at ‘0’ by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS does not change state (already at ‘0’ before entering in Stop mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character will not be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to ‘1’, then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to ‘0’, UART is enabled and it must receive *peripheral_clock* and *module_clock*.

47.4.3 General UART Definitions

Definitions of terms that occur the following discussions are given in this section.

- Bit Time—The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit—The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit—1 bit time of logic 1 that indicates the end of a data frame.
- BREAK—A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port transmit pin voltage is 1 and is said to be in a MARK state.
- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame—A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
- Framing Error—An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error—An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RXD input. Parity error is calculated only after an entire frame is received.
- Idle—One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error—An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RXD input.

47.4.3.1 $\overline{\text{RTS}}$—UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting ‘0’ on the $\overline{\text{RTS}}$ pin. Normally, the transmitter waits

until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion. When $\overline{\text{RTS}}$ is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

47.4.3.2 $\overline{\text{RTS}}$ Edge Triggered Interrupt

The input to the $\overline{\text{RTS}}$ pin can be programmed to generate an interrupt on a selectable edge. See Table 47-23 for summary of the operation of the $\overline{\text{RTS}}$ edge triggered interrupt (RTSF).

To enable the $\overline{\text{RTS}}$ pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the $\overline{\text{RTS}}$ edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the $\overline{\text{RTS}}$ input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 47-23. $\overline{\text{RTS}}$ Edge Triggered Interrupt Truth Table

$\overline{\text{RTS}}$	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On...	$\overline{\textit{interrupt\_uart}}$
X	0	X	X	0	Interrupt disabled	1
1–>0	1	0	0	0	Rising edge	1
0–>1	1	0	0	1	Rising edge	0
1–>0	1	0	1	1	Falling edge	0
0–>1	1	0	1	0	Falling edge	1
1–>0	1	1	X	1	Either edge	0
0–>1	1	1	X	1	Either edge	0

There is another $\overline{\text{RTS}}$ interrupt that is not programmable. The status bit RTSD asserts the $\overline{\textit{interrupt\_uart}}$ interrupt when the $\overline{\text{RTS}}$ delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

47.4.3.3 $\overline{\text{DTR}}$ - Data Terminal Ready

This signal indicates the general readiness of the Data Terminal Equipment (DTE). This signal is an input in DCE mode and an output in DTE mode. If the connection between the DCE and the DTE is established once, the $\overline{\text{DTR}}$ signal must remain active throughout the whole connection time. In general the $\overline{\text{DTR}}$ and $\overline{\text{DSR}}$ signals are responsible for establishing the connection. $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ are responsible for the data transfer and the transfer direction in the case of a half-duplex configuration. The $\overline{\text{DTR}}$ signal is like a "main switch". If the $\overline{\text{DTR}}$ signal is inactive the $\overline{\text{RTS}}$ and $\overline{\text{CTS}}$ signals have no effect. In DCE mode, an interrupt

(DTRD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion.

47.4.3.4 $\overline{\text{DSR}}$ - Data Set Ready

This signal indicates the general readiness of the DCE. This signal is an output in DCE mode and an input in DTE mode. The DCE uses this signal to inform the DTE that it is switched on, has completed all preparations and can communicate with the DTE. In DTE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the MCU from STOP mode on its assertion.

47.4.3.5 $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt

The $\overline{\text{DTR}}$ input pin (DCE mode) or $\overline{\text{DSR}}$ input pin (DTE mode) can be configured to cause an interrupt on a selectable edge. See Table 47-24 for summary of the operation of the $\overline{\text{DTR/DSR}}$ edge triggered interrupt. To enable the interrupt, set the DTREN bit (UCR3[13]) to ‘1’. Write a “one” to the DTRF bit (USR2[13]) to clear the interrupt flag.

The interrupt can be configured to occur on either the rising, falling, or either edge of the $\overline{\text{DTR/DSR}}$ input. Write to the DPEC[1:0] bits (UCR3[15:14]) to program which edge will cause an interrupt. If the bits are set to 00b and DTREN = 1, the interrupt will occur on the rising edge (default). If the bits are set to 01b and DTREN = 1, the interrupt will occur on the falling edge. If the bits are set to 1Xb and DTREN = 1, the interrupt will occur on either edge.

Table 47-24. $\overline{\text{DTR/DSR}}$ Edge Triggered Interrupt Truth Table

$\overline{\text{DTR}}$ / $\overline{\text{DSR}}$	DTREN	DPEC[1]	DPEC[0]	DTRF	Interrupt occurs on:	*$\overline{\text{interrupt\_uart}}$*
X	0	X	X	0	turned off	1
1->0	1	0	0	0	rising edge	1
0->1	1	0	0	1	rising edge	0
1->0	1	0	1	1	falling edge	0
0->1	1	0	1	0	falling edge	1
1->0	1	1	X	1	either edge	0
0->1	1	1	X	1	either edge	0

47.4.3.6 $\overline{\text{DCD}}$ - Data Carrier Detect

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE it has detected the carrier signal and the connection will be set up. This signal remains active while the connection remains established. In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to ‘1’ the interrupt enable bit (DCD, UCR3[9]). The change state is reflected in DCDDELT (USR2[6]). Also, the state of the Data Carrier Detect input is mirrored in the status register DCDIN (USR2[5]).

47.4.3.7 $\overline{\text{RI}}$ - Ring Indicator

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE that a ring just occurred. In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (RI, UCR3[8]). The change state is reflected in RIDELT (USR2[10]). Also, the state of the Ring Indicator input is mirrored in the status register RIIN (USR2[9]).

47.4.3.8 $\overline{\text{CTS}}$—Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the $\overline{\text{CTS}}$ trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

47.4.3.9 Programmable $\overline{\text{CTS}}$ Deassertion

The $\overline{\text{CTS}}$ output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the $\overline{\text{CTS}}$ pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

47.4.3.10 TXD—UART Transmit

This is the transmitter serial output. When operating in normal mode, NRZ encoded data is output. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted. For RS-232 applications, this pin must be connected to an RS-232 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 47-19.

47.4.3.11 RXD—UART Receive

This is the receiver serial input. When operating in normal mode, NRZ encoded data is expected. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received. External circuitry must convert the IR signal to an electrical signal. RS-232 applications require an external RS-232 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See Figure 47-19.

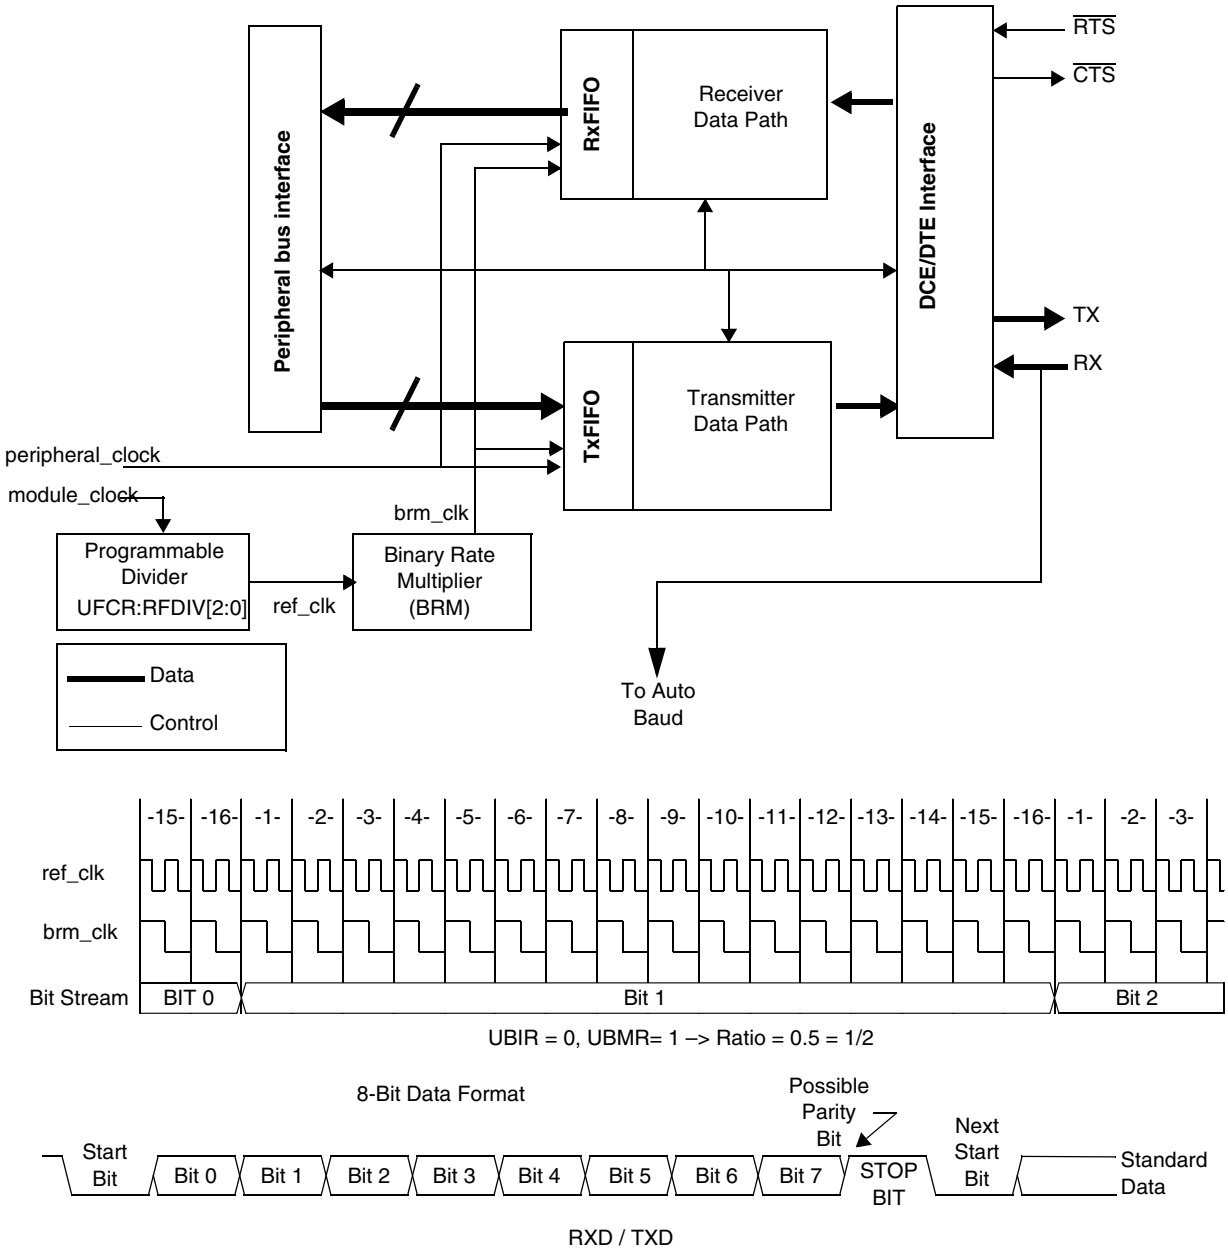

Figure 47-19. UART Simplified Block and Clock Generation Diagrams

47.4.4 Transmitter

The transmitter accepts a parallel character from the MCU and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character. When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. $\overline{\text{RTS}}$ can be used to provide flow-control of the serial data. When $\overline{\text{RTS}}$ is set to ‘1’, the transmitter finishes sending the character in progress (if any), stops, and waits for $\overline{\text{RTS}}$ to be set to ‘0’ again. Generation of BREAK characters and parity errors (for debugging

purposes) is supported. The transmitter operates from the clock provided by the BRM. Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error if the signal resp_sel is tied to 0.

47.4.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO. When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic does not immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset
- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See Figure 47-20.

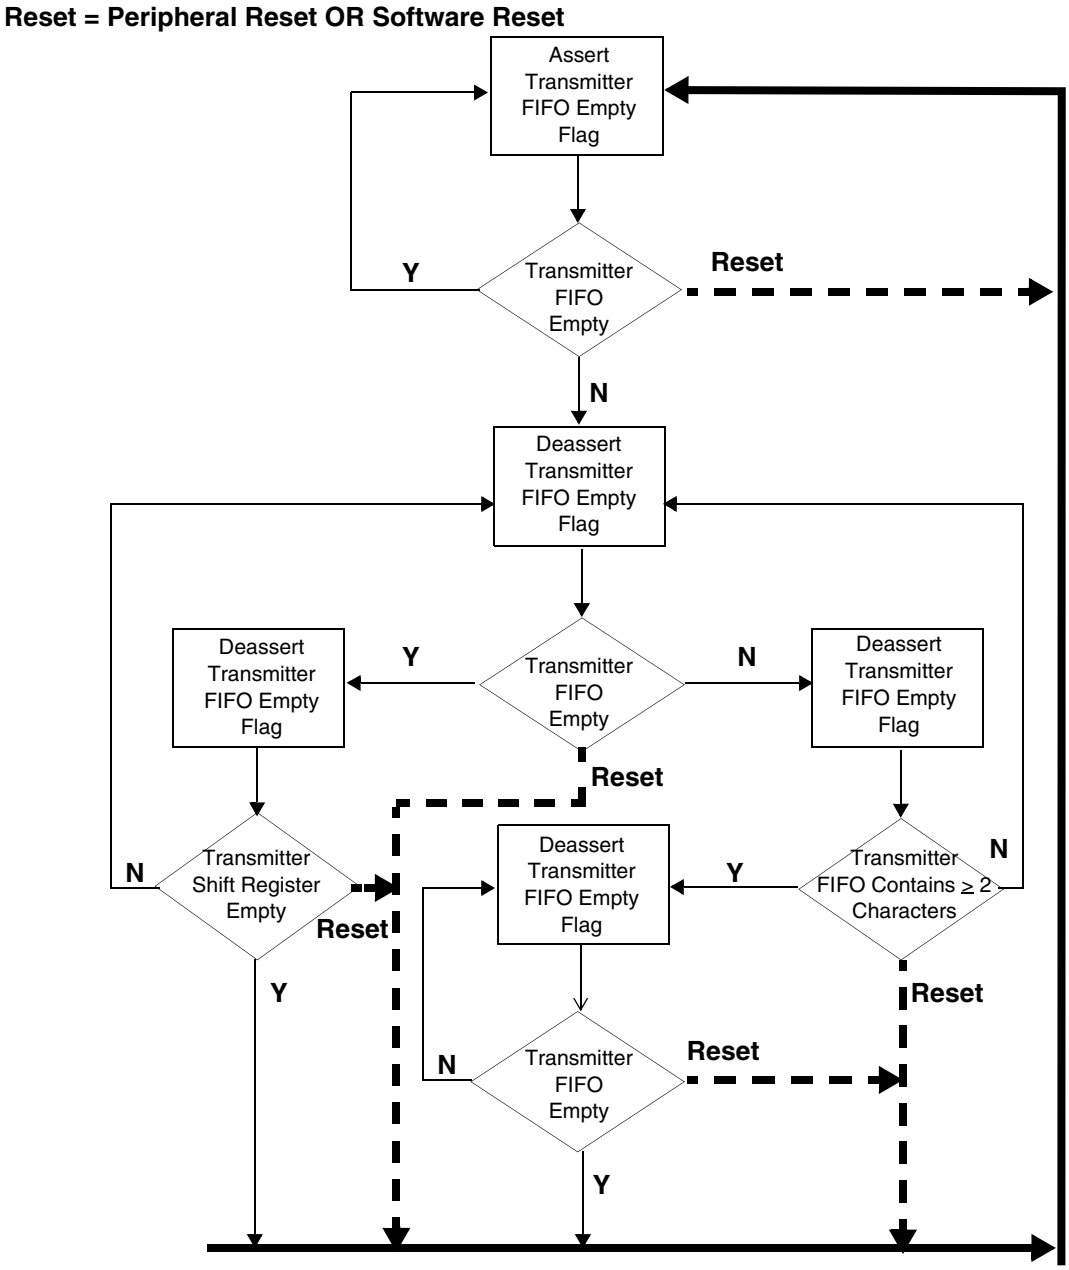

Figure 47-20. Transmitter FIFO Empty Interrupt Suppression Flow Chart

47.4.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset. The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

47.4.5 Receiver

See Figure 47-21 for the receiver flow chart. The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center. Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the MCU from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled.The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

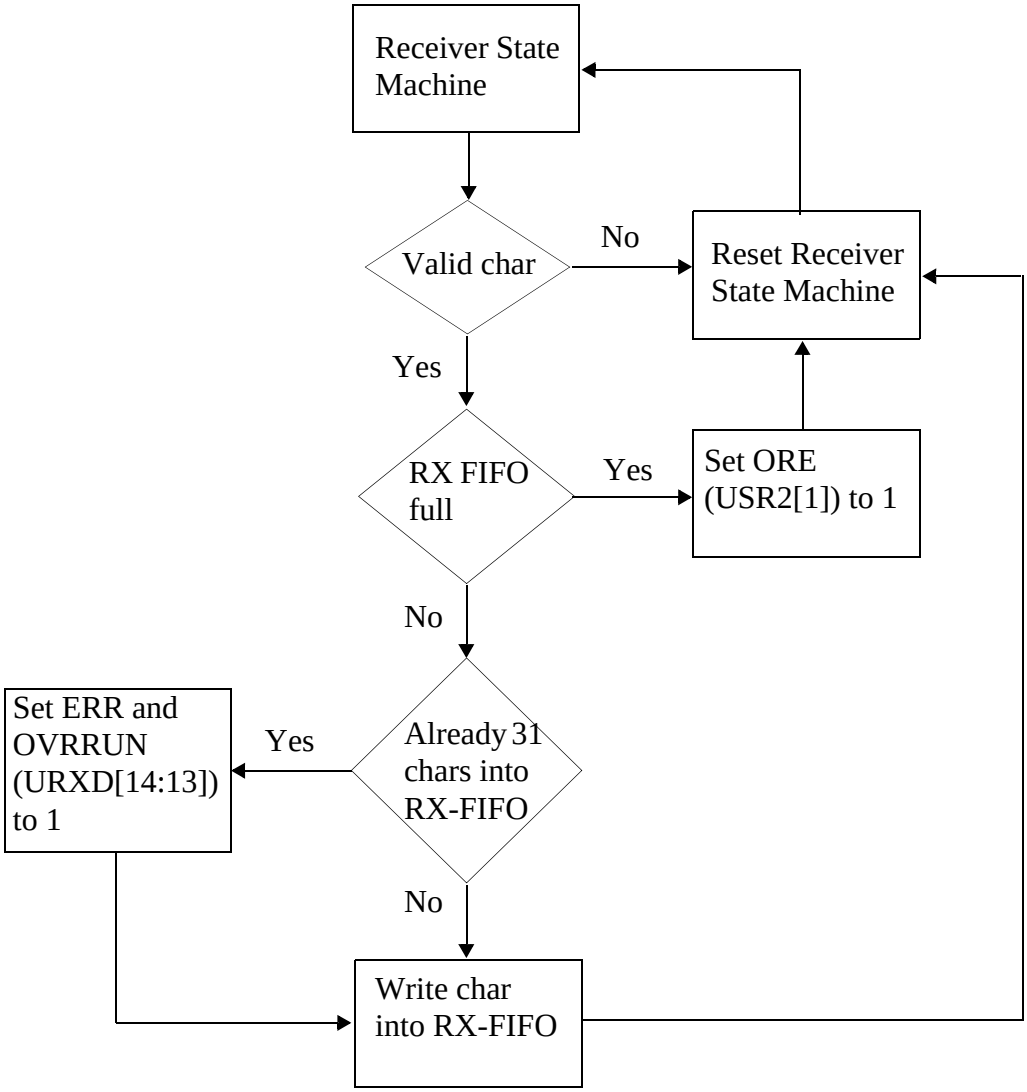

Figure 47-21. Receiver Flow Chart

47.4.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RXD pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see

Table 47-25). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 47-25. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
Note: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

47.4.5.2 Ageing Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This ageing character capability allows the UART to inform the MCU that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line. The ageing capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to MCU on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

47.4.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RXD line must be detected and secondly the RXD line must stays at low level for more than a half-bit duration. When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted

in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock*.

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the MCU is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RXD) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the MCU from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if MCU is in STOP mode (UART clocks are off when MCU in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the MCU from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RXD pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

47.4.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

47.4.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*. See Figure 47-22. The receiver is

provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see Table 47-26.

Table 47-26. Majority Vote Results

Samples	Vote
000	0
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 47-26). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

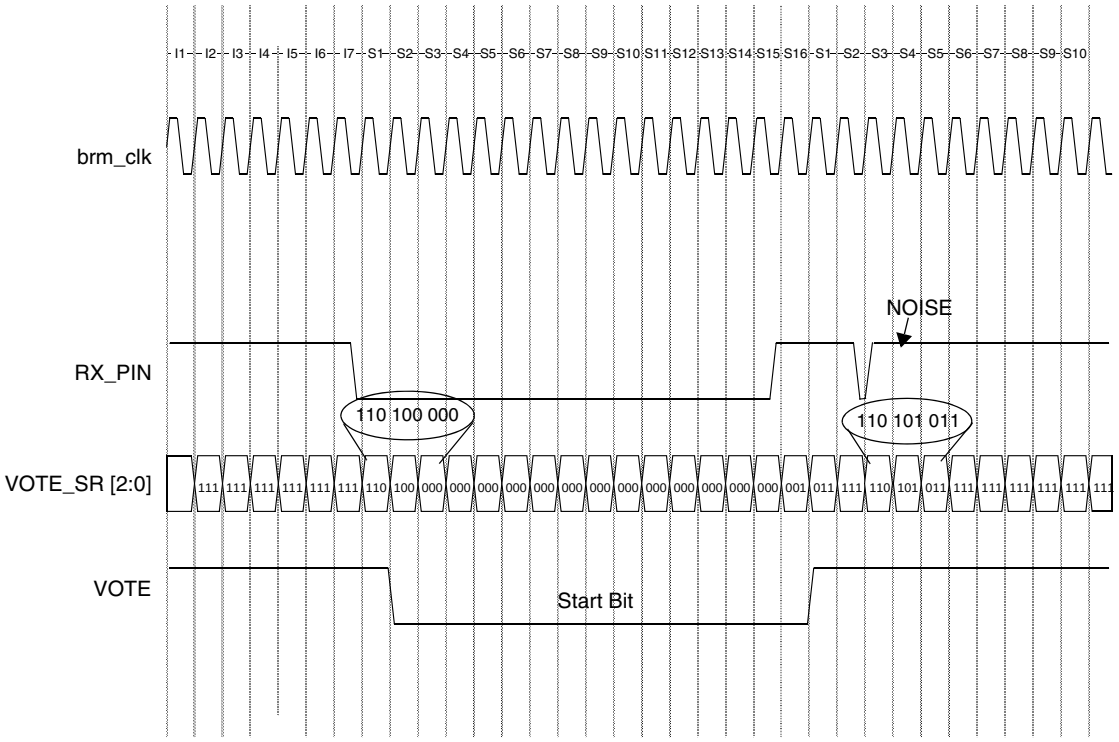

Figure 47-22. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RXD line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

See Section 47.4.7, “Infrared Interface” for more details.

47.4.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it. When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RXD) has been detected, UART start a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RXD), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.

UBIR = 0x000F

UBMR = UBRC - 1
```

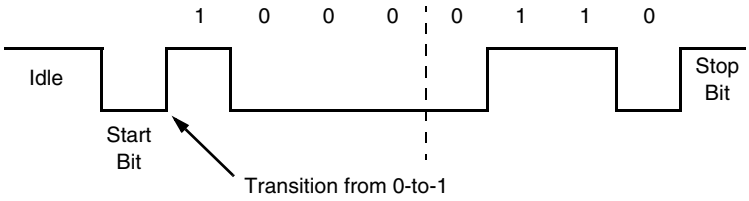
The updated values of the three registers can be read.

See Table 47-27 for list of parameters for baud rate detection and Figure 47-23 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 47-27. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	$\overline{\textit{interrupt\_uart}}$
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
Note: This table assumes that no other interrupt is set at the same time this interrupt is set for the $\overline{\textit{interrupt\_uart}}$ signal.			



Note: LSB transmitted first.

Figure 47-23. Baud Rate Detection Protocol Diagram

47.4.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character “A” or “a” to verify proper detection of the incoming baud rate. When an ASCII character “A” (0x41) or “a” (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt $\overline{interrupt\_uart}$ is generated.

When an ASCII character “A” or “a” is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character “A” or “a” is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active ($\overline{interrupt\_uart}$ = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character “A” or “a” following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

47.4.5.6.2 Baud Rate Automatic Detection Protocol Improved[1]

New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RXD line, the duration of the baud rate measurement has been extended. Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at

the next falling edge (end of bit0). As the character sent is always a “A” (41h) or a “a” (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate, So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on $\overline{interrupt\_uart}$ signal. This interrupt informs the MCU the BRM has just been set with the result of the bit length measurement. If needed, the MCU can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the MCU has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

- ACST is set only if ADBR is set to 1, for example, the UART is autobauding.
- Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

47.4.5.7 Escape Sequence Detection

An escape sequence typically consists of three characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence. Too much time between two of the “+” characters is interpreted as two “+” characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see Table 47-28). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

1.Several issues have been reported for ICs using the existing autobaud protocol, especially for 57.6 Kbit/s and 115.2 Kbit/s. As a consequence, this protocol has been improved. The old one is still available in the current UART IP, but several modifications can also be used in order to make this autobaud detection more reliable. If the user wants to keep with the old method, he has to set the bit ADNIMP (UCR3[7]) to 1. If this bit is not set (default), the autobaud improvements will be used. Those improvements are mainly grouped in two categories: the new baud rate measurement and the new ACST bit (and associated interrupt).

Table 47-28. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
…	…
0F8	498 ms
0F9	500 ms
…	…
9C3	5 s
…	…
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
Note: To calculate the time interval: (UTIM_Value + 1) × 0.002 = Time_Interval Example: (09C3 + 1) × 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider: UFCR[9:7] = 3’b100

Calculation of Frequency for ONEMS Register ***Eqn. 47-1***

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1with the internal divider: UFCR[9:7] = 3’b101

Calculation of Frequency for ONEMS Register ***Eqn. 47-2***

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

47.4.6 Binary Rate Multiplier (BRM)

The BRM sub-module receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock whose frequency is 16 times of baud rate. The UART transmitter will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

Frequency and Baud Rate for UBIR and UBMR ***Eqn. 47-3***

$$BaudRate = \frac{RefFreq}{\left(16 \times \frac{UBMR + 1}{UBIR + 1}\right)}$$

With

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Example 47-1. Integer Division ÷ 21

```
Reference Frequency = 19.44 MHz
UBIR = 0x000F
UBMR = 0x0014
Baud Rate = 925.7 kbit/s
```

NOTE

Observe that each value written to the registers is one less than the actual value.

Example 47-2. Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR + 1}{UBIR + 1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Example 47-3. Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

47.4.7 Infrared Interface

47.4.7.1 Generalities

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a “zero” is represented by a positive pulse, and a “one” is represented by no pulse (line remains low).

In the UART:

In TX: For each “zero” to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each “one” to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each “zero” transmitted while no pulse is expected for each “one” transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a “one” to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

47.4.7.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

47.4.7.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver. According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver cannot emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 us.

But user must take into account the electrical MPD associated to the transceiver on the receiver path. Typically this value is 2.0 us, but for some manufacturers MPD can go down to 1.0 us.

In order to understand the meaning of IRSC bit, one must understand how the RX path work in IrDA mode.

When UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with two different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means at any time, the user must insure the frequency of BRM_clock is high enough to measure the pulse. In the UART and for IRSC=0, the pulse must last at least two BRM clock cycles.

If this condition is not fulfilled, IRSC must be set to 1.

Two examples are presented, with the Minimum Pulse Duration equals to the MPD of the IrDA specification (in SIR).

Example 47-4. Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16*baud rate = 16 * 115.2 = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2* BRM_clock period is lower than 1.41 us. Lets check:

BRM_clock period = 1/1843000 = 542 ns

So 2*BRM_clock period = 1.09 us < 1.41 us. It is fine.

Example 47-5. Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to 16*19200 = 307.2 kHz. Check if 2* BRM_clock period < 1.41 us:

BRM_clock period =1/307200 = 3.25 us

So 2*BRM_clock period = 6.50 us >> 1.41 us. It does not work.

So, in this case, the BRM clock cannot be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. See Section 47.4.5.7, “Escape Sequence Detection.”

47.4.7.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

47.4.7.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit informs the user if IRSC bit has to be set or not.

Determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

Calculation of Baud Rate: ***Eqn. 47-4***

$$2 \times \text{BRMClockPeriod} < \text{MinPulseDuration}$$

So,

$$BRMClockFrequency > \frac{2}{MPD}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$BaudRate > \frac{1}{8 \times MinPulseDuration}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to1.

47.4.7.6 Programming IrDA Interface

47.4.7.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to MCU when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART

UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
RXTL[5:0] = 0x01: Default value

UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz

UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
```

```
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset

UCR3 = 0x0000
UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt is sent to MCU when a character is received.

47.4.7.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to MCU when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART

UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value

UBIR = 0x00FF

UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz

UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset

UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.

UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
```

```
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt is sent to MCU when a character is received.

47.4.8 Low Power Modes

Table 47-29 shows the UART functionality while in hardware controlled low-power modes. These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers will not change when getting into/out of low power modes.

Table 47-29. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

47.4.8.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit. While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

47.4.8.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of UART module continue to run during system Stop mode the UART will not do any transmission or reception.

The following UART interrupts wake the MCU processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the MCU from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

47.4.8.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

47.4.9 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
   a) All writes into the RX FIFO are prevented.
   b) The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

      RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

      RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

47.4.10 Reset

This section describes how to reset the module and explains special requirements related to reset.

47.4.10.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

47.4.10.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will remain the software reset signal at active for about 4 *module_clock* cycles. Programmer can follow the following software reset sequence:

1. Clear the $\overline{\text{SRST}}$ bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

47.4.11 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

47.4.12 Functional Timing

This section includes timing diagrams for functional signaling.

47.4.12.1 RS-232 Mode

When transmitting a byte, the UART first sends a Start Bit which is logic 0, followed by the data (general 8 bits, but could be 7 bits) followed by parity bit (optional) and one or two Stop Bits which is logic 1. The sequence is repeated for each byte sent. Figure 47-24 shows a diagram of a what a byte transmission would look like. The receiver also sample data according to this format.

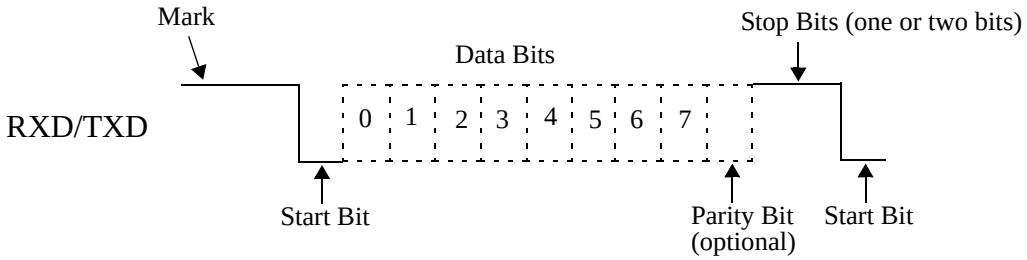


Figure 47-24. Timing Diagram of RS-232 Serial Data Line

47.4.12.2 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame. Figure 47-25 shows the timing of IR data line and corresponding UART frame. In this figure, an example data 0x65 is used.

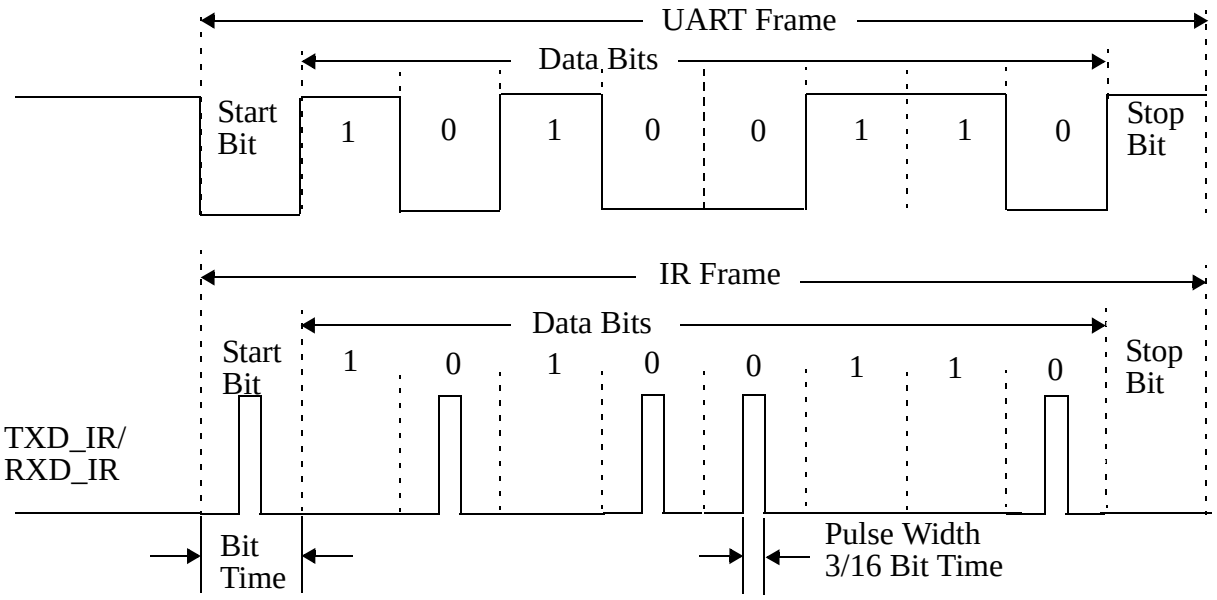

Figure 47-25. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

47.5 Initialization

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input UART clock = 100 MHz
- Baud rate = 921.6Kbps
- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x2127

Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C

Set CTS trigger level to 31,

5. UFCR = 0x089E

Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is 100MHz/5 = 20MHz.

Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

Enable the TRDY and RRDY interrupts.

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

Chapter 48
Universal Serial Bus OTG and Host (USBOH)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

The USBOH module contains all of the functionality required to support 2 independent USB ports, compatible with the USB 2.0 specification. In addition to the normal USB functionality, the module also provides support for direct connections to on-board USB peripherals with serial, UTMI or ULPI protocol, and supports multiple interface types for ULPI and serial transceivers.

48.1 Overview

The USBOH module provides high performance USB on-the-go (OTG) functionality, compliant with the USB 2.0 specification, the OTG supplement and the ULPI specification. The module consists of two independent USB cores (host core and OTG core), each with serial and ULPI USB ports.

In addition to the USB cores, the module provides for full-speed transceiverless link (TLL) operation on the host port. The OTG core also supplies the UTMI interface for the internal UTMI PHY.

Figure 48-1 shows a block diagram of USBOH.

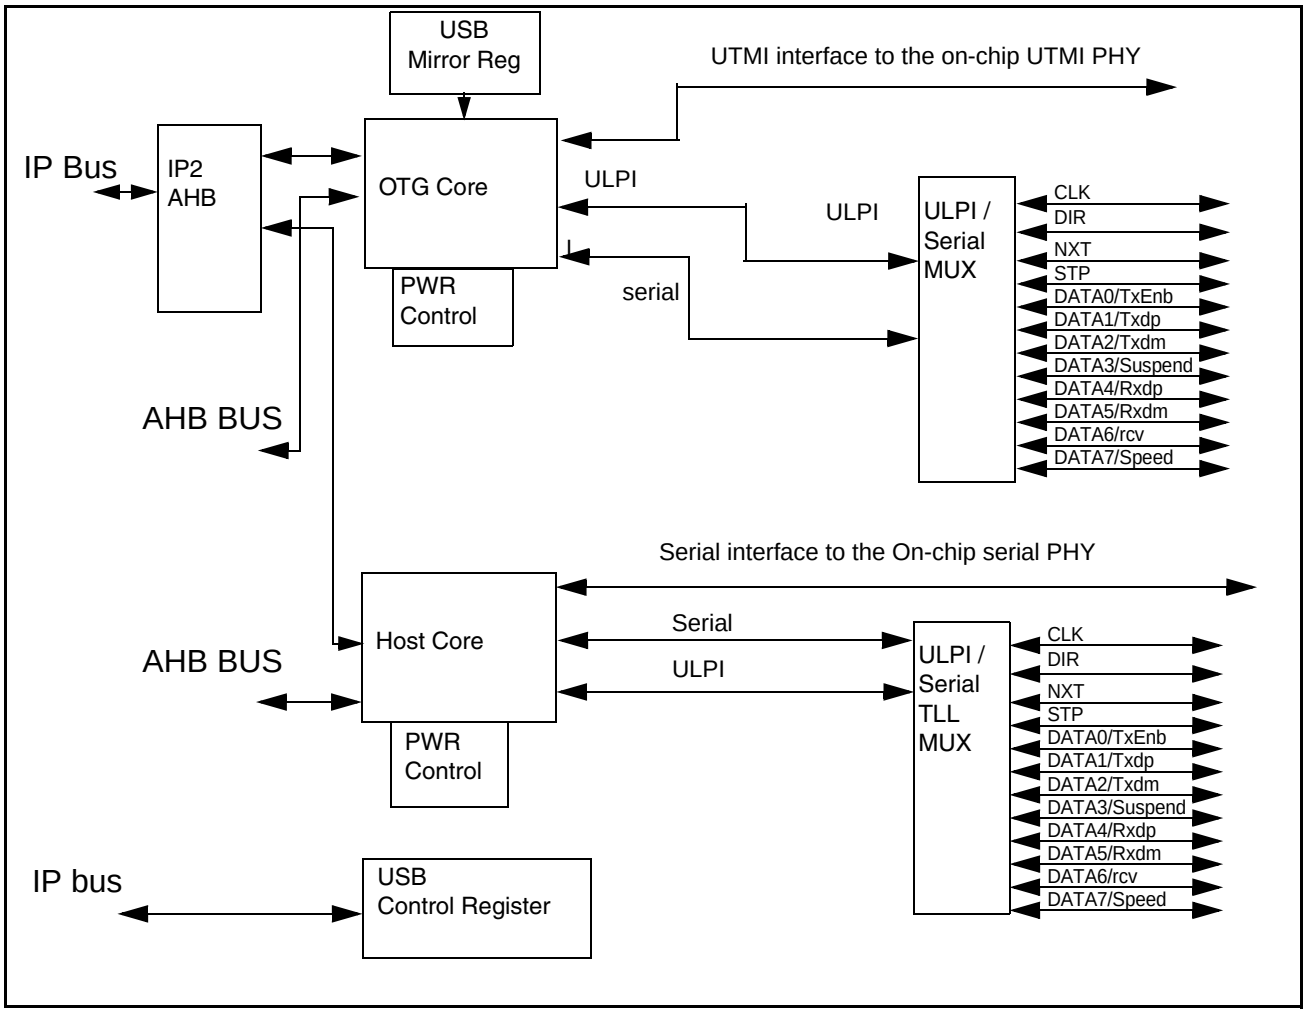

Figure 48-1. USBOH Block Diagram

48.1.1 Features

The USBOH module includes the following features:

- High-speed / full-speed / low-speed host-only core:
  - HS/FS ULPI compliant interface
  - Software-configurable for full-speed / low-speed interface for Serial transceiver
  - Full-speed transceiverless link logic (FS-TLL) for on-board connection to an FS/LS USB peripheral
  - Software-configurable interface for internal serial PHY, external serial PHY and ULPI PHY selection
- High-speed / full-speed / low-speed OTG core
  - HS/FS ULPI-compliant interface
  - Software-configurable for ULPI or serial transceiver interface

  - High-speed (with ULPI transceiver), full-speed and low-speed operation in host mode
  - High-speed (with ULPI transceiver), and full-speed operation in peripheral mode
  - Hardware support for OTG signaling, session request protocol and host negotiation protocol
  - Up to 8 bidirectional endpoints
  - Software-configurable interface for internal UTMI PHY, external serial PHY and external ULPI PHY selection
- Low power mode with local and remote wakeup capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller

48.1.2 Modes of Operation

USBOH modes of operation include normal and low-power modes.

48.1.2.1 Normal Mode

In normal mode, each USB core controls its corresponding port. Both host port and OTG port can work in a number of modes, which are described in Section 48.1.2.1.1, “Host Port Modes and Section 48.1.2.1.2, “OTG Port Modes” respectively.

In addition to these modes, each USB core interface can be configured for high-speed (480 Mbps) and/or full/low-speed operation (12/1.5 Mbps).

48.1.2.1.1 Host Port Modes

The host port supports ULPI and serial transceivers, as well as the internal Serial USB transceiver. The following modes are supported by the host port:

- Internal serial interface mode, used for connecting an on-chip Serial USB PHY
- External serial interface mode, used for connecting an on-board Serial USB PHY
- ULPI interface mode, which is the low pin-count standard for connecting off-chip high-speed USB transceivers. When the port is configured for ULPI mode, only a ULPI-compatible transceiver can be used.
- FS TLL mode, which is typically used for on-board USB connections to USB-capable peripherals. This mode emulates the functionality of two back-to-back connected transceivers, so host and peripheral can be connected without PHY. The FS-TLL is used in serial interface mode for full/low-speed transfers.

48.1.2.1.2 OTG Port Modes

The OTG port requires a transceiver and is intended for off-board USB connections. The following modes are supported by the OTG port:

- Serial interface mode. The port does not support dedicated signals for OTG signaling: instead, a transceiver with built-in OTG registers must be used. Typically, the transceiver registers are accessible over an I^2C or SPI interface

- ULPI mode. In this mode, a ULPI transceiver is connected to the port contacts to support high-speed off-board USB connections. ULPI mode is activated by writing the relevant register.
- UTMI mode. In this mode, the on-chip UTMI transceiver is connected to the USB module.

48.1.2.2 Low-Power Mode

Each USB core has an associated power control module that is controlled by the USB core and clocked on a 32 kHz clock. When a USB bus is idle, the transceiver can be placed in low-power (suspend) mode, after which the clocks to the USB core can be stopped. The 32 kHz low power clock must remain active, as it is needed for wakeup detection.

Either the local CPU or the remote USB host/peripheral can initiate a wakeup sequence to resume USB communication.

48.2 Memory Map/Register Definition

Table 48-1 shows the USBOH module memory map. For the base address of a particular module instantiation, see the system memory map.

The buffers are not accessible via the IP bus, so they do not appear in the memory map.

Table 48-1. USBOH Module Memory Map

48.2.1 Register Descriptions

This section describes only the registers that are additional to the HS-USB Core register set. For a detailed description of the registers inside the HS-USB controllers, see Section 48.4.1, “Register Interface”.

48.2.1.1 USB Control Register (USB_CTRL)

The USB control register controls the integration-specific features of the USB module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wakeup functionality.

Offset 0x0600 (USB_CTRL) Access: User read/write

Field	Description
31 OWIR	OTG wakeup interrupt request. This bit indicates that a wakeup interrupt request is received on the OTG port. This bit is cleared by disabling the wakeup interrupt. 0 No wakeup detected (default) 1 Wakeup interrupt request received
30–29 OSIC	OTG serial interface configuration. Controls the interface type of the OTG port when used with a serial transceiver. This bit field allows for configuring the serial interface for single ended or differential operation combined with bidirectional or unidirectional operation. 00 Differential/unidirectional (6-wire) 01 Differential/bidirectional (4-wire) 10 Single-ended/unidirectional (6-wire) (default) 11 Single-ended/bidirectional (3-wire)
28 OUIE	OTG ULPI interrupt enable. Controls whether or not interrupts from the ULPI transceiver trigger the wakeup logic. This bit is only meaningful when a ULPI transceiver is selected. 0 ULPI transceiver interrupts are ignored by the wakeup logic (default) 1 ULPI transceiver interrupts activate the wakeup logic
27 OWIE	OTG Wakeup interrupt enable. This bit enables or disables the OTG wakeup interrupt. Disabling the interrupt also clears the interrupt request bit. Wakeup interrupt enable must be turned off after receiving a wakeup interrupt and turned on again prior to going in suspend mode. 0 Interrupt disabled (default) 1 Interrupt enabled
26 HEX_TEN	Host external ULPI clock enable. Selects whether the host clock comes from external PHY or internal PLL. This bit must be set to 1 before setting the host core into ULPI mode. It must be cleared when setting the host core into FS serial mode 0 Select host clock from internal PLL (serial mode) (default) 1 Select host clock from external PHY (ULPI mode)
25 OEX_TEN	OTG external ULPI clock enable. Select whether the OTG clock comes from external PHY or internal PLL. This bit must be set to 1 before setting the OTG core into ULPI mode. It must be cleared when setting OTG core into FS serial mode 0 Select OTG clock from internal PLL (serial mode) (default) 1 Select OTG clock from external PHY (ULPI mode)
24 OPM	OTG power mask. Controls whether or not the external Vbus power and overcurrent detection are active for the OTG port. 0 The USBPWR signal asserts with the OTG core's Vbus power enable, and the assertion of the OC input is reported to the OTG core. (default) 1 The USBPWR and OC signals are not used by the OTG core.
23 HWIR	Host wakeup interrupt request. Indicates a pending wakeup request on host port 2. This bit is cleared by disabling the interrupt. The interrupt must be disabled for at least 2 clock cycles of the standby clock. 0 No wakeup interrupt received (default) 1 Wakeup interrupt received

Table 48-2. USB_CTRL Register Field Description (continued)

Field	Description
22–21 HSIC	Host serial interface configuration. Controls the interface type of the Host port when used with a serial transceiver. This bit field allows for configuring the serial interface for single ended or differential operation combined with bidirectional or unidirectional operation. 00 Differential/unidirectional (6-wire) 01 Differential/bidirectional (4-wire) 10 Single-ended/unidirectional (6-wire) (default) 11 Single-ended/bidirectional (3-wire)
20 HUIE	Host ULPI interrupt enable. Controls whether or not interrupts from the ULPI transceiver triggers the wakeup logic. This bit is only effective when a ULPI transceiver is selected. 0 ULPI transceiver interrupts are ignored by the wakeup logic.(default) 1 ULPI transceiver interrupts activate the wakeup logic
19 HWIE	Host wakeup interrupt enable. This bit enables or disables the host wakeup interrupt. Disabling the interrupt also clears the interrupt request bit. Wakeup interrupt enable must be turned off after receiving a wakeup interrupt and turned on again prior to going in suspend mode 0 Interrupt disabled (default) 1 Interrupt enabled
18 PP_HST	Power polarity for Host. Controls the polarity of the PWR output signal of Host 0 Low active (power is supplied when PWR is negated) (default) 1 High active (power is supplied when PWR is asserted)
17 OV_EN	AHB override enable This bit can be only used when cores (both OTG and Host) work in INC mode (configure SBUSCFG,base+0x90). When enabled, all INC AHB transfers will be overridden to INCR8 AHB transfer. 0 AHB override disable (default) 1 AHB override enable
16 HPM	Host power mask. The power mask bit controls whether or not the external Vbus power and overcurrent detection are active for the host port. 0 The USBPWR signal asserts the host core's Vbus power enable and the assertion of the OC input is reported to the host core.(default) 1 The USBPWR and OC signals are not used by the host core.
15 VBUS_WKEN	OTG VBUS wakeup enable The VBUS wakeup enable/disable of OTG. When using internal UTMI PHY and OTG works in device mode, if nothing attached to the OTG port and user want to enter into suspend mode to save power, set this bit will enable a wakeup event after VBUS pin changed (external USB Host is attached to the OTG port), this wakeup event will generate interrupt if OWIE is enabled. 0 OTG VBUS wakeup disable.(default) 1 OTG VBUS wakeup enable.
14 ID_WKEN	OTG ID wakeup enable The ID wakeup enable/disable of OTG. When using internal UTMI PHY and OTG works in device mode, if nothing attached to the OTG port and user want to enter into suspend mode to save power, set this bit will enable a wakeup event after ID pin changed (external USB Device is attached to the OTG port), this wakeup event will generate interrupt if OWIE is enabled. 0 OTG ID wakeup disable.(default) 1 OTG ID wakeup enable.

Table 48-2. USB_CTRL Register Field Description (continued)

Field	Description
13 OLKEN	OTG AHB lock enable The AHB lock enable/disable of OTG. 0 OTG lock disable. The OTG core will never use locked transfer to access memory (default) 1 OTG lock enable. The OTG core will always use locked transfer to access memory. When transfers are locked, the USB controller will keep the bus between bursts until it has filled it's internal TX FIFO or emptied it's RX FIFO
12 HLKEN	Host AHB lock enable The AHB lock enable/disable of Host. 0 Host lock disable. The Host core will never use locked transfer to access memory (default) 1 Host lock enable. The Host core will always use locked transfer to access memory. When transfers are locked, the USB controller will keep the bus between bursts until it has filled it's internal TX FIFO or emptied it's RX FIFO
11 PP_OTG	Power polarity. Controls the polarity of the PWR output signal of OTG. 1 High active (power is supplied when PWR is asserted) 0 Low active (power is supplied when PWR is negated)
10 XCSO	XCVR clock select for OTG port. This bit enables software to force the OTG port to use the internal 60 MHz clock. This is used when the PHY's 60 MHz clocks have not been supplied to the OTG port but the OTG port is in the XCVR supply clock mode. 0 OTG port is not forced to use the internal 60 MHz (default) 1 OTG port is forced to use the internal 60 MHz clock
9 XCSH	XCVR clock select for host port. This bit enables software to force the host port to use the internal 60 MHz clock. This is used when the PHY's 60 MHz clocks have not been supplied to the host port but the host port is in the XCVR supply clock mode. 0 Host port is not forced to use the internal 60 MHz (default) 1 Host port is forced to use the internal 60 MHz clock
8 IP_PUIDP	Dp pull-up Impedance select on the on-chip full-speed PHY. 0 Pull-up resistor 900 Ohm < R< 1575 Ohm (default) 1 Pull-up resistor 1425 Ohms < R< 3090 Ohms
7 IP_PUE_UP	This bit enables the Dp Pull-up resistor on the on-chip full-speed PHY. This bit must be 0 for host mode operation. 0 Pull-up resistor disabled (default) 1 Pull-up resistor enabled
6 IP_PUE_DWN	This bit enables the 15K ohm Dm/Dp pull-down resistors of the on-chip full-speed PHY. This bit must be set for host mode operation. 0 Pull-down resistor disabled (default) 1 Pull-down resistor enabled
5 HSTD	Host serial TLL disable. This bit controls whether or not the serial transceiverless link logic (FS-TLL) is enabled for the serial interface of host port. 0 Serial TLL is enabled (default) 1 Serial TLL is disabled
4 USBTE	Transceiver Enable. This bit controls the enable for the on-chip serial transceiver of the host controller. 0 Full Speed transceiver disabled (default) 1 Full Speed transceiver enabled

Table 48-2. USB_CTRL Register Field Description (continued)

Field	Description
3 OCPOL_OTG	Overcurrent polarity of OTG. This bit selects the polarity of OTG overcurrent. 0 Low active 1 High active (default)
2 OCPOL_HST	Overcurrent polarity of host. This bit selects the polarity of host overcurrent. 0 Low active 1 High active (default)
1 HOCS	Host overcurrent state. This bit shows the overcurrent state of the host. 1 The host has an overcurrent event 0 The host has no overcurrent event
0 OOCS	OTG overcurrent state. This bit is to show the overcurrent state of the OTG. 0 The OTG has no overcurrent event 1 The OTG has an overcurrent event

48.2.1.2 OTG Port Mirror Register (USB_OTG_MIRROR)

The OTG port is designed for operation with an external OTG transceiver. When a ULPI transceiver is in use, all OTG signaling is communicated over the ULPI data bus as described in the ULPI specification. However, when a serial transceiver is used, the interface for OTG signaling is not standardized. Most OTG transceivers use a serial interface like I2C or SPI to transfer the OTG signaling back to the CPU and/or USB core. In this case, the USB CORE has no direct connection the OTG signals in the transceiver.

The USB_OTG_MIRROR register provides a soft interface between the OTG signals in the transceiver and the OTG signal inputs to the USB core. The USB driver software is responsible for reading the OTG status registers in the transceiver over the serial interface and set the bits accordingly in the USB_OTG_MIRROR register, such that the USB controller knows the status of the transceiver.

The USB driver must be designed to meet the latency requirements as defined in the USB 2.0 OTG supplement specification.

Figure 48-3. USB_OTG_MIRROR Register

Table 48-3. USB_OTG_MIRROR Register Field Descriptions

Field	Description
31–9	Reserved, read as 0.
8 OUTMICLK	OTG UTMI PHY clock on detection. This read-only status bit indicates the external USB UTMI PHY clock is on and supplied to the module. 0 The OTG UTMI input clock is off 1 The OTG UTMI input clock is on
7 OULPICLK	OTG ULPI PHY clock on detection. This read-only status bit indicates the external USB ULPI PHY clock is on and supplied to the module. 0 The OTG ULPI input clock is off 1 The OTG ULPI input clock is on
6 HULPICLK	Host ULPI PHY clock on detection. This read-only status bit indicates the external USB ULPI PHY clock is on and is supplied to module. 0 The host ULPI input clock is off 1 The host ULPI input clock is on
5	Reserved, read as 0.
4 SESEND	B device session end. This bit is set by the USB driver when the PHY reports a session end condition. 0 Session active 1 Session end (0.2 V < Vbus < 0.8 V)
3 VBUSVAL	Vbus valid. The USB driver sets this bit when the transceiver reports Vbus valid. 0 Vbus invalid (Vbus < 4.4 V) 1 Vbus is valid (Vbus > 4.4 V)
2 BSESVLD	B session valid. This bit is set by the USB driver when a valid ‘B session’ level is detected on Vbus. 0 B Session is not valid (Vbus < 0.8 V) 1 B session is valid (0.8V < Vbus < 4.0 V)
1 ASESVLD	A session valid. This bit is set by the USB driver when a valid ‘A session’ level is detected on Vbus. 0 Session is not valid for A device. 1 A session is Valid (0.8 V < Vbus < 2.0 V)
0 IDDIG	OTG ID-contact status. This bit indicates to the USB core whether it operates as A-device or as B-device 0 ID contact is low -- operate as A-device 1 ID contact is high -- operate as B-device

48.2.1.3 OTG UTMI PHY Function Control Register (USB_PHY_CTRL_FUNC)

This register controls the on-chip UTMI PHY function signals.

Offset 0x0608 (USB_PHY_CTRL_FUNC) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 48-4. USB_PHY_CTRL_FUNC Register Diagram

Table 48-4. USB_PHY_CTRL_FUNC Register Field Description

Field	Description
31–28	Reserved, read as 0
27 CLKVLD	UTMI clock valid. This read-only bit indicates the clock from the on-chip UTMI PHY is valid and stable 0 The clock is not stable 1 The clock is stable
26 SUSP	UTMI suspend. This bit allows software to force the UTMI PHY in low power suspend. Clearing this bit is equivalent to setting the PHCD bit in the USB controller's PORTSC register with the exception that the PHY will not respond to wake-up requests when this bit is 0. 0 PHY in low power suspend mode 1 Normal operation. Low-power suspend controlled by USB controller. (default)
25 RESET	UTMI reset. This bit allows software to force a reset on the UTMI PHY. This should only be used in exceptional cases as the USB core will perform PHY reset when appropriate. Setting this bit will reset all in the UTMI PHY except the clock generation logic. 0 Normal operation (default) 1 PHY reset
24 USBEN	UTMI USB enable. Enables/disables the USB UTMI PHY. Clear this bit will reset all in the UTMI PHY include the clock generation logic. 0 Disable UTMI PHY 1 Enable UTMI PHY (default)
23 EVDO	UTMI external Vbus divider option. Enables off-chip resistor divider for Vbus 0 Disable (default) 1 Enable
22 LSFE	UTMI line state filter enable. Enables filtering of line state to account for skew between D+/D- signals 0 Disable 1 Enable (default)
21	Reserved. Default setting (0) is not to be changed.
20 VCTL_LD	UTMI vendor control load. For Freescale test use only.

Table 48-4. USB_PHY_CTRL_FUNC Register Field Description (continued)

Field	Description
19–16 VCTL_ADDR	UTMI vendor control address. For Freescale test use only.
15–8 VCTL_DATA	UTMI vendor control data. For Freescale test use only.
7–0 VSTS	UTMI vendor control status. For Freescale test use only.

48.2.1.4 OTG UTMI PHY Test Control Register (USB_PHY_CTRL_TEST)

1 NFC	UTMI no Frequency check. For Freescale test use only.
0 FT	UTMI function test. For Freescale test use only.

48.3 Functional Description

This section describes the functionality and the topology of the different building blocks of the USB module.

48.3.1 USB Host Controller

The host controller core can be configured for high-speed, full-speed or low-speed operation.

48.3.2 USB OTG Controller

The OTG controller offers high-speed (HS), full-speed (FS) and low-speed (LS) capabilities in host mode, and HS/FS in device mode.

48.3.2.1 OTG Controller Host Mode

The controller supports direct connection of a FS/LS device (without external hub) with external serial transceiver and HS/FS device with external ULPI transceiver. There is no separate transaction translator block in the system: this function has been implemented within the DMA and protocol engine blocks to support connection to FS/LS devices.

48.3.2.2 OTG Controller Peripheral (Device) Mode

Peripheral mode has the following features:

- Up to 8 bidirectional endpoints
- HS/FS operation
- Supports HNP and SRP OTG protocols
- Remote wakeup capable

48.3.3 USB Power Control Module

The HS-USB module supports low power suspend and wakeup functionality.

48.3.3.1 Entering Low Power Suspend Mode

Suspend mode is always entered under control of driver software by setting the appropriate bit in the PORTSC register. After the controller is suspended, the clocks to the USB block can be stopped.

48.3.3.2 Wakeup Events

The power control module monitors the USB bus when the USB core is in the suspend state. Depending on whether the core is on host or device mode, a number of wakeup conditions are detected. Upon detection of a wakeup condition, an interrupt (asynchronous) is generated on the CPU complex.

48.3.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote wakeup request

  A peripheral can request the host to reactivate the bus by driving wakeup signaling on the Dm/Dp lines. The power control module detects a J-K transition on the Dm/Dp lines and signal the wakeup request to the core.
- Wake on over-current

  If wake on over-current is enabled in the PORTSC registers, the power control module signals a wakeup condition to the USB core.

- Wake on disconnect

  The power control module detects disconnect events by monitoring the Dp/Dm lines. When a disconnect event is detected (Dm = Dp = 0) and the wake on disconnect is enabled in the PORTSC register, the core is notified.
- Wake on connect

  Similar to the wake on disconnect, the power control module detects a connect event (Dm or Dp assert) and signals this to the USB core by setting the pwrctl_wakeup signal if enabled in the PORTSC register.

48.3.3.2.2 Device Mode Events

When the OTG controller is configured for peripheral operation, the power control module detects the following events:

- Bus activity detection

  Any non-idle condition on the USB bus activates the wakeup output of the power control module to notify the USB core of the wakeup event.
- Device connection detection

  When using on-chip UTMI PHY, the USB module can enter into suspend mode if nothing is attached to the OTG port. After a device is connected to the port, the ID pin changes from 1 to 0, activating the wakeup output of the power control module which notifies the USB core of the wakeup event. This event is generated only if the proper bit is set in USB_CTL register
- Host connection detection

  When using on-chip UTMI PHY, the USB module can enter into suspend mode if nothing is attached to the OTG port. After a device is connected to the port, the VBUS pin changes from 0 to 1, activating the wakeup output of the power control module which notifies the USB core of the wakeup event.This event is generated only when proper bit is set in USB_CTL register

48.3.4 Full-Speed Transceiverless Link Logic (FS-TLL) Module

The transceiverless link logic circuit allows two microcontrollers to use USB as an interprocessor communication link (ICL) without using conventional USB transceivers. The TLL multiplexers support serial-type (FS-TLL) interfacing, which is available on the host port. FSL-TLL mode has the following properties:

- FS-TLL can be selected based on the type of USB peripheral. The FS/LS serial interface protocol is supported.
- The TLL can be disabled by setting the HSTD bit in the USB CONTROL register. This disables the FS-TLL module, and the host USB core works in conventional USB mode.
- The TLL meets the timing requirements of both host and device.

48.3.4.1 Serial FS-TLL Functional Description

The Serial FS-TLL is a logical representation of two serial transceivers connected by a USB cable. The USB bus DM/DP states are modeled internally in the FS-TLL function, such that the USB I/O port acts as if it were a transceiver.

In a regular USB implementation with serial PHYs, the speed selection on the USB bus is done by means of a pull-up resistor on the peripheral side either on the DM (low-speed) or the DP (full-speed) line. This pull-up resistor pulls one of the USB lines high when the bus is idle. This option cannot be modeled in logic, as the serial USB interface does not provide for such a signal. The FS-TLL multiplexer is therefore configured for full-speed only operation.

The IDLE condition of the bus is determined by the TxEnb signals and suspend signals on both sides of the multiplexer. When both TxEnb signals are high, or when one or both suspend signals are high, the idle condition is assumed. The FS-TLL module then drives TxDp high and TxDm low on both sides of the block.

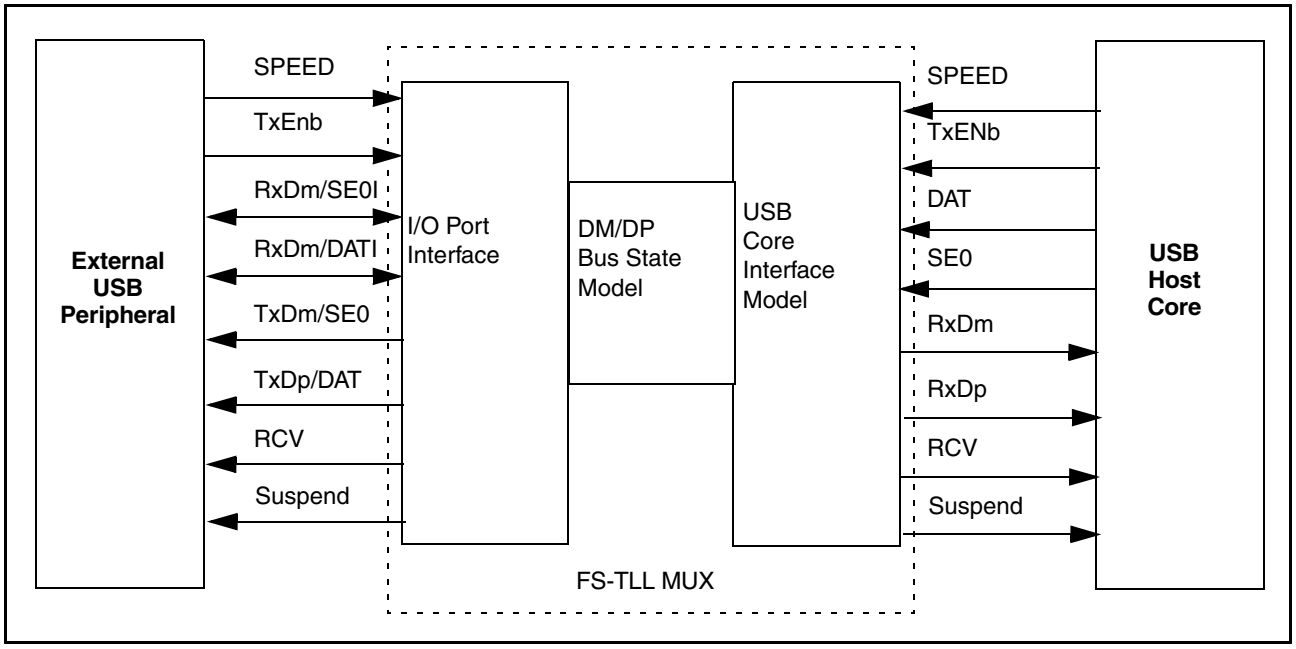

Figure 48-6. FS-TLL Multiplexer Functional Diagram

48.3.5 ULPI/Serial Multiplexer

Host and OTG cores can be configured by software for ULPI or serial PHY operation. The ULPI/serial multiplexer selects between ULPI interface signals and serial PHY interface signals. The multiplexer is controlled by the PHY select signals from the USB core and is switched when the software selects the interface mode.

The default configuration for the multiplexer is serial mode. Switching to ULPI mode is done by writing 0b10 to the parallel transceiver select (PTS) bits in the PORTSC register.

48.3.6 Interrupts

48.3.6.1 USB Core Interrupts

Each USB core uses one dedicated vector in the interrupt table. The vector numbers associated with each of the cores can be found in the “Interrupts and DMA Events” chapter.

With the exception of the wakeup interrupts, all of the interrupt sources are controlled in the USB cores. See Section 48.4, “Initialization/Application Information” for more details.

48.3.6.2 USB Wakeup Interrupts

Each USB core has an associated wakeup interrupt. The wakeup interrupts are generated outside the USB cores, but use the same vector as the corresponding core’s interrupt. These interrupt are generated by the power control modules that run on the 32 kHz standby clock.The wakeup interrupt works even when the USB and CPU clocks are disabled, so that a wakeup condition on the USB bus can reactivate the CPU clocks. USB clocks that were gated in the CCM module must be re-enabled by software.

Because the wakeup interrupt is generated and cleared on a 32 kHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wakeup interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously, because the request is clocked by the CPU clock. The software must then wait for at least three 32 kHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. As this interrupt is only used for USB low-power modes, it is sufficient to enable the wakeup interrupt just prior to entering USB suspend mode.

48.4 Initialization/Application Information

This section describes detailed application information for host and OTG ports. Some of the following content is related to host, and some relates to device. Device-related content is specific to OTG, while Host-related content applies to both ports.

48.4.1 Register Interface

Slave accesses from the controlling processor enables access to the configuration, control, and status registers. One function of the system address map is the registers base address, which must begin on a dword (32-bit) boundary. Register offset definitions are listed in the table below.

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are comprised of dynamic control or status registers that may be read-only, read/write, or read/write to clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

NOTE

Host mode EHCI compatibility begins at offset 0x100. If it is necessary to begin the EHCI register set at offset 0x000, the identification registers can be disabled from the address map by connecting the uppermost address bit of the slave interface to a logic level 1 and adjusting the offsets below accordingly.

Table 48-6. Interface Register Sets

Offset	Register Set	Explanation
0x000–0x0FC	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
0x100–0x124	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
0x140–0x1FC	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

48.4.1.1 Configuration, Control and Status Registers

Table 48-7 shows configuration, control and status registers, and their usage by different core types.

Table 48-7. Configuration, Control, and Status Registers by Core Type

48.4.1.3 Identification Registers

Identification registers provide information about the slave interface, and include a table of the hardware configuration parameters.

48.4.1.3.1 Identification Register (ID)

The Identification register (ID) provides a simple way to determine if the USB-HS OTG High-Speed USB On-The-Go USB 2.0 core is provided in the system. The ID register identifies the USB-HS OTG High-Speed USB On-The-Go USB 2.0 core and its revision. Figure 48-7 shows the register, and Table 48-9 provides field descriptions.

Offset 0x0000 (ID) Access: User read-only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–16	Reserved, read as 0.
15–8 RXADD	VUSB_HS_RX_ADD
7–0 RXBURST	VUSB_HS_RX_BURST

48.4.1.3.7 System Bus Interface Register (SBUSCFG)

This non-EHCI register controls the AMBA AHB burst length via the field AHBBRST.Figure 48-13 shows the register, and Table 48-15 provides field descriptions.

In all cases where unspecified burst lengths are allowed, single accesses can occur (usually when the transaction is not 32-bit word aligned).

When an INCR*x* burst size is selected and the transfer is not a multiple of the INCR*x* burst, the burst is decomposed in the different ways. With AHBBRST[2] = 1, the smaller bursts will be unspecified length. with AHBBRST[2] = 0, the smaller bursts will be smaller INCR*x* or singles.

For example, in a 22-word transfer the master sequences for different AHBBRST settings are:

- 101: INCR4+INCR4+INCR4+INCR4+INCR4+INCR(unspecified length)
- 110: INCR8+INCR8+INCR4+INCR(unspecified length)
- 111: INCR16+INCR4+INCR(unspecified length)
- 001: INCR4+INCR4+INCR4+INCR4+INCR4+SINGLE+SINGLE
- 010: INCR8+INCR8+INCR4+SINGLE+SINGLE
- 011: INCR16+INCR4+SINGLE+SINGLE
- 000: INC (with burst size 8) + INC (with burst size 8) + INC (with burst size 6)(when AHBBRST is zero, the default burst size is 8, decided by register BURSTSIZE)

Offset 0x0090 (SBUSCFG) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Figure 48-13. System Bus Interface Register (SBUSCFG)

Table 48-15. System Bus Interface Register Field Descriptions

Field	Description
31–3	Reserved, read as 0.
2–0 AHBBRST	AMBA AHB BURST. This field configures the m_hburst signal of the AMBA master interface. When this field is different from zero, the burst size is set internally to the value of the INCRx AMBA burst, and the value of the fields TXPBURST and RXPBURST in register BURSTSIZE are ignored (but the BURSTSIZE register can still be written/read while the AHBBRST field is nonzero). For the case of AHBBRST != 000 (NOT EQUAL) and when the data buffer start address is not aligned 4 bytes, then SINGLE transfers will occur for AHB write. 000 INCR burst of unspecified length 001 INCR4, non-multiple transfers of INCR4 are decomposed into singles 010 INCR8, non-multiple transfers of INCR8, are decomposed into INCR4 or singles (default value for TO2 and TO2.1) 011 INCR16, non-multiple transfers of INCR16, are decomposed into INCR8, INCR4 or singles 100 Reserved, not used 101 INCR4, non-multiple transfers of INCR4 are decomposed into smaller unspecified length bursts 110 INCR8, non-multiple transfers of INCR8 are decomposed into smaller unspecified length bursts 111 INCR16, non-multiple transfers of INCR16 are decomposed into smaller unspecified length bursts

48.4.1.4 Device/Host Capability Registers

Device/Host Capability registers specify the software limits, restrictions, and capabilities of the host/device controller implementation.

48.4.1.4.1 Capability Registers Length Register (CAPLENGTH)

This EHCI-compliant register is used to indicate which offset to add to the register base address at the beginning of the operational registers. Figure 48-14 shows the register.

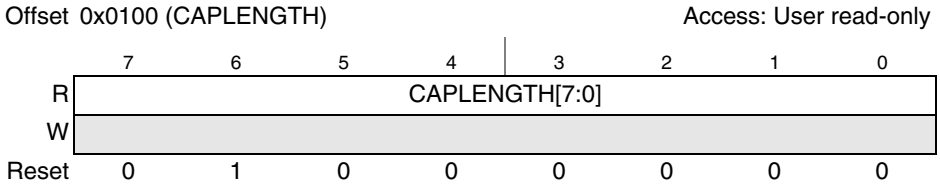

Figure 48-14. Capability Registers Length Register (CAPLENGTH)

48.4.1.4.2 Host Interface Version Number Register (HCIVERSION)

This register is EHCI-compliant. Figure 48-15 shows the register.

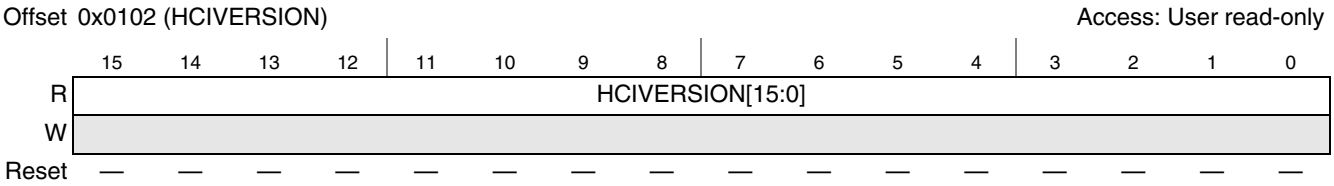

Figure 48-15. Host Interface Version Number Register Fields (HCIVERSION)

48.4.1.4.3 Host Control Structural Parameters Register (HCSPARAMS)

This register is EHCI compliant, with some extensions. Port steering logic capabilities are described in this register. Figure 48-16 shows the register, and Table 48-16 provides field descriptions.

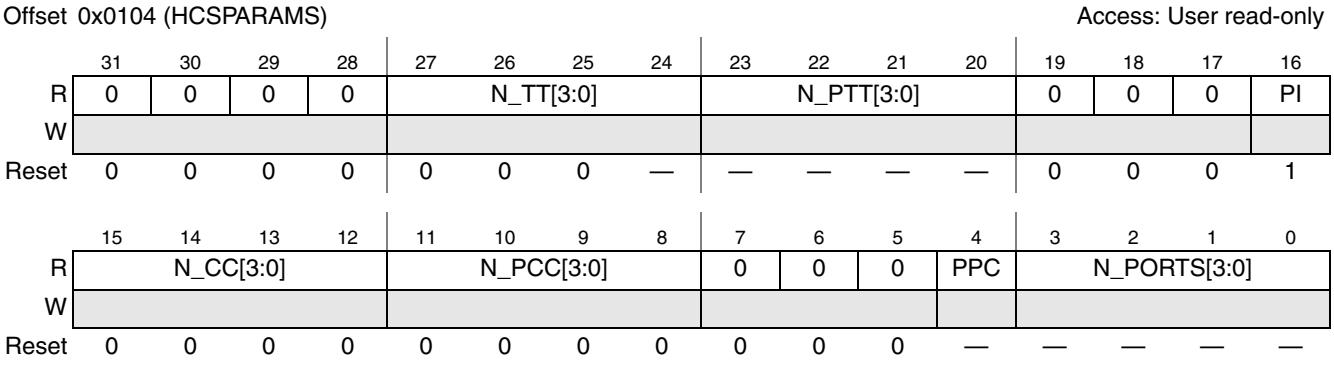

Figure 48-16. Host Control Structural Parameters Register (HCSPARAMS)

Table 48-16. Host Control Structural Parameters Register Field Descriptions

Field	Description
31–28	Reserved, read as 0.
27–24 N_TT[3:0]	Number of Transaction Translators (N_TT). This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. For multi-port host this field is equal 0001. For all other implementations, N_TT = 0000. This in a non-EHCI field to support embedded TT.
23–20 N_PTT[3:0]	Number of Ports per Transaction Translator (N_PTT). This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. For multi-port hosts this field always equal N_PORTS. For all other implementations, N_PTT = “0000”. This in a non-EHCI field to support embedded TT.
19–17	Reserved, read as 0.
16 PI	Port Indicator (P INDICATOR). This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writable field for controlling the state of the port indicator. This field is always 1.
15–12 N_CC[3:0]	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. A zero in this field indicates there are no internal Companion Controllers. Port-ownership hand-off is not supported. A value larger than zero in this field indicates there are companion USB1.1 host controller(s). Port-ownership handoffs are supported. High, Full- and Low-speed devices are supported on the host controller root ports. In this implementation this field is always 0.
11–8 N_PCC[3:0]	Number of Ports per Companion Controller. This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. In this implementation this field is always 0.
7–5	Reserved, read as 0.
4 PPC	Port Power Control. This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each PORTSC*x* register. This field is always 0 for a device-only implementation.
3–0 N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 0x1 to 0xF. A zero in this field is undefined. The number of ports for a host implementation is parametrizable from 1 to 8. This field is always 1 for device-only implementation.

48.4.1.4.4 Host Control Parameters Register (HCCPARAMS)

This EHCI-compliant register identifies multiple mode control (time-base bit functionality) addressing capability. Figure 48-17 shows the register, and Table 48-16 provides field descriptions.

Offset 0x0108 (HCCPARAMS) Access: User read-only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 48-17. Host Control Capability Parameters Register (HCCPARAMS)

Table 48-17. Host Control Capability Parameters Register Field Descriptions

Field	Description
31–16	Reserved, read as 0.
15–8 EECP[7:0]	EHCI extended capabilities pointer. For this implementation this field is always 0x00.
7–4 IST[7:4]	Isochronous scheduling threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is 0, the value of the least significant 3 bits indicates the number of microframes a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is 1, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field is always 0x0 for this implementation.
3	Reserved, read as 0.
2 ASP	Asynchronous schedule park capability. This bit is always set to 1 in this implementation, indicating that the host controller supports the park feature for high-speed queue heads in the asynchronous schedule. The park feature can be disabled or enabled and set to a specific level by using the asynchronous schedule park mode enable (ASPE) and asynchronous schedule park mode count (ASP) fields in the USBCMD register.
1 PFL	Programmable frame list flag. This bit is always set to 1 in this implementation, indicating that the system software can program the frame list size via the frame list size field (USBCMD register). The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.
0 ADC	64-bit addressing capability. This bit is always 0 in this implementation (no 64-bit addressing capability is supported).

48.4.1.4.5 Device Interface Version Number Register (DCIVERSION)

The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register. This register is not EHCI-compliant. Figure 48-18 shows the register.

Figure 48-19. Device Control Capability Parameters Register (DCCPARAMS)

Table 48-18. Device Control Capability Parameters Register Field Descriptions

Field	Description
31–9	Reserved, read as 0.
8 HC	Host Capable. When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable. When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5	Reserved, read as 0.
4–0 DEN[4:0]	Device Endpoint Number. This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field is 0. Valid values are 0–16.

48.4.1.5 Device/Host Timer Registers

The host/device controller drivers can measure time related activities using these timer registers. These registers are not part of the standard EHCI controller.

48.4.1.5.1 General Purpose Timer *n* Load Register (GPTIMER*n*LD, *n* = 0,1)

These registers contains timer duration or load values. It is not EHCI-compliant. See Section 48.4.1.5.2, "General Purpose Timer n Control Registers (GPTIMERnCTRL, n = 0, 1)" for a description of the timer functions.

Figure 48-20 shows the register, and Table 48-19 provides field descriptions.

Field	Description
31–24	Reserved, read as 0.
23–0 GPTLD	General Purpose Timer Load Value. This field is the value to be loaded into the GPTCNT countdown timer on a reset action. This value represents the time in microseconds minus 1 for the timer duration.

48.4.1.5.2 General Purpose Timer *n* Control Registers (GPTIMER*n*CTRL, *n* = 0, 1)

These non–EHCI-compliant registers contains the controls for the timers, and data fields that can be queried to determine the running count value. This timer has granularity of 1 µs, and can be programmed to a little over 16 seconds. There are two modes supported by the timers: one-shot and looped count. When a timer counter value transitions to zero, an interrupt can be generated though the use of the timer interrupts in the USBSTS and USBINTR registers.

Figure 48-21 shows the register, and Table 48-20 provides field descriptions.

Figure 48-21. General Purpose Timer *n* Controller Registers (GPTIMER*n*CTRL)

Table 48-20. General Purpose Timer *n* Controller Registers Field Descriptions

Field	Description
31 GPTRUN	General purpose timer run. This bit enables the GPT to run. 0 Timer Stop 1 Timer Run.
30 GPTRST	General purpose timer reset. Setting this bit to 1 reloads the GPTCNT field with the GPTLD value in the corresponding GPTIMER*n*LD register. 0 No action 1 Load counter value from GPTLD field (GPTIMER*n*LD register)
29–25	Reserved, read as 0.
24 GPMOD	General purpose timer mode. In one-shot mode the timer counts to zero, generates an interrupt and stop until the timer is reset by software. In repeat mode the timer counts to zero, generates an interrupt and automatically reloads the counter to begin again. 0 One-shot mode 1 Repeat mode
23–0 GPTCNT	General purpose timer counter. This field is the value of running timer.

48.4.1.6 Device/Host Operational Registers

Operational registers are comprised of dynamic control or status registers that may be read-only, read/write, or read/write-to-clear. The following sections define the use of these registers.

48.4.1.6.1 USB Command Register (USBCMD)

The serial bus host/device controller executes the command indicated in this register. Figure 48-22 shows the register, and Table 48-21 provides field descriptions.

Offset 0x0140 (USBCMD) Access: Field-dependent

Figure 48-22. USB Command Register (USBCMD)

Table 48-21. USB Command Register Field Descriptions

Field	Description
31–24	Reserved, read as 0.
23–16 ITC	Interrupt Threshold Control. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in microframes. 0x00 Immediate (no threshold) 0x01 1 microframe 0x02 2 microframes 0x04 4 microframes 0x08 8 microframes (default) 0x10 16 microframes 0x20 32 microframes 0x40 64 microframes
15, 3–2 FS	Frame list size. This field is Read/Write only if the programmable frame list (PFL) flag in the HCCPARAMS registers is set to 1: otherwise it is read-only. This field specifies the size of the frame list that controls which bits in the Frame Index Register are used for the Frame List Current index. 000 1024 elements (4096 bytes—Default value) 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes) Only the host controller uses this field.
14 ADTW	Add dTD Trip Wire (device mode only). This bit is used as a semaphore to ensure the to proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software, and is also cleared by hardware when the state machine is in a state for which adding a dTD to a primed endpoint may go unrecognized. For more information on the use of this bit, see the Device Operational Model section.

Table 48-21. USB Command Register Field Descriptions

Field	Description
13 SUTW	Set up trip wire (device mode only). This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a queue head (QH) by the DCD without being corrupted. If the setup lockout mode is off (See Section 48.4.1.6.16, "USB Device Mode Register (USBMODE)") then there exists a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software, and will be cleared by hardware when a hazard exists. For more information on the use of this bit, see the Device Operational Model section.
12	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable (OPTIONAL) — Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is set to 1, then this bit defaults to a 1 and is R/W. Otherwise the bit is cleared and read-only. Software uses this bit to enable or disable Park mode. When this bit is 1, park mode is enabled. When this bit is cleared, park mode is disabled. This bit defaults to 1 in this implementation.
10	Reserved, read as 0.
9–8 ASP	Asynchronous Schedule Park Mode Count (OPTIONAL) If the Asynchronous Park Capability bit in the HCCPARAMS register is set to 1, then this field defaults to 11 and is R/W: otherwise it defaults to 0 and is read-only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 01, 10, and 11. Software must not write a 0 to these bits when the ASPE bit in this register is set to 1, as this will result in undefined behavior. This field defaults to 11 in this implementation.
7 LR	Light Host/Device Controller Reset (OPTIONAL). This read-only.bit is always 0.
6 IAA	Interrupt on Async Advance Doorbell. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a 1 to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 Do not process the Asynchronous Schedule (default) 1 Use the ASYNCLISTADDR register to access theAsynchronous Schedule. Only the host controller uses this bit.
4 PSE	Periodic Schedule Enable. This bit controls whether the host controller skips processing the Periodic Schedule. 0 Do not process the Periodic Schedule (default) 1 Use the PERIODICLISTBASE register to access the PeriodicSchedule. Only the host controller uses this bit.

Table 48-21. USB Command Register Field Descriptions

Field	Description
1 RST	Controller Reset. Software uses this bit to reset the controller. This bit is cleared by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a 0 to this register. • Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HC Halted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. • Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, since the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop (RS) • Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to 1. When this bit is cleared, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a 1 to this field unless the host controller is in the Halted state (the HC Halted bit in the USBSTS register is set to 1). • Device Controller: Writing a 1 to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this bit will cause a detach event.

48.4.1.6.2 USB Status Register (USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus. Software clears certain bits in this register by writing a 1 to them, as described in Table 48-22. Figure 48-23 shows the register, and Table 48-22 provides field descriptions.

Figure 48-23. USB Status Register Fields (USBSTS)

Table 48-22. USB Status Register Field Descriptions

Field	Description
31–26	Reserved, read as 0.
25–24 TIE1, TIE0	General Purpose Timer Interrupt n. The TIE [n] bit is set to 1 when the counter in the GPTIMERnCTRL register transitions to zero. Writing a 1 to TIE [n] clears it.
23—17	Reserved, read as 0.
16 NAKI	NAK Interrupt Bit- Read Only. This bit is readonly. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all the enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status. This read-only bit reports the current real status of the Asynchronous Schedule. When cleared the asynchronous schedule status is disabled and if set to 1 the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). This bit is only used by the host controller.
14 PS	Periodic Schedule Status. This read-only bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). This bit is only used by the host controller.
13 RCL	Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. This bit is only used by the host controller.
12 HCH	Host Controller Halted. This read-only bit is 0 whenever the Run/Stop bit is set to 1. The Host Controller sets this bit to 1 after it has stopped executing because of the Run/Stop bit being cleared either by software or by the Host Controller hardware (due to an internal error). This bit is only used by the host controller.
11	Reserved, read as 0.

Table 48-22. USB Status Register Field Descriptions (continued)

Field	Description
10 ULPII	ULPI Interrupt. When the ULPI Viewport is present in the design, an event completion will set this interrupt. Used by both host & device controller. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1
9	Reserved, read as 0.
8 SLI	DC Suspend. When a device controller enters a suspend state from an active state, this bit is set to 1. The device controller clears the bit upon exiting from a suspend state. This bit is write 1 to clear, and is only used by the device controller.
7 SRI	SOF Received. When the device controller detects a Start Of (micro) Frame, this bit is set to 1. When a SOF is extremely late, the device controller automatically sets this bit to 1 to indicate that an SOF was expected. Consequently this bit is set roughly every 1 ms in device FS mode and every 125 μs in HS mode, and will be synchronized to the actual SOF that is received. Since the device controller is initialized to FS before connect, this bit is set at intervals of 1 ms during the prelude to connect and chirp. In host mode, this bit is set every 125 μs, and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit.
6 URI	USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to 1. Software can write a 1 to this bit to clear it. This bit is only used by the device controller.
5 AAI	Interrupt on Async Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Software can clear this bit by writing 1 to it. This bit is only used by the host controller.
4 SEI	System Error. This bit is set to 1 when an error response is seen to a read on the system interface. Software can clear this bit by writing 1 to it.
3 FRI	Frame List Rollover. The host controller sets this bit to1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the frame list size (FS) field of the USBCMD register) is 1024, the frame index register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Software can clear this bit by writing 1 to it. This bit is only used by the host controller.
2 PCI	Port Change Detect. • The Host Controller sets this bit to 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. • The Device Controller sets this bit to 1 when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DC Suspend bits, respectively. This bit is not EHCI-compatible.

Table 48-22. USB Status Register Field Descriptions (continued)

Field	Description
1 UEI	USB Error Interrupt (USBERRINT) — R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. See Section 4.15.1, “Reference Host Operation Model: Transfer/Transaction Based Interrupt” in the EHCI Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com) for a complete list of host error interrupt conditions.See section Device Error Matrix in the USB-HS OTG High-Speed USB On-The-Go DEV reference manual. The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) — R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

48.4.1.6.3 USB Interrupt Enable Register (USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt is active. The USB status register (USBSTS) still shows interrupt sources even if they are disabled by the USBINTR register, allowing polling of interrupt events by the software. Figure 48-24 shows the register, and Table 48-23 provides field descriptions.

Offset 0x0148 (USBINTR) Access: User read-write

Figure 48-24. USB Interrupt Enable Register Fields (USBINTR)

Table 48-23. USB Interrupt Enable Register Field Descriptions

Field	Description
31–26	Reserved, read as 0.
25–24 TIE[1:0]	When the TIE[*n*] bit is set to 1and the GPTINT[*n*] bit in the USBSTS register is set to 1, the controller issues an interrupt. The interrupt is acknowledged by software clearing the GPTINT[*n*] bit.
23–11	Reserved, read as 0.
10 ULPIE	When this bit is set to 1, and the ULPI Interrupt bit in the USBSTS register transitions, the controller will issue and interrupt. The interrupt is acknowledged by software writing a one to the ULPI Interrupt bit. Used by both host & device controller. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1.
9	Reserved, read as 0.

Table 48-23. USB Interrupt Enable Register Field Descriptions

Field	Description
8 SLE	When this bit is set to 1, and the DC Suspend bit in the USBSTS register transitions, the device controller issues an interrupt. The interrupt is acknowledged by software writing a one to the DC Suspend bit. Only used by the device controller.
7 SRE	When this bit is set to 1, and the SOF Received bit in the USBSTS register is set to 1, the device controller issues an interrupt. The interrupt is acknowledged by software clearing the SOF Received bit.
6 URE	When this bit is set to 1, and the USB Reset Received bit in the USBSTS register is set to 1, the device controller issues an interrupt. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller.
5 AAE	When this bit is set to 1, and the Interrupt on Async Advance bit in the USBSTS register is a one, the host controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller.
4 SEE	When this bit is a one, and the System Error bit in the USBSTS register is a one, the host/device controller issues an interrupt. The interrupt is acknowledged by software clearing the *System Error* bit.
3 FRE	When this bit is a one, and the Frame List Rollover bit in the USBSTS register is a one, the host controller issues an interrupt. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller.
2 PCE	When this bit is a one, and the Port Change Detect bit in the USBSTS register is a one, the host/device controller issues an interrupt. The interrupt is acknowledged by software clearing the *Port Change Detect* bit.
1 UEE	When this bit is a one, and the USBERRINT bit in the USBSTS register is a one, the host controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register.
0 UE	When this bit is a one, and the USBINT bit in the USBSTS register is a one, the host/device controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the *USBINT* bit.

48.4.1.6.4 USB Frame Index Register (FRINDEX)

In host mode, this register is used by the host controller to index the periodic frame list. The register updates every 125 µsec (once each microframe). Bits [*N*: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution, where *N* depends on the size of the frame list as set by system software in the frame list size field in the USBCMD register. This register must be written as a dword. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the Halted state as indicated by the HC halted (HCH) bit (USBSTS register). A write to this register while the Run/Stop (RS) bit (USBCMD register) is set to 1 produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read-only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] is checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] is set to the SOF value and FRINDEX [2:0] is set to zero (that is, SOF for 1 ms

frames). If FRINDEX [13:3] is equal to the SOF value, then FRINDEX [2:0] is incremented (that is, SOF for 125 µs microframes.)

Figure 48-25 shows the register, and Table 48-24 provides field descriptions.

Figure 48-25. USB Frame Index Register Fields (FRINDEX)

Table 48-24. USB Frame Index Register Field Descriptions

Field	Description
31–14	Reserved, read as 0.
13–0 FRINDEX	Frame Index. • In host mode, the value in this register increments at the end of each time frame (microframe). Bits [*N*: 3] are used for the frame list current index, so that each location of the frame list is accessed 8 times (frames or microframes) before moving to the next index. The following table illustrates values of *N* based on the value of the Frame List Size (FS) field in the USBCMD register, when used in host mode.

Frame List Size Field (USBCMD Register)	Number of Elements	*N*
0b000	1024	12
0b001	512	11
0b010	256	10
0b011	128	9
0b100	64	8
0b101	32	7
0b110	16	6
0b111	8	5

• In device mode the value is the current frame number of the last frame transmitted. It is not used as an index.
In either mode, bits 2:0 indicate the current microframe.
This field is a free-running counter: the reset value is undefined.

48.4.1.6.5 CTRLDSSEGMENT Register

This register is located at base address offset 0x0150, and is not used in this implementation.

48.4.1.6.6 Host Controller Frame List Base Address Register (PERIODICLISTBASE) and USB Device Address Register (DEVICEADDR)

Base address offset 0x0154 is occupied by the PERIODICLISTBASE register for host mode, and the DEVICEADDR register for device mode.

Host Controller Frame List Base Address Register (PERIODICLISTBASE)

This 32-bit register contains the beginning address of the periodic frame list in the system memory. HCD loads this register prior to starting the schedule execution by the host controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the frame index register (FRINDEX) to enable the host controller to step through the periodic frame list in sequence. Figure 48-26 shows the register, and Table 48-25 provides field descriptions.

Field	Description
31–12 BASEADR]	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. This field is only used by the host controller.
11–0	Reserved, read as 0.

Device Controller USB Device Address Register (DEVICEADDR)

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor. Figure 48-27 shows the register, and Table 48-26 provides field descriptions.

24–0	Reserved, read as 0.

48.4.1.6.7 Host Controller Next Asynchronous Address Register (ASYNCLISTADDR) and Device Controller Endpoint List Address Register (ENDPOINTLISTADDR)

Base address offset 0x0158 is occupied by the ASYNCLISTADDR register for host mode, and the ENDPOINTLISTADDR register for device mode.

Host Controller Next Asynchronous Address Register (ASYNCLISTADDR)

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read. Figure 48-28 shows the register, and Table 48-27 provides field descriptions.

4–0	Reserved, read as 0.

Device Controller Endpoint List Address Register (ENDPOINTLISTADDR)

In device mode, this register contains the address of the top of the endpoint list in system memory. Bits [10:0] of this register cannot be modified by the system software, and always return a zero when read.

The memory structure referenced by this physical memory pointer is assumed to be 64-byte.

Field	Description
31–17	Reserved, read as 0.
16–8 TXPBURST	Programmable TX Burst Length. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus. Default is the constant VUSB_HS_TX_BURST
7–0 RXPBURST	Programmable RX Burst Length. (Read/Write) This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory. Default is the constant VUSB_HS_RX_BURST.

48.4.1.6.9 TXFILLTUNING Register

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

UOG_TXFILLTUNING reset value = 0x00020000
UH1_TXFILLTUNING reset value = 0x00000000

Figure 48-31. TXFILLTUNING Register

Timing parameter definitions are as follows:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level

T_s = Total packet flight time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total packet time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a “backoff” event. When a backoff event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many backoff events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Backoffs can be minimized with use of the TSCHHEALTH (T_{ff}) described below.

Table 48-30. TXFILLTUNING Field Descriptions

Field	Description
31–22	Reserved, read as 0.
21–16 TXFIFOTHRES	FIFO Burst Threshold. This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the stream disable bit in USBMODE register is set.
15–13	Reserved, read as 0.
12–8 TXSCHHEALTH	Scheduler Health Counter. (Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7–0 TXSCHOH	Scheduler overhead. This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.26 μs when a device is connected in High-Speed Mode for OTG and SPH. The time unit represented in this register is 6.33 μs when a device is connected in Low/Full Speed Mode for OTG & SPH. The time unit represented in this register is always 1.267 the MPH product.

48.4.1.6.10 ULPI VIEWPORT

The register provides indirect access to the ULPI PHY register set. Although the core performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access. Figure 48-32 shows the register, and Table 48-31 provides field descriptions.

Offset 0x0170 (ULPIVIEWPORT) Access: User read-write

R W	ULPIDATRD								ULPIDATWR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 48-32. ULPI VIEWPORT

NOTE

- Writes to the ULPI through the VIEWPORT register can substantially disrupt standard USB operations. Currently no usage model has been defined where software should need to execute writes directly to the ULPI.
- Executing read operations though the ULPI Viewport should have no harmful side effects to standard USB operations.
- **T**he ULPI Viewport is only synthesized in the design if the ULPI option has been purchased & installed and the constant `VUSB_HS_PHY_ULPI` is set to `1`. If the ULPI interface is not enabled, this register will always read as 0.

The ULPI Viewport, can perform two types of operations: wakeup and read /write. The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode. The ULPI state can be determined by reading the sync. state bit (ULPISS). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPISS indicates a ‘0’ then read/write operations will not be able execute. Undefined behavior will result if ULPISS = 0 and a read or write operation is performed. To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPIPORT is constructed appropriately, the ULPIWU bit is 1 and the ULPIRUN bit is a 0. Poll the ULPI Viewport until ULPIWU is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPIDATWR, ULPIADDR, ULPIPORT, ULPIRW are constructed appropriately and the ULPIRUN bit is a 1. Poll the ULPI Viewport until ULPIRUN is 0 for the operation to complete. After ULPIRUN is 0, the ULPIDATRD is valid if the operation was a read.

An alternative to using the polling method above is to use the ULPI interrupt defined in the USB Status Register (USBSTS) and USB Interrupt Enable Register (USBINTR). When a wakeup or read/write operation is completed, the ULPI interrupt is set.

Table 48-31. ULPI VIEWPORT Field Descriptions

Field	Description
31 ULPIWU	ULPI Wakeup – Read/Write. Writing the '1' to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver can not set it back to '0'. Note: The driver must never execute a wakeup and a read/write operation at the same time.
30 ULPIRUN	ULPI Read/Write Run – Read/Write. Writing the '1' to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver can not set it back to '0'. Note: The driver must never execute a wakeup and a read/write operation at the same time.
29 ULPIRW	ULPI Read/Write Control – Read/Write. (0) – Read; (1) – Write. This bit selects between running a read or write operation.
28	Reserved, read as 0.
27 ULPISS	ULPI Sync State – Read Only. (1) – Normal Sync. State. (0) In another state (i.e. carkit, serial, low power) This bit represents the state of the ULPI interface. Before reading this bit, the ULPIPORT field should be set accordingly if used with the multi-port host. Otherwise, this field should always remain 0.
26–24 ULPIPORT	ULPI Port Number – Read/Write. For the wakeup or read/write operation to be executed, this value selects the port number the ULPI PHY is attached to in the multi-port host. The range is 0 to 7. This field should always be written as a 0 for the non-multi port products.
23–16 ULPIADDR	ULPI Data Address – Read/Write. When a read or write operation is commanded, the address of the operation is written to this field.
15–8 ULPIDATRD	ULPI Data Read – Read Only. After a read operation completes, the result is placed in this field.
7–0 ULPIDATWR	ULPI Data Write – Read/Write. When a write operation is commanded, the data to be sent is written to this field.

48.4.1.6.11 Endpoint NAK (ENDPTNAK)

48.4.1.6.13 CONFIGFLAG Register

This register (located at base address offset 0x0180), is not used in this implementation. A read from this register returns a constant of 0x0000_0001, to indicate that all port routines default to this host controller.

48.4.1.6.14 Port Status Control *x* Registers (PORTSC*x*, *x* = 1…8)

These registers are used differently for host and device controllers, as follows:

- Host Controller

  A host controller must implement one to eight port registers. The number of port registers implemented by a particular instantiation of a host controller is documented in the HCSPARAMs register. Software uses this information as an input parameter to determine how many ports require servicing.

  This register is only reset when power is initially applied or in response to a controller reset. The initial conditions of a port are:

  — No device connected

  — Port disabled

  If the port has port power control, this state remains until software applies power to the port by setting port power to one.

- Device Controller

  A device controller must implement only port register 1, and it does not support power control. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Figure 48-35 shows the register. Table 48-34 provides field descriptions.

Figure 48-35. Port Status Control *x* Registers (PORTSC*x*)

Table 48-34. Port Status Control *x* Registers Field Descriptions

Field	Description
31–30 PTS	Parallel Transceiver Select. This register bit pair is used in conjunction with the configuration constant VUSB_HS_PHY_TYPE to control which parallel transceiver interface is selected. If VUSB_HS_PHY_TYPE is set for 0,1,2, or 3 then this bit is read only. If VUSB_HS_PHY_TYPE is 3,4,5, or 6 then this bit is read/write. This field is reset to: 00 if VUSB_HS_PHY_TYPE = 0,4 – UTMI/UTMI+ 01 if VUSB_HS_PHY_TYPE = 1,5 – Reserved 10 if VUSB_HS_PHY_TYPE = 2,6 – ULPI 11 if VUSB_HS_PHY_TYPE = 3,7 – Serial/1.1 PHY (FS Only) This bit is not defined in the EHCI specification.
29 STS	Serial Transceiver Select. This register bit is used in conjunction with the configuration constant VUSB_HS_PHY_SERIAL to control whether the parallel or serial transceiver interface is selected for FS and LS operation. The Serial Interface Engine can be used in combination with the UTMI+ or ULPI physical interface to provide FS/LS signaling instead of the parallel interface. If VUSB_HS_PHY_SERIAL is set for 0 or 1 then this bit is read only. If VUSB_HS_PHY_SERIAL is 3 or 4 then this bit is read/write. This bit has no effect unless the parallel transceiver select (PTS) bit is set to UTMI+ or ULPI. The Serial/1.1 physical interface uses the serial interface engine for FS/LS signaling regardless of this bit value. This bit is not defined in the EHCI specification. **Note:** This bit is reserved for future operation and is a placeholder adding dynamic use of the serial engine in accord with UMTI+ and ULPI characterization logic.

Table 48-34. Port Status Control *x* Registers Field Descriptions (continued)

Field	Description
28 PTW	Parallel Transceiver Width. This register bit is used in conjunction with the configuration constant VUSB_HS_PHY8_16 to control whether the data bus width of the UTMI transceiver interface. If VUSB_HS_PHY8_16 is set for 0 or 1 then this bit is read only. If VUSB_HS_PHY8_16 is 2 or 3 then this bit is read/write. This bit is reset to 1 if VUSB_HS_PHY8_16 selects a default UTMI interface width of 16-bits else it is reset to 0. 0 8-bit [60MHz] UTMI interface is selected. 1 16-bit [30MHz] UTMI interface is selected. This bit has no effect if the serial interface is selected. This bit is not defined in the EHCI specification. **Note:** If this bit changes from 0 to 1, software must reset the clock generation logic in the UTMI PHY before enabling the controller core as follows: • Clear the UTMI USB enable bit (USBEN in the USB_PHY_CTRL_FUNC register) • Set USBEN.
27–26 PSPD	Port speed. This read-only field indicates the speed at which the port is operating. For HS mode operation in the host controller and HS/FS operation in the device controller the port routing steers data to the Protocol engine. For FS and LS mode operation in the host controller, the port routing steers data to the Protocol Engine w/ Embedded Transaction Translator. 00 Full Speed 01 Low Speed 10 High Speed 11 Reserved, not used. This bit is not defined in the EHCI specification.
25	Reserved, read as 0.
24 PFSC	Port Force Full Speed Connect – Read/Write. Default = 0. Setting this bit to 1 forces the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification, and is intended for debugging purposes.
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) – Read/Write. Default = 0. 0 PHY clock enabled. 1 PHY clock disabled. **Note:** The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend – Clock Disable when the device is not running (USBCMD Run/Stop=0) or the host has signaled suspend (PORTSC SUSPEND=1). Low power suspend will be cleared automatically when the host has signaled resume if using a circuit similar to that in. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend – Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. See for more discussion on clock disable and power down issues. This bit is not defined in the EHCI specification.
22 WKOC	Wake on Over-current Enable. Setting this bit to 1 enables the port to be sensitive to over-current conditions as wakeup events. This field is 0 if the Port Power *(*PP*)* is 0. This bit is output from the controller as signal pwrctl_wake_ovrcurr_en (OTG/host core only) for use by an external power control circuit.
21 WKDS	Wake on Disconnect Enable. Setting this bit to 1 enables the port to be sensitive to device disconnects as wakeup events. This field is 0 if Port Power *(*PP*)* is 0 or in device mode. This bit is output from the controller as signal pwrctl_wake_dscnnt_en (OTG/host core only) for use by an external power control circuit.

Table 48-34. Port Status Control *x* Registers Field Descriptions (continued)

Field	Description
20 WKCN	Wake on Connect Enable (WKCNNT_E) — Read/Write. Default = 0. Setting this bit to 1 enables the port to be sensitive to device connects as wakeup events. This bit is zero if Port Power (PP) is zero or in device mode. This bit is output from the controller as signal pwrctl_wake_dscnnt_en (OTG/host core only) for use by an external power control circuit.
19–16 PTC	Port Test Control. Any value other than 0x0 indicates that the port is operating in test mode. 0x0 TEST_MODE_DISABLE 0x1 J_ STATE 0x2 K_STATE 0x3 SE0 (host) / NAK (device) 0x4 Packet 0x5 FORCE_ENABLE_HS 0x6 FORCE_ENABLE_FS 0x7 FORCE_ENABLE_LS 0x8–0xFReserved See Chapter 7 of the USB Specification Revision 2.0 Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **Note:** Low speed operations are not supported as a peripheral device.[
15–14 PIC	Port Indicator Control — Read/Write. Default = 00. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. If P_INDICATOR bit is a one, then the bit is: Bit ValueMeaning 00 Port indicators are off 01 Amber 10 Green 11 Undefined See the USB Specification Revision 2.0 Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org for a description on how these bits are to be used. This field is output from the controller as signals port_ind_ctl_1 & port_ind_ctl_0 for use by an external led driving circuit.
13 PO	Port Owner—Read/Write. Default = 0. In this implementation, this bit is always 0.
12 PP	Port Power (PP)—Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. • If PPC = 0 (device-only implementation with no OTG capability), then PP = 0 (read-only). • If PPC = 1 (host/OTG controller), then this bit represents the current setting of the port power control switch (0=off, 1=on). A non-powered port (PP = 0), is non-functional and does not report attaches, detaches, etc. When an overcurrent condition is detected on a powered port (PP = 1), the PP bit in each affected port can be changed by the host controller driver from a one to a zero (removing power from the port).

Table 48-34. Port Status Control *x* Registers Field Descriptions (continued)

Field	Description
11–10 LS[1:0]	Line Status—Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. The encoding of the bits are: Bits [11:10]Meaning 00b SE0 10b J-state 01b K-state 11b Undefined In host mode, the use of line state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line state by the device controller driver is not necessary.
9 HSP	High-Speed Port — Read Only. Default = 0. 0 Host/device connected to the port is not in high-speed mode. 1 Host/device connected to the port is in high-speed mode. **Note:** HSP is redundant with PSPD(27:26) but remains in the design for compatibility. This bit is not defined in the EHCI specification.
8 PR	Port Reset. This bit is 0 if the Port Power (PP) bit is 0. • In Host Mode: This bit is read/write accessible. 0 Port is not in reset (Default) 1 Port is in reset. When software writes a 1 to this bit, the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit automatically changes to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* • In Device Mode: This bit is a read-only status bit. Device reset from the USB bus is also indicated in the USBSTS register.
7 SUSP	Suspend. Function in host and device modes is described as follows. In Host Mode: The bit is read/write, with the following settings: 0 Port not in suspend state (default). 1 Port in suspend state. The {Port Enabled, Suspend} bits of this register define the port states as follows: 0*n* Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The bit is a read-only status bit, with the following settings: 0 Port is not in suspend state (default). 1 Port is in suspend state.

Table 48-34. Port Status Control *x* Registers Field Descriptions (continued)

Field	Description
6 FPR	Force Port Resume • Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.* When the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation clear the bit the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not EHCI-compatible. • Device mode: After the device has been in Suspend State for 5 ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, the Port Change Detect bit in the USBSTS register is also set to one. 0 No resume (K-state) detected/driven on port (default). 1 Resume detected/driven on port.
5 OCC	Overcurrent Change—R/WC. Software clears this bit by writing 1. For host/OTG implementations the user can provide overcurrent detection to the vbus_pwr_fault input for this condition. 0 No change has occurred to overcurrent active status. 1 Change has occurred to overcurrent active status. For device-only implementations this bit is always 0.
4 OCA	Over-current Active—Read Only. This bit will automatically transition from one to zero when the overcurrent condition is removed. For host/OTG implementations the user can provide over-current detection to the vbus_pwr_fault input for this condition. For device-only implementations this bit is always 0. 0 This port does not have an over-current condition. (default) 1 This port currently has an over-current condition.
3 PEC	Port Enable/Disable Change—R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. • In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. • In Device mode: The device port is always enabled. (This bit is always 0)

Table 48-34. Port Status Control *x* Registers Field Descriptions (continued)

Field	Description
2 PE	Port Enabled/Disabled—Read/Write. • In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. 0 Port disabled (default) 1 Port enabled • In Device Mode: The device port is always enabled. (This bit is always 1)
1 CSC	Connect Status Change—R/WC. • In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. 0 No change in current connect status (default) 1 Change in current connect status. • In Device Mode: This bit is undefined in device controller mode.
0 CCS	Current Connect Status—Read Only. • In Host Mode: 0 No device is present. (default) 1 Device is present on port. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. • In Device Mode: A setting of 1 indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 Device is not attached. (default) 1 Device is attached.

48.4.1.6.15 On-the-Go Status and Control Register (OTGSC)

A host controller implements one On-The-Go (OTG) Status and Control register corresponding to Port 0 of the host controller.

The OTGSC register has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)

- OTG Controls(Read/Write)

The status inputs are debounced using a 1 msec time constant. Values on the status inputs that do not persist for more than 1 msec will not cause a status input register update or OTG interrupt. See also the USBMODE register.

Figure 48-36 shows the register, and Table 48-35 provides field descriptions.

Offset 0x01A4 (OTGSC) Access: field dependent

Figure 48-36. OTG Status Control Register (OTGSC)

Table 48-35. OTG Status Control Register Field Descriptions

Field	Description
31	Reserved, read as 0.
30 DPIE	Data Pulse Interrupt Enable
29 1msE	1 millisecond timer Interrupt Enable – Read/Write
28 BSEIE	B Session End Interrupt Enable – Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable – Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable – Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable – Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable – Read/Write. Setting this bit enables the USB ID interrupt.
23	Reserved, read as 0.
22 DPIS	Data Pulse Interrupt Status – Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when the CM field (USBMODE register) = 11(denoting host) and the port power bit (PORTSC0 register) = 0 (power off). Software must write 1 to clear this bit.
21 1msS	1 millisecond timer Interrupt Status – Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.

Table 48-35. OTG Status Control Register Field Descriptions (continued)

Field	Description
20 BSEIS	B Session End Interrupt Status – Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit
19 BSVIS	B Session Valid Interrupt Status – Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status – Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status – Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status – Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15	Reserved, read as 0.
14 DPS	Data Bus Pulsing Status – Read Only. A ‘1’ indicates data bus pulsing is being detected on the port.
13 1msT	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End – Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid – Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid – Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid – Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID – Read Only. 0 = A device, 1 = B device
7 HABA	Hardware Assist B-Disconnect to A-connect ñ Read/Write. 0 = Disabled. 1 = Enable automatic B-disconnect to A-connect sequence.
6 HADP	Hardware Assist Data-Pulse ñ Write to Set. 1 = Start Data Pulse Sequence.
5 IDPU	ID Pullup – Read/Write. This bit provide control over the ID pull-up resister; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing – Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination – Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 HAAR	Hardware Assist Auto-Reset ñ Read/Write. 0 = Disabled. 1 = Enable automatic reset after connect on host port.

Table 48-35. OTG Status Control Register Field Descriptions (continued)

Field	Description
1 VC	VBUS Charge – Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge – Read/Write. Setting this bit causes VBus to discharge through a resistor.

48.4.1.6.16 USB Device Mode Register (USBMODE)

Figure 48-37 shows the register, and Table 48-36 provides field descriptions.

Figure 48-37. USB Device Mode Register (USBMODE)

Table 48-36. USB Device Mode Register Field Descriptions

Field	Description
31–5	Reserved, read as 0.
4 SDIS	Stream Disable Mode. (0 – Inactive [default]; 1 – Active) • Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received will be responded to with a NYET handshake when stream disable is active. • Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **Note:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **Note:** The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See the Control Endpoint Operation Model. 0 Setup Lockouts On (default) 1 Setup Lockouts Off DCD requires use of the setup data buffer tripwire in the USB Command Register (USBCMD)

Table 48-36. USB Device Mode Register Field Descriptions (continued)

Field	Description
2 ES	Endian Select – Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. 0 Little endian [Default] 1 Big endian
1–0 CM	Controller Mode – R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller will default to an idle state and will need to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. 00Idle [Default for combination host/device] 01Reserved 10Device Controller [Default for device only controller] 11Host Controller [Default for host only controller]

48.4.1.6.17 Endpoint Setup Status Register (ENDPTSETUPSTAT)

This register is used in device mode only. Figure 48-38 shows the register, and Table 48-37 provides field descriptions.

Offset 0x01AC (ENDPTSETUPSTAT) Access: user read-write

Figure 48-38. Endpoint Setup Status Register (ENDPTSETUPSTAT)

Table 48-37. Endpoint Setup Status Register Field Descriptions

Field	Description
31–16	Reserved, read as 0.
15–0 ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from the Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See “Managing Endpoints” in the Device Operational Model section of the USB-HS OTG High-Speed USB On-The-Go DEV reference manual. This register is only used in device mode.

48.4.1.6.18 Endpoint Initialization Register (ENDPTPRIME)

This register is only used in device mode. Figure 48-39 shows the register, and Table 48-38 provides field descriptions.

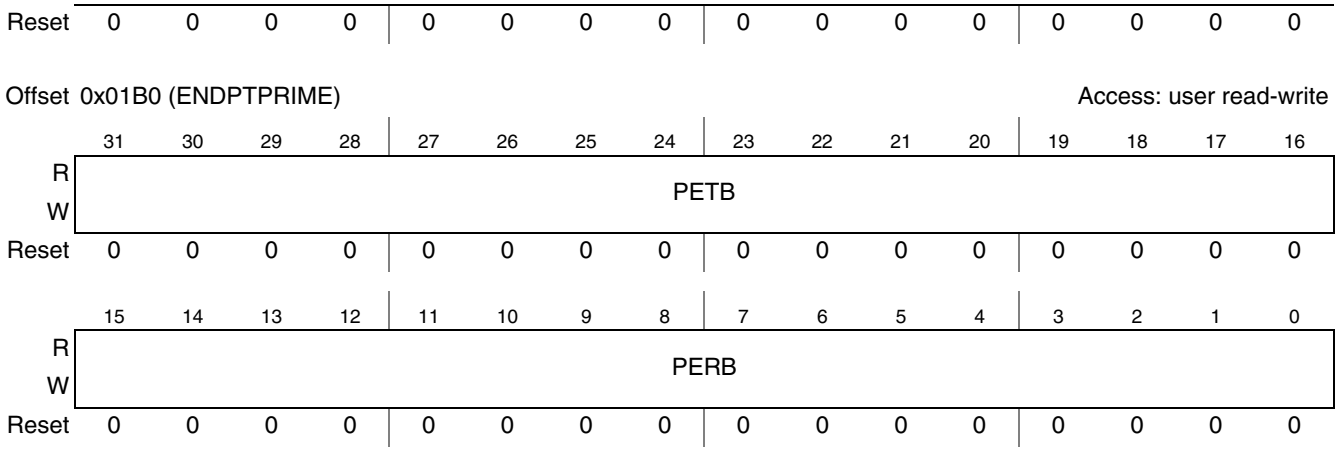

Figure 48-39. Endpoint Initialization Register (ENDPTPRIME)

Table 48-38. Endpoint Initialization Register Field Descriptions

Field	Description
31–16 PETB	Prime Endpoint Transmit Buffer – R/WS. For each endpoint a corresponding bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. Note: These bits will be momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[15] – Endpoint #15 PETB[1] – Endpoint #1 PETB[0] – Endpoint #0
15–0 PERB	Prime Endpoint Receive Buffer – R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. Note: These bits will be momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. Bit 15 – Endpoint #15 … Bit 0 – Endpoint #0

48.4.1.6.19 Endpoint De-Initialize Register (ENDPTFLUSH)

This register is only used in device mode. Figure 48-40 shows the register, and Table 48-39 provides field descriptions.

Offset 0x01B4 (ENDPTFLUSH) Access: user read-write

Figure 48-41. Endpoint Status Register (ENDPTSTAT)

Table 48-40. Endpoint Status Field Descriptions

Field	Description
31–16 ETBR	Endpoint Transmit Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. Note: These bits will be momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ETBR[15]– Endpoint #15 … ETBR[0]– Endpoint #0
15–0 ERBR	Endpoint Receive Buffer Ready -- Read Only. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. Note: These bits will be momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated. ERBR[15]– Endpoint #15 … ERBR[0]– Endpoint #0

48.4.1.6.21 Endpoint Complete Register (ENDPTCOMPLETE)

This register is only used in device mode. Figure 48-42 shows the register, and Table 48-41 provides field descriptions.

Offset 0x01BC (ENDPTCOMPLETE) Access: user read-write

23 TXE	TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.

Table 48-43. Endpoint Control *x* Registers Field Descriptions (continued)

Field	Description
22 TXR	TX Data Toggle Reset (WS) Write 1 – Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the Host and device.
21 TXI	TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
20	Reserved, read as 0.
19–18 TXT	TX Endpoint Type – Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source – Read/Write 0 Dual port memory buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall – Read/Write 0 Endpoint OK 1 Endpoint stalled This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above.
15–8	Reserved, read as 0.
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 – Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4	Reserved, read as 0.

Table 48-43. Endpoint Control *x* Registers Field Descriptions (continued)

Field	Description
3–2 RXT	RX endpoint type – Read/Write 00 Control 01 Isochronous 10 Bulk 11 Reserved
1 RXD	RX endpoint data sink – Read/Write 0 Dual Port Memory Buffer/DMA Engine (Default) Should always be written as zero.
0 RXS	RX Endpoint Stall – Read/Write 0 Endpoint OK. [Default] 1 Endpoint stalled This bit is set to 1 automatically upon receipt of a SETUP request if this endpoint is not configured as a control endpoint. It will be cleared automatically upon receipt a SETUP request if this endpoint is configured as a control endpoint, Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above,

48.4.1.7 OTG Operations

48.4.1.7.1 Register Bits Used for OTG Operations

The Register interface described in Section 48.4.1.6, “Device/Host Operational Registers” has separate behaviors for device mode and for host mode. However, during OTG operations it is necessary to perform tasks independent of the controller mode.

As described in Section 48.4.1.6.23, “Endpoint Control x Registers (ENDPTCTRLx, x = 1…15)” the only way to transition the controller mode out of host or device mode is by programming the controller reset bit in the USBCMD register. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

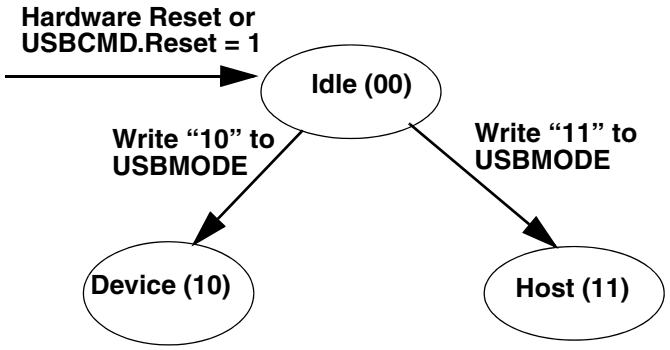

Figure 48-45. Controller Mode

The following register bits can be used for OTG operations. These bits are independent of the controller mode, and are not affected by a write to the reset bit in the USBCMD register:

- All identification registers
- All device/host capability registers
- OTG states control register (OTGSC): all bits
- PORTSC register:
  - Physical interface select
  - Physical interface serial select
  - Physical interface data width
  - Physical interface low power
  - Physical interface wake signals
  - Port indicators
  - Port power

48.4.1.7.2 Hardware Assist

The hardware assist provides automated response and sequencing that avoid significant interrupt latency response times introduced by software. The use of this additional circuitry is optional, and can be used to assist the auto-reset, data-pulse, and B-connect to A-connect sequences described below.

Auto-Reset Sequence

When the HAAR bit (OTGSC register) is set to 1, the host automatically starts a reset after a connect event. This shortcuts the normal process, where software is notified of the connect event and starts the reset. When the HAAR bit is set, software still receives notification of the connect event, but is not responsible to write the reset bit. Software will be notified again after the reset is complete via the enable change bit in the PORTSC register, which causes a port change interrupt.

This hardware assist ensures the OTG parameter TB_ACON_BSE0_MAX = 1 ms is met.

Data-Pulse Sequence

Writing a 1 to HADP (OTGSC register) will start a data pulse of approximately 7 ms in duration and then automatically cease the data pulsing. During the data pulse, the DP will be set and then cleared. This automation relieves software from accurately controlling the data-pulse duration. During the data pulse, the HCD can poll to see that the HADP and DP bit have returned low to recognize the completion or simply launch the data pulse and wait to see if a VBUS Valid interrupt occurs when the A-side supplies bus power.

This assist ensures that data pulsing meets the OTG requirement of between 5–10 ms.

B-Disconnect to A-Connect Sequence

During HNP, the B-disconnect occurs from the OTG A_suspend state and within 3 ms, the A device must enable the pullup on the DP leg in the A-peripheral state. If the HABA bit (OTGSC register) is set to 1,

the host controller port is in suspend mode, and the device disconnects, then hardware assist performs the following actions:

1. Reset the OTG core.
2. Write the OTG core into device mode.
3. Write the device run bit to a 1 and enable necessary interrupts, including:
    - USB reset enable (URE); enables interrupt on USB bus reset to device
    - Sleep enable (SLE); enables interrupt on device suspend
    - Port change detect enable (PCE); enables interrupt on device connect

When software has enabled this hardware assist, it must not interfere during the transition or write any register in the core until it gets an interrupt from the device controller signifying that a reset interrupt has occurred, or at least first verify that the core has entered device mode. HCD/DCD must not activate the core soft reset at any time since this action is performed by hardware. During the transition, the software may see an interrupt from the disconnect and/or other spurious interrupts (SOF, for example) that may or may not cascade and my be cleared by the soft reset depending on the software response time.

After the core has entered device mode by the hardware assist, the DCD must ensure that the ENDPTLISTADDR is programmed properly before the host sends a setup packet. Since the end of the reset duration, which may be initiated quickly (a few microseconds) after connect, will require at a minimum 50 ms, this is the time for which the DCD must be ready to accept setup packets after having received notification that the reset has been detected or simply that the OTG is in device mode which ever occurs first.

In the case where the A-peripheral fails to see a reset after the controller enters device mode and engages the DP-pullup, the device controller interrupt the DCD signifying that a suspend has occurred.

This assist ensures the parameter TA_BDIS_ACON_MAX = 3 ms is met.

48.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the enhanced host controller (hardware). The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a periodic schedule, periodic frame list, asynchronous schedule, isochronous transaction descriptors, split-transaction isochronous transfer descriptors, queue heads, and queue element transfer descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. isochronous data streams are managed using isochronous transaction descriptors. isochronous split-transaction data streams are managed with split-transaction isochronous transfer descriptors. all interrupt, control, and bulk data streams are managed via queue heads and queue element transfer descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writable fields. The host controller must preserve the read-only fields on all data structure writes.

48.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the PERIODICLISTBASE address register and the FRINDEX register. The periodic schedule is based on an array of pointers called the periodic frame list. The PERIODICLISTBASE address register is combined with the FRINDEX register to produce a memory pointer into the frame list. The periodic frame list implements a sliding window of work over time.

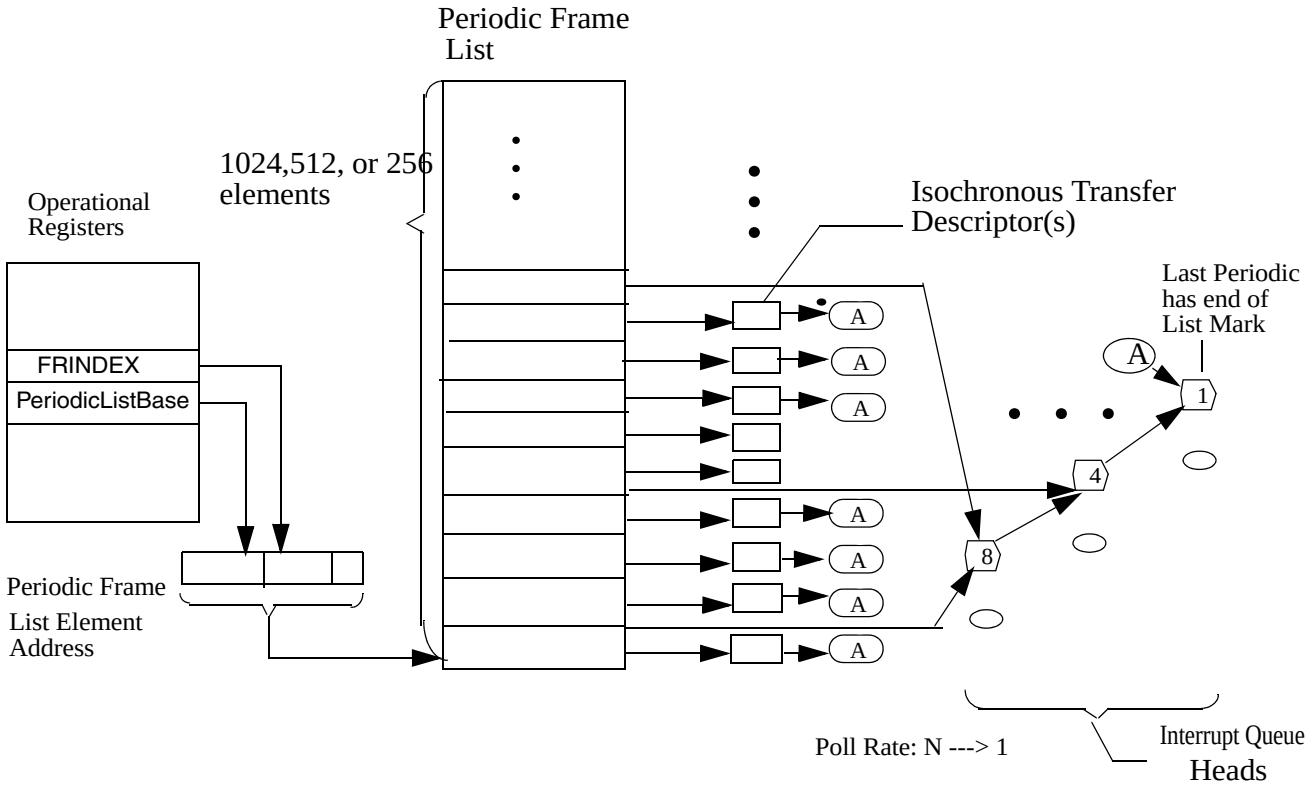

Figure 48-46. Periodic Schedule Organization

[1] Split transaction interrupt, bulk and control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4K-page aligned array of frame list link pointers. The length of the frame list is programmable via the frame list size (FS) bit in the USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current microframe. The link pointers are aligned on dword boundaries within the frame list.

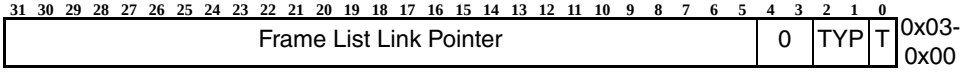

Figure 48-47. Format of Frame List Element Pointer

Frame list link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupts). System software should not place non-periodic schedule items into the periodic schedule.

The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing:

- The TYP field indicates the exact type of data structure being referenced by this pointer. TYP field encodings are given in Table 48-44.

Table 48-44. TYP Field Value Definitions

TYP Field Value	Meaning
00	Isochronous Transfer Descriptor
01	Queue Head
10	Split Transaction Isochronous Transfer Descriptor.
11	Frame Span Traversal Node.

- When the T bit (bit 0) is set to 1, the host controller never uses the value of the frame list pointer as a physical memory pointer.

48.4.2.2 Asynchronous List Queue Head Pointer

The asynchronous transfer list (at the location specified by the ASYNCLISTADDR register) is where all the control and bulk transfers are managed. The host controller uses this list only if at least one of the following conditions holds:

- The host controller reaches the end of the periodic list.
- The periodic list is disabled,
- The periodic list is empty.

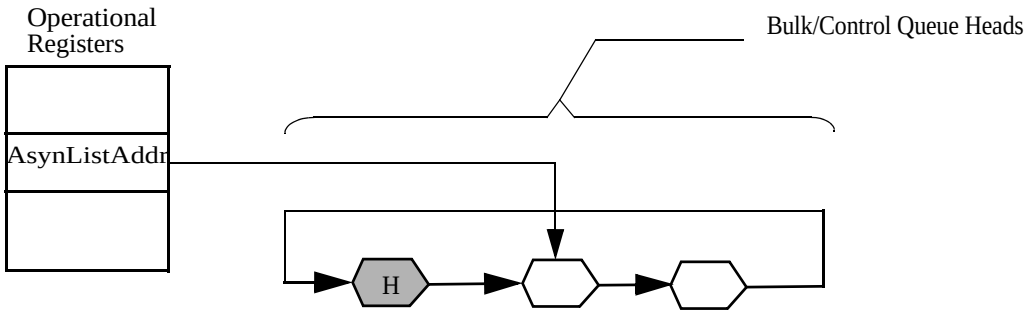

Figure 48-48. Asynchronous Schedule Organization

The asynchronous list is a simple circular list of queue heads. The ASYNCLISTADDR register is simply pointer to the *next* queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

48.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

Figure 48-49 shows the format of an isochronous transfer descriptor. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. iTDs must be aligned on a 32-byte boundary.

Figure 48-49. Isochronous Transaction Descriptor (iTD)

48.4.2.3.1 Next Link Pointer

The first dword of an iTD is a pointer to the next schedule data structure.

Table 48-45. Next Schedule Element Pointer

Bits	Description
31–5 LP	Link Pointer. These bits correspond to memory address signals [31:5], respectively. This field points to another isochronous transaction descriptor (iTD/siTD) or Queue Head (QH).
4–3	Reserved. These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2–1 TYP	QH/(s)iTD Select. This field indicates to the host controller whether the item referenced is an iTD, siTD or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor 11 FSTN (frame span traversal node)
0 T	Terminate. 0 Link Pointer field is valid. 1 Link Pointer field is not valid

48.4.2.3.2 iTD Transaction Status and Control List

Dwords 1 through 8 are eight slots of transaction control and status. Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The *PG* and *Transaction X Offset* fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three dwords of the buffer page pointer list, to execute a transaction on the USB.

Table 48-46. iTD Transaction Status and Control

Bits	Description	
31–28	**Status.** This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	**Active.** Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	**Data Buffer Error.** Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	**Babble Detected.** Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
	28	**Transaction Error (XactErr).** Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27–16	**Transaction X Length**. For an OUT, this field is the number of data bytes the host controller will send during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (e.g. 0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15	**Interrupt On Complete (IOC).** If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14–12	**Page Select (PG).** These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11–0	**Transaction X Offset**. This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

48.4.2.3.3 iTD Buffer Page Pointer List (Plus)

Dwords 9-15 of an isochronous transaction descriptor are nominally page pointers (4K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Since each pointer is a 4K-aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

Table 48-47. iTD Buffer Pointer Page 0 (Plus)

Bits	Description
31–12	**Buffer Pointer (Page 0).** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	**Reserved.** Bit reserved for future use and should be initialized by software to zero.
6–0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 48-48. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31–12	**Buffer Pointer (Page 1).** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11	**Direction (I/O). 0 = OUT; 1 = IN.** This field encodes whether the high-speed transaction should use an IN or OUT PID.
10–0	**Maximum Packet Size.** This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (.e.g. per microframe). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 48-49. iTD Buffer Pointer Page 2 (Plus)

Bits	Description
31–12	**Buffer Pointer.** This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–2	**Reserved.** This bit reserved for future use and should be set to zero.
1–0	**Multi.** This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (e.g. per microframe). The valid values are: 00 Reserved. A zero in this field yields undefined results. 01 One transaction to be issued for this endpoint per microframe 10 Two transactions to be issued for this endpoint per microframe 11 Three transactions to be issued for this endpoint per microframe

Figure 48-50. iTD Buffer Pointer Page 3-6

Bit	Description
31–12	**Buffer Pointer.** This is a 4K-aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11–0	**Reserved.** These bits reserved for future use and should be set to zero.

48.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

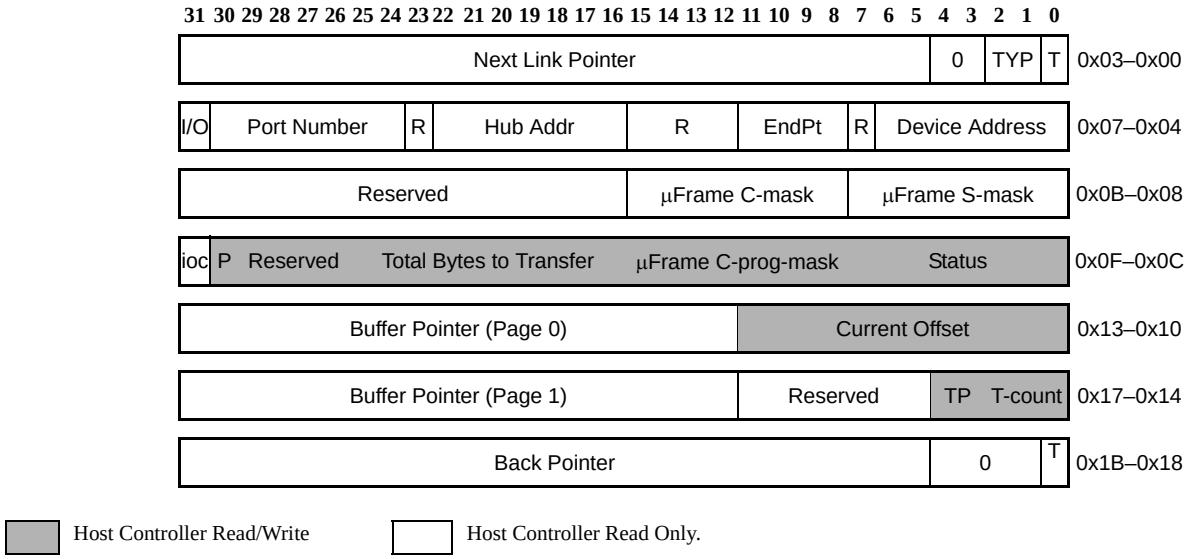

Figure 48-51. Split-transaction Isochronous Transaction Descriptor (siTD)

48.4.2.4.1 Next Link Pointer

Dword0 of a siTD is a pointer to the next schedule data structure.

Table 48-50. Next Link Pointer

Bits	Description
31–5	**Next Link Pointer (LP).** This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4–3	**Reserved.** These bits must be written as zeros.
2–1	**QH/(s)iTD Select (TYP).** This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: ValueMeaning 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor 11 FSTN (frame span traversal node)
0	**Terminate (T).** 1=Link Pointer field is not valid. 0=Link Pointer is valid.

48.4.2.4.2 siTD Endpoint Capabilities/Characteristics

Dwords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and microframe scheduling control.

Table 48-51. Endpoint and Transaction Translator Characteristics

Bits	Description
31	**Direction (I/O).0 = OUT; 1 = IN.** This field encodes whether the full-speed transaction should be an IN or OUT.
30–24	**Port Number.** This field is the port number of the recipient Transaction Translator.

Table 48-51. Endpoint and Transaction Translator Characteristics

23	**Reserved.** Bit reserved and should be set to zero.
22–16	**Hub Address.** This field holds the device address of the Companion Controllers' hub.
15–12	**Reserved.** Field reserved and should be set to zero.
11–8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	**Reserved.** Bit is reserved for future use. It should be set to zero.
6–0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 48-52. Microframe Schedule Control

Bits	Description
31–16	**Reserved.** This field reserved for future use. It should be set to zero.
15–8	**Split Completion Mask (μFrame C-Mask).** This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which microframes the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the μ*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7–0	**Split Start Mask (μFrame S-mask).** This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which microframes the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the μ*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

48.4.2.4.3 siTD Transfer State

Dwords 3-6 are used to manage the state of the transfer.

Table 48-53. siTD Transfer Status and Control

Bit	Description
31	**Interrupt On Complete (ioc).** 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it will assert a hardware interrupt at the next interrupt threshold.
30	**Page Select (P).** Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
29–26	**Reserved.** This field reserved for future use and should be set to zero.
25–16	**Total Bytes To Transfer.** This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15–8	**μFrame Complete-split Progress Mask (C-prog-Mask).** This field is used by the host controller to record which split-completes has been executed.
7–0	**Status.** This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:

Table 48-53. siTD Transfer Status and Control (continued)

	Bit	Definition
	7	**Active.** Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
	6	**ERR.** Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
	5	**Data Buffer Error**. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller will transmit an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
	4	**Babble Detected.** Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.
	3	**Transaction Error (XactErr).** Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Time-out, CRC, Bad PID, etc.). This bit will only be set for IN transactions.
	2	**Missed microframe.** The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
	1	**Split Transaction State (SplitXstate).** The bit encodings are as follows: 00 Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01 Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
	0	**Reserved.** Bit reserved for future use and should be set to zero.

48.4.2.4.4 siTD Buffer Pointer List (plus)

Dwords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each dword in this section are the 4K (page) aligned buffer pointers. The least significant 12 bits of each dword are used as additional transfer state.

Table 48-54. Buffer Page Pointer List (Plus)

Bits	Description
31–12	**Buffer Pointer List.** Bits [31:12] of dwords 4 and 5 are 4K paged aligned, physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* specifies the *current* active pointer
11–0	• Page 0: The 12 least significant bits of the Page 0 pointer give the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field)). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero). • Page 1: The least significant bits of Page 1 pointer is split into three sub-fields, as shown in the following table.

Bits	Description
11–5	Reserved.
4–3	**Transaction position (TP).** This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: 00 All. The entire full-speed transaction data payload is in this transaction (i.e. less than or equal to 188 bytes). 01 Begin. This is the first data payload for a full-speed that is greater than 188 bytes.transaction 10 Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11 End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
2–0	**Transaction count (T-Count).** Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

48.4.2.4.5 siTD Back Link Pointer

Dword 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD. This pointer cannot reference any other schedule data structure.

Table 48-55. siTD Back Link Pointer

Bits	Description
31–5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4–1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

48.4.2.5 Queue Element Transfer Descriptor (qTD)

This data structure is only used with a queue head. This data structure is used for one or more USB transactions. This data structure is used to transfer up to 20480 (5*4096) bytes. The structure contains two structure pointers used for queue advancement, a dword of transfer state, and a five-element array of data

buffer pointers. This structure is 32 bytes (or one 32-byte cache line). This data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

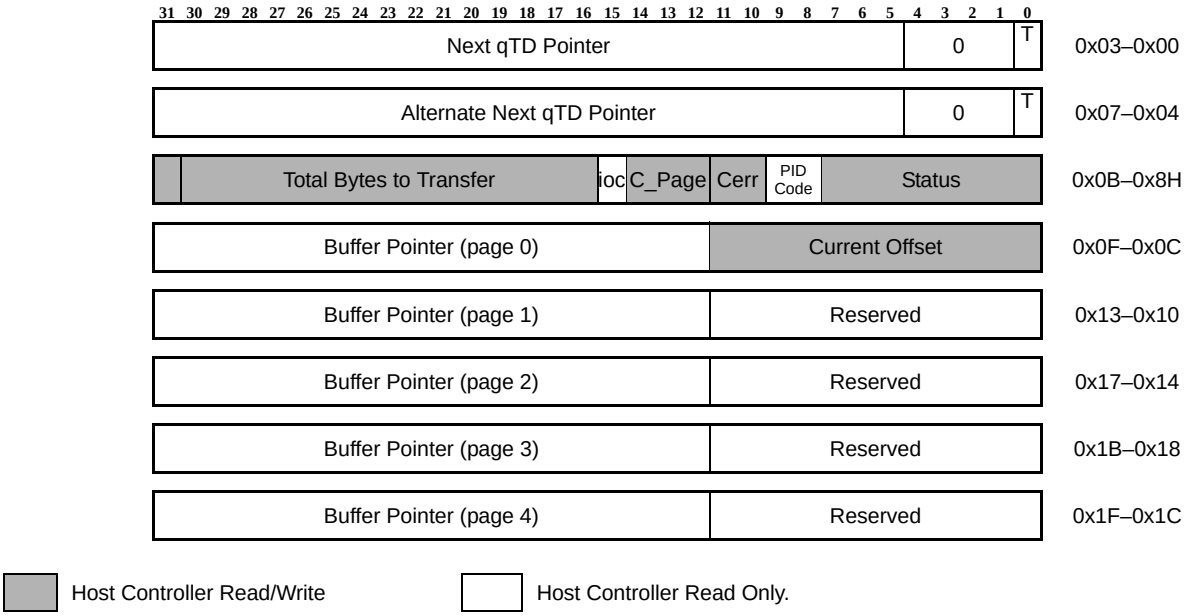

Figure 48-52. Queue Element Transfer Descriptor Block Diagram

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

48.4.2.5.1 Next qTD Pointer

The first dword of an element transfer descriptor is a pointer to another transfer element descriptor.

Table 48-56. qTD Next Element Transfer Pointer (Dword 0)

Bits	Description
31–5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4–1	Reserved. These bits are reserved and their value has no effect on operation.
0	Terminate (T). This bit indicates to the Host Controller that there are no more valid entries in the queue. 0 Pointer is valid (points to a valid Transfer Element Descriptor) 1 Pointer is invalid.

48.4.2.5.2 Alternate Next qTD Pointer

The second dword of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet. To be more explicit the host controller will always use this pointer when the current qTD is retired due to short packet.

Table 48-57. TD Alternate Next Element Transfer Pointer (Dword 1)

Bits	Description
31–5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4–1	Reserved. These bits are reserved and their value has no effect on operation.
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

48.4.2.5.3 qTD Token

The third dword of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

Table 48-58. qTD Token (Dword 2)

Bits	Description
31	Data Toggle. This is the data toggle sequence bit. The use of this bit depends on the setting of the *Data Toggle Control* bit in the queue head.
30–16	Total Bytes to Transfer. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4 Kbytes (0x5000). This is the maximum number of bytes that 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that *Total Bytes To Transfer* be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction will always be less than QHD.Maximum Packet Length. Although it is possible to create a transfer up to 20 Kbytes, this assumes the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16 Kbytes**. Therefore, the maximum recommended transfer is 16 Kbytes (0x4000).
15	Interrupt On Complete (IOC). If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.
14–12	Current Page (C_Page). This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0x0 to 0x4. The host controller is not required to write this field back when the qTD is retired.

Table 48-58. qTD Token (Dword 2) (continued)

11–10	Error Counter (CERR). This field is a 2-bit down-counter that keeps track of the number of consecutive errors detected while executing this qTD. • If this field is programmed with a nonzero value during setup, the host controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the Halted bit to a 1, and sets an error status bit for the error that caused CERR to decrement to zero. An interrupt is generated if the USB Error Interrupt Enable bit in the USBINTR register is set to a one. • If HCD programs this field to zero during set-up, the Host Controller will not count errors for this qTD and there will be no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD. The behavior of the CERR field for different error types is as follows: • Babble or stall detection automatically halts the queue head—CERR is not decremented. • Data buffer errors are host problems— CERR is not decremented. • Transaction errors cause CERR to be decremented. If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller is responsible to reset CERR to extend the total number of errors for this transaction. For example, CERR should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 0b00. See Section 48.4.3.12.2, “Split Transaction Interrupt” for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Section , “Asynchronous—Do Complete Split” for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP. **Note:** Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.
9–8	PID Code. This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. 00 OUT Token generates token (E1H) 01 IN Token generates token (69H) 10 SETUP Token generates token (2DH) (undefined if endpoint is an Interrupt the queue head is non-zero.) transfer type, e.g. μ*Frame S-mask* field in 11 Reserved
7–0	**Status.** This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. Table 48-59 shows the bit encodings.

Table 48-59. qTD Token (Dword 2) Status Field (bits 7–0) Bits Description

Status Field Bit	Description
7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
6	Halted. Set to a one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller will force a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table 48-59. qTD Token (Dword 2) Status Field (bits 7–0) Bits Description (continued)

4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Since "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
2	Missed microframe. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. Bit encodings are: 0 Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1 Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: 0 Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1 Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

48.4.2.5.4 qTD Buffer Page Pointer List

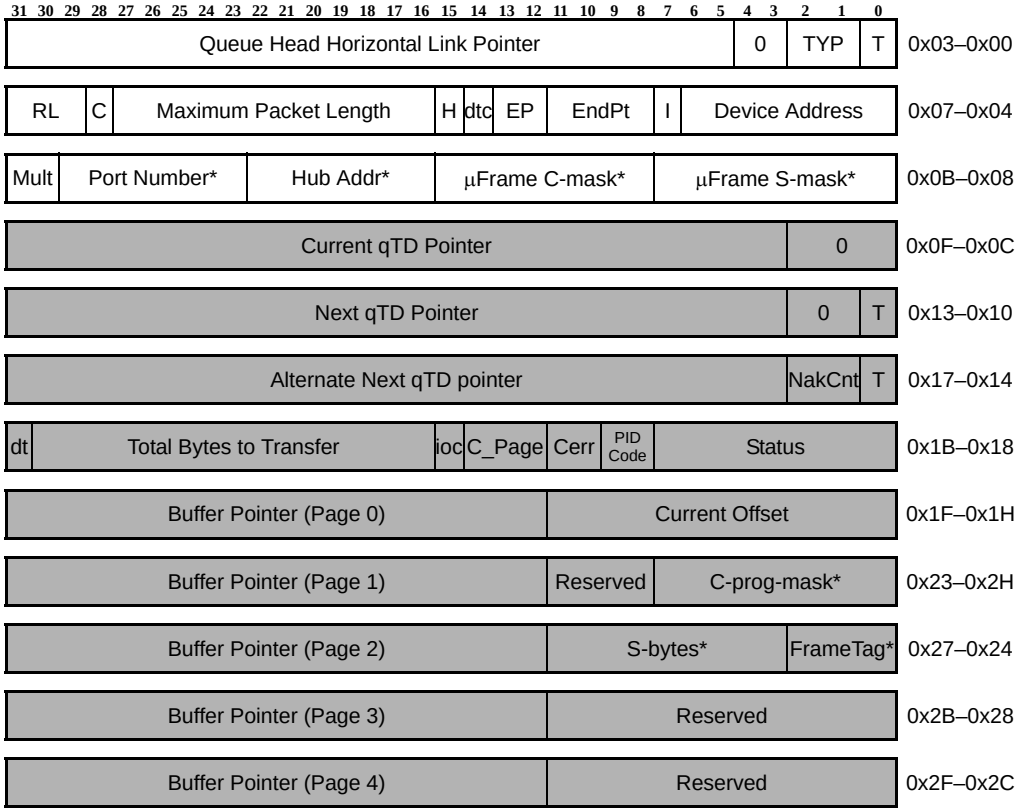
The last five dwords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes *Current Offset* field to the starting offset into the current page, where current page is selected via the value in the *C_Page* field.

Table 48-60. qTD Buffer Pointer(s) (Dwords 3-7)

Bits	Description
31–12	**Buffer Pointer List.** Each element in the list is a 4K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction via the new buffer pointer.
11–0	**Current Offset (Reserved).** This field is reserved in all pointers except the first one (e.g. Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zeros.

48.4.2.6 Queue Head



Transfer Overlay Transfer Results

Static Endpoint State

*These fields are used exclusively to support split transactions to USB 2.0 Hubs

Host Controller Read/Write Host Controller Read Only.

Figure 48-53. Queue Head Structure Layout

Queue Head Horizontal Link Pointer

The first dword of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

Table 48-61. Queue Head Dword 0

Bits	Description
31–5	**Queue Head Horizontal Link Pointer (QHLP).** This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4–3	**Reserved.** These bits must be written as zeros.

Table 48-61. Queue Head Dword 0 (continued)

2–1	**QH/(s)iTD Select (TYP).** This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: ValueMeaning 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor) 11 FSTN (frame span traversal node)
0	**Terminate (T).** 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

48.4.2.6.1 Endpoint Capabilities/Characteristics

The second and third dwords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint. There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

Table 48-62. Endpoint Characteristics: Queue Head Dword 1

Bit	Description
31:28	**Nak Count Reload (RL).** This field contains a value, which is used by the host controller to reload the Nak Counter field.
27	**Control Endpoint Flag (C).** If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to a zero.
26:16	**Maximum Packet Length.** This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).
15	**Head of Reclamation List Flag (H).** This bit is set by System Software to mark a queue head as being the head of the reclamation list.
14	**Data Toggle Control (DTC).** This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0 Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1 Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.

Table 48-62. Endpoint Characteristics: Queue Head Dword 1 (continued)

Bit	Description
13–12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are: 00 Full-speed (12 Mbps) 01 Low-speed (1.5 Mbps) 10 High-speed (480 Mbps) 11 Reserved. This field must not be modified by the host controller.
11:8	**Endpoint Number (Endpt).** This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	**Inactivate on Next Transaction (I).** This bit is used by system software to request that the host controller set the Active bit to zero. See Section , “Rebalancing the Periodic Schedule” for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the EPS field indicates a Full or Low-speed endpoint. Setting this bit to a one when the queue head is in the Asynchronous Schedule or the EPS field indicates a high-speed device yields undefined results.
6:0	**Device Address.** This field selects the specific device serving as the data source or sink.

Table 48-63. Endpoint Capabilities: Queue Head Dword 2

Bit	Description
31:30	**High-Bandwidth Pipe Multiplier (Mult).** This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: ValueMeaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per microframe 10b Two transactions to be issued for this endpoint per microframe 11b Three transactions to be issued for this endpoint per microframe
29:23	**Port Number.** This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22:16	**Hub Addr.** This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.

Table 48-63. Endpoint Capabilities: Queue Head Dword 2 (continued)

Bit	Description
15:8	**Split Completion Mask (μFrame C-Mask).** This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which microframes the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7:0	**Interrupt Schedule Mask (μFrame S-mask).** This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

48.4.2.6.2 Transfer Overlay

The nine dwords in this area represent a *transaction working space* for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the *Queue Head Horizontal Link Pointer* to the next queue head. The host controller will never follow the *Next Transfer Queue Element or Alternate Queue Element* pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The dword3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

Table 48-64. Current qTD Link Pointer

Bit	Description
31:5	**Current Element Transaction Descriptor Link Pointer.** This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4:0	**Reserved (R).** These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The dwords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an *overlay* because when the queue is advanced to the next queue element, the source queue element is *merged* onto this area. This area serves an execution cache for the transfer.

Table 48-65. Host-Controller Rules for Bits in Overlay (Dwords 5, 6, 8 and 9)

Dword	Bit	Description
5	4:1	**Nak Counter (NakCnt)μRW**. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	**Data Toggle.** The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	**Interrupt On Complete (IOC).** The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11:10	**Error Counter (C_ERR).** This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	**Ping State (P)/ERR.** If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7:0	**Split-transaction Complete-split Progress (C-prog-mask).** This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4:0	**Split-transaction Frame Tag (Frame Tag).** This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11:5	**S-bytes.** Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

48.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary. See section Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose HCIVERSION register indicates a revision implementation below 0x0096. FSTNs are not defined for implementations before 0x0096 and their use will yield undefined results.

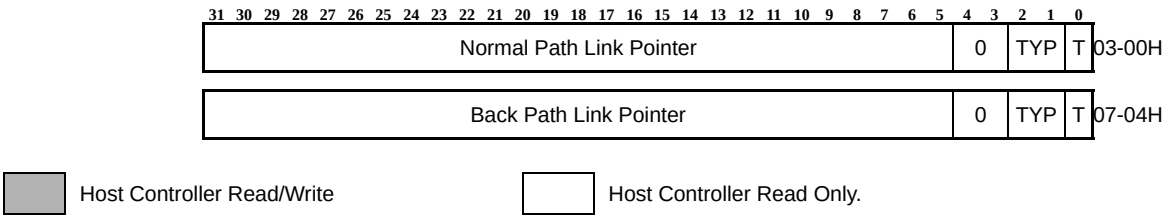


Figure 48-54. Frame Span Traversal Node Structure Layout

48.4.2.7.1 FSTN Normal Path Pointer

The first dword of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

Table 48-66. FSTN First Dword Fields Description

Bits	Description
31–5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4–3	Reserved. These bits must be written as 0s.
2–1	QH/(s)iTD/FSTN Select (TYP). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor) 11 FSTN (Frame Span Traversal Node)
0	Terminate (T). 0 Link Pointer is valid. 1 Link Pointer field is not valid.

48.4.2.7.2 FSTN Back Path Link Pointer

The second dword of an FTSN node contains a link pointer to a queue head. If the T bit in this pointer is a zero, then this FSTN is a *Save-Place* indicator. Its TYP field must be set by software to indicate the target data structure is a queue head. If the T bit in this pointer is set to 1, then this FSTN is the *Restore* indicator. When the T bit is 1, the host controller ignores the TYP field.

Table 48-67. FSTN Second Dword Field Descriptions

Bits	Description
31:5	**Back Path Link Pointer (BPLP).** This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4:3	**Reserved.** These bits must be written as 0s.
2:1	**TYP.** Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	**Terminate (T).** 1=Link Pointer field is not valid (i.e. the host controller must not use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (i.e. the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

48.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software). Each significant operational

feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

48.4.3.1 Host Controller Initialization

When the system boots, the host controller is enumerated, assigned a base address for the register space and BIOS sets the FLADJ register to a system-specific value. After initial power-on or software reset (by setting the RST bit in the USBCMD register, all of the operational registers are set at their default values, as illustrated in Table 48-68. After a hardware reset, only the operational registers not contained in the auxiliary power well will be at their default values.

Table 48-68. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USBCMD	0x0008_0B00[
USBSTS	0x0000_1000
USBINTR	0x0000_0000
FRINDEX	0x0000_0000
CTRLDSSEGMENT	0x0000_0000
PERIODICLISTBASE	Undefined
ASYNCLISTADDR	Undefined
CONFIGFLAG	0x0000_0001
PORTSC	0x0000_2000 (if PPC = 1, HCSPARAMS register) 0x0000_3000 (if PPC = 0, HCSPARAMS register)

In order to initialize the host controller, software should perform the following steps

- Program the CTRLDSSEGMENT register with 4-Gigabyte segment where all of the interface data structures are allocated.
- Write the appropriate value to the USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the PERIODICLIST BASE register. If there are no work items in the periodic schedule, all elements of the Periodic Frame List should have their *T-Bits* set to a one.
- Write the USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller *ON* via setting the *Run/Stop* bit.
- Write a 1 to CONFIGFLAG register to route all ports to the EHCI controller.

At this point, the host controller is up and running and the port registers will begin reporting device connects, etc. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled port enabled High-speed ports, but the schedules have not yet been enabled. The EHCI Host controller will not transmit SOFs to enabled Full- or Low-speed ports. In order to communicate with devices via the asynchronous schedule, system software must write the ASYNDLISTADDR register with the address of a control or

bulk queue head. Software must then enable the asynchronous schedule by writing a one to the *Asynchronous Schedule Enable* bit in the USBCMD register. In order to communicate with devices via the periodic schedule, system software must enable the periodic schedule by writing a one to the *Periodic Schedule Enable* bit in the USBCMD register. Note that the schedules can be turned on before the first port is reset (and enabled).

Any time the USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

48.4.3.2 Port Routing and Control

A USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers. Companion host controllers (cHCs) may be implementations of either universal or open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; e.g. Low-, Full-, and High-speed capability for every port. Figure 48-55 illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

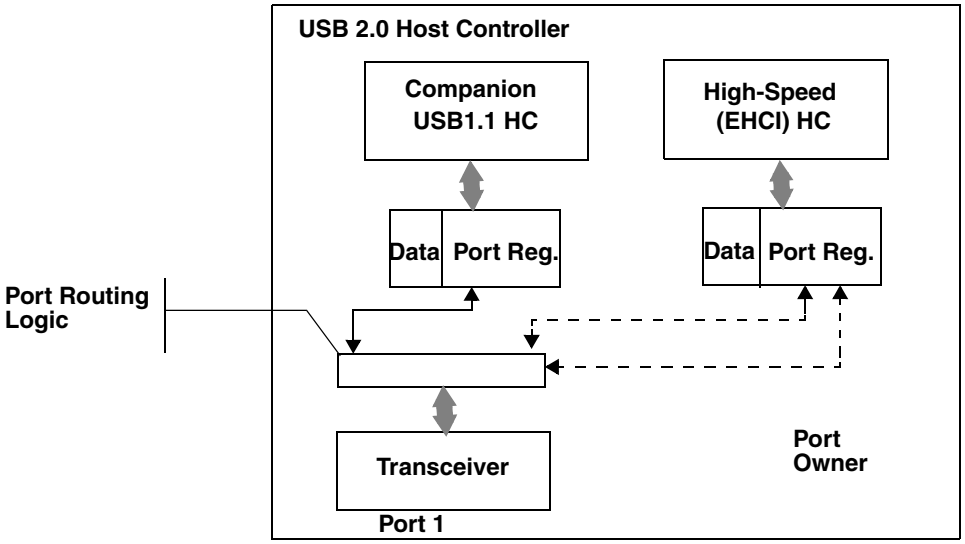

Figure 48-55. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller module has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Each transceiver can be controlled by either the EHCI host controller or one companion host controller. Routing logic lies between the transceiver and the port status and control registers.

NOTE

The USB Controllers on i.MX parts neither support nor require companion controllers to support full and low speed devices. Therefore, no port routing is present in the controller. Please refer to the Section 48.4.4.1, "Embedded Transaction Translator Function" for details.

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a *global* routing policy control field and per-port *ownership* control fields. The *Configured Flag* (*CF*) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes companion controllers, then the ports will still work in full- and low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (i.e. no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The *N_CC* field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When *N_CC* has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports will always fail the high-speed chirp during reset and the ports will not be enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Section 48.4.1.4.3, "Host Control Structural Parameters Register (HCSPARAMS)".

48.4.3.2.1 Port Routing Control via EHCI *Configured* (*CF*) Bit

Each port in the USB 2.0 host controller can be routed either to a single companion host controller or to the EHCI host controller. The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The *Configured Flag* (*CF*) bit is used to globally set the policy of the routing logic. Each port register has a *Port Owner* control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the *CF bit* transitions from a zero to a one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all *Port Owner* bits go to zero). While the *CF-bit* is a one, the EHCI Driver can control individual ports' routing via the *Port Owner* control bit. Likewise, whenever the *CF bit* transitions from a one to a zero (as a result of AUX power application, setting the RST bit in the USB command register, or software writing a zero to CF-bit), the port routing unconditionally routes all of the port

registers to the appropriate companion HC. The default value for the EHCI HC's *CF bit* (after AUX power application or setting RST to 1) is zero. Table 48-56 summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

Figure 48-56. Default Port Routing Depending on EHCI HC CF Bit

HC CF Bit Setting	Default Port Ownership	Explanation
0	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see Section 48.4.1.6.14, "Port Status Control x Registers (PORTSCx, x = 1…8)"). The EHCI HC can temporarily release control of the port to a companion HC by setting the PortOwner bit in the PORTSC register to a one.

48.4.3.2.2 Port Routing Control via *PortOwner* and Disconnect Event

Manipulating the port routing via the CF-bit is an extreme process and not intended to be used during normal operation. The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's PORTSC register (for handoffs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI CF-bit is set to a one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.
- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the *LineStatus* bits in the PORTSC register. If they indicate the attached device is a full-speed device (e.g. D+ is asserted), then the EHCI Driver sets the *PortReset* control bit to a one (and sets the *PortEnable* bit to a zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing a zero to the port reset bit. The reset process is actually complete when software reads a zero in the *PortReset* bit. The EHCI Driver checks the PortOwner bit in the PORTSC register. If set to a one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.

- At the time the EHCI Driver receives the port reset and enable request the *LineStatus* bits might indicate a low-speed device. Additionally, when the port reset process is complete, the *PortEnable* field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the PORTSC register to a one to release port ownership to a companion host controller.
- When the EHCI Driver sets *PortOwner* bit to a one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI PORTSC register observes and reports a disconnect event via the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to a one, a connect change set to a one and a connect status set to a zero. This information is derived directly from the EHCI port register. This will allow the hub driver to assume the device was disconnected during reset. It will acknowledge the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's *CF-bit* transitions from a 1b to a 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects will be detected by the EHCI port register and the process will repeat.

48.4.3.2.3 Example Port Routing State Machine

Figure 48-57 illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

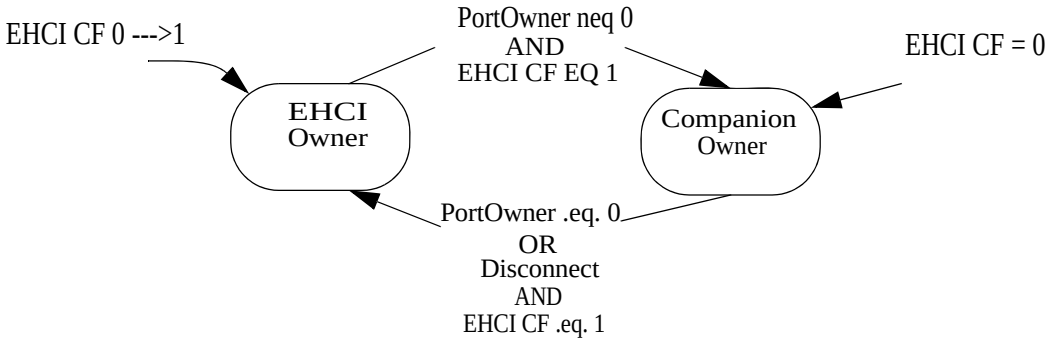

Figure 48-57. Port Owner Handoff State Machine

EHCI HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the EHCI HC's *Configure Flag* (*CF*) bit in the CONFIGFLAG register transitions from a zero to a one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver will acknowledge the disconnect by setting the connect status change bit to a zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes a zero to the *PortOwner* bit in the PORTSC register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the *Port Owner* field transitions from a zero to a one.
- When the HS-mode HC's *Configure Flag* (*CF*) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

48.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (See Section 48.4.1.4.3, "Host Control Structural Parameters Register (HCSPARAMS)"). When this bit is a zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the PPC bit is set to one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is denoted as Port Power Enable (PPE). PPE is controlled based on the states of the PPC bit, EHCI Configured (CF) bit and individual Port Power (PP) bits. Table 48-69 summarizes the PPE behavior.

Table 48-69. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	*n*	CHC	0	When the EHCI controller has not been configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.

Table 48-69. Port Power Enable Control Rules (continued)

0	1	*n*	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

[1] CHC (Companion Host Controller)

[2] EHC (EHCI Host Controller)

[3] PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists)

48.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI PORTSC register has an over-current status and over-current change bit. The functionality of these bits is specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document. The over-current condition effects the following bits in the PORTSC register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from 1 to 0.
- Over-current Change bits are set to1. On every transition of the Over-current Active bit the host controller will set the Over-current Change bit to 1. Software clears the Over-current Change bit by writing 1 to this bit.
- Port Enabled/Disabled bit is cleared. When this change bit gets set to 1, then the Port Change Detect bit in the USBSTS register is set to1.
- Port Power (PP) bits may optionally be cleared. There is no requirement in USB that a power provider shut off power in an over-current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from 0 to 1, the host controller also sets the Port Change Detect bit in the USBSTS register to 1. In addition, if the Port Change Interrupt Enable bit in the USBINTR register is set to 1, then the host controller issues an interrupt to the system. See Table 48-70 for summary behavior for over-current detection when the host controller is halted (suspended from a device component point of view).

48.4.3.3 Suspend/Resume

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub. Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely via software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wakeup events. The classes of wakeup events are:

- Remote-wakeup enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the PORTSC registers.

Selective suspend is a feature supported by every PORTSC register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the *Run/Stop* bit in the USBCMD register to a zero. The EHCI module can then be placed into a lower device state via the PCI power management interface (See Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs the system will resume operation and system software will eventually set the *Run/Stop* bit to a one and resume the suspended ports. Software must not set the *Run/Stop* bit to a one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the CPU is restarted. So, by definition, if software is running, clocks in the system are stable and the *Run/Stop* bit in the USBCMD register can be set to a one. There are also minimum system software delays defined in the PCI Power Management Specification. See this specification for more information.

48.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing a one into the appropriate PORTSC *Suspend* bit. Software must only set the *Suspend* bit when the port is in the enabled state (*Port Enabled* bit is a one) and the EHCI is the port owner (*Port Owner* bit is a zero).

The host controller may evaluate the *Suspend* bit immediately or wait until a microframe or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several microframes of activity on the port until the host controller evaluates the *Suspend* bit. The host controller must evaluate the *Suspend* bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing a one to the *Force Port Resume* bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Section 48.4.1.6.14, “Port Status Control x Registers (PORTSCx, x = 1…8)”). If system software

sets *Force Port Resume* bit to a one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 milliseconds after a port indicates that it is suspended (*Suspend* bit is a one) before initiating a port resume via the *Force Port Resume* bit. When *Force Port Resume* bit is a one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 milliseconds) then sets the *Force Port Resume* bit to a zero. When the host controller receives the write to transition *Force Port Resume* to zero, it completes the resume sequence as defined in the USB specification, and sets both the *Force Port Resume* and *Suspend* bits to zero. Software-initiated port resumes do not affect the *Port Change Detect* bit in the USBSTS register nor do they cause an interrupt if the *Port Change Interrupt Enable* bit in the USBINTR register is a one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μsec. The port's *Force Port Resume* bit is set to a one and the *Port Change Detect* bit in the USBSTS register is set to a one. If the *Port Change Interrupt Enable* bit in the USBINTR register is a one the host controller will issue a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 msec), then terminates the resume sequence by writing zero to the *Force Port Resume* bit in the port. The host controller receives the write of zero to *Force Port Resume*, terminates the resume sequence and sets *Force Port Resume* and *Suspend* port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the PORTSC register and observing that the *Suspend* and *Force Port Resume* bits are zero. Software must ensure that the host controller is running (that is, the *HCHalted* bit in the USBSTS register is a zero), before terminating a resume by writing a zero to a port's *Force Port Resume* bit. If *HCHalted* is a one when *Force Port Resume* is set to a zero, then SOFs will not occur down the enabled port and the device will return to suspend mode in a maximum of 10 milliseconds.

Table 48-70 summarizes the wakeup events. Whenever a resume event is detected, the *Port Change Detect* bit in the USBSTS register is set to a one. If the *Port Change Interrupt Enable* bit is a one in the USBINTR register, the host controller will also generate an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the *Port Change Detect* status bit in the USBSTS register.

Table 48-70. Behavior During Wakeup Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, Resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in PORTSC register is set to a one. Port Change Detect bit in USBSTS register set to a one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is a one. A disconnect is detected.	Depending in the initial port state, the PORTSC Connected Enable status bits are set to zero, and the Connect Change status bit is set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is a zero. A disconnect is detected.	Depending on the initial port state, the PORTSC Connect and Enable status bits are set to zero, and the Connect Change status bit is set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]

Table 48-70. Behavior During Wakeup Events (continued)

Port is not connected and the port's WKCNNT_E bit is a one. A connect is detected.	PORTSC Connect Status and Connect Status Change bits are set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is a zero. A connect is detected.	PORTSC Connect Status and Connect Status Change bits are set to a one. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is a one. An over-current condition occurs.	PORTSC Over-current Active, Over-current Change bits are set to a one. If Port Enable/Disable bit is a one, it is set to a zero. Port Change Detect bit in the USBSTS register is set to a one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is a zero. An over-current condition occurs.	PORTSC Over-current Active, Over-current Change bits are set to a one. If Port Enable/Disable bit is a one, it is set to a zero. Port Change Detect bit in the USBSTS register is set to a one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USBINTR register is a one.
[2] PME# asserted if enabled (Note: PME Status must always be set to a one).
[3] PME# not asserted.

48.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule. The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the PERIODICLISTBASE register (see Section 48.4.1.6.6, “Host Controller Frame List Base Address Register (PERIODICLISTBASE) and USB Device Address Register (DEVICEADDR)). The PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structure. In each microframe, if the periodic schedule is enabled (see Section , “Periodic Scheduling Threshold”) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It will only execute from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the PERIODICLISTBASE and the FRINDEX registers (see Figure 48-58). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a *next* link pointer of a schedule data structure having its *T-bit* set to a one. When the host controller encounters a *T-Bit* set to a one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. Once this transition is made, the host controller executes from the asynchronous schedule until the end of the microframe.

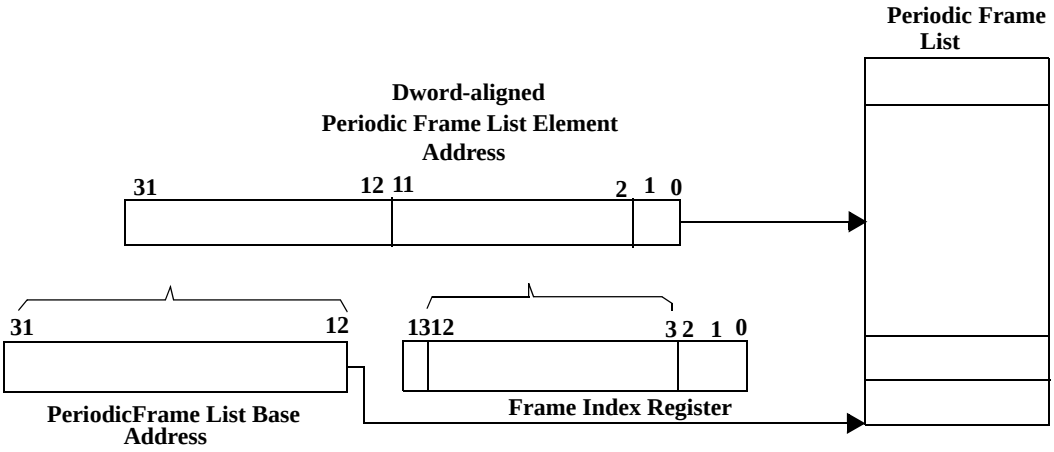

Figure 48-58. Derivation of Pointer into Frame List Array

When the host controller determines that it is time to execute from the asynchronous list, it uses the operational register *ASYNCLISTADDR* to access the asynchronous schedule, see Figure 48-59.

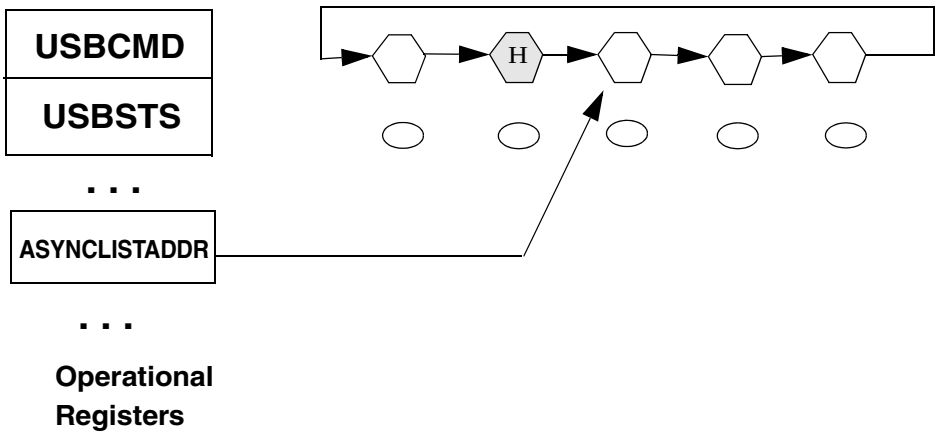

Figure 48-59. General Format of Asynchronous Schedule List

The *ASYNCLISTADDR* register contains a physical memory pointer to the *next* queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the *ASYNCLISTADDR* register. Software must set queue head *horizontal* pointer *T-bits* to a zero for queue heads in the asynchronous schedule. See Section 48.4.3.8, “Asynchronous Schedule” for complete operational details.

48.4.3.4.1 Example—Preserving Microframe Integrity

One of the requirements of a USB host controller is to maintain *Frame Integrity*. This means that the HC must preserve the microframe boundaries. For example: SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of microframe timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One

implication of this responsibility is that the HC must ensure that it does not start transactions that will not be completed before the end of the microframe. More precisely, no transactions should be started by the host controller, which cannot be completed in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it will complete before the end of the microframe.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction will take. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch *all* of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers could allow the host controller to know exactly whether there was enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the microframe. It is a reasonable assumption that software will never over-commit the microframe to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction will not be executed that *could* have been executed. However, under all circumstances, a transaction will never be started unless there is enough time in the frame to complete the transaction.

Transaction Fit—A Best-Fit Approximation Algorithm

A curve is calculated which represents the *latest* start time for every packet size, at which software will schedule the start of a periodic transaction. This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the microframe. A plot of these two curves is illustrated in Figure 48-60. The plot Y-axis represents the number of byte-times left in a frame.

The space between the *80%* and the *Last Start* plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and *Last Start* curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land *above* the function curve. The host controller will not start transactions whose results land below the function curve.

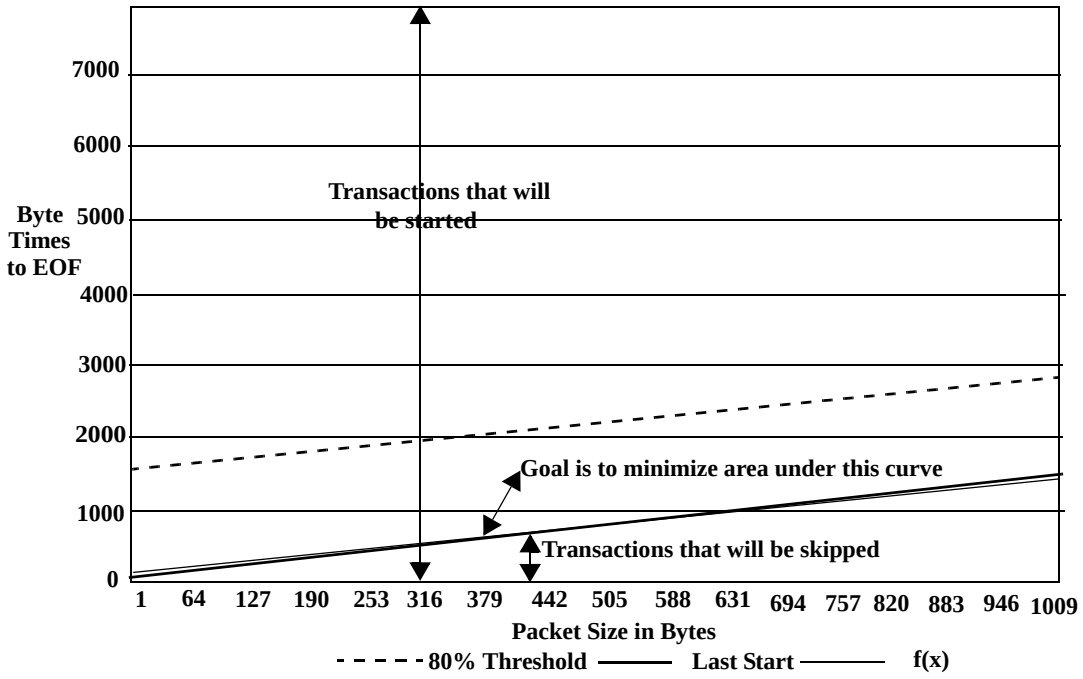

Figure 48-60. Best Fit Approximation

The *LastStart* line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used was a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in Table 48-71. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 48-71. Example Worse-Case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop….
Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop…
Host IPG	88	11	Same as above
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop…
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop…
		144	**Total**

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the

Last Start curve, without dipping below the *LastStart* line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 48-60 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
        Local Temp = MaximumPacketSize + 192
        Local rvalue = TRUE

        If MaximumPacketSize >= 128 then
                Temp += 128
        End If

        If Temp > HC_BytesLeftInFrame then
                Rvalue = FALSE
        End If
        Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and a hardware counter of the number of bytes left in the current microframe. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the *f*(*x*) plot was getting *close* to the *LastStart* line.

48.4.3.5 Periodic Schedule Frame Boundaries versus Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned. Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions via a microframe pipeline (see start- (SS) and complete- (CS) splits illustrated in Figure 48-61). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

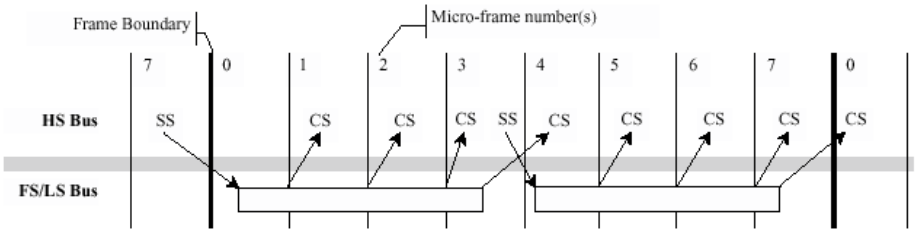

Figure 48-61. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as Figure 48-62 illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement a one microframe phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed via the Frame List Index Register (FRINDEX) documented in Section 48.4.1.6.4, “USB Frame Index Register (FRINDEX),” and initially illustrated in Section 48.4.3.4, “Schedule Traversal Rules”. Bits FRINDEX[2:0], represent the microframe number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one microframe. The one microframe delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in Figure 48-62. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

Figure 48-62 illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined. The host controller's view of the 1-millisecond boundaries is called *H-Frames*. The high-speed bus's view of the 1-millisecond boundaries is called *B-Frames*.

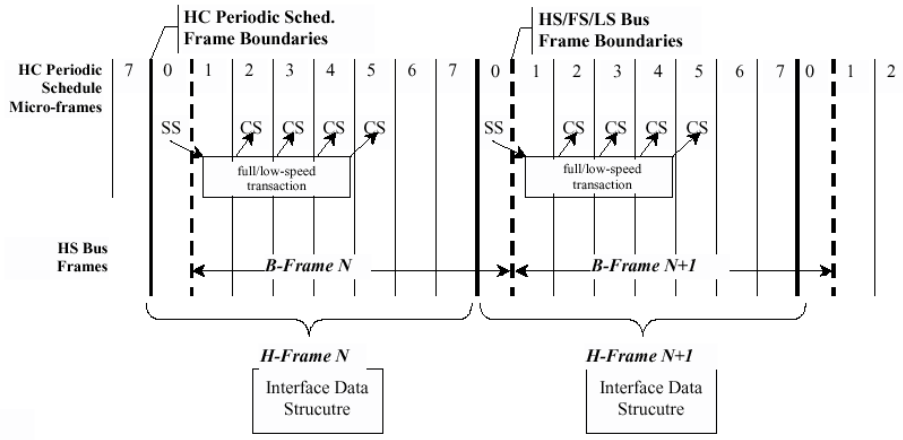

Figure 48-62. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Microframe numbers for the *H-Frame* are tracked by FRINDEX[2:0]. *B-Frame* boundaries are visible on the high-speed bus via changes in the SOF token's frame number. Microframe numbers on the high-speed bus are only derived from the SOF token's frame number (i.e. the high-speed bus will see eight SOFs with the same frame number value). *H-Frames* and *B-Frames* have the fixed relationship (i.e. *B-Frames* lag *H-Frames* by one microframe time) illustrated in Figure 48-62 . The host controller's periodic schedule is naturally aligned to *H-Frames*. Software schedules transactions for full- and low-speed periodic endpoints relative the *H-Frames*. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in Section 48.4.1.6.4, "USB Frame Index Register (FRINDEX)," the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one microframe count. Table 48-72 illustrates the required relationship between the value of FRINDEX and the value of SOFV. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. Section 48.4.1.6.4, "USB Frame Index Register (FRINDEX)" provides the requirements that software should adhere when writing a new value in FRINDEX.

Table 48-72. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b

N+1	N+1	001b	N+1	N+1	010b
N+1	N+1	010b	N+1	N+1	011b
N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

Where [F] = [13:3]; [μF] = [2:0]

48.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled via the *Periodic Schedule Enable* bit in the USBCMD register. If the *Periodic Schedule Enable* bit is set to a zero, then the host controller simply does not try to access the periodic frame list via the *PERIODICLISTBASE* register. Likewise, when the *Periodic Schedule Enable* bit is a one, then the host controller does use the *PERIODICLISTBASE* register to traverse the periodic schedule. The host controller will not react to modifications to the *Periodic Schedule Enable* immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the *Periodic Schedule Enable* bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b microframe. These work items must be removed from the schedule before the *Periodic Schedule Enable*

bit is written to a zero. The *Periodic Schedule Status* bit in the USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing a one (or zero) to the *Periodic Schedule Enable* bit in the USBCMD register. Software then can poll the *Periodic Schedule Status* bit to determine when the periodic schedule has made the desired transition. Software must not modify the *Periodic Schedule Enable* bit unless the value of the *Periodic Schedule Enable* bit equals that of the *Periodic Schedule Status* bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the USB. Figure 48-63 illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (e.g. closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

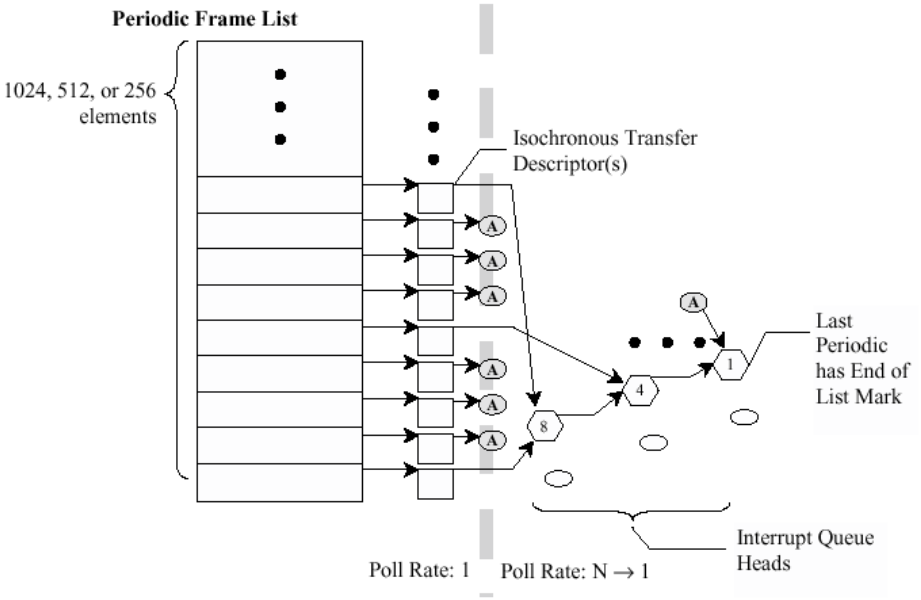

Figure 48-63. Example Periodic Schedule

48.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). There are four distinct sections to an iTD:

- The first field is the *Next Link Pointer.* This field is for schedule linkage purposes only;
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one microframe's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4K aligned pointers to physical memory.

- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

48.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Each iTD can span 8 microframes worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array. If the *active* bit in the *Status* field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the *Next* pointer to the next schedule data structure.

When the indexed *active* bit is a one the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, etc.). It also uses the *Page Select (PG)* field to index the *buffer pointer* array, storing the selected *buffer pointer* and the next sequential *buffer pointer*. For example, if *PG* field is a 0, then the host controller will store Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's *PG* field) and the transaction description's *Transaction Offset* field. The host controller uses the endpoint addressing information and *I/O-bit* to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the *Status* field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (example: page 0 pointer) selected by the active transaction descriptions' *PG* (example value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer will cross a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (example: page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the *Maximum Packet Size* field. An iTD supports high-bandwidth pipes via the *Mult* (multiplier) field. When the *Mult* field is 1, 2, or 3, the host controller executes the specified number of *Maximum Packet* sized bus transactions for the endpoint in the current microframe. In other words, the *Mult* field represents a transaction count for the endpoint in the current microframe. If the *Mult* field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the *Mult* field.

For OUT transfers, the value of the *Transaction X Length* field represents the total bytes to be sent during the microframe. The *Mult* field must be set by software to be consistent with *Transaction X Length* and *Maximum Packet Size*. The host controller will send the bytes in *Maximum Packet Size'*ed portions. After each transaction, the host controller decrements it's local copy of *Transaction X Length* by *Maximum Packet Size*. The number of bytes the host controller sends is always *Maximum Packet Size* or *Transaction X Length*, whichever is less. The host controller advances the transfer state in the transfer description,

updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues *Mult* transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use *Maximum Packet Size* to detect packet babble errors. The host controller keeps the sum of bytes received in the *Transaction X Length* field. After all transactions for the endpoint have completed for the microframe, *Transaction X Length* contains the total bytes received. If the final value of *Transaction X Length* is less than the value of *Maximum Packet Size*, then less data than was allowed for was received from the associated endpoint. This *short packet* condition does not set the *USBINT* bit in the USBSTS register to a one. The host controller will not detect this condition. If the device sends more than *Transaction X Length* or *Maximum Packet Size* bytes (whichever is less), then the host controller will set the *Babble Detected* bit to a one and set the *Active* bit to a zero. Note, that the host controller is not required to update the iTD field *Transaction X Length* in this error scenario. If the *Mult* field is greater than one, then the host controller will automatically execute the value of *Mult* transactions. The host controller will not execute all *Mult* transactions if:

- The endpoint is an OUT and *Transaction X Length* goes to zero before all the *Mult* transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before *Mult* transactions have been executed. The end of microframe may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next microframe. See Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

48.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N microframes. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

Figure 48-64 illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (i.e. the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one microframe's worth of transactions. The EHCI controller does not provide per-transaction results within a microframe. It treats the per-microframe transactions as a single logical transfer. On the left is the host controller’s frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

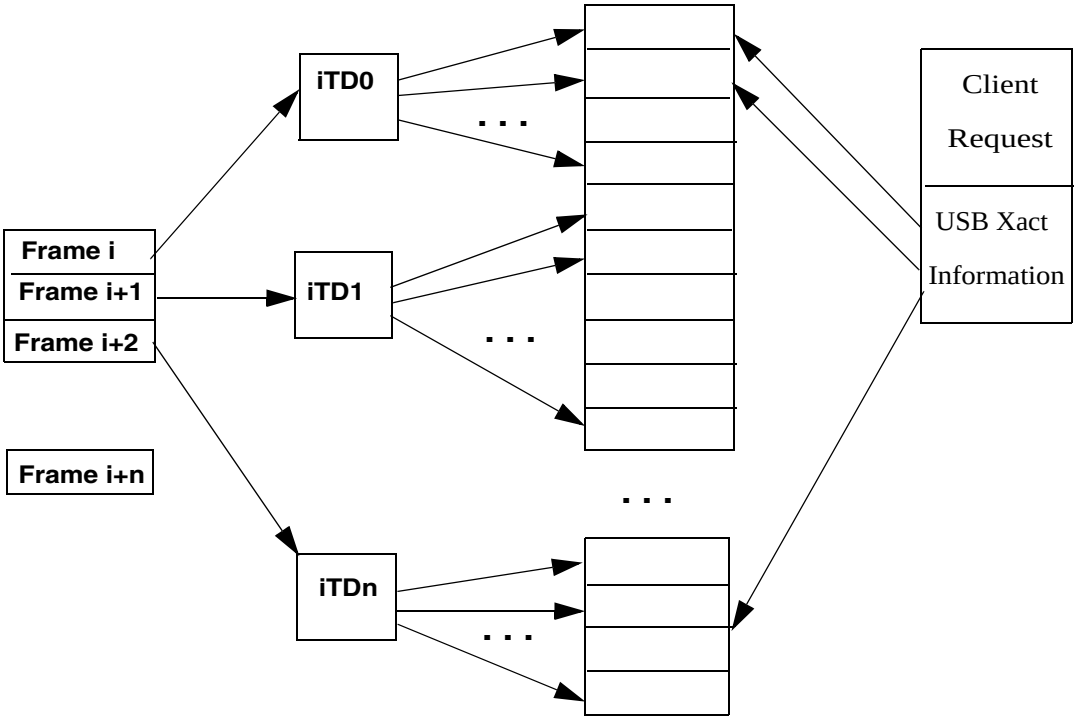

Figure 48-64. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the *PG* field is set to index the correct physical buffer page pointer and the *Transaction Offset* field is set relative to the correct buffer pointer page (e.g. the same one referenced by the *PG* field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current *Page Buffer Pointer* (as selected by the *PG* field) and concatenates to the *transaction offset* field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available *Page Buffer Pointer*. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer will wrap a page boundary. Doing so will yield undefined behavior. The host controller hardware is not required to 'alias' the page selector to page zero. USB 2.0 isochronous endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to a one.

Periodic Scheduling Threshold

The *Isochronous Scheduling Threshold* field in the HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures. It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the

current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 microframes worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. There are three basic caching models that account for the fact the isochronous data structures span 8 microframes. The three caching models are: no caching, microframe caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the FRINDEX register to determine the current frame and microframe the host controller is currently executing. Of course, there is no information about where in the microframe the host controller is, so a constant uncertainty-factor of one microframe has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the *Isochronous Scheduling Threshold* field. The host controller may pre-fetch data structures during a periodic schedule traversal (per microframe) but will always dump any accumulated schedule state at the end of the microframe. At the appropriate time relative to the beginning of every microframe, the host controller always begins schedule traversal from the frame list. Software can use the value of the FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 microframes in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the *Isochronous Scheduling Threshold* field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 microframes). Software uses the value of the FRINDEX register (plus the constant 1 uncertainty) to determine the *current* microframe/frame (assume modulo 8 arithmetic in adding the constant 1 to the microframe number). For any current frame N, if the current microframe is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current microframe is 7, then software can add isochronous transactions to Frame N + 2.

Microframe caching is indicated with a non-zero value in the least-significant 3 bits of the *Isochronous Scheduling Threshold* field. System software assumes the host controller caches one or more periodic data structures for the number of microframes indicated in the *Isochronous Scheduling Threshold* field. For example, if the count value were 2, then the host controller keeps a *window* of 2 microframes worth of state (current microframe, plus the next) on-chip. On each microframe boundary, the host controller releases the current microframe state and begins accumulating the next microframe state.

48.4.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled via the *Asynchronous Schedule Enable* bit in the USBCMD register. If the *Asynchronous Schedule Enable* bit is set to a zero, then the host controller simply does not try to access the asynchronous schedule via the *ASYNCLISTADDR* register. Likewise, when the *Asynchronous Schedule Enable* bit is a one, then the host controller does use the *ASYNCLISTADDR* register to traverse the asynchronous schedule. Modifications to the *Asynchronous Schedule Enable* bit are not necessarily immediate. Rather the new value of the bit will only be taken into

consideration the next time the host controller needs to use the value of the *ASYNCLISTADDR* register to get the next queue head.

The *Asynchronous Schedule Status* bit in the USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing a one (or zero) to the *Asynchronous Schedule Enable* bit in the USBCMD register. Software then can poll the *Asynchronous Schedule Status* bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the *Asynchronous Schedule Enable* bit unless the value of the *Asynchronous Schedule Enable* bit equals that of the *Asynchronous Schedule Status* bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the *ASYNCLISTADDR* register. The default value of the *ASYNCLISTADDR* register after reset is undefined and the schedule is disabled when the *Asynchronous Schedule Enable* bit is a zero.

Software may only write this register with defined results when the schedule is disabled. e.g. *Asynchronous Schedule Enable* bit in the USBCMD and the *Asynchronous Schedule Status* bit in the USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the *Asynchronous Schedule Enable* bit is set to one. The asynchronous schedule is actually enabled when the *Asynchronous Schedule Status* bit is a one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the *ASYNCLISTADDR* register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller “completes” processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the *ASYNCLISTADDR* register. Next time the asynchronous schedule is accessed, this is the first data structure that will be serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller “completes” processing the asynchronous schedule when one of the following events occur:

- The end of a microframe occurs.
- The host controller detects an empty list condition (see Section 48.4.3.8.3, “Empty Asynchronous Schedule Detection”)
- The schedule has been disabled via the *Asynchronous Schedule Enable* bit in the USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 48-59. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

48.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the *ASYNCLISTADDR* register, then enables the list by setting the *Asynchronous Schedule Enable* bit in the USBCMD register to a one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example qTD pointers have *T-Bit*s set to a one or reference valid qTDs and the *Horizontal Pointer* references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)

        --
        -- Requirement: all inputs must be properly initialized.
        --
        -- pQHeadCurrent is a pointer to a queue head that is
        -- already in the active list
        -- pQHeadNew is a pointer to the queue head to be added
        --
        -- This algorithm links a new queue head into a existing
        -- list
        --
        pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer

        pQueueHeadCurrent.HorizontalPointer = physicalAddressOf(pQueueHeadNew)

End InsertQueueHead
```

48.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section. There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting the *Asynchronous Schedule Enable* bit in the USBCMD register to a zero. Software can determine when the list is idle when the *Asynchronous Schedule Status* bit in the USBSTS register is a zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first

deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list via the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)

        --

        -- Requirement: all inputs must be properly initialized.

        --

        -- pQHeadPrevious is a pointer to a queue head that

        -- references the queue head to remove

        -- pQHeadToUnlink is a pointer to the queue head to be

        -- removed

        -- pQheadNext is a pointer to a queue head still in the

        -- schedule. Software provides this pointer with the

        -- following strict rules:

        --      if the host software is one queue head, then

        --      pQHeadNext must be the same as

        --      QueueheadToUnlink.HorizontalPointer. If the host

        --      software is unlinking a consecutive series of

        --      queue heads, QHeadNext must be set by software to

        --      the  queue head remaining in the schedule.

        --

        -- This algorithm unlinks a queue head from a circular list

        --

        pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQHeadNext

End UnlinkQueueHead
```

If software removes the queue head with the *H-bit* set to a one, it must select another queue head still linked into the schedule and set its *H-bit* to a one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its *H-bit* set to a one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, etc.). It cannot disturb the

removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (*Interrupt on Async Advance Doorbell* bit in the USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (*Interrupt on Async Advance* bit in the USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to a one, it also sets the command bit to a zero. The third bit is an interrupt enable (*Interrupt on Async Advance* bit in the USBINTR register) that is matched with the status bit. If the status bit is a one and the interrupt enable bit is a one, then the host controller will assert a hardware interrupt.

Figure 48-65 illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that will remain in the asynchronous schedule.

When the host controller observes that doorbell bit being set to a one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A & B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (i.e. traversed beyond queue head (B) in this example).

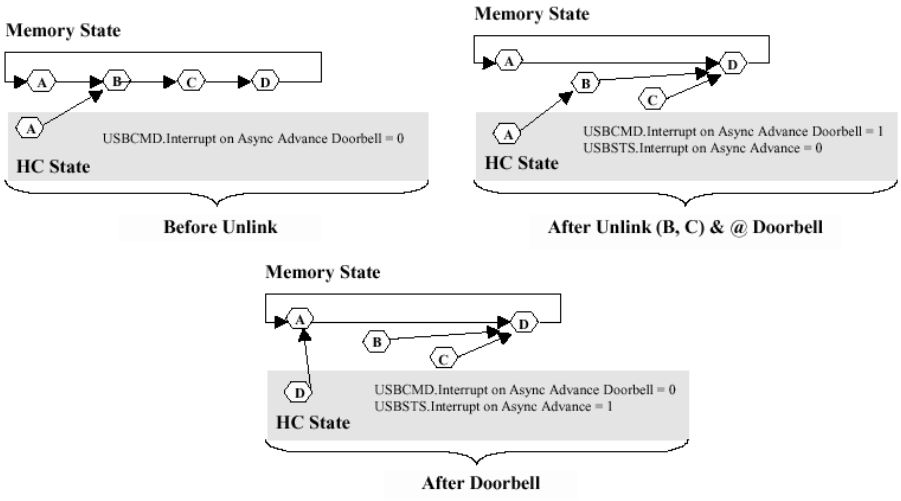

Figure 48-65. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (e.g. observed the head of the queue (twice)) before setting the *Advance on Async* status bit to a one.

Software may re-use the memory associated with the removed queue heads after it observes the *Interrupt on Async Advance* status bit is set to a one, following assertion of the doorbell. Software should acknowledge the *Interrupt on Async Advance* status as indicated in the USBSTS register, before using the doorbell handshake again.

48.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty. The queue head data structure (see Figure 48-53) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USBSTS register (*Reclamation*) that is set to a zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to a one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts: see Section 48.4.3.8.5, “Asynchronous Schedule Traversal—Start Event”).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is illustrated in Figure 48-66.

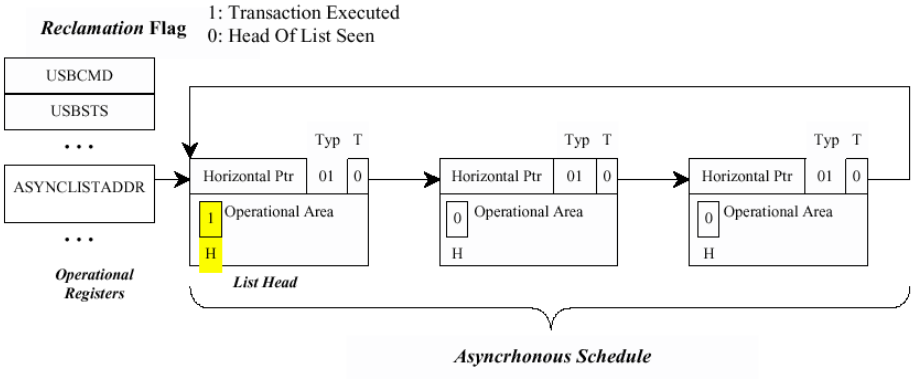

Figure 48-66. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to a one, and that it is always coherent with respect to the schedule.

48.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the microframe. It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the microframe. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller will cease traversal of the

Asynchronous schedule very early in the microframe. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current microframe, instead of waiting until the next microframe. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10µsec. The value is derived based on the analysis in Section , "Example Derivation for AsyncSchedSleepTime". The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-Microframe event occurs, or an empty list is detected. If the event is an End-of-Microframe, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, etc. so the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each microframe. Figure 48-67 illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

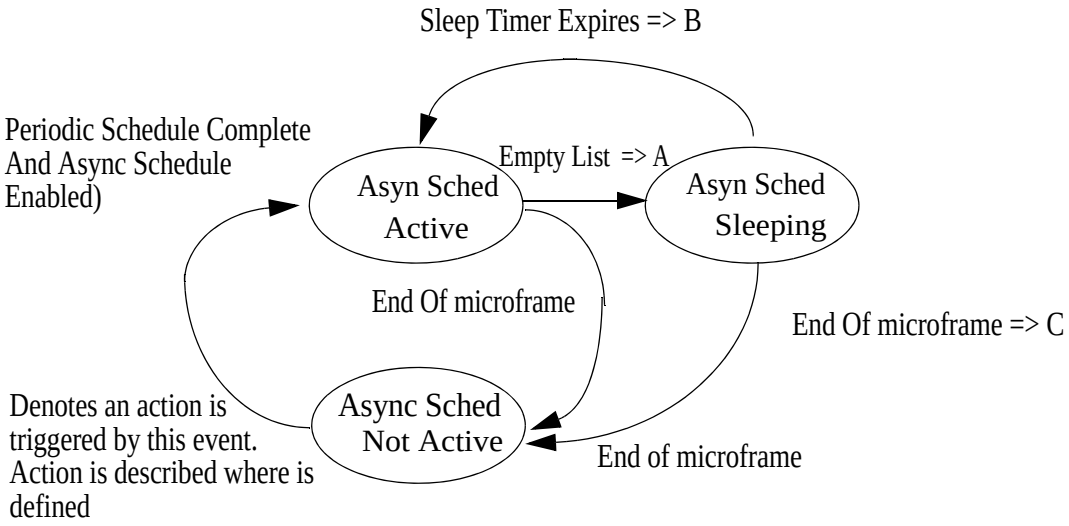

Figure 48-67. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in Figure 48-67 are defined in Table 48-73.

Table 48-73. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to a one and moves the Nak Counter reload state machine to WaitForListHead (see Section 48.4.3.9.1, “Nak Count Reload Control”).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine will not leave this state when the *Asynchronous Schedule Enable* bit in the USBCMD register is a zero.

This state is entered from **Async Sched Active** or **Async Sched Sleeping** states when the end-of-microframe event is detected.

Async Sched Active

This state is entered from the **Async Sched Not Active** state when the periodic schedule is not active. It is also entered from the **Async Sched Sleeping** states when the *AsynchronousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USBSTS register to a one.

While in this state, the host controller will continually traverse the asynchronous schedule until either the end of microframe or an empty list condition is detected.

Async Sched Sleeping

The state is entered from the **Async Sched Active** state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

Example Derivation for *AsyncSchedSleepTime*

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests. Table 48-74 summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (e.g. *footprint*, or *wall clock*) the transaction will take to complete.

Table 48-74. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk	—	—
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64	—	—
Type	Bulk	—	—
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (i.e. setup)
Size	8	—	—
Type	Cntrl	—	—

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller will get the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10µs sleep period would allow the host controller to get the NAK results on the first complete-split.

48.4.3.8.5 Asynchronous Schedule Traversal—*Start Event*

Once the HC has *idled* itself via the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each microframe. In addition, it may have idled itself early in a microframe. When this occurs (idles early in the microframe) the HC must occasionally *re-activate* during the microframe and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Section 48.4.3.8.4, “Restarting Asynchronous Schedule Before EOF”. Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the microframe is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Section 48.4.3.8.4, “Restarting Asynchronous Schedule Before EOF”).

48.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (Section 48.4.3.8.3, “Empty Asynchronous Schedule Detection”) depends on the proper management of the *Reclamation* bit in the USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (See Section 48.4.3.10.1, “Fetch Queue Head”).

It is required that the host controller sets the *Reclamation* bit to a one whenever an asynchronous schedule traversal *Start Event* occurs (as documented in Section 48.4.3.8.5, “Asynchronous Schedule Traversal—Start Event). The *Reclamation* bit is also set to a one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Section 48.4.3.10.3, “Execute Transaction”). The host controller sets the *Reclamation* bit to a zero whenever it finds a queue head with its *H-bit* set to a one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to a one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to a zero when executing from the periodic schedule.

48.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head (see Section 48.4.6.4.1, “Queue Head Initialization”). Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control via the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced via the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (i.e. like when the endpoint is the only one in the asynchronous schedule). The hub Nyets (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which will not complete until after the transaction on the classic bus completes.

There are two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. There are two operational modes associated with this counter:

- **Not Used.** This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- **Nak Throttle Mode.** This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller

will tolerate on each endpoint. In this mode, the HC will decrement the *NakCnt* field based on the token/handshake criteria listed in Table 48-75 The host controller must reload *NakCnt* when the endpoint successfully moves data (e.g. policy to reward device for moving data).

Table 48-75. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1]Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1 Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller will not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Section 48.4.3.9.1, “Nak Count Reload Control”.

Note that when all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller will detect an empty Asynchronous Schedule and idle schedule traversal (see Section 48.4.3.8.5, “Asynchronous Schedule Traversal—Start Event”).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Section 48.4.3.8.5, “Asynchronous Schedule Traversal—Start Event”. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

48.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Section 48.4.3.10.3, “Execute Transaction”). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Figure 48-53) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Section 48.4.3.8.5, “Asynchronous Schedule Traversal—Start Event” for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 48-66). Figure 48-68 illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: **Execute Transaction** (Figure 48-68). The host controller does not perform the nak counter reload operation if the RL field (see Figure 48-53) is set to zero.

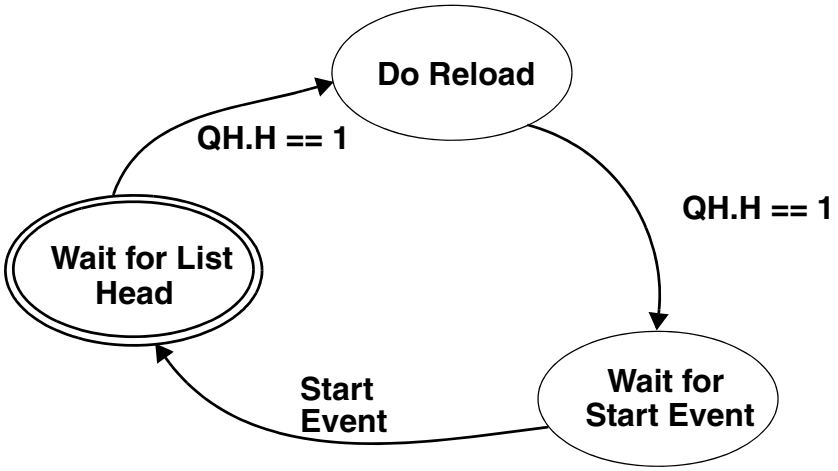

Figure 48-68. Example HC State Machine for Controlling Nak Counter Reloads

Wait for List Head

This is the initial state. The state machine enters this state from **Wait for Start Event** when a start event (as defined in Section 48.4.3.8.5, "Asynchronous Schedule Traversal—Start Event") occurs. The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule. This occurs when the host controller fetches a queue head whose *H-bit* is set to a one.

Do Reload

This state is entered from the **Wait for List Head** state when the host controller fetches a queue head with the *H-bit* set to a one. While in this state, the host controller will perform nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to a one is fetched. While in this state, the host controller will not perform nak counter reloads.

48.4.3.10 Managing Control/Bulk/Interrupt Transfers via Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Figure 48-53). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer.*

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,

- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller will set one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (e.g. the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (e.g. buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions will occur for the endpoint and the host controller will not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in Figure 48-69. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller will always *find* them if/when they are reachable.

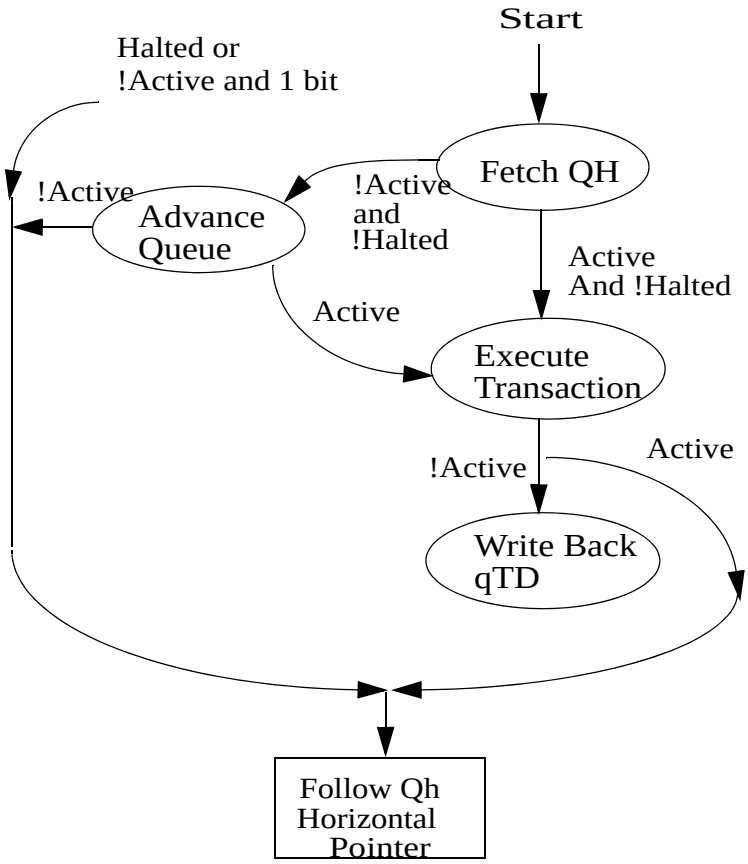

Figure 48-69. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The **Execute Transaction** state (Section 48.4.3.10.3, “Execute Transaction”) describes the basic requirements for all endpoints. Section 48.4.3.12.1, “Split Transactions for Asynchronous Transfers” and Section 48.4.3.12.2, “Split Transaction Interrupt” describe details of the required extensions to the **Execute Transaction** state for endpoints requiring split transactions.

Note: Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section 48.4.2.6, “Queue Head” for layout of a queue head):

- Valid static endpoint state
- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

48.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (Section 48.4.1.6.7, “Host Controller Next Asynchronous Address Register (ASYNCLISTADDR) and Device Controller Endpoint List Address Register (ENDPOINTLISTADDR)”. Additionally, it may be referenced from the *Next Link Pointer* field of an iTD, siTD, FSTN or another queue head. If the referencing link pointer has the TYP field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Figure 48-53.

While in this state, the host controller performs operations to implement empty schedule detection (Section 48.4.3.8.3, “Empty Asynchronous Schedule Detection”) and Nak Counter reloads (Section 48.4.3.9, “Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (i.e. *S-mask* is a zero), and
- The *H-bit* is a one, and
- The *Reclamation* bit in the USBSTS register is a zero.

When these criteria are met, the host controller will stop traversing the asynchronous list (as described in Section 48.4.3.8.3, “Empty Asynchronous Schedule Detection”). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is a one and the *Reclamation* bit is a one, then the host controller sets the *Reclamation* bit in the USBSTS register to a zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Section 48.4.3.9, “Operational Model for Nak Counter”.

This state is complete when the queue head has been read on-chip.

48.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the **FetchQHD** state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and

determines whether or not to perform an overlay. Note that if the *I-bit* is a one and the *Active* bit is a zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer.* Otherwise, the host controller uses the *Next qTD Pointer.* If *Next qTD Pointer*'s *T-bit* is set to a one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has it's *Active* bit set to a one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to a zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure. The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 48-62).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

48.4.3.10.3 Execute Transaction

The host controller enters this state from the **Fetch Queue Head** state only if the *Active* bit in *Status* field of the queue head is set to a one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Section 48.4.3.12.1, "Split Transactions for Asynchronous Transfers" and Section 48.4.3.12.2, "Split Transaction Interrupt".

Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (e.g. non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has a one in it. For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction**.**

Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (e.g. a zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria: The pre-operation is:

Checks the Nak counter reload state (Section 48.4.3.9, “Operational Model for Nak Counter”). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head’s *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the microframe to complete this transaction (see Section , “Transaction Fit—A Best-Fit Approximation Algorithm” for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to a one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller will exit this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to a zero, or
- There is not enough time in the microframe left to execute the next transaction (see Section , “Transaction Fit—A Best-Fit Approximation Algorithm” for an example method for implementing the frame boundary test).

[4] Note that for a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (e.g. advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Section 48.4.3.10.6, "Buffer Pointer List Use for Data Streaming with qTDs".

Note that the *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller will execute a zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller will detect a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to a zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (e.g. not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (e.g. decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory.

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *Maximum Packet Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Section , "Transaction Error".

The following events will cause the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from a one to a zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to a one and *Active* is set to a zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to a one and the *Active* bit is set to a zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.

- The *Total Bytes to Transfer* field is zero after the transaction completes. Note that for a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the **Advance Queue** state. See Section 48.4.3.12, “Split Transactions” for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (e.g. *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (e.g. a packet babble). This results in the host controller setting the *Halted* bit to a one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed via queue heads (control, bulk and interrupt). The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USBSTS register to a one. To halt the queue head, the *Active* bit is set to a zero and the *Halted* bit is set to a one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller will not advance the transfer state on a transaction that results in a *Halt* condition (e.g. no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USBSTS register is set to a one. If the *USB Error Interrupt Enable* bit in the USBINTR register is set to a one, a hardware interrupt is generated at the next interrupt threshold.

Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue

head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule. This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Section 48.4.3.10.3, "Execute Transaction" apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the HCCPARAMs register to a one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (e.g. *Asynchronous Schedule Park Mode Enable* bit in the USBCMD register is a zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (i.e. only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to a one and also set *Asynchronous Schedule Park Mode Count* field to a zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Section 48.4.3.10.3, "Execute Transaction". It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is a one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake. Table 48-76 summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 48-76. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum	Not zero	Not Zero	Allowed to perform another bus transaction.[1,2]
	Packet sized data	Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. [2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1 Note, the host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (e.g. expected DATA1 and received DATA0, or visa-versa).,

2 Note, this specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

48.4.3.10.4 Write Back qTD

This state is entered from the **Execute Transaction** state when the *Active* bit is set to a zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 48-76). The host controller uses the *Current qTD Pointer* field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back has been committed.

48.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is a one on exit from the **Execute Transaction** state, or
- When the host controller exits the **Write Back qTD** state, or
- If the **Advance Queue** state fails to advance the queue because the target qTD is not active, or

- If the *Halted* bit is a one on exit from the **Fetch QH** state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

48.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*. This means: if the buffer spans more than one physical page, it must obey the following rules (Figure 48-70 illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4K chunk beyond the first page, each buffer portion matches to a full 4K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction will span a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

Figure 48-70 illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page e.g. 2049 (e.g. 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4K page.

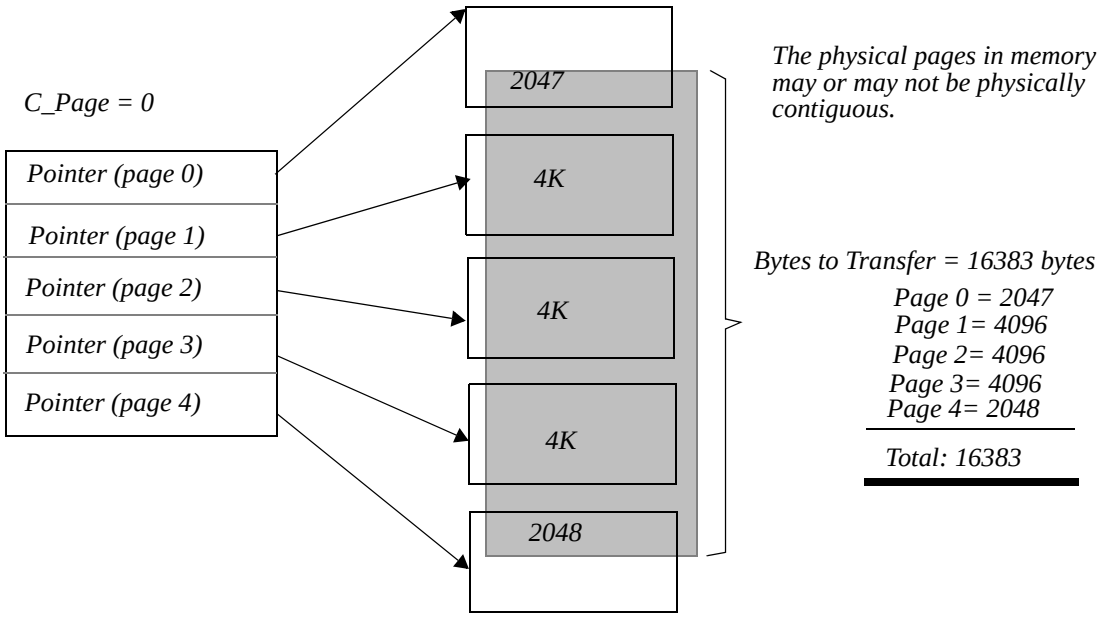

Figure 48-70. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller will increment *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (i.e. *C_Page*) when necessary. There are three conditions for how the host controller handles *C_Page*.

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (i.e. the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

Note that the only valid adjustment the host controller may make to *C_Page* is to increment by one.

48.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's *S-Mask* to indicate which microframe with-in

a 1 millisecond period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with a zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in Table 48-77.

Table 48-77. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, etc. *S-Mask* = 0x01	A queue head for the *bInterval* of 2 milliseconds (16 microframes) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during microframe 0 of the frame.
0, 2, 4, 6, 8, etc. *S-Mask* = 0x02	Another example of a queue head with a *bInterval* of 2 milliseconds is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during microframe 1 of the frame.

48.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller will set an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to a one, or whenever a transfer (qTD) completes with a short packet. If system software needs multiple qTDs to complete a client request (i.e. like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

48.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it will use in the next transaction to the endpoint (see Table 48-78, “Ping Control State Transition Table”). The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

Table 48-78 illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. See Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 48-78. Ping Control State Transition Table

Current	Event		Next
	Host	Device	
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr[1]	Do Ping
Do Ping	PING	Stall	N/C[2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C[2]

1 Transaction Error (XactErr) is any time the host misses the handshake.

2 No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (e.g. Active set to zero and Halt set to a one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to **Do Ping**. The Ping State bit has the following encoding:

Value	Meaning
0B	Do OUT The host controller will use an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller will use a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (i.e. start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

48.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol. See USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Section 48.4.2.4, “Split Transaction Isochronous Transfer Descriptor (siTD)”. Control, Bulk and Interrupt are managed using the queuing data structures (see Section 48.4.2.6, “Queue Head”). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

48.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an EPS field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head. All full-speed bulk and full-, low-speed control are managed via queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to **Do-Start-Split**. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to a one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be a zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is a zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is a one, the split transaction token's ET field is set to indicate a control endpoint. See Chapter 8 of USB Specification Revision 2.0 for details.

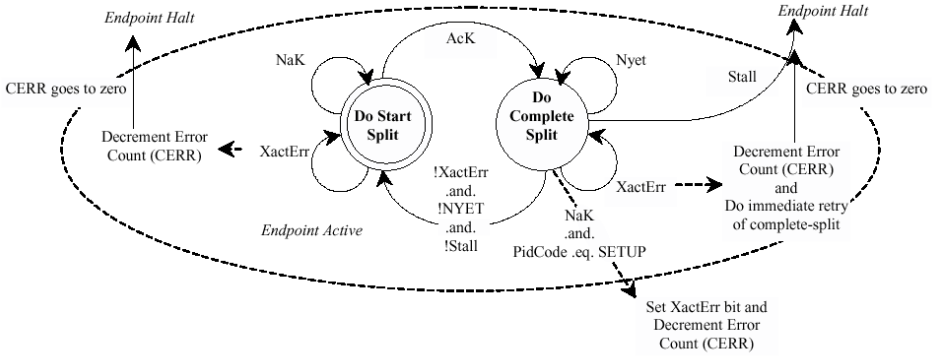

Figure 48-71. Host Controller Asynchronous Schedule Split-Transaction State Machine

Asynchronous—Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the **Do Complete Split** state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller will execute a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller will reload the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller will not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

Asynchronous—Do Complete Split

This state is entered from the **Do Start Split** state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller will execute a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller will reload the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr.*

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, etc. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the microframe to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next microframe, the first transaction from the schedule will be the retry for this endpoint. If *Cerr* went to zero, the host controller must halt the queue.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to a one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.
- If the *PidCode* indicates an IN, then any of following responses are expected:
- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller will advance the state of the transfer, e.g. move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller will then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.
- If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:
- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*,

whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller will then exit this state.

- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section 48.4.3.10, “Managing Control/Bulk/Interrupt Transfers via Queue Heads”).

48.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed via the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller will visit a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (i.e. takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, etc. occurs as defined in Section 48.4.3.10, “Managing Control/Bulk/Interrupt Transfers via Queue Heads,” but only occurs on the completion of a split transaction.

Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field. The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each endpoint will occur. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit microframes, or the data or response information in the pipeline is lost. Figure 48-72 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The **S** and ^{C}x labels indicate microframes where software can schedule start-splits and complete splits (respectively).

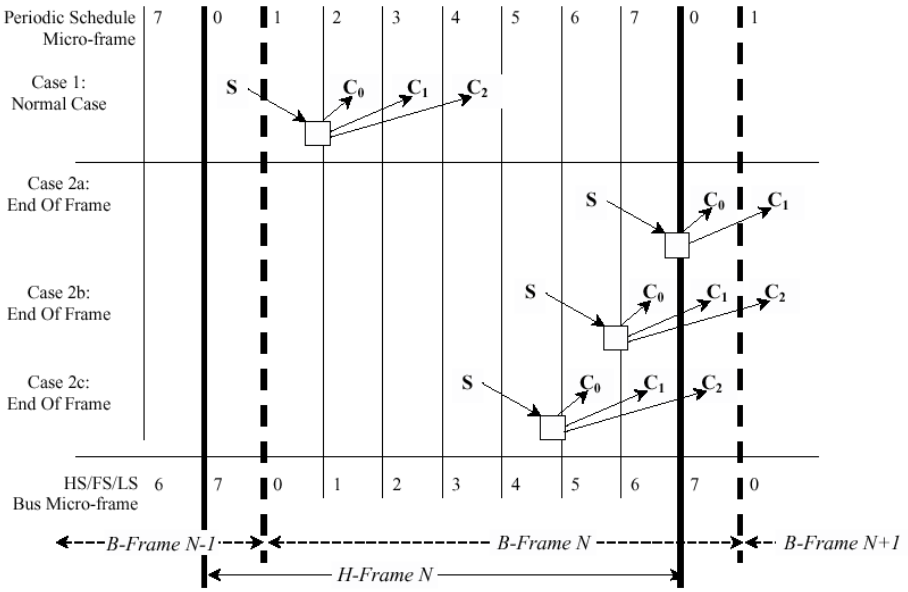

Figure 48-72. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in microframe 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs. Figure 48-73 illustrates the general layout of the periodic schedule.

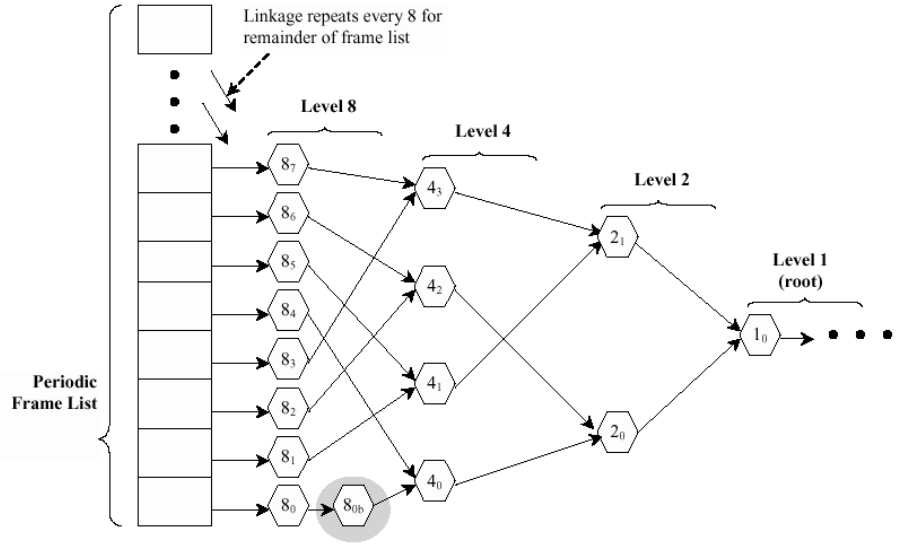

Figure 48-73. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Section , “Host Controller Operational Model for FSTNs” defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of a queue head (see Table 48-78, “Ping Control State Transition Table”). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the microframe (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 48-72, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates **Do_Start**, and the current microframe as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.

- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the microframes (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 48-72, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates **Do_Complete**, and the current microframe as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (i.e. boundary cases 2a through 2c). An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see Section 48.4.2.4.5, “siTD Back Link Pointer”).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

There are four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer. T-bit* set to zero.
- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to a one.
- Host controller FSTN traversal rules.

Host Controller Operational Model for FSTNs

When the host controller encounters an FSTN during microframes 2 through 7 it simply follows the node’s *Normal Path Link Pointer* to access the next schedule data structure. Note that the FSTN’s *Normal Path Link Pointer.T-bit* may set to a one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in microframes 0 or 1, it will save the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller’s rules for how it traverses the schedule and limits which data structures will be considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the microframe (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN’s *Back Path Link Pointer.*
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer.*

- Do not process a queue head (QH) whose EPS field indicates a high-speed device. Simply follow its horizontal link pointer.
- When a QH's EPS field indicates a Full/Low-speed device, the host controller will only consider it for execution if its *SplitXState* is **DoComplete** (note: this applies whether the *PID Code* indicates an IN or an OUT). See Section 48.4.3.10.3, "Execute Transaction" and Section , "Tracking Split Transaction Progress for Interrupt Transfers" for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction. Note that the host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Section , "Periodic Isochronous - Do Complete Split" for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.
- If the host controller determines that there is not enough time left in the microframe to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive microframe, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in Figure 48-74.

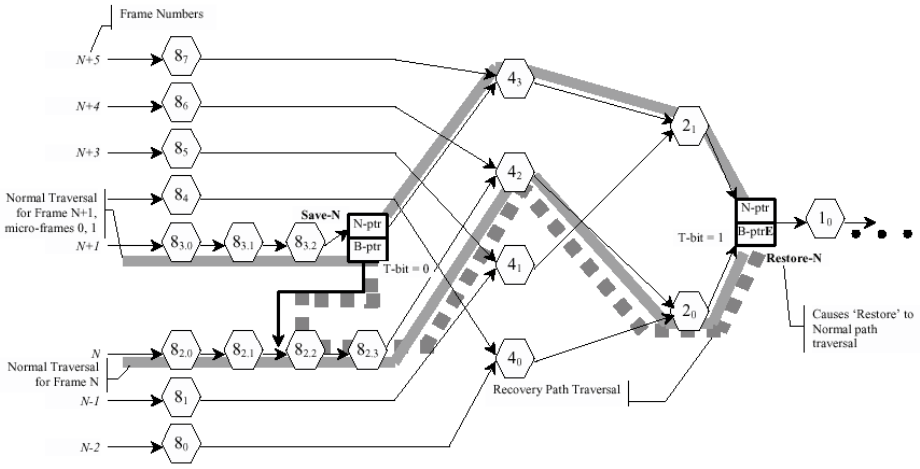

Figure 48-74. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (microframes 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in Figure 48-74 with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to a one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the

saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (e.g. Save-N.Normal Path Link Pointer). The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, **$8_{2.2}$**, **$8_{2.3}$**, **4_2**, **2_0**, **Restore-N**, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are bolded.In frame N (microframes 0-7), for this example, the host controller will traverse all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during microframes 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (i.e. normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (microframes 2-7), when the host controller encounters Save-Path FSTN Save-N, it will unconditionally follow Save-N.Normal Path Link Pointer. The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse. When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero. Note that *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to a one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to a one, as this will be use to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there will be times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth rebalance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost. For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the microframe number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to microframe are in the context of a microframe within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current microframe number. It is an eight-bit value calculated by the host controller at the beginning of every microframe. It is calculated from the three least significant bits of the *FRINDEX* register (i.e. *cMicroFrameBit* = (1

shifted-left(*FRINDEX*[2:0]))). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current microframe number. For example, if the current microframe is 0, then *cMicroFrameBit* will equal 0b00000001. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current microframe.

Figure 48-75 illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at **Do_Start** and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to **Do_Complete**. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the **Do_Complete** state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the **Do_Complete** state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (e.g. after the host tries the same transaction three times, and each encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

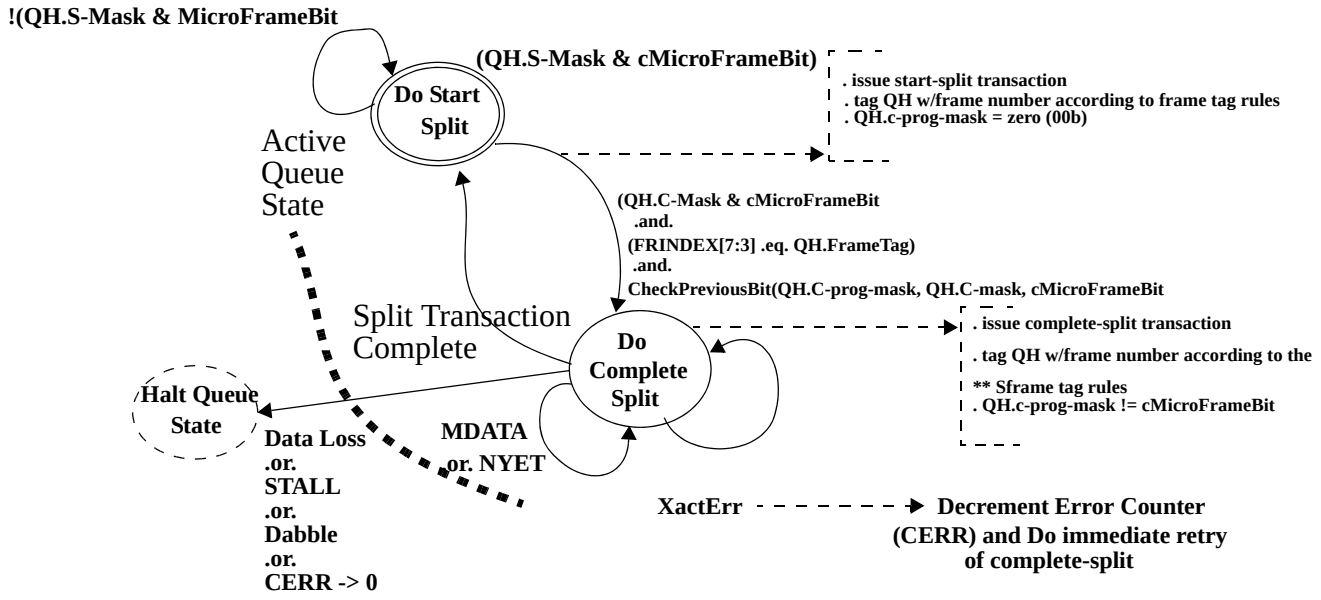

Figure 48-75. Split Transaction State Machine for Interrupt

**See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the **Do_Complete Split** state only after the split transaction is complete. This occurs when

one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (e.g. timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section , “Periodic Isochronous - Do Complete Split” for the definition of ‘Last’.

Each time the host controller visits a queue head in this state (once within the **Execute Transaction** state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section 48.4.6.4, “Managing Queue Heads”), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the **Do Start Split** state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the **Execute Transaction** state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- **Test A**. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this microframe.
- **Test B**. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- **Test C**. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

Algorithm Boolean CheckPreviousBit`(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)`

```
Begin

-- Return values:

-- TRUE - no error
```

```
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous microframe. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask)then
                          If not(previousBit bitAND QH.C-prog-mask) then
                 rvalue = FALSE;
         End if
End If
-- If the C-prog-mask already has a one in this bit position,
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
 rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- **Test D.** Check to see if a start-split should be executed in this microframe. Note this is the same test performed in the **Do Start Split** state (see Section , “Periodic Isochronous - Do Start Split”). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this microframe. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section 48.4.6.4, “Managing Queue Heads”). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the **Last** complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for **Last**. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.
- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the microframe to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the microframe to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (i.e. return to **Do Start Split**). This results in a retry of the entire OUT split transaction, at the next poll period. See Chapter 11 “Hubs” (specifically the section describing full- and low-speed interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section 48.4.3.10, “Managing Control/Bulk/Interrupt Transfers via Queue Heads”).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.

- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section 48.4.3.10, “Managing Control/Bulk/Interrupt Transfers via Queue Heads”).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.
- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the **Execute Transaction** state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. Table 48-79 lists the possible combinations and the appropriate action.

Table 48-79. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current microframe.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If PIDCode is an IN, then the Queue head must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect CERR. In either case, set the Missed Microframe bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	QH.FrameTag test failed. This means that exactly one or more H-Frames have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If PIDCode is an IN, then the Queue head must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect CERR. In either case, set the Missed Microframe bit in the status field to a one.

Table 48-79. Interrupt IN/OUT Do Complete Split State Execution Criteria (continued)

A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If PIDCode is an IN, then the Queue head must be halted. If PIDCode is an OUT, then the transfer state is not advanced and the state exited (e.g. start-split is retried). This is a host-induced error and does not effect CERR. In either case, set the Missed Microframe bit in the status field to a one. Note: When executing in the context of a Recovery Path mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a Recovery Path mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- **Rule 1:** If transitioning from **Do Start Split** to **Do Complete Split** and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 48-72).
- **Rule 2:** If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in **Do Complete Split** for cases 2a, 2b, and 2c (Figure 48-72).
- **Rule 3:** If transitioning from **Do_Start Split** to **Do Complete Split** and the current value of *FRINDEX*[2:0] is not 6, or currently in **Do Complete Split** and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 48-72).

Rebalancing the Periodic Schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation. This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (i.e. new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.

- If the *Active* bit is a one and the *SplitXState* is **DoStart** (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current microframe, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed it's final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Since the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

4. Set the *Halted* bit to a one, then
5. Set the *I-bit* to a zero, then
6. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

48.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (see Section 48.4.3.7, "Managing Isochronous Transfers Using iTDs" for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Section , "Split Transaction Scheduling Mechanisms for Interrupt" apply. Figure 48-76 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{s}x and ^{c}x labels indicate microframes where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

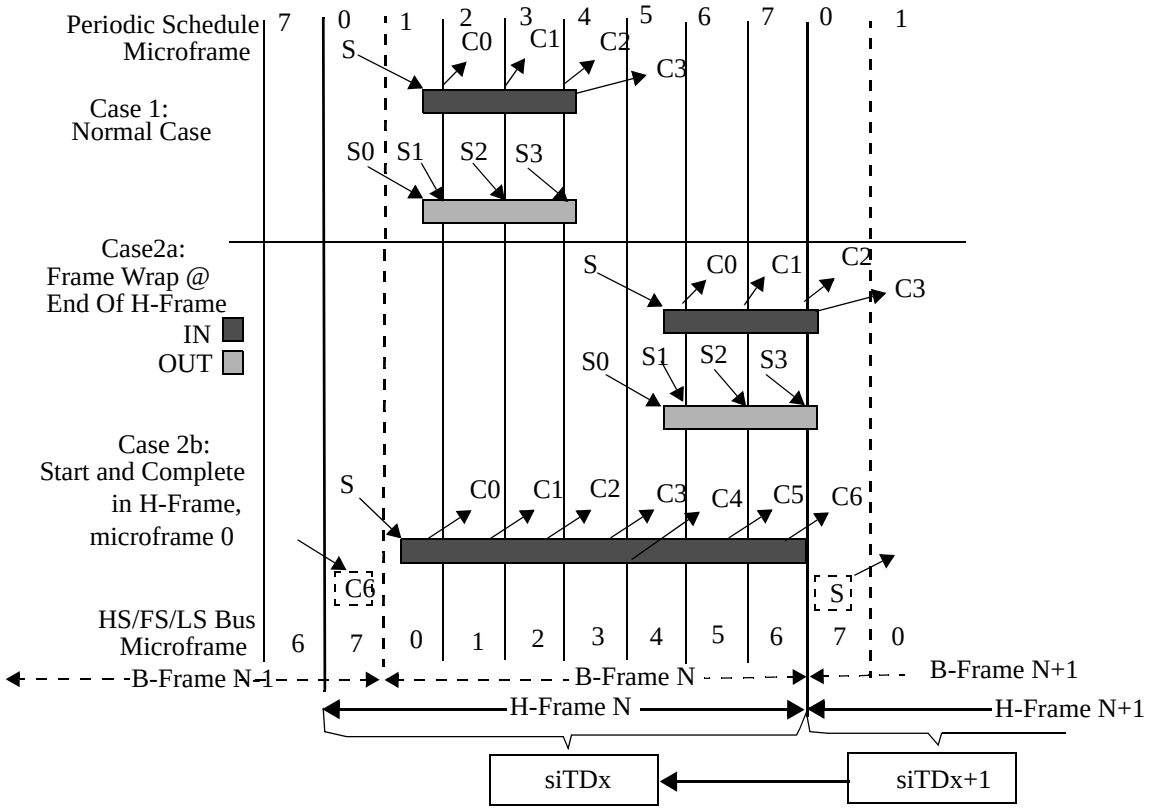

Figure 48-76. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame.* For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.
- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, microframes 6 or 7 (*H-Frame* microframe 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(e.g. it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction).
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same microframe. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Table 48-53). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section , “Split Transaction Execution State Machine for Interrupt”.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the microframe (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 48-76, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates **Do Start Split**, and the current microframe as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the microframes (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 48-76, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates **Do Complete Split**, and the current microframe as indicated by *FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.
- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. Figure 48-77 illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

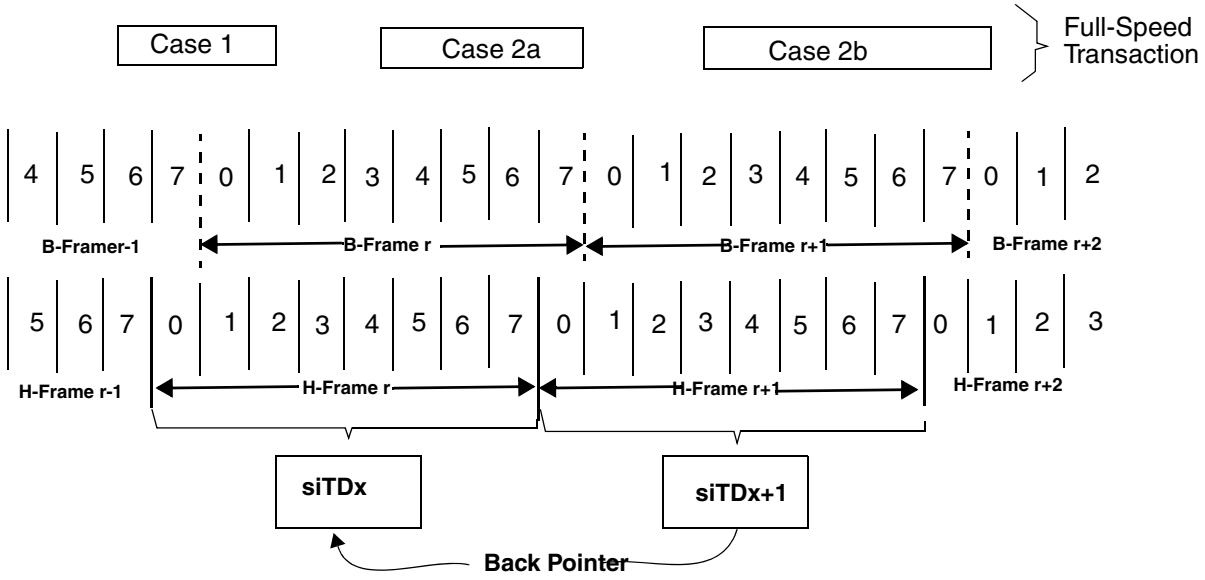

Figure 48-77. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction. $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during microframe 7 of $H\text{-}Frame_{Y+1}$, or microframe 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$ is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section , “Periodic Isochronous - Do Complete Split”.

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, microframe 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in microframe 1 of *H-Frame* N and the last complete-split would need to occur in microframe 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped microframes), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the microframes they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact microframe in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future microframe).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section , “Periodic Isochronous - Do Start Split” for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the microframe (FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. See Section , "Asynchronous—Do Complete Split," for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (e.g. high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a microframe boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the remaining bytes to the high-speed pipeline stage. At the microframe boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next microframe, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement it's *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (e.g. a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (e.g. state not advanced) and report the appropriate error to the client driver.

Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to microframe are in the context of a microframe within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section , "Tracking Split Transaction Progress for Interrupt Transfers", plus the variable *cMicroFrameBit* defined in Section , "Split Transaction Execution State Machine for Interrupt" to track the progress of an isochronous split transaction. Figure 48-78 illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states.

Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

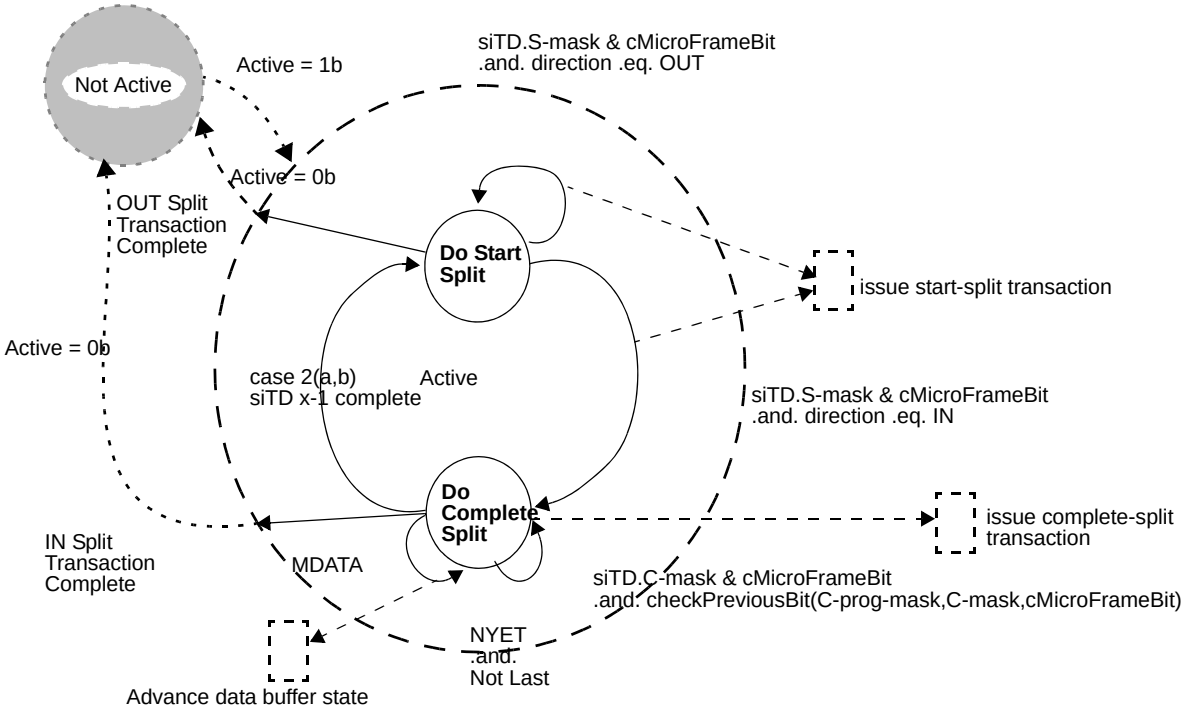

Figure 48-78. Split Transaction State Machine for Isochronous

Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state. An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from **Do Complete Split** when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (i.e. the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer

crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 48-77) is used to determine the initial value of *TP*. The initial cases are summarized in Table 48-80.

Table 48-80. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated. Table 48-81 illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

Table 48-81. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (e.g. greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 48-81.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to

detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (i.e. the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section , “Split Transaction for Isochronous - Processing Examples”.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Section , “Periodic Isochronous - Do Complete Split” can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed microframes. It can then set the siTD’s *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the **Do Start State** after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which microframe the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- **Test A**. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this microframe. This test is always applied to a newly fetched siTD that is in this state.
- **Test B**. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section , “Periodic Isochronous - Do Complete Split”). The sequence in which this test is applied depends on the current value of FRINDEX[2:0]. If FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(`siTD.C-prog-mask, siTD.C-mask, cMicroFrameBi`**t)**

```
Begin

        Boolean rvalue = TRUE;

        previousBit = cMicroFrameBit rotate-right(1)

        -- Bit-wise anding previousBit with C-mask indicates whether there was an intent

        -- to send a complete split in the previous microframe. So, if the

        -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
```

```
        -- happened.
        if previousBit bitAND siTD.C-mask then
                if not (previousBit bitAND siTD.C-prog-mask) then
                        rvalue = FALSE
                End if
        End if
        Return rvalue
End Algorithm
```

If Test A is true and FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 48-76). See Section , “Periodic Isochronous - Do Complete Split” for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,
- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry

more than two times. If the host controller exhausts the retries or the end of the microframe occurs, the *Active* bit is set to zero.

- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section , "Periodic Isochronous - Do Complete Split". If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.
- MDATA (and Last). See above description for testing for **Last**. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for **Last**. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from microframe X to X+1 and during microframe X, the transaction translator will respond with an MDATA and the data accumulated up to the end of microframe X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Microframe* status bit and sets the *Active* bit to a zero.

Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 48-76) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. Figure 48-78 enumerates the transaction state fields.

Table 48-82. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

Note: *TP* and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is **Do Complete Split**.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$*.Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is **Do Complete Split**), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 48-82) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is **Do Start Split**), then the host controller must set *Active* bit to a zero and *Missed microframe* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$'s *Active* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$'s back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$'s complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to **Do Start Split**. The host controller then determines whether the case 2b start split boundary condition exists (i.e. if *cMicroframeBit* is a 1b and $siTD_X$*.S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$*.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$*.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state

machines. The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the **Execute Transaction** queue head traversal state machine (see Figure 48-69).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, Table 48-83 illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 48-83. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDx		microframes								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask					1				Do Start Split
	C-Mask	1	1					1	1	
X+1	S-Mask					1				Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask					1				Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Since this is the case-2a frame-wrap case, *S-mask*s of all siTDs for this endpoint have a value of 10h (a one bit in microframe 4) and *C-mask* value of C3h (one-bits in microframes 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back Pointer T-bits* are set to zero).

The initial *SplitXState* of the first siTD is **Do Start Split**. The host controller will visit the first siTD eight times during frame X. The C-mask bits in microframes 0 and 1 are ignored because the state is **Do Start Split**. During microframe 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to **Do Complete Split**. During microframes 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has it's *SplitXState* initialized to **Do Complete Split**. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During microframes 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, microframe 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to **Do Start Split.** At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches microframe 4. If the split-transaction completes early (transaction-complete is defined in Section , “Periodic Isochronous - Do Complete Split”), i.e. before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to **Do Start Split** early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, microframe 1.

During *H-Frame X+2*, microframe 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses it's next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, microframe 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to **Do Start Split**. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches microframe 4.

48.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports. When the schedules are enabled, the EHCI host controller will access the schedules in main memory each microframe. This constant pinging of main memory is known to create CPU power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the CPU, based on recent history usage. In the more aggressive power saving modes, the CPU can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the CPU power management software can detect this activity over time and inhibit the transition of the CPU into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the CPU power management software from placing the CPU into its lowest power savings state.

USB Host controllers do not access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the CPU power management to get the CPU into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the CPU to reach it's low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the CPU will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing it's shared memory based data structures (schedule lists or otherwise).

48.4.3.14 Port Test Modes

EHCI host controllers must implement the port test modes **Test J_State**, **Test K_State**, **Test_Packet**, **Test Force_Enable**, and **Test SE0_NAK** as described in the USB Specification Revision 2.0. The system is only allowed to test ports that are owned by the EHCI controller (e.g. *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is **Test_Force_Enable**, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting the RST bit (USBCMD register) to a one.

48.4.3.15 Interrupts

The EHCI Host Controller hardware provides interrupt capability based on a number of sources. There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section 48.4.1.6.3, "USB Interrupt Enable Register (USBINTR)"). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight microframes. This means that the host controller will not generate interrupts any more frequently than once every eight microframes.

Section , "Host System Error" details the effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, CPU control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

The host controller is not required to negate a currently active interrupt condition when software clears the interrupt enables in the USBINR register (see Section 48.4.1.6.3, “USB Interrupt Enable Register (USBINTR)). The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USB Status Register (USBSTS) from 1 to 0.

48.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully. Table 48-84 lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 48-84. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1 If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Section , “Halting a Queue Head”.

2 The host controller received a response from the device, but it could not recognize the PID as a valid PID.

Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*. When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Section , “Halting a Queue Head”). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a microframe EOF.

NOTE

When a host controller detects a data PID mismatch, it must either disable the packet babble checking for the duration of the bus transaction, or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (e.g. expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction. This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction

errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USBSTS register to be set to a one. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USBSTS register is also set to a one.

Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USBSTS register is set to a one. If the *USB Interrupt Enable* bit is set in the USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

48.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section , "Interrupt on Async Advance").

Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one. If the *Port Change Interrupt Enable* bit in the USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USBCMD register. If it is a one, it sets the *Interrupt on Async Advance* bit in the USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section 48.4.3.8.2, “Removing Queue Heads from Asynchronous Schedule”.

Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors. The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USBCMD register is set to a zero.
- The following bits in the USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. Table 48-85 summarizes the required actions taken on the various host errors.

Table 48-85. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]

Table 48-85. Summary Behavior of EHCI Host Controller on Host System Errors (continued)

iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

[o] Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a Host System Error, software must reset the host controller via the RST bit in the USBCMD register before re-initializing and restarting the host controller.

48.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation and On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary. The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator – Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

48.4.4.1 Embedded Transaction Translator Function

The ARC USB-HS OTG High-Speed USB On-The-Go OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function

is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

48.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to HCSPARAMS – Host Control Structural Parameters
- N_PTT added to HCSPARAMS – Host Control Structural Parameters

48.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- is a new register.
- Addition of two-bit Port Speed (PSPD) to the PORTSC*x* registers.

48.4.4.1.3 Discovery

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation. The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, chirp completes successfully).

Since this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in the PORTSC*x* register.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in Table 48-86:

Table 48-86. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. **[where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (that is, Split target hub)]**	FS and LS device can be either downstream from a HS hub with HubAddr = X **[HubAddr > 0]** or directly attached **[where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (that is, Split target hub is the root hub)**

48.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator. Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) – Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

Note: When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

     - Maximum Packet Size must be less than or equal 64 or undefined behavior may result.
2. siTD (for direct attach FS) – Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behavior may result.

48.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Since the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator. Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. Table 48-87 summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 48-87. Summary of the Conditions of Handshakes

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

Note: The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits.

Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

USB 2.0 – 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

USB 2.0 – 11.17.4

- Transaction tracking for 2 data pipes.

USB 2.0 – 11.17.5

- Clear_TT_Buffer capability provided though the use of the register.

Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

USB 2.0 – 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in microframes 6)
  - Idle for more than 4 microframes
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 microframes

USB 2.0 – 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Some applications may not require transaction tracking up to a maximum of 16 periodic data pipes. The option to limit the tracking to only 4 periodic data pipes exists in the by changing the configuration constant VUSB_HS_TT_PERIODIC_CONTEXTS to 4. The result is a significant gate count savings to the core given the limitations implied.

CAUTION	**Note:** Limiting the number of tracking pipes in the EMBedded –TT to four (4) will impose the restriction that no more than 4 periodic transactions (INTERRUPT/ISOCHRONOUS) can be scheduled through the embedded-TT per frame. The number 16 was chosen in the USB specification because it is sufficient to ensure that the high-speed to full-speed periodic pipeline can remain full. Keeping the pipeline full puts no constraint on the number of periodic transactions that can be scheduled in a frame and the only limit becomes the flight time of the packets on the bus.

- Complete-split transaction searching.

Note: There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the Host Control Structural Parameters Register (HCSPARAMS) register.

48.4.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

48.4.4.3 USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode Register (USBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

48.4.4.3.1 Non-Zero Fields the Register File.

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode.

48.4.4.3.2 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125 µs interrupt for host mode. EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. See Section 48.4.1.6.2, “USB Status Register (USBSTS)” and Section 48.4.1.6.3, “USB Interrupt Enable Register (USBINTR)”.

48.4.4.4 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

48.4.4.4.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of microframes are timed precisely to 125 us using the transceiver clock as a reference clock. i.e. 60 Mhz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

48.4.4.5 Miscellaneous Variations from EHCI

48.4.4.5.1 Programmable Physical Interface Behavior

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the PORTSC*x* registers, providing a capability that is not defined by EHCI.

48.4.4.5.2 Discovery

Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the Port Status Control *x* Registers (*x* = 1…8) register for a duration of 10 ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the device.
- Software shall write a '0' to the reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed – *This information is redundant with the 2-bit Port Speed indicator above.*

48.4.4.5.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI since the release of revision 3.2.1. In earlier product revisions, the test packet mode was not EHCI compatible. An alternate host controller driver procedure is no longer necessary or supported.

48.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

Note: Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The ARC USB-HS OTG High-Speed USB On-The-Go core includes DCD Software called the USB 2.0 Device API. The Device API provides an easy to use Application Program Interface for developing device (peripheral) applications using the ARC USB-HS OTG High-Speed USB On-The-Go core. The Device API incorporates and abstracts for the application developer all of the elements of the program interface.

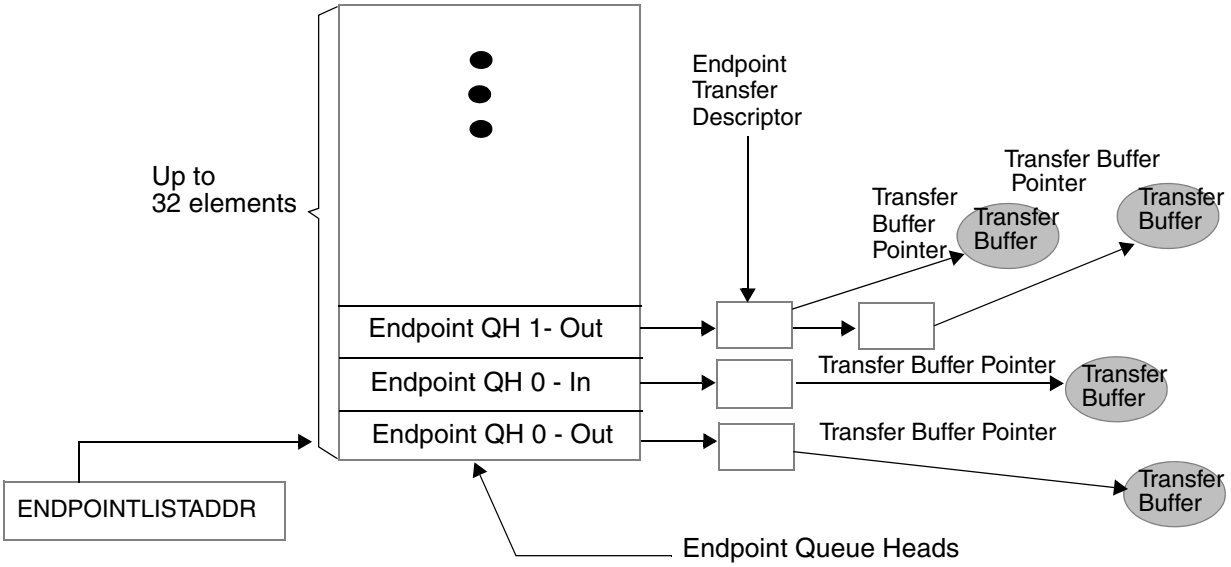

Figure 48-79. Endpoint Queue Head Organization

Device queue heads are arranged in an array in a continuous area of memory pointed to by the *ENDPOINTLISTADDR* pointer. The even –numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE The Endpoint Queue Head List must be aligned to a 2k boundary.

48.4.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status

DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

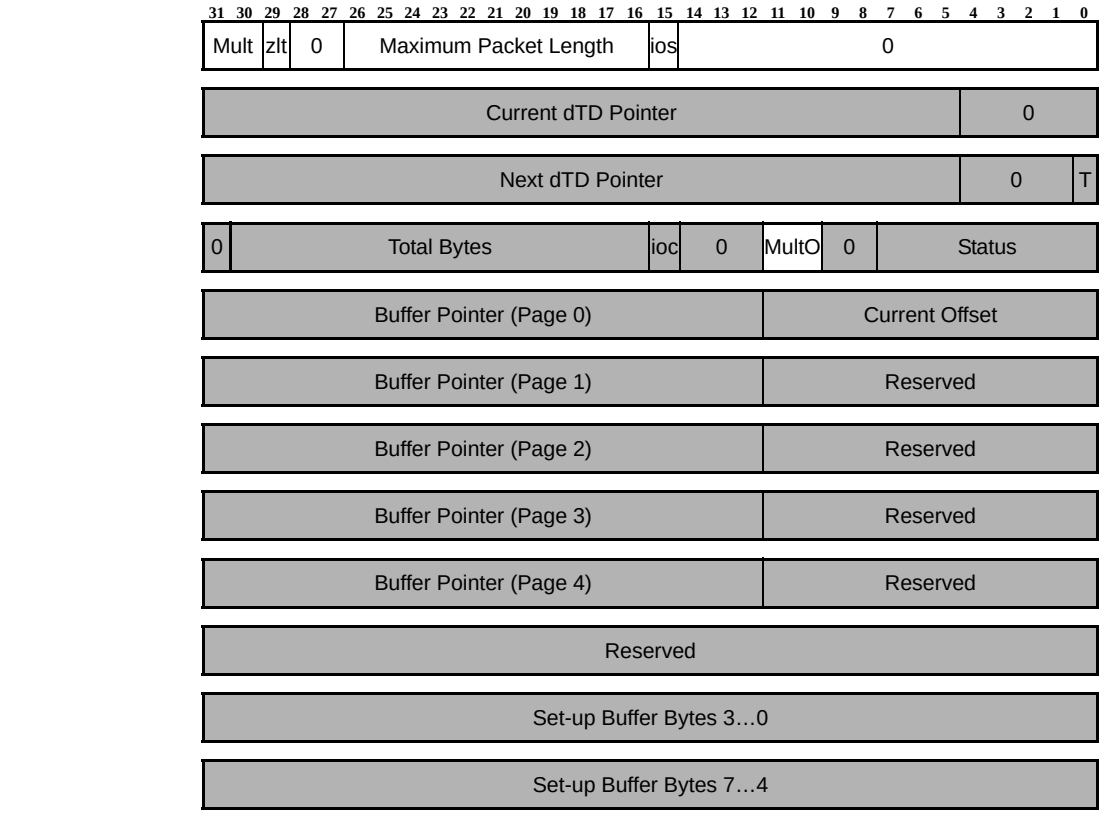

Figure 48-80. Endpoint Queue Head (dQH)

48.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 48-88. Endpoint Capabilities/Characteristics

Bit	Description
31:30	**Mult.** This field is used to indicate the number of packets executed per transaction description as given by the following: 00 – Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 – Execute 1 Transaction. 10 – Execute 2 Transactions. 11 – Execute 3 Transactions. Note: Non-ISO endpoints must set Mult=”00”. Note: ISO endpoints must set Mult=”01”, “10”, or “11” as needed.

29	**Zero Length Termination Select.** This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple. This bit is not relevant for Isochronous 0 – Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 – Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28:27	**Reserved.** These bit reserved for future use and should be set to zero.
26:16	**Maximum Packet Length.** This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	**Interrupt On Setup (IOS).** This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14:0	**Reserved.** Bits reserved for future use and should be set to zero.

48.4.5.1.2 Transfer Overlay

The seven DWords in the overlay area represent a transaction working space for the device controller. The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

48.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

Table 48-89. Next dTD Pointer

Bit	Description
31:5	**Current dTD.** This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4:0	**Reserved.** Bit reserved for future use and should be set to zero.

48.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

Note: Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

Table 48-90. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31:0	**Setup Buffer 0.** This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.

2	31:0	**Setup Buffer 1.** This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

48.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for given transfer. The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

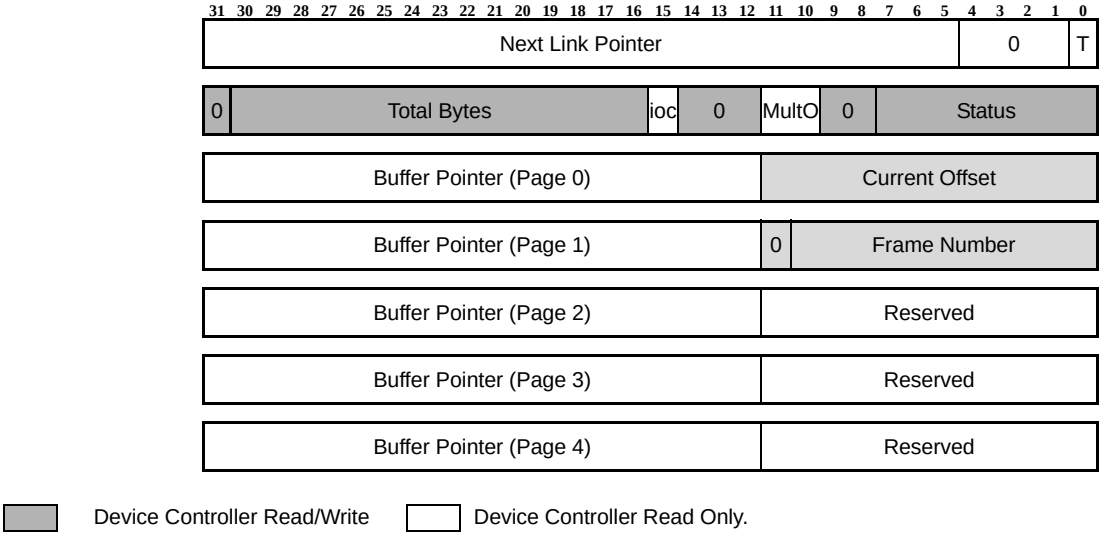

Figure 48-81. Endpoint Transfer Descriptor (dTD)

Table 48-91. Next dTD Pointer

Bit	Description
31:5	**Next Transfer Element Pointer.** This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4:1	**Reserved.** Bits reserved for future use and should be set to zero.
0	**Terminate (T).** 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

Table 48-92. dTD Token

Bit	Description
31	**Reserved.** Bit reserved for future use and should be set to zero.

30:16	**Total Bytes.** This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. **Therefore, the maximum recommended transfer is 16K(4000H).** If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	**Interrupt On Complete (IOC).** This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14:12	**Reserved**. Bits reserved for future use and should be set to zero.
11:10	**Multiplier Override (MultO).** This field can be used for transmit ISOs (that is, ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO=”00”.
9:8	**Reserved**. Bits reserved for future use and should be set to zero.
7:0	**Status.** This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4,2,0Reserved.

Table 48-93. dTD Buffer Page Pointer List

Bit	Description
31:12	**Buffer Pointer.** Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0;11:0	**Current Offset.** Offset into the 4kb buffer where the packet is to begin.
1;10:0	**Frame Number.** Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

48.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list **transfer descriptors**, pointed to by a **queue head**, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

The ARC USB-HS OTG High-Speed USB On-The-Go is shipped with a DCD called the ARC USB-HS OTG High-Speed USB On-The-Go Device API. The ARC USB-HS OTG High-Speed USB On-The-Go Device API provides an easy to use application interface for developing USB device (peripheral) applications. The ARC USB-HS OTG High-Speed USB On-The-Go Device API incorporates and abstracts for the application developer all of the information contained in the device operational model. For more information on the ARC USB-HS OTG High-Speed USB On-The-Go Device API, see the software design document for the precise USB 2.0 device API.

48.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a ‘1’. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

1. Set Controller Mode in the USBMODE register to device mode.
2. Allocate and Initialize device queue heads in system memory.

Note: Transitioning from host mode to device mode requires a device controller reset before modifying USBMODE.

   — Minimum: Initialize device queue heads 0 Tx & 0 Rx.
   — For information on device queue heads, see Section 48.4.5, “Device Data Structures.”

Note: All device queue heads must be initialized for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

3. Configure ENDPOINTLISTADDR Pointer.
   — For additional information on ENDPOINTLISTADDR, see the register table.
4. Enable the microprocessor interrupt associated with the ARC USB-HS OTG High-Speed USB On-The-Go core.
   — Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
   — For a list of available interrupts see the register tables in Section 48.4.1.6.3, “USB Interrupt Enable Register (USBINTR)” and Section 48.4.1.6.2, “USB Status Register (USBSTS)”.
5. Set Run/Stop bit to Run Mode in USB CMD register.

— After the Run bit is set, a device reset will occur. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the following Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register. It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

48.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'. After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0. The following state diagram depicts the state of a USB 2.0 device.

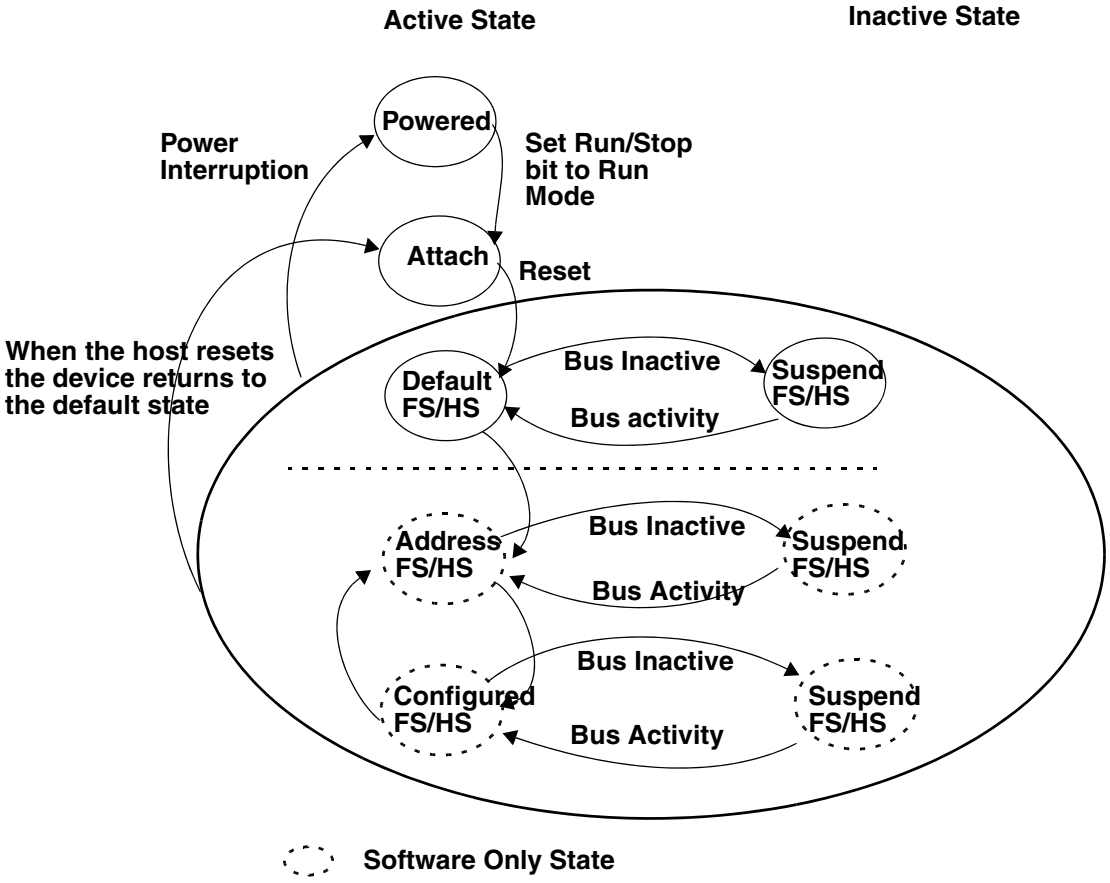

Figure 48-82. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

Table 48-94. Device Controller State Information Bits

Bit	Register
DCSuspend	USB Status Register (USBSTS)
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	Port Status Control x Registers (PORTSCx, x = 1…8)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRLx registers and initializing the associated queue heads.

48.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices. When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the ENDPTSETUPSTAT register and writing the same value back to the ENDPTSETUPSTAT register.

Clear all the endpoint complete status bits by reading the ENDPTCOMPLETE register and writing the same value back to the ENDPTCOMPLETE register.

Cancel all primed status by waiting until all bits in the ENDPTPRIME register are 0 and then writing 0xFFFFFFFF to the ENDPTFLUSH register.

Read the reset bit in the PORTSC*x* register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before the end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare).

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the PORTSC*x*, register to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to Chapter 9 (“Device Framework”) of the USB Specification.

Note: The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

48.4.6.2.2 Suspend/Resume

Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the PORTSCx register is set to 1, the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

Note: Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing

resume signaling to the upstream port. Resume signaling is sent upstream by writing 1 to the Resume bit in the in the PORTSC*x* register while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

Note: Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

Port Test Modes

Contact ARC International for port test mode capabilities.

48.4.6.2.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device. The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The ARC USB-HS OTG High-Speed USB On-The-Go device controller hardware supports up to the USB 2.0 maximum of 32 endpoint specified numbers. Each additional endpoint beyond the required endpoint position adds additional hardware logic. The maximum number of endpoint numbers available to the DCD is configured at hardware synthesis timer. After synthesis, the DCD can enable, disable and configure endpoint type up to the maximum selected during synthesis.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. If the maximum of 16 endpoint numbers, one for each endpoint direction are being used by the device controller, then 32 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

48.4.6.2.4 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRL*x* register. Each 32-bit ENDPTCTRL*x* is split into an upper and lower half. The lower half of ENDPTCTRL*x* is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half

of the ENDPTCTRL*x* register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization.

Table 48-95. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	'1'
Data Toggle Inhibit	'0'
Endpoint Type	"00" – Control "01" – Isochronous "10" – Bulk "11" – Interrupt
Endpoint Stall	'0'

48.4.6.2.5 Stalling

There are two occasions where the device controller may need to return to the host a STALL

The first occasion is the **functional stall**, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRL*x* register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A **protocol stall**, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRL*x* register can ensure that both stall bits are set at the same instant.

Note: Any write to the ENDPTCTRLx register during operational mode must preserve the endpoint type field (i.e. perform a read-modify-write).

Table 48-96. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

48.4.6.2.6 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe. For more information on data toggle, see the USB 2.0 specification.

Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a ‘1’ to the data toggle reset bit in the ENDPTCTRLx register. This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

Data Toggle Inhibit

Note: This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active (‘1’) causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

48.4.6.3 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification. At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as “**priming**” the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term “**flushing**” is used to describe the action of clearing a packet that was queued for execution.

Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH). After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Since only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus.

Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

48.4.6.3.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 48-97. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0

512	512	2	512	0	

Table 48-98. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

Note: The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

Note: All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

Interrupt/Bulk Endpoint Bus Response Matrix

Table 48-99. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK – NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR – System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

48.4.6.3.2 Control Endpoint Operation Model

Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

In hardware versions 2.3 and later, the setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

Setup Packet Handling (Pre-2.3 hardware)

- After receiving an interrupt and inspecting the USBMODE register to determine that a setup packet was received on a particular pipe:
  - 1. Duplicate contents of dQH.SsetupBuffer into local software byte array.
  - 2. Write 1 to clear the corresponding ENDPTSETUPSTAT bit and thereby disabling Setup Lockout. (i.e. the Setup Lockout activates as soon as a setup arrives. By writing to the ENDPTSETUPSTAT register, the device controller will accept new setup packets.)
  - 3. Process setup packet using local software byte array copy and execute status/handshake phases.
    - Note: After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed and deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

Note: To limit the exposure of setup packets to the setup lockout mechanism (if used), the DCD should designate the priority of responding to setup packets above responding to other packet completions.

Setup Packet Handling (2.3 hardware and later)

- Disable Setup Lockout by writing ‘1’ to Setup Lockout Mode (SLOM) in USB Device Mode Register (USBMODE). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

Note: Leaving the Setup Lockout Mode As ‘0’ will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting the ENDPTSETUPSTAT register to determine that a setup packet was received on a particular pipe:
  - 1. Write 1 to clear the corresponding ENDPTSETUPSTAT register bit.
  - 2. Write 1 to the Setup Tripwire (SUTW) bit in the USBCMD register.
  - 3. Duplicate contents of dQH.SetupBuffer into local software byte array.
  - 4. Read Setup TripWire (SUTW) in USB Command Register (USBCMD) register. (if set - continue; if cleared - goto 2)
  - 5. Write '0' to clear Setup Tripwire (SUTW) in USB Command Register (USBCMD) register.
  - 6. Process setup packet using local software byte array copy and execute status/handshake phases.

Note: Note: After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed and deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the ENDPTPRIME register is zero and the associated bit in the ENDPTSTAT register is a one. If a prime fails, that is the ENDPTPRIME bit goes to 0 and the ENDPTSTAT bit is not set to 1, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (ENDPTSTAT) to enforce data coherency with the setup packet.

Note: The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

Note: Error handling of data phase packets is the same as bulk packets described previously.

Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase. The DCD must also perform the same checks of the ENDPTSETUPSTAT as described above in the data phase.

Note: The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

Note: Error handling of data phase packets is the same as bulk packets described previously.

Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

Table 48-100. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK – NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR – System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

48.4.6.3.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes. Real time delivery by the device controller will is accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to IN requests to unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - — MULT counter reaches zero.
  - — Fulfillment Error [*Transaction Error* bit is set]
    - – # Packets Occurred > 0 AND # Packets Occurred < MULT

Note: For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - — MULT counter reaches zero.
  - — Non-MDATA Data PID is received**
    - – ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - — Overflow Error:
    - – Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - – Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - — Fulfillment Error [*Transaction Error* bit is set]
    - – # Packets Occurred > 0 AND # Packets Occurred < MULT
  - — CRC Error [*Transaction Error* bit is set

Note: For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro)frame number (FRINDEX register) can be used as a marker. To cause a packet transfer to occur at a specific (micro)frame

number [N], the DCD should interrupt on SOF during frame N-1. When the FRINDEX=N–1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro)frame N–1 so that the device controller will execute delivery during (micro)frame N.

CAUTION

Priming an endpoint towards the end of (micro)frame N-1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

Isochronous Endpoint Bus Response Matrix

Table 48-101. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

48.4.6.4 Managing Queue Heads

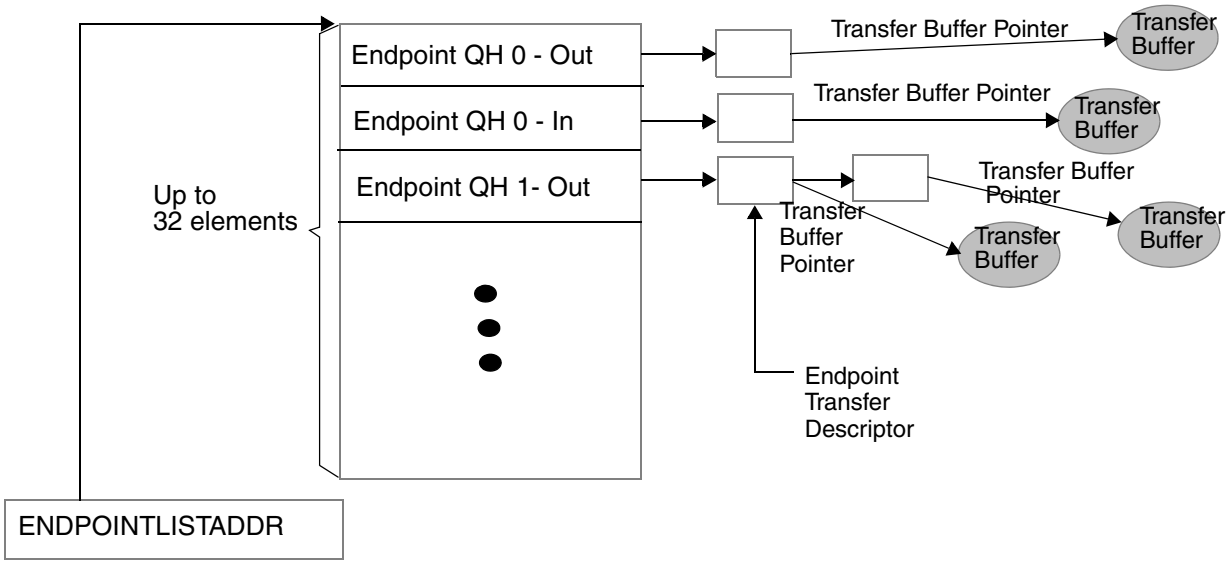

Figure 48-83. Endpoint Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 48-83. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors since pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

48.4.6.4.1 Queue Head Initialization

One pair of device queue heads must be initialized for each active endpoint. To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required for bandwidth, and in conjunction with the USB Chapter 9 protocol. *Note: In FS mode, the multiplier field can only be 1 for ISO endpoints.*
- Write the next dTD Terminate bit field to "1".
- Write the Active bit in the status field to "0".
- Write the Halt bit in the status field to "0".

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

48.4.6.4.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

The acknowledge must occur before continuing to process the setup packet.

After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH – RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in Section 48.4.6.5.5, "Flushing/De-priming an Endpoint".
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

48.4.6.5 Managing Transfers with Transfer Descriptors

48.4.6.5.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head. This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list.

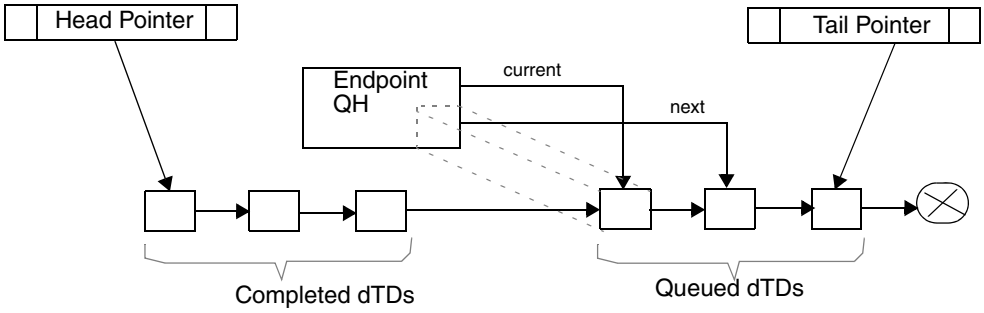

Figure 48-84. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers but it still remains the responsibility of the DCD to maintain the pointers.

48.4.6.5.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer. Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to 0b00000.

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

48.4.6.5.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty:

- — Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding)

- Case 1: Link list is empty
  - — 1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  - — 2. Clear active & halt bit in dQH (in case set from a previous error).
  - — 3. Prime endpoint by writing 1 to the correct bit position in the ENDPTPRIME register.
- Case 2: Link list is not empty
  - — 1. Add dTD to end of linked list.
  - — 2. Read correct prime bit in the ENDPTPRIME register – if ‘1’ DONE.
  - — 3. Set ATDTW bit in the USBCMD register to 1.
  - — 4. Read correct status bit in the ENDPTSTAT register (store in tmp. variable for later)
  - — 5. Read ATDTW bit in the USBCMD register.
    - – If 0 goto 3.
    - – If 1 continue to 6.
  - — 6. Write ATDTW bit in the USBCMD register to 0.
  - — 7. If status bit read in (4) is 1 DONE.
  - — 8. If status bit read in (4) is 0 then Goto Case 1: Step 1.

48.4.6.5.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

CAUTION

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Section 48.4.6.5.6, “Device Error Matrix”.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

48.4.6.5.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer. There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a 1 to the corresponding bit(s) in the ENDPTFLUSH register.
2. Wait until all bits in ENDPTFLUSH are 0.
   — Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read the ENDPTSTAT register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now ‘0’. If the corresponding bits are ‘1’ after step #2 has finished, then the flush failed as described in the following:
   — Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using the ENDPTFLUSH register. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

48.4.6.5.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 48-102. Device Error Matrix

Error	Description	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow	Number of bytes received exceeded max. packet size or total buffer length. **Note:** This error also sets the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those are not executed.	RX	Any	1	0
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.	RX	ISO	0	1
ISO Fulfillment Error	Hst failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the “dead” (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated.

48.4.6.6 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

48.4.6.6.1 High-Frequency Interrupts

High frequency interrupts in particular should be handed in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 48-103. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt [1] - **ENDPTSETUPSTATUS**	Copy contents of setup buffer and acknowledge setup packet (as indicated in section Managing Queue Heads). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt ** - **ENDPTCOMPLETE**	Handle completion of dTD as indicated in section Managing Queue Heads.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

[1] It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

48.4.6.6.2 Low-Frequency Interrupts

The low frequency events include the following interrupts. These interrupt can be handled in any order since they don't occur often in comparison to the high-frequency interrupts.

Table 48-104. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

48.4.6.6.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

Table 48-105. Error Interrupt Events

Interrupt	Action
USB Error Interrupt.	This error is redundant because it combines **USB Interrupt** and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of **USB Interrupt (w/ ENDPTCOMPLETE).**
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

Chapter 49
Watchdog Timer (WDOG)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

49.1 Overview

This section briefly introduces the module. The full description of the module is in Section 49.4, "Functional Description."

This section includes a top-level diagram (Figure 49-1) that shows the functional organization of the module, including all off-chip signals.

The watchdog timer (WDOG) module protects against system failures by providing a method of escaping from unexpected events or programming errors. After the WDOG module is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. After a time-out, the WDOG module asserts the internal system reset signal, wdog_rst, which goes to the System Reset Controller. There is also a provision for WDOG signal assertion by time-out counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter time-out is programmable. There is a power-down counter that gets enabled out of any reset (POR, Warm / Cold). This counter has a fixed time-out period of 16 seconds, after which it asserts the WDOG signal.

Flow diagrams for the time-out counter, power-down counter, and interrupt operations are shown in Figure 49-11, Figure 49-12, and Figure 49-13.

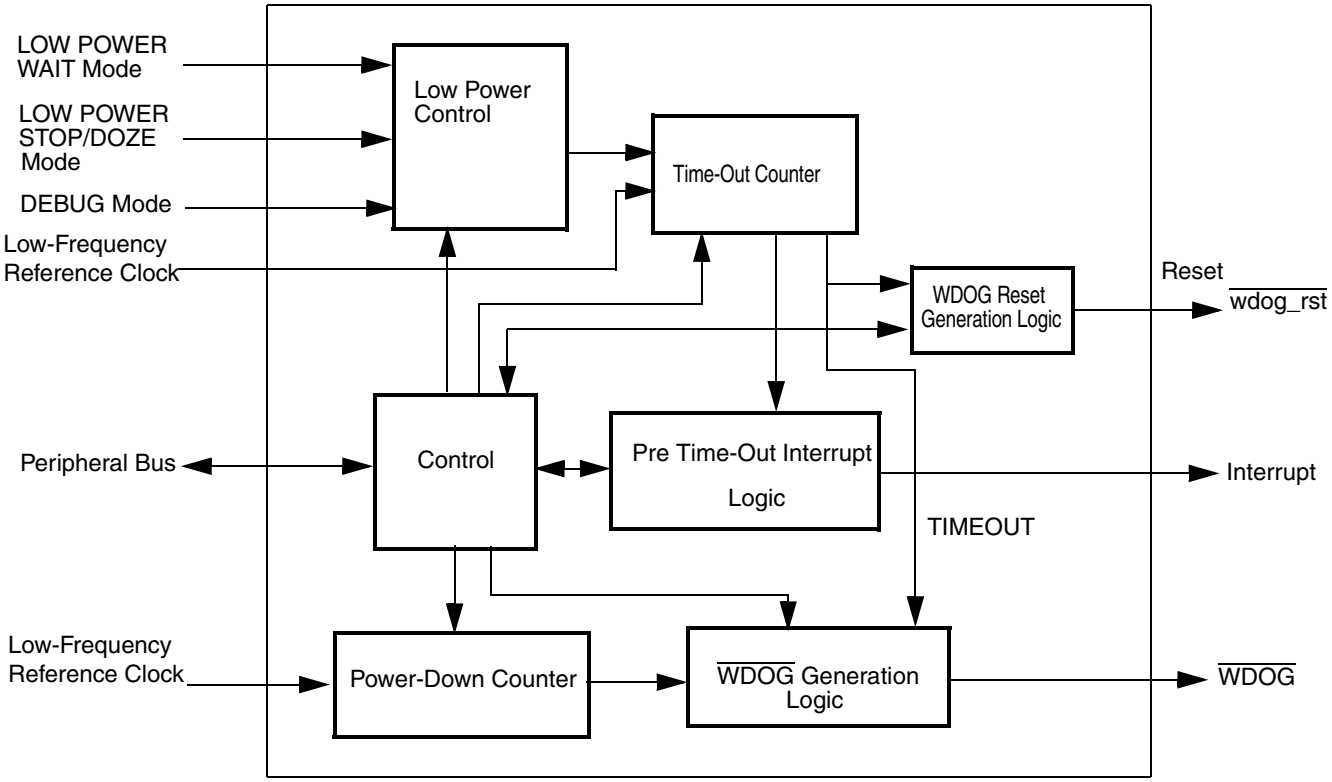

Figure 49-1. WDOG Block Diagram

49.1.1 Features

The WDOG module features include the following:

- A configurable time-out counter with time-out periods from 0.5 seconds up to 128 seconds and after time-out expiration results in assertion of the wdog_rst reset signal.
- Time resolution of 0.5 seconds.
- A configurable time-out counter that can be programmed to run or stop during low-power modes.
- A configurable time-out counter that can be programmed to run or stop during DEBUG mode.
- Programmable interrupt generation prior to time-out.
- The time duration between interrupt and time-out events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- A power-down counter with a fixed time-out period of 16 seconds which if not disabled after reset asserts the WDOG signal low.
  - The power-down counter is enabled out of any reset (POR, Warm / Cold reset) by default.

49.1.2 Modes and Operations

The WDOG module supports the following modes described in the indicated sections:

- Section 49.4.4, “Low-Power Modes”
- Section 49.4.5, “Debug Mode”

As described in Section 49.4.6, “Operations,” the WDOG module supports the operations described in the indicated sections:

- Section 49.4.6.1, “Watchdog Reset Generation”
- Section 49.4.6.2, “WDOG_B Generation”

49.2 External Signals

Table 49-1. Off-Chip Module Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
WDOG	O	This signal powers down the Chip. See Section 49.4.6.2, “WDOG_B Generation.”	1	—
wdog_rst	O	This signal is a reset source for the chip. See Section 49.4.6.1, “Watchdog Reset Generation.”	1	—

[1] The reset state values and pull-up/down requirements provided in this table are from the module-level perspective. To understand how the module is integrated at the SoC level, the system software developer must see discussions of the module in the appropriate SoC-level chapter(s). For example, a module signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

49.3 Memory Map and Register Definitions

The WDOG module has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the watchdog timer. Section 49.3.3, “Register Descriptions” provides the detailed descriptions for all of the WDOG module registers. Byte operations can be performed on these registers. If a 32-bit access is performed on these registers then the WDOG module does not generate any bus error and behaves normally, like a 16-bit access, making read/write possible. A 32-bit access should be avoided as the system might go to an unknown state.

49.3.1 Memory Map

Table 49-2 is the module memory map.

Table 49-2. Module Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (WCR)	Watchdog Control Register	R/W	0x0030	49.3.3.1/49-5
0x0002 (WSR)	Watchdog Service Register	R/W	0x0000	49.3.3.2/49-7
0x0004 (WRSR)	Watchdog Reset Status Register	R	0x000X	49.3.3.3/49-7
0x0006 (WICR)	Watchdog Interrupt Control Register	R/W	0x0004	49.3.3.4/49-8
0x0008 (WMCR)	Watchdog Miscellaneous Control Register	R/W	0x0001	49.3.3.5/49-9

49.3.2 Register Summary

Table 49-3 is the register summary table.

Table 49-3. Module Register Summary

Offset (and Name Abbreviation)		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

49.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 49-2 and Table 49-4 explain conventions used in register diagrams and tables.

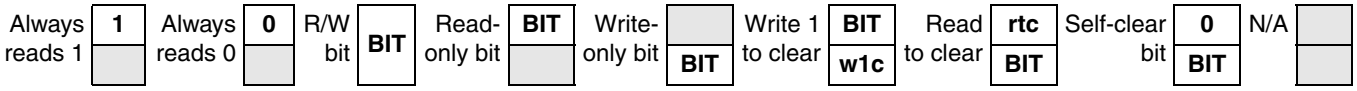

Figure 49-2. Register Field Conventions

Table 49-4. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

49.3.3.1 Watchdog Control Register (WCR)

The Watchdog Control Register (WCR) controls the WDOG timer operation. Figure 49-3 shows the register. Table 49-5 provides its field descriptions.

Offset 0x0000 (WCR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WT								WDW	0	WDA	SRS	WDT	WDE	WDBG	WDZST
Reset	0	0	0	0	0	0	0	0	0	0	1	1	--	0	0	0

Figure 49-3. WDOG Control Register

NOTE

- The WDZST, WDBG, and WDW fields are write once only bits. After the software performs a write access to these bits, all these bits are locked and cannot be reprogrammed until the next system-reset assertion.
- WDE is a write one, once only bit. After software writes a 1 to this bit, the bit cannot be reset/cleared until the next system reset.
- WDT is also a write one, once only bit. After software writes a 1 to this bit, the bit cannot be reset/cleared until the next POR (Power-on Reset). This bit does not gets reset/cleared by any system reset.

Table 49-5. WDOG Control Register Descriptions

Field	Description
15–8 WT	Watchdog time-out Field. This 8-bit field contains the time-out value that is loaded into the watchdog counter after the service routine has been performed or after the watchdog timer is enabled. After reset, WT[7:0] must have a value written to it before enabling the watchdog timer. Otherwise, the default count value is loaded into the counter. 0x00 0.5 Seconds (default) 0x01 1.0 Seconds. 0x02 1.5 Seconds. 0x03 2.0 Seconds. … 0xFF 128 Seconds. The time-out value can be written at any point in time, but it is loaded to the counter when WDOG is enabled or after the service routine has been performed. For more information, see Section 49.4.1, “Time-Out Event.”
7 WDW	Watchdog Disable for Wait. This bit determines the operation of WDOG during low-power WAIT mode. This is a write once only bit. 0 Continue WDOG timer operation (default). 1 Suspend WDOG timer operation.
6	Reserved.
5 WDA	$\overline{\text{WDOG}}$ assertion. Controls the software assertion of the $\overline{\text{WDOG}}$ signal. 0 Assert $\overline{\text{WDOG}}$ output. 1 No effect on system (default).
4 SRS	Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal $\overline{\text{wdog\_rst}}$. This bit automatically resets to 1 after it has been asserted to 0. **Note:** This bit does not generate a software reset to the module. 0 Assert system reset signal. 1 No effect on the system (default).
3 WDT	$\overline{\text{WDOG}}$ time-out assertion. Determines if the $\overline{\text{WDOG}}$ signal gets asserted upon a watchdog time-out event. This is a write-one once only bit. 0 No effect on $\overline{\text{WDOG}}$ (default). 1 Assert $\overline{\text{WDOG}}$ upon a Watchdog time-out event. **Note:** There is no effect on $\overline{\text{wdog\_rst}}$ (WDOG Reset) upon writing on this bit. The $\overline{\text{WDOG}}$ signal gets asserted along with $\overline{\text{wdog\_rst}}$ if this bit is set.

Table 49-5. WDOG Control Register Descriptions (Continued)

Field	Description
2 WDE	Watchdog Enable. Enables or disables the WDOG module. This is a write one once only bit. It is not possible to clear this bit by a software write after the bit is set. **Note:** This bit can be set/reset in debug mode (exception). 0 Disable the WDOG module (default). 1 Enable the WDOG module.
1 WDBG	Watchdog DEBUG Enable. Determines the operation of the WDOG module during DEBUG mode. This bit is write once-only. 0 Continue WDOG timer operation (default). 1 Suspend the watchdog timer.
0 WDZST	Watchdog Low-Power. Determines the operation of the WDOG module during low-power modes. This bit is write once-only. **Note:** The WDOG module can continue or suspend the timer operation in the low-power modes (STOP mode). 0 Continue timer operation (default). 1 Suspend the watchdog timer.

49.3.3.2 Watchdog Service Register (WSR)

When enabled, the WDOG module requires that a service sequence be written to the watchdog service register (WSR) to prevent the time-out condition. Figure 49-4 shows the register, Table 49-6 provides its field descriptions.

Offset 0x0002 (WSR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 49-4. Watchdog Service Register (WSR)

Table 49-6. Watchdog Service Register Description

Field	Description
15–0 WSR	Watchdog Service Register. This 16-bit field contains the watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: Write 0x 5555 to the Watchdog Service Register (WSR). Write 0x AAAA to the Watchdog Service Register (WSR).

NOTE

Executing the service sequence reloads the WDOG time-out counter.

49.3.3.3 Watchdog Reset Status Register (WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR is always asserted high. The register always indicates

the source of the last reset generated due to WDOG. read access to this register is with one wait state. Any write performed on this register generate a peripheral bus error.

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog time-out
- Software reset

Figure 49-5 shows the register; Table 49-7 provides its field descriptions.

Offset 0x0004 (WRSR) Access: User read-only

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	TOUT	SFTW
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—

Figure 49-5. Watchdog Reset Status Register (WRSR)

Table 49-7. Watchdog Reset Status Register Description

Field	Description
15–2	Reserved.
1 TOUT	Time-out. Indicates whether the reset is the result of a WDOG time-out. 0 Reset is not the result of a WDOG time-out. 1 Reset is the result of a WDOG time-out.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

49.3.3.4 Watchdog Interrupt Control Register (WICR)

The WICR controls the WDOG interrupt generation.

Figure 49-6 shows the register. Table 49-8 provides its field descriptions.

Offset 0x0006 (WICR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WIE	WTIS	0	0	0	0	0	0	WICT[7:0]							
W		w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Figure 49-6. Watchdog Interrupt Control Register (WICR)

Table 49-8. Watchdog Interrupt Control Register Description

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0. 0 Disable Interrupt (default). 1 Enable Interrupt. **Note:** This bit is a write once only bit. After the software makes a write access to this bit, the bit is locked and cannot be reprogrammed until the next system reset assertion.
14 WTIS	Watchdog TImer Interrupt Status bit reflects the timer interrupt status, whether interrupt has occurred or not. After the interrupt has been triggered, software must clear this bit by writing 1 to it. 0 No interrupt has occurred (default). 1 Interrupt has occurred
13–8	Reserved.
7–0 WICT	Watchdog interrupt count time-out (WICT) field determines how long before the counter time-out the interrupt must occur. The reset value is 0x04 and implies that an interrupt occurs 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds. WICT[7:0] = 0x00 Time duration between interrupt and time-out is 0 seconds. WICT[7:0] = 0x01 Time duration between interrupt and time-out is 0.5 seconds. … WICT[7:0] = 0x04 Time duration between interrupt and time-out is 2 seconds (default). … WICT[7:0] = 0xFF Time duration between interrupt and time-out is 127.5 seconds. **Note:** This field is write once only. After the software does a write access to this field, the field is locked and cannot be reprogrammed until the next system reset assertion

49.3.3.5 Watchdog Miscellaneous Control Register (WMCR)

WMCR Controls the power-down counter operation.

Figure 49-7 shows the Register. Table 49-9 shows the description.

Offset 0x0008 (WMCR) Access: User read-write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PDE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 49-7. Watchdog Miscellaneous Control Register

Table 49-9. Watchdog Miscellaneous Control Register Description

Field	Description
15–1	Reserved.
0 PDE	Power-Down Enable bit. Reset value of this bit is1 which means the power-down counter inside the WDOG is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. After it is disabled, this counter cannot be enabled again. See Section 49.4.3, “Power-Down Counter Event” for operation of this counter. 0 Power-Down Counter of WDOG is disabled. 1 Power-Down Counter of WDOG is enabled (default). **Note:** This bit is a write one once only bit. After software sets this bit, it cannot be reset until the next system reset.

49.4 Functional Description

49.4.1 Time-Out Event

The WDOG provides time-out periods from 0.5 seconds up to 128 seconds with a time resolution of 0.5 seconds. The user can determine the time-out period by writing to the WDOG time-out field (WT[7:0]) in the Watchdog Control Register (WCR). The WDOG has to be enabled by setting the WDE bit of Watchdog Control Register (WCR) for the time-out counter to start running. After the WDOG is enabled, the counter is activated, loads the time-out value and begins to count down from this programmed value. The timer times out when the counter reaches zero and the WDOG outputs a system reset signal, $\overline{\text{wdog\_rst}}$ and asserts $\overline{\text{WDOG}}$ (the WDT bit is set in the Watchdog Control Register (WCR)).

However the time-out condition can be prevented by reloading the counter with the new time-out value(WT[7:0] of WCR) if a service routine (See Section 49.4.1.1, “Servicing the WDOG to Reload the Counter”) is performed before the counter reaches zero. If any system errors occur that prevent the software from servicing the Watchdog Service Register (WSR), then the time-out condition occurs. By performing the service routine, the WDOG reloads its counter to the time-out value indicated by bits WT[7:0] of the Watchdog Control Register (WCR) and it re-starts the countdown.

A system reset resets the counter and places it in the idle state at any time during the countdown. The counter flow diagram is shown in Figure 49-11.

NOTE

The time-out value is reloaded to the counter at the time when the WDOG is enabled or after the service routine has been performed.

49.4.1.1 Servicing the WDOG to Reload the Counter

The proper service sequence to reload a time-out value to the counter begins by writing 0x 5555 followed by 0x AAAA to the Watchdog Service Register (WSR). Any number of instructions can be executed between the two writes. If the WSR is not loaded with 0x 5555 prior to writing 0x AAAA to the WSR, the counter is not reloaded. If any value other than 0x AAAA is written to the WSR after 0x 5555, the counter is not reloaded. This service sequence reloads the counter with the time-out value WT[7:0] of the Watchdog Control Register (WCR). The time-out value can be changed at any point of the time and the counter reloads this value whenever the core services the Watchdog.

49.4.2 Interrupt Event

Prior to time-out the WDOG can generate an interrupt which can be considered as a warning signal to indicate that the time-out occurs shortly. The time duration between the interrupt event and the time-out event can be controlled by writing to the WICT field of the Watchdog Interrupt Control Register (WICR). It can vary between 0 and 127.5 seconds. If the WDOG is serviced (Section 49.4.1.1, “Servicing the WDOG to Reload the Counter”) before interrupt generation, then the counter is reloaded with the time-out value WT[7:0] of the Watchdog Control Register (WCR) and an interrupt is not triggered.

49.4.3 Power-Down Counter Event

The power-down counter inside the WDOG module is enabled out of reset. This counter has a fixed time out value of 16 seconds, after which it drives the $\overline{\text{WDOG}}$ signal low to prevent this, the software must disable this counter by clearing the PDE bit of Watchdog Miscellaneous Control Register (WMCR) within 16 seconds of reset de-assertion. After it is disabled, this counter cannot be enabled again until the next system reset occurs. This feature is provided to prevent cores being hung up after reset, as WDOG is not enabled out of reset.

49.4.4 Low-Power Modes

49.4.4.1 STOP Mode

If the WDOG timer low-power bit (WDZST) in the Watchdog Control Register (WCR) is 0, the WDOG timer continues to operate using the low-frequency reference clock. If the WDZST bit is set to 1, then the WDOG Timer operation is suspended in Low-power STOP mode. Upon exiting Low-power STOP mode, the WDOG operation returns to what it was prior to entering STOP mode.

49.4.4.2 WAIT Mode

If the WDOG timer disable bit for low-power WAIT mode (WDW) bit in the Watchdog Control Register (WCR) is 0, the WDOG timer continues to operate using the low-frequency reference clock. If the low-power WAIT Enable (WDW) bit is set to 1, then the WDOG Timer operation is suspended. Upon exiting low-power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

NOTE

The WDOG timer is not able to detect events that occur for periods less than one low-frequency reference clock cycle. For example, in repeated WAIT mode entry/exit, if the RUN mode time is less than one low-frequency reference clock cycle and if the WDW bit is set, then the WDOG timer may never time out even though the system is in RUN mode for a finite duration, because the WDOG timer may not see any low-frequency reference clock edge during its wake time.

49.4.5 Debug Mode

The WDOG timer can be configured for continual operation, or the operation can be suspended during debug mode. If the WDOG debug enable (WDBG) bit is set to 1 in the Watchdog Control Register (WCR), the WDOG Timer operation is suspended in debug mode. In the case of the WDBG bit being set to 1 and Debug mode being entered, WDOG timer operation is suspended after 2 low-frequency reference clocks and similarly WDOG Timer operation is continued after 2 low-frequency reference clocks of Debug mode Exit. Register read and write accesses in Debug mode continue to function normally. Also, while in DEBUG mode, the WDE bit of Watchdog Control Register (WCR) can be enabled-disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG Timer operation is not suspended. Power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of Watchdog Control Register (WCR) is set/cleared while in DEBUG mode, it remains set/cleared even after exiting DEBUG mode.

49.4.6 Operations

This section describes the module's operations.

49.4.6.1 Watchdog Reset Generation

The WDOG generated reset signal $\overline{\text{wdog\_rst}}$ is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control Register (WCR).
- WDOG time-out. See Section 49.4.1, "Time-Out Event."

The $\overline{\text{wdog\_rst}}$ signal is asserted for one clock cycle of the low-frequency reference clock for both the time-out condition and software write occurrence. It remains asserted for 1 clock cycle of the low-frequency reference clock, even if a system reset is asserted in between. Figure 49-9 shows the timing diagram of this signal due to a time-out condition.

49.4.6.2 WDOG_B Generation

The WDOG module asserts $\overline{\text{WDOG}}$ under the following scenarios:

- Software write to WDA bit of Watchdog Control Register (WCR). $\overline{\text{WDOG}}$ Signal remains asserted as long as the WDA bit is 0.
- WDOG time-out condition, WDT bit of Watchdog Control Register (WCR) must be set for this scenario. Description of the time-out condition can be found in the Section 49.4.1, "Time-Out Event." $\overline{\text{WDOG}}$ Signal remains asserted until a Power-on Reset (POR) occurs. It gets cleared after the POR occurs and not due to any other system reset. Figure 49-10 shows the timing diagram of $\overline{\text{WDOG}}$ due to time-out condition.
- WDOG Power-down Counter time-out, PDE bit of Watchdog Miscellaneous Control Register (WMCR) is not cleared in this scenario. Description of this counter can be found in the Section 49.4.3, "Power-Down Counter Event." The $\overline{\text{WDOG}}$ Signal remains asserted for one clock cycle of the low-frequency reference clock.

Figure 49-8 shows the scenarios under which $\overline{\text{WDOG}}$ gets asserted.

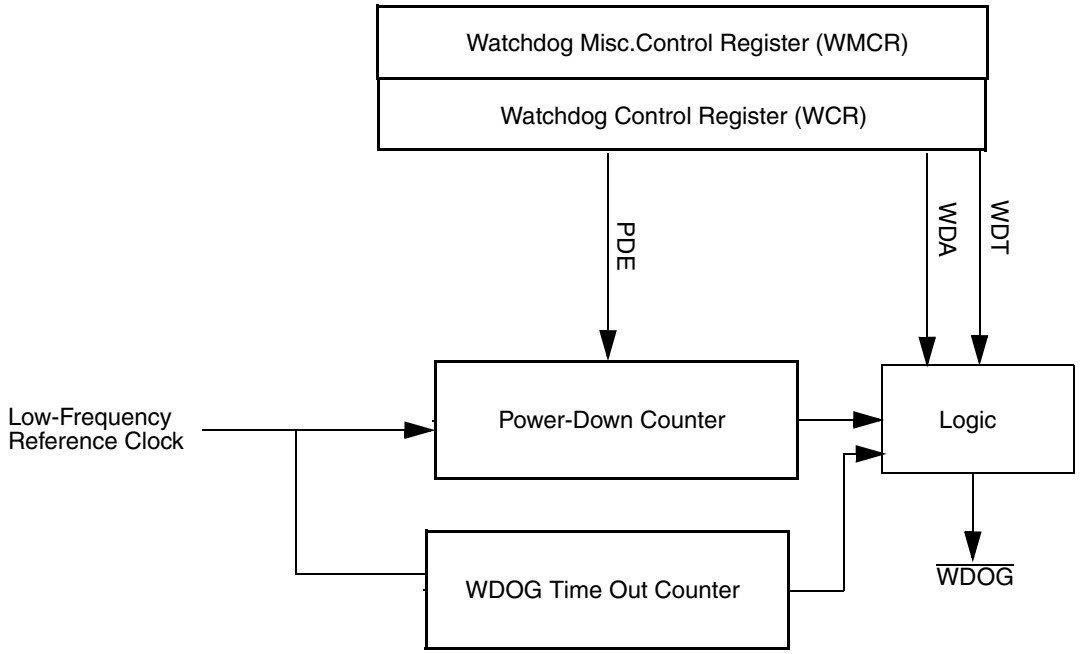

Figure 49-8. $\overline{\text{WDOG}}$ Generation

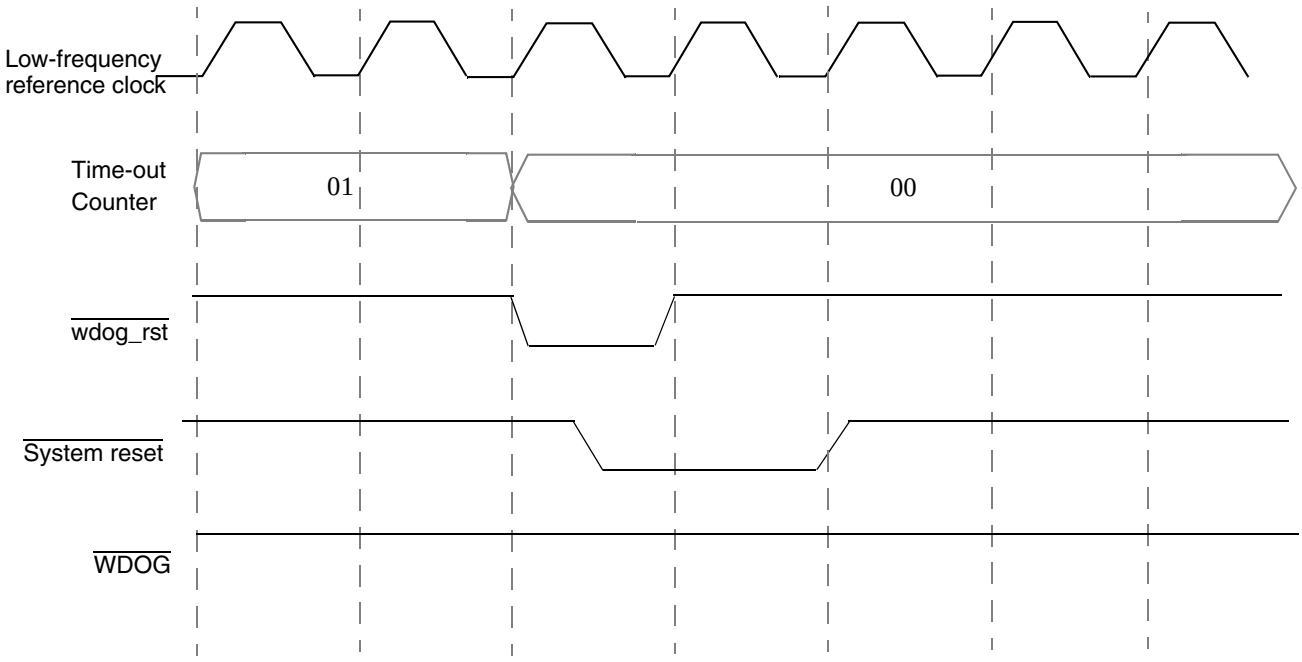

Figure 49-9. WDOG Time-Out Condition/WDT Bit Is Not Set

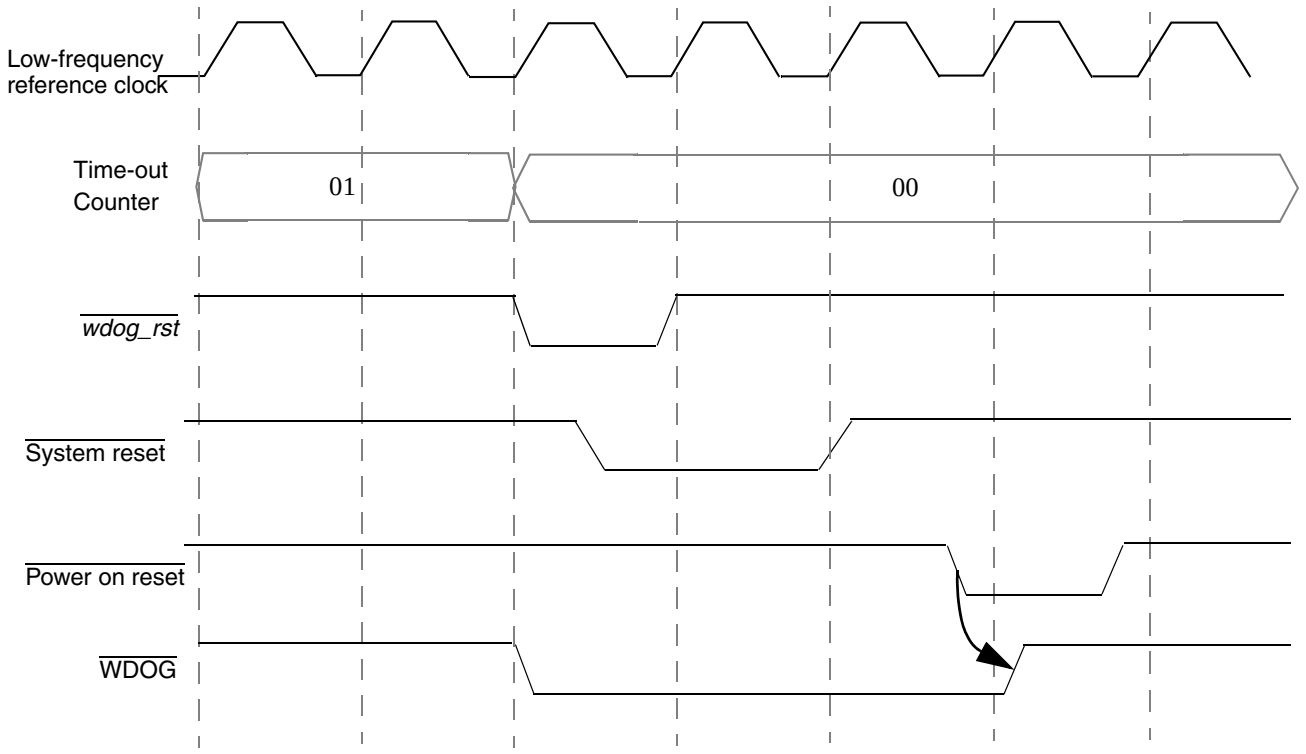

Figure 49-10. WDOG Time-Out Condition/WDT Bit Is Set

49.4.7 Clocks

This section describes clocks and special clocking requirements of the module.

The WDOG module uses the low-frequency reference clock for its counter and control operations. The peripheral bus clock is used for register Read/Write operations.

The low-frequency reference clock is a free running clock and cannot be gated. The peripheral bus clock cannot be gated and is selectively switched ON whenever Read/Write operations take place.

49.4.8 Reset

This section describes how to reset the module and explains special requirements related to reset.

The module is reset by a system reset and has the following consequences:

- The WDOG counter is disabled.
- The Power-Down counter is enabled and starts counting.

49.4.9 Interrupt

The WDOG module has the feature of Interrupt generation before time-out. The interrupt is generated only if the WIE bit in the Watchdog Interrupt Control Register (WICR) is set. The exact time at which the interrupt occurs prior to time-out depends on the value of the WICT field of the Watchdog Interrupt

Control Register (WICR). As an example, if the WICT field has a value of 0x04, then the interrupt is generated 2 seconds prior to time-out. After the interrupt is triggered, the WTIS bit in the Watchdog Interrupt Control Register (WICR) is set. The software need to clear this bit to negate the Interrupt. If the WDOG is serviced before the interrupt generation then the counter is reloaded with the time-out value WT[7:0] of Watchdog Control Register (WCR) and an interrupt is not be triggered.

49.4.10 Flow Diagrams

A flow diagram of watchdog operation is shown in Figure 49-11, Figure 49-12 and Figure 49-13.

49.5 Initialization

The following programming sequence initializes the WDOG module:

- The WMCR[PDE] bit is cleared to disable the power-down counter.
- The WMCR[WDT] field is programmed for a sufficient time-out value.
- The WDOG module is enabled by setting the WMCR[WDE] bit so that the time-out counter loads the WMCR[WDT] field value and starts counting.

Chapter 50
Wireless External Interface Module (WEIM)

This chapter describes the wireless external interface module (WEIM) implemented on this device, and covers the following topics:

- Section 50.2, “External Signal Description”
- Section 50.3, “Memory Map and Register Definition”
- Section 50.4, “Functional Description”
- Section 50.5, “Initialization/Application Information”

50.1 Overview

The wireless external interface module (WEIM) handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous and synchronous access to devices with SRAM-like interfaces.

Figure 50-1 shows a top-level WEIM block diagram. The external signals shown in Figure 50-1 are described in Section 50.2, “External Signal Description” (see Table 50-2).

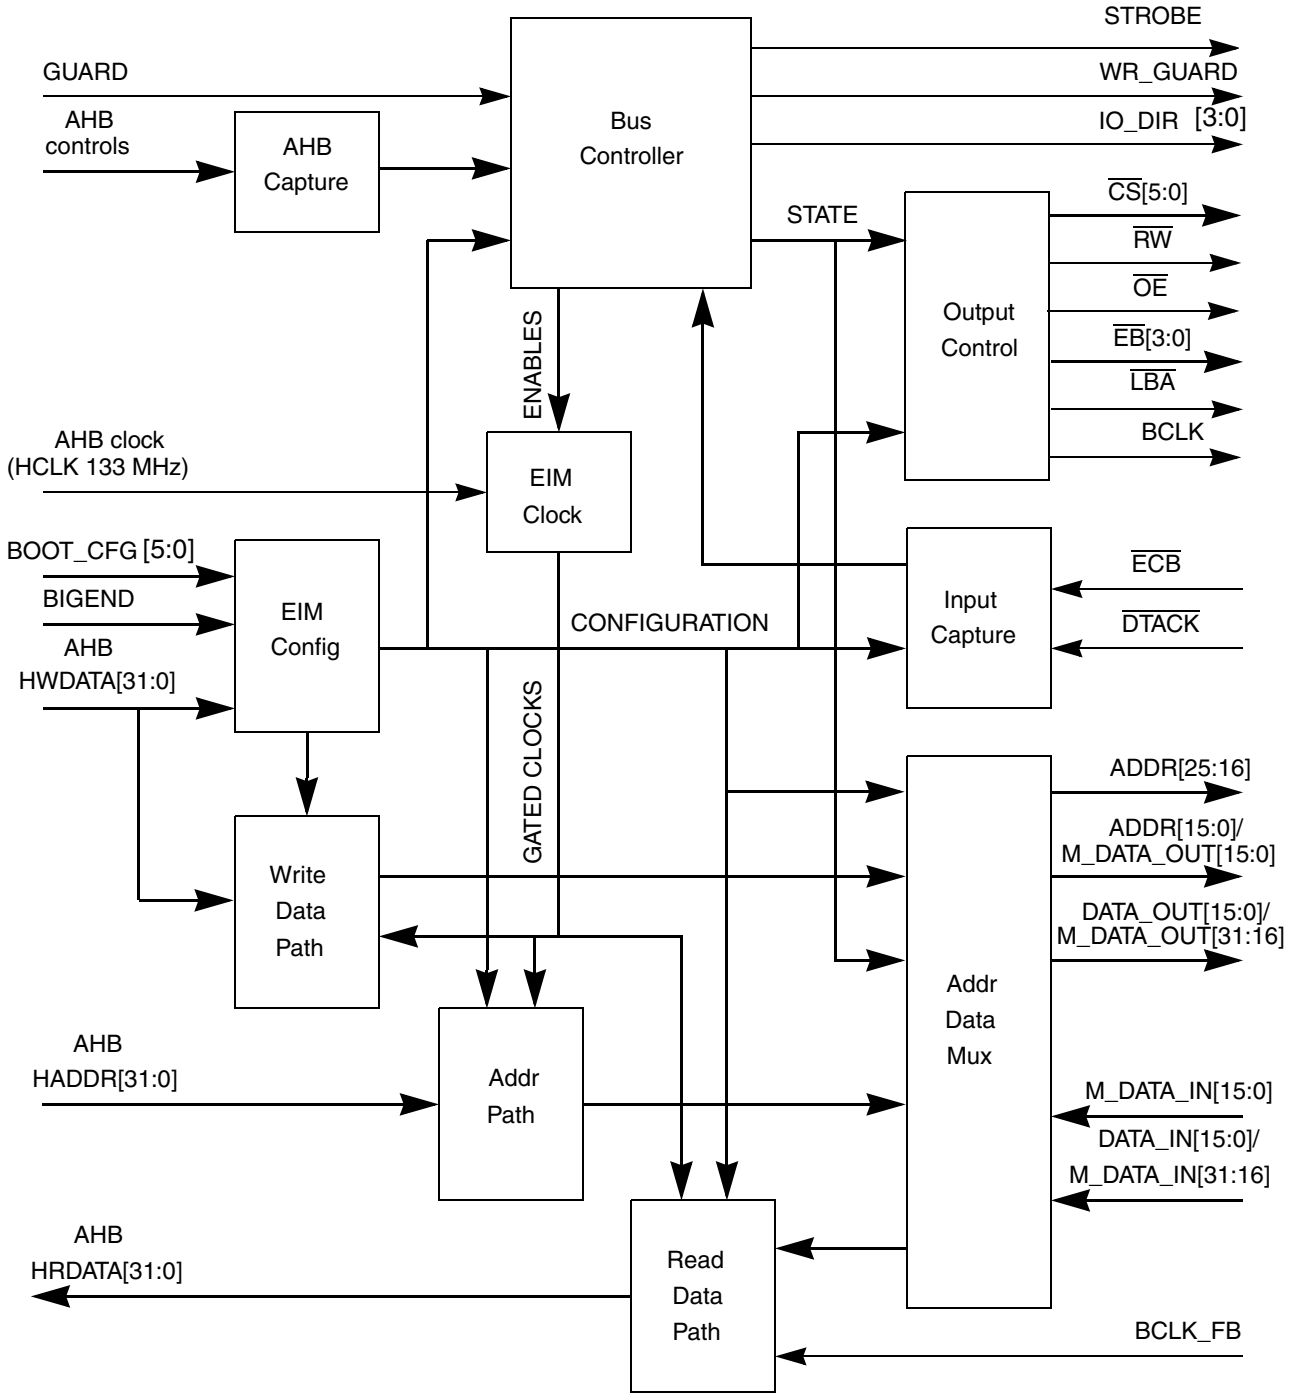

Figure 50-1. WEIM Block Diagram

50.1.1 Features

The WEIM includes the following features:

- Six chip selects for external devices, with $\overline{CS0}$ and $\overline{CS1}$ each covering a range of 128 Mbytes and $\overline{CS2}$–$\overline{CS5}$ each covering a range of 32 Mbytes
- $\overline{CS0}$ range can be increased to 256 Mbytes when collapsed with $\overline{CS1}$
- Selectable protection for each chip select
- Programmable data port size for each chip select
- Asynchronous accesses with programmable setup and hold times for control signals
- Synchronous memory burst read mode support for AMD, Intel, and Micron burst Flash memory
- Synchronous memory burst write mode support for PSRAM (CellularRAM™ from Micron, Infineon, and Cypress), fixed write latency support
- Support for multiplexed address / data bus operation
- External cycle termination/postpone with $\overline{DTACK}$ signal
- Programmable wait-state generator for each chip select
- Support for big-endian and little-endian modes of operation per access
- ARM AHB slave interface

50.1.2 Modes of Operation

The WEIM has six modes of operation. No dedicated low-power mode is included, because most of the clocks are gated when there are no accesses to the WEIM, providing maximum energy conservation.

The WEIM modes of operation are as follows:

- Asynchronous mode. This is a non-burst mode is used for NOR Flash and SRAM access. In this mode a single data is read/written with each access (asserted address). Timings are controlled by preset values in the chip select control registers. In this mode, the size of data writes should match the external data bus width. For example, only half-word writes should be performed if the external memory bus width is 16 bits.
- Synchronous read mode. This is a burst mode is used for reading Flash memory devices. In this mode, after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK clock generated by WEIM. An access may be delayed by the assertion of the external $\overline{ECB}$ signal after the first word of data.
- Page mode.This mode is used for memory burst read, but the address is asserted for each data in the burst as $\overline{LBA}$ and BCLK operate asynchronously. In this mode the setup time is greater for the first data burst than for the remaining data in the burst (from the same page).
- Synchronous read/write mode for PSRAM synchronous mode and peripherals with write burst capability. In this mode both reads and writes are synchronous. Access may be additionally delayed according to the $\overline{ECB}$ state before the first piece of data arrives (refresh wait enable).
- DTACK mode. This is a non-burst mode used for PCMCIA accesses. In this mode WEIM waits for $\overline{DTACK}$ acknowledge until 1024 counts of the AHB clock have passed. In this mode $\overline{DTACK}$ can be used as either posedge or level sensitive, according to WSC field and EW bit settings.

- Multiplexed Address/Data mode. This mode supports multiplexing of addresses and data bits on the same pins for synchronous/asynchronous accesses to 32-bit data width memory devices.

50.2 External Signal Description

This section provides an overview and detailed description of WEIM external signals.

50.2.1 Overview

Table 50-2 lists input and output signals between the WEIM and the external devices.

Table 50-2. Signal Properties

Name	Port	Function	Direction	Reset State
ADDR[25:16]	—	Address bus MSB / $\overline{EB}$[3:2], CRE	Out	Low
ADDR[15:0]/ M_DATA_OUT[15:0]	—	Address bus LSB / Output data multiplexed bus LSB	Out	Low
BCLK	—	Burst Clock	Out	Low
BCLK_FB	—	Feedback burst clock	In	—
BIGEND	—	Data endian mode	In	—
BOOT_CFG[5:0]	—	Boot configuration	In	—
$\overline{CS}$[5:0]	—	Chip selects	Out	High
DATA_IN[15:0]/ M_DATA_IN[31:16]	—	Input data bus LSB / Input data multiplexed bus MSB	In	—
DATA_OUT[15:0]/ M_DATA_OUT[31:16]	—	Output data bus LSB / Output data multiplexed bus MSB	Out	Low
$\overline{DTACK}$	—	Data transfer acknowledge / wait	In	—
$\overline{EB}$[3:0]	—	Enable Byte	Out	High
$\overline{ECB}$	—	End current burst / wait	In	—
GUARD	—	Input guard	In	—
IO_DIR[3:0]	—	I/O direction	Out	Low
$\overline{LBA}$	—	Load burst address	Out	High
M_DATA_IN[15:0]	—	Input data multiplexed bus LSB	In	—
$\overline{OE}$	—	Output enable	Out	High
$\overline{RW}$	—	Read/write	Out	High
WR_GUARD	—	Write guard	Out	High

50.2.2 Detailed Signal Descriptions

Table 50-3 gives a detailed description of the WEIM signals.

Table 50-3. WEIM Detailed Signal Descriptions

Signal	I/O	Description
ADDR[25:16]	IO	Address Bus MSB. These signals are used as address bits [25:16]. In multiplexed mode these signals do not change their state. If the corresponding AUS*x* bit is set in the WEIM control register, these signals reflect AHB address bits [25:16]. If the AUS*x* bit is not set, these signals represent AHB address bits [27:18] for word width memory, [26:17] for half-word width memory and [25:16] for byte-width memory. In the multiplexed mode (MUM = 1 in the chip select *x* additional control register), then ADDR[25:24] or ADDR[24:23] (depending on the CRER bit setting in the WEIM control register) are also used as $\overline{EB}$[3:2] outputs. ADDR[23] or ADDR[25] is also used as the CRE output in PSRAM mode (PSR=1).
ADDR[15:0]/ M_DATA_OUT [15:0]	IO	Multiplexed Address Bus LSB/Output Data Bus LSB. In non-multiplexed mode these signals are used as address bits [15:0]. If the corresponding AUS*x* bit is set in the WEIM control register, these signals reflect AHB address bits [15:0]. If the AUSx bit is not set, these signals reflect AHB address bits [17:2] for word width memory, [16:1] for half-word width memory and [15:0] for byte width memory. In multiplexed address/data mode these bits are multiplexed between address and output data bits [15:0]. The behavior in multiplexed address/data mode is affected by the LBA, LBN and LAH fields in the chip select control registers. In synchronous multiplexed mode the behavior is affected by the BCS, BCD and LAH fields. The bidirectional LSB address/data bus is made in IO PAD from M_DATA_IN[15:0] and ADDR[15:0]/M_DATA_OUT[15:0].
BCLK	O	Burst Clock. This active-high output signal BCLK is used to clock external, burst-capable devices to synchronize the loading and incrementing of addresses and delivery of burst read and write data to/from the WEIM. Its behavior is affected by the BCM bit in the WEIM configuration register and the SYNC, BCD and BCS fields in the chip select control registers. BCLK can start on both rising and falling edge of HCLK.
BCLK_FB	I	Burst Clock Feedback. This input is used to provide the input data sampling clock at high data speeds. It is a feedback from the I/O pin of the BCLK output signal that is used to align the clock used by the memory with the clock used to sample the read data.
BIGEND	I	Big/Little Endian. This input is used to provide big/little-endian support in the WEIM. WEIM supports big- and little-endian accesses according Table 50-4. WEIM also supports mixing big- and little-endian accesses.
BOOT_CFG [5:0]	O	Boot configuration. These input pins determine the state of some WEIM configuration bits after hardware reset. Settings are given in the following table. **BOOT_CFG Bits** / **Configured Bits** / **Location of Configured Bits** 5 / AUS0 / WEIM configuration register (WCR) 4 / MUM / Chip select 0 upper control register (CSCR0U) 3 / MAS / WEIM configuration register 2:0 / DSZ[2:0] / Chip select 0 upper control register (CSCR0U)
$\overline{CS}$[5:0]	O	Chip selects. The $\overline{CS}$[5:0] signals are chip selects active-low output pins. The behavior is affected by the CSA and CSN fields in the chip select control registers. The $\overline{CS}$[0] address space range can be increased to 256 Mbytes by merging the $\overline{CS}$[0] and $\overline{CS}$[1] ranges. In this case the merged address space (MAS) bit is set in the WEIM configuration register, and the $\overline{CS}$[1] pin is used as address line A26. As shown in Table 50-6, the chip select signals are asserted based on a decode of address lines [31:24] (when enabled).

Table 50-3. WEIM Detailed Signal Descriptions (Continued)

Signal	I/O	Description
DATA_IN[15:0]/ M_DATA_IN [31:16]	IO	Input Data Bus LSB / Input Data Multiplexed Bus MSB. These signals are the input data bus used to transfer data from external devices. In a non multiplexed mode it is LSB, in a multiplexed mode it is MSB. The bidirectional LSB data bus are made in the IO PAD from DATA_IN[15:0]/M_DATA_IN[31:16] and DATA_OUT[15:0]/M_DATA_OUT[31:16].
DATA_OUT[15:0]/ M_DATA_OUT [31:16]	0	Output Data Bus LSB / Output Data Multiplexed Bus MSB. These signals are the output data bus used to transfer data to an external devices. In non-multiplexed mode it is LSB, and in multiplexed mode it is MSB. The bidirectional LSB data bus is made in IO PAD from DATA_IN[15:0]/M_DATA_IN[31:16] and DATA_OUT[15:0]/M_DATA_OUT[31:16].
$\overline{\text{DTACK}}$	I	Data Transfer Acknowledge. This input signal is used to externally terminate a data transfer when enabled. For $\overline{\text{DTACK}}$ enabled cycles, the bus time-out monitor generates a bus error if $\overline{\text{DTACK}}$ is asserted and is not negated before 1024 clocks have elapsed. This signal is used in two modes: with rising edge detection or with level detection with an insensitiveness time. Edge detection mode is used for devices like PCMCI cards. Level detection mode is used for asynchronous devices like ATI graphics controllers. $\overline{\text{DTACK}}$ control keeps backward compatibility with previous architectures that used it in the Application processors.
$\overline{\text{EB}}$[3:0]	O	Enable Byte. Those active-low output pins indicate active data bytes for the current access. They may be configured to assert for both read and write cycles or for write cycles only, as programmed in the chip select control registers. $\overline{\text{EB}}$[0] corresponds to DATA_OUT[7:0] and M_DATA_OUT[7:0]. $\overline{\text{EB}}$[1] corresponds to DATA_OUT[15:8] and M_DATA_OUT[15:8]. $\overline{\text{EB}}$[2] corresponds to M_DATA_OUT[23:16]. $\overline{\text{EB}}$[3] corresponds to M_DATA_OUT[31:24]. In the multiplexed mode (MUM = 1), $\overline{\text{EB}}$[3:2] also are multiplexed to the ADDR[25:24] bits (or ADDR[24:23], depending on the CRER bit setting in the WEIM control register). For write accesses the behavior of $\overline{\text{EB}}$ is affected by the EBWA, EBWN, and EBC fields in the chip select control registers. For read accesses the behavior of $\overline{\text{EB}}$ is affected by the EBRA and EBRN fields in the chip select control registers.
$\overline{\text{ECB}}$	I	End Current Burst (WAIT). This active-low input signal $\overline{\text{ECB}}$ is asserted by external burst capable devices. It is serviced in synchronous mode only (SYNC=1). This signal can be used in two different modes depending on the EW bit setting in the chip select control register, as follows: • In ECB mode (EW=0) $\overline{\text{ECB}}$ indicates the end of the current (continuous) burst sequence. Following assertion, the WEIM terminates the current burst sequence and initiate a new one. • In wait mode (EW=1) the memory device asserts this signal to insert wait states during refresh collisions or during a row boundary crossing. Following assertion, the WEIM does not terminate the current burst sequence and continues it once WAIT is negated. $\overline{\text{ECB}}$ has a pull-up resistor in I/O. For burst devices $\overline{\text{ECB}}$/WAIT output should be configured to change one cycle before data is ready (before delay).
GUARD	I	Guard. This active-high input signal indicates that I/O is locked by another module and current access should be postponed until I/O is unlocked. GUARD and WR_GUARD together are used in back-to-back accesses between memory controllers to avoid contention on the shared pins.

Table 50-3. WEIM Detailed Signal Descriptions (Continued)

Signal	I/O	Description
IO_DIR[3:0]	O	IO Direction. These active-high output signals indicate I/O direction (0 for input and “1” for output). Bidirectional buses are made in the I/O module from the ADDR[15:0]/M_DATA_OUT[15:0] and M_DATA_IN[15:0]and from the DATA_OUT[15:0]/M_DATA_OUT[31:16] and DATA_IN[15:0]/M_DATA_IN[31:16]. Bit IO_DIR[0] corresponds to ADDR[7:0]/M_DATA_OUT[7:0] / M_DATA_IN[7:0], bit IO_DIR[1] corresponds to ADDR[15:8]/M_DATA_OUT[15:8] / M_DATA_IN[15:8], bit IO_DIR[2] corresponds to DATA_OUT[7:0]/M_DATA_OUT[23:16] / DATA_IN[7:0]/M_DATA_IN[23:16], bit IO_DIR[3] corresponds to DATA_OUT[15:8]/M_DATA_OUT[31:24] / DATA_IN[15:8]/M_DATA_IN[31:24].
$\overline{\text{LBA}}$	O	Load Burst Address. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of $\overline{\text{LBA}}$ indicates that a valid address is present on the address bus. Its behavior is affected by the SYNC bit, BCD, BCS, LBA and LBN fields in the Chip Select control registers. In asynchronous mode (SYNC=0) $\overline{\text{LBA}}$ length decreased by LBA and LBN fields. In the synchronous mode (SYNC=1) $\overline{\text{LBA}}$ length is equal BCD + BCS + LBN + 1 half AHB clock cycles.
M_DATA_IN[15:0]	I	Multiplexed Data Input Bus. These signals are the LSB input data bus used to transfer data from an external devices in multiplexed mode. The bidirectional LSB address/data bus is made in IO PAD from M_DATA_IN[15:0] and ADDR[15:0]/M_DATA_OUT[15:0].
$\overline{\text{OE}}$	O	Output Enable. This active-low output signal $\overline{\text{OE}}$ indicates the bus access is a read, and enables slave devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN fields in the Chip Select control registers.
$\overline{\text{RW}}$	O	Read/Write. The $\overline{\text{RW}}$ output signal indicates if the current bus access is a read or write cycle. A high (logic one) level indicates a read cycle and a low (logic zero) level indicates a write cycle. Its behavior is affected by the RWA and RWN fields in the Chip Select control registers.
STROBE	O	Strobe. This signal allows capture current access controls, address and data on logic analyzer. sync. and async. accesses are supported.
WR_GUARD	O	WR_GUARD. This active-high output signal indicates that I/O is locked by WEIM. (It is asserted also in Extra Dead Cycles time). WR_GUARD and GUARD together are used in back-to-back accesses between memory controllers to avoid contention on the shared pins.

Table 50-4 shows example of WEIM input-output signals for different AHB and port configurations.

Table 50-4. WEIM Out/In Data in Case AHB Out/In Data is 0xB3B2_B1B0

50.3 Memory Map and Register Definition

The WEIM module includes 19 user-accessible 32-bit registers. These registers are accessible only in supervisor mode, with 32-bit reads and writes.

The WEIM registers can be summarized as follows:

- The WEIM configuration register (WCR) contains control bits that configure the WEIM for different modes of operation.
- In addition, each chip select has three chip select control registers denoted as upper, lower, and additional respectively. These registers are identical for chip selects 1–5, but for chip select 0 the registers' reset states depend on the BOOT_CFG input.

Complete decoding is not performed, so shadowing can occur with these registers. The user should not attempt to address these registers at any other address location other than those listed in the Table 50-5 and Table 50-6.

50.3.1 Memory Map

The memory map for the WEIM is shown in the Table 50-5 and the memory map for the Chip Select memory ranges is shown in the Table 50-6.

Table 50-5. WEIM Memory Map

Address	Use	Access	Reset	Section/Page
0x0000 (CSCR0U)	Chip Select 0 Upper Control Register	R/W	0x0000_1E00	50.3.3.1/50-15
0x0004 (CSCR0L)	Chip Select 0 Lower Control Register	R/W	0xA000_0841[1]	50.3.3.2/50-20
0x0008 (CSCR0A)	Chip Select 0 Additional Control Register	R/W	0x0000_5000	50.3.3.3/50-23
0x0010 (CSCR1U)	Chip Select 1 Upper Control Register	R/W	0x0000_0000	50.3.3.1/50-15
0x0014 (CSCR1L)	Chip Select 1 Lower Control Register	R/W	0x0000_0000	50.3.3.2/50-20

Table 50-6. Chip Selection Memory Map

Address	Use	Access
0xA0000000 ... 0xA7FF_FFFF	$\overline{CS0}$ memory region	R/W
0xA8000000 ... 0xAFFF_FFFF	$\overline{CS1}$ memory region	R/W
0xB0000000 ... 0xB1FF_FFFF	$\overline{CS2}$ memory region	R/W
0xB2000000 ... 0xB3FF_FFFF	$\overline{CS3}$ memory region	R/W
0xB4000000 ... 0xB5FF_FFFF	$\overline{CS4}$ memory region	R/W
0xB6000000 ... 0xB7FF_FFFF	$\overline{CS5}$ memory region	R/W

50.3.2 Register Summary

Figure 50-2 shows the key to the register fields and Table 50-7 shows the register figure conventions.

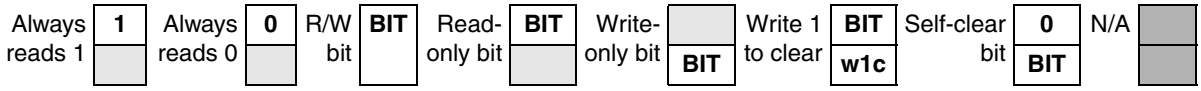

Figure 50-2. Key to Register Fields

Table 50-7. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read-only. Writing this bit has no effect.
W	Write-only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.

Table 50-7. Register Figure Conventions (Continued)

Convention	Description
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

50.3.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bits and field function follow the register diagrams, in bit order. The 96 bits used to control each chip select are divided into three registers: chip select *x* upper control register (CSCR*x*U), chip select *x* lower control register (CSCR*x*L) and chip select *x* additional control register (CSCRxA).

- Bits [95:64] are located in the chip select *x* upper control register (see Figure 50-3).
- Bits [63:32] are located in the chip select *x* lower control register (see Figure 50-4).
- Bits [31:0] are located in the chip select *x* additional control register (see Figure 50-5).

Table 50-8 provides a summary of the registers in the WEIM module. For the base address of a particular module instantiation, see the system memory map.

Table 50-8. WEIM Register Summary

Base Address Offset (Name Abbreviation)		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0000 (CSCR0U)	R	SP	WP	BCD		BCS				PSZ		PME	SYNC	DOL

[1] The WSC field (bits 8 - 13) reset value is 011110 for CS0U register and is 0 for all others.

Table 50-9. Chip Select *x* Upper Control Register Field Descriptions

Field	Description
31 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in a error response on the AHB and no assertion of the chip select output.
30 WP	Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset. 0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response on the AHB and no assertion of the chip select output.
29–28 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal AHB bus frequency (HCLK 133 MHz). See 50.4.4/50-31 for more information on the burst clock divisors. An example is shown in Figure 50-41. When the BCM bit is set in the WEIM configuration register, BCD is ignored. BCD is cleared by a hardware reset. **Note:** When working with DOL=BCD=0, SYNC=1,FCE should be configured to 1 and EDC field should be configured to 4, because of tight timings in the controller. 00 Divide AHB clock by 1 01 Divide AHB clock by 2 10 Divide AHB clock by 3 11 Divide AHB clock by 4

Table 50-9. Chip Select *x* Upper Control Register Field Descriptions (Continued)

Field	Description
27-24 BCS	Burst Clock Start. If SYNC = 1 this bit field determines the number of half cycles after address assertion before the first rising edge of BCLK is seen. See example on the Figure 50-41. A value of 0 results in a half clock delay, not an immediate assertion. When the BCM bit is set in the WEIM configuration register, this overrides the BCS bits. BCS is cleared by a hardware reset. **Note:** when working in synchronous mode when DOL=BCD=0/1 and FCE=1, BCS should be configured to an odd number (1,3,5,...). 0000 1 half AHB clock cycle. 0001 2 half AHB clock cycles. ... 1111 16 half AHB clock cycles.
23–22 PSZ	Page Size. If PME is clear the PSZ bit field indicates memory burst length in words (where *word* is defined by the DSZ field) and should be properly initialized for mixed wrap/increment AHB accesses support. Continuous PSZ value corresponds to continuous burst length setting of the external memory device. If PME is set (set to 1) the PSZ bit field indicates number of words (where “word” is defined by the port size in DSZ field) in a page in memory. This ensures that the WEIM does not burst past a page boundary at increment access when the PME bit is set. PSZ is cleared by a hardware reset. See Table 50-10 for PSZ Bit Field Combinations.
21 PME	Page Mode Emulation. This bit enables page mode emulation in burst mode. When PME is set (and SYNC equals 1), the external address is asserted for each piece of data requested. Additionally, the $\overline{\text{LBA}}$ and BCLK signals behave in the same way when an asynchronous access is performed (see Figure 50-25). PME is cleared by a hardware reset. 0 Disables page mode emulation 1 Enables page mode emulation
20 SYNC	Synchronous Burst Mode Enable. This bit enables synchronous burst mode if PME is clear (see also PME and PSR description). When enabled, the WEIM is capable of interfacing to burst Flash devices through additional burst control signals: BCLK, $\overline{\text{LBA}}$, and $\overline{\text{ECB}}$ (see example on the Figure 50-29). The sequencing of these additional I/Os is controlled by other WEIM configuration register bit settings as described in Section 50.4.3/50-31. If SYNC = 1 and PSR = 0, reads will be performed synchronously and writes will be performed asynchronously. If SYNC = 1 and PSR = 1, both reads and writes will be performed synchronously. SYNC =1, PSR = 1 and PME =1 is a reserved configuration forbidden for use. SYNC is cleared by a hardware reset. 0 Disables synchronous burst mode 1 Enables synchronous burst mode

Table 50-9. Chip Select *x* Upper Control Register Field Descriptions (Continued)

Field	Description
19–16 DOL	Data Output Length. If the SYNC is set (equals 1) the DOL bit field specifies number of wait states during the burst access after the delay of the first data according to the settings shown below (see examples on the Figure 50-25 and Figure 50-40). The reset value 0 specifies that burst data is held for a single AHB clock period. As AHB clock frequencies increase, it may become necessary to delay sampling the data for multiple AHB clock periods in order to meet burst memory setup and/or frequency specifications and/or WEIM data setup time requirements. DOL has no effect on burst data length when SYNC = 0. DOL is cleared by a hardware reset. Bit 19, in addition, allows to write with fixed latency, to support this mode for PSRAM ver.1.5 and above. **Note:** When working with DOL=BCD=0, SYNC=1,FCE should be configured to 1 and EDC field should be configured to 4. 0000 1 AHB clock cycle data length. 0001 2 AHB clock cycles data length. ... 1111 16 AHB clock cycles data length. 0111 8 AHB clock cycle data length. 1000 1 AHB clock cycle data length, fixed write latency. 1001 2 AHB clock cycles data length, fixed write latency. ... 1111 8 AHB clock cycle data length, fixed write latency.
15–14 CNC	Chip Select Negation Clock Cycles. This bit field specifies the minimum number of clock cycles a chip select must remain negated after it is negated (but doesn't guarantee negation for back-to-back accesses, it requires EDC using) according to the settings shown below. See examples on the Figure 50-12, and Figure 50-13. CNC has no effect on write accesses when any CSA bit is set. CNC is cleared by a hardware reset. The number of clock cycles of this field can be increased using the CNC2 bit in the appropriate Chip Select Additional Control Register. The number of AHB clock cycles produced by both bit fields is shown in. 00 0 Minimum number of AHB clock cycles $\overline{CS}$ must remain negated. 01 1 Minimum number of AHB clock cycles $\overline{CS}$ must remain negated. 10 2 Minimum number of AHB clock cycles $\overline{CS}$ must remain negated. 11 3 Minimum number of AHB clock cycles $\overline{CS}$ must remain negated.
13–8 WSC	Wait State Control. This bit field programs the number of wait-states for an access to the external device connected to the chip select (see Figure 50-7). For SYNC = 1 WSC programs the number of AHB clock cycles required for the initial access (see Figure 50-25, and Figure 50-32) of a memory burst sequence initiated by the WEIM to an external burst device. For EW = 1 after the wait cycle count expires $\overline{ECB}$ is sampled and the cycle terminates when the $\overline{ECB}$ is negated. On other case WEIM special watch dog counter check that $\overline{ECB}$ will not be asserted for more than 1024 AHB clocks. Additionally in this case WEIM suppresses $\overline{LBA}$ generation after next $\overline{ECB}$ assertion (during increment burst at page boundary crossing). For write accesses the number of wait-states is increased according WWS value or decreased by DWW (see Table 50-11). WSC = 11_1111 indicates operation in a positive edge-sensitive DTACK mode. It selects $\overline{DTACK}$ input as access length control sign (instead of default WSC counter). It means that access length is determined by $\overline{DTACK}$ length. WSC is set to 01_1110 by a hardware reset for CSCR0. WSC is cleared by a hardware reset for CSCR1 – CSCR5. **Note:** WSC usage when SYNC=1, PSR=1 and FCE=1 is to mask the ECB_B signal for read accesses, and should be determined from the access time of the specific connected memory. **Note:** For SYNC=1, PSR=0 and DOL=0 the WSC value should be at least 4. **Note:** For SYNC=1, MUM =0, WSC≥ 2(BCD + 1) + (BCS + LBN + 2)/2. **Note:** For SYNC=1, MUM =1, WSCŠ 2(BCD + 1) + (BCS + LBN + 2 + LBH) + 2/2.

Table 50-9. Chip Select *x* Upper Control Register Field Descriptions (Continued)

Field	Description
7 EW	$\overline{ECB}$/WAIT. This bit determines how WEIM supports the $\overline{ECB}$ input in the synchronous mode. In asynchronous mode this bit determines the operation of level-sensitive DTACK mode. (see Table 50-18 for EW effect on WEIM operation modes) 0 For SYNC = 1, if $\overline{ECB}$ goes to low state in the middle of a memory burst access, then the WEIM starts a new access by asserting the current AHB address to the ADDR pins and LBA assertion (ECB mode). If SYNC = 0 and WSC=111111, the WEIM waits for $\overline{DTACK}$ posedge for access termination. 1 if $\overline{ECB}$ goes to low state in the middle of a memory burst access, then the WEIM waits until $\overline{ECB}$ goes high (WAIT mode) to continue current access; at the end of the first access in burst, it allows the delay of $\overline{ECB}$ negation until 1024 clocks. For SYNC = 0, WEIM begins access and after (2+DCT) clocks tests $\overline{DTACK}$ input. If $\overline{DTACK}$ is low WEIM waits. If $\overline{DTACK}$ is high, then it loads the WSC value (see Figure 50-27 and Figure 50-28). **Note:** EW configuration does not influence the controller behavior when a nonaligned burst access occurs in the page boundary. For example, INC16 memory configuration is used when the burst start address is 0xF8 (nonaligned, should be 0xE0), in that case, the controller makes another access to the next page to complete the initial burst access.
6–4 WWS	Write Wait State. This bit field determines whether additional wait-states are required for write cycles (see Table 50-11). This is useful for writing to memories that require additional data setup time (see example on Figure 50-9). The DWW field should be zero when this field is in use. WWS is cleared by a hardware reset. **Note:** To decrease write wait states use the DWW bit field.
3–0 EDC	Extra Dead Cycles. This bit field determines whether idle cycles are inserted before a new access (see example in Figure 50-10). If the currently accessed CS EDC field is not empty then idle cycles are inserted before next access except for two conditions: current access is an asynchronous write (its SYNC = 0) or the next access is an asynchronous read from the same chip select. This field is used in two cases: • Slow memory or peripherals that use long CS or $\overline{OE}$ to output data hold times to prevent data bus contention on back-to-back external transfers. • Synchronous accesses (SYNC = 1) to provide $\overline{CS}$ high minimum pulse width (even for back-to-back accesses). The EDC field is cleared by a hardware reset. **Note:** When working with DOL=BCD=0, SYNC=1,FCE=1 EDC field should be configured to 4. 0000 0 No idle AHB clock cycles inserted. 0001 1 1 Idle AHB clock cycle inserted. ... 1111 15 AHB clock cycles inserted.

Table 50-10. PSZ Bit Field Values

PSZ	PME=0 Memory Burst Length	PME=1 Number of Words in Page
00	4	4
01	8	8
10	16	16
11	continuous	32

Figure 50-4. Chip Select *x* Lower Control Register

1 OEA (bits 28-31) reset value is 1010 for CSCR0L and 0 for CSCR*x*L with *x* > 0.

2 EBC (bit 11) reset value is 1 for CSCR0L and 0 for CSCR*x*L with *x* > 0.

3 DSZ (bits 8 - 10) reset value is determined by BOOT_CFG inputs for CSCR0L. For CSCRxL with *x* > 0, the reset value is 0.

4 CSN (bits 4 - 7) reset value is 0100 for CSCR0L and 0 for CSCRxL with *x* > 0.

5 Bit 0 reset value is 1 for CSCR0L and 0 for CSCR*x*L with *x* > 0.

Table 50-12. Chip Select *x* Lower Control Register Field Descriptions

Field	Description
31–28 OEA	$\overline{OE}$ Assert. This bit field determines when $\overline{OE}$ is asserted during a read cycle. For SYNC = 0, OEA determines the number of half clocks before $\overline{OE}$ asserts during a read cycle. For SYNC = 1, after the initial memory burst access, $\overline{OE}$ is asserted continuously for subsequent memory burst accesses, and is not affected by OEA (see memory burst read timing diagrams for more detail); the behavior of $\overline{OE}$ on the initial memory burst access is the same as when SYNC = 0 (see example on the Figure 50-25). The OEA field do not affect the cycle length. OEA is set to 1010 by a hardware reset for CSCR0L register and is cleared for other registers. **Note:** Minimum time $\overline{OE}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles between $\overline{OE}$ assertion and end of access 0001 1 Half AHB clock cycle between $\overline{OE}$ assertion and end of access ... 1111 15 Half AHB clock cycles between $\overline{OE}$ assertion and end of access
27–24 OEN	$\overline{OE}$ Negate. This bit field determines when $\overline{OE}$ is negated during a read cycle (see example on the Figure 50-20). Setting the SYNC bit (SYNC = 1) overrides OEN and $\overline{OE}$ negates at the end of a read access and no sooner. OEN does not affect the cycle length, except in posedge sensitive DTACK mode. OEN is cleared by a hardware reset. **Note:** The term “end of a read access” is the nearest possible address, data or control signal change by another access (an own next access or an access from others pin shared controller). **Note:** Minimum time $\overline{OE}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles between $\overline{OE}$ negation and end of access 0001 1 Half AHB clock cycle between $\overline{OE}$ negation and end of access ... 1111 15 Half AHB clock cycles between $\overline{OE}$ negation and end of access
23–20 EBWA	$\overline{EB}$ Write Assert. This bit field determines when $\overline{EB}$ [3:0] is asserted during write cycles (see example on the Figure 50-8). This is useful to meet data setup time requirements for slow memories. EBWA does not affect the cycle length. EBWA is cleared by a hardware reset. **Note:** Minimum time $\overline{OE}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles before $\overline{EB}$ is asserted. 0001 1 Half AHB clock cycle before $\overline{EB}$ is asserted. ... 1111 15 Half AHB clock cycles before $\overline{EB}$ is asserted.
19–16 EBWN	$\overline{EB}$ Write Negate. This bit field determines when $\overline{EB}$ [3:0] outputs are negated during a write cycle (see example on the Figure 50-8). This is useful to meet data hold time requirements for slow memories. EBWN does not affect the cycle length, except in posedge sensitive DTACK mode. Setting the SYNC bit (SYNC = 1) overrides EBWN and $\overline{EB}$ negates at the end of a write access and according AHB hbstrb[3:0]. EBWN is cleared by a hardware reset. **Note:** Minimum time $\overline{OE}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles between $\overline{EB}$ negation and end of access. 0001 1 Half AHB clock cycle between $\overline{EB}$ negation and end of access. ... 1111 15 Half AHB clock cycles between $\overline{EB}$ negation and end of access.

Table 50-12. Chip Select *x* Lower Control Register Field Descriptions (Continued)

Field	Description
15–12 CSA	$\overline{CS}$ Assert. This bit field determines when chip select is asserted for devices that require additional address setup time (see example on the Figure 50-11). It does not affect the cycle length. CSA is cleared by a hardware reset. **Note:** The CSA bit setting affects both reads and writes for all WEIM modes. 0000 0 Half AHB clock cycles before $\overline{CS}$ is asserted. 0001 1 Half AHB clock cycle before $\overline{CS}$ is asserted. ... 1111 15 Half AHB clock cycles before $\overline{CS}$ is asserted.
11 EBC	Enable Byte Control. This bit indicates the types of access that assert Enable Byte outputs $\overline{EB}$[3:0] (see example on Figure 50-7). The $\overline{EB}$[3:0] outputs can be configured as byte write enables. EBC is set by a hardware reset for CSCR0L register and is cleared for other registers. 0 Both read and write accesses assert the $\overline{EB}$[3:0] 1 Only write accesses assert the $\overline{EB}$[3:0], thus configuring as byte write enables
10–8 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown in the Table 50-13. DSZ is mapped by a hardware reset for CSCR0L by the value of the BOOT_CFG [2:0] bits. BOOT_CFG [2] maps to DSZ [2], BOOT_CFG [1] maps to DSZ [1] and BOOT_CFG [0] maps to DSZ [0]. DSZ and MUM (multiplexed mode) affected on data port location as it shown in the Table 50-13. DSZ is cleared by a hardware reset for CSCR1L–CSCR5L.
7–4 CSN	$\overline{CS}$ Negate. This bit field determines when chip select is negated for devices that require additional address/data hold times (see example on the Figure 50-11). CSN affects only asynchronous (read and write) accesses (SYNC=0), and is ignored on synchronous (SYNC=1). CSN does not affect the cycle length, except in positive edge sensitive DTACK mode. CSN is set to 0100 by a hardware reset for CSCR0L register and is cleared by a hardware reset for other registers. 0000 0 Half AHB clock cycles between $\overline{CS}$ negation and end of access. 0001 1 Half AHB clock cycle between $\overline{CS}$ negation and end of access. ... 1111 15 Half AHB clock cycles between $\overline{CS}$ negation and end of access.
3 PSR	Pseudo SRAM Enable (Burst Write Enable). This bit enables four functions for Pseudo SRAM (for example CellularRAM™) or any other device that support these modes: a burst write, a write wrap disable, a read wait state increase and a memory control register accessibility. If PSR=1then a memory burst write is enable (with SYNC = 1). In this mode the WRAP bit is masked on write time, unless WWU bit is set in the CSCRxA register, and wait state on read is automatically increased to WSC +1 (see Figure 50-40 and Figure 50-41). With PSR = 1 and SYNC = 1, during a write access the RWA field is ignored and RW_B is asserted at the start of the write cycle. An asynchronous access (SYNC=0) should be used with PSR=1 and CRE=1 to write to the memory control register. With PSR = 1, A23 is set to zero during read cycles and reflects the CRE bit value during write accesses. This limits the contiguous memory address range to that provided by A0 to A22 when PSR is set. PSR is cleared by a hardware reset. **Note:** This bit is also used when working with NOR Flash memory type for burst read accesses only. 0 PSRAM mode is disabled 1 PSRAM mode is enabled

Table 50-12. Chip Select *x* Lower Control Register Field Descriptions (Continued)

Field	Description
2 CRE	Control Register Enable. This bit indicates CRE memory pin state while writing to CS address space, for PSRAM control register write. For PSR=1 the CRE bit will be driven on pin ADDR[23] in a write access time. CRE is cleared by a hardware reset. **Note:** SYNC = 0 should be used to access to PSRAM control register. 0 CRE pin 0 1 CRE pin 1
1 WRAP	Wrap Memory Mode. This bit indicates that memory is in the wrap mode. The size of wrap is set using the PSZ field. In case not matching wrap boundaries in both the memory (PSZ field) and AHB access on the current address WEIM puts address on address bus and generates $\overline{\text{LBA}}$ signal (see example on the Figure 50-37). WRAP is cleared by a hardware reset. 0 Memory is in not in wrap mode. 1 Memory is in wrap mode.
0 CSEN	$\overline{\text{CS}}$ Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSCR0L to allow CSCR0L to select from an external boot ROM. CSEN is cleared by a hardware reset to CSCR1L–CSCR5L. 0 Chip select function is disabled; attempts to access an address mapped by this chip select results in a error respond on the AHB and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid AHB access.

1 MUM (bit 15) reset value is determined by the settings of the BOOT_CFG inputs (see BOOT_CFG signal description in Table 50-3) for CSCR0A and 0 for other registers

2 LAH (bits 13, 14) reset value is 10 for CSCR0A and 0 for other registers

3 LBN (bits 10 -12) reset value is 100 for CSCR0A and 0 for other registers

Table 50-14. Chip Select *x* Additional Control Register Field Descriptions

Field	Description
31–28 EBRA	$\overline{EB}$ Read Assert. This bit field determines when $\overline{EB}$ [3:0] is asserted during read cycles (see example on the Figure 50-25). EBRA does not affect the cycle length. EBRA is cleared by a hardware reset. **Note:** Minimum time $\overline{EB}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles before $\overline{EB}$ asserted. 0001 1 Half AHB clock cycle before $\overline{EB}$ asserted. ... 1111 15 Half AHB clock cycles before $\overline{EB}$ asserted.
27–24 EBRN	$\overline{EB}$ Read Negate. This bit field determines when $\overline{EB}$ [3:0] outputs are negated during a read cycle (see example on the Figure 50-20). EBRN does not affect the cycle length, except when in positive edge sensitive DTACK mode. Setting the SYNC bit (SYNC = 1) overrides EBRN and $\overline{EB}$ negates at the end of a read access but not sooner. EBRN is cleared by a hardware reset. **Note:** Minimum time $\overline{EB}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles between $\overline{EB}$ negation and end of access. 0001 1 Half AHB clock cycle between $\overline{EB}$ negation and end of access. ... 1111 15 Half AHB clock cycles between $\overline{EB}$ negation and end of access.

Table 50-14. Chip Select *x* Additional Control Register Field Descriptions (Continued)

Field	Description
23–20 RWA	$\overline{RW}$ Assertion. This bit field determines when $\overline{RW}$ is asserted during write cycles. (see example on the Figure 50-28). RWA is cleared by a hardware reset. **Note:** Minimum time $\overline{RW}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles $\overline{RW}$ delay 0001 1 Half AHB clock cycle $\overline{RW}$ delay. ... 1111 15 Half AHB clock cycles $\overline{RW}$ delay.
19–16 RWN	$\overline{RW}$ Negation. This bit field determines when $\overline{RW}$ is negated during a write cycle (see example on the Figure 50-28). RWN does not affect the cycle length, except in posedge sensitive DTACK mode. Setting the SYNC bit (SYNC = 1) overrides RWN and $\overline{RW}$ negates at the end of a write access and no sooner. RWN is cleared by a hardware reset. **Note:** Minimum time $\overline{RW}$ is asserted is one clock cycle. 0000 0 Half AHB clock cycles between $\overline{RW}$ negation and end of access. 0001 1 Half AHB clock cycle between $\overline{RW}$ negation and end of access. ... 1111 15 Half AHB clock cycles between $\overline{RW}$ negation and end of access.
15 MUM	Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses (see examples in Figure 50-43 - Figure 50-46). Port mapping is defined in the Table 50-13. MUM is cleared by a hardware reset for CSCR1A - CSCR5A. For CSCR0A, MUM is configured at reset time with the BOOT_CFG[4] (see BOOT_CFG description in Table 50-3). 0 Non-multiplexed mode 1 Multiplexed mode
14–13 LAH	$\overline{LBA}$ to Address Hold. This bit field determines address hold time after LBA negation for MUM = 1 only. See example on the Figure 50-43 and Figure 50-44. LAH is cleared by a hardware reset for CSCR1A - CSCR5A. For CSCR0A LAH is set to 10 by hardware reset. 00 02 AHB half clock cycles between $\overline{LBA}$ negation and address invalid. 01 13 AHB half clock cycle between $\overline{LBA}$ negation and address invalid. 10 24 AHB half clock cycles between $\overline{LBA}$ negation and address invalid. 11 35 AHB half clock cycles between $\overline{LBA}$ negation and address invalid.
12–10 LBN	$\overline{LBA}$ Negation. This bit field determines when $\overline{LBA}$ is negated. For SYNC=0 and MUM =0 LBN determines how many half AHB clock cycle will be between $\overline{LBA}$ negation and end of access (see example on the Figure 50-8). For SYNC=0 and MUM =1 this field determines $\overline{LBA}$ length (see example on the Figure 50-44). Negation time and $\overline{LBA}$ lengths are listed in Table 50-15. For SYNC=1 (MUM=0 and MUM=1) $\overline{LBA}$ negation occurs (LBN+BCD+1) half AHB clock cycles after first BCLK posedge detection. LBN does not affect the cycle length, except in positive edge sensitive DTACK mode. LBN is cleared by a hardware reset for CSCR1A - CSCR5A. For CSCR0A LBN is set to 100 by hardware reset. **Note:** Minimum of time $\overline{LBA}$ to be asserted is a one clock for MUM = 0 and two clocks for MUM = 1.

Table 50-14. Chip Select *x* Additional Control Register Field Descriptions (Continued)

Field	Description
9–8 LBA	$\overline{\text{LBA}}$ Assertion. This bit field determines when $\overline{\text{LBA}}$ is asserted according the settings shown below (see example on the Figure 50-11). LBA is cleared by a hardware reset. **Note:** LBA field affects all modes. **Note:** Minimum of time $\overline{\text{LBA}}$ to be asserted is a one clock for MUM = 0 and two clocks for MUM = 1. 00 0 AHB half clock cycles between beginning of access and $\overline{\text{LBA}}$ assertion. 01 1 AHB half clock cycle between beginning of access and $\overline{\text{LBA}}$ assertion. 10 2 AHB half clock cycles between beginning of access and $\overline{\text{LBA}}$ assertion. 11 3 AHB half clock cycles between beginning of access and $\overline{\text{LBA}}$ assertion.
7–6 DWW	Decrease Write Wait State. This bit field in combination with WWS determines whether write cycles are shorter than the read cycles (see Table 50-11). The WWS field should be zero when this field is in use. DWW is cleared by a hardware reset.
5–4 DCT	$\overline{\text{DTACK}}$ Check Time. This bit field determines time of insensitivity at the beginning of access for SYNC=0 and EW=1 according to the settings shown below (see example on the Figure 50-27). DCT is a number of clock cycles between $\overline{\text{CS}}$ assertion and first $\overline{\text{DTACK}}$ check. DCT is cleared by a hardware reset. 00 2 AHB clock cycles between $\overline{\text{CS}}$ assertion and first $\overline{\text{DTACK}}$ check. 01 6 AHB clock cycles between $\overline{\text{CS}}$ assertion and first $\overline{\text{DTACK}}$ check. 10 8 AHB clock cycles between $\overline{\text{CS}}$ assertion and first $\overline{\text{DTACK}}$ check 11 12 AHB clock cycles between $\overline{\text{CS}}$ assertion and first $\overline{\text{DTACK}}$ check.
3 WWU	Write Wrap Unmask. This bit allow unmask WRAP bit in case PSR = 1 and write access. WWU is cleared by a hardware reset. 0 Prevents Wrap during write access 1 Allow wrap on write
2 AGE	Acknowledge Glue Enable. This bit is used to enable/disable glue logic between external $\overline{\text{DTACK}}$ and internal control logic. The glue logic is a flip-flop that is reset by $\overline{\text{CS}}$ assertion, Its data input is a constant 1 and $\overline{\text{DTACK}}$ goes to its clock input. This glue logic is used to synchronize posedge of the external $\overline{\text{DTACK}}$ in worst-noise or slow edge growth conditions. AGE is cleared by a hardware reset. 0 Disable glue logic 1 Enable glue logic
1 CNC2	Chip Select Negation Clock Cycles, Bit [2]. This bit is used to increase the CNC field to a 3-bit field. See description CNC field in the Chip Select *x* Upper Control Register. CNC2 is cleared by a hardware reset. The number of AHB clock cycles produced by both bit fields is shown in Table 50-16
0 FCE	Feedback Clock Enable. This bit is used to enable / disable data capture by BCLK_FB. If FCE=1 WEIM used addition one clock to synchronize feedback clock captured data to AHB clock, so read access is slow then FCE=0. FCE is cleared by a hardware reset. **Note:** when working in synchronous mode DOL=BCD=1, FCE bit should be configured to 1 (FCE=0 in this specific mode is not supported) 0 Data captured using AHB clock 1 Data captured using BCLK_FB

Table 50-17. WEIM Control Register Field Descriptions

Field	Description
31–20	Reserved
19 ECP5	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS5 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of ECB in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
18 ECP4	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS4 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of $\overline{ECB}$ in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
17 ECP3	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS3 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of ECB in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
16 ECP2	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS2 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of ECB in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
15 ECP1	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS1 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of ECB in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
14 ECP0	$\overline{ECB}$ Capture Phase. This bit indicates in which phase of HCLK the BCLK is generated to the memory for synchronous CS0 write accesses. This bit is XORed with BCS[0] bit in write accesses to determine the BCLK starting phase to memory and it also influence on capturing of ECB in the WEIM design. 0 BCLK starting phase is as BCS[0] bit indicates. 1 BCLK starting phase is the opposite of BCS[0] bit indicates for write accesses only.
13 AUS5	Address Unshifted for CS5. This bit indicates an unshifted mode for address assertion for CS5 accesses. This bit is cleared by a hardware reset. 0 Address shifted according CS5 port size. 1 Address unshifted

Table 50-17. WEIM Control Register Field Descriptions (Continued)

Field	Description
12 AUS4	Address Unshifted for CS4. This bit indicates an unshifted mode for address assertion for CS4 accesses. This bit is cleared by a hardware reset. 0 Address shifted according CS4 port size. 1 Address unshifted
11 AUS3	Address Unshifted for CS3. This bit indicates an unshifted mode for address assertion for CS3 accesses. This bit is cleared by a hardware reset. 0 Address shifted according CS3 port size. 1 Address unshifted
10 AUS2	Address Unshifted for CS2. This bit indicates an unshifted mode for address assertion for CS2 accesses. This bit is cleared by a hardware reset. 0 Address shifted according CS2 port size. 1 Address unshifted
9 AUS1	Address Unshifted for CS1. This bit indicates an unshifted mode for address assertion for CS1 accesses. This bit is cleared by a hardware reset. 0 Address shifted according CS1 port size. 1 Address unshifted
8 AUS0	Address Unshifted for CS0. This bit indicates an unshifted mode for address assertion for CS0 accesses. In the unshifted mode AHB address is transmitted to address pins without port size independent shift. This mode is used when working with different data widths in the multi-chip package. 0 Address shifted according CS0 port size. 1 Address unshifted
7–3	Reserved
2 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. Don't use BCM = 1 in work configuration. BCM is cleared by a hardware reset. 0 The burst clock runs only when accessing a chip select range with the SYNC bit set; when the burst clock is not running it remains in a logic 0 state; when the burst clock is running it is configured by the BCD and BCS fields in the chip select control register. 1 The burst clock runs on every memory access (independent of chip select configuration)
1 CRER	CRE output Relocation. 0 CRE on ADDR[23] 1 CRE on ADDR[25] (ADDR[24:23] are used as EB[3:2] in the multiplexed mode MUM=1)
0 MAS	Merged Address Space. This bit indicates merged address space mode. If MAS is set the $\overline{CS1}$ address space is merged with $\overline{CS0}$ for a total of 256 (for half-word width port and 512 for word width port) Mbytes. $\overline{CS1}$ output is used as A26. 3 0 Standard address space. 1 Merged address space.

50.4 Functional Description

This section provides the functional description for the WEIM module.

50.4.1 Configurable Bus Sizing

The WEIM supports byte, halfword, and word operands allowing access to 8-bit, 16-bit, and multiplexed 32-bit ports. The port size is programmable via the DSZ field in the corresponding Chip Select control register. In addition, the portion of the data bus used for transfer to or from an 8-bit port is programmable via the same DSZ field. An 8-bit port can reside on DATA_IN/OUT bus bits [15:8] or [7:0]. A 16-bit port resides on DATA_IN/OUT bus bits [15:0]. A 32-bit multiplexed port resides on M_DATA_IN/OUT bus bits [31:0].

NOTE

Misaligned transfers are not supported.

A word access to or from an 8-bit port requires four external bus cycles to complete the transfer. A word access to or from a 16-bit port requires two external bus cycles to complete the transfer. A halfword access to or from an 8-bit port requires two external bus cycles to complete the transfer.

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The WEIM address bus is configured according to DSZ field and AUSx bits: the AHB address bits are shifted 1 or 2 bits right for half-word or word width ports, respectively.

The WEIM has a data multiplexer which takes the four bytes of the AHB interface data bus and routes them to their required positions to properly interface to memory and peripherals.

50.4.2 WEIM Operational Modes

WEIM has 9 main operational modes selected by control fields settings as described in the Table 50-18. For details see corresponding bit fields descriptions.

Table 50-18. WEIM Operation Modes Field Settings

Control fields					Brief Mode Description
SYNC	PME	MUM	EW	WSC	
0	0	0	0	< 11_1111	Asynchronous
		1	0		Asynchronous multiplexed
		0	1		Asynchronous level sensitive DTACK mode
		0	0	11_1111	Asynchronous posedge sensitive DTACK mode
1	1	0	0	< 11_1111	Page mode emulation
	0	0	0		Synchronous burst with restart on $\overline{\text{ECB}}$ negation
		1	0		Synchronous multiplexed burst with restart on $\overline{\text{ECB}}$ negation
		0	1		Synchronous burst with wait on $\overline{\text{ECB}}$ negation
		1	1		Synchronous multiplexed burst with wait on $\overline{\text{ECB}}$ negation

50.4.3 Burst Mode Memory Operation

With memory burst mode enabled (SYNC = 1), the WEIM attempts to translate AHB burst accesses to memory burst accesses, being limited by the memory burst length, predefined PSZ value, or memory and AHB WRAP/INCR boundary crossing non-matching. The WEIM only displays the first address accessed in a memory burst sequence unless the page mode emulation (PME) bit is set.

WEIM may translate from a series of AHB sequential accesses to one or few memory bursts, but not from two AHB nonsequential accesses to one memory burst.

For the first access in a memory burst sequence, the WEIM asserts $\overline{\text{LBA}}$—causing the external burst device to latch the starting burst address—and then toggles the burst clock (BCLK) a predefined number of cycles to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

Memory burst accesses are terminated by the WEIM whenever it detects that:

- the next AHB access is not sequential,
- next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the AHB and memory,
- current memory burst length reached,
- by the external burst device request if it needs additional cycles to retrieve the next requested memory location.

In the last case, the burst memory device provides an $\overline{\text{ECB}}$ (or WAIT) feedback signal to the WEIM whenever it is necessary to terminate/postponed the on-going burst sequence. If EW = 0 WEIM initiate a new (with long first access) memory burst sequence, if EW = 1 WEIM only waits $\overline{\text{ECB}}$ negation to continue current memory burst sequence. Additionally EW = 1 allows wait states insertion after wait state counter expired, but $\overline{\text{ECB}}$ still asserted. Over this a new memory burst sequence should be generated.

The synchronous mode is also used for burst Cellular RAM, which supports memory burst writes, that is enabled by PSR = 1.

50.4.4 Burst Clock Divisor

In some cases it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency which is less than the operating frequency of the internal bus. The internal AHB bus frequency (HCLK 133 MHz) can be divided by two, three, or four for presentation on the external bus in burst mode operation.

By programming the BCD field to various values, two signals on the external bus are affected; $\overline{\text{LBA}}$ and BCLK. The $\overline{\text{LBA}}$ signal is asserted according to LBA field programming and remain asserted until the first falling edge of the BCLK signal. The BCLK signal runs with a 50% duty cycle until a non-sequential internal request is received or an external $\overline{\text{ECB}}$ signal is recognized.

Caution should be exercised when programming these fields to ensure the WSC and DOL fields are coordinated to provide the desired external bus waveforms. BCD and DOL fields should always get the same value when configured. As an example, if the BCD field is programmed to 01, the DOL field should

be programmed to 0001. If the BCD field is programmed to 10, the DOL field should be programmed to 0010.

The BCM bit in the WEIM configuration register has priority over the BCD field. If BCM = 1, the BCLK runs at full frequency on every memory access (both with SYNC=1 and with SYNC=0). The BCM bit is used mainly for system debug mode. It has no functional use of the WEIM.

50.4.5 Burst Clock Start

In an effort to allow greater flexibility in achieving the minimum number of wait states on bursted accesses, the user can determine when they want the BCLK to start toggling. This allows the BCLK to be skewed from point of data capture on the AHB clock by any number of AHB clock phases. Care must be exercised when setting BCS field in conjunction with the BCD, WSC, and DOL fields. See the external timing diagrams from Section 50.6.4, "Burst Memory Accesses Timing Diagrams," for some examples of how to use the BCS, BCD, WSC, and DOL fields together.

50.4.6 Page Mode Emulation

Setting the PME and SYNC bits causes the WEIM to perform memory bursted accesses by emulating page mode operation. The $\overline{\text{LBA}}$ signal remains asserted for the entire access, the burst clock does not send a signal, and the external address asserts for each access are made. The initial access timing is dictated by the WSC field, and the page mode access timing is dictated by the DOL field.

The external timing diagrams in Section 50.6.2, "Page Mode Timing Diagrams," provide examples.

The WEIM can only take advantage of improved page timing for sequential accesses. Accesses that are on the page but are not sequential in nature have their timing dictated by the WSC field. The page size can be set via the PSZ field to 4, 8, 16, or 32 words (the word size is determined by the data width of the external memory, such as the DSZ field).

50.4.7 PSRAM Mode Operation

A control bit PSR is provided to enable PSRAM operation. For SYNC = 1 this bit enables a memory burst write. In this mode, the WRAP bit on write time is automatic masked (according to the CellularRAM™ specification, wrap is only supported for read accesses) unless WWU bit is set. Initial wait state value is automatic incremented on read access (see Figure 50-40 and Figure 50-41).

The EW bit determines how WEIM support $\overline{\text{ECB}}$ input. For SYNC = 1 if $\overline{\text{ECB}}$ goes to low state in the middle of memory burst access then WEIM only waits it'll go high (WAIT mode) to continue current access; at the end of first access in memory burst it allows to wait $\overline{\text{ECB}}$ negation during PSRAM refresh insertion.

The CRE bit and an unused address line can be used to drive the control register enable (CRE) memory input to load the PSRAM configuration registers. For PSR = 1 the CRE bit will be driven on pin ADDR[23] in a write access time.

NOTE

SYNC = 0 should be used to access to PSRAM control register.

50.4.8 Multiplexed Address/Data Mode

A control bit MUM allows support memory with multiplexed address/data bus both in the asynchronous and in the synchronous modes. The LBN and LBH bit fields should be used for properly bus timing setup (see Figure 50-43 through Figure 50-46).

50.4.9 Mixed AHB/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different lengths, WEIM interprets burst signals and generates additional $\overline{\text{LBA}}$ signals whenever there appear unequal address or burst boundary crossing conditions (see section Section 50.4.3, “Burst Mode Memory Operation”). The PSZ field and WRAP bit can be used to notify WEIM about current memory burst and wrap conditions for proper external address generation. In case of non-matching boundaries between the memory and AHB access, WEIM starts a new memory burst access by putting the address from AHB on the address bus and generating the $\overline{\text{LBA}}$ signal. For example, Table 50-20 shows how WEIM interprets various types of AHB accesses in case memory is configured to 8 beat burst with wrap.

50.4.10 AHB Bus Cycles Support

WEIM uses an ARM AHB slave interface. It has a 32-bit bus, and supports the four transfer types defined in the AHB specification (IDLE, BUSY, NONSEQ, and SEQ). SEQ mode only supports 32-bit accesses.

Table 50-19 shows the supported AHB. AHB cycles are translated into the necessary cycles on the memory side. For example, in case ARM cache is configured to 8-beat burst with wrap, for optimal operation a synchronous Flash and cellular RAM memory should be configured to 16-word or 8-word wrap burst mode when using 16-bit or 32-bit data ports, respectively. WEIM uses the WRAP bit and PSZ field to support different memory configurations. The controller splits the transaction when needed in some cases, as described in Section 50.4.3, “Burst Mode Memory Operation”.

Table 50-19. AHB Burst Cycles Supported

HBURST	TYPE	Supported	Description
000	SINGLE	Yes	Single transfer
001	INCR	Yes	Incrementing burst
010	WRAP4	Yes	4-beat wrapping burst
011	INCR4	Yes	4-beat incrementing burst
100	WRAP8	Yes	8-beat wrapping burst
101	INCR8	Yes	8-beat incrementing burst
110	WRAP16	Yes	16-beat wrapping burst
111	INCR16	Yes	16-beat incrementing burst

Table 50-20 shows examples of AHB bus sequential accesses breaking in to external memory bursts for memory configured to 8-beat burst with wrap, for different AHB burst types and start addresses. In Table 50-20, $\overline{\text{LBA}}$(X) means start memory burst access ($\overline{\text{LBA}}$ generation) from address X (all addresses in hex form).

Table 50-20. External Memory Bursts Start Addresses for Some AHB Burst Accesses

AHB burst type	Memory data port width	AHB burst start address							
		0	4	8	C	10	14	18	1C
WRAP8	16-bit	$\overline{\text{LBA}}$(0) $\overline{\text{LBA}}$(10)	$\overline{\text{LBA}}$(4) $\overline{\text{LBA}}$(10) $\overline{\text{LBA}}$(0)	$\overline{\text{LBA}}$(8) $\overline{\text{LBA}}$(10) $\overline{\text{LBA}}$(0)	$\overline{\text{LBA}}$(C) $\overline{\text{LBA}}$(10) $\overline{\text{LBA}}$(0)	$\overline{\text{LBA}}$(10) $\overline{\text{LBA}}$(0)	$\overline{\text{LBA}}$(14) $\overline{\text{LBA}}$(0) $\overline{\text{LBA}}$(10)	$\overline{\text{LBA}}$(18) $\overline{\text{LBA}}$(0) $\overline{\text{LBA}}$(10)	$\overline{\text{LBA}}$(1C) $\overline{\text{LBA}}$(0) $\overline{\text{LBA}}$(10)
	32-bit	$\overline{\text{LBA}}$(0)	$\overline{\text{LBA}}$(4)	$\overline{\text{LBA}}$(8)	$\overline{\text{LBA}}$(C)	$\overline{\text{LBA}}$(10)	$\overline{\text{LBA}}$(14)	$\overline{\text{LBA}}$(18)	$\overline{\text{LBA}}$(1C)

Some examples are shown in Figure 50-32 through Figure 50-39.

50.4.11 DTACK Mode

In DTACK mode, the WEIM timing depends on $\overline{\text{DTACK}}$ input signal. This signal may be used in two ways: by posedge sensitive or by level sensitive (with an initial insensitiveness time).

Posedge sensitive mode is set by setting WSC=111111 (which implies EW=0) and selecting $\overline{\text{DTACK}}$ input as the access length control signal (instead of the default WSC counter). In this case, access length is determined by $\overline{\text{DTACK}}$ length. WEIM begins negating control signals after approximately 1.5 clock (synchronization delay) in the sequence, according to the negation control fields.

NOTE

It may be required to program CSA and/or CSN fields for a correct word access to 16 or 8-bit port in this mode if the corresponding module is CS-sensitive. In this case, the maximum value of CSN is 6.

Level sensitive mode is set by EW=1 (imply WSC < 111111). There access length is controlled by WSC. In this case WEIM begins access (by CS assertion) and after some clocks (according DCT field) checks $\overline{\text{DTACK}}$ input. If $\overline{\text{DTACK}}$ is low WEIM waits $\overline{\text{DTACK}}$ high state and reload wait state counter (see

Figure 50-27 and Figure 50-28). For sequential AHB accesses where CS does not negate during the burst, DTACK is checked on the first access only.

Glue logic enabled by the AGE bit of the CSCR*x*A register can be used for noisy or slow-rising DTACK. See the AGE bit description for more details.

50.4.12 Internal Input Data Capture

In the typical case the input data is not sampled by the WEIM, but it is sampled by the AHB master on the rising edge of HCLK when HREADY is high. WEIM asserts the HREADY signal to the AHB master (according to the WSC or DOL counting correspondingly). This enables better performance on the data path.

There are two cases when input data are sampled inside the WEIM:

- The first case is when an access size is larger then a port size. In this case, WEIM samples all the data coming from the memory device except the last one of that transaction. For example if there is a word access to the byte wide memory, the WEIM captures the first three input bytes internally and drives them together with the last byte to the AHB master (the last byte is not sampled in the WEIM). The WEIM captures data by the rising edge of HCLK when WSC (or DOL if it is part of a burst) time is expired and (if it depends) suitable ECB or DTACK input condition.
- The second case is when a feedback clock is used (FCE=1) for synchronous burst. Data will be sampled on the rising edge of the feedback clock (when the WSC or DOL time expired and input conditions are kept), and then the captured data is again sampled by HCLK before it is driven to the AHB master.

50.4.13 Error Conditions

The following conditions cause an error signal:

- Access to a disabled chip select (access to a mapped chip select address space where the CSEN bit in the corresponding chip select control register is clear)
- Write access to a write-protected chip select address space (the WP bit in the corresponding chip select control register is set)
- User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select control register is set)
- User read or write access to a chip select control register or the WEIM configuration register
- Byte or halfword access to a chip select control register or the WEIM configuration register
- DTACK acknowledge is absent more then 1024 clocks
- WAIT negation more then 1024 clocks.

50.5 Initialization/Application Information

WEIM is ready to work with CS0 after hardware reset, but it has been configured for very slow access (for booting) without additional setup and hold times. The other CS are disabled by hardware reset, and must be initialized before use by writing to the high and low configuration registers.

Example 50-1 shows how to prepare WEIM and 16-bit Flash memory to work in the synchronous mode.

Example 50-1. WEIM and Flash Memory Initialization for Working in Synchronous Mode

```
@; config WEIM to Async access with EDC, OEA, RWA, RWN, EBC, 16 bit port and PSR
        WRITE WEIM_CSCR2U, 0x12020802
        WRITE WEIM_CSCR2L, 0x80330d03

@ ; config Flash to WRAP 8 mode (by half word accesses)
        WRITE_H (CS2_BASE_ADDR+0x2384), 0x60    @ ; offset = 0x11c2 << 1 for 16 bit port
        WRITE_H (CS2_BASE_ADDR+0x2384), 0x03

        WRITE_H (CS2_BASE_ADDR+0x0), 0xff       @ ; Flash to read mode

@ ; config to WEIM Sync access with WRAP8, 16 bit port
        WRITE WEIM_CSCR2U, 0x13510802
        WRITE WEIM_CSCR2L, 0x80330d03
```

50.6 External Bus Timing Diagrams

The following timing diagrams show memory or peripheral accesses with different timing parameters. All examples done for $\overline{CS0}$, but are valid for any others chip select. $\overline{EB}$ means one from current used $\overline{EB}$[3:0]

For asynchronous mode:

- Figure 50-7 through Figure 50-13 show half-word read and write accesses to half-word-width memory.
- Figure 50-14 through Figure 50-24 shows word read and write accesses to half-word-width memory.
- Figure 50-25 shows page mode timing diagrams. Figure 50-26 through Figure 50-28 shows two kinds of $\overline{DTACK}$ accesses.
- Figure 50-43 and Figure 50-44 shows asynchronous data exchange in multiplexed address/data mode with word-width memory.

For synchronous (burst) mode:

- Figure 50-29 shows synchronous word read accesses to half-word-width memory.
- Figure 50-30 shows recommended parameter setting using for synchronous accesses: BCLK clock has a short pulse at the end of access.
- Different cases of wrap/increment states on AHB and memory are shown in Figure 50-32 through Figure 50-39 for burst size 4. AHB increment/wrap accesses with another length are made like this.
- PSRAM read and write accesses are shown in the Figure 50-40 and Figure 50-41.
- Figure 50-45 and Figure 50-46 show synchronous data exchange in multiplexed address/data mode with word width memory.

Appendix B
Revision History

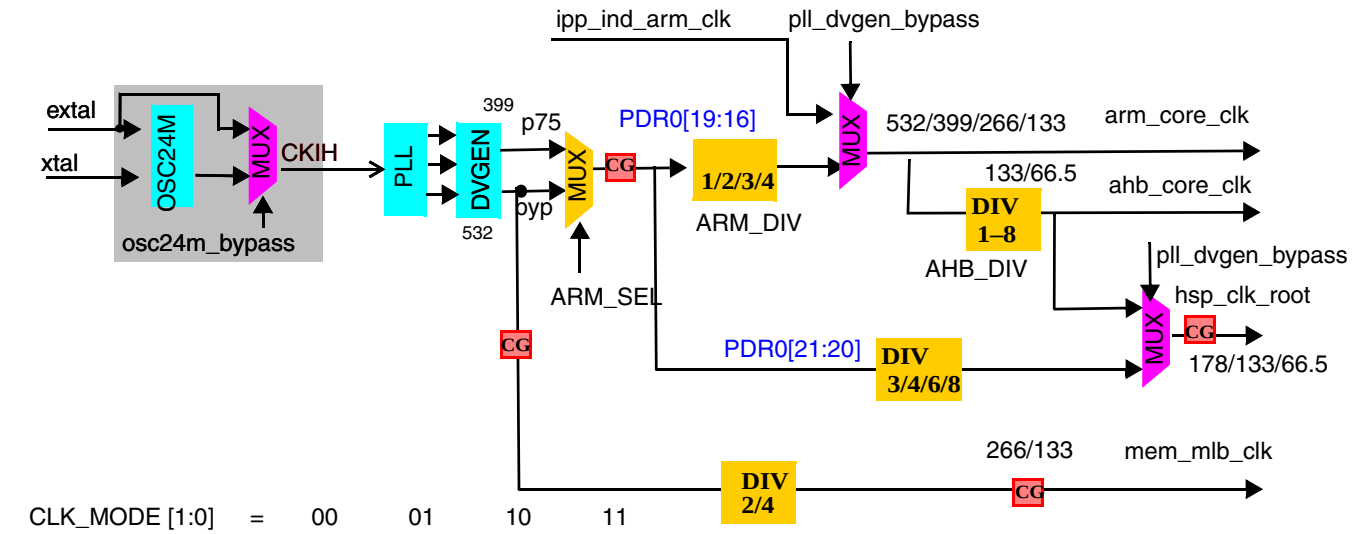
This appendix provides a list of the major differences between the *MCIMX35 Multimedia Applications Processor Reference Manual*, Revision 2 through Revision 3.

Section, Page	Changes
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following note in the description of field “0, SRE”: “This bit only applies to pads configured as output.”
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following note in the description of field “2-1, DSE”: “This bit only applies to pads configured as output.”
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following note in the description of field “3, ODE”: “This bit only applies to pads configured as output.”
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following note in the description of field “7-4, PULL_KEEP_CTL”: “Not all possibilities are implemented on every pad. See register description for pad.”
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following note in the description of field “8, HYS”: “This bit only applies to pads configured as input.”
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, changed the name of field “13” from “DVS” to “DRIVER_VOLTAGE”.
4.3.1.1, 8	In Figure 4-7, “SW_PAD_CTL Register Generic Format (GPIO Pins)”, changed the name of field “13” from “DVS” to “DRIVER_VOLTAGE”.
4.3.1.1, 8	In Table 4-3, “SW_PAD_CTL Field Descriptions (GPIO Pins)”, added the following sentence in the note within the description of field “13, DRIVER_VOLTAGE”: “This bit only applies to pads configured as output.”
4.3.2, 11	In Table 4-5, “Reference Characteristics for DDR_TYPE Types at 25o C,” added row for SDRAM at 1.8 V.
5.4, 3	Updated Figure 5-2, “Top-Level Diagram”: – Replaced the block name “Audio_Mux” with “Audio Clock Mux Structure”.

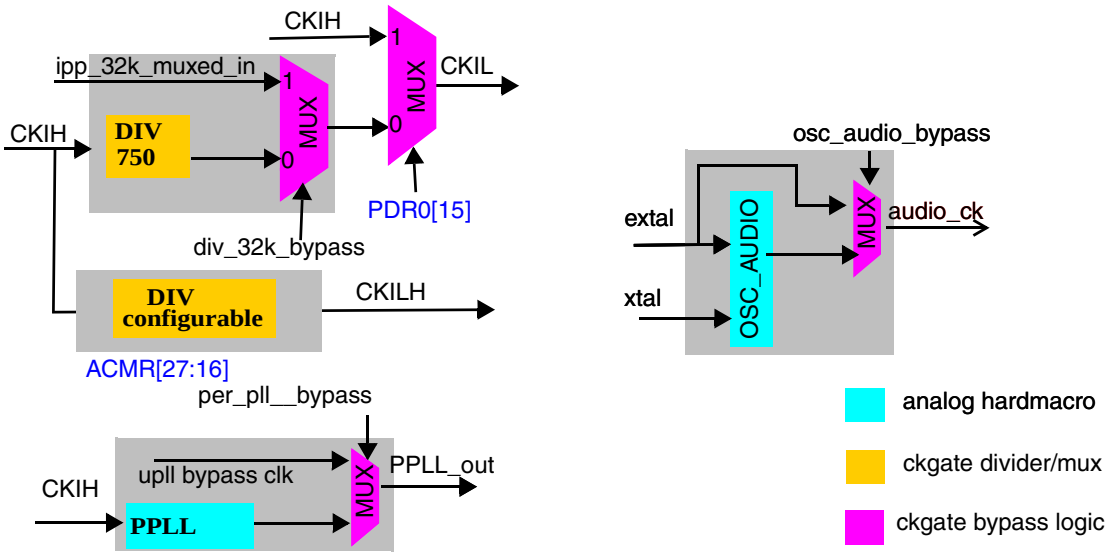
	– Removed the “SSI1” block. – Removed “SSI2” from the “SPDIF, SSI2, ESAI” block.
5.4, 3	Updated Figure 5-3, “DPLLs”.
5.4, 4	Updated Figure 5-4, “Clock Generation” and changed the figure caption from “Clock Generation for Core 1” to “Clock Generation”.
5.4, 5	Updated Figure 5-5, “IPG Baud Clocks Generation” and changed the figure caption from “Special Clocks Generation for Core” to “IPG Baud Clocks Generation”.
5.4, 7	Updated Figure 5-7, “ARM11P Core Clocks”.
5.4, 7	Updated Figure 5-8, “IPU”.
5.4, 7	Updated Figure 5-9, “MLB”.
5.4, 8	Updated Figure 5-10, “Audio Clock Mux Structure”.
7.2, 1	In the first bulleted list of Section 7.2, “Boot Configuration”, replaced “BMOD[1:0]” with “BOOT_MODE[1:0]”.
7.2, 2	In Table 7-1, “Boot Mode Summary”, replaced the column name “BMOD[1:0]” with “BOOT_MODE[1:0]”.
7.2, 2	In Table 7-1, “Boot Mode Summary”, updated the description of “Startup mode” row to read as follows: “BT_MEM_CTL[1:0] = b11. This mode is useful for software development using JTAG-capable development tools. Upon reset the PC register will remain at address 0x00000000. This means no ROM code has run so far and the state of all internal SOC registers are untouched. The system is ready to run any application that is loaded to it via a JTAG debugging tool. You can still connect to the SOC via JTAG in other boot modes but in this mode it is guaranteed that all internal SOC registers are at their default (or reset) values.”
7.2.1, 2	In Table 7-2, “Fuse Descriptions”, updated the settings description for the “BT_PAGE_SIZE[1:0]” row to read as follows: “If BT_MEM_CTL = NAND Flash then 00 512 bytes 01 2 Kbytes 10 4 Kbytes (128 bytes spare) 11 4 Kbytes (218 bytes spare)”
7.2.3, 5	In Table 7-4, “GPIO Pins Used for Boot”, updated Contact rows from “CS” to “CSI” for CS_D8 to CS_D15.
7.2.3, 9	In Table 7-6, “eFuse Settings for Boot Device Type”, updated Input Contact rows from “CS” to “CSI” for CS_D8 to CS_D11.
7.2.3, 18	In Table 7-13, “eFuse Settings for xMMC and xSD Boot”, updated Input Contact rows from “CS” to “CSI” for CS_D10 and CS_D11.

7.4, 7	In the second sentence of Section 7.4, “Boot Modes”, replaced “BMOD” with “BOOT_MODE[1:0]”.
7.4.1, 7	In the first sentence of Section 7.4.1, “Internal Boot Mode”, replaced “BMOD” with “BOOT_MODE[1:0]”.
7.4.1.4, 11	In Table 7-8, “Flash Header and Super Root Key Variables”, updated the comments description for the “app_code_barker” row to read as follows: “app_code_barker must be set to 0x0000_00B1”
7.4.1.6, 15	In Table 7-12, “Fuse Settings for NAND Flash”, updated the settings description for the “BT_PAGE_SIZE[1:0]” row to read as follows: “00 512 bytes 01 2 Kbytes 10 4 Kbytes (128 bytes spare) 11 4 Kbytes (218 bytes spare)”
7.4.2, 20	In the first sentence of Section 7.4.2, “External Boot Mode”, replaced “BMOD” with “BOOT_MODE[1:0]”.
7.4.3, 20	In first and second bulleted list of Section 7.4.3, “Serial Download Boot Mode”, replaced “BMOD” with “BOOT_MODE[1:0]”.
8.2, 3	In Table 8-2, “Power Supply Requirements”, in the eighth row changed the Module name from “Fusebox Read” to “Fusebox Program”.
10.1.2, 3	In the second paragraph of Section 10.1.2, “Features”, under fifth bulleted item: – Changed the second sub-bulleted item “ESAI-1, receiving clock and transmitting clock” to “SSI-1, receiving clock and transmitting clock”. – Changed the third sub-bulleted item “ESAI-2, receiving clock and transmitting clock” to “SSI-2, receiving clock and transmitting clock”. – Removed the fourth sub-bulleted item “ESAI-3, receiving clock and transmitting clock”.
11.4.2, 19	In Table 11-3, “ATA Register Summary” grayed-out bits “8-15” because SECTOR_SIZE is a 8-bit register.
11.4.2, 19	In Table 11-3, “ATA Register Summary” for the ATA_CONTROL register corrected the field name of field “11-10” from “dma_sel” to “dma_select”.
11.4.3.8, 36	In Figure 11-55, “SYS_DMA_BADDR Register” corrected the reset values. Earlier the reset value was given only for a single bit.
11.4.3.9, 37	In Figure 11-56, “ADMA_SYS_ADDR Register” corrected the reset values. Earlier the reset value was given only for a single bit.
12.4.2.1.2, 16	Shown diagram for the Figure 12-7, “Block Diagram For Example 1”.
12.4.2.1.2, 17	Shown diagram for the Figure 12-8, “Example Using Internal Ports for Transmit Data”.
13.2.3.4, 14	In Table 13-8, “INTDISNUM Register Field Descriptions”, corrected the field name for bit “5-0” from “ENNUM” to “DISNUM”.

13.2.3.7, 17	In Figure 13-11, “Normal Interrupt Priority Level 7 Register (NIPRIORITY7)”, corrected the bit names.
13.2.3.7, 18	In Table 13-11, “NIPRIORITY7 Register Field Descriptions”, corrected the bit name for bit “27-24” from “NIPR63” to “NIPR62”.
13.2.3.7, 18	In Figure 13-12, “Normal Interrupt Priority Level 6 Register”, corrected the bit names.
13.2.3.7, 19	In Table 13-12, “NIPRIORITY6 Register Field Descriptions”, corrected the bit name for bit “19-16” from “NIPR53” to “NIPR52”.
13.2.3.7, 21	In Figure 13-15, “Normal Interrupt Priority Level 4 Register”, corrected the figure title from “Normal Interrupt Priority Level 4 Register” to “Normal Interrupt Priority Level 3 Register”.
14.2, 2	In Table 14-1, “External Signal Properties”, replaced “CLKMOD[1:0]” with “CLK_MODE[1:0]”.
14.3.3.1, 9	In Table 14-5, “CCMR Field Descriptions”, replaced “CLKMOD” with “CLK_MODE[1:0]” in the description of field 3, “MPE”.
14.3.3.2, 11	In Figure 14-3, “Post Divider Register 0 (PDR0)”, updated bits “11–0” to reserved. Previously bit “11–9” was AUTO_MUX_DIV” and bit “0” was “AUTO_CON”.
14.3.3.2, 11	In Table 14-6, “PDR0 Field Descriptions”:
	– In the bit description of bit “14–12”, updated “111 Divided by 7” to “111 Divided by 8”.
	– Changed bit “11–0” to reserved.
14.3.3.2, 11	In Table 14-6, “PDR0 Field Descriptions”, added row for bit 22. Earlier it was missing.
14.3.3.7, 18	In Table 14-11, “RCSR Field Descriptions” modified the first sentence of the description of bit “11-10” as follows: “These two read-only bits show the boot mode as read from the BOOT_MODE[1:0] pins when the device comes out of reset.”
14.3.3.10, 25	In Table 14-14, “ACMR Field Descriptions”, added the following note to the descriptions of bits “15–12, ESAI_AUDIO_CLK_SEL”, “11–8, SPDIF_AUDIO_CLK_SEL”, “7–4, SSI1_AUDIO_CLK_SEL”, and “3–0, SSI2_AUDIO_CLK_SEL”: “Bit field values 1011 through 1111 are reserved and will result in no clock source being selected”.
14.3.3.12, 31	In Table 14-19, “CGR2 Registers Mapping”, added row for the “RTIC” module.
14.4.1, 45	In Figure 14-24, “MCIMX35 Clock Generation Scheme 1”, updated the figure note.
14.4.1, 45	In Figure 14-24, “MCIMX35 Clock Generation Scheme 1”, replaced “CLKMOD [1:0]” with “CLK_MODE [1:0]”.
14.4.1, 45	Updated Figure 14-24, “MCIMX35 Clock Generation Scheme 1”as follows:



CLK_MODE [1:0]	=	00	01	10	11
OSC_24m_bypass	=	0	1	1	1
OSC_audio_bypass	=	0	1	1	1
pll_dvgen_bypass	=	0	1	0	1
per_pll_bypass	=	0	1	0	1
div_32k_bypass	=	0	0	0	1



14.4.1.1.1, 47 Replaced “CLKMOD” with “CLK_MODE[1:0]”.

14.4.1.1.3, 48 Replaced “CLKMOD” with “CLK_MODE[1:0]”.

14.4.2.1, 50 In the third bulleted item of second paragraph of Section 14.4.2.1, “Functional Description of the Reset Module”, updated WDOG_RST description to read as follows:

	“optional reset input from the watchdog timer”.
14.4.3.2.4, 56	Updated fourth paragraph of the Section 14.4.3.2.4, “Stop Mode”.
14.4.3.3, 58	In Section 14.4.3.3, “Dynamic Voltage Frequency Scaling Support”, updated the last sentence of first paragraph to read as follows: “The frequency of the core clock domain can be changed only by configuring the con_mux_div bits in PDR0.”
15.4.2, 5	In Table 15-3, “CLKCTL Memory Map”, updated Reset value for “L2 Data Memory Val Register” from “0x0000_0000” to “0x0000_0515”.
15.4.4.3, 9	In Table 15-7, “Clear Control Register Field Descriptions”, corrected the bit name of bit “10-0” from “GP_SER” to “GP_CER”.
15.4.4.4, 10	In Table 15-8, “General Purpose Status Register Field Descriptions”, corrected the table title from “Clear Control Register Field Descriptions” to “General Purpose Status Register Field Descriptions”.
15.4.4.5, 10	In Table 15-9, “L2_MEM_VAL Register Field Descriptions”, removed the “Reset Value” column.
15.4.4.5, 10	In Figure 15-7, “L2_MEM_VAL Register”, updated offset value from “0x43F0_C010” to “0x0010”, reset value from “0x0000_0000” to “0x0000_0515”.
15.4.4.5, 10	In Table 15-9, “L2_MEM_VAL Register Field Descriptions”, updated the reset values and bit description for bits “12”, “11–8”, “7–4” and “3–0”.
19.3.1, 12	In Table 19-3, “ESAI Memory Map”, replaced base address offset value from “0x40xx” to “0x00xx”.
19.3.1, 12	In Table 19-3, “ESAI Memory Map”, corrected the base address offset of “Transmit Data Register 0” from “0x0080–0x0094 (TX0-TX5)” to “0x0080 (TX0)”.
19.3.1, 12	In Table 19-3, “ESAI Memory Map”, corrected the base address offset of “Receive Data Register 0” from “0x00A0–0x00AC (RX0-RX3)” to “0x00A0 (RX0)”.
19.3.2, 14	In Table 19-5, “ESAI Register Summary”, replaced the base address offset “0x0080–0x0094 (TX0-TX5)” with “0x0080 (TX0)”.
19.3.2, 14	In Table 19-5, “ESAI Register Summary”, replaced the base address offset “0x00A0–0x00AC (RX0-RX3)” with “0x00A0 (RX0)”.
19.3.2, 14	In Table 19-5, “ESAI Register Summary”, replaced base address offset value from “0x40xx” to “0x00xx”.
19.3.3.1, 18	In Figure 19-3, “ESAI Transmit Data Register”, replaced base address offset value from “Offset 0x4000 (ETDR)” to “Offset 0x0000 (ETDR)”.
19.3.3.2, 19	In Figure 19-4, “ESAI Receive Data Register”, replaced base address offset value from “Offset 0x4004 (ERDR)” to “Offset 0x0004 (ERDR)”.
19.3.3.3, 20	In Figure 19-5, “ESAI Control Register”, replaced base address offset value from “Offset 0x4008 (ECR)” to “Offset 0x0008 (ECR)”.

19.3.3.4, 21	In Figure 19-6, “ESAI Status Register”, replaced base address offset value from “Offset 0x400C (ESR)” to “Offset 0x000C (ESR)”.
19.3.3.5, 22	In Figure 19-7, “Transmit FIFO Configuration Register”, replaced base address offset value from “Offset 0x4010 (TFCR)” to “Offset 0x0010 (TFCR)”.
19.3.3.6, 24	In Figure 19-8, “Transmit FIFO Status Register”, replaced base address offset value from “Offset 0x4014 (TFSR)” to “Offset 0x0014 (TFSR)”.
19.3.3.7, 25	In Figure 19-9, “Receive FIFO Configuration Register”, replaced base address offset value from “Offset 0x4018 (RFCR)” to “Offset 0x0018 (RFCR)”.
19.3.3.8, 26	In Figure 19-10, “Receive FIFO Status Register”, replaced base address offset value from “Offset 0x401C (RFSR)” to “Offset 0x001C (RFSR)”.
19.3.3.9, 27	In Figure 19-11, “ESAI Transmit Data Registers”, replaced base address offset value from “Offset 0x4080–0x4094 (TX0 - TX5)” to “Offset 0x0080–0x0094 (TX0 - TX5)”.
19.3.3.11, 31	In Figure 19-14, “ESAI Transmit Slot Register”, replaced base address offset value from “Offset 0x4098 (TSR)” to “Offset 0x0098 (TSR)”.
19.3.3.12, 32	In Figure 19-15, “ESAI Receive Data Registers”, replaced base address offset value from “Offset 0x40A0–0x40AC (RX0 - RX3)” to “Offset 0x00A0–0x00AC (RX0 - RX3)”.
19.3.3.14, 33	In Figure 19-16, “ESAI Status Register”, replaced base address offset value from “Offset 0x40CC (SAISR)” to “Offset 0x00CC (SAISR)”.
19.3.3.15, 35	In Figure 19-17, “Receive Common Control Register”, replaced base address offset value from “Offset 0x40D0 (SAICR)” to “Offset 0x00D0 (SAICR)”.
19.3.3.16, 38	In Figure 19-19, “ESAI Transmit Control Register”, replaced base address offset value from “Offset 0x40D4 (TCR)” to “Offset 0x00D4 (TCR)”.
19.3.3.17, 46	In Figure 19-22, “ESAI Transmitter Clock Control Register”, replaced base address offset value from “Offset 0x40D8 (TCCR)” to “Offset 0x00D8 (TCCR)”.
19.3.3.18, 50	In Figure 19-25, “ESAI Receive Control Register”, replaced base address offset value from “Offset 0x40DC (RCR)” to “Offset 0x00DC (RCR)”.
19.3.3.19, 54	In Figure 19-26, “ESAI Receiver Clock Control Register”, replaced base address offset value from “Offset 0x40E0 (RCCR)” to “Offset 0x00E0 (RCCR)”.
19.3.3.20, 57	In Figure 19-27, “ESAI Transmit Slot Mask Register A”, replaced base address offset value from “Offset 0x40E4 (TSMA)” to “Offset 0x00E4 (TSMA)”.
19.3.3.21, 58	In Figure 19-28, “ESAI Transmit Slot Mask Register B”, replaced base address offset value from “Offset 0x40E8 (TSMB)” to “Offset 0x00E8 (TSMB)”.
19.3.3.22, 59	In Figure 19-29, “ESAI Receive Slot Mask Register A”, replaced base address offset value from “Offset 0x40EC (RSMA)” to “Offset 0x00EC (RSMA)”.
19.3.3.23, 60	In Figure 19-30, “ESAI Receive Slot Mask Register B”, replaced base address offset value from “Offset 0x40F0 (RSMB)” to “Offset 0x00F0 (RSMB)”.
19.3.3.25, 61	In Figure 19-31, “Port C Direction Register”, replaced base address offset value from “Offset 0x40F8 (PRRC)” to “Offset 0x00F8 (PRRC)”.

19.3.3.26, 62	In Figure 19-32, “Port C Control Register”, replaced base address offset value from “Offset 0x40FC (PCRC)” to “Offset 0x00FC (PCRC)”.
Chapter 20	Replaced the complete Chapter 20, “Enhanced Secured Digital Host Controller Version 2 (eSDHCv2)”.
21.3.1, 10	In Table 21-4, “ESDRAMC Memory Map”, replaced the reset value for “Enhanced SDRAM Control Register 1 (ESDCTL1)” from “0x0112_0080” to “0x8112_0080”.
21.3.3.1, 14	In Figure 21-4, “Enhanced SDRAM Control Register 0 (ESDCTL0)”, replaced the reset value of field 31 (SDE), from “1” to “0”.
21.3.3.1, 15	In Figure 21-5, “Enhanced SDRAM Control Register 1 (ESDCTL1)”, replaced the reset value of field 31 (SDE), from “0” to “1”.
21.3.3.1, 15	In Table 21-8, “Enhanced SDRAM Control Register (ESDCTLn) Field Descriptions”, added the following note in the description of field 11–10, “PWDT”: “When PWDT is enabled, and LPMD or DVFS requests are required by the system, PWDT must be disabled before the requests are granted. PWDT can only be re-enabled after these modes are exited.”
21.3.3.1, 15	In Figure 21-5, “Enhanced SDRAM Control Register 1 (ESDCTL1)”, replaced the reset value from “0x0112_0080” to “0x8112_0080”.
21.3.3.1, 15	In Table 21-8, “Enhanced SDRAM Control Register (ESDCTLn) Field Descriptions”, updated the field description of field “31 (SDE)” to read as follows: “Enhanced SDRAM controller enable. This control bit enables/disables the enhanced SDRAM controller. Writing 1 to both control bits enables the module for both chip selects. Clearing both SDE bits disables the module, and all clocks within the module shuts off (with the exception of register accesses). When the value of both SDE bits is 0, the module is disabled. 0 Disabled (reset value for ESDCTL0) 1 Enabled (reset value for ESDCTL1)”
21.3.3.2, 19	In Table 21-9, “ESDCFGn Field Descriptions”, updated the field description of field “9–8 (t_{CAS})” to read as follows: “SDRAM CAS latency. This field determines the latency between a read command and the availability of data on the bus, as shown in Figure 21-15. This field does not affect the second and subsequent data words in a burst. This control field has no effect on write cycles. CAS latency is initialized to 3 clocks following a hardware reset. 00 3 clocks only for LPDDR and DDR2 CAS latency 01 Reserved 10 2 clocks SDR and LPDDR SDRAM CAS latency 11 3 clocks SDR SDRAM CAS latency”.

21.3.3.3, 32	In Table 21-11, “Enhanced SDRAM Miscellaneous Register Field Descriptions”, updated the field description of field “9, DDR2_EN” to read as follows: “Regular (non- mobile) DDR2 device is connected. This bit is common for both chip selects. 0 DDR2 device is not used (reset value) 1 DDR2 device is used. Note: When this bit is asserted, the MDDR_EN bit and the DDR_EN bit must also be asserted.”
25.3.3.7, 10	Added the following sentence at the end of the first paragraph in the description of GPIO Interrput Status Register (ISR): “To make sure the ISR register content can be read out correctly, software should read the register two times.”
29.3.3.9, 13	In Figure 29-11, “Product Revision Register” updated the reset value from “0x--” to “0x82”.
29.3.3.9, 13	In Table 29-11, “Product Revision Register Field Descriptions” added the following note: “The values for PROD_REV and PROD_VT for the i.MX35 device are hard coded as 0x10 and 0x02, respectively (Register PREV= 0x82). Both of these values do not have significance for the user and should be ignored.”
29.3.3.10, 14	In Table 29-12, “Silicon Revision Register Field Descriptions” updated the description of field “7–0, SILICON_REV” to read as follows: “Mask Set Revision. The mask set revision used in fabrication of the part. The value changes with each change to the mask set. Setting according to mask set revision. 0×00 = TO 1.0, First silicon 0×10 = TO 2.0, Current production, "V" devices 0×11 = TO 2.1, Current production, "J" devices”.
31.4.4.2, 272	Updated the first sentence of the second paragraph to read as follows: “Each FIFO contains sixteen pages, the page size is eight 64-bit words.”
33.4.3.2, 6	Added diagram for Figure 33-4, “KPSR Register Diagram”.
33.4.3.2, 6	In Table 33-7, “Keypad Status Register Field Descriptions” added row for field “15–10”.
35.3.2, 10	In Table 35-2, “MAX Memory Map” in the first column replaced all the Base Address Offset “0x4xxx” with “0x0xxx”.
35.3.4.1, 13	In Figure 35-4, “Master Priority Register (MPR0–MPR4)” replaced all the Base Address Offset “0x4xxx” with “0x0xxx”.
35.3.4.2, 15	In Figure 35-5, “Slave General-Purpose Control Register n” replaced all the Base Address Offset “0x4xxx” with “0x0xxx”.

35.3.4.3, 17	In Figure 35-6, “Master General-Purpose Control Register n”, replaced all the Base Address Offset “0x4xxx” with “0x0xxx”.
39.2.1, 4	In Table 39-1, “NFC Signal Properties”, updated the reset value of the “NF_16BIT_SEL” signal from “1” to “0”.
Chapter 42	Removed section “Software Interface”.
42.10.3.1, 48	In Table 42-13, “MC0PTR Field Descriptions”, removed the following sentence from the description of field “31–0, MC0PTR”: “Refer to the API document MOT-SFS-IAPI-SAS-001 (version 0.04) for the use of this register.”
42.10.3.4, 50	In Figure 42-16, “Channel Start (HSTART) Register”, replaced access right from “User Read Only” with “User Read/Write”.
42.14, 102	Updated introduction of Section 42.14, “SDMA Initialization” to read as follows: “This section provides a quick description of several initialization procedures.”
Chapter 43	Removed sections “SPDIFTxCChannelProf_h (STCSPH)” and “SPDIFTxCChannelProf_L (STCSPL)”.
43.1, 1	In Figure 43-1, “SPDIF Transceiver Data Interface Block Diagram”, removed “SPDIFTxCChannelProf_h Register” and “SPDIFTxCChannelProf_l Register” blocks.
43.3.1, 3	In Table 43-2, “SPDIF Register Map”, removed rows for “SPDIFTxCChannelProf_h (STCSPH)” and “SPDIFTxCChannelProf_l (STCSPL)” registers.
43.3.1, 3	In Table 43-2, “SPDIF Register Map”, replaced all register offset addresses “0x80xx” with “0x00xx”.
43.3.2.1, 4	In Table 43-3, “SPDIF Config Register (SCR) Field Descriptions”, updated the description of field “4–2, TxSEL” to read as follows: 000 Off and output 0 001 Feed-through SPDIFIN 101 Tx normal operation
43.3.2.1, 4	In Figure 43-3, “SPDIF Config Register (SCR)”, replaced “Address 0x8000” with “Address 0x0000”.
43.3.2.1, 4	In Table 43-3, “SPDIF Config Register (SCR) Field Descriptions”, added the following sentence in the description of field 4–2, “TxSel”: “Others: Reserved”
43.3.2.2, 5	In Figure 43-4, “CDText_Control Register (SRCD)”, replaced “Address 0x8004” with “Address 0x0004”.
43.3.2.3, 6	In Figure 43-5, “PhaseConfig Register (SRPC)”, replaced “Address 0x8008” with “Address 0x0008”.
43.3.2.3, 6	In Table 43-5, “PhaseConfig Register Field (SRPC) Descriptions”, added the following note in the description of field 10–7, “ClkSrc_Sel”:

	“IOMUX clk is selected by IOMUXC_SPDIF_HCKT_CLK2_SELECT_INPUT, see Table 1227”.
43.3.2.4, 7	In Figure 43-6, “InterruptEn Register (SIE)”, replaced “Address 0x800C” with “Address 0x000C”.
43.3.2.4, 8	In Figure 43-7, “InterruptStat Register (SIS)”, replaced “Address 0x8010” with “Address 0x0010”.
43.3.2.4, 8	In Figure 43-8, “InterruptClear Register (SIC)”, replaced “Address 0x8010” with “Address 0x0010”.
43.3.2.5.1, 10	In Figure 43-9, “SPDIFRcvLeft Register (SRL)”, replaced “Offset: 0x8014” with “Offset: 0x0014”.
43.3.2.5.1, 10	In Figure 43-10, “SPDIFRcvRight Register (SRR)”, replaced “Offset: 0x8018” with “Offset: 0x0018”.
43.3.2.5.1, 10	In Figure 43-11, “SPDIFRcvCChanel_h Register (SRCSH)”, replaced “Offset: 0x801C” with “Offset: 0x001C”.
43.3.2.5.2, 11	In Figure 43-12, “SPDIFRcvCChannel_l Register (SRCSL)”, replaced “Offset: 0x8020” with “Offset: 0x0020”.
43.3.2.5.3, 11	In Figure 43-13, “UChannelRcv Register (SRU)”, replaced “Offset: 0x8024” with “Offset: 0x0024”.
43.3.2.5.4, 11	In Figure 43-14, “QChanelRcv Register (SRQ)”, replaced “Offset: 0x8028” with “Offset: 0x0028”.
43.3.2.6.1, 12	In Figure 43-15, “SPDIFTxLeft Register (STL)”, replaced “Offset: 0x802C” with “Offset: 0x002C”.
43.3.2.6.2, 12	In Figure 43-16, “SPDIFTxRight (STR) Register”, replaced “Offset: 0x8030” with “Offset: 0x0030”.
43.3.2.6.3, 13	In Figure 43-17, “SPDIFTxCChannelCons_h Register (STCSCH)”, replaced “Offset: 0x8034” with “Offset: 0x0034”.
43.3.2.6.4, 13	In Figure 43-18, “SPDIFTxCChannelCons_l Register (STCSCL)”, replaced “Offset: 0x8038” with “Offset: 0x0038”.
43.3.2.6.5, 13	In Figure 43-19, “FreqMeas Register”, replaced “Offset: 0x8044” with “Offset: 0x0044”.
43.3.2.7, 14	In Figure 43-20, “SPDIFTxClk Register (STC)”, replaced “Offset: 0x8050” with “Offset: 0x0050”.
43.3.2.7, 14	In Table 43-18, “Tx_Div_Reg Register (STC) Field Descriptions”, added the following text in the description of field 10–8, “TxClk_Source”: “100 MLBCLK input, 110 Ground input, no clock, 111 Ground input, no clock”
Chapter 48	Removed the “Signal Properties” table.
Chapter 48	Removed section “Software Model”.

Chapter 48 — Removed section “External Signal Description” and subsection “Overview”.

48.1, 1 — In Section 48.1, “Overview”, modified the first sentence of the second paragraph to read as follows:

“In addition to the USB cores, the module provides for full-speed transceiverless link (TLL) operation on the host port.”

48.1.2.1.1, 3 — In Section 48.1.2.1.1, “Host Port Modes”:

– Modified the first sentence of the first paragraph to read as follows:

“The host port supports ULPI and serial transceivers, as well as the internal Serial USB transceiver.”

– Modified the first sentence of the third bullet to read as follows:

“ULPI interface mode, which is the low pin-count standard for connecting off-chip high-speed USB transceivers.”

48.2, 4 — In Table 48-1, “USBOH Module Memory Map”, added rows for ENDPTNAK and ENDPTNAKEN registers below the ULPI Viewport register.

48.2, 4 — In Table 48-1, “USBOH Module Memory Map”:

– Replaced Base Address Offset from “0x02xx” with “0x04xx”.

– Replaced Base Address Offset from “0x03xx” with “0x05xx”.

– Added a row for Base Address Offset “0x0490” after “0x048c”.

48.2.1.1, 7 — In Table 48-2, “USB_CTRL Register Field Description”, updated the field descriptions of register fields “13”, “12”, “8”, “7”, “6”, and “4” to read as follows:

Table 48--3. USB_CTRL Register Field Description

Field	Description
13 OLKEN	OTG AHB lock enable The AHB lock enable/disable of OTG. 0 OTG lock disable. The OTG core will never use locked transfer to access memory (default) 1 OTG lock enable. The OTG core will always use locked transfer to access memory. When transfers are locked, the USB controller will keep the bus between bursts until it has filled it’s internal TX FIFO or emptied it’s RX FIFO
12 HLKEN	Host AHB lock enable The AHB lock enable/disable of Host. 0 Host lock disable. The Host core will never use locked transfer to access memory (default) 1 Host lock enable. The Host core will always use locked transfer to access memory. When transfers are locked, the USB controller will keep the bus between bursts until it has filled it’s internal TX FIFO or emptied it’s RX FIFO
8 IP_PUIDP	Dp pull-up Impedance select on the on-chip full-speed PHY. 0 Pull-up resistor 900 Ohm < R< 1575 Ohm (default) 1 Pull-up resistor 1425 Ohms < R< 3090 Ohms.

Table 48--3. USB_CTRL Register Field Description

Field	Description
7 IP_PUE_UP	This bit enables the Dp Pull-up resistor on the on-chip full-speed PHY. This bit must be 0 for host mode operation. 0 Pull-up resistor disabled (default) 1 Pull-up resistor enabled.
6 IP_PUE_DWN	This bit enables the 15K ohm Dm/Dp pull-down resistors of the on-chip full-speed PHY. This bit must be set for host mode operation. 0 Pull-down resistor disabled (default) 1 Pull-down resistor enabled.
4 USBTE	Transceiver Enable. This bit controls the enable for the on-chip serial transceiver of the host controller. 0 Full Speed transceiver disabled (default) 1 Full Speed transceiver enabled

48.2.1.3, 12

In Table 48-4, “USB_PHY_CTRL_FUNC Register Field Description”, updated the field descriptions of register fields “26”, “25, 20”, “19–16”, “15–8”, and “7–0” to read as follows:

Table 48--5. USB_PHY_CTRL_FUNC Register Field Description

Field	Description
26 SUSP	UTMI suspend. This bit allows software to force the UTMI PHY in low power suspend. Clearing this bit is equivalent to setting the PHCD bit in the USB controller’s PORTSC register with the exception that the PHY will not respond to wake-up requests when this bit is 0. 0 PHY in low power suspend mode 1 Normal operation. Low-power suspend controlled by USB controller. (default)
25 RESET	UTMI reset. This bit allows software to force a reset on the UTMI PHY. This should only be used in exceptional cases as the USB core will perform PHY reset when appropriate. Setting this bit will reset all in the UTMI PHY except the clock generation logic. 0 Normal operation (default) 1 PHY reset
20 VCTL_LD	UTMI vendor control load. For Freescale test use only.
19–16 VCTL_ADDR	UTMI vendor control address. For Freescale test use only.
15–8 VCTL_DATA	UTMI vendor control data. For Freescale test use only.
7–0 VSTS	UTMI vendor control status. For Freescale test use only.

48.2.1.4, 13

In Table 48-5, “USB_PHY_CTRL_TEST Register Field Descriptions”, updated the field descriptions of register fields “4–3”, “2”, “1”, and “0” to read as follows:

Table 48-6. USB_PHY_CTRL_TEST Register Field Descriptions

Field	Description
4–3 TM	UTMI test mode selection. For Freescale test use only.
2 LB	UTMI loop back. For Freescale test use only.
1 NFC	UTMI no Frequency check. For Freescale test use only.
0 FT	UTMI function test. For Freescale test use only.

48.3.3, 14

In Section 48.3.3, “USB Power Control Module”, modified the first sentence to read as follows:

“The HS-USB module supports low power suspend and wakeup functionality.”

48.3.3.1, 14

Modified the section name from “Entering Suspend Mode” to “Entering Low Power Suspend Mode”.

48.3.3.2, 14

Removed the following sentence from Section 48.3.3.2, “Wakeup Events”:

“This interrupt also re-activates the clocks if these were stopped during the suspend.”

48.3.3.2.1, 14

In the last paragraph of Section 48.3.3.2.1, “Host Mode Events”, replaced “Dm or Dp high” with “Dm or Dp assert”.

48.3.6.1, 17

In Section 48.3.6.1, “USB Core Interrupts”, modified the last sentence of the second paragraph to read as follows:

“See Section 48.4, “Initialization/Application Information” for more details.”

48.3.6.2, 17

In Section 48.3.6.2, “USB Wakeup Interrupts”, added the following sentence at the last of the first paragraph:

“USB clocks that were gated in the CCM module must be re-enabled by software.”

48.4.1.1, 17

In Table 48-7, “Configuration, Control, and Status Registers by Core Type”, added rows for ULPIVIEW, ENDPTNAK, and ENDPTNAKEN before the CONFIGFLAG register.

48.4.1.2, 21

In Table 48-8, “HS-USB Register Summary”, removed text “[Optional]” from “ULPI Viewport [Optional]”.

48.4.1.2, 21

In Table 48-8, “HS-USB Register Summary”, modified name and description of 0x0178 (ENDPTNAK) below the reserved field “0x0174”.

48.4.1.2, 21

In Table 48-8, “HS-USB Register Summary”, modified name and description of “0x017C (ENDPTNAKEN)” below “0x0178”.

48.4.1.3.1, 24	In Figure 48-7, “Identification Register (ID) Fields”, updated the reset values to “E241_FA05”.
48.4.1.3.1, 25	In Table 48-9, “Identification Register Field Descriptions”, updated the description of the register field “31–24” to “Reserved”.
48.4.1.3.4, 27	In Figure 48-10, “Device Hardware Parameters Register (HWDEVICE)”, updated the reset values.
48.4.1.3.5, 27	In Figure 48-11, “TX Buffer Hardware Parameters Register (HWTXBUF)”, updated the reset values.
48.4.1.3.6, 28	In Figure 48-12, “RX Buffer Hardware Parameters Register (HWRXBUF) Fields”, updated the reset values.
48.4.1.3.7, 28	In the fourth paragraph, added the following bulleted item at the end of the bulleted list: “000: INC (with burst size 8) + INC (with burst size 8) + INC (with burst size 6) (when AHBBRST is zero, the default burst size is 8, decided by register BURSTSIZE)”
48.4.1.3.7, 29	In Figure 48-13, “System Bus Interface Register (SBUSCFG)”, updated the reset values.
48.4.1.3.7, 29	In Table 48-15, “System Bus Interface Register Field Descriptions”, updated the description of the register field “2–0” to read as follows: “AMBA AHB BURST. This field configures the m_hburst signal of the AMBA master interface. When this field is different from zero, the burst size is set internally to the value of the INCRx AMBA burst, and the value of the fields TXPBURST and RXPBURST in register BURSTSIZE are ignored (but the BURSTSIZE register can still be written/read while the AHBBRST field is nonzero). For the case of AHBBRST != 000 (NOT EQUAL) and when the data buffer start address is not aligned 4 bytes, then SINGLE transfers will occur for AHB write. 000 INCR burst of unspecified length 001 INCR4, non-multiple transfers of INCR4 are decomposed into singles 010 INCR8, non-multiple transfers of INCR8, are decomposed into INCR4 or singles (default value for TO2 and TO2.1) 011 INCR16, non-multiple transfers of INCR16, are decomposed into INCR8, INCR4 or singles 100 Reserved, not used 101 INCR4, non-multiple transfers of INCR4 are decomposed into smaller unspecified length bursts 110 INCR8, non-multiple transfers of INCR8 are decomposed into smaller unspecified length bursts 111 INCR16, non-multiple transfers of INCR16 are decomposed into smaller unspecified length bursts”

48.4.1.4.2, 30 In Figure 48-15, “Host Interface Version Number Register Fields (HCIVERSION)”, updated the reset values.

48.4.1.4.5, 33 In Figure 48-18, “Device Interface Version Number Register (DCIVERSION)”, updated the reset values.

48.4.1.6.1, 36 In Figure 48-22, “USB Command Register (USBCMD)”, updated definitions of bits “14” and “12”.

48.4.1.6.1, 36 In Table 48-21, “USB Command Register Field Descriptions”, updated field descriptions of fields “14” and “12” to read as follows:

Table 48-22. USB Command Register Field Descriptions

Field	Description
14 ADTW	Add dTD Trip Wire (device mode only). This bit is used as a semaphore to ensure the to proper addition of a new dTD to an active (primed) endpoint’s linked list. This bit is set and cleared by software, and is also cleared by hardware when the state machine is in a state for which adding a dTD to a primed endpoint may go unrecognized. For more information on the use of this bit, see the Device Operational Model section.
12	Reserved

48.4.1.6.1, 36 In the description of field 13, “SUTW” of Table 48-21, “USB Command Register Field Descriptions”:

– Modified the reference in the third sentence to Section 48.4.1.6.16, “USB Device Mode Register (USBMODE)”.

– Modified the last sentence to read as follows:

“For more information on the use of this bit, see the Device Operational Model section.”

48.4.1.6.2, 39 In Figure 48-23, “USB Status Register Fields (USBSTS)”, updated definitions of bits “25”, “24”, and “16”.

48.4.1.6.2, 39 In Table 48-22, “USB Status Register Field Descriptions”, updated the following field descriptions:

Table 48-23. USB Status Register Field Descriptions

Field	Description
25–24 TIE1,TIE0	General Purpose Timer Interrupt n. The TIE [n] bit is set to 1 when the counter in the GPTIMERnCTRL register transitions to zero. Writing a 1 to TIE [n] clears it.
23—17	Reserved, read as 0.
16 NAKI	NAK Interrupt Bit- Read Only. This bit is readonly. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all the enabled TX/RX Endpoint NAK bits are cleared.

48.4.1.6.3, 41 In Figure 48-24, “USB Interrupt Enable Register Fields (USBINTR)”, updated definitions of bits 25 to “TIE1”, 24 to “TIE0”, 19 to “UPIA”, 18 to “UAIE”, and 16 to “NAKI”.

48.4.1.6.3, 41

In Table 48-23, “USB Interrupt Enable Register Field Descriptions”, updated the following field descriptions:

Table 48-24. USB Interrupt Enable Register Field Descriptions

Field	Description
25–24 TIE1,TIE0	When the TIE[n] bit is set to 1and the GPTINT[n] bit in the USBSTS register is set to 1, the controller issues an interrupt. The interrupt is acknowledged by software clearing the GPTINT[n] bit.
23–20	Reserved, read as 0
19 UPIE	USB Host Periodic Interrupt Enable When this is one, and the USBHSTPERINT bit in the USBSTS register is one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledges by software clearing the USBHSTPERINT bit.
18 UAIE	USB Host Async. Interrupt Enable When this is one, and the USBHSTASYNCINT bit in the USBSTS register is one, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledges by software clearing the USBHSTASYNINT bit.
17	Reserved. These bits are reserved and should be set zero.
16 NAKE	NAK Interrupt Enable This bit is set by software if it wants to enable the hardware interrupt for the NAK Interrupt bit. If both this bit and the corresponding NAK Interrupt bit are set, a hardware interrupt is generated.
15-11	Reserved

48.4.1.6.8, 47

In Figure 48-30, “Host Controller AHB burst length control (BURSTSIZE)”, updated figure title “Host Controller AHB burst length control (BURSTSIZE)” with “Host Controller AHB burst length control (BURSTSIZE)”.

48.4.1.6.8, 47

In Table 48-29, “Host Controller AHB burst length control Field Descriptions”, updated the table title “Host Controller AHB burst length control Field Descriptions” with “Host Controller AHB burst length control Field Descriptions”.

48.4.1.6.9, 47

In Figure 1, “Reset values for the two instances of this register: UOG_TXFILLTUNING reset value = 0x00020000 UH1_TXFILLTUNING reset value = 0x00000000”:

– Replaced reset value of bit “17” from “1” to “*”.

– Added the following footnote for the figure:

“Reset values for the two instances of this register:

UOG_TXFILLTUNING reset value = 0x00020000

UH1_TXFILLTUNING reset value = 0x00000000”

48.4.1.6, 49

In this section, added new sub-sections for “Endpoint NAK (ENDPTNAK)” and “Endpoint NAK Enable (ENDPTNAKEN)” registers after Section 48.4.1.6.10, “ULPI VIEWPORT”.

48.4.1.6.10, 49 — Updated heading name from “ULPI Viewport [Optional]” to “ULPI Viewport”.

48.4.1.6.14, 53 — In Figure 48-35, “Port Status Control x Registers (PORTSCx)”, updated the reset values.

48.4.3.2, 94 — In Section 48.4.3.2, “Port Routing and Control”, added the following note:

“The USB Controllers on i.MX parts neither support nor require companion controllers to support full and low speed devices. Therefore, no port routing is present in the controller. Please refer to the Section 48.5.5.1 Embedded Transaction Translator Function for details.”

48.4.3.2, 94 — In Section 48.4.3.2, “Port Routing and Control”, updated the third sentence of the third paragraph to read as follows:

“The Configured Flag (CF) bit is the global routing policy control.”

48.4.3.2.1, 95 — In Section 48.4.3.2.1, “Port Routing Control via EHCI Configured (CF) Bit”, updated the third sentence of the first paragraph to read as follows:

“The Configured Flag (CF) bit, is used to globally set the policy of the routing logic.”

50.3.3.2, 23 — In Table 50-13, “DSZ Bit Field Values”, updated the data port size of bit “100” to read as follows:

Table 50-13. DSZ Bit Field Values

DSZ	Data Port Size	
	MUM=0	MUM=1
100	Reserved	Reserved

50.3.3.3, 24 — In Table 50-14, “Chip Select x Additional Control Register Field Descriptions”, updated the field description of bit field “14–13, LAH” to read as follows:

“LBA to Address Hold. This bit field determines address hold time after LBA negation for MUM = 1 only.

See example on the Figure 50-43 and Figure 50-44. LAH is cleared by a hardware reset for CSCR1A - CSCR5A.

For CSCR0A LAH is set to 10 by hardware reset.

00 2 AHB half clock cycles between LBA negation and address invalid.

01 3 AHB half clock cycle between LBA negation and address invalid.

10 4 AHB half clock cycles between LBA negation and address invalid.

11 5 AHB half clock cycles between LBA negation and address invalid.”

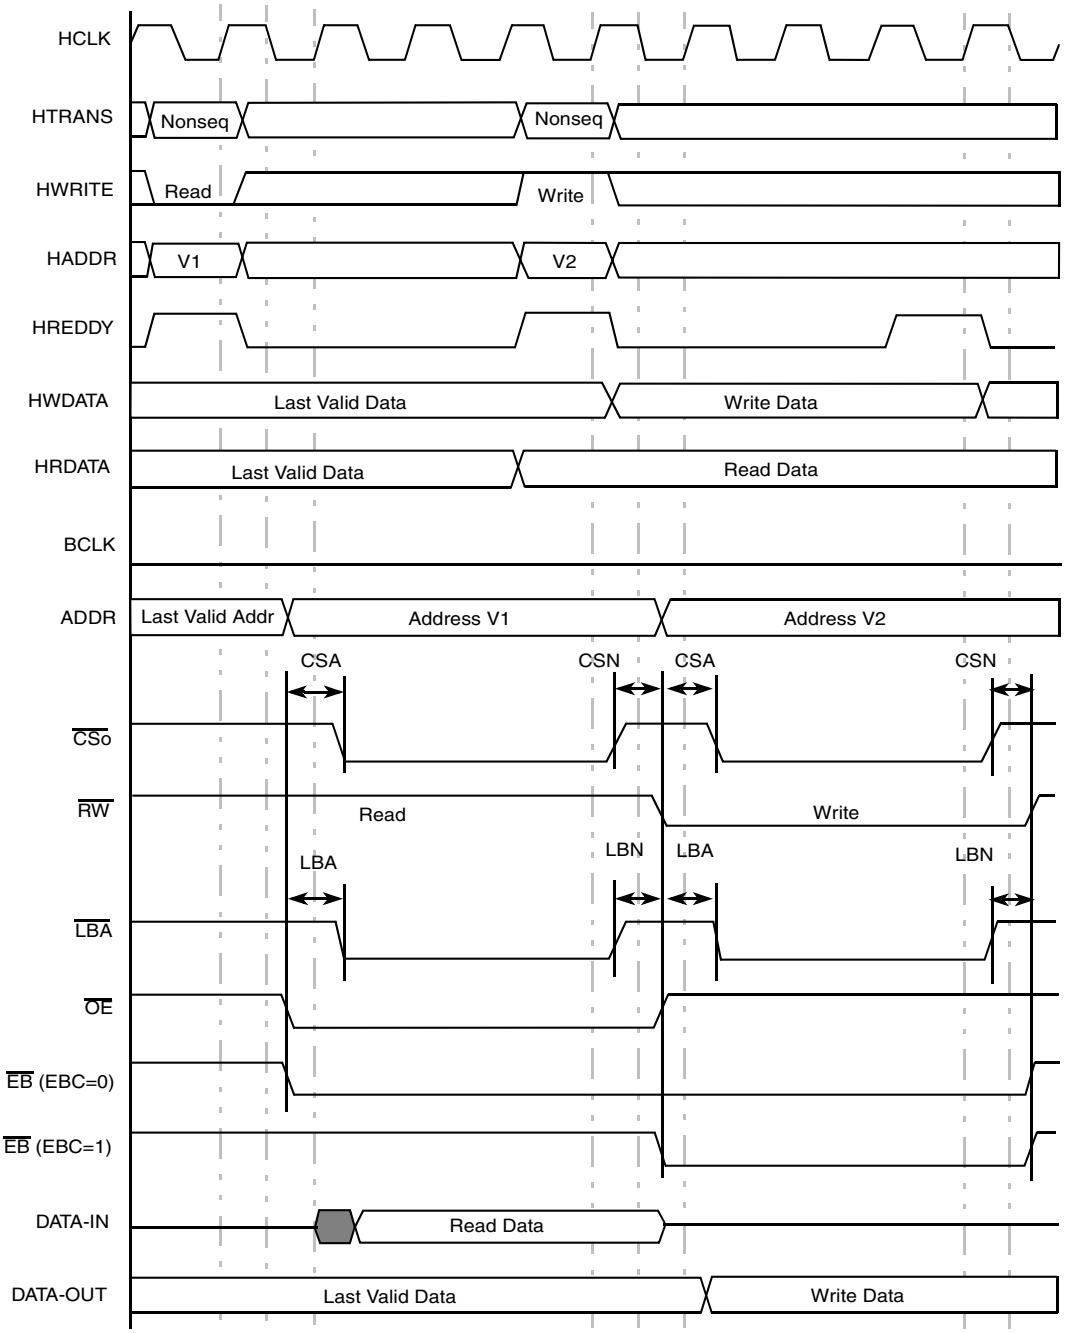
50.3.3.4, 28 — In Table 50-17, “WEIM Control Register Field Descriptions”, removed the following sentence from the description of field “0, MAS”:

“This bit is configured at reset time with the BOOT_CFG[3] pin.”

50.3.3.4, 28 — In Table 50-17, “WEIM Control Register Field Descriptions”, removed the following sentence from the description of field “8, AUS0”:

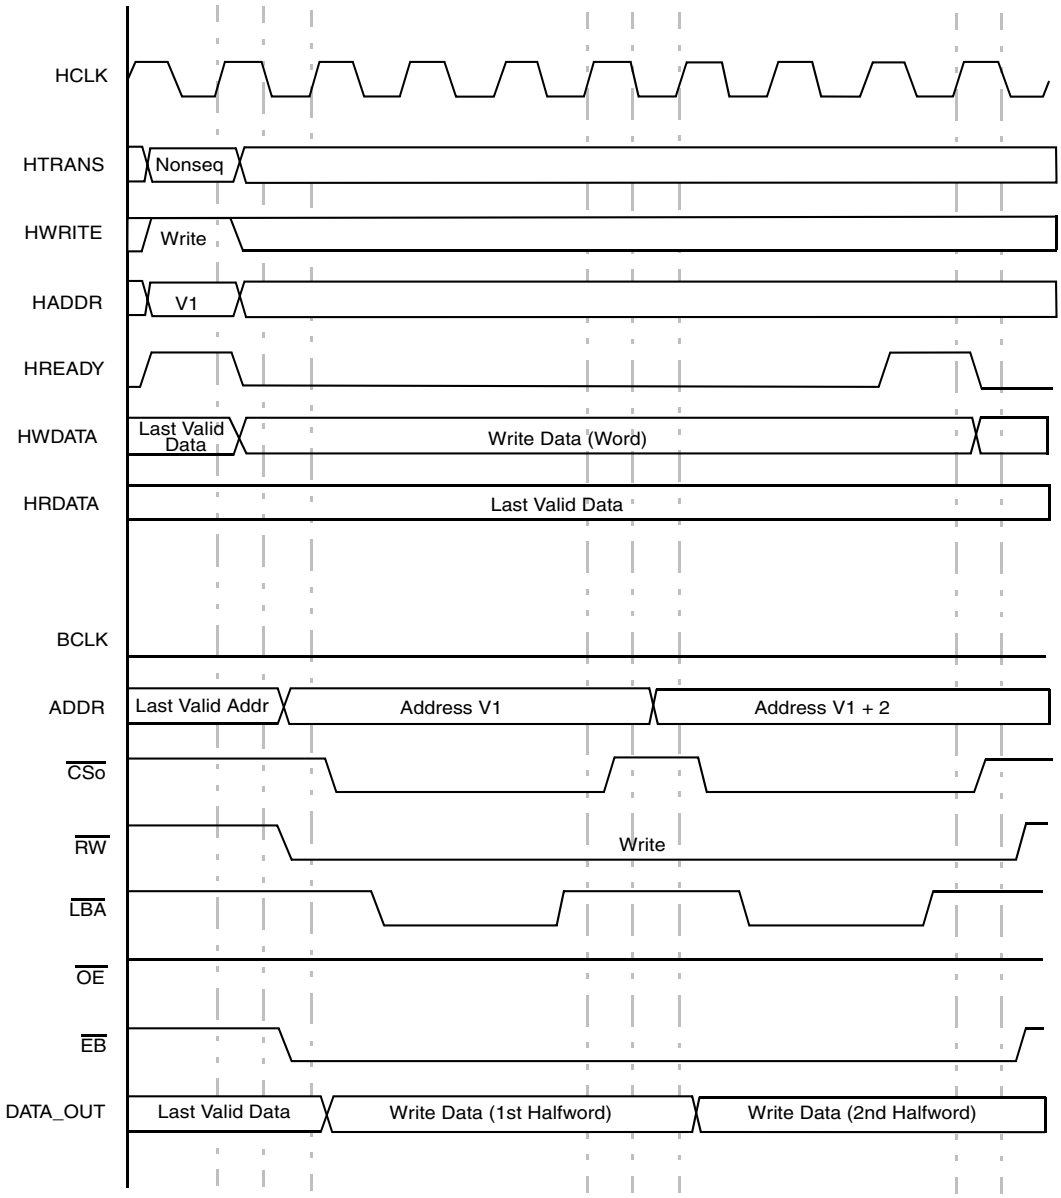
"This bit is configured at reset time with the BOOT_CFG[5] pin."

50.6.1.1, 41 Updated Figure 50-11, "Read and Write Accesses, WSC=3, CSA=1, CSN=1, LBA=1, LBN=1" as follows:



50.6.1.2, 54

Updated Figure 50-24, “Write Access, WSC=2, CSA=1, WWS=1, CSN=1” as follows:



Appendix A, 720 — Updated Table 1049, “Register: IOMUXC_GPIO1_IPP_IND_G_IN_10_SELECT_INPUT” as follows:

Offset (IOMUXC_GPIO1_IPP_IND_G_IN_10_SELECT_INPUT) 0x0830													Access: User read / write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DAISY	
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Appendix A — Replaced “1XXX: Enabled” with “1XXX: Keeper Enabled” throughout the chapter.

Appendix A — Replaced

“0000: Pull/Kepper Disabled, Keeper, 100KOhm Pull Down

0001: Pull/Kepper Disabled, Keeper, 47KOhm Pull Up

0010: Pull/Kepper Disabled, Keeper, 100KOhm Pull Up

0011: Pull/Kepper Disabled, Keeper, 22KOhm Pull Up

0100: Pull/Kepper Disabled, Pull, 100KOhm Pull Down

0101: Pull/Kepper Disabled, Pull, 47KOhm Pull Up

0110: Pull/Kepper Disabled, Pull, 100KOhm Pull Up

0111: Pull/Kepper Disabled, Pull, 22KOhm Pull Up”

with

“0xxx: Pull/Keeper Disabled” throughout the chapter.

Appendix A — Replaced

“1000: Enabled, Keeper, 100KOhm Pull Down

1001: Enabled, Keeper, 47KOhm Pull Up

1010: Enabled, Keeper, 100KOhm Pull Up

1011: Enabled, Keeper, 22KOhm Pull Up”

with

“10xx: Keeper Enabled” throughout the chapter.

Appendix A — Replaced

“1: Enabled” with “1: Keeper Enabled” throughout the chapter.
