i.MX35 (MCIMX35) Multimedia Applications Processor Reference Manual Book I

Rev. 3
11/2010

Chapter 1
IC Architecture Overview

This chapter introduces the i.MX35 architecture.

1.1 i.MX35 Overview

The MCIMX35 platform is intended to support the following:

- External connectivity via Bluetooth
- Multistandard audio playback
- Multistandard video playback of 30 fps at QVGA (320 x 240) resolution
- Open OS support (Linux, WinCE, QNX, other auto RTOS)

The i.MX35 is partitioned into two major subsystems as shown in Figure 1-1: the ARM1136 platform, and the SDMA platform with external memory interface (EMI).

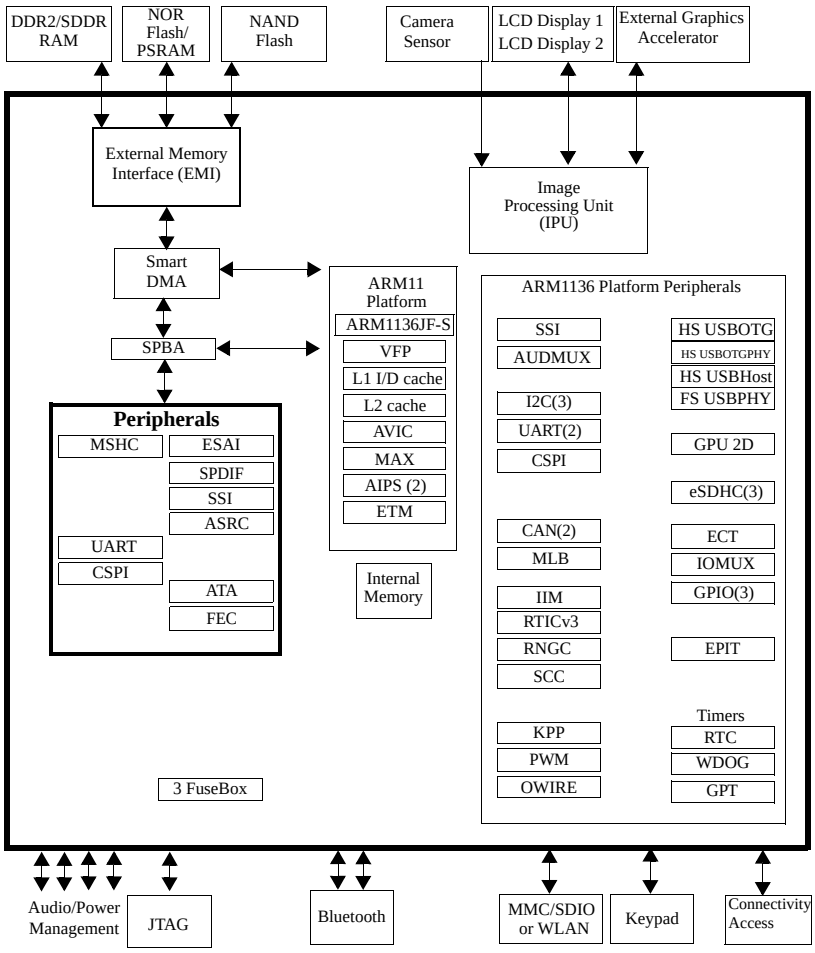

Figure 1-1. i.MX35 High-Level Block Diagram

1.1.1 Key Features

The i.MX35 ARM1136 platform is based on the ARM1136 platform. The ARM1136 platform has the following features:

- ARM1136JF-S processor
- 16-Kbyte level-one (L1) instruction cache
- 16-Kbyte L1 data cache
- 128-Kbyte level-two (L2) cache
- Vector floating point unit (VFP11)
- Maximum frequency of the core (including VFP11), L1, and L2 caches is:
  - 400 MHz at 1.2 V minimum
  - 532 MHz at 1.55 V minimum

To boost the multimedia performance, the following hardware accelerators are integrated:

- Image processing unit (IPU)
- 2-D graphics accelerator

Security functions are enabled and accelerated by the following hardware:

- Secure JTAG controller (SJC). Protects JTAG from debug port attacks by regulating or blocking access to the system debug features.
- Real-time integrity checker type2 (RTICv3). RTIC type1, enhanced with SHA-256 engine.
- Secure RAM module and security monitor (SCC), providing 2 Kbytes of secure storage of sensitive information in both on-chip and off-chip RAM, non-volatile memory
- High assurance boot (HAB) with SHA-256
- Random number generator controller (RNGC) capable of generating 32-bit random numbers

The memory system consists of the following levels:

- Level-1 cache
  - Instruction (16 Kbytes)
  - Data (16 Kbytes)
- Level-2 cache
  - Unified instruction and data (128 Kbytes)
- Level-2 memory
  - Boot ROM, including HAB (32 Kbytes)
  - Internal SRAM (128 Kbytes)
  - Secure RAM (2 Kbytes)

The i.MX35 is built around the following system buses:

- 64-bit AMBA AHB 2.0 (AHB-64)—Used by most of the high bandwidth bus master peripherals, such as IPU and GPU2D.
- 32-bit AMBA AHB 2.0 (AHB)—Used by most of the bus master peripherals, such as SDMA, RTICv3, USB, EMI, and so forth; see the block diagram for the complete list.
- 32-bit IP bus—Used for control (and slow data traffic) of most of the SoC peripheral devices.

The i.MX35 enables the following interfaces to external devices:

- Two CAN interfaces
- One CE-ATA interface
- Two SDIO 2.0/MMC 4.2 interfaces (up to 416 Mbps each)
- Two CSPI (up to 52 Mbps each)
- DDR2 and 32 bit SDRAM (up to 133 MHz)
- Enhanced serial audio interface (ESAI)
- Ethernet 10/100 Mbps
- Flash controller—MLC/SLC, NAND, and NOR
- GPIO with interrupt capabilities

- Three I^2C (up to 400 Kbps each)
- Secure JTAG
- Keypad port
- Memory Stick PRO
- Media local bus (MLB) interface
- 1-Wire module
- Parallel camera sensor (4/8/10/16-bit data port for video color models YCC, YUV, 30 MPixels/s)
- Parallel display (primary up to 24-bit, 1024 x 1024)
- P-ATA (up to 66 Mbytes/s)
- PWM
- S/PDIF transceiver
- Two SSIs
- Three UARTs (up to 4.0 Mbps each)
- One USB 2.0 Host (up to 480 Mbps) with FS PHY
- One USB 2.0 OTG (up to 480 Mbps) controller with HS OTG PHY

1.2 Architecture Overview

1.2.1 Functional Domains Overview

The i.MX35 consists of the following major subsystems:

- ARM1136 platform
- SDMA Platform and EMI

1.2.1.1 ARM1136 Platform Overview

The ARM1136 platform is responsible for running the operating system and applications software, providing the user interface, and supplying access to integrated and external peripherals. The look and feel of the device depends on the software running on this processor, ultimately tying market acceptance to the availability of a wide variety of off-the-shelf, third-party software and development tools. Over the past couple of years, the ARM CPU family has emerged as the de facto standard for mobile application processors. To leverage this growing software base, the ARM1136 platform is based on the ARM architecture. With high-frequency operation and coupled with an L2 cache, the ARM1136 platform achieves multimedia and graphics performance to meet the targets for this market. The ARM1136 platform is built around an ARM1136JF-S core with 16-Kbyte instruction and 16-Kbyte data L1 caches, an MMU, a 128-Kbyte L2 cache, a multi-ported crossbar switch, and advanced debug and trace interfaces.

The ARM11 core is intended to operate at a maximum frequency of 532 MHz to support the required multimedia use cases, such as concurrent video playback CIF at 30 fps and MP3 audio decode. Furthermore, an image processing unit is integrated into the ARM1136 platform to offload the ARM11 core from performing functions such as color-space conversion, image rotation and scaling, graphics overlay, and pre- and post-processing.

Peripheral functionality belonging to the ARM1136 platform includes the user interface, connectivity, display, security, and memory interfaces, and 128 Kbytes of multipurpose SRAM. This SRAM can be used as audio RAM, scratch-pad RAM by the ARM11, or it can be accessed by the IPU for use as a display buffer for partial display refresh during deep sleep mode (DSM).

1.2.1.2 SDMA Platform and EMI Overview

The SDMA platform is composed of the SDMA peripherals, a Smart DMA engine (SDMA), and a number of miscellaneous modules. For maximum flexibility, some peripherals are directly accessible by the SDMA engine.

The external memory subsystem represents a significant investment in chipset cost and board area. High-performance processors such as the ARM11 require a significant amount of bus bandwidth to achieve their maximum potential. The challenge here is to maximize the performance while minimizing the bandwidth. To achieve that, the i.MX35 includes a hierarchical memory architecture including L1 caches, unified L2 cache and M2 memory. This reduces the bandwidth demands for the external bus and external memory. The external memory subsystem supports a flexible external memory system, including support for SDRAM (SDR and DDR) and NAND Flash.

1.2.2 Advanced Power Management Overview

To address the continuing need to reduce power consumption, the following techniques have been incorporated into the i.MX35 processor:

- Clock gating
- Power gating
- Power-optimized synthesis
- Well biasing
- Dynamic process and temperature compensation (DPTC)
- Dynamic voltage and frequency scaling (DVFS)

By inserting gating into the clock paths, unused portions of the chip can be disabled. Since static CMOS logic consumes only leakage power, significant power savings can be realized. The i.MX35 clock gating is inserted both manually on a large functional block basis and automatically within the blocks during logic synthesis. Synthesis tools are not only capable of inserting clock gates automatically, but they can also be instructed to minimize power consumption of logic through gate substitution and rearranging of terms to minimize unnecessary transitions. The i.MX35 integrates both clock gating and power optimization into the synthesis design flow.

Well biasing is applying a voltage that is greater than Vdd to the nwells and lower than Vss to the pwells. The effect of applying this well back bias voltage is to reduce the subthreshold channel leakage. For the 90-nm digital process, it is estimated that the subthreshold leakage will be reduced by a factor of 10 over the nominal leakage.

Additionally, the supply voltage for internal logic can be reduced from 1.4 V to 1.2 V to 1.0 V during periods of inactivity.

1.2.3 Modules Inventory

Table 1-1 describes the ARM1136 core.

Table 1-1. i.MX35 Cores

Core Acronym	Core Name	Brief Description	Integrated Memory Includes
ARM11 or ARM1136	ARM1136 platform and memory	The ARM1136 platform consists of the ARM1136JF-S™ core, the ETM real-time debug modules, a 6 × 5 multilayer AHB crossbar switch, and a “primary AHB” complex.	• 16-Kbyte instruction L1 cache • 16-Kbyte data L1 cache • 128-Kbyte L2 cache • 32-Kbyte ROM • 128-Kbyte RAM

Table 1-2 provides summary descriptions of the modules on the chip and their functionality, as well as names of the subsystem platforms to which they belong.

Table 1-2. Digital and Analog Modules

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
1-WIRE	1-Wire interface	ARM	ARM1136 platform peripherals	1-Wire provides the communication line to a 1-Kbit add-only memory. The interface can send or receive 1 bit at a time.	Chapter 9, “1-Wire Module (1-Wire)”
ASRC	Asynchronous sample rate converter	SDMA	Connectivity peripherals	The ASRC is designed to convert the sampling rate of a signal associated to an input clock into a signal associated to a different output clock. It supports concurrent sample rate conversion of about – 120 dB THD + N. The sample rate conversion of each channel is associated to a pair of incoming and outgoing sampling rates.	Chapter 10, “Asynchronous Sample Rate Converter (ASRC)”
ATA	ATA module	SDMA	Connectivity peripherals	The ATA block is an AT attachment host interface. Its main use is to interface with IDE hard disk drives and ATAPI optical disk drives. It interfaces with the ATA device over a number of ATA signals.	Chapter 11, “Advanced Technology Attachment (ATA)”
AUDMUX	Digital audio mux	ARM	Multimedia peripherals	The AUDMUX is a programmable interconnect for voice, audio, and synchronous data routing between host serial interfaces (SSIs) and peripheral serial interfaces (audio codecs). The AUDMUX has two sets of interfaces: internal ports to on-chip peripherals, and external ports to off-chip audio devices. Data is routed by configuring the appropriate internal and external ports.	Chapter 12, “Digital Audio Multiplexer (AUDMUX)”
CAN(2)	CAN module	ARM	Connectivity peripherals	The CAN protocol is primarily designed as a vehicle serial data bus running at 1 Mbps.	Chapter 24, “Controller Area Network (FlexCAN)”

Table 1-2. Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
CCM	Clock control module	ARM	Clocks	This block generates all clocks for the peripherals in the SDMA platform. The CCM also manages ARM1136 platform low-power modes (WAIT, STOP), disabling peripheral clocks appropriately for power conservation, and provides alternate clock sources for the ARM1136 and SDMA platforms.	Chapter 14, "Clock Controller Module (CCM)"
CSPI(2)	Configurable serial peripheral interface	SDMA, ARM	Connectivity peripherals	This module is a serial interface equipped with data FIFOs (first in first out). Each master/slave-configurable SPI module is capable of interfacing to both serial port interface master and slave devices. The CSPI ready (SPI_RDY) and slave select (SS) control signals enable fast data communication with fewer software interrupts.	Chapter 16, "Configurable Serial Peripheral Interface (CSPI)"
EMI	External memory interface	SDMA	External memory interface	The EMI module provides access to external memory for the ARM and other masters. It is composed of the following main submodules: • M3IF provides arbitration between multiple masters requesting access to the external memory. • The SDRAM CTRL interfaces to DDR2 and SDR interfaces. • NANDFC provides an interface to NAND Flash memories. • The WEIM interfaces to NOR flash and PSRAM.	Chapter 17, "External Memory Interface (EMI)"
EPIT(2)	Enhanced periodic interrupt timer	ARM	Timer peripherals	Each EPIT is a 32-bit "set and forget" timer that starts counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention. It has a 12-bit prescaler to adjust the input clock frequency to the required time setting for the interrupts, and the counter value can be programmed on the fly.	Chapter 18, "Enhanced Periodic Interrupt Timer (EPIT)"
ESAI	Enhanced serial audio interface	SDMA	Connectivity peripherals	The enhanced serial audio interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other DSPs. The ESAI consists of independent transmitter and receiver sections, each with its own clock generator.	Chapter 19, "Enhanced Serial Audio Interface (ESAI)"

Table 1-2. Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
eSDHCv2 (3)	Enhanced secure digital host controller	ARM	Connectivity peripherals	The eSDHCv2 consists of four main modules: CE-ATA, MMC, SD and SDIO. CE-ATA is a hard drive interface that is optimized for embedded applications of storage. The multimedia card (MMC) is a universal, low-cost, data storage and communication media for applications such as electronic toys, organizers, PDAs, and smartphones. The secure digital (SD) card is an evolution of MMC and is specifically designed to meet the security, capacity, performance, and environment requirements inherent in emerging audio and video consumer electronic devices. SD cards are categorized into memory and I/O. A memory card enables a copyright protection mechanism that is compatible with with the SDMI security standard. SDIO cards provide high-speed data I/O (such as wireless LAN via SDIO interface) with low-power consumption.	Chapter 20, "Enhanced Secured Digital Host Controller (eSDHC)"
FEC	Ethernet	SDMA	Connectivity peripherals	The Ethernet media access controller (MAC) is designed to support both 10- and 100-Mbps Ethernet/IEEE 802.3® networks. An external transceiver interface and transceiver function are required to complete the interface to the media.	Chapter 23, "Fast Ethernet Controller (FEC)"
GPIO(3)	General purpose I/O modules	ARM	Pins	Used for general purpose input/output to external ICs, each GPIO module supports 32 bits of I/O.	Chapter 25, "General Purpose Input/ Output Module (GPIO)"
GPT	General purpose timers	ARM	Timer peripherals	Each GPT is a 32-bit "free-running" or "set-and-forget" mode timer with a programmable prescaler and compare and capture registers. A timer counter value can be captured using an external event and can be configured to trigger a capture event on either the leading or trailing edge of an input pulse. When the timer is configured to operate in set-and-forget mode, it is capable of providing precise interrupts at regular intervals with minimal processor intervention. The counter has output compare logic to provide the status and interrupt at comparison. This timer can be configured to run either on an external clock or on an internal clock.	Chapter 26, "General Purpose Timer (GPT)"
GPU2D	Graphics processing unit 2Dv1	ARM	Multimedia peripherals	This module accelerates 2-D graphics performance.	Chapter 27, "Graphics Processing Unit (GPU)"

Table 1-2. Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
I^2C(3)	I^2C module	ARM	ARM1136 platform peripherals	Inter-integrated circuit (I^2C) is an industry-standard, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. I^2C is suitable for applications requiring occasional communications over a short distance among many devices. The interface operates at up to 100 kbps with maximum bus loading and timing. The I^2C system is a true multiple-master bus, with arbitration and collision detection that prevent data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer.	Chapter 28, "Inter IC Module (I2C)"
IIM	IC identification module	ARM	Security modules	The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, and various control signals requiring a fixed value.	Chapter 29, "IC Identification Module (IIM)"
IOMUX	External signals and pin multiplexing	ARM	Pins	Each I/O multiplexer provides a flexible, scalable multiplexing solution with the following features: • Up to eight output sources multiplexed per pin • Up to four destinations for each input pin • Unselected input paths held at constant levels for reduced power consumption	Chapter 4, "External Signals and Pin Multiplexing"
IPUv1	Image processing unit	ARM	Multimedia peripherals	The IPU supports video and graphics processing functions. It also provides the interface for image sensors and displays. The IPU performs the following main functions: • Preprocessing of data from the sensor or from the external system memory • Postprocessing of data from the external system memory • Post-filtering of data from the system memory with support of the MPEG-4 (both deblocking and deringing) and H.264 postfiltering algorithms • Displaying video and graphics on a synchronous (dumb or memory-less) display • Displaying video and graphics on an asynchronous (smart) display • Transferring data between IPU sub-modules and to/from the system memory with flexible pixel reformatting	Chapter 31, "Image Processing Unit (IPU)"
KPP	Keypad port	ARM	Connectivity peripherals	Can be used for either keypad matrix scanning or general purpose I/O.	Chapter 33, "Keypad Port (KPP)"

Table 1-2. Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
MLB	Media local bus	ARM	Connectivity peripherals	The MLB is designed to interface to an automotive MOST ring.	Chapter 36, "MediaLB Device Module (MLB)"
OSCAUD	OSC audio reference oscillator	Analog	Clock	The OSCAUDIO oscillator provides a stable frequency reference for the PLLs. This oscillator is designed to work in conjunction with an external 24.576-MHz crystal.	—
OSC24M	OSC24M—24-MHz reference oscillator	Analog	Clock	The signal from the external 24-MHz crystal is the source of the CLK24M signal fed into USB PHY as the reference clock and to the real-time clock (RTC).	—
PWM	Pulse-width modulator	ARM	ARM1136 platform peripherals	The pulse-width modulator (PWM) has a 16-bit counter and is optimized to generate sound from stored sample audio images. The PWM can also generate tones. It uses 16-bit resolution and a 4 × 16 data FIFO to generate sound.	Chapter 40, "Pulse-Width Modulator (PWM)"
RTC	Real-time clock	ARM	Clocks	Provides the ARM1136 platform with a clock function (days, hours, minutes, seconds) and includes alarm, sampling timer, and minute stopwatch capabilities.	Chapter 41, "Real Time Clock (RTC)"
SDMA	Smart DMA engine	SDMA	System controls	The SDMA provides DMA capabilities inside the processor. It is a shared module that implements 32 DMA channels and has an interface to connect to the ARM1136 platform subsystem, EMI interface, and the peripherals.	Chapter 42, "Smart Direct Memory Access (SDMA) Controller"
SJC	Secure JTAG controller	ARM	Pins	The secure JTAG controller (SJC) provides debug and test control with maximum security.	Chapter 44, "Secure JTAG Controller (SJC)"
SPBA	SDMA peripheral bus arbiter	SDMA	System controls	The SPBA controls access to the SDMA peripherals. It supports shared peripheral ownership and access rights to an owned peripheral.	Chapter 45, "Shared Peripheral Bus Arbiter (SPBA)"
S/PDIF	Serial audio interface	SDMA	Connectivity peripherals	Sony/Philips digital transceiver interface	Chapter 43, "Sony/Philips Digital Interface (SPDIF)"
SSI(2)	Synchronous serial interface	SDMA, ARM(2)	Connectivity peripherals	The SSI is a full-duplex serial port that allows the processor connected to it to communicate with a variety of serial protocols, including the Freescale Semiconductor SPI standard and the I^2C sound (I^2S) bus standard. The SSIs interface to the AUDMUX for flexible audio routing.	Chapter 46, "Synchronous Serial Interface (SSI)"

Table 1-2. Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Domain[a]	Subsystem	Brief Description	Chapter
UART(3)	Universal asynchronous receiver/ transmitters	SDMA	Connectivity peripherals	Each UART provides serial communication capability with external devices through an RS-232 cable using the standard RS-232 non-return-to-zero (NRZ) encoding format. Each module transmits and receives characters containing either 7 or 8 bits (program-selectable). Each UART can also provide low-speed IrDA compatibility through the use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission).	Chapter 47, "Universal Asynchronous Receiver/ Transmitter (UART)"
USBOH	High-speed USB on-the-go	SDMA	Connectivity peripherals	The USB module provides high performance USB on-the-go (OTG) functionality (up to 480 Mbps), compatible with the USB 2.0 specification, the OTG supplement, and the ULPI 1.0 low pin count specification. The module has DMA capabilities handling data transfer between internal buffers and system memory.	Chapter 48, "Universal Serial Bus OTG and Host (USBOH)"
WDOG	Watchdog modules	ARM	Timer peripherals	Each module protects against system failures by providing a method of escaping from unexpected events or programming errors. Once activated, the timer must be serviced by software on a periodic basis. If servicing does not take place, the watchdog times out and then either asserts a system reset signal or an interrupt request signal, depending on the software configuration.	Chapter 49, "Watchdog Timer (WDOG)"

a. ARM = ARM1136 platform, SDMA = SDMA platform

Chapter 2
Memory Map

The i.MX35 memory design is hierarchical, with two levels of cache between the microprocessors and the external memory.

The memory map is dependent on how peripherals are connected to the advanced high-performance bus (AHB) and IP (AIPS) interface, and on how decoding is performed in the AHB domain.

This chapter is organized as follows:

- "Section 2.1, "System Memory Map," describes the system memory map.
- "Section 2.2, "SDMA Peripheral Memory Map," describes the SDMA master IP bus peripheral memory map.

NOTE

All addresses referenced are physical addresses.

2.1 System Memory Map

Table 2-1 shows the system memory map for the i.MX35.

Table 2-1. System Memory Map

Address Range		Size	Region
Start	End		
0x0000_0000	0x0000_3FFF	16 Kbytes	ROM (32KB)
0x0000_4000	0x0040_3FFF	4 Mbytes	Reserved
0x0040_4000	0x0040_7FFF	16 Kbytes	ROM (32KB)
0x0040_8000	0x0FFF_FFFF	252 Mbytes (minus 32 Kbytes)	Reserved
0x1000_0000	0x1001_FFFF	128 Kbytes	Internal RAM
0x1002_0000	0x1FFF_FFFF	256 Mbytes (minus 128 Kbytes)	Reserved for RAM aliasing
0x2000_0000	0x2FFF_FFFF	256 Mbytes	Graphics processing unit (GPU2D)
0x3000_0000	0x3FFF_FFFF	256 Mbytes	L2 cache controller (L2CC) configuration registers
0x4000_0000	0x43EF_FFFF	63 Mbytes	Reserved
0x43F0_0000	0x43F0_3FFF	16 Kbytes	ARM IP bus (AIPS) 1 control registers
0x43F0_4000	0x43F0_7FFF	16 Kbytes	ARM1136 platform MAX
0x43F0_8000	0x43F0_BFFF	16 Kbytes	ARM1136 platform event monitor (EVTMON)

a. WEIM CS0 and CS1 can be collapsed to form a single 256-Mbyte region from 0xA000_0000 to 0xAFFF_FFFF.

2.2 SDMA Peripheral Memory Map

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers. All of the data accessible to SDMA scripts make up the data memory space of the SDMA. The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word.

The SDMA can perform only 32-bit access to shared peripheral registers. For i.MX35, shared peripherals registers are treated as if byte addressed. This is a consequence of connections through the SPBA shared peripheral bus outside of the SDMA. The result is that although 4 Kwords of address space (16 Kbyte) is allocated for each peripheral, only the first 4 Kbytes of the peripherals' register space can be accessed. For example, the shared peripheral register at address 0x3000 is mapped also to addresses 0x3001, 0x3002, and 0x3003. A read or write access to any of these 4 addresses will respond as if the access was to address 0x3000.

Table 2-2 shows the memory map of the shared peripherals to SDMA-accessible memory space.

Table 2-2. SDMA Peripheral Memory Map

Peripheral	Base Address	Size	Comments
SDMA internal memory	0x0000	4 KWords	map to SDMA Internal ROM/RAM
Reserved	0x1000	4 KWords	Reserved
Reserved	0x2000	4 KWords	Reserved
UART-3	0x3000	4 KWords	map to 4 Kbytes of UART-3 address space
CSPI-2	0x4000	4 KWords	map to 4 Kbytes of CSPI-2 address space
SSI-2	0x5000	4 KWords	map to 4 Kbytes of SSI-2 address space
Reserved	0x6000	4 KWords	Reserved

Table 2-2. SDMA Peripheral Memory Map (Continued)

Peripheral	Base Address	Size	Comments
SDMA internal registers	0x7000	4 KWords	map to SDMA registers
ATA	0x8000	4 KWords	map to 4 Kbytes of ATA address space
MSHC	0x9000	4 KWords	map to 4 Kbytes of MSHC address space
SPDIF	0xA000	4 KWords	map to 4 Kbytes of SPDIF address space
ASRC	0xB000	4 KWords	map to 4 Kbytes of IIM address space
Reserved	0xC000	4 KWords	Reserved
ESAI	0xD000	4 KWords	map to 4 Kbytes of ESAI address space
FEC	0xE000	4 KWords	map to 4 Kbytes of FEC address space
SPBA registers	0xF000	4 KWords	map to 4 Kbytes of SPBA address space

Chapter 3
Interrupts and DMA Events

This chapter is divided into two sections:

- Section 3.1, “ARM1136 Platform Interrupts,” provides the assignments for the interrupt requests of the ARM1136 Platform.
- Section 3.2, “SDMA Event Mapping,” defines the DMA events.

3.1 ARM1136 Platform Interrupts

The AVIC is designed to handle up to 64 interrupt requests. Table 3-1 lists the ARM1136 platform interrupt sources.

Table 3-1. ARM1136 Platform Interrupt Sources (By Interrupt)

IRQ	Interrupt Source	Interrupt Description
0	Reserved	
1	Reserved	
2	OWIRE	
3	I2C-3	
4	I2C-2	
5	Reserved

37	ASRC DMA2	ASRC channel B RX
38	ASRC DMA3	ASRC channel C RX
39	ASRC DMA4	ASRC channel A TX
40	ASRC DMA5	ASRC channel B TX
41	ASRC DMA6	ASRC channel C TX
42	Reserved	

Table 3-3. SDMA Event Mapping (By Event Number) (continued)

Event Number	DMA Source	Description
43	Reserved	
44	Reserved	
45	Reserved	
46	Reserved	
47	Reserved	
48	Reserved	

[1] While the capture of a 2-megapixel image requires a data buffer of up to 4 Mbytes, Linux does not support such a large, contiguous data buffer. This means the SDMA cannot be used for direct data transfers from the IPU. However, the IPU can support noncontiguous data buffers by periodically updating the IPU FIFO pointers after each buffer is full. The proposed solution is to connect the IPU functional interrupt to SDMA, as shown in this table.

[2] GEMK trigger to the SDMA. This does not map GEMK memory to the SDMA, but when the GEMK is done, it triggers the SDMA to move data from the external ARM1136 platform space to the external SDMA platform space.

Table 3-4 shows SDMA event mapping by source.

Table 3-4. SDMA Event Mapping (By Source)

Event Number	DMA Source	Description
36	ASRC DMA1	ASRC channel A RX
37	ASRC DMA2	ASRC channel B RX
38	ASRC DMA3	ASRC channel C RX
39	ASRC DMA4	ASRC channel A TX
40	ASRC DMA5	ASRC channel B TX
41	ASRC DMA6	ASRC channel C TX
4	ATA RX FIFO	
3	ATA TX FIFO	
2	ATA TXFER end	
8	CSP-1 RX	CSPI-1 receive
6	CSP-2 RX	CSPI-2 receive
9	CSPI-1 TX	CSPI-1 transmit
7	CSPI-2 TX	CSPI-2 transmit
1	DPTC, DVFS	
31	ECT	CTI trigger out
32	ESAI RX	
33	ESAI TX	
0	EXT DMA 0	External DMA request 0 from GPIO1[0]
14	EXT DMA 1	External DMA request 1 from GPIO1[1]

Table 3-4. SDMA Event Mapping (By Source) (continued)

13	SPDIF TX	
28	SSI-1 RX0	SSI-1 receive channel 0
29	SSI-1 RX0	SSI-1 transmit channel 0
26	SSI-1 RX1	SSI-1 receive channel 1
27	SSI-1 TX1	SSI-1 transmit channel 1
24	SSI-2 RX0	SSI-2 receive channel 0
22	SSI-2 RX1	SSI-2 receive channel 1
25	SSI-2 TX0	SSI-2 transmit channel 0
23	SSI-2 TX1	SSI-2 transmit channel 1
18	UART-1 RX	UART1 receive
19	UART-1 TX	UART1 transmit
16	UART-2 RX	UART2 receive
17	UART-2 TX	UART2 transmit
10	UART-3 RX	UART3 receive
11	UART-3 TX	UART3 transmit

[1] While the capture of a 2-megapixel image requires a data buffer of up to 4 Mbytes, Linux does not support such a large, contiguous data buffer. This means the SDMA cannot be used for direct data transfers from the IPU. However, the IPU can support noncontiguous data buffers by periodically updating the IPU FIFO pointers after each buffer is full. The proposed solution is to connect the IPU functional interrupt to SDMA, as shown in this table.

[2] GEMK trigger to the SDMA (not to make GEMK memory mapped to SDMA, but when the GEMK is done, it can trigger to SDMA, which can then move data from external ARM1136 platform space to external BP space).

Chapter 4
External Signals and Pin Multiplexing

The i.MX35 device has a limited number of pins, and most pins are shared among multiple signals. This chapter describes the external I/O signals and pin multiplexing (muxing) to help users understand pin assignment and the operation of the input-output multiplexer (IOMUX). It is also intended to enable software developers to do appropriate muxing programming.

4.1 IOMUX Overview

The muxing hardware in i.MX35 is composed of the following:

- IOMUX: combinational logic that does the muxing.
- IOMUX_CTL: muxing controller, which controls signal muxing and pin settings.

The IOMUX module deals with signal multiplexing, and consists of combinatorial logic built with a basic IOMUX cell. Each pin, which is shared by multiple signals, has a related IOMUX cell to handle signal multiplexing.

The IOMUX_CTL module consists of registers and deals with pin characteristic settings, such as I/O driver voltage, slew rate, drive strength, open drain and pull/keeper, and so on.

Figure 4-1 shows a simplified SoC block diagram of pin muxing with two typical cases:

- Case1 is a regular muxing example: Module A, Module B, and Module GPIO share the same pin through the IOMUX, and muxing is controlled by the IOMUX_CTL.
- Case2 is an example of no-muxing: the pin is dedicated to Module C, signals are directly connected between Module C and the pin, and no IOMUX cell is involved.

Each IOMUX cell can support up to eight mux modes (ALT0~ALT7), which means each pin can ultimately be shared by eight signals.

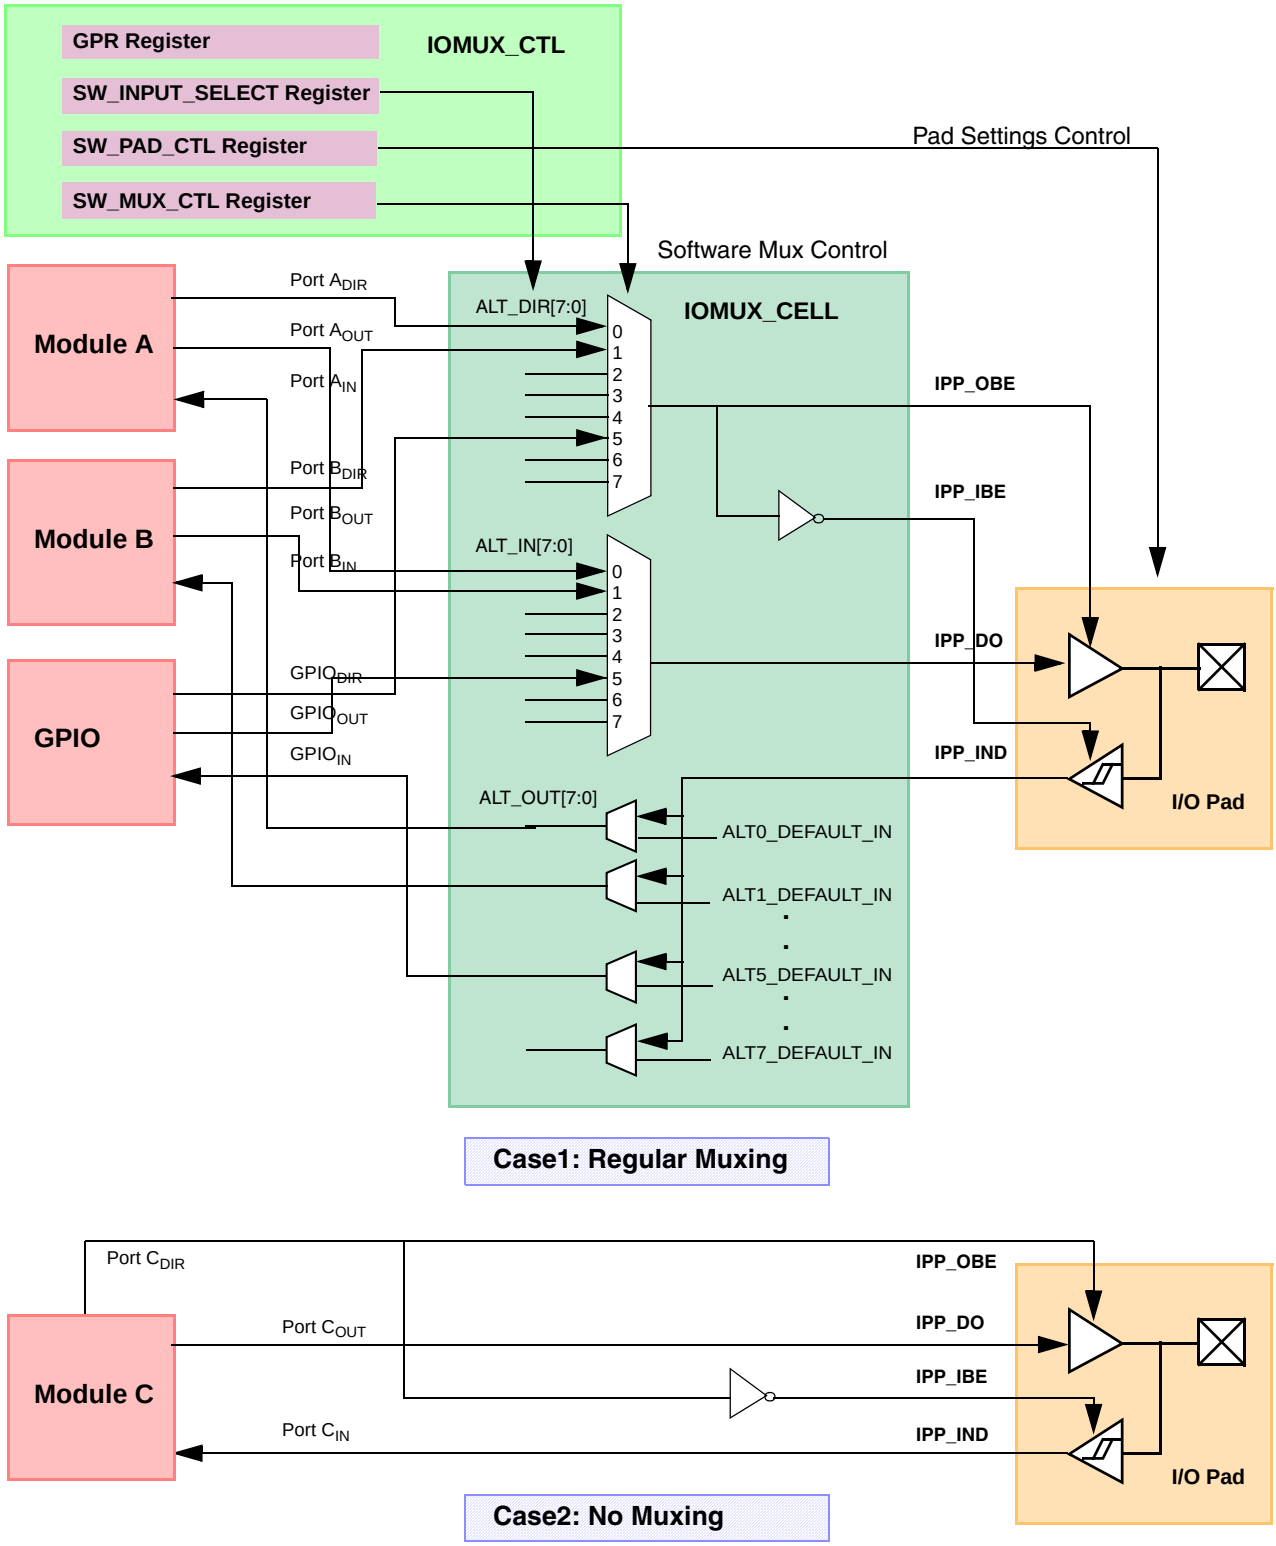

Figure 4-1. Pin Multiplexing Block Diagram

4.2 Pin-Muxing Control

This section describes how to select the mux mode for each pin through software programming. After chip reset, each pin works in its primary mode, ALT0. Boot code or software programming are required to enable the alternate modes (ALT1–ALT7).

Each pin's signal muxing is controlled by a Software Multiplexer Control (SW_MUX_CTL) register. Each SW_MUX_CTL register handles pin muxing for only one pin. The SW_MUX_CTL register also has the ability to enable a loopback feature. See Section 4.2.1, "SW_MUX_CTL Register Definition," for more information.

The Software Select Input (SW_SELECT_INPUT) register is user-accessible during IOMUX programming which is required when there are multiple pins as muxing options. See Section 4.2.2, "SW_SELECT_INPUT Register Definition," for more information. Section 4.6, "Daisy Chain List,"also provides information about SW_SELECT_INPUT settings.

4.2.1 SW_MUX_CTL Register Definition

Each 32-bit SW_MUX_CTL register controls the signal multiplexing for one IOMUX cell. The SW_MUX_CTL register is partitioned into two fields: Mux Mode Select Field (MUX_MODE) and Software Input On Field (SION). MUX_MODE controls the signal muxing on each pin, and SION controls loopback and GPIO capture features (some individual pins do not have the SION bit option).

When the SION bit is cleared, the pin works in normal mode. In this case the I/O direction is determined by the selected mux mode.

When the SION bit is asserted, the pin works in loopback mode. All modes' input path is forced on by software, and the pin value feeds through into all modes' input. In loopback mode, users can capture the pin values using a GPIO module.

The SW_MUX_CTL registers have the naming convention:

IOMUXC_SW_MUX_CTL_PAD_<*Pin_Name*>,

where <*Pin_Name*> is the pin's name, which is different for each register.

Figure 4-2 shows the general format of an SW_MUX_CTL register. Table 4-1 shows the field descriptions.

IOMUXC_SW_MUX_CTL_PAD_<*Pin_Name*> Access: User read-write

4 SION	Software Input On Field. 0 Normal mode: IO is determined by the selected mux mode. (default) 1 Loopback mode: Input feed-through, loopback feature enabled.
3	Reserved
2–0 MUX_MODE	Mux Mode Select Field. Select one of the IOMUX modes to be used for the pin: <*Pin_Name*> 000 Select ALT0 mux mode (default) 001 Select ALT1 mux mode 010 Select ALT2 mux mode 011 Select ALT3 mux mode 100 Select ALT4 mux mode 101 Select ALT5 mux mode 110 Select ALT6 mux mode 111 Select ALT7 mux mode

4.2.1.1 Loopback Examples

The following examples illustrate how to use the loopback feature for bus-status detection and GPIO capture.

Example 1: Bus-Status Detection

Figure 4-3 shows the case where module A drives the pin while simultaneously receiving or detecting the pin value or bus status.

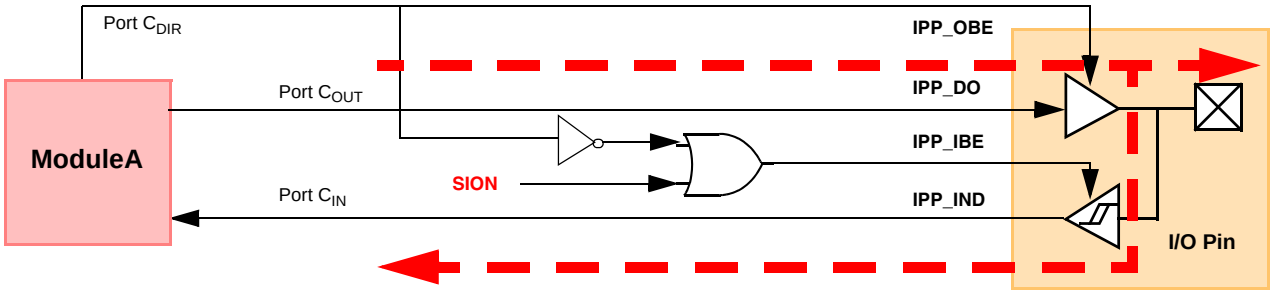

Figure 4-3. Loopback Example1: Bus-Status Detection

Example 2: GPIO Capture

Figure 4-4 shows the case where module A drives the pin while the GPIO Module captures the pin value or bus status.

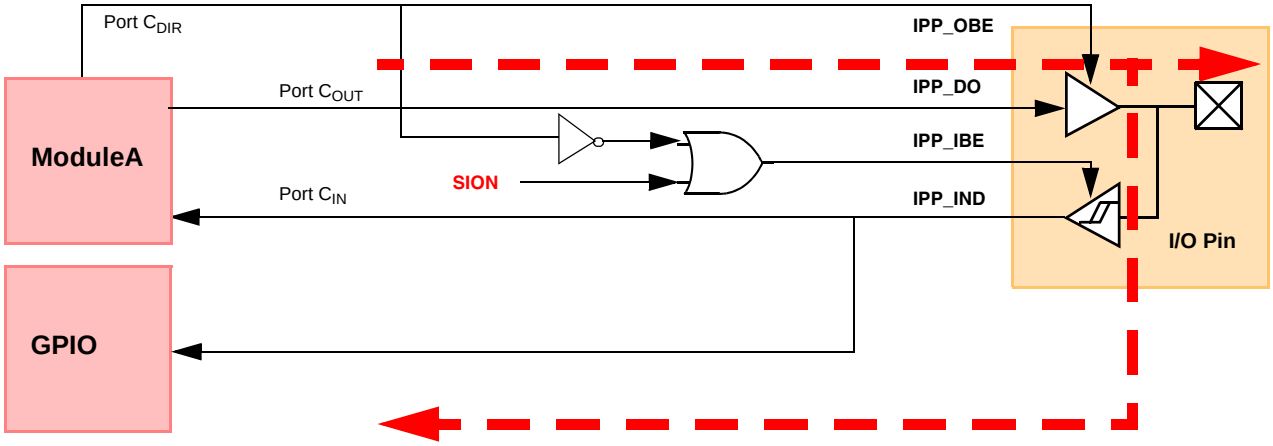

Figure 4-4. Loopback Example 2: GPIO Capture

4.2.2 SW_SELECT_INPUT Register Definition

Each Software Select Input Control (SW_SELECT_INPUT) is a 32-bit register, and is used to control the input path to avoid multi-driving problems. This register is only required when multiple pins drive the same internal port. This usually happens when one input port has multiple pin-muxing options on different pins.

For example, in Figure 4-5, both pin A and pin B could be used as the input pin of an on-chip IP instance, and serve as Port C options. In such cases, a SW_SELECT_INPUT register is used to select the driving

pin. Section 4.6, “Daisy Chain List,” provides all instances and ports that are involved in the daisy chain, and also lists pins and their corresponding SW_SELECT_INPUT register values.

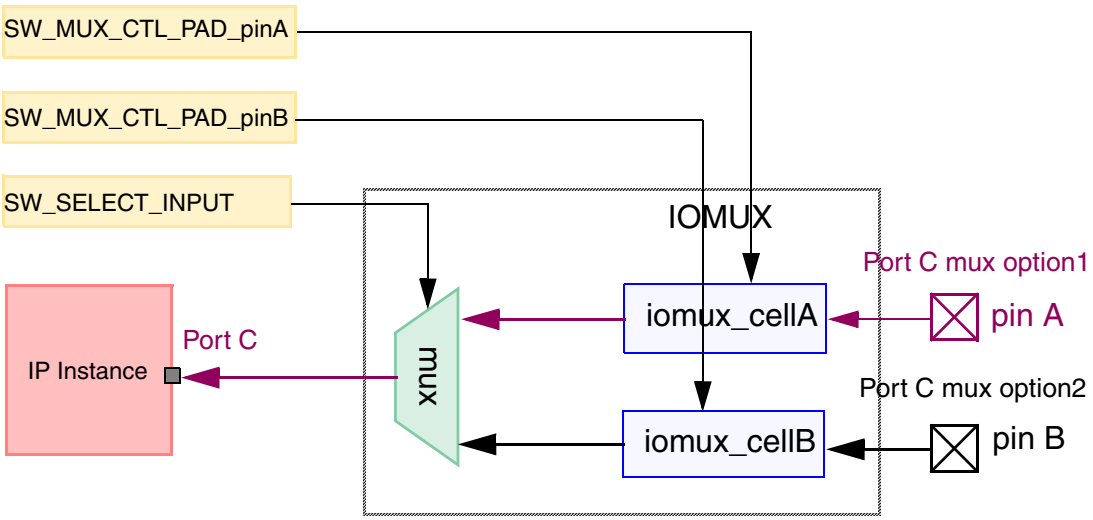

Figure 4-5. Select Input from Pins

Two steps are required during IOMUX software programming in such cases. For example, in Figure 4-5, if pin A is selected to work as the driving pin of Port C, then the following IOMUX programming steps are required:

1. Set IOMUXC_SW_MUX_CTL_PAD_<*pinA*> to select the correct mux mode for Port C.
2. Set IOMUXC_<*Instance*>_<*PortC*>_SELECT_INPUT to select the input driving from pin A.

SW_SELECT_INPUT registers follow the naming convention:

IOMUXC_<*Instance*>_<*Port*>_SELECT_INPUT.

Figure 4-6 shows the general format of an SW_SELECT_INPUT register. Table 4-2 shows the field descriptions.

Table 4-2. SW_SELECT_INPUT Field Descriptions

Field	Description
31–3	Reserved
2–0 Daisy	The actual width of the Daisy field is equal to the number of driving pins. For example, if there are two driving pins then bits [2:1] are reserved, and bit 0 is the actual Daisy field. Users can select a specific drive pin for an input port of a module to solve the multi-driving problem (this is referred to as “daisy chaining”). Table 4-12 lists the Daisy field settings corresponding to different pin assignments for different input ports.

4.3 Pin-Setting Control

This section describes how to set characteristic settings of each pin through software programming. The Software Pad Control (SW_PAD_CTL) register controls I/O driver voltage, slew rate, drive strength, open drain, pull/keeper, DDR type, and so on. See Section 4.3.1, “Software Pad Control (SW_PAD_CTL) Register Definition,” for a full description.

DDR type settings for DDR pins are controlled in groups instead of pin-by-pin. This is implemented by SW_PAD_CTL_GRP registers. See Section 4.3.2, “Software Pad Group Control (SW_PAD_CTL_GRP) Register Definition,” for more information.

4.3.1 Software Pad Control (SW_PAD_CTL) Register Definition

Each SW_PAD_CTL register is a 32-bit register that controls the software-configurable characteristics of an I/O pin. The configurable settings include Slew Rate, Drive Strength, Open Drain, Pull/Keeper, Hysteresis, and so on.

The generic formats of the SW_PAD_CTL register for GPIO and DDR pins are described in Section 4.3.1.1, "SW_PAD_CTL Generic Register Format for GPIO Pins," and Section 4.3.1.2, "SW_PAD_CTL Generic Register Format for DDR Pins," respectively.

Not all SW_PAD_CTL registers implement every bit defined in the generic definition. Some characteristics of specific pins may have fixed settings that are not software configurable. Only those characteristics with CFG() in detailed pin mux Table 4-14 are software-configurable.

SW_PAD_CTL registers follow the naming convention: IOMUXC_SW_PAD_CTL_PAD_<*Pin_Name*>.

4.3.1.1 SW_PAD_CTL Generic Register Format for GPIO Pins

Figure 4-7 and Table 4-3 show the generic SW_PAD_CTL register definition for GPIO pins. Reset values are different for different registers, depending on the registers' functionality.

Note: This bit only applies to pads configured as output.</td></tr>
<tr><td>0
SRE</td><td>Slew Rate Control Bit. This bit selects between FAST/SLOW slew rate output.
0 Slow slew rate
1 Fast slew rate, used for high frequency designs
Note: This bit only applies to pads configured as output.</td></tr>
</table>

4.3.1.2 SW_PAD_CTL Generic Register Format for DDR Pins

For DDR pins, DDR type is configured in groups, not pin-by-pin. Group characterization is described in Section 4.3.2, “Software Pad Group Control (SW_PAD_CTL_GRP) Register Definition.” If a characteristic is configurable as a group, then the corresponding bit in the SW_PAD_CTL register is not used.

Figure 4-8 and Table 4-4 show the SW_PAD_CT:L register definition related to DDR pins. Reset values are different for different registers, depending on the registers' functionality.

IOMUXC_SW_PAD_CTL_PAD_<*Pin_Name*> Access: User read-write

7 PKE	Keeper Enable Bit. This bit enables the internal keeper capability of the DDR pin. The DDR pin has no Pull capability. 0 Internal Keeper Disabled 1 Internal Keeper Enabled
6-3	Reserved
2–1 DSE	Drive Strength Control Bits. These bits select Standard, High or Max pin drive strength. Drive strength characteristics of the pins in a group depend on the DDR_TYPE setting in the group's software pad group control register, as described in Section 4.3.2, "Software Pad Group Control (SW_PAD_CTL_GRP) Register Definition." 00 Nominal or Standard drive strength 01 High drive strength 1*n* Max drive strength
0	Reserved

4.3.2 Software Pad Group Control (SW_PAD_CTL_GRP) Register Definition

The Software Pad Group Control (SW_PAD_CTL_GRP) registers are 32-bit registers that are used to configure specific characteristic of a group of pins. A pin group is defined as a set of pins sharing a common I/O pin settings. There are five groups of DDR pins, each is controlled by a different SW_PAD_CTL_GRP register.

The DDR pins can have one of three types: Mobile DDR (default), SDRAM, and DDR2. The working mode for pins in a particular group is controlled by the DDR_TYPE field setting for that group's SW_PAD_CTL_GP register. Reference characteristics for the three different types are given in Table 4-5. As shown in Table 4-5, Mobile DDR and DDR2 operate at the same voltage and with appropriate board design and signal routing, either can be used for DDR and DDR2 devices.

Table 4-5. Reference Characteristics for DDR_TYPE Types at 25° C

DDR_TYPE	Voltage	Drive Strength	Current	Equivalent Impedance
Mobile DDR	1.8 V ±10%	Standard	3.6 mA	90 Ω
		High	7.2 mA	45 Ω
		Max	10.8 mA	20 Ω
SDRAM	1.8 V ±10%	Standard	—	—
		High	—	—
		Max	5.7 mA	50 Ω
	3.3 V ±10%	Standard	4 mA	90 Ω
		High	8 mA	45 Ω
		Max	12 mA	30 Ω
DDR2	1.8 V ±10%	—[a]	13.4 mA	20 Ω

a. For DDR2 type drive strength is not configurable, and the DSE field in the SW_PAD_CTL register has no functionality.

SW_PAD_CTL_GRP registers follow the naming convention:

IOMUXC_SW_PAD_CTL_GRP_DDRTYPE_GRP*n*,

where *n* is the pins' group number (*n* = 1…5).

Figure 4-9 and Table 4-6 show the SW_PAD_CT:L_GRP register definition.

4.4 Special Functionality

This section provides information about special registers and functionalities in IOMUX_CTL module.

4.4.1 General Purpose Register (GPR)

The 32-bit General Purpose Register is used by SoC integration or as software-configurable general purpose control signal.

Addres s Offset: 0x0000 Access: User read-write

Table 4-8. IOMUXC_GPRA Field Descriptions

Field	Description
31–3	Reserved. Not used in SoC integration.
2 TAMPER DETECT	Asserting this bit will enable Tamper Detect Logic. Tamper detect cannot be disabled until the next reset. Writing 0 to this bit has no effect.
1 SDCTL_CSD1_SEL_B	EMI Chip Select Control Bit for SDCTL over WEIM. Select multiplexed chip select (CS3) between SDRAM/DDR and WEIM in EMI. See the EMI, SDCTL, and WEIM chapters for more details. 0 SDCTL chip select 1 WEIM chip select
0 SDCTL_CSD0_SEL_B	EMI Chip Select Control Bit for SDCTL over WEIM. Select multiplexed chip select (CS2) between SDRAM/DDR and WEIM in EMI. See the EMI, SDCTL, and WEIM chapters for more details. 0 SDCTL chip select 1 WEIM chip select

4.4.2 Loopback and GPIO Capture

Loopback means that the module drives the pin and also receives the pin value as an input. GPIO capture means that the module drives the pin and the value is captured by GPIO module.

These features are available through the SION (Software Input On) bit of the SW_MUX_CTL register (Section 4.2.1, “SW_MUX_CTL Register Definition”). When the SION bit is set to 1, it enables the input path of all mux modes on the pin by forcing IPP_IBE = 1 (see Figure 4-1), regardless of the original pin direction control.

4.4.3 Boot-Related Pins

The boot modes are mainly controlled by two dedicated boot pins BOOT_MODE0 and BOOT_MODE1. Additional boot parameters such as the specific boot mode and path during the boot process are determined either by eFuse values (via the IIM) or by GPIO pins, depending on whether the GPIO_BT_SEL eFuse is 1 or 0 respectively. Table 4-9 shows the boot functions which correspond to the different eFuses/GPIO boot pins. For more details, see Chapter 7, “System Boot”.

If the GPIO_BT_SEL eFuse is cleared, the GPIO boot pins are latched by the CCM on chip reset and no extra software pin-mux programming is required. After reset, these pins work as normal GPIO pins in their default functionality (ALT0 mode).

Table 4-9. Boot-Related Pins

Pin Name	Direction at Boot	eFuse Name	Function at Boot
BOOT_MODE0	INPUT	N/A	Boot mode select pins
BOOT_MODE1	INPUT	N/A	
CSI_D8	INPUT	BT_MEM_CTRL[0]	Boot memory device
CSI_D9	INPUT	BT_MEM_CTRL[1]	
CSI_D10	INPUT	BT_MEM_TYPE[0]	Boot memory type
CSI_D11	INPUT	BT_MEM_TYPE[1]	
CSI_D12	INPUT	BT_PAGE_SIZE[0]	NAND Flash page size
CSI_D13	INPUT	BT_PAGE_SIZE[1]	
CSI_D14	INPUT	BT_ECC_SEL	Define 4/8-bit ECC
CSI_D15	INPUT	BT_USB_SRC[0]	USB PHY selection
CSI_HSYNC	INPUT	BT_USB_SRC[1]	
CSI_VSYNC	INPUT	BT_BUS_WIDTH	NAND bus width

4.4.4 Special Pins

Table 4-10 lists the special pins supported in the device.

Table 4-10. Special Pins List

Pin Name	Mux Mode	Function Name	Detailed Description
EXT_ARMCLK	ALT0	External ARM clock	External clock input for ARM clock, used for function test when internal ARM clock is bypassed.
I2C1_CLK	ALT6	External peripheral clock	External peripheral clock source, used when Peripheral PLL is bypassed
CAPTURE	ALT4	External 32-KHz clock	External 32KHz clock input, used when internal 24MHz oscillator is powered off, which could be configured either from pin of CAPTURE or CSPI1_SS1.
CSPI1_SS1	ALT2		
CLKO	ALT0	Clock out	Clock-out pin from CCM. Clock source is controllable and can also be used for debug.
GPIO1_0	ALT1	Power ready	PMIC power ready signal, which can be configured either from GPIO1_0 or TX1
TX1	ALT1		
TEST_MODE	ALT0	Test control	Device enters into test mode when TEST_MODE pin is asserted.

Table 4-10. Special Pins List (Continued)

Pin Name	Mux Mode	Function Name	Detailed Description
GPIO1_1	ALT6	Tamper detect	Tamper-detect logic is used to issue a security violation. This logic is activated if the tamper-detect input is asserted. Tamper detect logic is enabled by the bit IOMUXC_GPRA[2]. After enabling the logic, it is impossible to disable it until the next reset.
TTM_PAD	ALT0	Thermal resistor	Used for Freescale factory test only. Users must either float this signal or tie it to GND

4.5 Register Memory Map

Table 4-11 is the IOMUX_CTL register memory map. For a particular module's base address, see the system memory map.

4.6 Daisy Chain List

Table 4-12 lists all the instances and ports which are involved in the daisy chain, and the SW_SELECT_INPUT register values corresponding to different pin assignments. The SW_SELECT_INPUT registers follow the naming convention of IOMUXC_<Instance>_<Port>_SELECT_INPUT.

For example: to make pin “HCKT” work as the input port “p5_input_rxclk_amx” of instance AUDMUX, then pin “HCKT” can be configured to work in “ALT1” mode, and register “IOMUXC_AUDMUX_P5_INPUT_RXCLK_AMX_SELECT_INPUT” can be configured to value “0x0” to resolve the daisy chain.

Table 4-12. Daisy Chain List

Instance	Input Port	Pin	Mode	SW_SELECT_INPUT Value
AUDMUX	p5_input_rxclk_amx	HCKT	ALT1	0x0
		RTS2	ALT6	0x1
	p5_input_rxfs_amx	HCKR	ALT1	0x0

4.7.2 Detailed Pin Multiplexing Description.

Table 4-14 shows in detail the pin muxing and pad settings of each pin. The Pin Name column lists the device's pins, and the Instance column lists the instantiated on-chip IP modules. For each pin that supports pin muxing, there is a related IOMUX cell to deal with the muxing control. Each IOMUX cell can support up to eight alternative muxing modes ALT0–ALT7, where ALT0 is the default mode. The Pad Settings column shows the pad characteristic setting of each pin.

In order to clarify the significance of Table 4-14, the table entries corresponding to the CAPTURE pin (first row) are explained as follows.

- The Mode-Instance-Port entries in a given row describe the pin's function in the different muxing modes. For example, in ALT0 muxing mode, the CAPTURE pin is used as the capture input pin CAPIN1 of the GPT module; in ALT4 mode, the same pin is used for the CCM external 32 kHz clock input; and so on. The muxing mode ALT*n* is specified by programming the corresponding SW_MUX_CTL register, as described in Section 4.2.1, "SW_MUX_CTL Register Definition."
- The Pad Settings entries describe the different possible settings for the pin. Only characteristics denoted as CFG (…) are software configurable by programming the corresponding SW_PAD_CTL register, as described in Section 4.3.1, "Software Pad Control (SW_PAD_CTL) Register Definition." For example,
  - "*Drive Strength—CFG (Nominal)*" indicates the drive strength is software-configurable, with nominal (standard) as the default setting.
  - "*Pull / Keep Enable—CFG (Enabled)*" indicates pull resistor or keeper is software-configurable, and enabled by default.
  - "*Slew Rate—SLOW*" indicates the slew rate of this pin is set as slow, and is not software-configurable.

Chapter 5
Clock Distribution

5.1 Introduction

This chapter provides programmers with complementary documentation on the programming model of the i.MX35 clock distribution. The following information is included:

- Global clock architecture
- Clock divider registers (frequency scaling)

This clock distribution diagrams are the initial clock descriptions to be used in the design and integration of the device. The details and register locations may change as the integration is implemented.

5.2 Overview

The description of the clock architecture is essentially based on a series of block diagrams, Figure 5-1 through Figure 5-10, showing the different levels of abstraction from the top level down to block levels.

Chapter 6
Reset

6.1 Reset Type/Source

The reset types for the i.MX35 are as follows:

- Power-on-reset (POR)
- System reset
- Watchdog timer (WDOG) reset
- JTAG reset

The reset sequence is controlled by the clock controller module (CCM). See Section 14.4.2, “Reset Controller,” in Chapter 14, “Clock Controller Module (CCM),” for more information on the reset controller. The reset sequence continues to cycle, dependent on the low-frequency clock signal, CKIL. If a CKIL clock is not detected, the reset sequence waits until the CKIL clock is detected.

The reset sequence also checks for the following conditions before each step:

- IIM fuse read-completion flag
- NFC boot code copy completed

6.2 Reset Sequence

This section includes reset sequences for the following:

- Power-on-reset
- System reset
- WDOG reset
- JTAG reset

6.2.1 Power-On-Reset (POR)

A power-on reset (POR) resets the entire device, including the PLL and the fusebox; all data is lost. A POR is initiated by a qualified reset on the por_b input pin.

The POR follows this sequence:

1. 4 CKIL clock cycles after the por_b pin is released, the PLL, fuse, and CCM reset releases.
2. After a PLL lock, the ARM clock and other clocks (such as the IPG clock) start.
3. IIM reads the fuse after IPG clock started. and the iim_fuse_latch signal asserts after the read is complete.
4. After one IPG clock, the EMI reset releases.

5. Wait 22 CKIL cycles to confirm the completion of the NFC boot code download.
6. The ccm_per_reset_b and ccm_reset_out_b pins release after a few ARM clock cycles.

6.2.2 System Reset

A system reset is initiated by setting the reset_in_b pin. The reset must be asserted for at least 4 CKIL cycles to confirm it is a real reset, or else it is ignored.

When there is an external qualified low condition of duration greater than 4 CKIL cycles, the system reset follows this sequence:

1. 1 IPG cycle after the reset_in_b pin is released, an EMI reset is released.
2. Wait 22 CKIL cycles to confirm NFC boot code is downloaded.
3. Wait for a few ARM clocks to release the ccm_per_reset_b pin and the ccm_reset_out_b pin.

The RTC, PLL, and CCM are not reset on a system reset.

6.2.3 WDOG Reset

A WDOG reset can be triggered by the WDOG software configuration. There are two kinds of WDOG reset:

- WDOG timeout reset
- WDOG software reset

The WDOG reset sequence is as follows:

1. WDOG is active for at least one CKIL cycle.
2. 1 IPG cycle after the WDOG reset is released, an EMI reset is released.
3. Wait 22 CKIL cycles to confirm completion of an NFC boot code download.
4. Wait a few ARM clock cycles to release ccm_per_reset_b and ccm_reset_out_b.

The RTC, PLL, and CCM do not reset on a WDOG reset.

6.2.4 JTAG Reset

A JTAG reset is controlled by the SJC module. The sequence is the same as for a system reset or a wdog reset. The RTC, PLL, CCM are not reset on a wdog reset.

6.3 Reset Status Register

The reset status register is located in the CCM. The reset status register captures all reset sources that were set since the last time the software cleared the bits. Software must clear the bits, or else the bits are invalid.

Chapter 7
System Boot

7.1 Introduction

The i.MX35 processor starts booting from a power-on reset (POR) or warm reset. The boot ROM supports features such as booting from various external memory devices, support for downloading code through a ROM bootloader, capability for device configuration, and secure boot. The boot ROM is responsible for reading inputs such as the boot pins and eFuses to determine the behavior of the boot flow.

This out-of-reset boot sequence makes use of the high-assurance boot (HAB) library to provide a secure boot environment. A high-assurance boot is a combination of hardware and software, with the use of a PKI (public key infrastructure) protocol to protect the system from executing unauthorized images or programs. In order for the HAB to allow user code to run, the code must be signed by the private key holder that matches with the public key on the device. The HAB library in the processor's ROM also provides a number of API functions to allow the user to authenticate any defined region and signature at run-time.

This device also supports HAB-bypass mode or direct external boot, in which the processor can boot directly from external memory, as traditional microprocessors do.

The ROM also provides a mechanism to download and flash new code via a serial connection. Typically a downloader application is downloaded to RAM, thus facilitating Flash programming. The download uses a high-speed USB (on UTMI or ULPI PHYs), a full-speed USB (on serial PHY), or a UART connection.

The boot capabilities are substantially different on i.MX35 packages depending on the HAB type security configuration. Full flexibility is supported in the development (or engineering) configuration, but significant limitations are imposed on the production (or secure) configuration. A third option in which the security features are disabled is also supported.

7.2 Boot Configuration

The device's boot sequence is determined and controlled as follows:

- Boot type is determined by the values of boot mode contacts BOOT_MODE[1:0] sampled at exit from reset and stored in the RCSR register of the system reset controller CCM module. Table 7-1 describes the boot type options.
- Additional boot configuration settings are obtained either from programmable eFuses or by contacts sampled at POR negation. Selection between these two options is based on the value of the GPIO_BT_SEL fuse (default: unblown):
  - If GPIO_BT_SEL is blown, then all boot options are configured by eFuses as detailed in Table 7-2 below. Boot ROM code software may read the values from the RCSR, or from the eFuses, via the IIM module.
  - If GPIO_BT_SEL is left unblown, then the various boot options are determined by sampling dedicated contacts at out-of-reset. Every eFuse option is overridden with a dedicated contact(s), such that same functionality is available under both boot options. Table 7-4 lists boot option contacts. In this case, regardless of fuse values the boot ROM code reads the options' values from the RCSR register of the SRC module.

Table 7-1. Boot Mode Summary

BOOT_MODE[1:0]	Boot Mode	Boot Details
00	Internal boot	Executing ROM code, which handles booting from following sources. See Section 7.4.1, "Internal Boot Mode," for more details.
10	External (direct) boot	HW only (Direct boot via the interface, independent of boot ROM code) boot from WEIM interface and NAND boot. See Section 7.4.2, "External Boot Mode," for more details.
10	Startup mode	BT_MEM_CTL[1:0] = b11. This mode is useful for software development using JTAG-capable development tools. Upon reset the PC register will remain at address 0x00000000. This means no ROM code has run so far and the state of all internal SOC registers are untouched. The system is ready to run any application that is loaded to it via a JTAG debugging tool. You can still connect to the SOC via JTAG in other boot modes but in this mode it is guaranteed that all internal SOC registers are at their default (or reset) values.
11	Serial boot loader	Load and execute code, via serial devices (USB (High-Speed, via integrated PHY or external[a]) and UART). See Section 7.4.3, "Serial Download Boot Mode," for more details.

a. For typical application board usage, the internal PHY options is recommended. The use of an external transceiver is not recommended, and would come at the expense of availability of pins.

7.2.1 Boot Options and eFuse Settings

Table 7-2 shows the eFuse settings used by the ROM in the boot process. The default value for these fuses is unburned, except for HAB_TYPE, which has the default setting of Engineering.

Table 7-2. Fuse Descriptions

eFuse	Definition	Settings
DIR_BT_DIS	Direct external memory boot disable	0 Direct boot to external memory is allowed 1 Direct boot to external memory is not allowed
BT_MEM_CTL[1:0]	Boot memory control type (memory device)	00 WEIM 01 NAND Flash 10 ATA HDD 11 Expansion device (SD, eSD, MMC, eMMC, serial ROM)
BT_PAGE_SIZE[1:0]	NAND Flash page size. Used with conjunction with the BT_MEM_CTL[1:0] setting.	If BT_MEM_CTL = NAND Flash then 00 512 bytes 01 2 Kbytes 10 4 Kbytes (128 bytes spare) 11 4 Kbytes (218 bytes spare)
BT_SPARE_SIZE[1:0]	Specifies the size of spare bytes for NAND Flash devices (BT_MEM_CTL[1:0] = NAND Flash) BT_SPARE_SIZE[0] is used as a fast boot mode indication for the eSD 2.10 protocol.	00 16 bytes spare (For 0.5 Kbyte page size device) 01 64 bytes spare (For 2 Kbyte page size device) 10 128 bytes spare (For 4 Kbyte page size device) 11 218 bytes spare (For 4 Kbyte page size device) If the bootable device is SD then: *n*0 FAST_BOOT bit 29 in ACMD41 argument is 0 *n*1 FAST_BOOT bit 29 in ACMD41 argument is 1

Table 7-2. Fuse Descriptions (Continued)

eFuse	Definition	Settings
BT_BUS_WIDTH	Bus width. Used with conjunction with the BT_MEM_CTL[1:0] setting. For SPI, determines device type (EEPROM or serial Flash)	BT_MEM_CTL[1:0] = NAND Flash 0 8 bit 1 16 bit BT_MEM_CTL[1:0] = WEIM (NOR) 0 16 bit 1 Reserved BT_MEM_CTL[1:0] = Expansion Device (SPI) 0 2-byte address SPI device (EEPROM) 1 3-byte address SPI device (serial Flash)
BT_MEM_TYPE[1:0]	Boot memory type. Interpreted by boot ROM software according to BT_MEM_CTL setting. Signals are interpreted by hardware to alter delays and timing in support of direct boot.	If BT_MEM_CTL = WEIM then 00 NOR 01 Reserved 10 Reserved 11 Reserved If BT_MEM_CTL = NAND Flash 00 3 address cycles 01 4 address cycles 10 5 address cycles 11 6 address cycles BT_MEM_CTL = ATA HDD 00 Reserved 01 P-ATA HDD 10 Reserved 11 Reserved If BT_MEM_CTL = Expansion Card Device 00 SD, MMC, eMMC, or eSD 01 Reserved 10 Serial ROM via I^2C 11 Serial ROM via SPI
BT_SDMMC_SRC	Chooses the specific eSDHC controller used for boot.	00 eSDHC-1 01 eSDHC-2 10 eSDHC-3
BT_ECC_SEL	Defines 4- or 8-bit ECC. Also used as a fast boot mode indication for eMMC 4.3 protocol.	0 4-bit ECC. 1 8-bit ECC. If the bootable device is MMC then: 0 Don't use eMMC fast boot mode. 1 Use eMMC fast boot mode.
BT_USB_SRC[1:0]	USB PHY selection	00 UTMI PHY 01 ULPI PHY 10 Serial PHY: ATLAS 11 Serial PHY: PHILIPS ISP1301
BT_EEPROM_CFG	Selects whether device configuration data (DCD) is loaded from EEPROM prior to boot from other devices. **Note:** Not applicable when EEPROM is used as boot device.	0 Use EEPROM DCD 1 Don’t use EEPROM DCD
BT_WEIM_MUXED	Selects whether or not WEIM is in muxed mode.	For BT_MEM_CTL[1:0] = WEIM (NOR) 0 Not muxed 1 WEIM in address muxed mode

Table 7-2. Fuse Descriptions (Continued)

eFuse	Definition	Settings
GPIO_BT_SEL	GPIO boot select. Determines whether certain boot fuse values are obtained from eFuses or from GPIO	0 Fuse values are determined by GPIO contacts 1 Fuse values are determined by eFuses
HAB_TYPE[2:0]	Security type	001 Engineering (allows any code to be flashed and executed, even if it has no valid signature) (default) 100 Security disabled (For internal/testing use) OthersProduction (security on)
SRK0_HASH[255:0]	Most significant byte of 256-bit hash value of super root key (SRK0_HASH)	Used by HAB library.
HAB_CUS[1:0]	HAB customer code. Selects customer code, as input to HAB.	Used by HAB library.
DIE-X-CORDINATE[7:0] DIE-Y-CORDINATE[7:0] WAFER_NO[4:0] LOT_NO_ENC[42:40] LOT_NO_ENC[39:32] LOT_NO_ENC[31:24] LOT_NO_ENC[23:16] LOT_NO_ENC[15:8] LOT_NO_ENC[7:0] MANU_CRC[15:8] MANU_CRC[7:0]	Device unique ID, 64-bit UID.	Used by HAB library.

7.2.2 Page per Block Settings

Table 7-3 shows the page per block settings at boot, as a function of page size.

In general, the Page per Block setting, may not have a one-to-one relation to block size. However, most devices used follow the relations listed in table below. For Boot, it does not matter, as the page-per-block setting is important for write accesses, and not read. However, to have a clear definition at boot, the page-per-block settings used are described below.

Table 7-3. Page per Block Settings

Page Size	Page per Block
512 Bytes	32
2 Kbytes	64
4 Kbytes	128

7.2.3 Boot Configuration by GPIO Pin Settings

Table 7-4 lists GPIO pins associated with different eFuses. The GPIO pins listed are sampled at boot and can be used to override fuse values when the GPIO_BT_SEL fuse is unblown.

Table 7-4. GPIO Pins Used for Boot

Contact	eFuse Name	Details
BOOT_MODE0	N/A	Boot mode selection
BOOT_MODE1		
CSI_D11	BT_MEM_TYPE[1]	Pin value overrides eFuse setting when GPIO_BT_SEL fuse is unblown.
CSI_D10	BT_MEM_TYPE[0]	
CSI_D8	BT_MEM_CTRL[0]	
CSI_D9	BT_MEM_CTRL[1]	
CSI_D12	BT_PAGE_SIZE[0]	
CSI_D13	BT_PAGE_SIZE[1]	
CSI_D14	BT_ECC_SEL	
CSI_D15	BT_USB_SRC[0]	
CSI_VSYNC	BT_BUS_WIDTH	
CSI_HSYNC	BT_USB_SRC[1]	

7.3 Boot Sequence

Figure 7-1 shows the i.MX35 boot sequence flow. Color coding (see legend) indicates the controlling sources (hardware only, boot contacts, or eFuses).

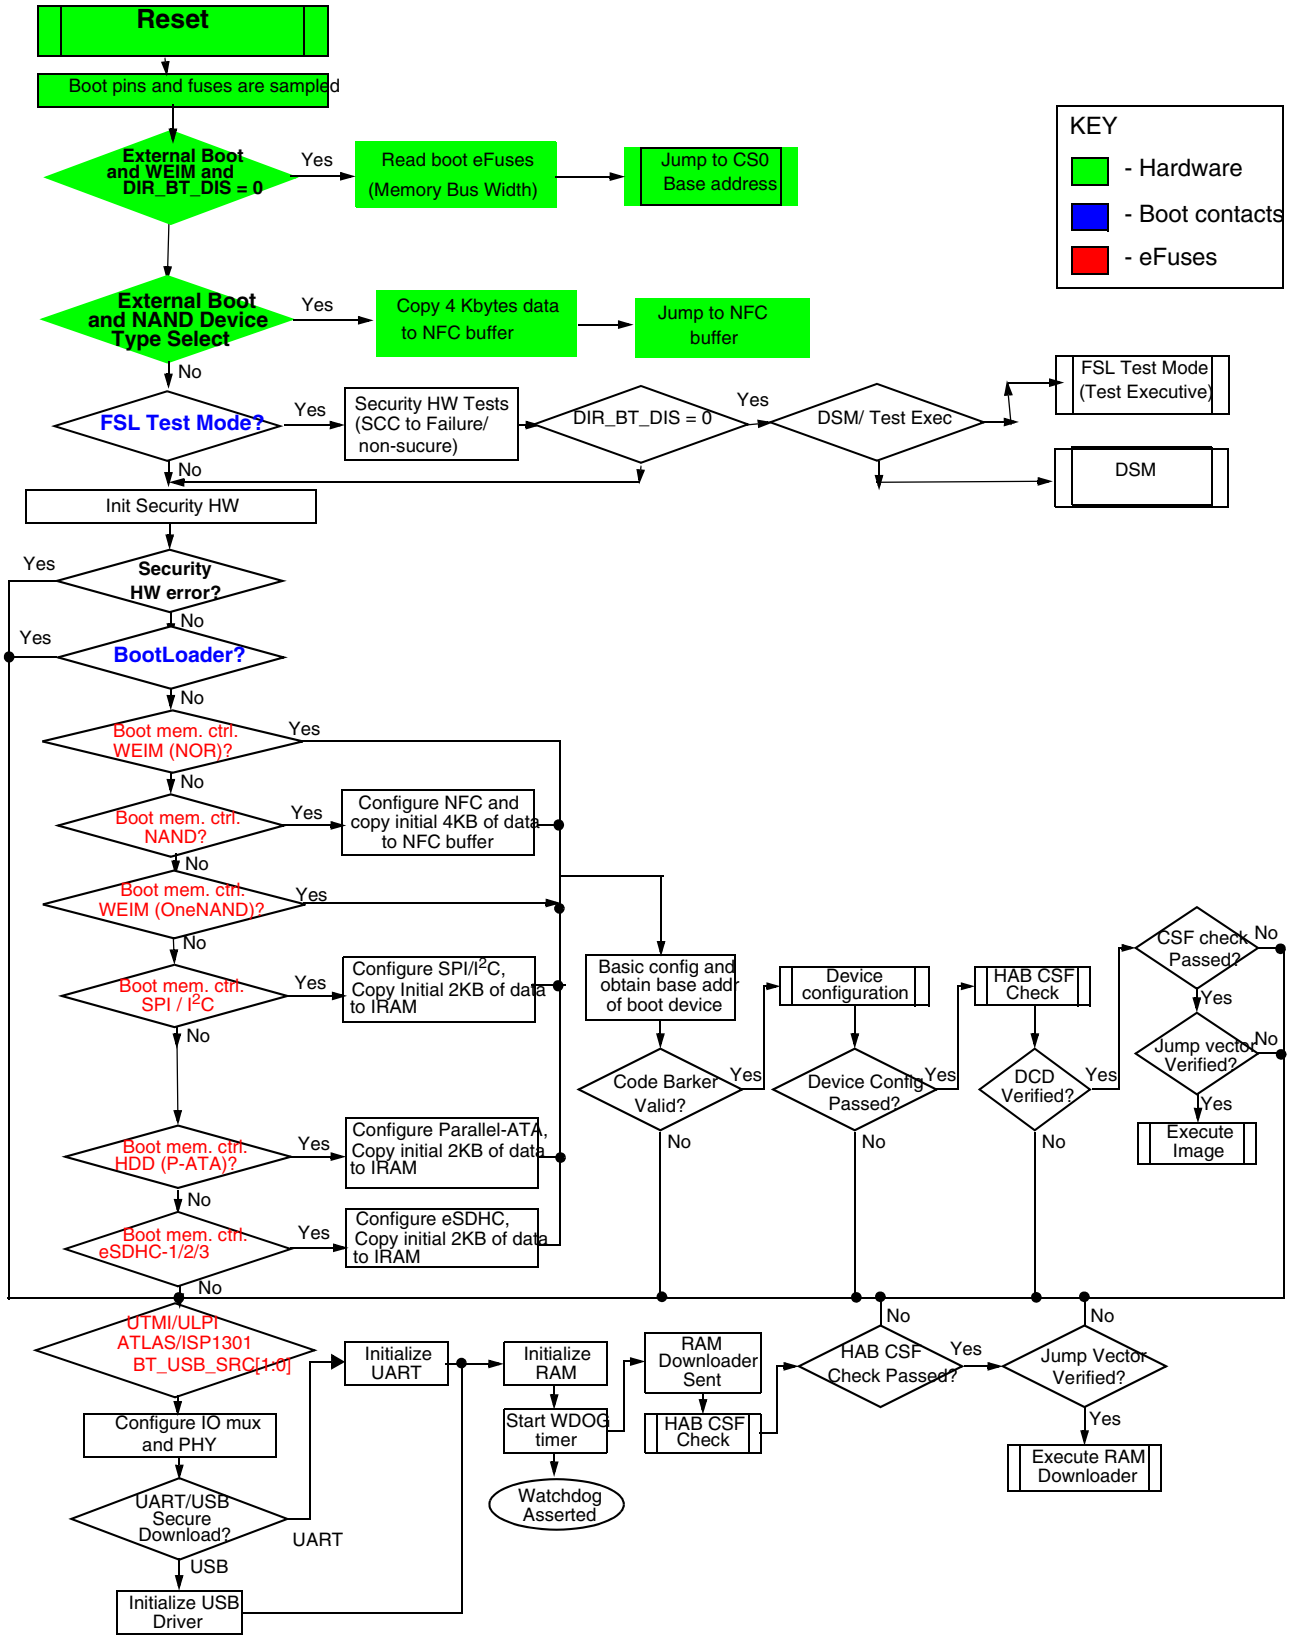

Figure 7-1. i.MX35 Boot Sequence

7.4 Boot Modes

This section provides detailed information on the different boot modes summarized in Table 7-1. Boot mode is determined by BOOT_MODE[1:0] contact values, as shown in Table 7-1.

7.4.1 Internal Boot Mode

Internal boot is selected by driving a value of 0b00 on the BOOT_MODE[1:0] contacts at device power up. The boot code in internal ROM performs the following steps:

1. Initializes hardware
2. Validates application image using the HAB library
3. Jumps to an address derived from the application image.

If any error occurs during internal boot, the boot code jumps to the UART/USB secure download.

Internal boot mode is the only mode in which secure boot and secure serial download of the device are possible.

7.4.1.1 Security Settings for Internal Boot

Internal boot modes can have one of three security levels:

- Production: This level is intended for shipping products. All HAB functions are executed and security hardware is initialized (the SCC enters the secure state), Device configuration data (DCD) is processed if present, and software in Flash or downloaded to RAM is authenticated by HAB prior to execution. The first error detected is logged, and the boot flow is aborted with control passing to the download mode. With this level, execution does not leave the internal ROM unless the target executable image has been authenticated.
- Engineering: This level is intended for use during the development phases of a product. All HAB functions are executed as for a production device. Security hardware is initialized (except the SCC is left in non-secure state), DCD is processed if present, and software in Flash or downloaded to RAM is authenticated by HAB prior to execution. The first error detected is logged, but has no influence on the boot flow. Therefore, with this level, it is possible to develop software without requiring that each build be signed for HAB authentication, since the device boots even if the code signatures are missing.
- Security Disabled: This level is intended for nonsecure devices such as external boot devices that must be initially programmed using the internal ROM download mode. All HAB functions are bypassed, security hardware is not initialized (except the SCC is forced into nonsecure state), DCD is not processed, and software in Flash or downloaded to RAM is not authenticated by HAB prior to execution.

7.4.1.2 Basic Initialization

Table 7-5 shows the clock settings (configured by ROM code) required for internal boot. On reset the core has access to all shared peripherals.

Table 7-5. Clock Settings for Internal Boot

Clock	Frequency
ap_core_clk	266 MHz
ap_ahb_clk	133 MHz
ap_ipg_clk	66.5 MHz
usb_clk	60 MHz
nfc_clk	21.6 MHz

7.4.1.3 Supported Devices for Internal Boot

The i.MX35 supports the following boot devices:

- 32- or 16-bit NOR Flash via WEIM Interface (located on CS0)
- 16-bit OneNAND Flash via WEIM interface. (located on CS0)
- MLC NAND and SLC NAND Flash via NFC interface
  - Page size 512 bytes, 2 or 4 Kbytes
  - Bus width 8- or 16-bit
  - 4- or 8-bit error checking (ECC)
  - P-ATA HDD with P-ATA interface
- SD, MMC, eSD, and eMMC via eSDHC interface. Supports all types of cards: high capacity, standard capacity, dual-voltage and high voltage.
  - Supports eSD fast boot and eMMC boot mode via all eSDHC ports
- Serial ROM and serial Flash
  - Serial peripheral interface (SPI) protocol via CSPI module
  - I^2C protocol via I^2C module

The device type is determined by the BT_MEM_CTL and BT_MEM_TYPE eFuses (or corresponding GPIO pins). Table 7-6 shows the settings corresponding to each device type.

Table 7-6. eFuse Settings for Boot Device Type

eFuse	Input Contact	Settings
BT_MEM_CTL[1:0]	CSI_D9, CSI_D8	00 WEIM 01 NAND Flash 10 ATA HDD 11 Expansion device (SD, eSD, MMC, eMMC, or serial ROM)
BT_MEM_TYPE[1:0]	CSI_D11, CSI_D10	If BT_MEM_CTL = WEIM then 00 NOR 01 Reserved 10 Reserved 11 Reserved If BT_MEM_CTL = NAND Flash 00 3 address cycles 01 4 address cycles 10 5 address cycles 11 6 address cycles BT_MEM_CTL = ATA HDD 00 Reserved 01 P-ATA HDD 10 Reserved 11 Reserved If BT_MEM_CTL = expansion card device 00 SD, MMC, eMMC, or eSD 01 Reserved 10 Serial ROM via I^2C 11 Serial ROM via SPI

7.4.1.4 Flash Header

The Flash header is a data structure that the boot ROM reads from Flash that provides information about the application. The Flash header must be located at a fixed address offset depending on the type of external Flash device connected to i.MX35. Table 7-7 shows the required address offsets for each device type.

Table 7-7. Flash Header Offset

Flash Type	Base Address Offset (Bytes)
NOR	0x1000 (4 Kbyte)
NAND	0x0400 (1 Kbyte)
OneNAND	0x0100 (256 bytes)
SD/MMC	0x0400 (1 Kbyte)
P-ATA	0x0400 (1 Kbyte)
I^2C/CSPI Serial ROM/Serial Flash	0x0400 (1 Kbyte)

Figure 7-2 shows the data arrangement for the Flash header.

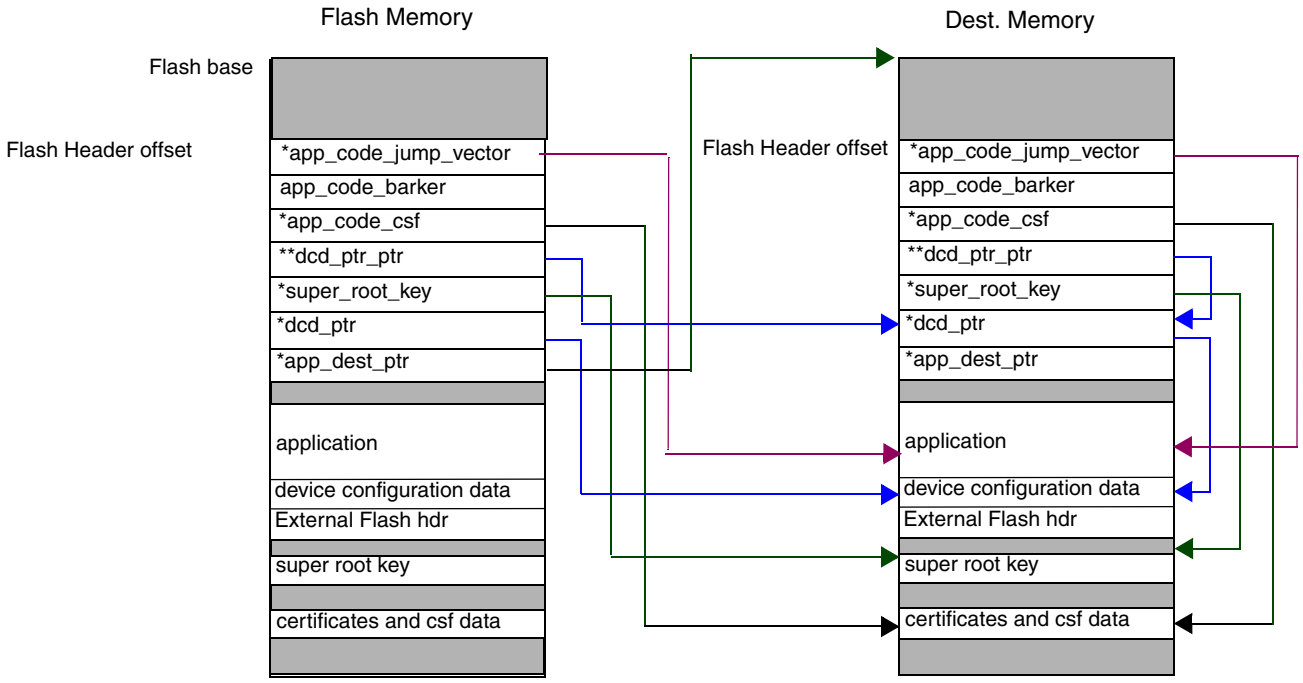

Figure 7-2. Flash Header (for Devices other than NOR Flash)

The Flash header must conform to the structure defined below:

```
typedef struct
{
    UINT32              *app_code_jump_vector;
    UINT32              app_code_barker;
    UINT32              *app_code_csf;
    DCD_T               **dcd_ptr_ptr;
    hab_rsa_public_key  *super_root_key;
    DCD_T               *dcd_ptr;
    UINT32              *app_dest_ptr;
} FLASH_HDR_T;
```

In this structure definition:

- DCD_T is a structure that defines the device configuration table. Section 7.4.1.4.3, “Device Configuration Data (DCD)” provides more details.
- hab_rsa_public_key is a structure that defines the super root key, as follows:

```
typedef struct
{
    UINT8   rsa_exponent[MAX_EXP_SIZE];     /* RSA public exponent */
    UINT8   *rsa_modulus;                   /* RSA modulus pointer */
    UINT16  exponent_size;                  /* Exponent size in bytes */
    UINT16  modulus_size;                   /* Modulus size in bytes */
    BOOLEAN init_flag;                      /* Indicates if key initialized */
} hab_rsa_public_key;
```

- UINT8, UINT16, and UINT32 represents 8-, 16- and 32-bit unsigned integer respectively
- BOOLEAN is an 8 bit flag indicating TRUE or FALSE

Table 7-8 defines the variables listed in the Flash header structure defined above:

Table 7-8. Flash Header and Super Root Key Variables

Variable Name	Significance	Comments
app_code_jump_vector	Pointer to address of first instruction of the application	—
app_code_barker	Value used by ROM to verify whether Flash device has been programmed	app_code_barker must be set to 0x0000_00B1
app_code_csf	Pointer to certificate and command sequence file (CSF) data	CSF data is used by HAB library (in ROM) to verify that the application is authentic
dcd_ptr_ptr	Double pointer: points to the dcd_ptr also contained in the Flash header structure	—
super_root_key	Pointer to super root key data	Super root key must conform to hab_rsa_public_key structure
dcd_ptr	Pointer to device configuration data (DCD) table	See Section 7.4.1.4.3, “Device Configuration Data (DCD),” for DCD table details
app_dest_ptr	Pointer to location in destination RAM where the ROM copies the application from Flash memory	—

Table 7-9 defines the variables listed in the hab_rsa_public_key structure defined above:

Table 7-9. Super Root Key Variables

Variable Name	Significance	Comments
super_root_key	Pointer to super root key data	Super root key must conform to hab_rsa_public_key structure
rsa_exponent	Exponent of RSA key	Maximum exponent size is 4 bytes
rsa_modulus	Pointer to RSA key modulus.	—
exponent_size	Exponent size in bytes	Must be less than or equal to the maximum exponent size.
modulus_size	Modulus size in bytes	Must be between 128 and 256 inclusive

7.4.1.4.1 Additional Flash Header for Data Length Specification

Several boot devices require an additional Flash header that specifies the length of the data to be read from boot device. This additional header is located immediately after the DCD table, and has the following structure:

```
/* Flash Header Structure */
typedef struct {
    UINT32  length;         /* Length of data to be read */
} FLASH_CFG_PARMS_T;
```

In this Flash header structure, the parameter ‘length’ determines the length of image to copy to destination RAM.

Boot devices that require the additional Flash header include:

- NAND Flash
- OneNAND
- P-ATA
- MMC, eMMC, SD, eSD
- EEPROM, serial Flash

7.4.1.4.2 Flash Header for SD/MMC/eSD/eMMC Boot Devices

The image data in the boot device should be located at address offset 0. eSDHC automatically generates CRC code during eSDHC data write/read from *e*SD or *e*MMC, and eSDHC updates the CRC in the CRC status register.

To boot in this case, the boot software performs the following operations:

1. Copy the first 2 Kbytes of boot data into internal RAM
2. Check for errors using CRC
   a) If no error is detected, then jump to the Flash header (1-Kbyte offset from beginning of the boot data) to authenticate the application if required.
   b) If an error is detected, the boot ROM code logs an error and jumps to USB/UART bootloader. The logged error can be queried via the serial protocol.

Flash Header for I^2C/CSPI Serial ROM/Serial Flash Boot Devices

Table 7-7 shows the location of image data within the boot device.

To boot from serial ROM, the boot software performs the following operations:

1. Copy the first 2 Kbytes of boot data from serial boot devices into internal RAM
2. Use the Barker value to check for errors
   a) If no error is detected, then jump to the Flash header (1-Kbyte offset from beginning of the boot data) to authenticate the application if required.
   b) If an error is detected, the boot ROM code logs an error and jumps to USB/UART bootloader. The logged error can be queried via the serial protocol.

7.4.1.4.3 Device Configuration Data (DCD)

Some peripherals need to be configured in order to be used efficiently. On reset, the device uses the default register values for all peripherals in the system. These settings typically are not ideal for achieving optimal system performance. For example, the EIM default settings allow the core to interface to a NOR Flash device immediately out of reset. This means that the core can interface with any NOR Flash device, but performance is slow. Also, some peripherals, such as SDRAM, might require some registers to be programmed before you can use it. WEIM (for NOR flash) and ESDRAMC (for SDRAM) registers and MDC registers are set up using device configuration data (DCD). ROM bootstrap has a provision for accommodating solutions to these scenarios. To allow users to configure the device for better performance, the ROM reads a DCD table from the Flash device. The ROM determines the location of the DCD table

based on information located in the Flash header. This DCD table is an array of (access type, address and value) pairs preceded by a Barker code and length field. The size of this array is limited to 60 in the ROM bootstrap.

Table 7-10. DCD Block

Field Name	Description	Size (Bytes)
DCD-barker	Barker code for error check	4
DCD-block-length	The total length in bytes of the DCD block (excluding this length field as well as the Barker code)	4
The two preceding fields are followed by an array of structures with following fields		
DCD-address-type	Type of pointer (byte, halfword, word, wait/read) in the following field	4
DCD-address	Absolute address of the register to be programmed	4
DCD-value	Value to be programmed at above address	4

NOTE

The DCD is read as 32-bit words, and must therefore be aligned on a word boundary.

The set of registers programmable with DCD must be restricted for security. Since the device configuration block is only post-authenticated (i.e. after it has already been used), the restriction has to be very tight. The ROM bootstrap performs boundary checking of DCD-address in the device configuration block against the valid range of addresses. The allowed register sets by the device configuration block are defined in the table below:

Table 7-11. DCD Valid Modules

Clock Controller Module (CCM)
UART
Universal Synchronous Bus (USBOH3)
IOMUX (drive strength registers SW_PAD_CTL only)
Watchdog (WDOG)
NAND Flash controller (NFC)
Enhanced synchronous dynamic RAM controller (ESDRAMC)
Wireless external interface module (WEIM)
Enhanced SD host controller (eSDHC1 and 2)
External Interface Module
I^2C
Multi Master Memory Interface Module (M3IF)
Configurable serial peripheral interface (CSPI) 1
Chip select 0–4
CSD0–1

The ROM bootstrap maintains an array of lower and upper addresses for each module allowed to be programmable through DCD. This array is utilized for verifying any attempt to configure a register other than that are allowed. ROM bootstrap determines the size of the block by reading DCD-block-length and copies it into internal RAM. An error is generated under any of the following conditions:

- Any register address is outside the predefined range.
- The length of the DCD exceeds the maximum acceptable size (MAX_HW_CFG_SIZE) in bytes. The maximum of 60 elements for the array equals MAX_HW_CFG_SIZE of 720 bytes.
- Any other failure.

If successful, ROM bootstrap configures the HW registers and failure would lead to non-initialization of intended modules. DCD error (such as writing to a non-supported address such as ROM PATCH) causes the ROM boot code to jump to the serial boot loader.

The DCD table structure DCD_T is defined as follows:

```
typedef struct
{
        DCD_PREAMBLE_T preamble; /* Preamble */
        /* Type / Address / data elements */
        DCD_TYPE_ADDR_DATA_T type_addr_data[count]; /*count is a hardcoded value < 60*/
} DCD_T;
```

The DOC_PREAMBLE_T structure is defined as follows:

```
typedef struct
{
        UINT32 barker; /* Barker for sanity check */
        UINT32 length; /* Device configuration structure length (not including preamble) */
} DCD_PREAMBLE_T;
```

The DOC_TYPE_ADD_DATA_T structure is defined as follows:

```
typedef struct
{
        UINT32 type; /* Type of pointer (byte, halfword, word, wait/read) */
        UINT32 *addr; /* Address to write to */
        UINT32 data; /* Data to write */
} DCD_TYPE_ADDR_DATA_T;
```

DCD_T typically contains the configuration data for watchdog (WDOG), SDRAM, and EIM and so on. An example DCD table configuration is as follows:

```
DCD_T device_config_data =
{
    {
     IROM_DCD_BARKER, // assuming this is pre-defined as macro
     (18 * sizeof(DCD_TYPE_ADDR_DATA_T))
    },

    {
        {0x00000002, (UINT32 *)0x53fdc000, 0x00003F7E}, /* WDOG WCR */
        {0x00000002, (UINT32 *)0x53fdc004, 0x00005555}, /* WDOG WSR */
        {0x00000002, (UINT32 *)0x53fdc004, 0x0000aaaa}, /* WDOG WSR */
        {0x00000004, (UINT32 *)0xb8002000, 0x14110802}, /* EIM CTL H 0x11134722 */
```

```
        {0x00000004, (UINT32 *)0xb8002004, 0x80330d01}, /* EIM CTL L -0x50331D01- 16 Bit */
         {0x00000004, (UINT32 *)0xb8002008, 0x00000800}, /* EIM CTL A */
        {0x00000002, (UINT32 *)0xa0002394, 0x00000060}, /* EIM CS0 -6F0C- 16 Bit */
        {0x00000002, (UINT32 *)0xa0002394, 0x00000003}, /* EIM CS0 -6F0C- 16 Bit */
        {0x00000002, (UINT32 *)0xa0000000, 0x000000ff}, /* EIM CS0 - R/A - 16 Bit */
        {0x00000004, (UINT32 *)0xb8001004, 0x000ac7a8}, /* SDRAM CS0 CFG0 - Timing */
        {0x00000004, (UINT32 *)0xb8001000, 0x92110080}, /* SDRAM CS0 CTL0 - Enable */
        {0x00000004, (UINT32 *)0x80000400, 0x00000000}, /* SDRAM CS0 - Precharge */
        {0x00000004, (UINT32 *)0xB8001000, 0xa2110080}, /* SDRAM CS0 - Refresh */
        {0x00000004, (UINT32 *)0x80000000, 0x00000000}, /* SDRAM CS0 - Refresh */
        {0x00000004, (UINT32 *)0x80000000, 0x00000000}, /* SDRAM CS0 - Refresh */
        {0x00000004, (UINT32 *)0xB8001000, 0xb2110080}, /* SDRAM CS0 - Load Mode */
        {0x00000001, (UINT32 *)0x80000033, 0x00000000}, /* SDRAM CS0 - Load Mode */
        {0x00000004, (UINT32 *)0xB8001000, 0x82114c80}, /* SDRAM CS0 - Norm Mode */
}
};
```

In boot flow the DCD data is used prior to being verified.The DCD data must be included as part of memory regions verified indicated in one of the HAB CSF commands.

7.4.1.5 NOR Flash Boot Operation

Boot from NOR Flash interface via the WEIM interface is supported for debug purposes. It should be used on special cases only. The WEIM port does not have dedicated contacts, and as a result, the muxing of the bus is set at boot only, by the boot ROM code. The NOR Flash interface works in asynchronous mode, and supports either muxed address/data or nonmuxed schemes, based on the eFuse settings. See Table 7-2 for details.

7.4.1.6 NAND Flash Boot Operation

Most MLC/SLC NAND Flash devices from different vendors are supported by the boot ROM.

Table 7-12 shows the parameters used to configure the external NAND Flash. In particular, NAND Flash boot requires that BT_MEM_CTL be set to 0b01. These parameters are either provided by eFuses or sampled on GPIO pins during boot.

Table 7-12. Fuse Settings for NAND Flash

eFuse	Definition	Settings
BT_MEM_CTL[1:0]	Boot memory device type	Must be set to 0b01 for NAND Flash boot
BT_PAGE_SIZE[1:0]	NAND Flash Page Size.	00 512 bytes 01 2 Kbytes 10 4 Kbytes (128 bytes spare) 11 4 Kbytes (218 bytes spare)
BT_SPARE_SIZE[1:0]	Specifies the size of spare bytes for NAND Flash devices BT_SPARE_SIZE[0] is used as a fast boot mode indication for the eSD 2.10 protocol.	00 16 bytes spare (For 0.5 Kbyte page size device) 01 64 bytes spare (For 2 Kbyte page size device) 10 128 bytes spare 11 218 bytes spare If the bootable device is SD then: *n*0 FAST_BOOT bit 29 in ACMD41 argument is 0 *n*1 FAST_BOOT bit 29 in ACMD41 argument is 1

Table 7-12. Fuse Settings for NAND Flash (Continued)

eFuse	Definition	Settings
BT_BUS_WIDTH	NAND bus width.	0 8 bit 1 16 bit
BT_MEM_TYPE[1:0]	Boot Memory Type.	00 3 address cycles 01 4 address cycles 10 5 address cycles 11 6 address cycles
BT_ECC_SEL	Defines 4- or 8-bit ECC.	0 4-bit ECC. 1 8-bit ECC.

Since MLC NAND Flash devices do not guarantee error-free boot blocks, the i.MX35 boot code requires that the first 4 Kbytes of boot code be duplicated in a subsequent block to serve as a second copy option. The boot ROM code makes use of the duplicate boot code according to the following procedure:

1. On device power-on, the boot ROM copies the first 4 Kbytes of boot code from the NAND Flash to the NFC buffer.
2. ROM code checks the first 4 Kbytes of boot data copied in step 1 above.
   a) If no ECC error, then DCD is verified.
      – If DCD verification is successful, then the rest of the boot code image is copied to destination RAM (internal RAM or SDRAM) and secure boot is performed.
      – If ECC detects an error, then the boot ROM code copies the duplicate 4 Kbytes of boot data from NAND Flash.
      – If there is no error in then data copy, then the boot code image is copied to destination RAM (internal RAM or SDRAM), and secure boot is performed.
      – If an error is detected in the duplicate boot code, then the boot ROM code logs an error and jumps to the USB/UART bootloader. The logged error can be queried via the serial protocol.

7.4.1.6.1 NAND Boot Devices Address Cycle Values

In the case of NAND boot, there is no software lookup table in boot ROM to determine the address cycle value; this value is determined by the eFuses. The various NAND Flash configuration parameters are obtained from eFuses as described in Table 7-12.

7.4.1.6.2 NAND Boot Error Detection and Correction

NFC automatically generates an ECC code for both main and spare data during eNFC data load/read to/from NAND Flash, and NFC updates ECC in the ECC status register. NFC performs error detection and error correction.If the number of ECC errors does not exceed the allowable limit (four for 4-bit ECC, eight for 8-bit ECC) then the boot code corrects those errors.

On device power-on, the boot ROM copies the first 4 Kbytes of boot code from NAND Flash device to the NFC buffer. To accommodate possible read errors, the user is required to duplicate the first 4 Kbytes of boot code to the subsequent block, to serve as a second copy option.

The boot ROM code utilizes the duplicate boot code according to the following flow:

1. If no ECC errors are detected in first boot block, boot execution performs the secure internal boot.
2. If ECC Error is detected in first 4 Kbytes boot data from the first block, the boot ROM code copies the 4-Kbyte boot data from the subsequent block:
   a) If no error detected in the subsequent boot block, boot flow continues performing the secure internal boot.
   b) If an error is detected in the subsequent boot block, the boot ROM code logs an error and jumps to USB/UART bootloader. The logged error can be queried via the serial protocol.

7.4.1.7 OneNAND Flash Boot Operation

OneNAND Flash devices are only available with a 16-bit interface. The ROM OneNAND Flash driver gets the device page size by issuing a software command to the device and collecting the response from the device after system power-up.

OneNAND Flash boot proceeds as follows:

1. At system power-up, OneNAND automatically copies 1 Kbyte of data from the start of the Flash array (sector 0 and sector 1, page 0, block 0) to its boot RAM. This data includes the Flash header.
2. Boot ROM copies the 1-Kbyte boot RAM contents to the destination address (defined in the application header) and decrements the length of the image to be read from OneNAND by 1 Kbyte.
   — The copying operation is a simple memory copy (The boot RAM area is memory mapped).
   — The length of image to be read from OneNAND is specified in Flash header structure shown in Figure 7-2 below.

Any failure in the data load from OneNAND Flash causes the boot ROM to switch to serial download.

7.4.1.8 ATA-HDD (P-ATA) Boot Operation

Boot is enabled from ATA-6 compatible devices. The first 512 bytes from offset zero in device is reserved. The image should be flashed at offset 512 bytes (corresponding to logical block address 1 or LBA 1).

7.4.1.8.1 Flash Header for P-ATA Boot Devices

The image data in P-ATA should be located at an offset of 512 bytes (corresponding to logical block address 1 or LBA 1).

To boot from P-ATA, the boot software performs the following operations:

1. Copy the first 2 Kbytes of boot data from P-ATA into internal RAM
2. Use the Barker value to check for errors
   a) If no error is detected, then jump to the Flash header (1 Kbyte offset from beginning of the boot data) to authenticate the application in engineering or production mode.
   b) If an error is detected, the boot ROM code logs an error and jumps to USB/UART bootloader. The logged error can be queried via the serial protocol.

7.4.1.9 MMC, eMMC, SD, eSD Boot Operation

Internal boot is supported from MMC, eMMC, SD and eSD devices. Table 7-13 shows the eFuse settings, corresponding input contact and their effects on the boot configuration. Only 1-bit bus width is used by the boot ROM.

The boot partition used by the device is determined by the Ext_CSD[179] internal register bit BOOT_PARTITION_ENABLE field.

Table 7-13. eFuse Settings for *x*MMC and *x*SD Boot

eFuse	Input Contact	Settings
BT_MEM_CTL[1:0]	CSI_D11, CSI_D10	Setting of 0b11 is required for boot from *x*MMC or *x*SD devices.
BT_SPARE_SIZE[0]	—	If the bootable device is SD then: 0 FAST_BOOT bit 29 in ACMD41 argument is 0 1 FAST_BOOT bit 29 in ACMD41 argument is 1
BT_SDMMC_SRC	—	00 eSDHC-1 01 eSDHC-2 10 eSDHC-3
HAB_CUS[1:0]	—	Determined by HAB

7.4.1.9.1 MMC and eMMC Card Identification and Initialization

During the identification and initialization phase, MMC and eMMC follow the same sequence:

- The card bus frequency is set to 312.5 kHz
- Card voltage validation is performed. High voltage settings are checked
- The card capacity is checked (both high- and low-capacity MMC/eMMC cards are supported).

After identification and initialization are complete, the boot code switches to the card bus frequency of 16.666 MHz.

7.4.1.9.2 eMMC Card Boot Partition and Special Boot Mode

For eMMC cards, the boot partition can be selected after the card is initialized. The ROM reads the BOOT_PARTITION_ENABLE field in the internal register Ext_CSD[179] to determine the boot partition. If no boot partition is specified, then ROM boots from the user partition by default.

eMMC devices support a special feature that identifies the eMMC device during boot. This feature can be selected by BT_ECC_SEL fuse, and is supported for eMMC devices on eSDHC-1, eSDHC-2, and eSDHC-3. This feature is initiated by pulling the CMD line low while BOOT ACK is enabled. The steps are as follows:

1. The eMMC device sends the BOOT ACK to ROM via DATA0
2. ROM waits 50 ms for BOOT ACK [S010E]
   - If the BOOT ACK is received, then the eMMC is booted in “Boot mode”.
   - If BOOT ACK is not received, then the device boots as a normal MMC card from the selected boot partition.

7.4.1.9.3 SD and eSD Boot Operation

During the identification and initialization phase, SD and eSD follow the same sequence:

- The card bus frequency is set to 312.5 kHz.
- Card voltage validation is performed. High voltage settings are checked. If the check fails, low-voltage settings are checked.
- The card capacity is checked (both high- and low-capacity SD/eSD cards are supported).

During card initialization, the boot code tries to set the boot partition for all SD or eSD devices. If this fails, the boot code assumes card the card is a normal SD card. For the normal SD card of an eSD device without a boot partition, this step will return failure.

After identification and initialization are complete, the boot code switches to the card bus frequency of 16.666 MHz.

ROM also supports FAST_BOOT mode booting from eSD cards. This mode can be selected by the BT_SPARE_SIZE[0] fuse.

The boot ROM uses a 1-bit access to the card. Application code can switch to 4-bit or 8-bit mode.

7.4.1.10 Serial ROM Boot Operation

The i.MX35 supports boot from serial memory devices, such as EEPROM and Serial Flash via the SPI (CSPI-1, at chip select #1) and I²C (I2C-1) interfaces. Boot ROM determines the device type and interface according to the eFuse (or equivalent input contact) settings shown in Table 7-14.

Table 7-14. eFuse Settings for Serial ROM

eFuse	Input Contact	Settings
BT_MEM_CTL[1:0]	CSI_D8, CSI_D9	Must be 0b11 for serial ROM
BT_BUS_WIDTH	CSI_VSYNC	0 2-byte address SPI device (EEPROM) 1 3-byte address SPI device (serial Flash)
BT_MEM_TYPE[1:0]	CSI_D11, CSI_D10	00 Not used for serial ROM 01 Reserved 10 Serial ROM via I²C 11 Serial ROM via SPI

7.4.1.10.1 Serial ROM Boot via SPI

For SPI boot, the serial ROM must reside on chip select #1 of the CSPI-1 module. Serial ROM type (EEPROM or serial Flash) is determined by the BT_BUS_WIDTH setting, as shown in Table 7-14.

7.4.1.10.2 Serial ROM Boot via I²C

For I²C boot, the serial ROM must connect to the I2C-1 module.

Table 7-15 shows the device select codes used by the device to boot from EEPROM.

Table 7-15. EEPROM via I²C Device Select Code

	Device Type Identifier				Chip Enable Address[a]			RW
Bits	7	6	5	4	3	2	1	0
Device Select Code	1	0	1	0	0	0	0	RW

a. These address bits, should be configured at the memory device, to match this '000' value.

NOTE

At boot, the frequency should not exceed 400 kHz for an input clock source of 32 MHz.

7.4.2 External Boot Mode

External boot is selected by driving a value of 0b10 on the BOOT_MODE[1:0] contacts at device power-up. In addition, the eFuse DIR_BT_DIS must be unblown. In this mode, the core boots directly from external memory (in the case of the WEIM) or running NAND Flash boot.

External boot modes are considered as non-secure by definition: the software in Flash is executed regardless of its authenticity, and the SCC is automatically put into non-secure state so that it cannot be used to decrypt information with the device-unique secret key.

The supported direct external Flash types are as follows:

- NOR Flash via WEIM. i.MX35 supports muxed or nonmuxed address data boot from the WEIM interface
- NAND Flash boot

7.4.3 Serial Download Boot Mode

The serial downloader is invoked under the following conditions:

- Serial download is explicitly specified (BOOT_MODE[1:0] = 0b11)
- ROM is in internal boot (BOOT_MODE[1:0] = 0b00) and eFuse values are not valid for any external device.
- Security hardware failure
- Run-time exception occurs
- Error is returned by HAB functions in production mode

To determine the active serial port, either UART or USB, MCU ROM polls the UART and USB status register for about 32 seconds. If there is no activity on either port within the predefined polling loop time, then the ROM powers down the device using WDOG. In the USB/UART bootloader valid case, the WDOG is serviced periodically. If the communication between the Host and BB IC hangs for more than 32 sec or the processor goes into an endless loop, then WDOG expires and powers down the device.

If UART is selected as the communication path, then the UART is configured for baud rate 115.2 kbps, parity disable, 1 stop bit, and 8-bit TX-RX character length; and data is downloaded using the serial protocol. Else, if USB is selected, then the USB core and the external transceiver are configured.

Figure 7-3 shows the USB/UART boot flow.

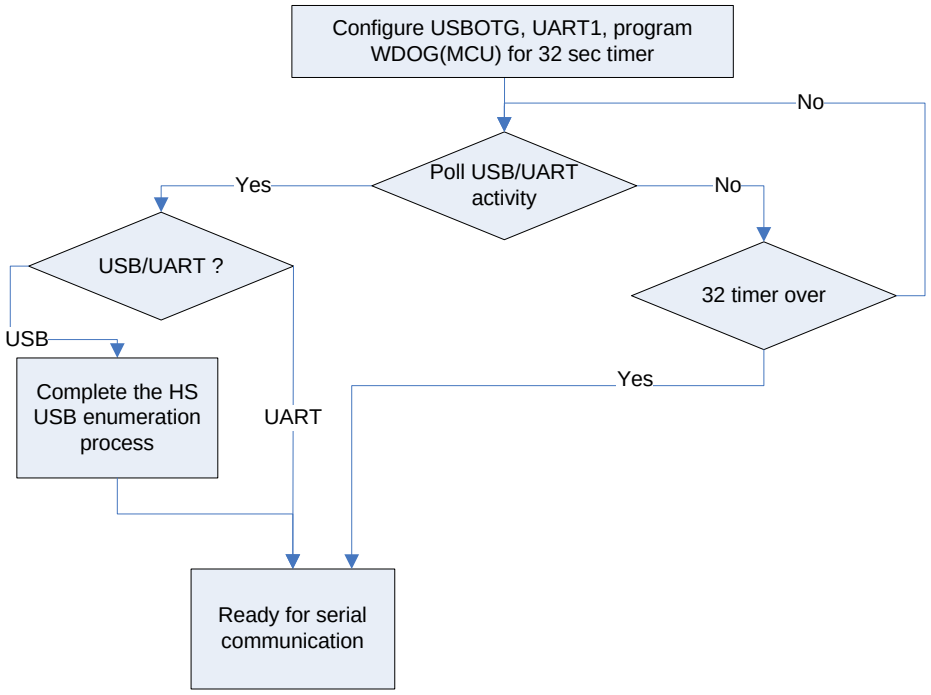

Figure 7-3. USB/UART Boot Flow

7.4.3.1 USB Configuration Details

The i.MX35 supports high-speed (HS for UTMI, ULPI) and full-speed (FS for ATLAS and ISP1301) low-level USBOTG function device drivers.

The USB interface is determined by the eFuses BT_USB_SRC[1:0]. Table 7-16 shows supported boot modes and the corresponding eFuse settings.

Table 7-16. Supported Boot Modes

Boot Mode	BT_USB_SRC eFuse Value
UTMI PHY	BT_USB_SRC[1:0] = 00
ULPI PHY	BT_USB_SRC[1:0] = 01
Serial PHY: Atlas	BT_USB_SRC[1:0] = 10
Serial PHY: Philips 1301	BT_USB_SRC[1:0] = 11

Table 7-17 shows the VID, PID, and strings used for the USB device driver.

Table 7-17. USB Device Driver Information

Descriptor	Value	Remarks
VID	0x15A2	Freescale vendor number
PID	0x0030	Allocated based on Before Part Number
String Descriptor 1	Freescale Semiconductor, Inc.	Manufacturer
String Descriptor 2	SP Blank RINGO SE Blank RINGO NS Blank RINGO	Product
String Descriptor 4	Freescale Flash	—
String Descriptor 5	Freescale Flash	—

Figure 7-4 shows a typical USB boot flow.

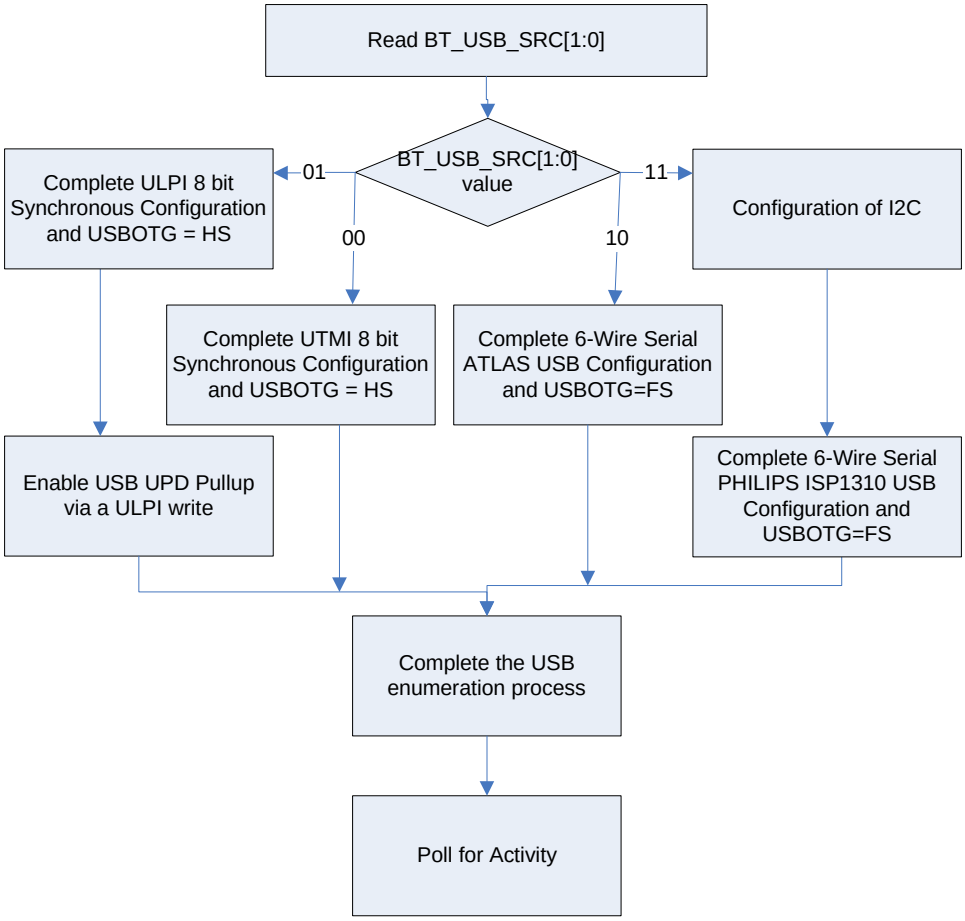

Figure 7-4. USB Boot Flow

7.4.3.2 Serial Download Protocol

This section describes the serial download protocol used for all boot devices in the serial bootloader on i.MX35.

Each stage in the protocol begins with a command issued by the host to the device, followed by a response from the device to the host. For most commands, that completes the protocol stage. The exception is the Write File command, which has an additional data stream sent from the host to the device after the response.

The protocol is terminated by the host issuing a Write File command with application file type. After processing the Write File commands, the device interprets the next command as a Completed command, and resumes execution of the boot flow in order to authenticate the downloaded application (if required) and then execute it.

7.4.3.2.1 Get Status

The Get Status command retrieves the error log stored during a failed boot (or the success code when the serial bootloader is deliberately selected). Table 7-18 shows the Get Status commands and responses.

Table 7-18. Get Status Command

Command	0x05	0x05	—	—	—	—	—	—	—	—	—
Response	SC	SC	SC	SC	SC	N/A	N/A	N/A	N/A	N/A	N/A

The fields in Table 7-18 have the following interpretation:

- SC: Status code. Four copies of the status code are sent.
- —: Don’t care (but must be present)
- N/A: There is no response.

7.4.3.2.2 Read Memory

The Read Memory command, shown in Table 7-19, reads a stream of bytes, half-words or words of data starting from a given address in memory. At production-level security, this command is ignored.

Table 7-19. Read Memory Command

Command	0x01	0x01	A[3:0]		DS	C[3:0]	—	—	—	—	—
Response (success)	ACK[3:0]		Data stream starting from lowest address								
Response (failure)	ACK[3:0]		N/A		N/A	N/A	N/A	N/A	N/A	N/A	N/A

The fields have the following interpretation:

- A[3:0]—Target address (most-significant byte first).
- DS—Data Size (0x08 = byte, 0x10 = half-word, 0x20 = word). Unsupported DS values result in the failure response.

- C[3:0]—Number of data elements (bytes, half-words or words as appropriate) in data stream (most-significant byte first).
- ACK[3:0]—0x56, 0x78, 0x78, 0x56.
- —: Don’t Care (but must be present)
- N/A—No response.

7.4.3.2.3 Write Memory

The Write Memory command, shown in Table 7-20, writes a byte, half-word or word of data to a given address in memory.

Table 7-20. Write Memory Command

Command	0x02	0x02	A[3:0]		DS	—	—	—	—	D[3:0]	—
Response (success)	ACK[3:0]			0x12	0x8A	0x8A	0x12	N/A	N/A	N/A	N/A
Response (failure)	ACK[3:0]			N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A

The fields have the following interpretation:

- A[3:0]—Target address (most-significant byte first).
- DS—Data Size (0x08 = byte, 0x10 = half-word, 0x20 = word). Unsupported DS values result in the failure response.
- D[3:0]—Data to write, most-significant byte first. For DS = 0x08, only D[0] is used. For DS =0x10, only D[1:0] is used.
- ACK[3:0]—0x12, 0x34, 0x34, 0x12 for production-level security, and 0x56, 0x78, 0x78, 0x56 otherwise.
- —: Don’t Care (but must be present)
- N/A—No response.

At production-level security, the address ranges that may be written are restricted to those listed for DCD. Attempts to write outside of the valid ranges are ignored and result in the failure response. For other security levels, no restrictions apply to the target address.

7.4.3.2.4 Re-enumerate

The Re-enumerate command resets the USB connection with an updated descriptor.

Table 7-21 shows the Re-enumerate commands and responses.

Table 7-21. Re-Enumerate Command

Command	0x09	0x09	—	—	—	—	—	—	—	SN[3:0]	—
Response	0x89	0x23	0x23	0x89	N/A	N/A	N/A	N/A	N/A	N/A	N/A

The fields have the following interpretation:

- SN[3:0]—Serial number for enumeration descriptor.
- —: Don’t Care (but must be present)
- N/A—No response.

7.4.3.2.5 Write File

The Write File command, shown in Table 7-22, writes a stream of bytes to a given address in memory. The byte stream may be assigned a file type in order to distinguish CSF, DCD and application files. An application file type leads to the termination the serial download protocol, with the next command (whatever the command byte values) being treated as the Completed command.

Table 7-22. Write File Command

Command	0x04	0x04	A[3:0]		—	C[3:0]	—	—	—	—	FT
Response	ACK[3:0]		N/A							
Data	Byte stream with data for lowest address first.									

The fields in Table 7-22 have the following interpretation:

- A[3:0]—Target address (most-significant byte first).
- C[3:0]—Number of bytes in data stream (most-significant byte first).
- FT—File Type (0xAA = application (terminates protocol), 0xCC = CSF, 0xEE = DCD). With unrecognized FT values, the file is still downloaded, but the pointers to the three essential files are not modified.
- ACK[3:0]—0x12, 0x34, 0x34, 0x12 for production-level security and 0x56, 0x78, 0x78, 0x56 otherwise.
- —: Don’t Care (but must be present)
- N/A—No response.

At production-level security, the address ranges that may be written are restricted to those listed for DCD. Attempts to write outside of the valid ranges are ignored and result in the failure response. For other security levels, no restrictions apply to the target address.

7.4.3.2.6 Completed Command

The Completed command, shown in Table 7-23, is required after the Write File command with application file type in order to terminate the protocol. The content of the command is irrelevant, but a command must be sent. This command triggers authentication and DCD processing (if required) followed by execution of the application. At production-level security, if application authentication fails, the serial download protocol resumes, with the status code for authentication failure available through the Get Status command.

Table 7-23. Completed Command

Command	—	—	—	—	—	—	—	—	—	—	—
Response	0x88	0x88	0x88	0x88	N/A	N/A	N/A	N/A	N/A	N/A	N/A

The fields in Table 7-23 have the following interpretation:

- —: Don't Care (but must be present)
- N/A—No response.

7.4.4 Error Logging

All the ROM errors are logged to the pu_irom_error_status variable, at address 0x1000_18DC.

7.5 High Assurance Boot (HAB)

The high assurance boot (HAB) component of the ROM protects against the potential threat of attackers modifying areas of code or data in programmable memory to make it behave in an incorrect manner. The HAB also prevents attempts to gain access to features that should not be available. The integration of the HAB feature with the ROM code ensures that i.MX35 does not enter an operational state if the existing hardware security modules have detected a condition that may be a security compromise or areas of memory deemed to be important have been modified.

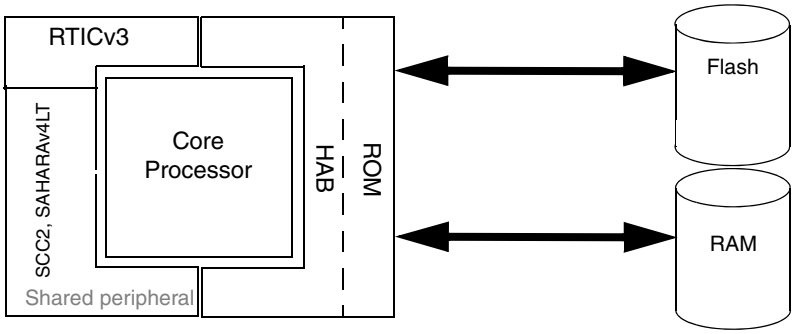

Figure 7-5. Secure Boot Components

Figure 7-5 illustrates the components used during a secure boot. The ARM core has independent HAB libraries and makes use of the shared RTICv3, shared SAHARAv4LT and shared SCC2. The HAB provides support for SHA-256 message digests and RSA encryption operations. The HAB supports SHA-256 through SAHARAv4LT, RTICv3 hardware modules or through a software implementation that runs on the core processor. The RSA encryption operations are performed by software.

The HAB requires the location of two components in Flash: the starting address of the super root key (SRK) data and the starting address of the command sequence file (CSF) data. Both of these components are defined in the Flash header (Figure 7-2). The SRK defined in the application data located in Flash is validated by the HAB. The HAB performs a SHA-256 hash digest of the SRK provided in the application data. It then compares the computed hash with the value stored in the eFuses. If validation of the SRK is unsuccessful then ROM enters the serial bootloader.

The CSF provides the signature and certificate information for the Flash image. The CSF is generated by using a client/server Code Signing Tool (CST).

7.5.1 HAB Types

Table 7-24 shows HAB types, and indicates their effects on the boot flow.

Table 7-24. HAB Types

HAB TYPE	HAB_TYPE Fuse Value	Action
HAB_ENGINEERING	0x1	Initialize secure hardware, execute DCD block and authenticate applications prior to their execution. Any errors detected are logged, but have no influence on the boot flow.
HAB_PRODUCT	0x2	Initialize secure hardware, execute DCD block and authenticate applications prior to their execution. Any errors detected are logged and control passes to the USB/UART Bootloader.
HAB_SEC_DISABLED	0x4	Bypass HAB functions: do not initialize SHW, do not execute HW Configuration block and do not authenticate applications prior to their execution.

7.5.2 Function Prototypes

Three HAB functions are available to application code residing outside of the ROM. An additional function is also available to enter the ROM serial bootloader directly. These functions can be considered trustworthy since they are located in ROM and cannot be changed.

7.5.2.1 pu_irom_boot_decision

Syntax:

```
void pu_irom_boot_decision(void)
```

Description:

Entry point for the serial downloader. Performs the check of whether to use UART or USB for the serial bootloader.

Inputs:

- None.

Returned Value:

- None.

PreConditions/Assumptions:

- GPIO for selecting USB Serial PHY and ULPI PHY is set appropriately.

Post Conditions:

- None.

7.5.2.2 hab_csf_check

Syntax:

```
hab_result hab_csf_check(
UINT8    csf_count,
UINT32   *csf_list);
```

Description:

Performs integrity checks on software in programmable memory as instructed by CSFs.

Inputs:

The number of CSFs to be processed and their locations

Returned Value:

The structure

```
typedef struct
{
    unsigned char status; /* Status code */
    unsigned char type; /* HAB type from Table 7-24 */
} hab_result;
```

with processor TYPE and one of the following status codes:

- HAB_PASSED if all CSFs are valid and all verifications in all CSFs are satisfied.
- HAB_DATA_OUT_OF_BOUNDS if csf_count is 0, csf_count exceeds maximum length of CSF chain or csf_list is NULL.
- Appropriate error code for other failures as stated in Table 7-26.
- HAB_FAILURE otherwise.

Pre Condition/Assumptions:

- Verified blocks list and subordinate keys list are initialized.
- The parameter csf_list points to a list of length csf_count.

Post Condition:

- The verified blocks list contains the list of successfully verified data blocks, padded at the end of the list to indicate that no more verified block is available.
- The subordinate keys list contains successfully validated subordinate keys.
- If HAB_SHA1_RTIC_KEEP, HAB_RSA_SHA1_RTIC_KEEP, HAB_SHA256_RTIC_KEEP and HAB_RSA_SHA256_RTIC_KEEP algorithm types are used in CSF commands, the RTIC hash digest registers and runtime enable masks are initialized in preparation for run-time mode operation.

7.5.2.3 hab_assert_verification

Syntax:

```
hab_result hab_assert_verification(
UINT8    *block_start,
UINT32    block_length);
```

Description:
Perform only after a CSF Check. Determines if a block of data lies within the regions of the pre-authenticated block or the regions verified during CSF Check.
The state of the SCC (if enabled and the processor TYPE is not engineering) is also tested to ensure that the hardware is secure.

Inputs:

Starting address and length (in bytes) of the data block.

Returned Value:

The structure:

```
typedef struct
{
    unsigned char status; /* Status code */
    unsigned char type; /* HAB type from Table 7-24 */
} hab_result;
```

with processor TYPE and one of the following status codes:

- HAB_PASSED if all tests pass,
- HAB_FAIL_ASSERT if block is not pre-authenticated or in regions verified during CSF Check,
- HAB_SCC_NOT_SECURE if SCC is not in the secure state and processor TYPE is not engineering,
- HAB_FAILURE otherwise.

Pre Condition/Assumptions:

- The verified blocks list contains (start, length) pairs of 32 bit unsigned integer values, padded at the end of the list to indicate that no more verified block is available. If the given block has been verified or pre-authenticated, it is assumed to lie wholly within the boundaries of a single block in the verified blocks list.

Post Condition:
None.

7.5.3 API Jump Table Addresses

The address of the HAB functions are available via a jump table defined in the ROM. Table 7-25 lists the functions and the associated jump table address.

Table 7-25. HAB API Jump Table Addresses

HAB API Function	Jump Table Address
hab_csf_check	0x8C
hab_assert_verification	0x90
pu_irom_boot_decision	0x0040_5FE0

7.5.4 HAB Status Codes and Algorithm Types

Table 7-26. HAB Status Codes

Name	Description	Value
HAB_DATA_OUT_OF_BOUNDS	Data specified is out of bounds.	0x8D
HAB_FAIL_ASSERT	Error during Assert Verification.	0x55
HAB_FAIL_HASH_VERIFICATION	Hash verification failed (including hash verification on certificates).	0x36
HAB_FAIL_PK_VER	Certificate parsing failed, or the certificate contained an unsupported key (including unsupported key length).	0x33
HAB_FAIL_SIG_VERIFICATION	Signature verification failed (including signature verification on certificate).	0x35
HAB_FAIL_SUPER_ROOT_INSTALL	Super-Root key installation failed.	0x47
HAB_FAILURE	Failure not matching any other description.	0x39
HAB_INVALID_CSF_COMMAND	CSF Command Sequence contains an unsupported command identifier.	0x4B
HAB_INVALID_CSF_HEADER	Absence of expected CSF Header (including mismatched HAB Version).	0x4E
HAB_INVALID_CSF_LENGTH	CSF length is unsupported.	0x4D
HAB_INVALID_CSF_TYPE	CSF TYPE does not match processor TYPE.	0x2E
HAB_INVALID_CSF_UID	CSF UID does not match either processor UID or generic UID.	0x2D
HAB_INVALID_CSF_CODE	CSF Customer/Product code does not match processor Customer/Product code.	0x3A
HAB_INVALID_KEY_INDEX	Key index is either unsupported, or an attempt is made to overwrite the Super-Root key from a CSF command.	0x87
HAB_PASSED	Successful operation completion.	0xF0
HAB_SCC_NOT_SECURE	SCC unexpectedly not in Secure State.	0x17
HAB_SECURE_RAM_BAD_KEY	SecureRAM secret key invalid.	0x1E
HAB_SECURE_RAM_CLR_FAIL	SecureRAM initialization failure.	0x1D
HAB_SECURE_RAM_FAIL	SecureRAM Self Test failure.	0x1B
HAB_SCC_FAIL	SCC unexpectedly not in Non-Secure State	0x53

Table 7-26. HAB Status Codes (Continued)

Name	Description	Value
HAB_SECURE_RAM_INT_ERR	SecureRAM internal failure.	0x2B
HAB_SECURE_RAM_SEC_KEY	SecureRAM secret key unexpectedly in use.	0x27
HAB_SAHARA_FAIL	SAHARA failure.	0x3C
HAB_SAHARA_SCC_FAIL	SAHARA/SCC connectivity failure.	0x59
HAB_RTIC_REGION_FAIL	All RTIC regions are allocated.	0xA3
HAB_RTIC_SCC_FAIL	RTIC/SCC connectivity failure.	0x93
HAB_SHW_DISABLED	SHW is not enabled.	0x0F
HAB_UNINITIALISED_KEY_INDEX	An attempt is made to read a key from the list of subordinate public keys at a location where no key is installed.	0x8B
HAB_UNSUPPORTED_ALGORITHM	Algorithm type is either invalid or otherwise unsupported (for example, Debug Port activated while the HAC of a non-engineering processor TYPE is in use).	0x8E
HAB_INVALID_WRITE_REG	Write operation to register failed.	0x66

Chapter 8
Power Management

The clock controller module (CCM) supports several power management techniques to reduce active and static power consumption.

8.1 Power Saving Methodology

This section discusses power savings (active power savings and leakage power savings) and power modes.

8.1.1 Active Power Savings

Active power savings includes the following:

- Dynamic voltage frequency scaling (DVFS) reduces active power consumption by scaling voltage and frequency according to required MIPs.
- Dynamic process temperature compensation (DPTC) reduces active power consumption by adjusting supply voltage according to the individual device's characteristics and ambient temperature.
- Clock gating reduces active power consumption by gating the clock to each module while the module is in idle state.

8.1.1.1 Dynamic Voltage Frequency Scaling (DVFS)

The CCM allows simple software dynamic voltage frequency scaling. The frequency of the core clock domain and the voltage of the chip can be changed on the fly while all modules (including the core) continue their normal operation. The voltage of the device can be changed through the CSPI port to the power management integrated circuit (PMIC). The frequency of the core clock domain can be changed by configuring the postdivider only in the CCM. Additionally, the CCM can be configured to generate an ARM clock on the fly with frequency 532 MHz, 399 MHz, 266 MHz, or 133 MHz, while the AHB clock frequency is maintained at 133 MHz.

8.1.1.2 Dynamic Process Temperature Compensation (DPTC)

The DPTC module detects the minimum operating voltage for the device, taking into account the maximum level of processing activity and ambient temperature for a given frequency. The DPTC inputs predefined values for processor-speed performance measurements and generates an interrupt if the value of the supply voltage must be updated.

8.1.1.3 Clock Gating

The CCM has clock gating to reduce dynamic power consumption while each module is idle. Clock gating can be controlled by software configuration or system low-power modes. The gating cell is within the CCM for each clock root, and some gating cells are in front of the divider to save more power while gating the clock.

8.1.2 Leakage Power Savings

Leakage power savings includes the following:

- Active well bias (AWB) reduces static power consumption by applying back bias on transistors. AWB can be applied on ARM11P and EMI while they are not functioning (in low-power modes). AWB can help reduce the leakage power for the ARM11 platform and EMI in the device. In some low-power modes, the CCM can control the ARM11 and EMI to apply back bias on transistors.
- Low-power mode can reduce the system power to several levels. The ARM core can be put into standby mode, clocks can be gated, in some cases PLLs can be stopped, and the oscillator can be powered off. Furthermore, the core logic voltage can be reduced to state-retention level when the device is idle. Low-power mode can be configured to power off the oscillator and thus save power. In stop mode the core logic is idle, and the supply voltage can be reduced.

8.1.3 Power Modes

Table 8-1 shows the low-power modes for the device.

Table 8-1. Low-power Modes

Mode	Core	ARM11P MAX	Modules	MPLL	PPLL[b]	Osc24M[a]	Osc Audio[b]
Run	Active	Active	Active, Idle or Disabled [c]	On	On/off	On	On/off
Wait	Disabled	Active	Active, Idle or Disabled [c]	On	On/off	On	On/off
Doze	Disabled	Disabled	Active, Idle, or Disabled [c]	On	On/off	On	On/off
Stop	Disable	Disable	Disabled [d]	Off	Off	On/Off	Off
State-Retention[e]	Disable	Disable	Disabled	Off	Off	On/Off	Off
Static[a]	Disable	Disable	Disabled	Off	Off	Off	Off

a. The 24 MHz oscillator is the source of the PLL reference clock, and it is also the default source of the CKIL. It should be kept on in RUN/WAIT/DOZE mode, and can be configured to keep on or power off in STOP mode. While Osc24M is powered off in STOP mode, all clocks are off including the CKIL. The power consumption is the lowest in this mode. This special STOP mode is called static stop mode.

b. The PPLL and the oscillator audio can be configured by software to work or not in each mode. In STOP mode, it is better to close them to save power.

c. During run, wait and doze modes, the software can configure the modules to be active or off.

d. Some modules, for example, IPU self-refresh mode, can operate in STOP mode while the CKIL is still working.

e. The CCM_CCMR[VSTBY] software bit can be configured to reduce the logic core supply from 1.1 V to 1.0 V. This special STOP mode is called state-retention mode.

The following example interrupt sources may be used to wake up the ARM core:

- USB
- KPP
- UART1, UART2, UART3
- FlexCAN

Some interrupts need CKIL to be running to generate, but others can generate without the CKIL in the same way as the interrupt triggered by FlexCAN.

8.2 Supplies

Table 8-2 describes the device power supply requirements.

Table 8-2. Power Supply Requirements

Module	Minimum Voltage	Typical Voltage	Maximum Voltage
Digital Logic Domain	1.0	1.2	1.65
DDR Pins	1.75	1.8	1.9
Other Pins	3.0	3.3	3.6
MLB	2.25	2.5	2.75
USB PHY	3.0	3.3	3.6
USB VBUS	4.5	5.0	5.5
24 Mhz Oscillator	3.0	3.3	3.6
Fusebox Program	3.0	3.3	3.6
PLL Domain	1.4	1.5	1.65
FLASH	3.0	3.3	3.6
HDD	3.0	3.3	3.6
MMC	3.0	3.3	3.6

8.3 Power Up Sequence

The general power-up sequence is as follows:

1. Turn on the digital logic domain QVCCx and IO power supply:
2. Turn on all analog power supply.

8.4 Handshake Signals

The PMIC and the device have handshake signals for state-retention function in low-power mode. While entering low-power mode, if the CCM wants to lower core logic to 1.0 V, it asserts ccm_vstby_pmic to PMIC. While exiting from low-power mode, the ccm_vstby_pmic signal negates, and the PMIC sends back the pmic_rdy (active) signal to confirm that the PMIC is ready and the voltage has been recovered from 1.0 V.

Chapter 9
1-Wire Module (1-Wire)

9.1 Overview

The 1-Wire module provides the communication link to a generic 1-Kbit add-only memory. The module sends or receives one bit at a time with an option for software to manage the data using bytes. The required protocol for accessing the generic 1-Wire device is defined by Maxim-Dallas. The generic 1-Wire device holds battery characteristics information.

Figure 9-2 shows a block diagram of the 1-Wire module.

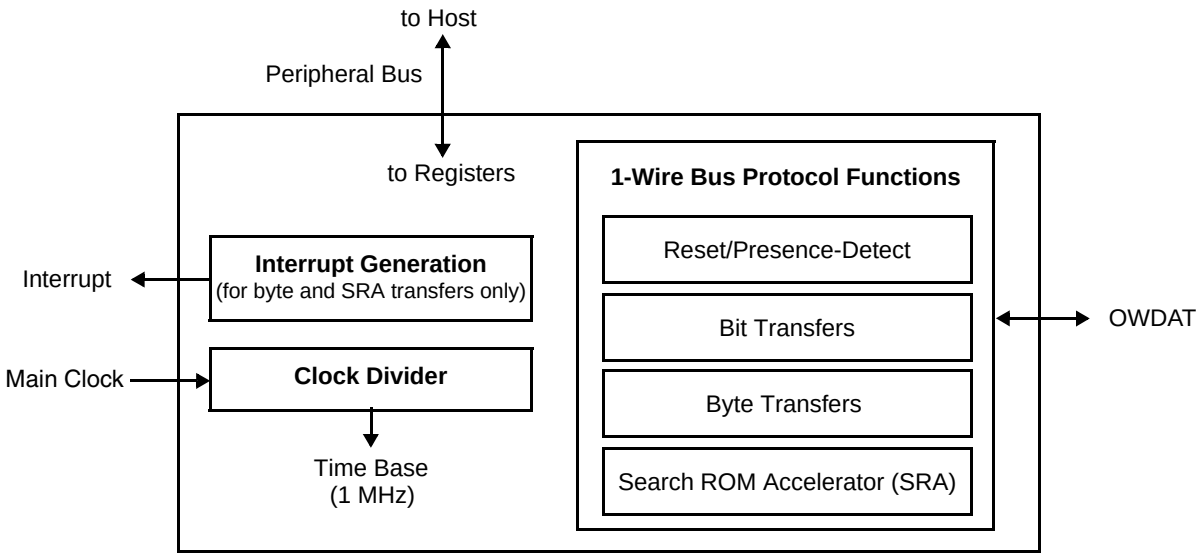

Figure 9-1. 1-Wire Module Block Diagram

9.1.1 Features

The 1-Wire module includes the following features:

- Performs the 1-Wire bus protocol to communicate with an external 1-Wire device.
- Provides a clock divider to generate a 1-Wire bus reference clock (derived from the main clock provided internally to the module).
- Supports byte transfers with optional interrupts for more efficient programming.
- Provides search ROM accelerator mode to speed the search ROM protocol.

9.1.2 Modes of Operation

The 1-Wire module supports the following operations:

- Normal operating modes (See Section 9.4.1, “Normal Operating Modes.”)
  - — Bit or byte transfers
  - — Reset/presence-detect pulse
  - — Search ROM accelerator mode
- Low-power mode (See Section 9.4.2, “Low-Power Mode.”)

9.2 External Signals

Table 9-1 shows the signal that interfaces with a generic 1-Wire device.

Table 9-1. 1-Wire Module Signal

Signal	I/O	Function
OWDAT	I/O	1-Wire bus Requires an external pull-up resistor. The recommended resistor value is specified by the generic 1-Wire device used in a given system.

9.3 Memory Map and Register Definition

This section provides the module memory map and detailed descriptions of all registers.

9.3.1 Memory Map

Table 9-2 shows the 1-Wire memory map.

Table 9-2. 1-Wire Memory Map

Base Address Offset	Register	Access	Reset Value	Section/Page
0x0000 (CONTROL)	Control register	R/W	0x0000	9.3.2.1/9-3
0x0002 (TIME_DIVIDER)	Time divider register	R/W	0x0000	9.3.2.2/9-4
0x0004 (RESET)	Reset register	R/W	0x0000	9.3.2.3/9-4

9.3.2 Register Descriptions

This section provides the detailed descriptions for the registers. All registers are byte-addressable.

9.3.2.1 Control Register (CONTROL)

The control register is used to initiate the reset/presence-detect sequence and bit transfers. The register also provides the presence-detect status and bit-read status.

Figure 9-2 shows the register. Table 9-3 describes the register fields.

Offset 0x0000 (CONTROL) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 9-2. Control Register

Table 9-3. Control Register Field Descriptions

Field	Description
15–8	Reserved
7 RPP	Reset/Presence-detect Pulse. This bit is self-clearing and is cleared after the presence or absence of an external device is determined. See Section 9.4.1.1, “Reset/Presence-detect Pulse.” When writing: 0 Do nothing. 1 Generate reset pulse and sample the bus for the presence pulse from the external device. When reading: 0 Reset pulse complete. 1 Sequence not complete.
6 PST	Presence Status. This bit is valid after the RPP bit is self-cleared. 0 Device is not present. 1 Device is present.
5 WR0	Write 0. This bit is self-clearing and is cleared when the write of the bit is complete. See Section 9.4.1.2.1, “Write-0 Sequence.” When writing: 0 Do nothing. 1 Write a 0 bit to the interface. When reading: 0 Write sequence complete. 1 Sequence not complete.

Table 9-3. Control Register Field Descriptions (Continued)

Field	Description
4 WR1	Write 1 / Read. This bit is self-clearing and is cleared when the write sequence is complete. See Section 9.4.1.2.2, "Write-1 / Read Sequence." When writing: 0 Do nothing 1 Write a 1 bit to the interface and sample the bus. When reading: 0 Sequence complete. 1 Sequence not complete.
3 RDST	Read Status. This bit is valid after the WR1 bit is self cleared. 0 A 0 has been sampled. 1 A 1 has been sampled.
2–0	Reserved

9.3.2.2 Time Divider Register (TIME_DIVIDER)

The time divider register is used for dividing the main clock (ipg_clk) input down to 1 MHz to generate the module's time base.

Figure 9-3 shows the register. Table 9-4 describes the register fields.

Offset 0x0002 (TIME_DIVIDER) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1 SRA	Search ROM Accelerator. This bit is cleared when the reset-presence-pulse bit CONTROL[RPP] is set. 0 Deactivate the search ROM accelerator. 1 Switch to search ROM accelerator mode.
0	Reserved

9.3.2.5 Transmit/Receive Register (TX/RX)

Data sent and received from the 1-Wire module passes through the transmit/receive (TX/RX) register. The 1-Wire module is double-buffered with separate transmit and receive buffers connected to the TX/RX register. See Section 9.4.1.3, “Byte Transfers.”

Figure 9-6 shows the register. Table 9-7 describes the register fields.

Offset 0x0008 (TX/RX) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	DATA							
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 9-6. Transmit/Receive Register

Table 9-7. Transmit/Receive Register Field Descriptions

Field	Description
15–8	Reserved
7-0 DATA	Data byte. When writing: The data byte is written to the transmit buffer. When reading: A data byte is read from the receive buffer. The data is valid only when INTERRUPT[RBF] is set.

9.3.2.6 Interrupt Register (INTERRUPT)

Flags for the reset/presence-detect sequence and byte transfer operations are located in the interrupt register. These flags can generate an interrupt if the corresponding enable bit is set in the interrupt enable register.

If interrupts are enabled, reading the interrupt register clears the interrupt even if all the current flags are not cleared; the interrupt service routine should clear all pending flags during each routine call.

NOTE

When a byte is written to the transmit/receive register, software then waits for a transmit shift register empty (TSRE) interrupt to occur. When the TSRE flag is set, the receive buffer full (RBF) flag is also set. The RBF flag does not trigger an interrupt, assuming it is disabled. however, software should read the transmit/receive register to clear the RBF flag in order to give a proper status of the pending interrupts.

Figure 9-7 shows the register. Table 9-8 describes the register fields.

Offset 0x000A (INTERRUPT) Access: User read

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	RSRF	RBF	TSRE	TBE	PDR	PD
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

Figure 9-7. Interrupt Register

Table 9-8. Interrupt Register Field Descriptions

Field	Description
15–6	Reserved
5 RSRF	Receive shift register full. Hardware automatically clears this flag when data in the receive shift register is transferred to the receive buffer. 0 The receive shift register is empty or currently receiving data. 1 A byte is waiting in the receive shift register to be transferred to the receive buffer.
4 RBF	Receive Buffer Full. This flag is cleared when software reads the byte from the TX/RX register. This flag prevents new data from being shifted into the receive buffer from the receive shift register. 0 No new data 1 A byte is waiting to be read from the TX/RX register.
3 TSRE	Transmit Shift Register Empty. Hardware automatically clears this flag when data in the transmit buffer is transferred to the transmit shift register. 0 Sending data 1 The transmit shift register is empty and is ready to receive the next byte from the Transmit buffer.
2 TBE	Transmit Buffer Empty. This flag is cleared when software writes a byte to the TX/RX register. 0 The Transmit buffer is currently sending data to the transmit shift register. 1 Nothing to transmit
1 PDR	Presence Detect Result. When a presence-detect (PD) interrupt occurs, this bit reflects the result of the presence-detect sequence. Note that this bit does not generate an interrupt. 0 Device found 1 Device not found
0 PD	Presence Detect. After an 1-Wire reset has been issued, this flag is set after the appropriate amount of time for a presence detect pulse to have occurred. This flag is cleared when software reads the interrupt register. 0 A reset/presence-detect sequence has not been issued. 1 Reset/presence-detect sequence has completed. The result is provided in the PDR bit.

9.3.2.7 Interrupt Enable Register (INTERRUPT_EN)

The interrupt enable register allows the system programmer to specify the source of interrupts. During a reset (hardware or software), all bits in this register are cleared, disabling all interrupt sources.

Figure 9-8 shows the register. Table 9-9 describes the register fields.

Offset 0x000C (INTERRUPT_EN) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	ERSF	ERBF	ETSE	ETBE	IAS	EPD
W																
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 9-8. Interrupt Enable Register

Table 9-9. Interrupt Enable Register Field Descriptions

Field	Description
15–6	Reserved
5 ERSF	Enable receive shift register full interrupt. 0 Disable interrupt. 1 Enable interrupt.
4 ERBF	Enable Receive Buffer Full Interrupt. 0 Disable interrupt. 1 Enable interrupt.
3 ETSE	Enable Transmit Shift Register Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
2 ETBE	Enable Transmit Buffer Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
1 IAS	Interrupt Trigger Active State. This bit determines the polarity for all interrupts. Note that this bit is not an interrupt-enable bit. 0 Active high interrupt 1 Active low interrupt
0 EPD	Enable Presence Detect. 0 Disable interrupt. 1 Enable interrupt.

9.4 Functional Description

The 1-Wire module interfaces with a generic 1-Kbit add-only memory through a simple 1-bit bus. Software uses the 1-Wire bus to program and read the 1-Kbyte memory.

The protocol involves first issuing one of four ROM function commands before the EPROM is accessible:

- Read ROM
- Match ROM
- Search ROM
- Skip ROM

Through the 1-Wire bus, the host software interfaces with the generic 1-Wire device and allows the required commands to be issued to control the EPROM of a generic 1-Wire device. The host (through the 1-Wire interface) is the bus master, and the generic 1-Wire device(s) are the slave(s)

9.4.1 Normal Operating Modes

The 1-Wire module supports the following 1-Wire bus protocol functions:

- Reset/presence-detect pulse using the control register (See Section 9.4.1.1, “Reset/Presence-detect Pulse.”)
- Bit transfers using the control register (See Section 9.4.1.2, “Bit Transfers.”)

- Byte transfers using the TX/RX register (See Section 9.4.1.3, “Byte Transfers.”)
- Search ROM accelerator mode using the command register and the TX/RX register (See Section 9.4.1.4, “Search ROM Accelerator Mode.”)

9.4.1.1 Reset/Presence-detect Pulse

The 1-Wire module provides for an automated initialization sequence for the 1-Wire bus. Software initiates the initialization sequence by setting CONTROL[RPP]. The automated initialization sequence is as follows:

1. Generate a reset pulse.
2. Listen for a response from an external device by sampling for the 1-Wire device presence bit.
3. After an amount of time determined by the 1-Wire standard, latch the presence bit (true or false) in CONTROL[PST].

If an external device is detected (PST = 1), software can begin communications on the 1-Wire bus.

The presence pulse is used by the 1-Wire to determine if at least one generic 1-Wire device is connected. Software determines if more than one generic 1-Wire device exists; see Section 9.4.1.1, “Reset/Presence-detect Pulse.”

9.4.1.2 Bit Transfers

After the initialization sequence (see Section 9.4.1.1, “Reset/Presence-detect Pulse), software can write and read one bit at a time using the control register.

9.4.1.2.1 Write-0 Sequence

The Write-0 sequence writes a zero bit to the generic 1-Wire device. Setting the CONTROL[WR0] bit initiates the Write-0 pulse sequence. Once the write is complete, the WR0 bit is automatically cleared.

9.4.1.2.2 Write-1 / Read Sequence

The Write-1 sequence writes a one bit to the generic 1-Wire device. Setting the CONTROL[WR1] bit initiates the Write-1 pulse sequence. Once the write is complete, the WR1 bit is automatically cleared.

Because the Write-1 and Read timings are identical, this sequence also reads a bit from the bus. The sampled value is stored in the read status bit CONTROL[RDST] and is valid after the WR1 bit is self-cleared.

9.4.1.3 Byte Transfers

After the initialization sequence (see Section 9.4.1.1, “Reset/Presence-detect Pulse”), software can transfer a byte at a time using the TX/RX register. Writing to the register connects to the Transmit buffer; reading to the register connects to the receive buffer. See Figure 9-9.

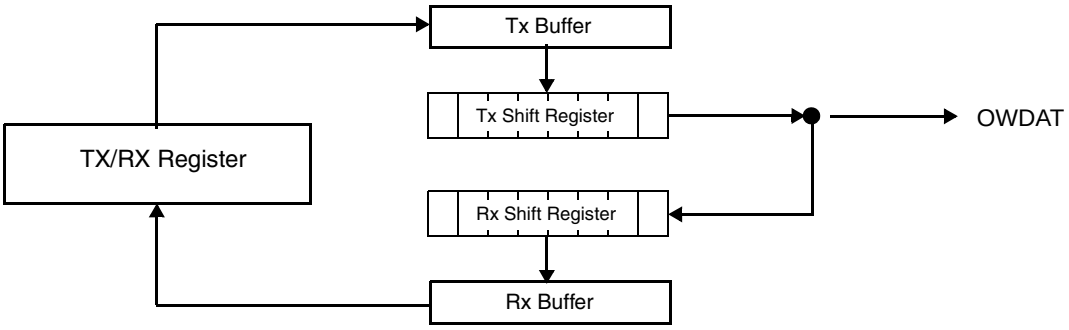

Figure 9-9. Byte Transfers

The transmit buffer connects to an internal transmit shift register where data is shifted serially onto the bus LSB first. Similarly, the receive buffer connects to an internal receive shift register where data is sampled serially from the bus.

Software can read a byte from the generic 1-Wire device as follows:

1. Write 0xFF to the transmit/receive register location (connected to the transmit buffer).
2. Wait for the receive-buffer-full (INTERRUPT[RBF]) interrupt (or poll the flag bit directly if the interrupt is disabled). During this time, the hardware is writing ones on the bus while sampling the wired-AND of the data from the device. The read data is shifted into the receive shift register. When a byte is collected in the receive shift register, the data is transferred to the receive buffer, and the RBF flag is set.
3. Read from the transmit/receive register location (connected to the receive buffer) upon receiving the RBF interrupt.

If the receive buffer is full, new data is not shifted from the receive shift register until the current data is read. To prevent the loss of data, software must read the TX/RX register to clear the receive-buffer-full flag (INTERRUPT[RBF]). This allows the receive shift register to shift new data into the receive buffer.

9.4.1.4 Search ROM Accelerator Mode

In search ROM accelerator mode, the 1-Wire module relieves software from having to perform single-bit operations on the bus and helps to determine whether more than one generic 1-Wire device exists.

The host transmits the 16-byte search value based on the last ROM value found. These 16 bytes are 0x00 for the first run. The 16 bytes returned contain the new ROM code and are also used to generate the next 16 bytes to transmit. This process is repeated until serial numbers duplicate to find all devices.

The 1-Wire module enters search ROM accelerator mode when COMMAND[SRA] is set. This protocol specifies that the bus master read two bits (a bit and its complement), then writes a bit to specify which devices should remain on the bus for further processing. This mode requires that a reset followed by the search ROM command (0xF0) has already been issued on the 1-Wire bus.

The 1-Wire module automatically exits search ROM accelerator mode if the 1-Wire bus is re-initialized; see Section 9.4.1.1, “Reset/Presence-detect Pulse.”

9.4.2 Low-Power Mode

The 1-Wire module automatically goes into low-power mode whenever it is not communicating with a generic 1-Wire device. The main clock is gated off in low-power mode.

As soon as software writes to any register, the 1-Wire module exits low-power mode.

9.4.3 Clocks

The 1-Wire module takes a main clock as a module input and passes it through a clock divider (see the block diagram in Figure 9-1). Software must program the divider factor to generate a 1-MHz clock that is used as an internal time base for the module, as given by Equation 9-1.

$$\text{time\_base} = \text{main\_clock} \div (\text{TIME\_DIVIDER[DVDR]} + 1) \qquad \textit{Eqn. 9-1}$$

For example, if the main clock frequency is 30 MHz, the value to write to the divider register is 29. If the main clock input frequency is not an integer, the programmer must ensure the time base frequency is within the range given by Equation 9-2.

$$0.98\ \text{MHz} \leq \text{time\_base} \leq 1.02\ \text{MHz} \qquad \textit{Eqn. 9-2}$$

NOTE

A main clock frequency below 10 MHz causes improper function of the module.

9.4.4 Reset

The 1-Wire module supports two levels of reset: hardware and software.

9.4.4.1 Hardware Reset

Whenever a device reset occurs, a hard reset is performed on the 1-Wire module, clearing all values written to all registers.

9.4.4.2 Software Reset

Software initiates a software reset by setting the reset bit RESET[RST]. A software reset clears all data written to the registers except for the command and interrupt registers (COMMAND, INTERRUPT).

Note that the reset register (RESET) itself is not cleared during a software reset. Software must clear the RST bit to release the software reset.

9.4.5 Interrupts

The 1-Wire generates interrupts through the programming of the interrupt enable register; see Section 9.3.2.7, “Interrupt Enable Register (INTERRUPT_EN).” The 1-Wire can generate interrupts under the following conditions:

- Receive shift register or buffer full

- Transmit shift register or buffer empty
- Presence detect

Once any of these conditions are met, the interrupt register (see Section 9.3.2.6, “Interrupt Register (INTERRUPT)”) sets the corresponding bit and generates an interrupt if enabled in the interrupt enable register. The IAS bit within the interrupt enable register determines if the interrupt generated is active low, or active high. By default all interrupts are active high, and software should not modify IAS.

Chapter 10
Asynchronous Sample Rate Converter (ASRC)

10.1 Introduction

Figure 10-1 shows the system view of the ASRC module and other related modules.

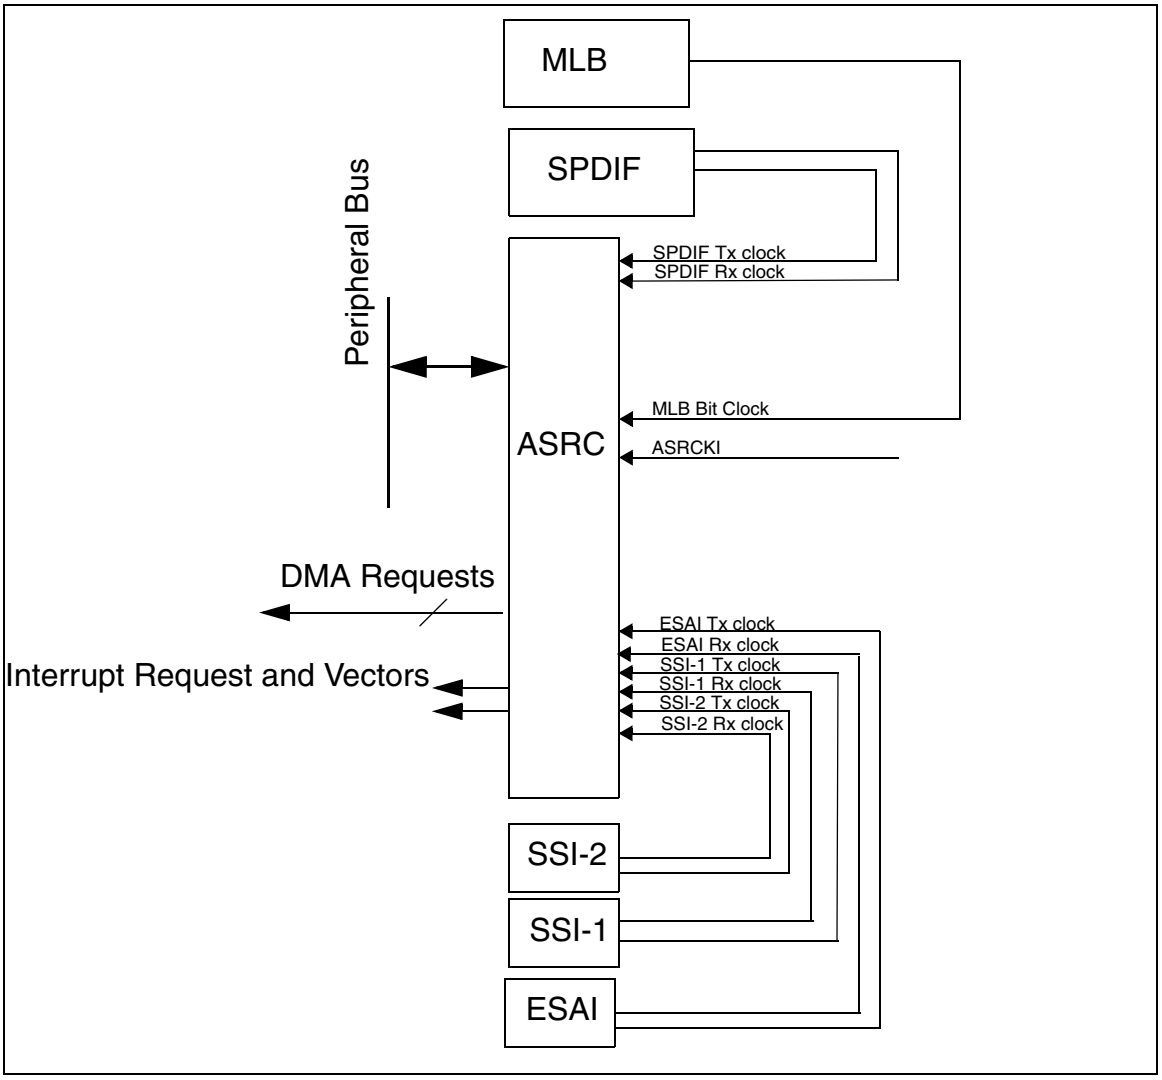

Figure 10-1. System Overview

Figure 10-2 shows the block diagram.

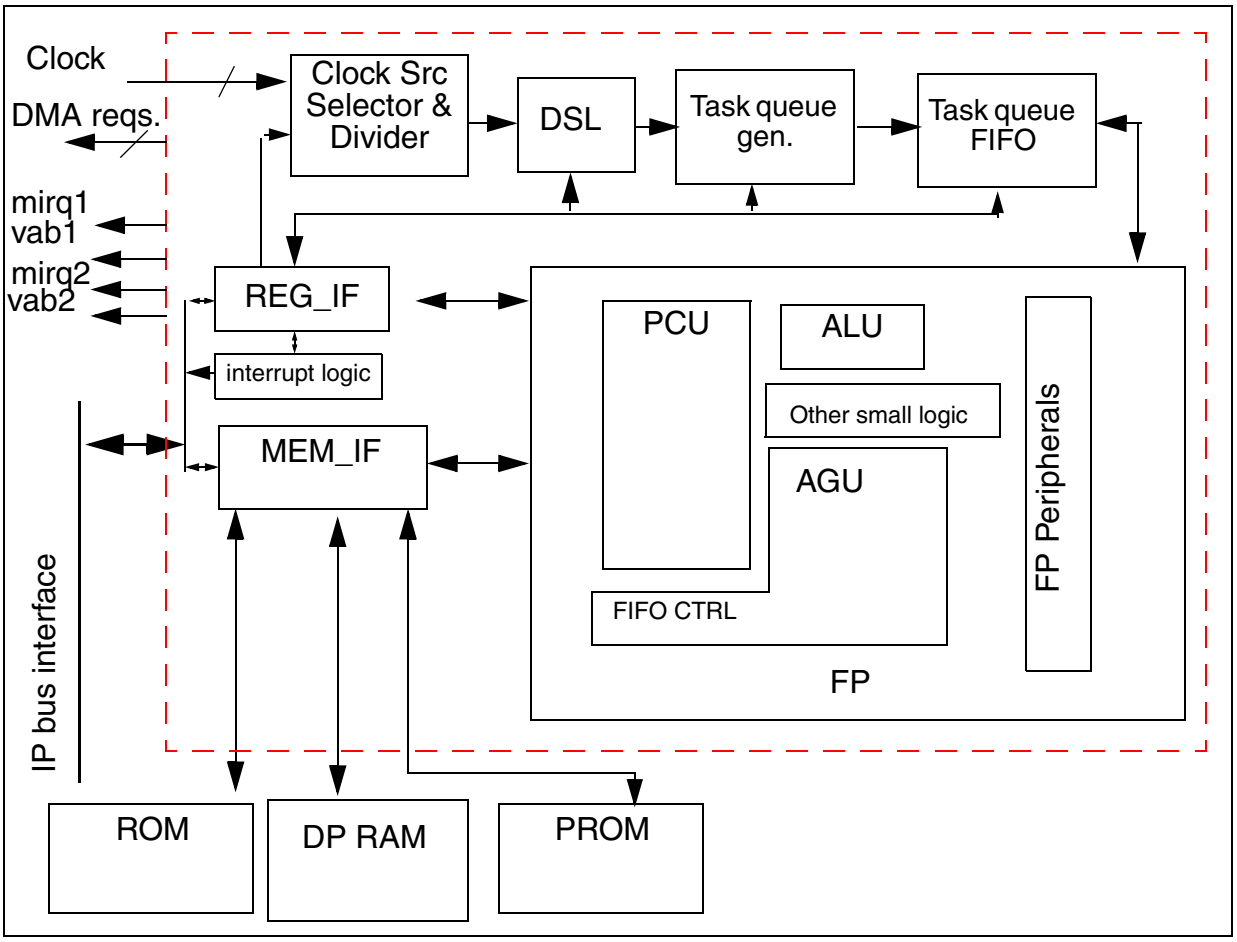

Figure 10-2. ASRC Block Diagram

10.1.1 Overview

The incoming audio data to this chip may be received from various sources at different sampling rates. Also, the outgoing audio data of this chip may have different sampling rates, and it can also be associated to output clocks that are asynchronous to the input clocks.

The asynchronous sample rate converter (ASRC) converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock.The ASRC supports concurrent sample rate conversion of up to 10 channels of about –120dB THD+N. The sample rate conversion of each channel is associated to a pair of incoming and outgoing sampling rates. The ASRC supports up to three sampling rate pairs.

The ASRC is hard-coded, implemented as a coprocessor, and requires minimal CPU intervention.

10.1.2 Features

Table 10-1 shows the ASRC module specifications.

Table 10-1. ASRC Specifications

Parameters	Test Conditions	Minimum	Typical	Maximum	Unit
Channels Supported	—	2	2*n	10	—
Pairs of Rate Conversion	—	1	—	3	—
THD + N	120 MHz < Fmaster < 160 MHz	—	–120	—	dB
Dynamic Range	—	—	—	144	dB
Settling Time	—	—	40	—	ms

Other features include the following:

- Individual association of each channel to one of the sampling rate pairs
- Support ratio (Fsin/Fsout) range between 1/24 to 8
- Designed for rate conversion between 44.1 kHz, 32 kHz, 48 kHz, and 96 kHz. The useful signal bandwidth is below 24 kHz.
- Other input sampling rates in the range of 8 kHz – 100 kHz are also supported, but with less performance.
- Other output sampling rates in the range of 30 kHz to 100 kHz are also supported, but with less performance.
- Limited support for the case when the output sampling rate is between 8 kHz – 30 kHz. The limitation is the supported ratio (Fsin/Fsout) range.
- Automatic accommodation to slow variations in the incoming and outgoing sampling rates.
- Linear phase
- Tolerant to sample clock jitter
- Designed for real-time streaming audio usage. Can be used for non-realtime streaming audio usage when the input sampling clocks are not available.

Clock and data connection features include the following:

- The sampling rate clocks are directly connected to the ASRC model and the ratio estimation of the input clocks with output clocks is done in ASRC hardware.
- In any usage case, the output sampling clocks must be activated.
- In a real-time streaming audio case, both input and output sampling-rate clocks need to be activated.
- In a non-realtime streaming audio case, the input sampling rate clocks can be avoided by setting ideal-ratio values into the ASRC interface registers.
- The clock signals come from the following modules:
  - ESAI, receiving clock and transmitting clock
  - SSI-1, receiving clock and transmitting clock
  - SSI-2, receiving clock and transmitting clock

  - SPDIF, receiving clock and transmitting clock
  - MLB clock
  - CORE master clock derivative (default: 768 kHz)
- The exchange of audio data is done by the CORE accessing the ASRC module through registers defined on the IP bus interface.

10.1.3 Modes of Operation

10.1.3.1 Data Transfer Schemes

10.1.3.1.1 Data Input Modes

The input mode for each of the three channel sets may be set independently. Three modes of supplying data to the ASRC input FIFOs are available:

- Polling
- Interrupt
- DMA

In all input-data transfer schemes, the ASRC fetches data from each enabled FIFO and processes the data sample-by-sample after each rising edge of the associated input sampling clock until the FIFO level reaches a kHz threshold. After the threshold is reached, the ASRC requests data. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples.

If the ASRC attempts to fetch data from an empty FIFO, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIERn_AOLIE bit is set), an interrupt is generated.

When writing data to an input FIFO, you must ensure that it is in a predefined sequence. For example, when writing to an input FIFO, the sequence should be: channel_0, channel_1, channel_2,..., channel_n, channel_0, channel_1, channel_2, etc. The number of channels per set must be an even number.

Mode 1 (Polling Mode):

Polling mode is the default mode following power-on or individual reset, and is selected by clearing the associated channel set A, B, or C data-input interrupt enable bit (ASRIER_ADIEx, where x=A, B or C). In this mode, data-input interrupts are disabled. When the FIFO level is below the threshold, the associated status bit (ASRSTR_AIDEx, where x=A, B, or C) is set. To clear the status bit, the FIFO must be written with enough data to raise the level above the threshold.

Mode 2 (Interrupt Mode):

The ASRC input FIFOs can also be serviced by interrupts. To enable interrupts, the corresponding data-input interrupt enable bits (ASRIER_ADIEx, where x=A, B, or C) should be set. An interrupt is automatically generated any time the input FIFO level is below the threshold. The interrupt is cleared when enough data is written to the FIFO to raise the level above the threshold.

Mode 3 (DMA Mode):

The ASRC input FIFOs can also be filled using DMA. In this mode, the data-input interrupt-enable bits (ASRIER_ADIEx, where x=A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

10.1.3.1.2 Data Output Modes

The output mode for each of the 3 channel sets (A, B, and C) may be set independently. Three modes of retrieving data from the ASRC output FIFOs are available:

- Polling
- Interrupt
- DMA

In all output-data transfer schemes, the ASRC places a processed sample into the associated output FIFO. After a threshold is reached, the ASRC requests that data be transferred out of the FIFO. The FIFO size for each channel set is 64 samples and the threshold is set at 32 samples.

If the ASRC attempts to place data into a FIFO that is already full, an error is generated and the ASRSTR_AOLE bit is set. If the ASRC overload interrupt is enabled (ASRIERn_AOLIE bit is set), an interrupt is generated.

Each output FIFO is organized in the same channel order in which the associated input FIFO was written.

Mode 1 (Polling Mode):

The ASRC output FIFOs can be serviced by polling. In this mode, ensure the associated output-data interrupt enable bit (ASRIER_ADOEx, where x=A, B, or C) is cleared. In this mode, all output-data interrupts are disabled. Any time the output FIFO exceeds the threshold, the associated status bit (ASRSTR_AODFx, where x = A, B, or C) is set. To clear the status bit, enough data must be read from the associated output FIFO to lower the level below the threshold.

Mode 2 (Interrupt Mode):

The ASRC output FIFOs may also be serviced using interrupts. To enable this mode, the corresponding output-data interrupt-enable bits (ASRIER_ADOEx, where x = A, B, or C) should be set. Any time the output FIFO level exceeds the threshold, an interrupt is automatically generated. The interrupt is cleared when enough data is read from the FIFO to lower the level below the threshold.

Mode 3 (DMA Mode):

The ASRC output FIFOs can also be read using DMA. In this mode, the output-data interrupt-enable bits (ASRIER_ADOEx, where x =A, B, or C) should be cleared and the DMA controller should be configured to use the ASRC as a request source.

10.2 Memory Map and Register Definition

This section includes the memory map table and register definitions.

10.2.1 Memory Map

Table 10-2 shows the ASRC memory map.

Table 10-2. Block Memory Map

1 Note that R/W registers may contain some read-only or write-only bits.
2 Master clock of 200 MHz is assumed.
3 Master clock of 200 MHz is assumed.

10.2.2 Register Descriptions

The format for the register descriptions are shown in Figure 10-3 and Table 10-3.

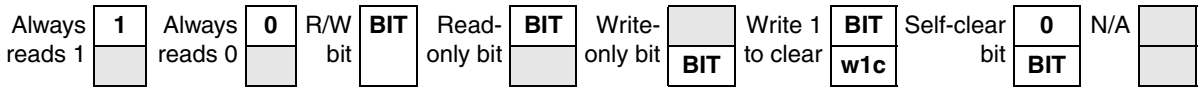

Figure 10-3. Key to Register Fields

Table 10-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero (previously designated slfclr).
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

10.2.2.1 ASRC Control Register (ASRCTR)

The control register (ASRCTR) is a 24-bit read/write register that controls the ASRC operations.

Offset 0x0 — Access: User read/write

Figure 10-4. ASRC Control Register (ASRCTR)

The bit definitions are shown in Table 10-4.

Table 10-4. ASRC Control Register (ASRCTR) Bits

Field	Description
23	Reserved.
22 ATSC	**ASRC Pair C Automatic Selection For Processing Options** When this bit is 1, pair C automatically updates its pre-processing and post-processing options (ASRCFG:PREMODC, ASRCFG:POSTMODC see page 11) based on the frequencies detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see page 25 and page 26). When this bit is 0, the user is responsible for choosing the proper processing options for pair C. This bit should be disabled when {USRC, IDRC}={1,1}.
21 ATSB	**ASRC Pair B Automatic Selection For Processing Options** When this bit is 1, pair B automatically updates its pre-processing and post-processing options (ASRCFG:PREMODB, ASRCFG:POSTMODB see page 11) based on the frequencies detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see page 25 and page 26). When this bit is 0, the user is responsible for choosing the proper processing options for pair B. This bit should be disabled when {USRB, IDRB}={1,1}.
20 ATSA	**ASRC Pair A Automatic Selection For Processing Options** When this bit is 1, pair A automatically updates its pre-processing and post-processing options (ASRCFG:PREMODA, ASRCFG:POSTMODA see page 11) based on the frequencies detected. To use this option, the two parameter registers(ASR76K and ASR56K) should be set correctly (see page 25 and page 26). When this bit is 0, the user is responsible for choosing the proper processing options for pair A. This bit should be disabled when {USRA, IDRA}={1,1}.
19	Reserved. Should be written as zero for compatibility.
18 USRC	**Use Ratio for Pair C** Use ratio as the input to ASRC. This bit is used in conjunction with the IDRC control bit.

Table 10-4. ASRC Control Register (ASRCTR) Bits

Field	Description
17 IDRC	**Use Ideal Ratio for Pair C** When USRC=0, this bit has no usage. When USRC=1 and IDRC=0, the ASRC internal measured ratio is used. When USRC=1 and IDRC=1, the ideal ratio from the interface register ASRIDRHC, ASRIDRLC is used. In this mode, it is suggested to manually set ASRCFG:POSTMODC, ASRCFG:PREMODC according to Table 10-17 on page 10-29.
16 USRB	**Use Ratio for Pair B** Use ratio as the input to ASRC. This bit is used in conjunction with IDRB control bit.
15 IDRB	**Use Ideal Ratio for Pair B** When USRB=0, this bit has no usage. When USRB=1 and IDRB=0, the ASRC internal measured ratio is used. When USRB=1 and IDRB=1, the ideal ratio from the interface register ASRIDRHB, ASRIDRLB is used. In this mode, it is suggested to manually set ASRCFG:POSTMODB, ASRCFG:PREMODB according to Table 10-17 on page 10-29.
14 USRA	**Use Ratio for Pair A** Use ratio as the input to ASRC. This bit is used in conjunction with IDRA control bit.
13 IDRA	**Use Ideal Ratio for Pair A** When USRA=0, this bit has no usage. When USRA=1 and IDRA=0, the ASRC internal measured ratio is used. When USRA=1 and IDRA=1, the ideal ratio from the interface register ASRIDRHA, ASRIDRLA is used. In this mode, it is suggested to manually set ASRCFG:POSTMODA, ASRCFG:PREMODA according to Table 10-17 on page 10-29.
12-5	Reserved. Should be written as zero for compatibility.
4 SRST	**Software Reset** This bit is a self-clear bit. Once it has been written as 1, it will generate a software reset signal inside the ASRC module. After nine cycles of the master clock, this reset process ends, and this bit is cleared automatically.
3 ASREC	**ASRC Enable C** Enable operation of conversion set C of the ASRC module. When the ASREC bit is cleared, operation of conversion set C is disabled.
2 ASREB	**ASRC Enable B** Enable operation of conversion set B of the ASRC module. When the ASREB bit is cleared, operation of conversion set B is disabled.
1 ASREA	**ASRC Enable A** Enable operation of conversion set A of the ASRC module. When the ASREA bit is cleared, operation of conversion set A is disabled.
0 ASRCEN	**ASRC Enable** Enable operation of the ASRC module.

10.2.2.2 Interrupt Enable Register (ASRIER)

ASRIER is used to enable interrupts, and it is read/write register.

Figure 10-5. Interrupt Enable Register (ASRIER)

Table 10-5. Interrupt Enable Register (ASRIER)

Field	Description
23-8	Reserved. Should be written as zero for compatibility.
7 AFPWE	**FP in Wait State Interrupt Enable** Enables the FP in wait state interrupt.
6 AOLIE	**Overload Interrupt Enable** Enables the overload interrupt.
5 ADOEC	**Data Output C Interrupt Enable** Enables the data output C interrupt.
4 ADOEB	**Data Output B Interrupt Enable** Enables the data output B interrupt.
3 ADOEA	**Data Output A Interrupt Enable** Enables the data output A interrupt.
2 ADIEC	**Data Input C Interrupt Enable** Enables the data input C interrupt.
1 ADIEB	**Data Input B Interrupt Enable** Enables the data input B interrupt.
0 ADIEA	**Data Input A Interrupt Enable** Enables the data input A Interrupt.

10.2.2.3 Channel Number Configuration Register (ASRCNCR)

The channel number configuration register (ASRCNCR) is a 24-bit read/write register that sets the number of channels used by each ASRC conversion pair.

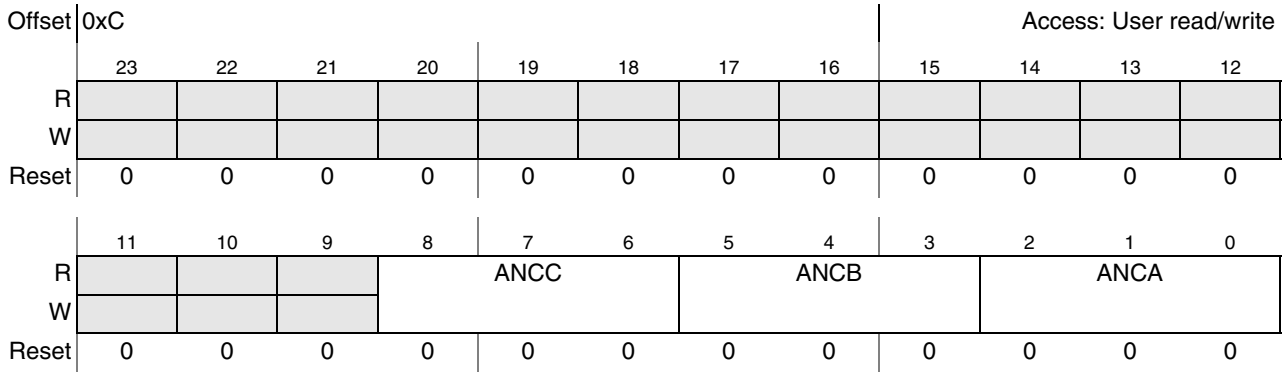

Figure 10-6. Channel Number Configuration Register (ASRCNCR)

Table 10-6 shows the ASRCNCR field descriptions.

Table 10-6. Channel Number Configuration Register (ASRCNCR)

Field	Description
23-9	Reserved. Should be written as zero for compatibility.
8-6 ANCC	**Number of C Channels** 000- 0channels in C (Pair C is disabled) 001- 2channel in C 010- 4channels in C 011- 6channels in C 100- 8channels in C 101- 10channels in C
5-3 ANCB	**Number of B Channels** 000- 0channels in B (Pair B is disabled) 001- 2channel in B 010- 4channels in B 011- 6channels in B 100- 8channels in B 101- 10channels in B
2-0 ANCA	**Number of A Channels** 000- 0channels in A (Pair A is disabled) 001- 2channel in A 010- 4channels in A 011- 6channels in A 100- 8channels in A 101- 10channels in A
Note: ANCC+ANCB+ANCA<=10.	

10.2.2.4 Filter Configuration Status Register (ASRCFG)

The configuration status register (ASRCFG) is a 24-bit read/write register that sets and/or automatically senses the ASRC operations.

Offset 0x10 — Access: User read/write

Figure 10-7. Filter Configuration Status Register (ASRCFG)

The bits definitions are shown in Table 10-7.

Table 10-7. Filter Configuration Status Register (ASRCFG)

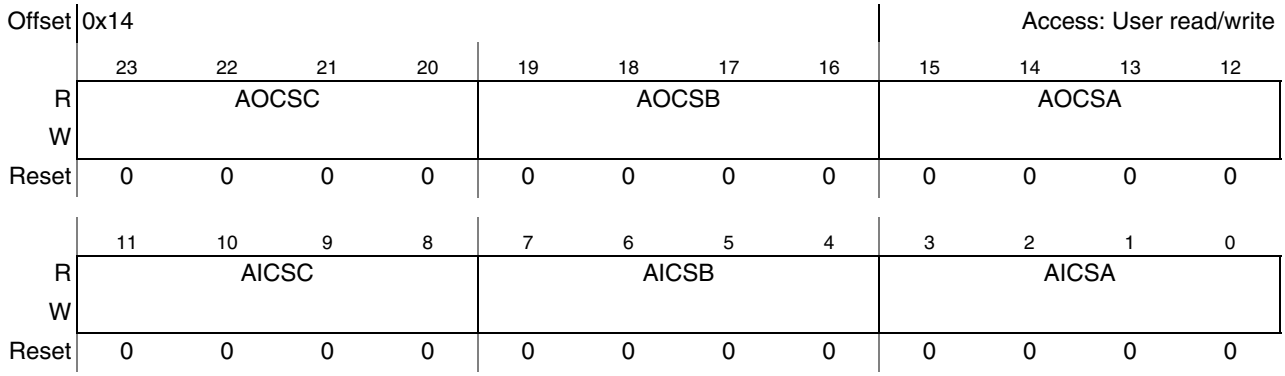
Field	Description
23 INIRQC	**Initialization for Conversion Pair C is served** When this bit is 1, it means the initialization for conversion pair C is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREC=0 or ASRCTR:ASRCEN=0).
22 INIRQB	**Initialization for Conversion Pair B is served** When this bit is 1, it means the initialization for conversion pair B is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREB=0 or ASRCTR:ASRCEN=0).
21 INIRQA	**Initialization for Conversion Pair A is served** When this bit is 1, it means the initialization for conversion pair A is served. This bit is cleared by disabling the ASRC conversion pair (ASRCTR:ASREA=0 or ASRCTR:ASRCEN=0).
20 NDPRC	**Default Parameters for RAM-stored Parameters For Conversion Pair C** 0 - Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 - Do not use default parameters for RAM-stored parameters. Use the parameters already stored in RAM.
19 NDPRB	**Default Parameters for RAM-stored Parameters For Conversion Pair B** 0 - Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 - Do not use default parameters for RAM-stored parameters. Use the parameters already stored in RAM.
18 NDPRA	**Default Parameters for RAM-stored Parameters For Conversion Pair A** 0 - Use default parameters for RAM-stored parameters. Override any parameters already in RAM. 1 - Do not use default parameters for RAM-stored parameters. Use the parameters already stored in RAM.
17-16 POSTMODC [1-0]	**Post-Processing Configuration for Conversion Pair C** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. These bits will be read/write by user if ASRCTR:ATSC=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSC=1 (see page 8). These bits set the selection of the post-processing configuration.

Table 10-7. Filter Configuration Status Register (ASRCFG)

Field	Description
15-14 PREMODC [1-0]	**Pre-Processing Configuration for Conversion Pair C** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1 11 - Select passthrough mode. In this case, POSTMODC[1-0] have no use. These bits are read/write by user if ASRCTR:ATSC=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSC=1 (see page 8). These bits set the selection of the pre-processing configuration.
13-12 POSTMODB [1-0]	**Post-Processing Configuration for Conversion Pair B** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. These bits will be read/write by user if ASRCTR:ATSB=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSB=1 (see page 8). These bits set the selection of the post-processing configuration.
11-10 PREMODB [1-0]	**Pre-Processing Configuration for Conversion Pair B** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 11 - Select passthrough mode. In this case, POSTMODB[1-0] have no use. These bits are read/write by user if ASRCTR:ATSB=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSB=1 (see page 8). These bits set the selection of the pre-processing configuration.
9-8 POSTMODA [1-0]	**Post-Processing Configuration for Conversion Pair A** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. These bits are read/write by user if ASRCTR:ATSA=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSA=1 (see page 8). These bits set the selection of the post-processing configuration.
7-6 PREMODA [1-0]	**Pre-Processing Configuration for Conversion Pair A** 00 - Select Upsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 01 - Select Direct-Connection as defined in Section 10.5.1.1, “Signal Processing Flow”. 10 - Select Downsampling-by-2 as defined in Section 10.5.1.1, “Signal Processing Flow”. 11 - Select passthrough mode. In this case, POSTMODA[1-0] have no use. These bits are read/write by user if ASRCTR:ATSA=0, and can also be automatically updated by the ASRC internal logic if ASRCTR:ATSA=1 (see page 8). These bits set the selection of the pre-processing configuration.
5-0	**Reserved. Should be written as zero for compatibility.**

10.2.2.5 ASRC Clock Source Register (ASRCSR)

The clock source register (ASRCSR) is a 24-bit read/write register that controls the sources of the input and output clocks of the ASRC.



Offset	0x14												Access: User read/write

10.2.2.6 ASRC Clock Divider Registers (ASRCDR1, ASRCDR2)

The clock divider registers (ASRCDR1, ASRCDR2) are two 24-bit read/write registers that control the division factors of the ASRC input and output clock sources.

Figure 10-10. Clock Divider Register -2 (ASRCDR2)

Table 10-9. Clock Divider Register -1 (ASRCDR1)

Field	Description
23-21 AOCDB	**Output Clock Divider B** Specify the divide ratio of the output clock divider B. The divide ratio may range from 1 to 8 (AOCDB[2:0] = 000 to 111).
20-18 AOCPB	**Output Clock Prescaler B** Specify the prescaling factor of the output prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
17-15 AOCDA	**Output Clock Divider A** Specify the divide ratio of the output clock divider A. The divide ratio may range from 1 to 8 (AOCDA[2:0] = 000 to 111).
14-12 AOCPA	**Output Clock Prescaler A** Specify the prescaling factor of the output prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.
11-9 AICDB	**Input Clock Divider B** Specify the divide ratio of the input clock divider B. The divide ratio may range from 1 to 8 (AICDB[2:0] = 000 to 111).
8-6 AICPB	**Input Clock Prescaler B** Specify the prescaling factor of the input prescaler B. The prescaling ratio may be any power of 2 from 1 to 128.
5-3 AICDA	**Input Clock Divider A** Specify the divide ratio of the input clock divider A. The divide ratio may range from 1 to 8 (AICDA[2:0] = 000 to 111).
2-0 AICPA	**Input Clock Prescaler A** Specify the prescaling factor of the input prescaler A. The prescaling ratio may be any power of 2 from 1 to 128.

Table 10-10. Clock Divider Register -2 (ASRCDR2)

Field	Description
23-12	Reserved. Should be written as zero for compatibility.
11-9 AOCDC	**Output Clock Divider C** Specify the divide ratio of the output clock divider C. The divide ratio may range from 1 to 8 (AOCDC[2:0] = 000 to 111).
8-6 AOCPC	**Output Clock Prescaler C** Specify the prescaling factor of the output prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

Table 10-10. Clock Divider Register -2 (ASRCDR2)

Field	Description
5-3 AICDC	**Input Clock Divider C** Specify the divide ratio of the input clock divider C. The divide ratio may range from 1 to 8 (AICDC[2:0] = 000 to 111).
2-0 AICPC	**Input Clock Prescaler C** Specify the prescaling factor of the input prescaler C. The prescaling ratio may be any power of 2 from 1 to 128.

10.2.2.7 ASRC Status Register (ASRSTR)

The ASRC status register (ASRSTR) is a 24-bit read-write register to report the status of the ASRC module and clear the overload interrupt request and AOLE flag bit.

Offset 0x20 — Access: User read-only

	23	22	21	20	19	18	17	16	15	14	13	12

Figure 10-11. ASRC Status Register (ASRSTR)

Reading the status register returns the current state of ASRC.

Table 10-11 gives the field descriptions for the ASRSTR.

Table 10-11. Status Register (ASRSTR)

Field	Description
23-22	Reserved. Should be written as zero for compatibility.
21 DSLCNT	**DSL Counter Input to FIFO ready** When set, this bit indicates that new DSL counter information is stored in the internal ASRC FIFO. When clear, this bit indicates that new DSL counter information is in the process of storing in the internal ASRC FIFO. When ASRIER:AFPWE=1, the rising edge of this signal triggers an interrupt request. Writing any value with this bit set clears the interrupt request triggered by the rising edge of this bit.
20 ATQOL	**Task Queue FIFO overload** When set, this bit indicates that the task queue FIFO logic is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
19 AOOLC	**Pair C Output Task Overload** When set, this bit indicates that the pair C output task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.

Table 10-11. Status Register (ASRSTR)

Field	Description
18 AOOLB	**Pair B Output Task Overload** When set, this bit indicates that the pair B output task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
17 AOOLA	**Pair A Output Task Overload** When set, this bit indicates that the pair A output task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
16 AIOLC	**Pair C Input Task Overload** When set, this bit indicates that the pair C input task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
15 AIOLB	**Pair B Input Task Overload** When set, this bit indicates that the pair B input task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
14 AIOLA	**Pair A Input Task Overload** When set, this bit indicates that the pair A input task is overloaded. This bit may be used in conjunction with the overload interrupt to determine the cause of the error condition. The bit is cleared when writing ASRCTR:AOLIE as 1.
13 AODOC	**Output Data Buffer C has overflowed** When set, this bit indicates that the output data buffer C has overflowed. When clear, this bit indicates that output data buffer C has not overflowed.
12 AODOB	**Output Data Buffer B has overflowed** When set, this bit indicates that the output data buffer B has overflowed. When clear, this bit indicates that output data buffer B has not overflowed.
11 AODOA	**Output Data Buffer A has overflowed** When set, this bit indicates that output data buffer A has overflowed. When clear, this bit indicates that output data buffer A has not overflowed.
10 AIDUC	**Input Data Buffer C has underrun** When set, this bit indicates that input data buffer C has underrun. When clear, this bit indicates that input data buffer C has not underrun.
9 AIDUB	**Input Data Buffer B has underrun** When set, this bit indicates that input data buffer B has underrun. When clear, this bit indicates that input data buffer B has not underrun.
8 AIDUA	**Input Data Buffer A has underrun** When set, this bit indicates that input data buffer A has underrun. When clear, this bit indicates that input data buffer A has not underrun.
7 FPWT	**FP is in wait states** This bit is for debug only. When set, this bit indicates that filter processor is in wait states. When clear, this bit indicates that filter processor is not in wait states. If ASRCTR:AFPWE=1 and ASRCTR:ASDBG=1, an interrupt is triggered when this bit is set.

Table 10-11. Status Register (ASRSTR)

Field	Description
6 AOLE	**Overload Error Flag** When set, this bit indicates that the task rate is too high for the ASRC to handle. The reasons for overload may be: – too high input clock frequency, – too high output clock frequency, – incorrect selection of the pre-filter, – low DSP/ASRC system clock, – too many channels, – underrun, – or any combination of the reasons above. Since the ASRC uses the same hardware resources to perform various tasks, the real reason for the overload is not straightforward, and it should be carefully analyzed by the user. If ASRCTR:AOLIE=1, an interrupt is triggered when this bit is set. Writing any value with this bit set as one into the status register clears this bit and the interrupt request proposed by this bit.
5 AODFC	**Number of data in Output Data Buffer C is greater than the threshold** When set, this bit indicates that the amount of data already existing in ASRDORC is greater than the threshold and that data can be read and the core/DSP can read data from ASRDORC. When AODFC is set, the ASRC generates the data output C interrupt request, if enabled (that is, ASRCTR:ADOEC = 1). A DMA request is always generated when the AODFC bit is set, but a DMA transfer takes place only if a DMA channel is active and configured to trigger on this event.
4 AODFB	**Number of data in Output Data Buffer B is greater than the threshold** When set, this bit indicates that the amount of data already existing in ASRDORB is greater than the threshold and that data can be read from ASRDORB. When AODFB is set, the ASRC generates the data output B interrupt request, if enabled (that is, ASRCTR:ADOEB = 1). A DMA request is always generated when the AODFB bit is set, but a DMA transfer takes place only if a DMA channel is active and configured to trigger on this event.
3 AODFA	**Number of data in Output Data Buffer A is greater than the threshold** When set, this bit indicates that the amount of data already existing in ASRDORA is greater than the threshold and that data can be read from ASRDORA. When AODFA is set, the ASRC generates the data output A interrupt request, if enabled (that is, ASRCTR:ADOEA = 1). A DMA request is always generated when the AODFA bit is set, but a DMA transfer takes place only if a DMA channel is active and configured to trigger on this event.
2 AIDEC	**Number of data in input data buffer C is less than the threshold** When set, this bit indicates that the amount of data still available in ASRDIRC is less than the threshold and that data can be written to ASRDIRC. When AIDEC is set, the ASRC generates the data input C interrupt request, if enabled (that is, ASRCTR:ADIEC = 1). A DMA request is always generated when the AIDEC bit is set, but a DMA transfer takes place only if a DMA channel is active and configured to trigger on this event.
1 AIDEB	**Number of data in input data buffer B is less than the threshold** When set, this bit indicates that the amount of data still available in ASRDIRB is less than the threshold and that data can be written to ASRDIRB. When AIDEB is set, the ASRC generates the data input B interrupt request, if enabled (that is, ASRCTR:ADIEB = 1). A DMA request is always generated when the AIDEB bit is set, but a DMA transfer takes place only if a DMA channel is active and configured to trigger on this event.
0 AIDEA	**Number of data in input data buffer A is less than the threshold** When set, this bit indicates that the amount of data still available in ASRDIRA is less than the threshold and that data can be written to ASRDIRA. When AIDEA is set, the ASRC generates the data input A interrupt request, if enabled (that is, ASRCTR:ADIEA = 1). A DMA request is always generated when the AIDEA bit is set, but a DMA transfer takes place only if a DMA channel is active and triggered by this event.

10.2.2.8 Parameter Registers (ASRPM1~ASRPM5)

Parameter registers determine performance. They are read/write and should be set before the ASRC is enabled. Recommended values are shown in Table 10-12.

Table 10-12. Parameter Registers (ASRPM1~ASRPM5)

Register	Offset	Access	Reset Value	Recommended Value
ASRCPM1	0x40	R/W	0x00_0000	0x7FFFFF
ASRCPM2	0x44	R/W	0x00_0000	0x255555
ASRCPM3	0x48	R/W	0x00_0000	0xFF7280
ASRCPM4	0x4C	R/W	0x00_0000	0xFF7280
ASRCPM5	0x50	R/W	0x00_0000	0xFF7280

10.2.2.9 ASRC Task Queue FIFO Register(ASRTFR1)

These registers define and show the parameters for the ASRC inner task queue FIFOs.

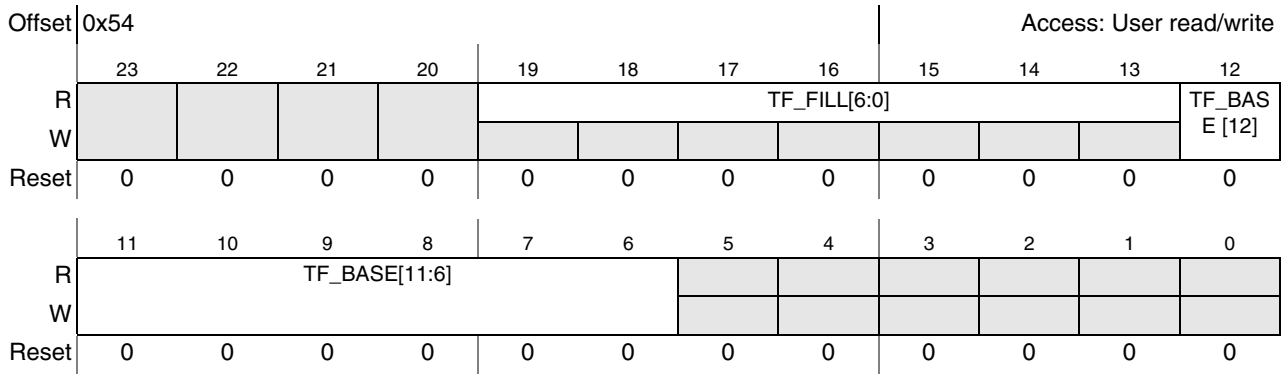

Figure 10-12. ASRC Task Queue FIFO Register 1(ASRTFR1)

Table 10-13. ASRC Task Queue FIFO Register 1 (ASRTFR1)

Field	Description
23-20	Reserved. Should be written as zero for compatibility.
19-13 TF_FILL	Display the task queue FIFO fill.
12-6 TF_BASE	Set and display the base address for task queue FIFO. Recommended value is: 0x7C.
5-0	Reserved. Should be written as zero for compatibility.

10.2.2.10 Channel Counter Register (ASRCCR)

The channel counter register (ASRCCR) is a 24-bit read/write register that sets and reflects the current specific input/output FIFO accessed through the IP bus interface for each ASRC conversion pair.

Offset 0x5C — Access: User read/write

	23	22	21	20	19	18	17	16	15	14	13	12

Figure 10-14. Channel Counter Register (ASRCCR)

The bits definitions are shown in Table 10-14.

Table 10-14. Channel Counter Register (ASRCCR)

Field	Description
23-20 ACOC	**The channel counter for Pair C's output FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair C's output FIFO's usage. The value can be any value between [0, ANCC-1]
19-16 ACOB	**The channel counter for Pair B's output FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair B's output FIFO's usage. The value can be any value between [0, ANCB-1]
15-12 ACOA	**The channel counter for Pair A's output FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair A's output FIFO's usage. The value can be any value between [0, ANCA-1]
11-8 ACIC	**The channel counter for Pair C's input FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair C's input FIFO's usage. The value can be any value between [0, ANCC-1]
7-4 ACIB	**The channel counter for Pair B's input FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair B's input FIFO's usage. The value can be any value between [0, ANCB-1]
3-0 ACIA	**The channel counter for Pair A's input FIFO** These bits stand for the current channel being accessed through the IP bus interface for Pair A's input FIFO's usage. The value can be any value between [0, ANCA-1]

10.2.2.11 Ideal Ratio Registers for Pair A, High/Low Part (ASRIDRHA, ASRIDRLA)

The ideal ratio registers (ASRIDRHA, ASRIDRLA) hold the ratio value IDRATIOA. IDRATIOA = $Fs_{inA}/Fs_{outA} = Ts_{outA}/Ts_{inA}$ is a 32-bit fixed point value with 26 fractional bits. This value is only useful when the USRA and IDRA bits in the ASRCTR register are both set to 1.

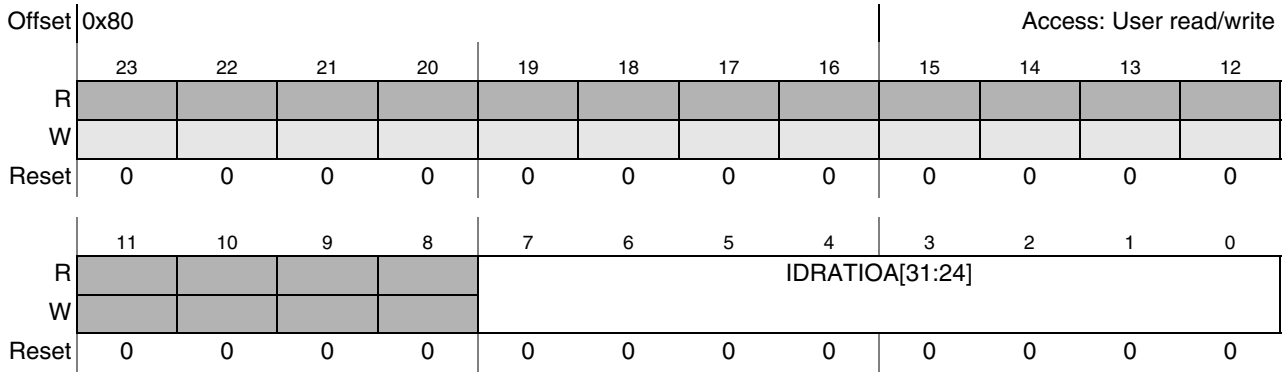

Figure 10-15. Ideal Ratio Register for Pair A, High Part (ASRIDRHA)

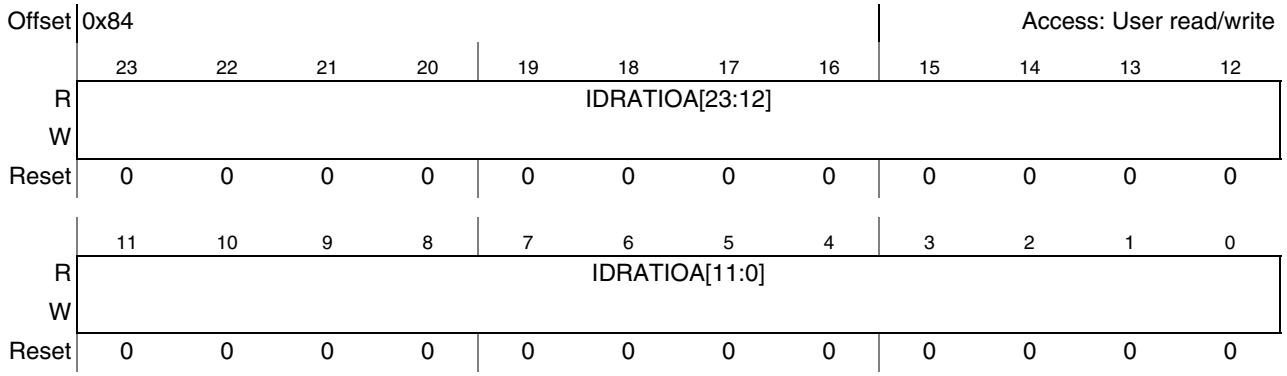

Figure 10-16. Ideal Ratio Register for Pair A, Low Part (ASRIDRLA)

10.2.2.12 Ideal Ratio Registers for Pair B, High/Low Part (ASRIDRHB, ASRIDRLB)

The ideal ratio registers (ASRIDRHB, ASRIDRLB) hold the ratio value IDRATIOB. IDRATIOB = $Fs_{inB}/Fs_{outB} = Ts_{outB}/Ts_{inB}$ is a 32-bit fixed point value with 26 fractional bits. This value is only useful when the USRB and IDRB bits in the ASRCTR register are both set to 1.

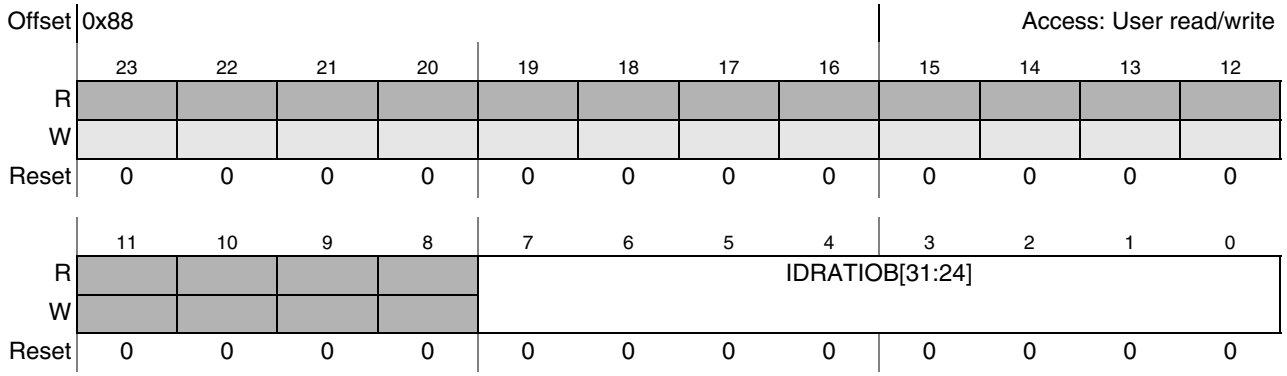

Figure 10-17. Ideal Ratio Register for Pair B, High Part (ASRIDRHB)

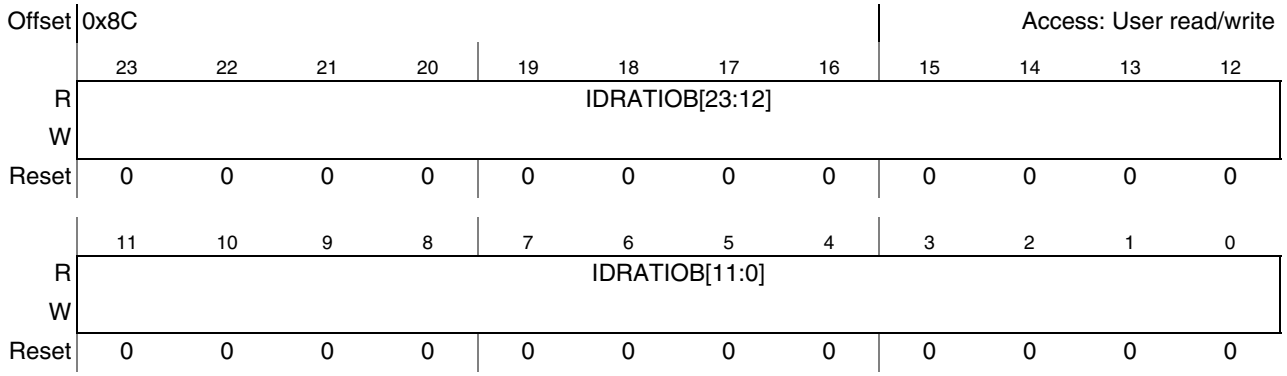

Figure 10-18. Ideal Ratio Register for Pair B, Low Part (ASRIDRLB)

10.2.2.13 Ideal Ratio Registers for Pair C, High/Low Part (ASRIDRHC, ASRIDRLC)

The ideal ratio registers (ASRIDRHC, ASRIDRLC) hold the ratio value IDRATIOC. IDRATIOC = $Fs_{inC}/Fs_{outC} = Ts_{outC}/Ts_{inC}$ is a 32-bit fixed point value with 26 fractional bits. This value is only useful when the USRC and IDRC bits in the ASRCTR register are both set to 1.".

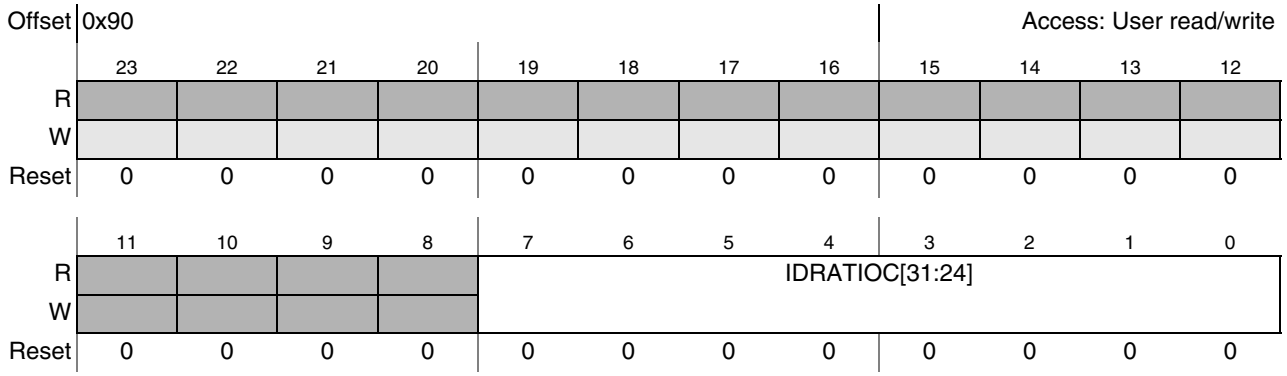

Figure 10-19. Ideal Ratio Register for Pair C, High Part (ASRIDRHC)

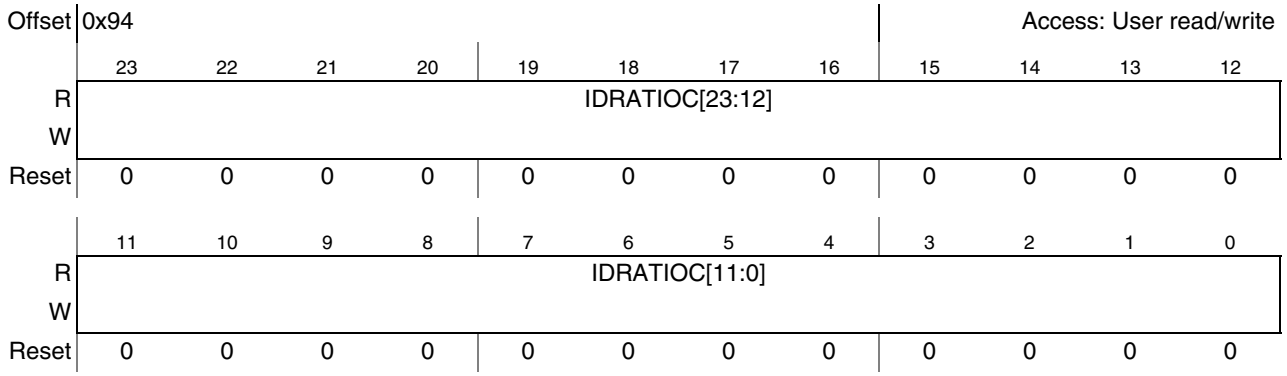

Figure 10-20. Ideal Ratio Register for Pair C, Low Part (ASRIDRLC)

10.2.2.14 ASRC 76 KHz Period Register in Terms of Master Clock (ASR76K)

The register (ASR76K) holds the period of the 76 kHz sampling clock in terms of the master clock. ASR76K = Fs_{master}/Fs_{76k}. Reset value is 0x0A47 which assumes that Fs_{master}=200 MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see page 8 and page 12).

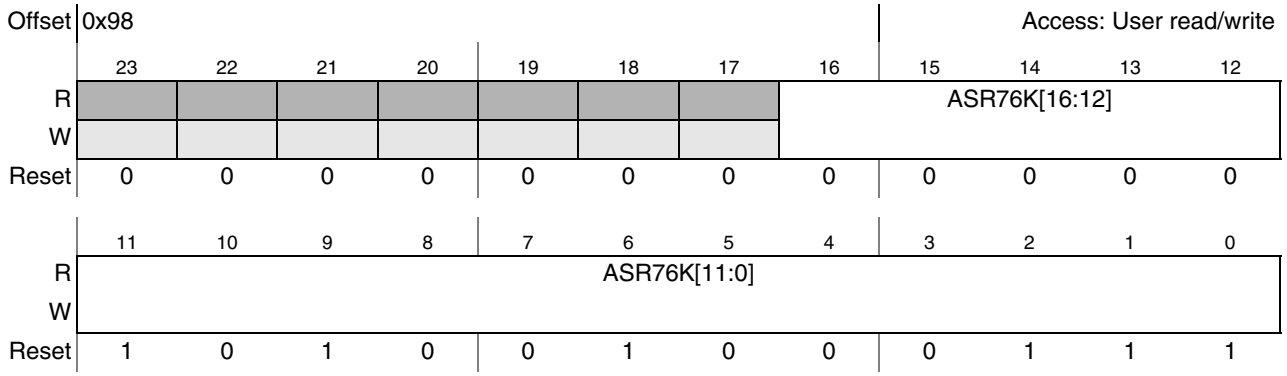

Figure 10-21. ASRC 76 kHz period register(ASR76K)

10.2.2.15 ASRC 56 kHz Period Register in Terms of Master Clock (ASR56K)

The register (ASR56K) holds the period of the 56 kHz sampling clock in terms of the master clock. ASR56K = Fs_{master}/Fs_{56k}. Reset value is 0x0DF3 which assumes that Fs_{master}=200 MHz. This register is used to help the ASRC internal logic to decide the pre-processing and the post-processing options automatically (see page 8 and page 12).

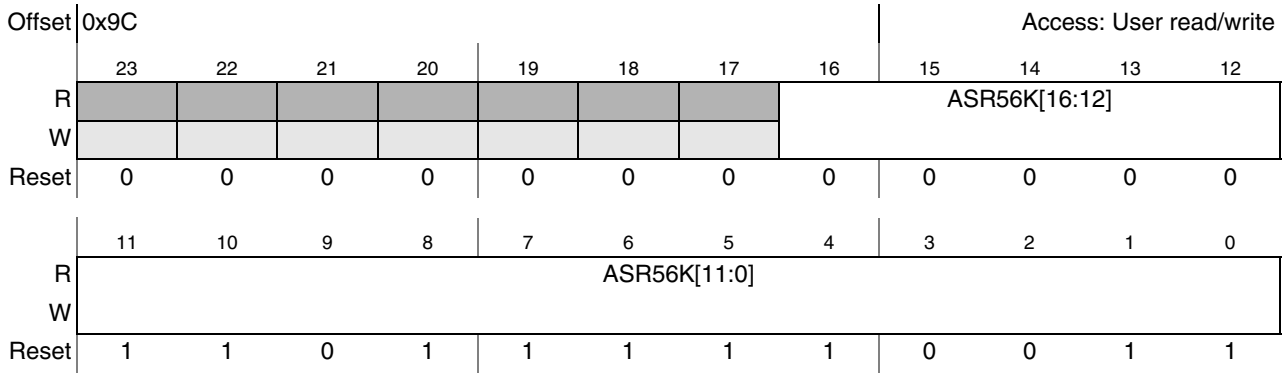

Figure 10-22. ASRC 56 kHz Period Register (ASR56K)

10.3 Interrupts

The ASRC has several interrupts events. When the interrupt request is active, the interrupt vector has the following choices:

Table 10-15. Interrupt Vector

Offset	Description
0x0	ASRC Pair A input data needed
0x2	ASRC Pair B input data needed
0x4	ASRC Pair C input data needed

Table 10-15. Interrupt Vector

Offset	Description
0x6	ASRC Pair A output data ready
0x8	ASRC Pair B output data ready
0xA	ASRC Pair C output data ready
0xC	ASRC Overload
0xE	ASRC FP Wait State

10.4 DMA requests

The ASRC has six DMA requests. They are directly connected to the lowest six status bits in the ASRSTR register.

Table 10-16. DMA Requests

Type	Description
0	ASRC Pair A input data needed
1	ASRC Pair B input data needed
2	ASRC Pair C input data needed
3	ASRC Pair A output data ready
4	ASRC Pair B output data ready
5	ASRC Pair C output data ready

10.5 Functional Description

10.5.1 Algorithm Description

10.5.1.1 Signal Processing Flow

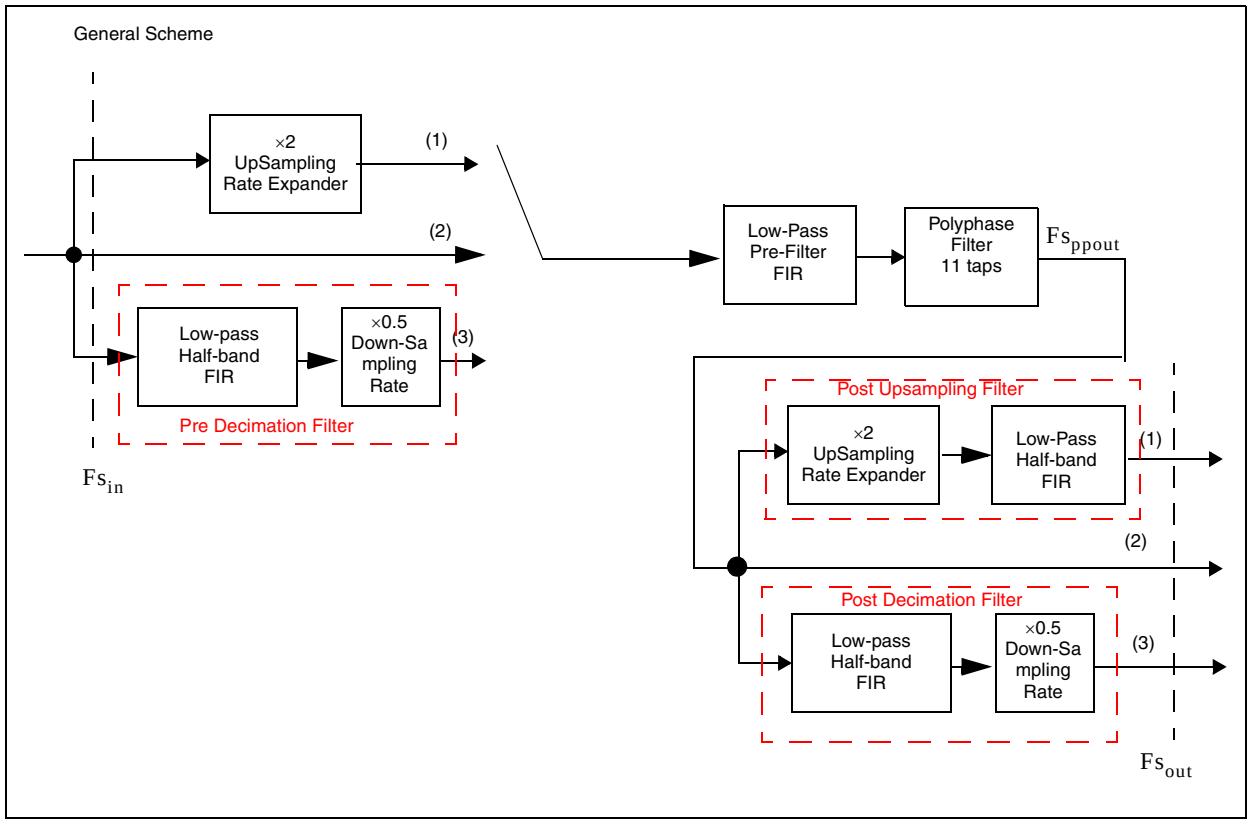

Figure 10-23. Signal Processing Configurations

Figure 10-23 shows the possible configurations of the ASRC. Each configuration consists of 2 to 4 stages:

- ×2 up-sampling rate expander (zero insertion only) (Input Branch 1), or direct connection (Input Branch 2), or low-pass pre decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Input Branch 3),
- low-pass pre-filter, the low-pass bandwidth is at most $0.25 \times Fs$, where Fs is the sampling rate of the input signal to this low-pass pre-filter,
- polyphase filter,
- ×2 post upsampling filter (consisting of a ×2 up-sampling rate expander (zero insertion only) with low-pass half-band FIR filter) (Output Branch 1), or direct connection (Output Branch 2), or low-pass post decimation filter (consisting of a low-pass half-band FIR filter with x0.5 downsampling rate decimator) (Output Branch 3).

By flowing through different processing branches, and different setup of the pre-filter, this ASRC scheme can be used to handle different requirement of rate conversion.

Configuration (a): Input Branch 1+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (b): Input Branch 1+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (c): Input Branch 1+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/2$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (d): Input Branch 2+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (e): Input Branch 2+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (f): Input Branch 2+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/4$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

Configuration (g): Input Branch 3+Output Branch 1: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}/2$.

Configuration (h): Input Branch 3+Output Branch 2: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = Fs_{out}$.

Configuration (i): Input Branch 3+Output Branch 3: The signal bandwidth observed before the polyphase filter is at most $BW_{in} = Fs_{in}/8$.The signal sampling rate of the polyphase filter output is $Fs_{ppout} = 2Fs_{out}$.

The suggested branches of the pre-processing and post-processing operations with respect to the standard sampling rates are shown below in Table 10-17

Table 10-17. : Pre-Processing, Post-Processing Options

{Pre_Proc, Post_Proc}	Fsout (kHz)								
	8	32	44.1	48	64	88.2	96	128	192
Comments: In the {Pre_Proc, Post_Proc} pair, the meaning of the values are: Pre_Proc: • 0 --- Pre-processing Branch 1 as shown in Figure 10-23 • 1 --- Pre-processing Branch 2 as shown in Figure 10-23 • 2 --- Pre-processing Branch 3 as shown in Figure 10-23, decimation-by-2 Post_Proc: • 0 --- Post-processing Branch 1 as shown in Figure 10-23 • 1 --- Post-processing Branch 2 as shown in Figure 10-23 • 2 --- Post-processing Branch 3 as shown in Figure 10-23

Comments:
In the {Pre_Proc, Post_Proc} pair, the meaning of the values are:
Pre_Proc:

- 0 --- Pre-processing Branch 1 as shown in Figure 10-23
- 1 --- Pre-processing Branch 2 as shown in Figure 10-23
- 2 --- Pre-processing Branch 3 as shown in Figure 10-23, decimation-by-2

Post_Proc:

- 0 --- Post-processing Branch 1 as shown in Figure 10-23
- 1 --- Post-processing Branch 2 as shown in Figure 10-23
- 2 --- Post-processing Branch 3 as shown in Figure 10-23

10.5.1.2 Operation of the Filter

10.5.1.2.1 Support of Physical Clocks

This design supports only physical sampling clocks. The clocks can be the clocks from the SPDIF, ESAI, SSI, MLB or PLL.

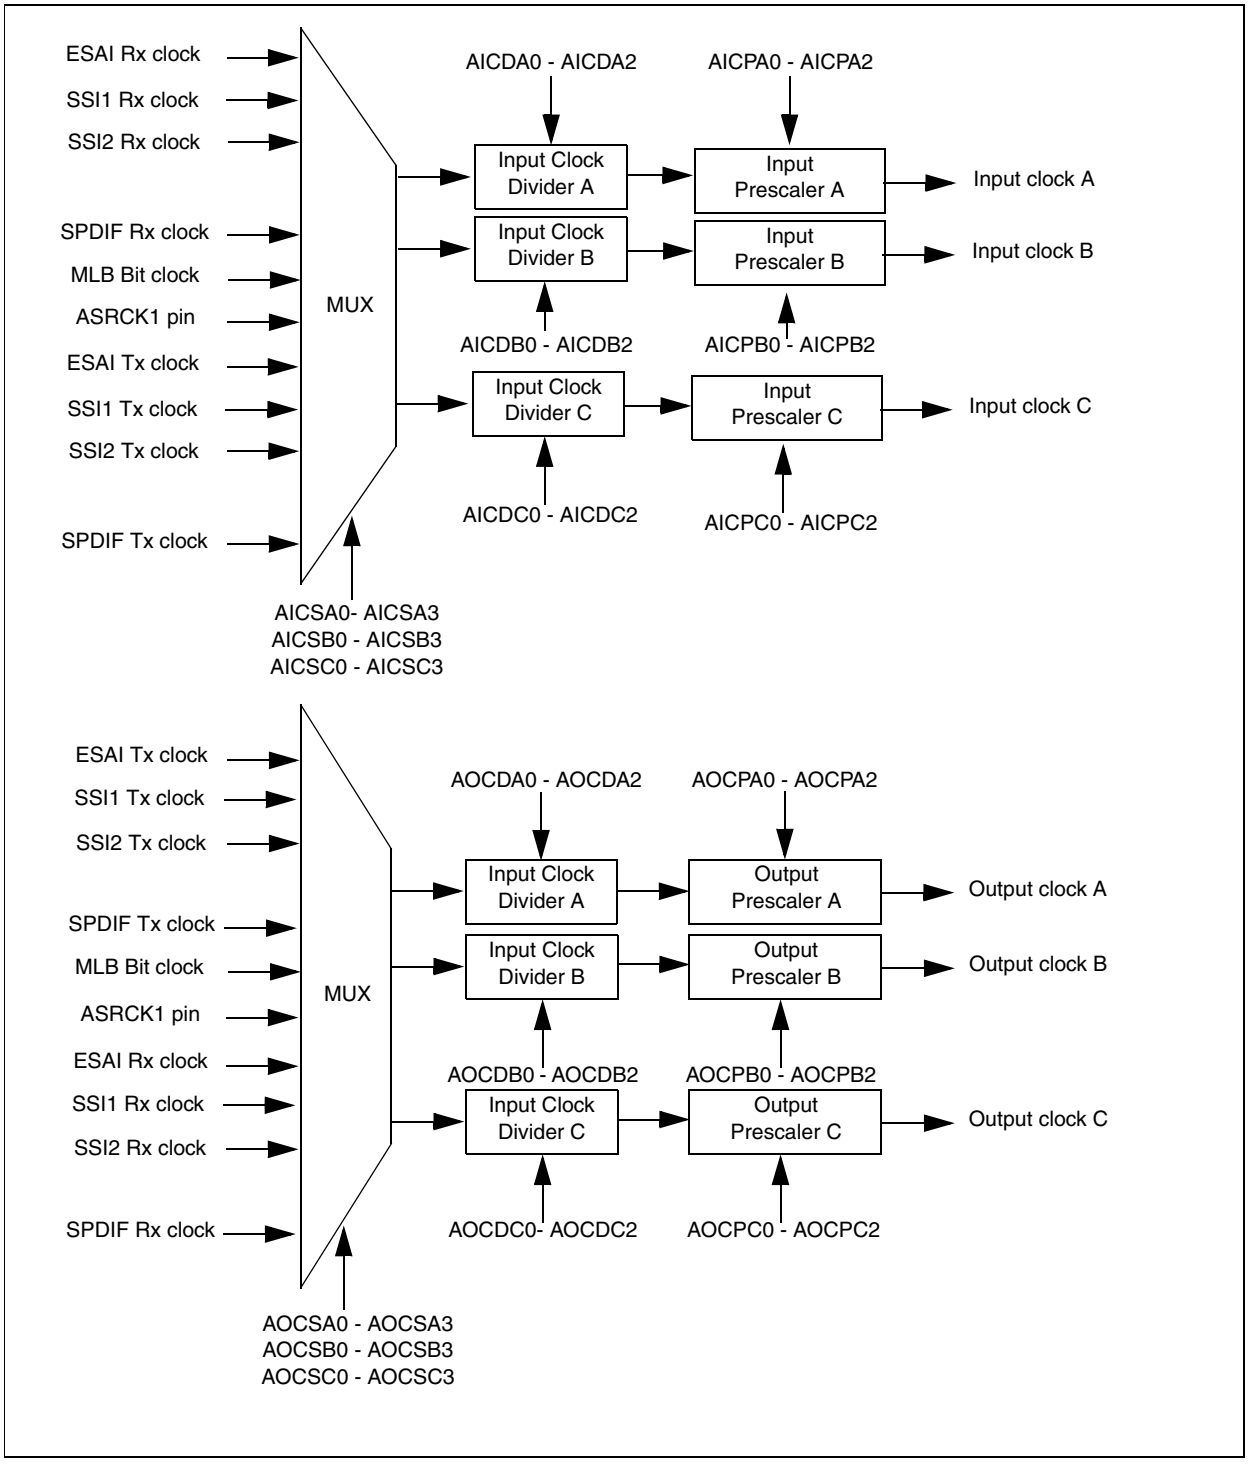

Figure 10-24. Clock Source Selector and Divider

Software can set the Clock Source Register (ASRCSR) and the Clock Divider Register to select the desired clock source and divide it to the needed sample rate clock for use by the ASRC. The clocks have the

following restriction. If the prescaler is set to 1, the clock divider can only be set to 1 and the clock source must have a 50% duty cycle.

Chapter 11
Advanced Technology Attachment (ATA)

11.1 Overview

The ATA block is an AT attachment host interface, which is compatible with the ATA-6 standard. Its main use is to interface with IDE hard disc drives and ATAPI optical disc drives. It interfaces with the ATA device over a number of ATA signals.

See Figure 11-1 for the block diagram of the ATA interface.

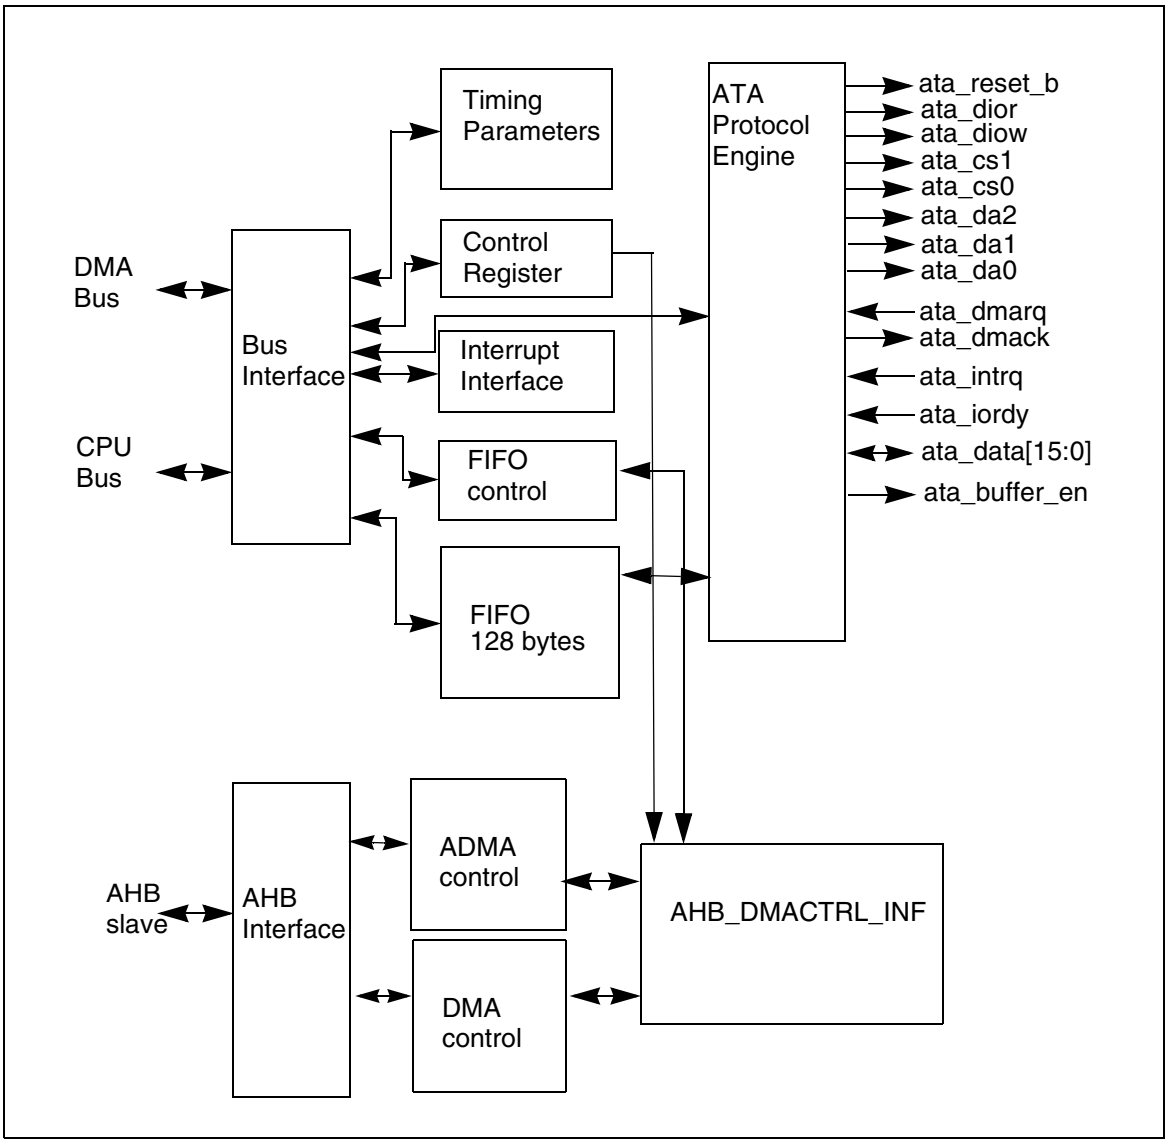

Figure 11-1. ATA Interface Block Diagram

In Figure 11-1, the CPU and DMA buses communicate with the host processor and host DMA unit, respectively. The AHB bus enables direct transfers to and from external memory. All internal registers are visible from both the CPU and DMA buses, allowing smart DMA access to program the interface.

Two access modes are possible over the ATA bus: PIO mode and DMA mode. There are also two types of DMA mode: DMA slave mode (controlled by the host DMA) and DMA master mode (controlled by the internal DMA master). See Section 11.1.2, “Modes of Operation,” for more information about these access modes.

11.1.1 Features

The ATA interface includes the following features:

- Programmable timing on the ATA bus. Works with a wide range of bus frequencies.
- Compatible with ATA-6 specification
  - Supports PIO modes 0–4
  - Supports multiword DMA (MDMA) modes 0, 1, and 2
  - Supports ultra DMA (UDMA) modes 0–4 with a bus clock of at least 50 MHz
  - Supports ultra DMA (UDMA) mode 5 with a bus clock of at least 80 MHz
- 128-byte FIFO included within the interface
- FIFO receive, transmit, and end-of-transmission alarms to DMA unit
- Zero-wait cycles transfer between DMA bus and FIFO (enables fast FIFO reads/writes)
- Supports AMBA 2.0 specification
- Supports 32-bit system memory addressing
- Supports DMA reads/writes by IPS bus (DMA slave mode)
- Supports single DMA reads and writes by the AHB bus (DMA master mode)
- Supports scatter-gather (ADMA) DMA reads and writes by the AHB bus (DMA master mode)
- Supports 1-, 2-, 4-, 8-, 16-, and 32-words burst length set by software

11.1.2 Modes of Operation

The interface offers two alternative modes of operation, PIO mode and DMA mode (which includes DMA slave and DMA master modes).

11.1.2.1 PIO Mode

An access to the ATA bus in PIO mode occurs whenever an ATA PIO register is read or written to by the host CPU or the host (smart) DMA unit. During a PIO transfer, the incoming IP bus cycle is translated to an ATA PIO bus cycle by the ATA protocol engine. No buffering of data occurs, so the host CPU or host DMA cycle is stalled until the ATA bus read data is available on read, or is stalled until the IP bus data can be put on the ATA bus during a write.

PIO accesses can be made at any time, even during a running ATA DMA transfer. In this case, the DMA transfer is paused, the PIO cycle is completed, and the DMA transfer is resumed.

11.1.2.2 DMA Mode

In DMA mode, data is transferred between the ATA bus and the FIFO. Two different DMA protocols are supported on the ATA bus: ultra DMA (UDMA) mode and multiword DMA (MDMA) mode. These are described in more detail in the sections indicated below.

In DMA mode transfers, data is transferred between the ATA bus and the FIFO. Either the host smart DMA unit or the internal DMA master is responsible to write/read data to/from the FIFO to keep the transfer

going. The case where the smart DMA unit is responsible is designated as DMA slave mode; while the case where the internal DMA master is responsible is designated as DMA master mode.

In DMA slave mode, the fifo_rcv_alarm and fifo_tx_alarm signals are sent to the host DMA unit to avoid FIFO overflow and underflow, respectively. An additional alarm signal (fifo_txfer_end_alarm) signals the end of the transfer to the smart DMA, which then completes the transfer and informs the CPU. Further details on these alarm signals are given in Section 11.4.3.6, "FIFO Alarm Register (FIFO_ALARM)."

In DMA master mode, prior to transfer, the DMA master must be programmed with the burst length, DMA system start base address or ADMA descriptor table start address (if a descriptor table has been prepared), and DMA mode. DMA transfer to the AHB bus is initiated when the DMA master receives the sys_dma_req signal. Further details on DMA master mode operation are given in Section 11.5.6, "Using DMA Master Mode to Receive Data From the ATA Bus," and Section 11.5.7, "Using DMA Master Mode To Transmit Data to the ATA bus."

The typical packet size is 32 bytes (8 32-bit words), but other packet sizes can also be handled.

Further details on DMA mode may be found in the following sections:

- Section 11.5.4, "Receiving Data from ATA Bus in DMA Slave Mode"
- Section 11.5.5, "Transmitting Data to ATA Bus in DMA Slave Mode"
- Section 11.5.6, "Using DMA Master Mode to Receive Data From the ATA Bus"
- Section 11.5.7, "Using DMA Master Mode To Transmit Data to the ATA bus"

11.2 External Signal Description

Table 11-1 lists the signals between this module and peripherals within the chip.

Table 11-1. Signal Properties

Name	Function	Reset State	Type
ata_reset_b	ATA bus reset signal. Active low. If active, The ATA device is reset[1]	0	out
ata_dior	ATA bus read strobe	1	out
ata_diow	ATA bus write strobe	1	out
ata_cs1	ATA bus chip select 1	1	out
ata_cs0	ATA bus chip select 0	1	out
ata_da2	ATA bus address line 2	0	out
ata_da1	ATA bus address line 1	0	out
ata_da0	ATA bus address line 0	0	out
ata_dmarq	ATA bus DMA request	—	in
ata_dmack	ATA bus DMA acknowledge	1	out
ata_intrq	ATA bus interrupt request	—	in
ata_iordy	ATA bus iordy	—	out
ata_data[15:0]	ATA data bus (little-endian)	Hi-z	tristate in-out

[1]This signal is a standard ATA bus signal. It conforms with the ATA specification.

11.2.1 Signal Descriptions

For a detailed description of the ATA bus signals, see the ATA-6 specification.

11.2.1.1 ata_reset_b (out)

When negated, the ATA reset signal indicates the ATA bus is in reset state. The ATA bus is in reset whenever the appropriate bit in the control register is cleared. After system reset, the ATA bus is reset.

11.2.1.2 ata_dior (out)

During PIO and MDMA transfers, the DIOR ATA signal functions as a read strobe. During UDMA data in bursts, it functions as HDMARDY. During UDMA data out burst mode, it functions as host strobe.

11.2.1.3 ata_diow (out)

During PIO and MDMA transfers, the DIOW ATA signal functions as a write strobe. During UDMA burst mode, it is used by the host terminate running UDMA transfers.

11.2.1.4 ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0 (out)

The address group of the ATA bus consists of the chip selects ata_cs0 and ata_cs1, and the address lines ata_da2, ata_da1, and ata_da0. All five lines follow the same timing.

11.2.1.5 ata_dmarq (in)

The ATA bus device DMA request is pulled high by the device if it wants to transfer data using MDMA or UDMA mode.

11.2.1.6 ata_dmack (out)

The ATA bus host DMA acknowledge is pulled low by the host when it grants the DMA request.

11.2.1.7 ata_intrq (in)

The ATA bus interrupt request is pulled high by the device whenever it wants to interrupt the host CPU.

11.2.1.8 ata_iordy (in)

The ATA bus IORDY line has three functions:

- IORDY—Active low, wait during PIO cycles
- DDMARDY—Active low, device ready during UDMA out-transfers
- DSTROBE—Device strobe during UDMA in-transfers

11.2.1.9 ata_data[15:0] (in/out—tristate)

The ATA data bus signal carries data to/from the ATA device.

11.2.1.10 ata_buffer_en

When the buffer direction control signal is asserted, data is driven outward to the device; when negated, data is driven inward to the host.

11.2.2 ATA Bus Timing

This section describes the ATA bus timing and explains how to ensure that the ATA interface meets timing requirements. Timing diagrams and timing relation equations are provided.

11.2.2.1 Timing Parameters

Table 11-6 shows the ATA timing parameters and their determining factors. Determining factors include the system design, the bus buffer used, the cable delay and the cable skew.

Table 11-2. Timing Parameters

Name	Meaning	Controlled by
T	Bus clock period	clock generator
ti_ds	Set-up time ata_data to ata_iordy edge (UDMA-in only)	top level design
ti_dh	hold time ata_iordy edge to ata_data (UDMA-in only)	top level design
tco	propagation delay bus clock L-to-H to ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data, ata_buffer_en	top level design
tsu	set-up time ata_data to bus clock L-to-H	top level design
tsui	set-up time ata_iordy to bus clock H-to-L	top level design
thi	hold time ata_iordy to bus clock H to L	top level design
tskew1	Max difference in propagation delay bus clock L-to-H to any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	top level design
tskew2	Max difference in buffer propagation delay for any of following signals ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_dior, ata_diow, ata_dmack, ata_data (write), ata_buffer_en	transceiver
tskew3	Max difference in buffer propagation delay for any of following signals ata_iordy, ata_data (read)	transceiver
tbuf	Max buffer propagation delay	transceiver
tcable1	cable propagation delay for ata_data	cable
tcable2	cable propagation delay for control signals ata_dior, ata_diow, ata_iordy, ata_dmack	cable
tskew4	Max difference in cable propagation delay between ata_iordy and ata_data (read)	cable
tskew5	Max difference in cable propagation delay between (ata_dior, ata_diow, ata_dmack) and ata_cs0, ata_cs1, ata_da2, ata_da1, ata_da0, ata_data (write)	cable
tskew6	Max difference in cable propagation delay without accounting for ground bounce	cable

11.2.2.2 PIO Mode Timing

11.2.2.2.1 PIO Read Mode Timing

A timing diagram for PIO read mode is given in Figure 11-3.

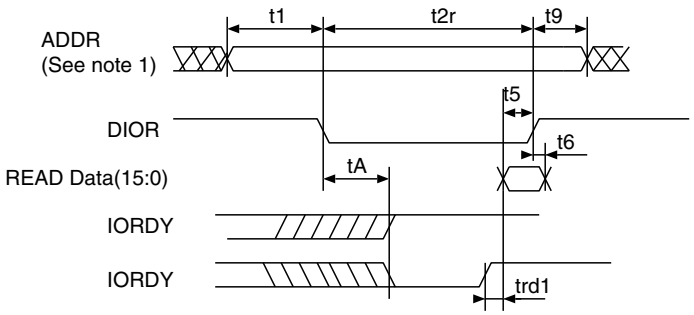

Figure 11-3. PIO Read Mode Timing

To meet timing requirements, a number of timing parameters must be controlled. Table 11-4 shows relations between different timing parameters, and identifies parameters in the ATA timing registers which may be programmed by the user to satisfy timing constraints (see Section 11.4.3.2, “Timing Registers”).

In Table 11-4 (and Table 11-6 below), the first column lists parameters from the ATA specification; the second column refers to timing parameters shown in Figure 11-3; the third column shows the relation between these timing parameters and programmable values; and the fourth column identifies the registers that may be programmed to meet the timing relations.

Table 11-4. Timing Parameter Relations for PIO Read

ATA Parameter	PIO Read Mode Timing Parameter[1]	Relation	Programmable Register
t1	t1	t1(min) = time_1 * T - (tskew1 + tskew2 + tskew5)	time_1
t2 (read)	t2r	t2(min) = time_2r * T - (tskew1 + tskew2 + tskew5)	time_2r
t9	t9	t9(min) = time_9 * T - (tskew1 + tskew2 + tskew6)	time_9
t5	t5	t5(min) = tco + tsu + tbuf + tbuf+ tcable1 + tcable2	time_2 (affects tsu and tco)
tA	tA	tA(min) = (1.5 + time_ax) * T - (tco + tsui + tcable2 + tcable2 + 2*tbuf)	time_ax
trd	trd1	trd1(max) = (-trd)+ (tskew3 + tskew4) trd1(min) = (time_pio_rdx - 0.5)*T - (tsu + thi) (time_pio_rdx - 0.5) * T > tsu + thi + tskew3 + tskew4	time_pio_rdx
t0	—	t0(min) = (time_1 + time_2r+ time_9) * T	time_1, time_2r, time_9

[1] See Figure 11-3.

11.2.2.2.2 PIO Write Mode Timing

A timing diagram for PIO write mode is given in Figure 11-5.

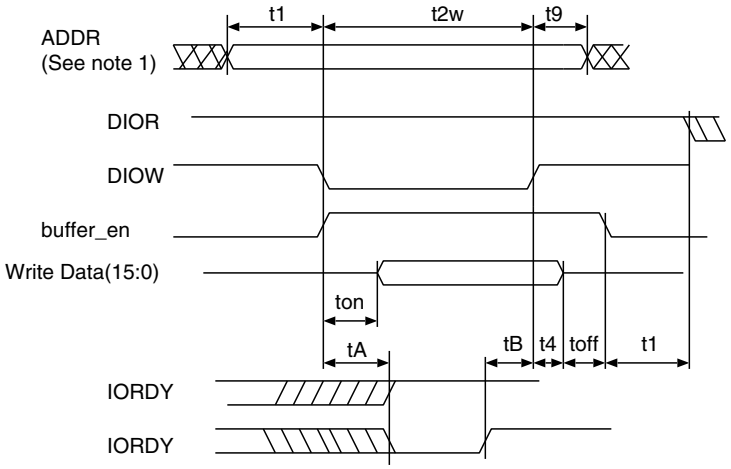

Figure 11-5. PIO Write Mode Timing

Table 11-6 shows relations between timing parameters, and identifies parameters in the ATA timing registers which may be programmed by the user to meet timing constraints (see Section 11.4.3.2, "Timing Registers").

Table 11-6. Timing Parameters Relations for PIO Write

ATA Parameter	PIO Write Mode Timing Parameter[1]	Relation	Programmable Value
t1	t1	t1(min) = time_1 * T - (tskew1 + tskew2 + tskew5)	time_1
t2 (write)	t2w	t2(min) = time_2w * T - (tskew1 + tskew2 + tskew5)	time_2w
t9	t9	t9(min) = time_9 * T - (tskew1 + tskew2 + tskew6)	time_9
t3	—	t3(min) = (time_2w - time_on)* T - (tskew1 + tskew2 +tskew5)	if not met, increase time_2w
t4	t4	t4(min) = time_4 * T - tskew1	time_4
tA	tA	tA = (1.5 + time_ax) * T - (tco + tsui + tcable2 + tcable2 + 2*tbuf)	time_ax
t0	—	t0(min) = (time_1 + time_2 + time_9) * T	time_1, time_2r, time_9
—	—	Avoid bus contention when switching buffer on by making ton long enough	—
—	—	Avoid bus contention when switching buffer off by making toff long enough	—

[1] See Figure 11-5.

11.2.2.3 Timing in Multiword DMA (MDMA) Mode

Figure 11-7 and Figure 11-8 show read and write timings respectively for MDMA mode.

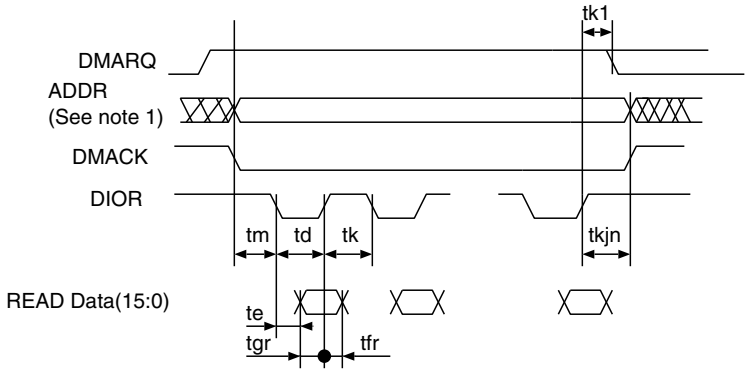

Figure 11-7. MDMA Read Timing

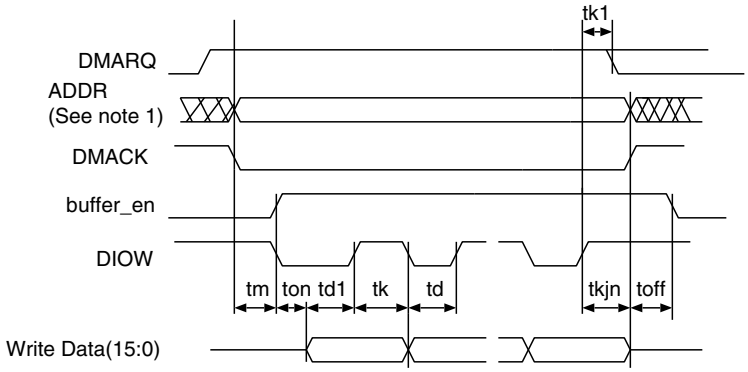

Figure 11-8. MDMA Write Timing

To meet timing requirements for MDMA mode, a number of timing parameters must be controlled. Table 11-9 shows the relations between different timing parameters, and identifies parameters in the ATA timing registers which may be programmed by the user to satisfy timing constraints (see Section 11.4.3.2, "Timing Registers").

In Table 11-9, the first column lists parameters from the ATA specification; the second column refers to timing parameters shown in Figure 11-3; the third column shows the relation between these timing parameters and programmable values; and the fourth column identifies the registers which may be programmed to meet timing constraints.

Table 11-9. Timing Parameter Relations for MDMA Read and Write

ATA Parameter	MDMA Read TIming[1] and MDMA Write TIming[2]	Relation	Programmable Value
tm, ti	tm	tm(min) = ti(min) = time_m * T - (tskew1 + tskew2 + tskew5)	time_m
td	td, td1	td1(min) = td(min) = time_d * T - (tskew1 + tskew2 + tskew6)	time_d
tk	tk[3]	tk(min) = time_k * T - (tskew1 + tskew2 + tskew6)	time_k
t0	—	t0(min) = (time_d + time_k) * T	time_d, time_k
tg (read)	tgr	tgr(min-read) = tco + tsu + tbuf + tbuf + tcable1 + tcable2 tgr(min-drive) = td - te(drive)	time_d
tf (read)	tfr	tfr(min) = 5 ns	(met by design)
tg(write)	—	tg(min-write) = time_d * T -(tskew1 + tskew2 + tskew5)	time_d

Table 11-9. Timing Parameter Relations for MDMA Read and Write (Continued)

ATA Parameter	MDMA Read TIming[1] and MDMA Write TIming[2]	Relation	Programmable Value
tf(write)	—	tf(min-write) = time_k * T - (tskew1 + tskew2 + tskew6)	time_k
tL	—	tL(max) = (time_d + time_k-2)*T - (tsu + tco + 2*tbuf + 2*tcable2)	time_d, time_k[4]
tn, tj	tkjn	tn= tj= tkjn = time_jn * T - (tskew1 + tskew2 + tskew6)	time_jn
—	ton toff	ton = time_on * T - tskew1 toff = time_off * T - tskew1	—

1 See Figure 11-7.

2 See Figure 11-8.

3 tk1 in the MDMA figures (Figure 11-7 and Figure 11-8) equals (tk -2*T)

4 tk1 in the MDMA figures equals (tk -2*T)

11.2.2.4 Timing for Ultra DMA (UDMA) Data In-Transfers

Figure 11-10 shows timing for the start of a UDMA data in-transfer.

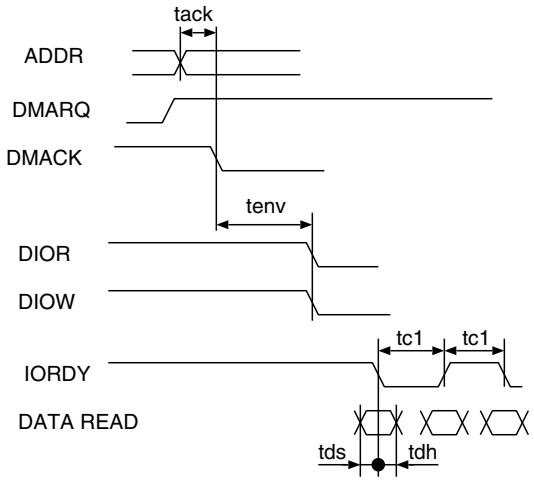

Figure 11-10. Timing for Start of UDMA Data In-transfer

Figure 11-11 shows timing for host termination of a UDMA data in-transfer.

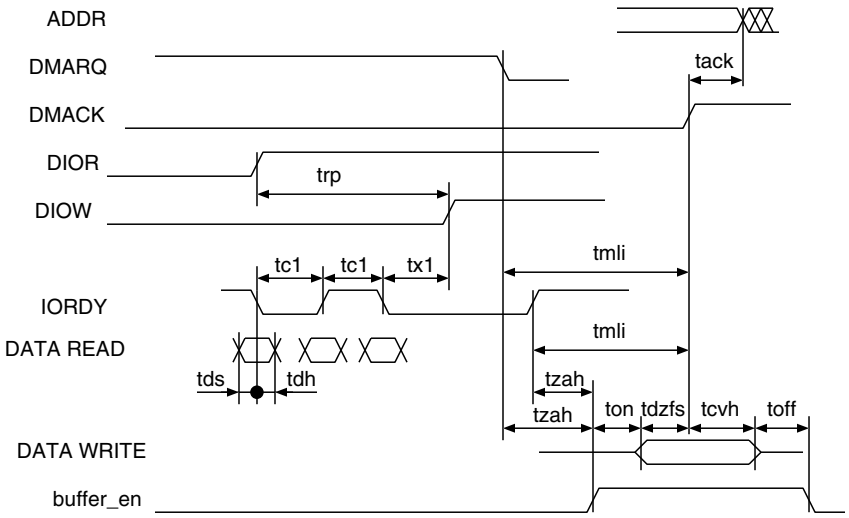

Figure 11-11. Timing for Host Termination of UDMA Transfer

Figure 11-12 shows timing for device termination of a UDMA data in-transfer.

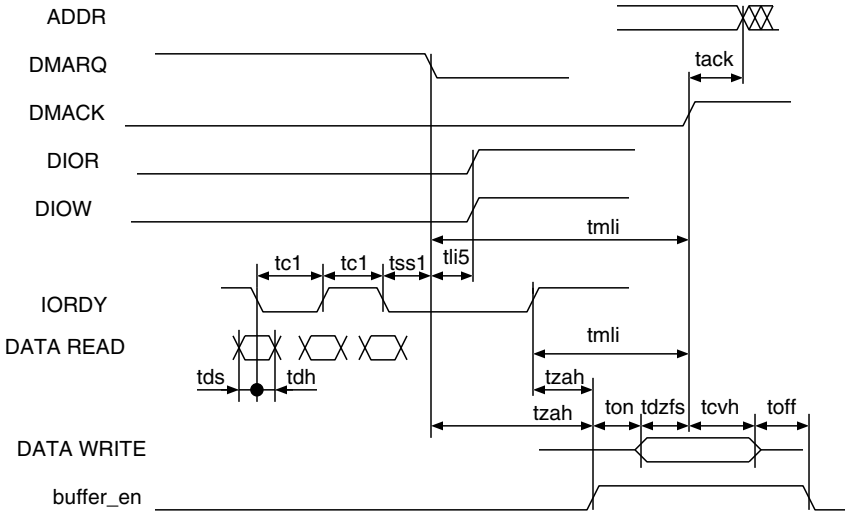

Figure 11-12. Timing for Device Termination of a UDMA Transfer

Timing parameters for UDMA data in-bursts are listed in Table 11-13. The UDMA in-burst timing parameters listed in the second column refer to Figures 11-10 through 11-12.

Table 11-13. Timing Parameter Relations for UDMA Data In-Bursts

ATA Parameter	UDMA In-burst Timing Parameter	Relation	Programmable Value
tack	tack	tack(min) = (time_ack * T) - (tskew1 + tskew2)	time_ack
tenv	tenv	tenv(min) = (time_env * T) - (tskew1 + tskew2) tenv(max) = (time_env * T) + (tskew1 + tskew2)	time_env
trp	trp	trp(min) = time_rp * T - (tskew1 + tskew2 + tskew6)	time_rp
—	tx1[1]	(time_rp * T) - (tco + tsu + 3T + 2 *tbuf + 2*tcable2) > trfs (drive)	time_rp

Table 11-13. Timing Parameter Relations for UDMA Data In-Bursts (Continued)

ATA Parameter	UDMA In-burst Timing Parameter	Relation	Programmable Value
tmli	tmli1	tmli1(min) = (time_mlix + 0.4) * T	time_mlix
tzah	tzah	tzah(min) = (time_zah + 0.4) * T	time_zah
tdzfs	tdzfs	tdzfs = (time_dzfs * T) - (tskew1 + tskew2)	time_dzfs
tcvh	tcvh	tcvh = (time_cvh *T) - (tskew1 + tskew2)	time_cvh
—	ton toff[2]	ton = time_on * T - tskew1 toff = time_off * T - tskew1	—

1 There is a special timing requirement in the ATA host that requires the internal DIOW to go only high three clocks after the last active edge on the DSTROBE signal. The equation given on this line tries to capture this constraint.

2 Make ton and toff big enough to avoid bus contention.

11.2.2.5 Timing for UDMA Data Out-Transfers

Figure 11-14 shows the timing for the start of a UDMA data out-transfer.

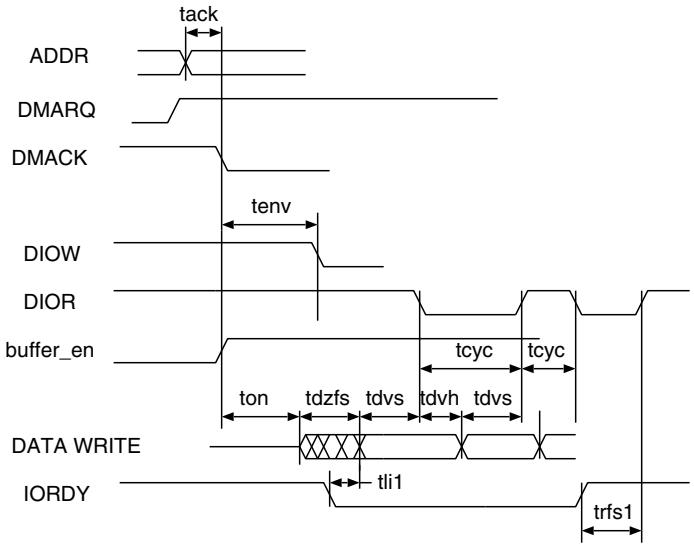

Figure 11-14. Timing of Start of UDMA Data Out-Transfer

Figure 11-15 shows the timing for host termination of a UDMA data out-transfer.

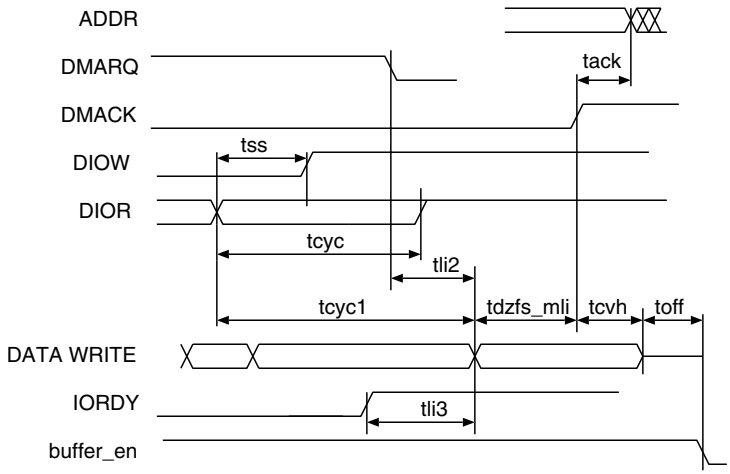

Figure 11-15. Timing of Host Termination of UDMA Data Out-Transfer

Figure 11-16 shows timing for device termination of a UDMA data out-transfer.

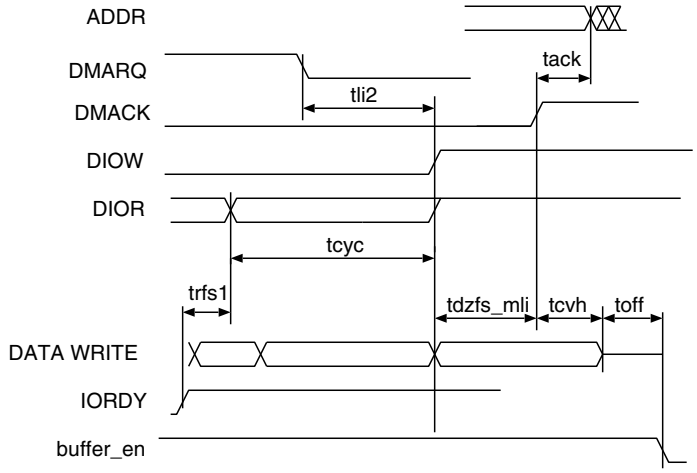

Figure 11-16. Timing for Device Termination of UDMA Data Out-Transfer

Timing parameters and relations for UDMA data out-bursts are listed in Table 11-17. The UDMA out-burst timing parameters listed in the second column refer to Figures 11-14 through 11-16.

Table 11-17. Timing Parameters and Relations for UDMA Out-Burst

ATA Parameter	UDMA Out-burst Timing Parameter	Timing Relation	Programmable Value
tack	tack	tack(min) = (time_ack * T) - (tskew1 + tskew2)	time_ack
tenv	tenv	tenv(min) = (time_env * T) - (tskew1 + tskew2) tenv(max) = (time_env * T) + (tskew1 + tskew2)	time_env
tdvs	tdvs	tdvs = (time_dvs * T) - (tskew1 + tskew2)	time_dvs
tdvh	tdvh	tdvs = (time_dvh * T) - (tskew1 + tskew2)	time_dvh
tcyc	tcyc	tcyc = time_cyc * T - (tskew1 + tskew2)	time_cyc
t2cyc		t2cyc = time_cyc * 2 * T	time_cyc

Table 11-17. Timing Parameters and Relations for UDMA Out-Burst (Continued)

ATA Parameter	UDMA Out-burst Timing Parameter	Timing Relation	Programmable Value
trfs1	trfs	trfs = 1.6 * T + tsui + tco + tbuf + tbuf	—
—	tdzfs	tdzfs = time_dzfs * T - (tskew1)	time_dzfs
tss	tss	tss = time_ss * T - (tskew1 + tskew2)	time_ss
tmli	tdzfs_mli	tdzfs_mli =max(time_dzfs, time_mli) * T - (tskew1 + tskew2)	—
tli	tli1	tli1 > 0	—
tli	tli2	tli2 > 0	—
tli	tli3	tli3 > 0	—
tcvh	tcvh	tcvh = (time_cvh *T) - (tskew1 + tskew2)	time_cvh
—	ton toff	ton = time_on * T - tskew1 toff = time_off * T - tskew1	—

11.3 Advanced DMA in DMA Master Mode

Two optional DMA algorithms are supported for the Host Controller in DMA master mode:

- Single DMA (SDMA): After an SDMA transfer command is completed, a DMA interrupt is generated and the new system address is programmed by the Host Driver. The 32-bit System Address Register is used as a data pointer and limited to 32-bit system memory addressing.
- Advanced DMA (ADMA): ADMA defines a programmable descriptor table in the system memory. The Host Driver can calculate the system address at the sector boundary and programs the descriptor table before executing ADMA. This reduces the frequency of interrupts to the host system, and higher speed DMA transfer is realized because a Host CPU intervention is not needed during a long DMA-based data transfer. Furthermore, ADMA can support 32-bit or 64-bit system memory addressing. In ADMA, the 64-bit ADMA System Address Register is used as a Descriptor pointer instead of the 32-bit System Address Register.

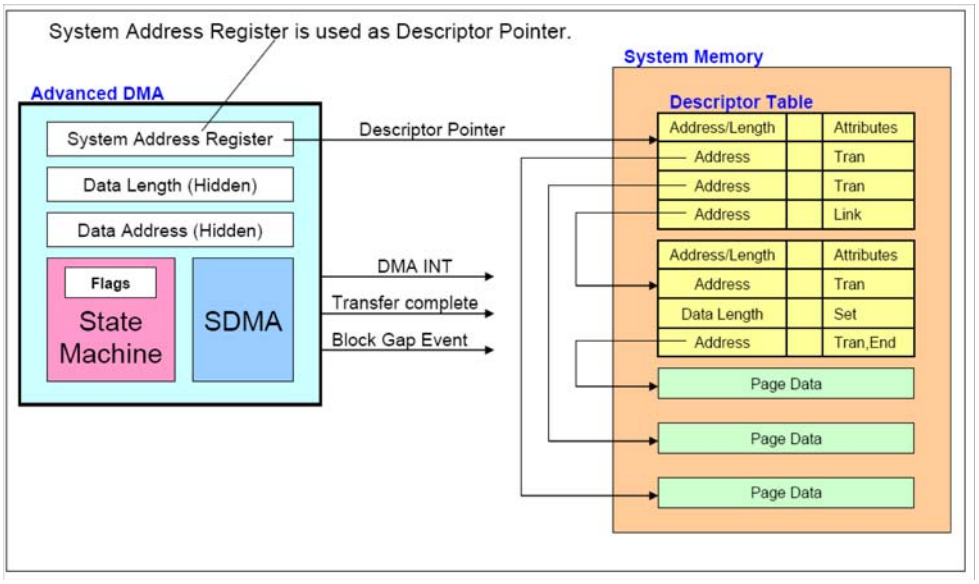

Figure 11-18. Host Controller Block Diagram

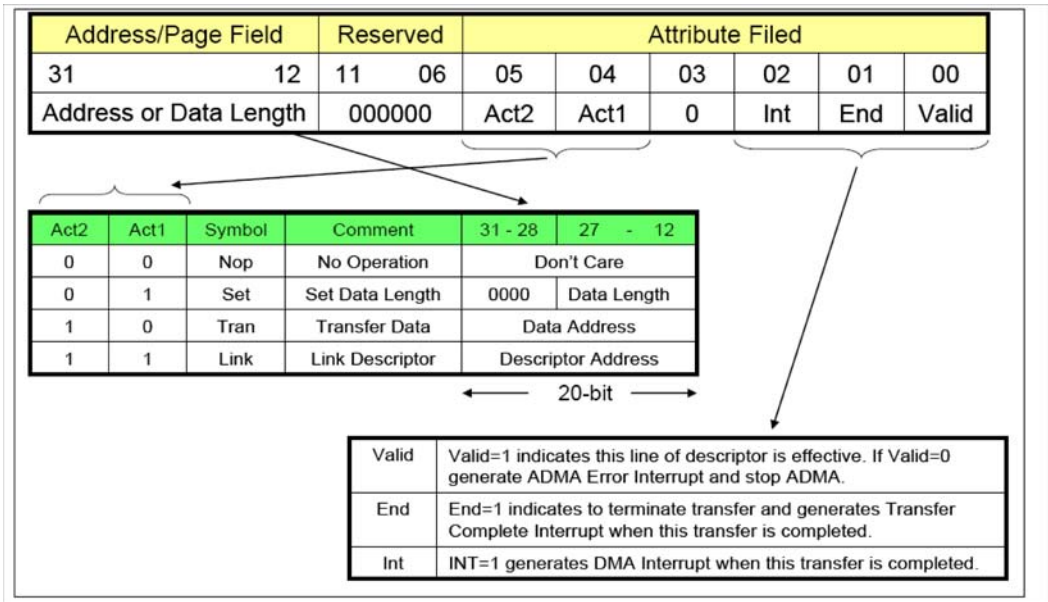

Figure 11-19. 32-Bit Descriptor Table Definition

NOTE

Data length is specified in the same way as the transfer Sector Size of the Sector Size Register. For example, 0x0001 indicates 1 byte, 0x0200 indicates 512 bytes, and so on. The data length should be a multiple of the sector size.

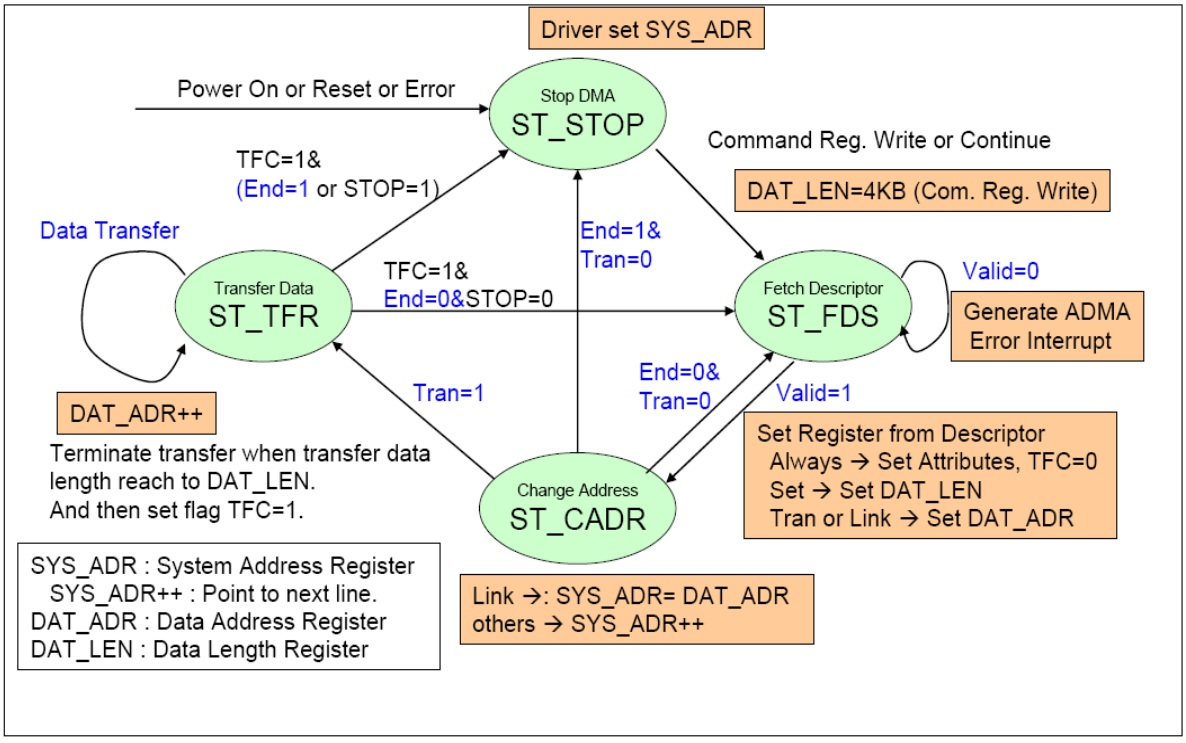

Figure 11-20. State Diagram for ADMA

11.4 Memory Map and Register Definitions

11.4.1 Memory Map

Table 11-1 shows the ATA memory map.

Table 11-1. ATA Memory Map

Address	Register	Description	Access	Reset Value	Section/Page
Offset: 00 (TIME_OFF)	TIME_OFF	transceiver timing parameter. Controls toff	R/W	0x01	11.4.3.2.1/11-23

Table 11-1. ATA Memory Map (Continued)

Address	Register	Description	Access	Reset Value	Section/Page
Offset: BC[3] (DRIVE_COMMAND)	DRIVE_ COMMAND	drive command register	Write-only	—	11.4.3.13/11-39
Offset: BC (DRIVE_STATUS)	DRIVE_STATUS	drive status register	Read-only	—	11.4.3.13/11-39
Offset: D8[4] (DRIVE_ALT_STATUS)	DRIVE_ALT_ STATUS	Drive alternate status register	Read-only	—	11.4.3.13/11-39
Offset: D8 (DRIVE_CONTROL)	DRIVE_ CONTROL	Drive control register	Write-only	—	11.4.3.13/11-39

1 Dashes in “Reset Value” column indicate that some bits in the register have no reset value.

2 An access at offset A0 reads or writes the 16-bit drive data register.

3 The drive command and drive status registers are both at offset BC. A write at offset BC accesses the drive command register, while a read at the same offset accesses the drive status register.

4 The drive alternate status and drive control registers are both at offset D8. A write at offset D8 accesses the drive control register, while a read at the same offset accesses the drive alternate status register.

11.4.2 Register Summary

Figure 11-21 shows the key to the register fields and Table 11-2 shows the register figure conventions.

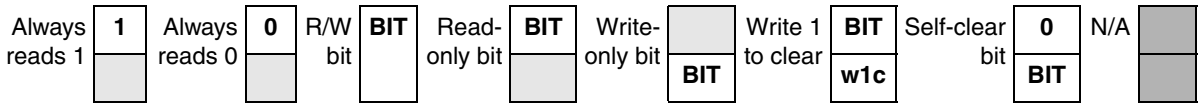

Figure 11-21. Key to Register Fields

Table 11-2. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit’s value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.

Table 11-2. Register Figure Conventions (Continued)

Convention	Description
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 11-3 summarizes the ATA registers. The registers at offsets A0 through D8 are addressable, but not present in the ATA interface module. These registers are not included in Table 11-3—they are described in Section 11.4.3.13, "Drive Registers Connected to ATA Bus."

11.4.3 Register Descriptions

This section contains the detailed register descriptions for the ATA registers.

11.4.3.1 Byte Order

The ATA interface works both in little-endian or big-endian mode. The addresses of all registers are the same in either mode. The 16-bit and 32-bit registers represent strings of 2 or 4 bytes. The byte order in the 16-bit or 32-bit register is dependent on the mode selection.

- Little-endian mode, 16- or 32-bit register:
  - bits [7:0]: byte 0
  - bits [15:8]: byte 1

  - bits [23:8]: byte 2
  - bits [31:24]: byte 3
- Big-endian mode, 32-bit register
  - bits [31:24]: byte 0
  - bits [23:16]: byte 1
  - bits [15:8]: byte 2
  - bits [7:0]: byte 3
- Big-endian, 16-bit register
  - bits [15:8]: byte 0
  - bits [7:0]: byte 1

11.4.3.2 Timing Registers

The registers at offsets 0x00 through 0x17 contain timing parameters. These timing parameters control the timing on the ATA bus.

Every timing parameter is 8 bits wide and can assume valid values between 0x01 and 0xFF. The reset value for all registers is 0x01.

11.4.3.2.1 TIME_OFF Register

Figure 11-22 shows the valid bits in the TIME_OFF register, and Table 11-1 describes the bit fields.

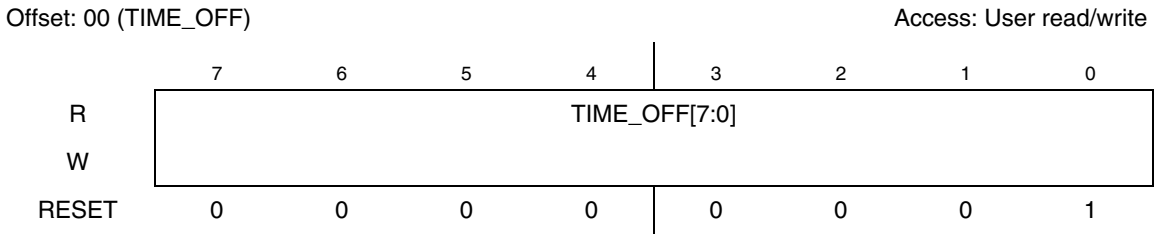

Figure 11-22. TIME_OFF Register

11.4.3.2.2 TIME_ON Register

Figure 11-23 shows the valid bits in the TIME_ON register, and Table 11-1 describes the bit fields.

Figure 11-45 shows the valid bits in the TIME_CYC register, and Table 11-1 describes the bit fields.

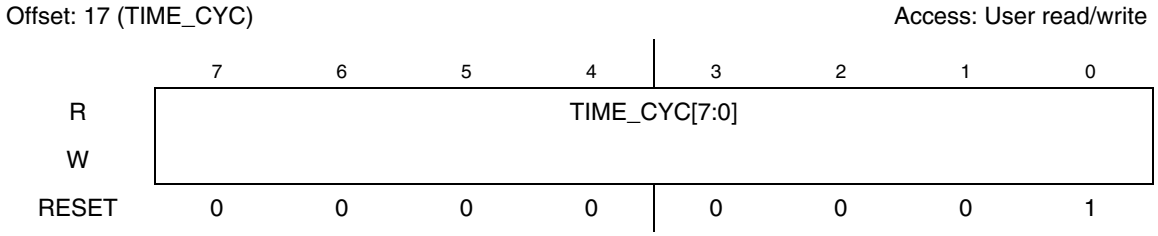

Figure 11-45. TIME_CYC

11.4.3.3 FIFO Data Registers

11.4.3.3.1 FIFO_Data Register in 16-bit and 32-bit Modes (FIFO_DATA_16, FIFO_DATA_32)

The FIFO_DATA register is used to read or write data to the internal FIFO. It can be accessed as a 16-bit register or as a 32-bit register. Word writes (respectively long writes) put two bytes (respectively four bytes) into the FIFO. Word reads (respectively long reads) read two bytes (respectively four bytes) from the FIFO.

Figure 11-46 shows the valid bits in the FIFO_Data Register in 16-bit mode.

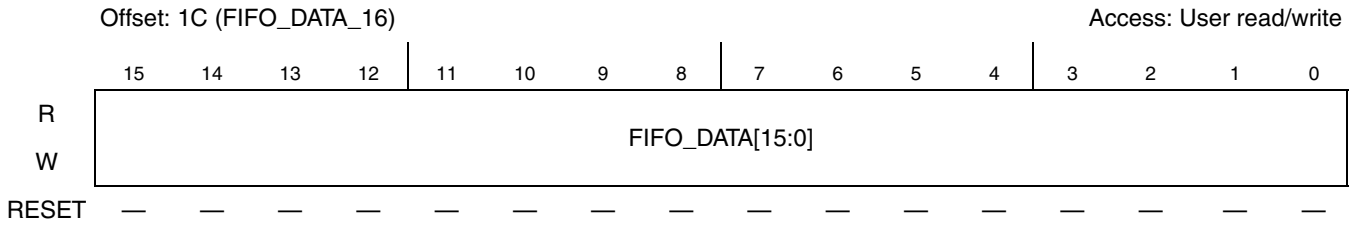

Figure 11-46. FIFO_Data Register In 16-bit Mode

Figure 11-47 shows the valid bits in the FIFO_Data Register in 32-bit mode.

RESET:	0	0	0	0	0	0	0	0

Figure 11-49. ATA Control Register

Table 11-4. ATA Control Register Field Descriptions

Field	Description
15-13	Reserved
12 dma_srst	This field controls if internal DMA controller is in reset or enabled 0 > internal DMA controller normal operation 1 > internal DMA controller reset
11-10 dma_select	This field controls DMA mode selected 00 > Single DMA select 01 > 32-bit ADMA select 10 > 64-bit ADMA select 11 > reserved
9 dma_start_stop	This field controls DMA master start or stop 0 > stop DMA master 1 > start DMA master
8 dma_enable	This field controls DMA master enable 0 > DMA master is disable 1 > DMA master is enable
7 fifo_rst_b	This field controls the internal FIFO reset 0 FIFO reset 1 FIFO normal operation
6 ata_rst_b	This bit controls the level on the ata_reset_b pin, which controls the reset of the internal ATA protocol engine. 0 ata_reset_b = 0, ATA drive is reset, and internal protocol engine reset. 1 ata_reset_b = 1, ATA drive is not reset; internal protocol engine normal operation.
5 fifo_tx_en	FIFO transmit enable. This bit controls whether the FIFO makes transmit data requests to the DMA. If enabled, the FIFO requests the DMA to refill it whenever the FIFO level drops below the alarm threshold. 0 FIFO refill by DMA disabled 1 FIFO refill by DMA enabled
4 fifo_rcv_en	FIFO receive enable. This bit controls whether the FIFO makes receive data requests to the DMA. If enabled, the FIFO requests the DMA to empty it whenever the FIFO level meets or exceeds the alarm threshold. 0 FIFO empty by DMA disabled 1 FIFO empty by DMA enabled
3 dma_pending	DMA pending bit. This bit controls whether the ATA interface responds to a DMA request originating in the drive. If this bit is set, the ATA interface starts a MDMA or UDMA burst whenever the drive asserts the ata_dmarq signal. 0 ATA interface does not start DMA burst 1 ATA interface starts MDMA or UDMA burst whenever drive asserts dmarq
2 dma_ultra_selected	This bit determines the protocol (UDMA or MDMA) for any new DMA burst 1=UDMA protocol is used 0=MDMA protocol is used

Table 11-4. ATA Control Register Field Descriptions (Continued)

Field	Description
1 dma_write	This bit determines the data direction on any new DMA burst 1=DMA out burst, ATA interface writes to drive 0=DMA in burst, ATA interface reads from drive
0 iordy_en	This bit determines whether ata_iordy handshake is used during PIO mode 1=IORDY handshake is used 0=IORDY is disregarded

11.4.3.5 Interrupt Registers

The three interrupt registers control the interrupt interface between the ATA module and the CPU/DMA. Two interrupts (ipbus_int and fifo_txfe_end_alarm) are controlled by these registers, as follows:

- The ipbus_int interrupt is controlled by bits 1,2,3,4,5 and 6 of the interrupt registers. It is asserted if one of the 6 bits is set in the interrupt_pending register, while the same bit is set in the interrupt_enable register. This interrupt goes to the CPU.
- The fifo_txfer_end_alarm interrupt is controlled by bit 7 of the interrupt registers. If ata_intrq1 is set in both the interrupt enable and interrupt pending register, then fifo_txfer_end_alarm is asserted. The purpose of this interrupt is to inform the DMA that the running data transfer has ended. This interrupt goes to the smart DMA.

11.4.3.5.1 Interrupt Pending Register (INTERRUPT_PENDING)

Figure 11-50 shows the valid bits in the interrupt pending register, and Table 11-5 describes the bit fields.

Table 11-5. Interrupt Pending Register Field Description

Field	Description
7 ata_intrq1	ATA interrupt request 1. This bit reflects the value of the ata_intrq interrupt input. It is set in the when the drive interrupt is pending, and cleared otherwise. The interrupt clear register has no influence on this bit.
6 fifo_underflow	FIFO underflow. This bit reports FIFO underflow. Sticky bit. It is set when there is a FIFO underflow condition. It is cleared by writing a ‘1’ to this bit in the interrupt clear register.
5 fifo_overflow	FIFO overflow. This bit reports FIFO overflow. Sticky bit. It is set when there is a FIFO overflow condition. It is cleared by writing a ‘1’ to this bit in the interrupt clear register.

Table 11-5. Interrupt Pending Register Field Description (Continued)

Field	Description
4 controller_idle	Controller Idle. This bit reports controller idle. It is set when the ATA protocol engine is idle, there is no activity on the ATA bus. It is cleared when there is activity on the ATA bus. The interrupt clear register has no influence on this bit.
3 ata_intrq2	ATA interrupt request 2. This bit reflects the value of the ata_intrq interrupt input. It is set when the drive interrupt is pending, and cleared otherwise. It has exactly same functioning as ata_intrq1, but this bit affects ipbus_int, while the other affects interrupt to the DMA.
2 dma_err	DMA error. This bit reflects Single DMA error or ADMA error interrupt.It is set in the interrupt pending register when AHB bus response error, ADMA read or write error and ADMA length mismatch error happen. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int is active, signaling interrupt to the CPU. It is cleared by writing a '1' to this bit in the interrupt clear register
1 dma_trans_over	DMA transfer over. This bit reflects Single DMA or ADMA read or write transfer over. It is set in the interrupt pending register when Single DMA or ADMA transfer is over without error. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int is active, signaling interrupt to the CPU. It is cleared by writing a '1' to this bit in the interrupt clear register.
0	Reserved

11.4.3.5.2 Interrupt Enable Register (INTERRUPT_ENABLE)

Table 11-6. Interrupt Enable Register Field Description

Field	Description
7 ata_intrq1	ATA interrupt request 1. If this bit is set, then fifo_txfer_end_alarm is driven to the DMA when the corresponding bit is set in the interrupt enable register. This informs the DMA that the current transfer is finished. The interrupt clear register has no influence on this bit.
6 fifo_underflow	FIFO underflow. If this bit is set, then ipbus_int is driven to the CPU when the corresponding bit is set in the interrupt enable register.
5 fifo_overflow	FIFO overflow. If this bit is set, then ipbus_int is driven to the CPU when the same bit is set in the interrupt enable register.
4 controller_idle	Controller Idle. If this bit is set, then ipbus_int is driven to the CPU when the same bit is set in the interrupt enable register. The interrupt clear register has no influence on this bit.

Table 11-6. Interrupt Enable Register Field Description

Field	Description
3 ata_intrq2	ATA interrupt request 2. This bit reflects the value of the ata_intrq interrupt input. If this bit is set, then ipbus_int is driven to the CPU when the same bit is set in the interrupt enable register. This informs the CPU that the drive is requesting attention. The interrupt clear register has no influence on this bit.
2 dma_err	DMA error. This bit reflects Single DMA error or ADMA error interrupt.It is set in the interrupt pending register when AHB bus response error, ADMA read or write error and ADMA length mismatch error happen. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int is active, signaling interrupt to the CPU. It is cleared by writing a ‘1’ to this bit in the interrupt clear register
1 dma_trans_over	DMA transfer over. This bit reflects Single DMA or ADMA read or write transfer over. It is set in the interrupt pending register when Single DMA or ADMA transfer is over without error. When the bit is set in the interrupt pending register, and the same bit is set in the interrupt enable register, ipbus_int is active, signaling interrupt to the CPU. It is cleared by writing a ‘1’ to this bit in the interrupt clear register.

11.4.3.6 FIFO Alarm Register (FIFO_ALARM)

This register contains the threshold (in 16-bit halfword units) which triggers fifo_rcv_alarm or fifo_tx_alarm signals to the DMA interface.

- If the fifo_rcv_en bit is set in the ATA control register and fifo_fill ≥ fifo_alarm, then the fifo_rcv_alarm signal is asserted to request the DMA to empty the FIFO.
- If the fifo_tx_en bit is set in the ATA control register and fifo_fill < fifo_alarm), then the fifo_tx_alarm signal is asserted to request the DMA to refill the FIFO.

For single DMA and ADMA transfers, the recommended value for FIFO_ALARM is 0x20.

Figure 11-53 shows the valid bits in the FIFO alarm register.

Figure 11-55. SYS_DMA_BADDR Register

This register contains the system memory address for a DMA transfer. When the host controller stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only if a transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.

11.4.3.9 ADMA_SYS_ADDR Register

See Figure 11-56 for an illustration of valid bits in the ADMA_SYS_ADDR register.

RESET:	0	0	0	0	0	0	0	0

Figure 11-56. ADMA_SYS_ADDR Register

This register holds the byte address of the executing command of the descriptor table. The 32-bit descriptor uses the lower 32 bits of this register (only the 32-bit descriptor is supported). At the start of ADMA, the host driver sets the starting address of the descriptor table. The ADMA engine increments this register address on every fetch of a descriptor command. When the ADMA is stopped at the block gap, this register indicates the address of the next executable descriptor command. When the ADMA error interrupt is generated, this register holds the valid descriptor address depending on the ADMA state.

11.4.3.10 BLOCK_CNT Register

Figure 11-59. SECTOR_SIZE Register

11.4.3.13 Drive Registers Connected to ATA Bus

Some drive registers are addressable but are not present in the ATA interface module. These are listed in Table 11-10. If a read or write access is made to one of these registers, the read or write is mapped to a PIO read or write cycle on the ATA bus, and the corresponding register in the device attached to the ATA bus is accessed. No description of these registers is given here; consult the ATA specification for information on these registers.

If the drive_data register is accessed while the ATA interface operates in big-endian mode, the bytes to/from the ATA bus are swapped. No swaps occur in little-endian mode or for the other registers.

Table 11-10. Drive Registers connected to ATA Bus

Address	Name	Description	Access
Offset: A0 (DRIVE_DATA)	drive_data	Drive data register	R/W
Offset: A4 (DRIVE_FEATURES)	drive_features	Drive features register	R/W

Offset: D8 (DRIVE_CONTROL)	drive_control	Drive control register	Write-only

11.5 Functional Description

The ATA interface provides two alternative modes for communication with the ATA peripherals connected to the ATA bus:

- PIO mode read/write operations through the ATA bus
- DMA transfers through the ATA bus, including:
  - DMA slave mode transfers between host and FIFO, which utilize the IPS bus
  - DMA master mode transfers between external memory and FIFO, which utilize the AHB bus

The operation of the peripheral under these two modes is described in detail in subsequent sections.

11.5.1 Resetting the ATA Bus

The ATA bus reset ata_reset_b is asserted whenever ata_rst_b (bit #6) of the ATA control register is cleared (see Section 11.4.3.4, “ATA Control Register (ATA_CONTROL)”). Clearing the bit also resets the ATA protocol engine. When the bit is set, the reset is released.

11.5.2 Programming ATA Bus Timing and iordy_en

The timing of the ATA interface is programmable using the 24 timing registers described in Section 11.4, "Memory Map and Register Definitions." Programming the registers requires that the ATA bus be idle, so before reprogramming the user should ensure the following:

a) The dma_pending bit in the ATA control register is cleared (see Section 11.4.3.4, "ATA Control Register (ATA_CONTROL)").

b) The controller_idle bit in the interrupt pending register is set (see Section 11.4.3.5.1, "Interrupt Pending Register (INTERRUPT_PENDING)").

These two conditions can be met by first clearing dma_pending and then waiting until controller_idle is set before reprogramming the timing parameters. If dma_pending was set before the reprogramming started, it should be set again after the new timing is in effect to allow the drive to finish the current DMA transfer.

The bus timing should only be reprogrammed during an ongoing DMA transfer when the operating system requires a change in the bus clock (for example, in dynamic voltage frequency scaling).

The controller_idle bit must be set before reprogramming the bus timing: otherwise, the new timing values may affect a bus cycle that is still running and cause an error. PIO reads or writes to the ATA bus terminate after the bus cycle with the CPU has been terminated.

The iordy_en bit in the ATA control register determines whether the ATA interface responds to the drive's IORDY signal. Just as with timing registers, it should only be reprogrammed when dma_pending is cleared and controller_idle is set.

11.5.3 Access to ATA Bus in PIO Mode

Before accessing the ATA bus in PIO mode, the user must do the following:

a) Set the ata_rst_b bit in the ATA control register

b) Program the timing parameters

The drive is accessed in PIO mode simply by reading or writing to the correct drive register. The bus cycle is translated to an ATA cycle, and the drive is accessed.

Reads and writes to the drive are not possible while the ATA bus is in reset; the attempted operation fails and is discarded.

11.5.4 Receiving Data from ATA Bus in DMA Slave Mode

In DMA receive slave mode, the protocol engine transfers data from the drive to the FIFO using the multiword DMA (MDMA) or ultra DMA (UMDMA) protocol. The transfer pauses when any of the following conditions occur:

- The FIFO is full.
- The drive negates its DMA request signal ata_dmarq.
- The dma_pending bit in the ata_control register is cleared.

When the condition is removed, the transfer restarts. At the end of the transfer, the drive signals the host by asserting the ata_intrq signal. Alternatively, the host can read the device status register, which also indicates when the transfer has ended.

The transfer of data from FIFO to memory is handled by the host system DMA. DMA data transfers from device to host are set up as follows:

1. Make sure the ATA bus is not in reset and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty or by resetting it.
3. Initialize the DMA channel connected to fifo_rcv_alarm. Every time the fifo_rcv_alarm is high, the DMA should read <packetsize> 32-bit words from the FIFO, and store them in main memory (here “packetsize” is defined as the number of 32-bit words in a packet; typically, packetsize = 8). This keeps the transfer going while avoiding FIFO overrun.
4. Write 2*<packetsize> to the FIFO alarm register (note that this setting corresponds to one packet of data, because the alarm threshold is specified in units of 16-bit halfwords). Thus the FIFO notifies the DMA when there is at least one packet ready for transfer.
5. Ensure the FIFO is out of reset by setting the fifo_rst_b bit in the ATA control register (see Section Section 11.4.3.4, “ATA Control Register (ATA_CONTROL)”).
6. Set the fifo_rcv_en bit in the ATA control register. This enables the DMA to empty the FIFO.
7. Set the dma_pending bit, and clear the dma_write bit. Also, program ultra_mode_selected=0 (for MDMA) or ultra_mode_selected=1 (for UDMA).

Steps (1–7) have prepared the host side of the DMA.

8. Send commands to the drive in PIO mode that cause it to request DMA transfer on the ATA bus (consult the ATA specification for the specifics of this operation).
9. At this point, when the drive requests a DMA transfer by pulling ata_dmarq high, the ATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically to the FIFO, and from there to the host memory.
10. During the transfer, the host can monitor for end of transfer by reading some device ATA registers. These reads cause the running DMA to pause; after the read is complete, the DMA resumes. Alternatively, the host can wait until the drive asserts ata_intrq, which also indicates end of transfer.
11. When the transfer ends, the host or host DMA should wait until the controller_idle bit is set in the ATA control register, then read the remaining halfwords from the FIFO and transfer these to memory. Note that there may be less than <packetsize> remaining 32-bit words, in which case the transfer is not performed automatically by the DMA.

11.5.5 Transmitting Data to ATA Bus in DMA Slave Mode

In DMA transmit mode, the protocol engine transfers data from the FIFO to the drive using the multiword DMA (MDMA) or ultra DMA (UDMA) protocol. The transfer pauses when one of following conditions occurs:

- The FIFO is empty
- The drive negates its DMA request signal ata_dmarq
- The dma_pending bit in the ata_control register is cleared

When the condition is removed, the transfer restarts. At the end of the transfer, the drive signals the host by asserting the ata_intrq signal. Alternatively, the host can read the device status register, which also indicates when the transfer has ended.

The transfer of data from FIFO to memory is handled by the host system DMA. DMA data transfers from host to device are set up as follows:

1. Make sure the ATA bus is not in reset, and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty or by resetting it.
3. Initialize the DMA channel connected to fifo_tx_alarm. Every time the fifo_tx_alarm signal is high, the DMA should read <packetsize> 32-bit words from the main memory and write them to the FIFO (typical packetsize is 8 32-bit words). Program the DMA so that it does not transfer more than <sectorsize> 32-bit words total.
4. Write FIFO_SIZE – 2 × <packetsize> to the FIFO alarm register. In this way, FIFO notifies the DMA when there is room for at least one additional packet. FIFO_SIZE is given in 16-bit halfwords: the typical value is 64 halfwords, or 128 bytes.
5. Prepare the ATA for a DMA transfer from host to device as follows:
   a) Make sure the FIFO is out of reset by setting bit fifo_rst_b in the ATA control register (see Section Section 11.4.3.4, “ATA Control Register (ATA_CONTROL)”).
   b) Program fifo_tx_en=1 in the ATA control register. This enables the FIFO to be filled by DMA.
   c) Program dma_pending =1 and dma_write=1. Also, program ultra_mode_selected =0 (for MDMA) or ultra_mode_selected=1 (for UDMA).

Steps (1-5) have prepared the host side of the DMA.

6. Send commands to the drive in PIO mode that cause it to request a DMA transfer on the ATA bus (consult the ATA specification for the specifics of this operation).
7. At this point, when the drive requests a DMA transfer by pulling ata_dmarq high, the ATA interface acknowledges with ata_dmack, and the transfer starts. Data is transferred automatically from the FIFO, and also from host memory to FIFO.
8. During the transfer, the host can monitor for end of transfer by reading some device ATA registers. These reads cause the running DMA to pause; after the read is completed, the DMA resumes. Alternatively, the host can wait unit the drive asserts ata_intrq, which also indicates end of transfer.

When the transfer ends, no additional FIFO manipulations are needed.

11.5.6 Using DMA Master Mode to Receive Data From the ATA Bus

In DMA master mode for receiving data from the ATA bus, the internal DMA engine initializes a burst data write transfer on the AHB bus when the internal signal *sys_dma_req* is asserted.

Sys_dma_req is asserted when these conditions occur:

- *fifo_rcv_alarm* in DMA read
- In a DMA read, the data left in the FIFO is not enough to trigger the fifo_alarm, but the sector word counter has not reached a sector boundary

Sys_dma_req is negated when these conditions occur:

- A burst transfer ends
- DMA start is set
- The host is not active

For single DMA, burst length is the minimum set by software, FIFO alarm, and left data number in the last sector word counter.

For ADMA, burst length is the minimum set by software, FIFO alarm, left data number in the last sector word counter, and left data number indicated in a descriptor pair.

The following list describes the steps in setting up a DMA data transfer from the device to external memory:

1. Make sure that the ATA bus is not in reset, and that all timing registers are programmed
2. Make sure the FIFO is empty by reading it until empty, or by resetting it.
3. To make the ATA ready for a DMA transfer from device to host, do the following:
   a) Make sure the FIFO is out of reset by setting the bit fifo_rst_b to 1 in the ata_control register.
   b) Program fifo_rcv_en=1 in the ata_control register. This enables the FIFO to by emptied by the DMA.
   c) Program dma_pending =1, dma_write=0, ultra_mode_selected=0/1 in the ata_control register. ultra_mode_selected should be 1; it should be 0 if you want to transfer data using MDMA mode.
4. To make the internal DMA controller ready for a DMA transfer, do the following:
   a) Program fifo_alarm, burst_length, block_cnt, DMA system start base address (data buffer start address) for single DMA mode, or ADMA system address (descriptor table start address) for ADMA mode.
   b) Program dma_en = 1, dma_select=01 (if you select ADMA mode), dma_start_stop=1. If you select ADMA mode, make sure that the descriptor table is ready before starting a DMA transfer.
5. Now the host side of the DMA is ready. Send commands to the drive in PIO mode that cause it to request a DMA transfer on the ATA bus. The nature of these commands is beyond the scope of this document. See the ATA specification for information on communicating with the drive.
6. When the drive requests a DMA transfer by pulling *ata_dmarq* high, the ATA interface acknowledges with *ata_dmack*, and the transfer starts. Data is transferred automatically to the FIFO, and then to the external memory.
7. When *sys_dma_req* is asserted, the DMA engine will write burst length data from FIFO to external memory.
8. During the transfer, the host can detect end of transfer by waiting for a dma_trans_over interrupt. After the end of transfer is detected, the host must reset dma_start_stop to 0.

11.5.7 Using DMA Master Mode To Transmit Data to the ATA bus

In DMA master mode for transmitting data to the ATA bus, the internal DMA engine initializes a burst data read transfer on the AHB bus when the internal signal *sys_dma_req* is asserted.

Sys_dma_req is asserted when these conditions occur:

- *fifo_tx_alarm* in DMA write

Sys_dma_req is negated when these conditions occur:

- A burst transfer ends
- DMA start is set
- The host is not active

For Single DMA, burst length is the minimum set by software and the FIFO alarm.

For ADMA, burst length is the minimum set by software, the FIFO alarm, and the left data number indicated in a descriptor pair.

The following list describes the steps in setting up a DMA data transfer from external memory to the device:

1. Make sure the ATA bus is not in reset, and all timing registers are programmed.
2. Make sure the FIFO is empty by reading it until empty, or by resetting it.
3. To make the ATA ready for a DMA transfer from host to device, do following:
   a) Make sure the FIFO is out of reset by setting bit *fifo_rst_b* to 1 in the ATA control register.
   b) Program *fifo_tx_en*=1 in *ata_control* register. This enables the FIFO to be filled by DMA.
   c) Program *dma_pending* =1, *dma_write*=1, *ultra_mode_selected*=0/1 in *ata_control* register. ultra_mod_selected should be 1 if you want to transfer data using UDMA mode, it should be 0 if you want to transfer data using MDMA mode.
4. To make the internal DMA controller ready for a DMA transfer, do the following:
   a) Program fifo_alarm, burst_length, block_cnt, and the DMA system start base address (data buffer start address) for single DMA mode, or ADMA system address (descriptor table start address) for ADMA mode.
   b) Program dma_en = 1, dma_select=01(if select ADMA mode), dma_start_stop=1. If select ADMA mode, it is necessary to make sure descriptor table is ready before start DMA transfer.
5. When *sys_dma_req* is asserted, DMA engine will read a burst length data from external memory to FIFO.
6. Now, the host side of the DMA is ready. Send commands to the drive in PIO mode that cause it to request DMA transfer on the ATA bus. The nature of these commands is beyond the scope of this document. You should consult the ATA specification to know how to communicate with the drive.
7. When the drive now requests DMA transfer by pulling *ata_dmarq* high, the ATA interface acknowledges with *ata_dmack*, and the transfer starts. Data is transferred automatically from the FIFO if FIFO is not empty.

8. During the transfer, the host can detect end of transfer by waiting for ata_intrq2 interrupt. After the end of transfer is detected, the host must reset dma_start_stop to 0.

11.6 Initialization and Application of ATA

If the host asserts RESET, the ATA device executes the hardware reset protocol, regardless of power management mode. For more details about the power-on and hardware reset protocol, see the ATA specification).

The host issues an IDENTIFY DEVICE command after the power-on reset or hardware reset protocol is complete, in order to determine the current status of features implemented by the device.

Chapter 12
Digital Audio Multiplexer (AUDMUX)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

Table 12-1 defines terms used in this chapter.

Table 12-1. Definition Of Terms

Term	Definition
PTCR	Port Timing Control Register
PDCR	Port Data Control Register
CNMCR	CE Bus Network Mode Control Register
FSPOL	Frame sync polarity
CLKPOL	Clock polarity
TFSDIR	Transmit Frame Sync Direction Control
TCLKDIR	Transmit Clock Direction Control
RFSDIR	Receive Frame Sync Direction Control
RCLKDIR	Receive Clock Direction Control
TFSEL	Transmit Frame Sync Port Select
RFSEL	Receive Frame Sync Port Select
TCSEL	Transmit Clock Port Select
RCSEL	Receive Clock Port Select
RXDSEL	Receive Data Port Select
INMMASK	Internal Network Mode Masking
CE Bus	Consumer Electronic Bus
CEN	CE Bus Enable
CNTHI	CE Bus disable signal High Period Count
CNTLO	CE Bus disable signal Low Period Count

12.1 Overview

The Digital Audio Mux (AUDMUX) provides a programmable interconnect device for voice, audio, and synchronous data routing between host serial interfaces (such as SSI) and peripheral serial interfaces (that

is, audio and voice CODECs, also known as coder-decoders). The AUDMUX interconnections allow multiple, simultaneous, audio/voice/data flows between the ports in point-to-point or point-to-multipoint configurations. This section includes a top level diagram that shows the functional organization of the module, including all off-chip signals.

The AUDMUX allows the audio system connectivity to be modified through programming (as opposed to altering the PCB schematics of the system). Figure 12-1 shows the block diagram. The full description of the module is in Section 12.4, “Functional Description.”

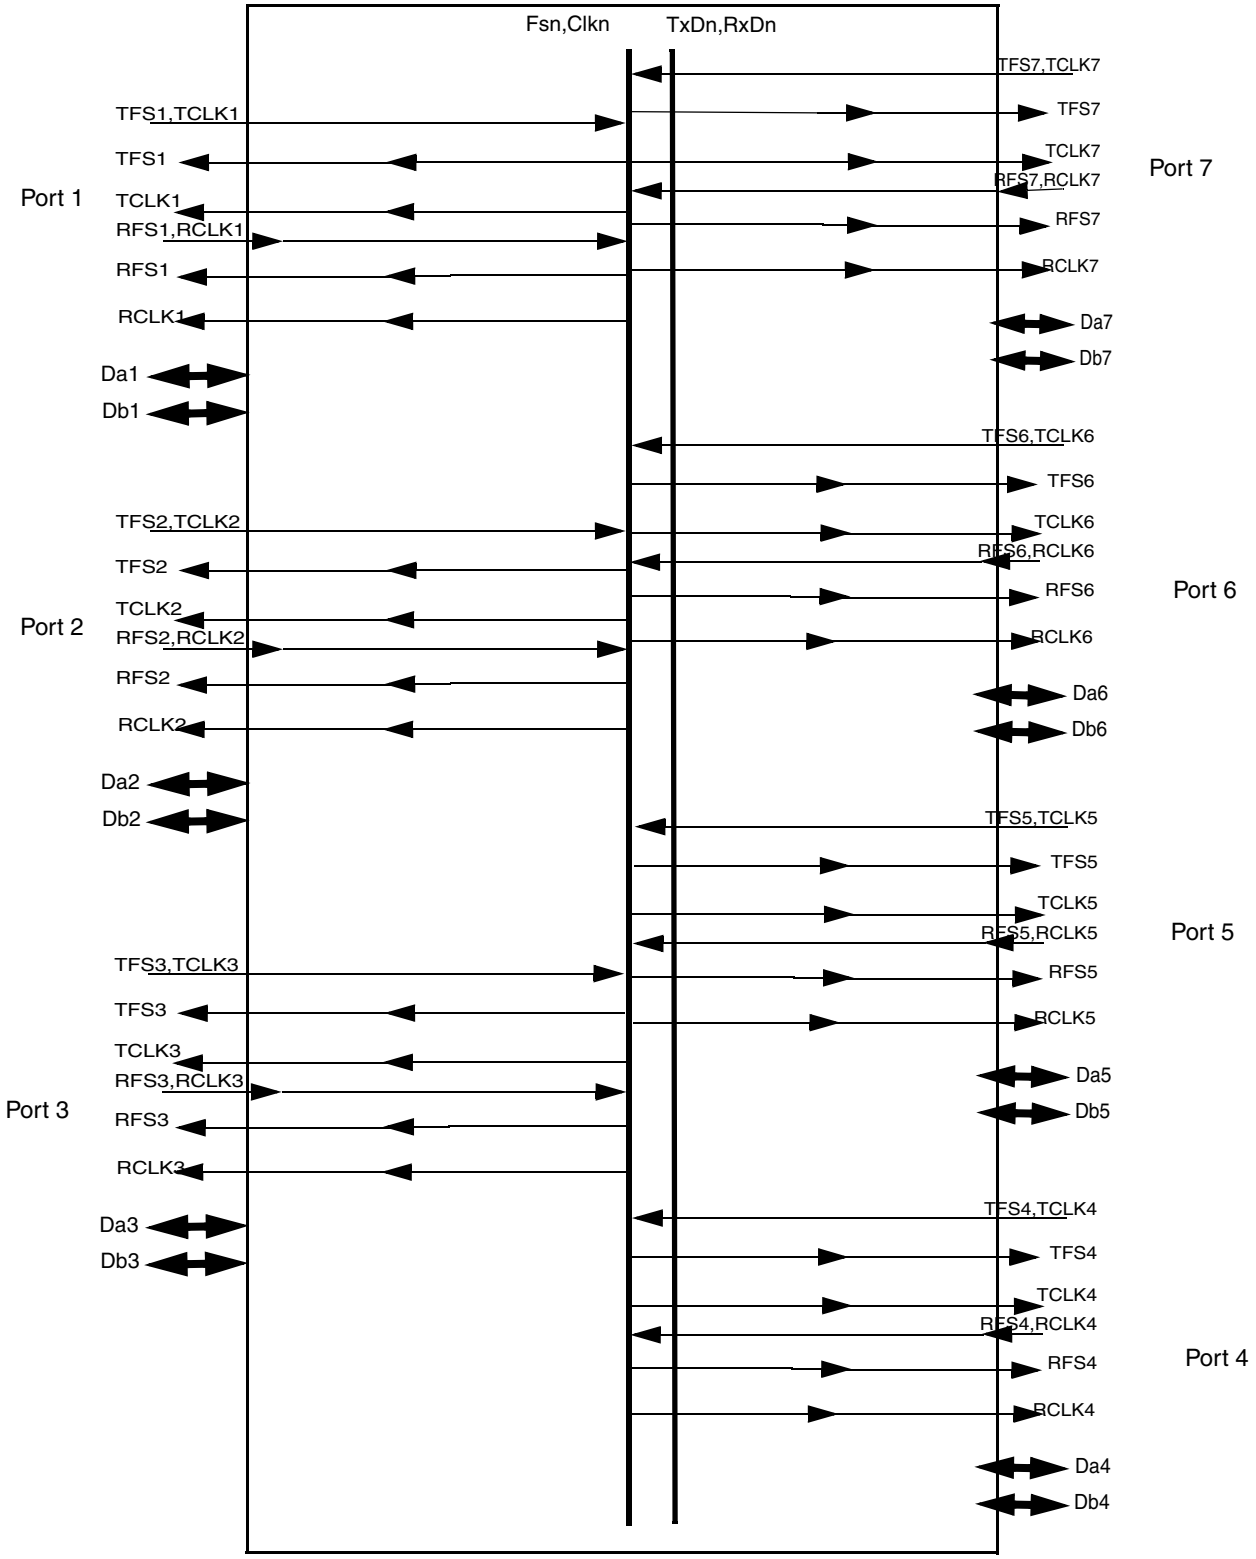

Figure 12-1. AUDMUX Block Diagram

12.1.1 Features

Key features of the module include the following:

- Three internal ports
- Four external ports
- Full 6-wire SSI interfaces for asynchronous receive and transmit
- Configurable 4-wire (synchronous) or 6-wire (asynchronous) peripheral interfaces
- Independent Tx/Rx Frame sync and clock direction selection for host or peripheral
- Each host interface's capability to connect to any other host or peripheral interface in a point-to-point or point-to-multipoint (network mode)
- Transmit and receive data switching to support external network mode
- CE Bus network mode to provide synchronous switching on RxD

12.1.2 Modes of Operation

Each AUDMUX port can be configured to operate in the following modes:

- Normal mode—the port is connected point-to-point to a single other port
- Internal network mode—the port is connected point-to-multipoint to multiple other ports
- CE bus network mode—the port receives data from the CE bus port (port 7) and one other port as selected by software.

Additionally, each port can operate in synchronous or asynchronous timing modes.

Modes of operation are described in more detail in Section 12.1.2, "Modes of Operation."

12.2 External Signal Description

Table 12-2 lists AUDMUX pin-level signals for the external ports, where:

- P*n* is P4, through P7
- $m = n - 3$.

The port is configured as an external port by a static system-level signal input p*n*_int_ext_select.

Table 12-2. Off-Chip Module Signals

Name	Module Port	I/O	Function	Reset State	Pull-up
AUDm_TXD	P*n*	I/O	Transmit Data from Pn	1	Active
AUDm_RXD	P*n*	I/O	Receive Data at Pn	1	Active
AUDm_TXC	P*n*	I/O	Transmit Clock input/output at Pn	1	—
AUDm_RXC	P*n*	I/O	Receive Clock input/output at Pn	1	—
AUDm_TXFS	P*n*	I/O	Transmit Frame sync input/output at Pn	1	—
AUDm_RXFS	P*n*	I/O	Receive Frame sync input/output at Pn	1	—

12.3 Memory Map and Register Definitions

This section includes the module memory map and detailed descriptions of all registers. For the base address of a particular module instantiation, see the system memory map.

12.3.1 Memory Map

The AUDMUX memory map is shown in Table 12-3.

Table 12-3. AUDMUX Memory Map

Address	Register	Access	Reset Value	Section/Page
0x0000 (PTCR1)	Port Timing Control Register 1	RW	0xAD40_0800	12.3.3.4/12-8
0x0004 (PDCR1)	Port Data Control Register 1	RW	0x0000_A000	12.3.3.5/12-10

1 *n* ranges from 1 through 7.

12.3.3 Register Descriptions

There are two configuration registers for each port. There is also a separate register for CE Bus Network mode control. Each pair of configuration registers is identical for each port; however, the default values following a reset differ as shown in Table 12-3.

- Section 12.4.3.1, “Default Port Configuration” describes the default configuration of the ports.
- Section 12.4.3.2, “Default CE Bus Configuration” describes the default configuration of the CE Bus.

12.3.3.1 Default Port Configuration

After a reset, each port defaults to normal mode (PDCR*n*[MODE] = 00) with synchronous timing mode (PTCR*n*[SYN] = 1) enabled.

The default port-to-port connections are as follows:

- Port 1 to Port 6
  - Port 6 provides the clock and frame sync.
- Port 2 to Port 5
  - Port 5 provides the clock and frame sync.
- Port 3 to Port 4
  - Port 4 provides the clock and frame sync.
- Port 7 to Port 7 (in data loopback mode)
  - Clock and frame syncs are inputs.

12.3.3.2 Default CE Bus Configuration

The default configuration of all the ports is to set the MODE field to normal mode (that is, no port selects CE Bus network mode). Correspondingly, the default configuration of the CEN field in the CNMCR is clear. To minimize AUDMUX setup for audio testing, the rest of the CNMCR fields default to the following configuration:

- FSPOL is set.
- CLKPOL is set.
- CNTHI is set to 16.
- CNTLOW is set to 16.

This configuration uses a frame sync that is logic high when asserted.

The clock is driven by the transmitter on the rising edge and is sampled by the receiver on the falling edge. The AUDMUX switches between devices on the rising edge; this provides a buffer of one-half clock period between the moment data is sampled and when the AUDMUX switches between devices. See Figure 12-16 for a timing diagram where FSPOL and CLKPOL are both set.

CNTHI and CNTLOW are set to 16 to allow CE Bus to drive data during timeslot 1 and the other device to drive data during timeslots 0, 2,..., N-1 where N is the number of timeslots used and each timeslot has 16 bits.

12.3.3.3 Register Conventions

Figure 12-2 and Table 12-5 explain conventions used in register diagrams and tables.

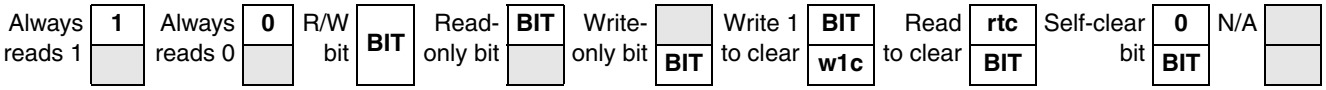

Figure 12-2. Register Field Conventions

Table 12-5. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)

Table 12-5. General Register Conventions (Continued)

Convention	Description
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

12.3.3.4 Port Timing Control Register *n* (PTCR*n*)

PTCR*n* is the Port Timing Control Register for Port *n*, where *n* ranges from 1 through 7.

Offset 0x0000 (PTCR1) Access: User read/write

Table 12-6. Port Timing Control Register Field Descriptions

Field	Description
31 TFSDIR	Transmit Frame Sync Direction Control. This bit sets the direction of the TxFS pin of the interface as an output or input. When set as an input, the TFSEL settings are ignored. When set as an output, the TFSEL settings determine the source port of the frame sync. 0 TxFS is an input. 1 TxFS is an output.
30–27 TFSEL[3:0]	Transmit Frame Sync Select. Selects the source port from which TxFS is sourced. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
26 TCLKDIR	Transmit Clock Direction Control. This bit sets the direction of the TxClk pin of the interface as an output or input. When set as an input, the TCSEL settings are ignored. When set as an output, the TCSEL settings determine the source port of the clock. 0 TxClk is an input. 1 TxClk is an output.
25–22 TCSEL[3:0]	Transmit Clock Select. Selects the source port from which TxClk is sourced. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
21 RFSDIR	Receive Frame Sync Direction Control. This bit sets the direction of the RxFS pin of the interface as an output or input. When set as an input, the RFSEL settings are ignored. When set as an output, the RFSEL settings determine the source port of the frame sync. 0 RxFS is an input. 1 RxFS is an output.
20–17 RFSEL[3:0]	Receive Frame Sync Select. Selects the source port from which RxFS is sourced. RxFS can be sourced from TxFS and RxFS from other ports. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
16 RCLKDIR	Receive Clock Direction Control. This bit sets the direction of the RxClk pin of the interface as an output or input. When set as an input, the RCSEL settings are ignored. When set as an output, the RCSEL settings determine the source port of the clock. 0 RxClk is an input. 1 RxClk is an output.

Table 12-6. Port Timing Control Register Field Descriptions (Continued)

Field	Description
15–12 RCSEL[3:0]	Receive Clock Select. Selects the source port from which RxClk is sourced. RxClk can be sourced from TxClk and RxClk from other ports. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 . . . x110 Port 7 x111 Reserved
11 SYN	Synchronous/Asynchronous Select. When SYN is set, synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals (that is, the port is a 4-wire interface). When SYN is cleared, asynchronous mode is chosen and separate clock and frame sync signals are used for the transmit and receive sections (that is, the port is a 6-wire interface). 0 Asynchronous mode 1 Synchronous mode (default)
10–0	Reserved

12.3.3.5 Port Data Control Register *n* (PDCR*n*)

Table 12-7. PDCR (Port *n*) Field Descriptions

Field	Description
31–16	Reserved
15–13 RXDSEL[2:0]	Receive Data Select. Selects the source port for the RxD data. RXDSEL is ignored if MODE = 01 (that is, Internal Network Mode is enabled). xxx Port number for RxD 000 Port 1 . . . 110 Port 7 111 Reserved
12 TXRXEN	Transmit/Receive Switch Enable. Swaps the transmit and receive signals. 0 No switch (Transmit Pin = Transmit, Receive Pin = Receive) 1 Switch (Transmit Pin = Receive, Receive Pin = Transmit)
11–10	Reserved
9–8 MODE[1:0]	Mode Select. This field selects the mode in which the port is to operate. The modes of operation include the following: • Normal mode, in which the RxD from the port selected by RXDSEL is routed to the port. • Internal Network mode in which RxD from other ports are ANDed together. RXDSEL is ignored. INMMASK determines which RxD signals are ANDed together. • CE Bus Network mode, in which the port receives data from CE Bus port (Port 7) and any other port as selected by RXDSEL[3:0] in different time slots within a frame. The ce_bus_dis signal routes the data from the CE Bus port if low; otherwise, data from the other port (as selected by RXDSEL) is routed to the port. 00 Normal mode 01 Internal Network mode 10 CE Bus Network mode 11 Reserved
7–0 INMMASK[7:0]	Internal Network Mode Mask. Bit mask that selects the ports from which the RxD signals are to be ANDed together for internal network mode. Bit 6 represents RxD from Port 7 and bit0 represents RxD from Port 1. 0 Includes RxDn for ANDing 1 Excludes RxDn from ANDing

12.3.3.6 CE Bus Network Mode Control Register (CNMCR)

Figure 12-5 shows the CE bus network mode control register.

Figure 12-5. CE Bus Network Mode Control Register (CNMCR)

Table 12-8 shows the CNCMR field descriptions.

Table 12-8. CNMCR Field Descriptions

Field	Description
31–19	Reserved
18 CEN	CE Bus enable. This signal controls the generation of ce_bus_dis signal. If set, the ce_bus_dis signal is generated as per the CNTHI and CNTLOW settings. 0 CE Bus disable signal is held low. 1 CE Bus disable signal is generated.
17 FSPOL	Frame Sync Polarity Select. This field selects the frame sync polarity of the CE Bus port (Port 7) used for the generation of ce_bus_dis signal. 0 Polarity 0 1 Polarity 1
16 CLKPOL	Clock Polarity Select. This field selects the bit clock polarity of the CE Bus port (Port 7) used for generation of ce_bus_dis signal. 0 Polarity 0 1 Polarity 1
15–8 CNTHI[7:0]	CE Bus disable signal high period count. This field selects the number of bit clocks for which the CE Bus disable signal ce_bus_dis is to remain high following the detection of the frame sync, that is, when CE Bus is not transferring data. This allows the user to specify the time until the CE Bus starts transmitting (with respect to the beginning of timeslot 0). 00000000 0 bit clock period 00000001 1 bit clock period 00000010 2 bit clock period . . . . 11111111= 255 bit clock period • If operating in 4-wire mode (SYN is set), the clock used for ce_bus_dis generation is selected by the TCSEL[3:0] field of Port 7's control register PTCR7. The frame sync used for ce_bus_dis generation is selected by the TFSEL[3:0] field of Port 7's control register PTCR7. If operating in 6-wire mode (SYN is clear), the clock used for ce_bus_dis generation is selected by the RCSEL[3:0] field of Port 7's control register PTCR7. The frame sync used for ce_bus_dis generation is selected by the RFSEL[3:0] field of Port 7's control register PTCR7.

Table 12-8. CNMCR Field Descriptions (Continued)

Field	Description
7–0 CNTLOW[7:0]	CNTLOW - CE Bus disable signal low period count. This field selects the number of bit clocks for which the CE Bus disable signal ce_bus_dis is to remain low, that is, when CE Bus is transferring data. 00000000 = 0 bit clock period 00000001 = 1 bit clock period 00000010 = 2 bit clock period . . . . 11111111 = 255 bit clock period • If operating in 4-wire mode (SYN is set), the clock used for ce_bus_dis generation is selected by the TCSEL[3:0] field of Port 7's control register PTCR7. The frame sync used for ce_bus_dis generation is selected by the TFSEL[3:0] field of Port 7's control register PTCR7. If operating in 6-wire mode (SYN is clear), the clock used for ce_bus_dis generation is selected by the RCSEL[3:0] field of Port 7's control register PTCR7. The frame sync used for ce_bus_dis generation is selected by the RFSEL[3:0] field of Port 7's control register PTCR7.

12.3.3.6.1 CE_Bus_dis Signal Generation Limitations

Certain restrictions are in place for the utilization of CE Bus network mode. They are as follows:

- Only early frame syncs are supported.
- CE Bus data transfers only take place in contiguous time slots.
- Only one port can be connected to the CE Bus port at a time.
- CE Bus Network mode can be used for only two ports (Port 7 and one other port)

Transmission of data by CE bus and frame sync generation by the master (CE bus/port) occurs on the same clock edge. This assures a 1/2-bit delay between the moment the RxD lines are switched inside the AUDMUX (as driven by ce_bus_dis) and the moment the receive data is sampled by the serial interface.

12.4 Functional Description

This section provides a complete functional description of the AUDMUX module. Figure 12-1 shows the AUDMUX block diagram.

12.4.1 AUDMUX Ports Overview

There is no functional difference among Ports 1 through 7. The main difference is whether a port is connected to an on-chip serial interface (for example, SSI) or connected to the chip's pads to connect to off-chip serial devices (that is, any 4-wire or 6-wire external SSI, voice, I2S, or AC97 CODEC).

Port 7 can be physically connected to any of the peripherals previously mentioned, as well as the CE Bus. The limitation of connecting CE Bus only at Port 7 is because of data selection in CE bus network mode at Ports 1 to 7. Ports 1 to 6 communicate with CE Bus devices by being configured to connect to Port 7.

All ports can be configured as four- or six-wire interfaces. When configured as a six-wire interface, the additional RFS and RCLK signals of the interface enable the serial interface to be used in asynchronous mode with separate receive and transmit clocks.

All ports have a Tx/Rx switch to provide flexibility in supporting network mode configurations. The Tx/Rx switch enables the transmit and receive data lines to be swapped so that mastership of the serial bus can be passed among multiple external devices connected to a single port.

In addition to supporting the default (point-to-point) normal mode, all ports also support two special types of network mode—internal network mode and CE bus network mode. With internal network mode, a point-to-multipoint network configuration with an arbitrary number of slaves can be supported if the external slaves are put into the high-impedance state (as defined in the SSI network mode protocol) and have pull-up resistors on their TxD contacts. (Alternatively, this can be viewed as requiring a pull-up resistor on the corresponding AUDMUX RxD contact.) With CE bus network mode, a point-to-multipoint network with two slaves can be supported; the slaves do not have to put the TxD line into high-impedance state, and they do not require any pull-up resistors.

Bit clock direction selection enables each port to be configured as a master or slave in the flow.

Possible scenarios include:

- SSI (internal port) drives a voice CODEC and a BT (Blue tooth) CODEC (both on external Port 6) and the Bottom Connector (on external Port 7) simultaneously using network mode. SSI is the master.
- An external processor (external port - Port 5) drives a voice CODEC and a BT CODEC (both on external Port 6) and the Bottom Connector (on Port 7) simultaneously using network mode. The external processor is the master.

12.4.2 Operating Modes

The following terms are used in the descriptions of AUDMUX operating modes:

- Network mode—Time-division multiplexed protocol for sending unique data to multiple devices on a serial bus.
- Internal network mode—Physical bus configuration where multiple serial buses are effectively connected within the AUDMUX via digital logic to create point-to-multipoint connectivity. An arbitrary number of devices are supported. Devices must be put into the high-impedance state as specified by the network mode protocol. TxDATA lines of devices must be pulled high.
- External network mode—Physical bus configuration where multiple serial buses are electrically connected together on a printed circuit board (that is, external to the AUDMUX). Devices must put their TxDATA lines into the high-impedance state as specified by the network mode protocol.
- CE bus network mode—Physical bus configuration where multiple serial buses are effectively connected within the AUDMUX via digital logic in order to create point-to-multipoint connectivity. This mode can only utilize three AUDMUX ports simultaneously. One of the ports must be Port 7. Devices do not have to be put into the high-impedance state, nor do they require pull-up resistors on their TxDATA contacts.

12.4.2.1 Port Receive Data Modes

Each port has logic to select which data lines are used to create the RxD line for the corresponding host interface. Figure 12-6 shows the logic used to create the RxD line for Port 1. This logic has the following modes of operation (as determined by MODE[1:0]):

- Normal mode—see Section 12.4.2.1.1, "Normal Mode" for more information
- CE bus network mode—see Section 12.4.2.1.3, "CE Bus Network Mode" for more information
- Internal network mode—see Section 12.4.2.1.2, "Internal Network Mode" for more information

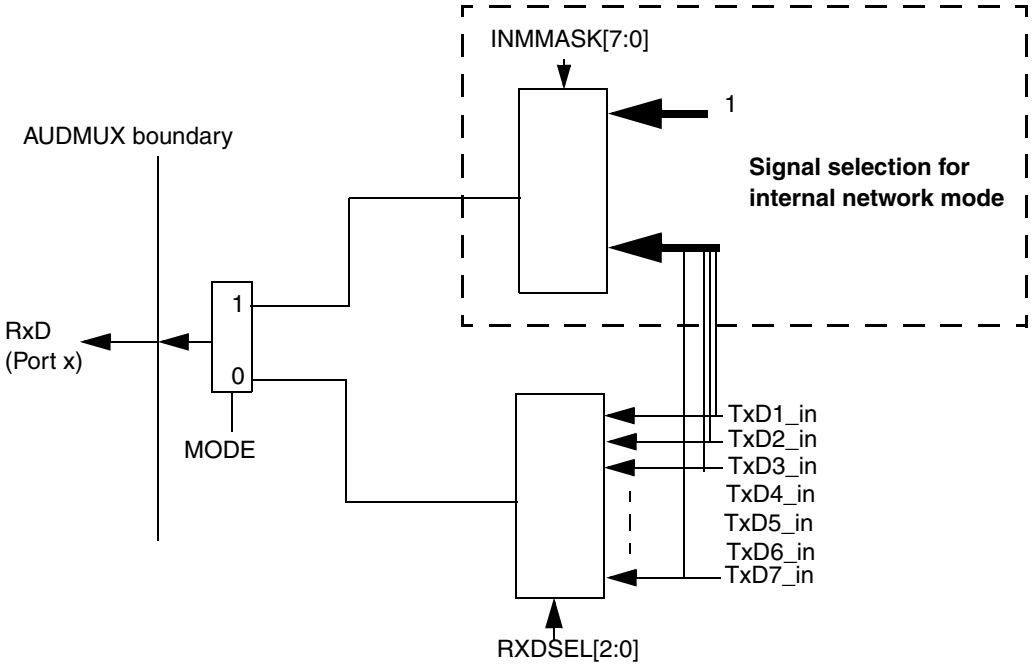

Figure 12-6. Receive Data Logic for Port *n*

12.4.2.1.1 Normal Mode

In normal mode (MODE = 00), the port is connected in a point-to-point configuration (as a master or a slave) and the RXDSEL[2:0] setting selects the transmit signal from any port. In normal mode, any data format can be used (that is, SSI normal mode, SSI network mode, AC-97, and others.

12.4.2.1.2 Internal Network Mode

In internal network mode (MODE = 01), the output of the AND gate is routed (via the output of the port) to the RxD signal of the corresponding host interface. The INMMASK bit vector selects the transmit signals of the ports that are to be connected in network mode. The transmit signals received at the AUDMUX ports (TxDn_in) are ANDed together to form the output. In internal network mode, only one device can be transmitting in its predesignated timeslot and all other transmit signals must remain high (be in high-impedance state and pulled-up). Therefore, non-active signals in the selection will be high and do not influence the output of the AND gate.

Network mode is a protocol where a master SSI is connected to more than one slave SSI device and communication occurs on a time-slotted frame. Though network mode can allow master-slave and slave-slave communication, internal network mode supports only master-slave communication.

There are two scenarios where internal network mode can be used with external network mode:

1. Slave-only devices are attached to an external port.
2. A master device is attached to an external port and all slave devices connected to the same external port are disabled.

NOTE

When internal network mode is enabled at an external port, RXDSEL[3:0] for RxDn_obe selection is ignored and RxD_obe is always driven high (that is, asserted for all timeslots). All slave devices connected to the same port must be disabled.

Internal Network Mode Example 1

SSI_m and SSI_n are used with Port 4 in internal network mode as shown in Figure 12-7. No pull-up resistors are required because the interfaces combined in internal network mode are on-chip interfaces.

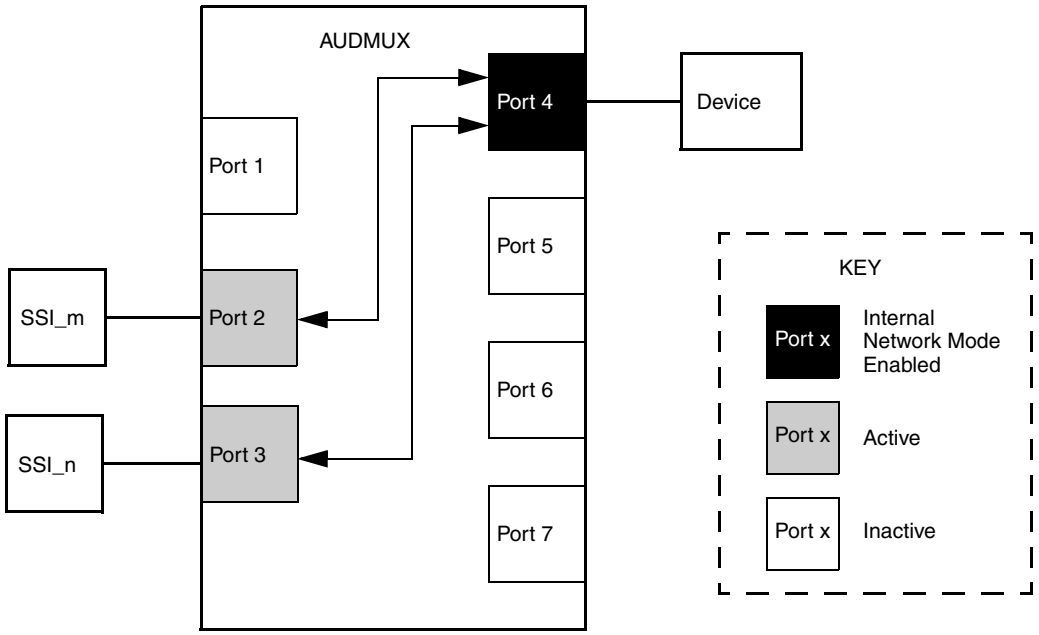

Figure 12-7. Block Diagram For Example 1

See Figure 12-8 for the timing diagram of Example 1. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for SSI_m and SSI_n (as well as their output enables) are shown. The on-chip interfaces drive a logic ‘1’ when their output enables are logic ‘0’. The combined TxDATA line, which is the logical AND of the individual TxDATA lines, is used for Port 4’s TxDATA line.

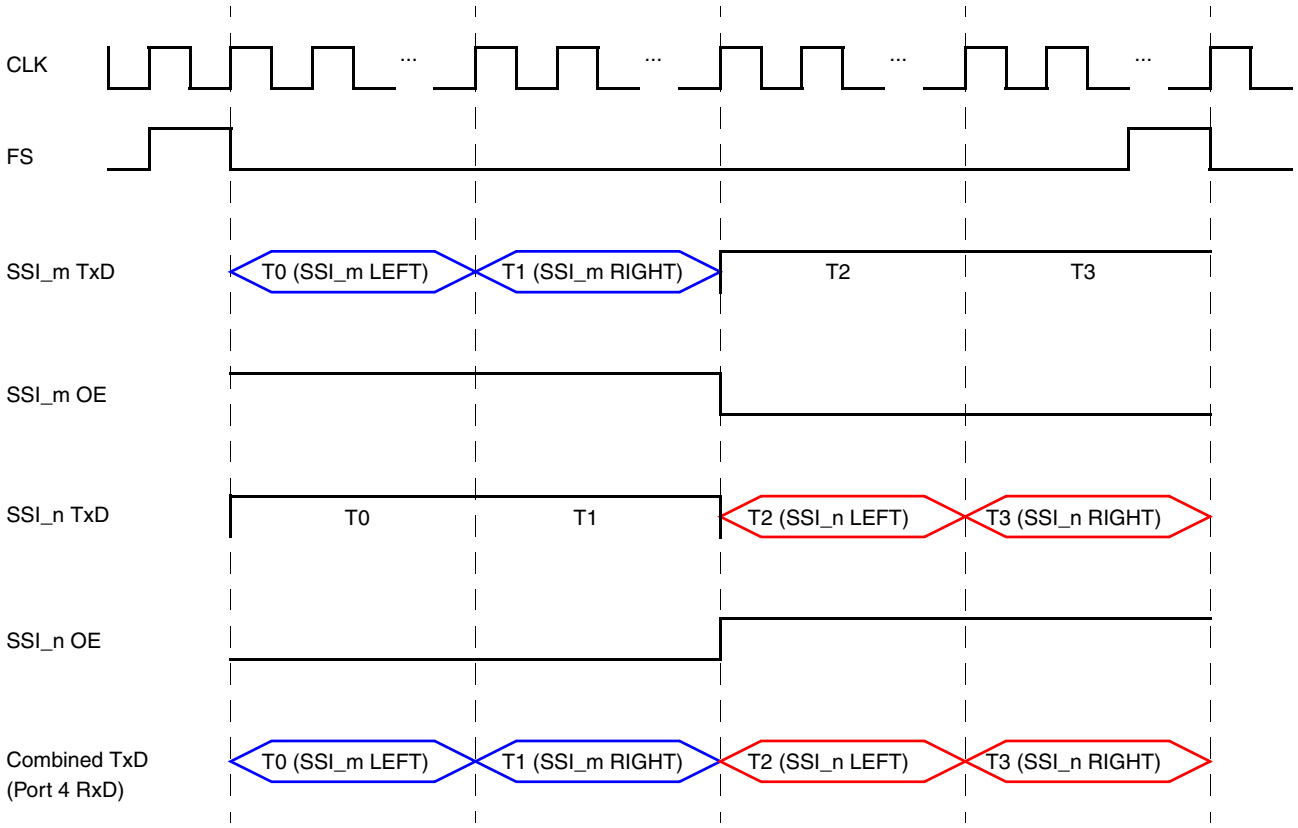

Figure 12-8. Example Using Internal Ports for Transmit Data

Internal Network Mode Example 2

Figure 12-9 shows the case where SSI, port 4, and port 5 are used with port 6 in internal network mode. Port 4 and port 5 are external ports so pull-up resistors are required on the port 4 RxDATA and port 5 RxDATA contacts. This example shows the timing associated with using adjacent timeslots for the SSI, Port 4, and Port 5.

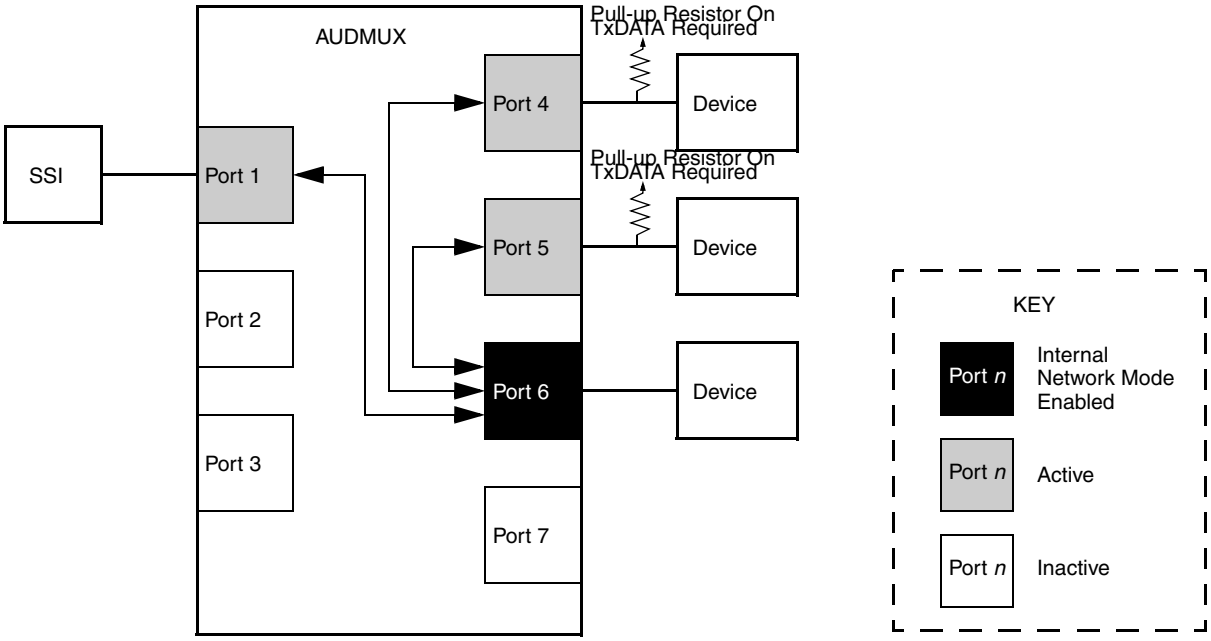

Figure 12-9. Block Diagram for Example 2

The resistance value of the pull-up resistors must be sufficiently high such that a value of 0 can be pulled up to logic 1 within half of a period of the bit clock. The required resistance must be no larger than:

$$R_{max} = 1 / (2 \times f_{bc} \times C)$$

where:

f_{bc} is the frequency of the bit clock

C is the total system capacitance (including capacitance of ICs, board traces, and so on)

Figure 12-10 shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots. Adjacent timeslots are allocated to SSI, port 4, port 5, and port 4, respectively.

The data lines for the SSI, port 4, and port 5 are shown. The SSI transmits a logic 1 when its corresponding output enable is a logic 0. The data lines from port 4 and port 5 at the contact are pulled high by pull-up resistors when they are in the high-impedance state. The data lines from port 4 and port 5 at the AUDMUX are pure digital signals and are constantly driven. The combined TxDATA line, which is the logical AND of the SSI, port 4, and port 5's TxDATA lines, is used for port 6's TxDATA line.

The highlighted areas in Figure 12-10 show the transition time that occurs while a TxDATA line is being pulled high. In this example, this transition time is a maximum of half the period of the serial bit clock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bit clock frequency and system capacitance.

Hysteresis must be enabled at port 4's RxDATA contact and port 5's RxDATA contact to prevent the digital signals created by the contact from toggling rapidly during the pull-up period. The contacts typically require a transition within 25 ns unless hysteresis is enabled. Instead of using hysteresis, one could select

a pull-up resistor sufficiently high to pull-up the signal at the contact within 25 ns; however, that would result in a higher resistance value and higher current drain.

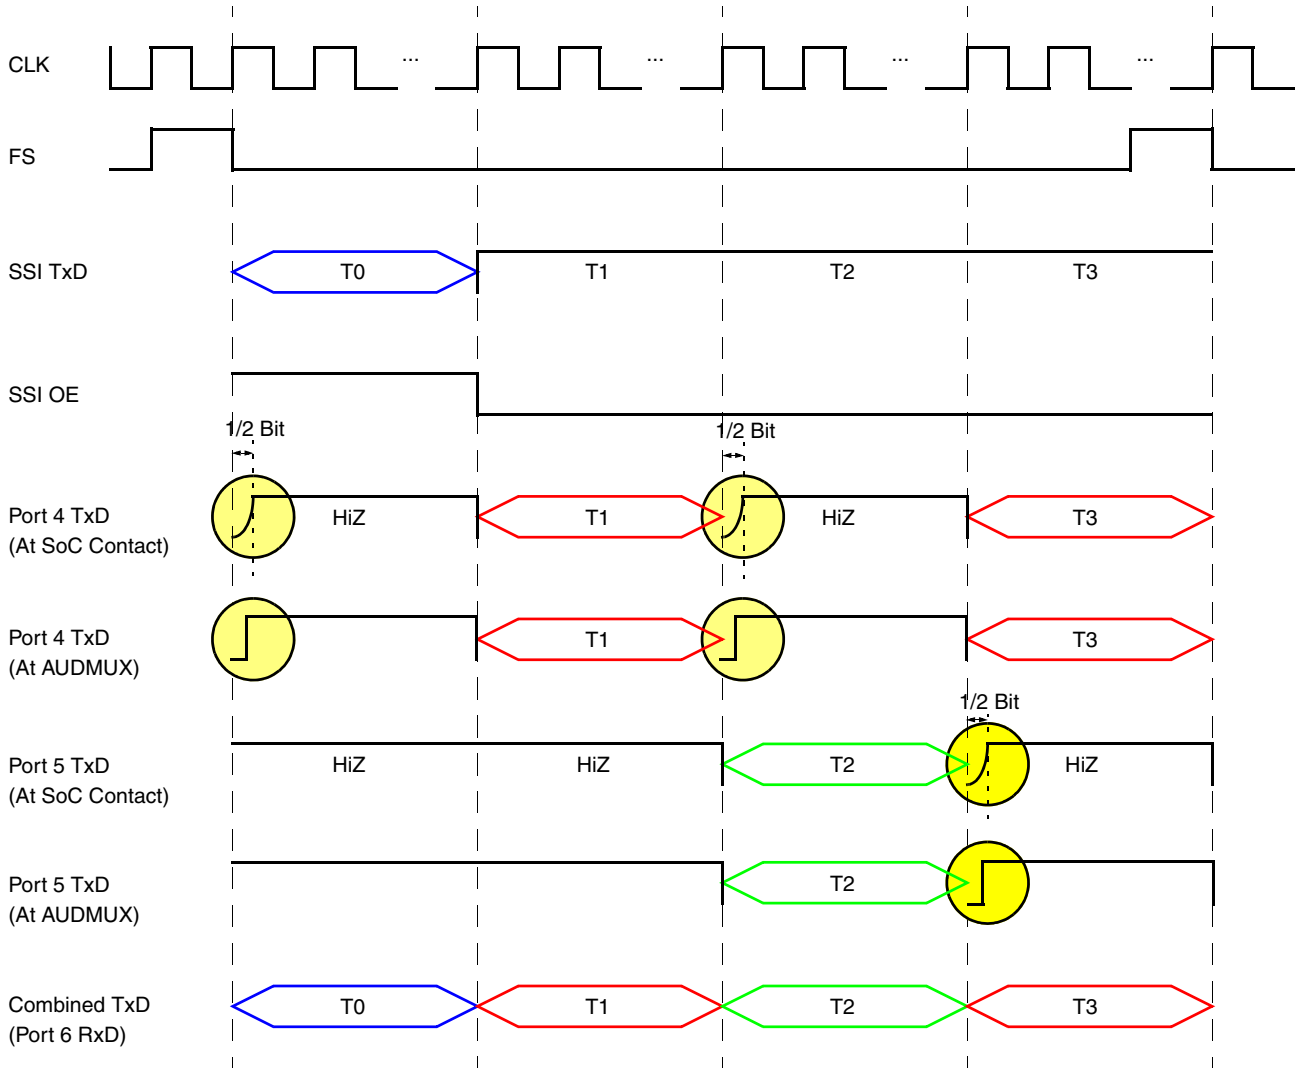

Figure 12-10. Example Using External Ports for Transmit Data in Consecutive Timeslots

Internal Network Mode Example 3

Figure 12-11 shows the case where SSI and port 4 are used with port 6 in internal network mode. Since port 4 is an external port, a pull-up resistor is required on the port 4 TxDATA contact. This example shows the timing associated with inserting empty timeslots after the timeslots have been used by external ports.

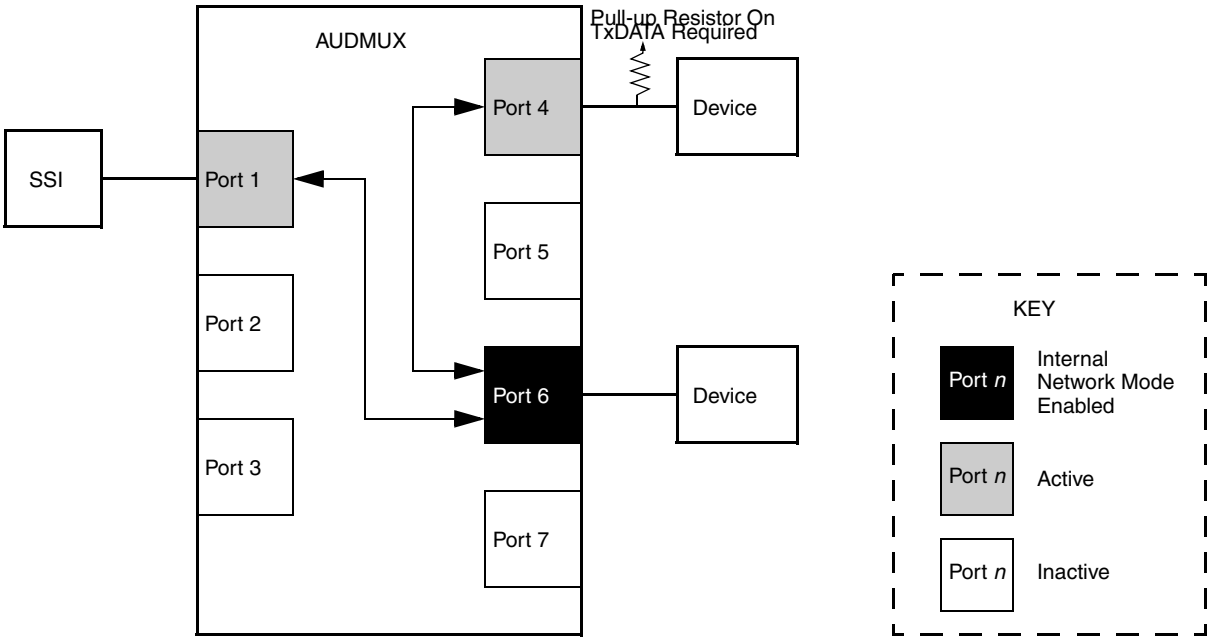

Figure 12-11. Block Diagram for Example 3

The resistance value of the pull-up resistor must be sufficiently high such that a logic 0 can be pulled up to logic 1 by the time that the next occupied timeslot occurs. This allows a much weaker pull-up to be used as compared to Example 2. The required resistance must be no larger than:

$$R_{max} = (4 \times n + 1) / (2 \times f_{bc} \times C)$$

where:

n is the number of bits per timeslot

f_{bc} is the frequency of the bit clock

C is the total system capacitance (ICs, board traces, and so on)

Figure 12-12 shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots. In this example, empty timeslots are inserted after the timeslots have been used by external ports.

The data lines for the SSI and Port 4 are shown. The SSI transmits a logic 1 when its corresponding output enable is a logic 0. The data line from Port 4 at the contact is pulled high by a pull-up resistor when they are in the high-impedance state. The data line from Port 4 at the AUDMUX is a pure digital signal and is constantly driven. The combined TxDATA line, which is the logical AND of the SSI and Port 4's TxDATA lines, is used for Port 6's RxDATA line.

The highlighted areas in Figure 12-12 show the transition time that occurs while port 4's TxDATA line is being pulled high. In this example, this transition time is a maximum of two timeslots plus 1/2 the period of the serial bit clock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bit clock frequency and system capacitance.

Hysteresis must be enabled at port 4's RxDATA contact to prevent the digital signal created by the contact from toggling rapidly during the extended pull-up period. The contacts typically require a transition within 25 ns unless hysteresis is enabled.

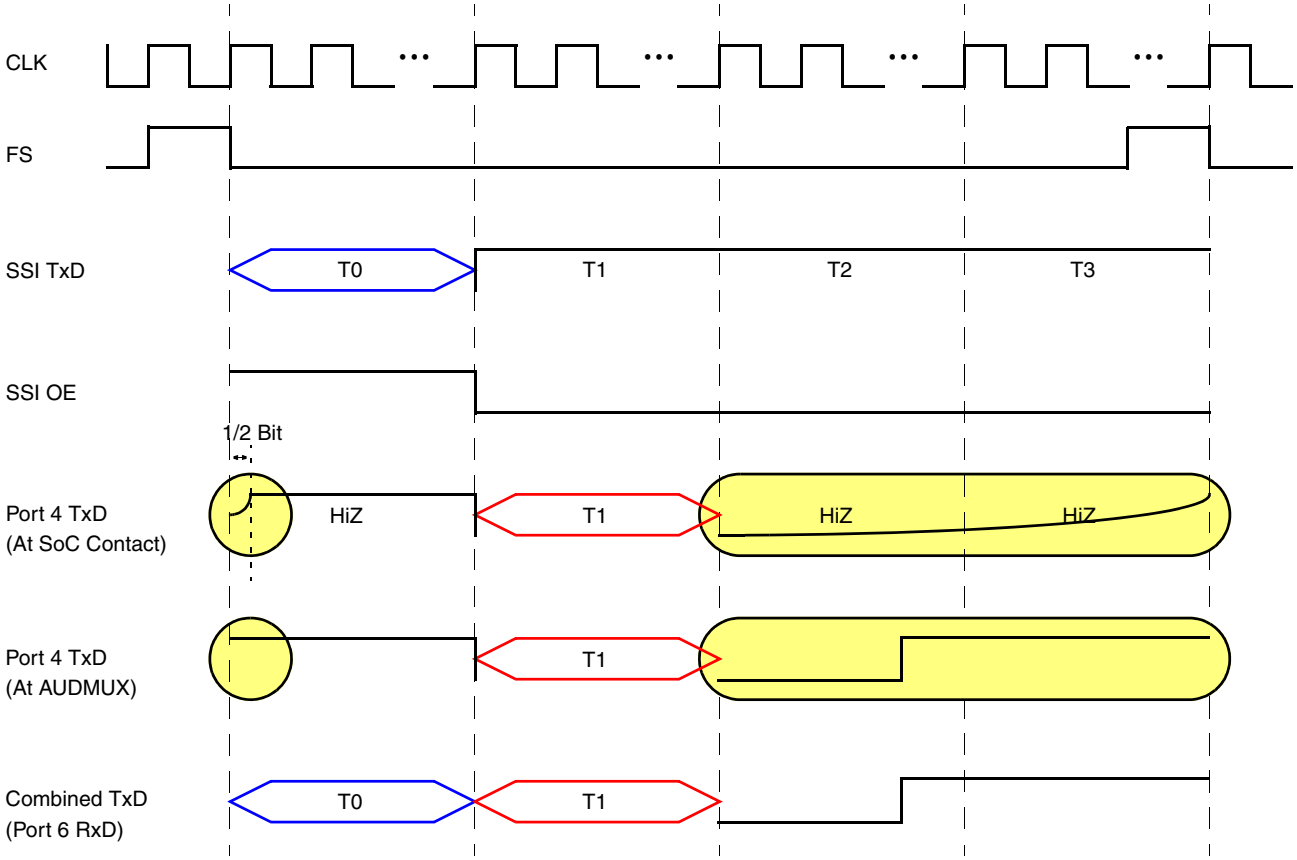

Figure 12-12. Example Using External Ports for Transmit Data In Nonconsecutive Timeslots

12.4.2.1.3 CE Bus Network Mode

To support network mode with devices connected to CE bus, a special network mode has been added. In CE bus network mode (MODE[1:0] = 10), a 2 × 1 multiplexer is used to synchronously switch between two ports (that is, network slaves) as determined by a signal called ce_bus_dis, which is generated by the AUDMUX. CE bus network mode supports switching between two ports. One of the ports is the CE bus port (Port 7) and the other port is selected by RXDSEL[2:0]. In contrast to internal network mode, external ports do not require pull-up resistors, as the CE bus network mode logic switches data lines according to the timeslot timing.

ce_bus_dis Signal Generation

The AUDMUX uses clock and frame sync timing to generate the ce_bus_dis signal (and thus drive the synchronous multiplexer used in CE bus network mode). The CE bus controls a contiguous block of timeslots. In addition, each timeslot is controlled by one of the two ports. For example, Port 7 (CE bus) could transmit in timeslots 1-2 and Port 6 could transmit in timeslots 0 and 3.

If the CEN bit is set, the ce_bus_dis signal generation logic is enabled. Otherwise, the signal generation logic is disabled and the ce_bus_dis signal remains low.

The CNTLOW[7:0] field controls the number of bit clock periods for which the ce_bus_dis signal is held low. This establishes the length of the CE Bus port's timeslot(s).

The CNTHI[7:0] field controls the number of bit clock periods for which the ce_bus_dis signal is held high after frame sync detection. This establishes the number of bits between the frame sync detection and the start of the CE bus port's timeslot(s). The internal counter used to determine the deassertion of the ce_bus_dis signal is reset on every frame sync. This assures that the number of bit clock periods during which the ce_bus_dis signal is held high after the assertion of frame sync is always correct.

The Port 7 control register PTCR7 selects the frame sync used to generate the ce_bus_dis signal. If the SYN bit is set, then frame sync is determined by the TFSDIR and TFSEL[3:0] fields of PTCR7. If the SYN bit is clear (that is, Port 7 is 6-wire), then TxFS is determined by the TFSDIR and TFSEL[3:0] and the RxFS is determined by the RFSDIR and RFSEL[3:0] fields.

Similarly, the Port 7 control register PTCR7 determines the bit clock used for counting the low and high periods of the ce_bus_dis signal. If the SYN bit is set, then the bit clock is determined by the TCLKDIR and TCSEL[3:0] fields of PTCR7. If the SYN bit is clear (that is, Port 7 is 6-wire), then TxCLK is determined by the TCLKDIR and TCSEL[3:0] and the RxCLK is determined by RCLKDIR and RCSEL[3:0] fields of PTCR7.

The FSPOL and CLKPOL fields of the CNMCR determine the frame sync and bit clock polarities used for frame sync detection. Different scenarios with combinations of frame sync and bit clock polarities are shown in Figure 12-13, Figure 12-14, Figure 12-15, Figure 12-16, and Figure 12-17. For all these scenarios, CEN is set to 1. In RxD*n*_in, *n* can be any number from 1 and 6.

The CE bus network mode control register CNMCR is used to control the generation of the ce_bus_dis signal. See Section 12.3.3.6, "CE Bus Network Mode Control Register (CNMCR)," for complete details on the CNMCR.

12.4.2.2 Transmit Data Output Enable Assertion

The TxDATA line from the internal network mode master (connected at any internal port) is put into the high-impedance state at the contact depending upon the assertion or negation of TxD_obe. Its corresponding output enable is generated by the network mode master.

In the case of an external network mode master (connected at an external port), the corresponding TxD_obe is always asserted after the port data register configuration.

12.4.2.3 Tx/Rx Switch and External Network Mode

External network mode is the traditional network mode connection. It is called external network mode to differentiate from the internal network mode. In external network mode, devices are connected to a single external port in a star or multi-drop configuration.

In network mode, there can be only one master (driving the frame sync and clock source) with the other devices configured in normal slave mode or network slave mode. Unlike internal network mode, both master-slave and slave-slave communication can take place in external network mode. CODEC devices transmit on a single timeslot while processor serial interfaces (that is, SSI) can process more than one timeslot of data while in network master or slave mode.

Figure 12-18 shows the Tx/Rx data switch. RxD_obe is the output buffer enable signal and RxD_out is the data transmit signal from the serial interface. The TxD_in signal is the receive data signal going towards the RXDSEL multiplexers of all ports.

D_TxRx is the data contact that serves as the chip-level transmit data contact when the TxRx switch is not enabled. D_RxTx is the data contact that serves as the chip-level receive data contact when the TxRx switch is not enabled. The roles of these contacts are reversed when the TxRx switch is enabled.

When TXRXEN is disabled (TXRXEN=0), RxD_out is routed to D_TxRx and D_RxTx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Db_obe.

When the Tx/Rx switch is enabled (TXRXEN=1), RxD_out is routed to D_RxTx and D_TxRx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Da_obe.

If the RXDSEL*n*[2:0] field for any port *n* is configured to select data from an internal port, the output buffer enable is selected by RXDSEL*n*[2:0] and is routed to Da*n*_obe / Db*n*_obe. In the case when the RXDSEL*n*[2:0] field for port *n* is configured to select data from an external port, the output buffer enable is always high and routed to Da*n*_obe / Db*n*_obe, depending on the TXRXEN*n* switch configuration.

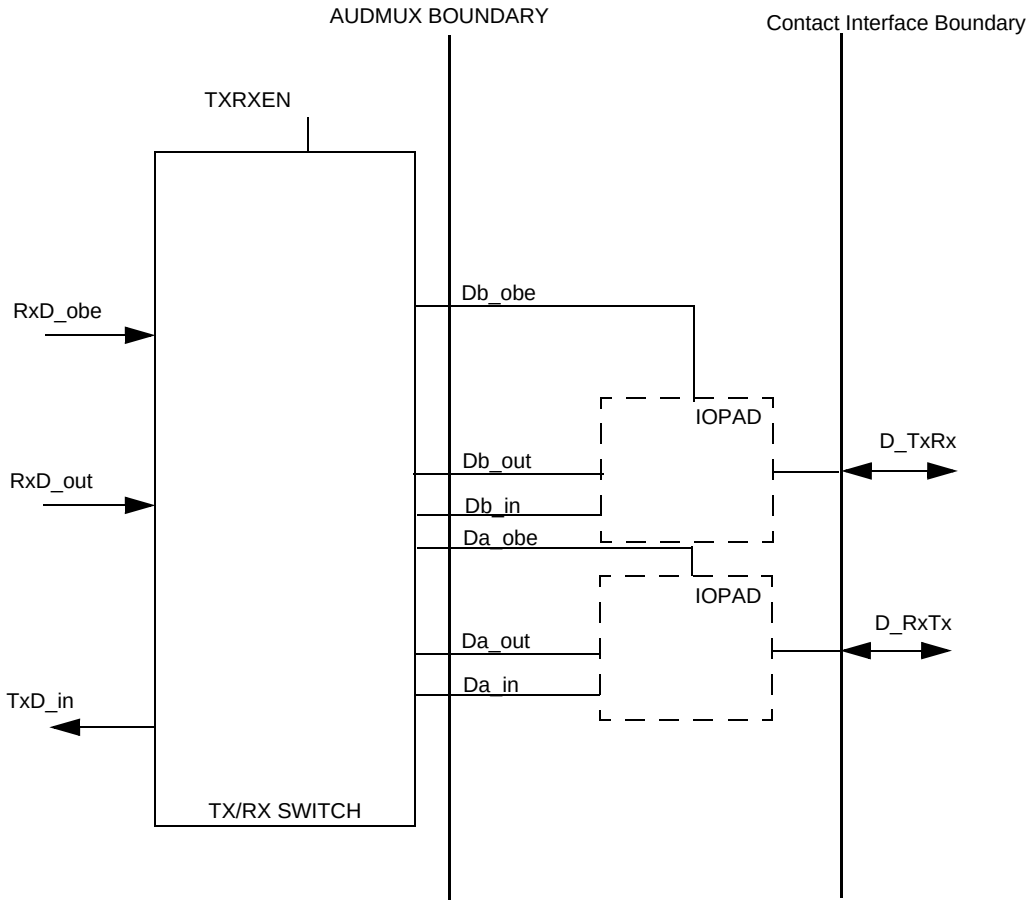

Figure 12-18. Tx/Rx Switch

12.4.2.4 Timing Modes

The AUDMUX ports are constructed as 6-wire interfaces. However, they can be used either in synchronous or asynchronous modes as determined by the SYN bit.

12.4.2.4.1 Synchronous Mode (4-Wire Interface)

In synchronous mode, the port has a 4-wire interface (that is, RxD, TxD, TxCLK, TxFS). The receive data timing is determined by TxCLK and TxFS.

As shown in Figure 12-19, port *n* signals can be routed to port *m*, producing 6-wire to 4-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are the input frame sync and bit clocks from the serial interface (port *n*) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

The TFS_out and TCLK_out are selected at port *n* by the TFSEL and TCSEL multiplexer settings, respectively. RFS_out and RCLK_out are selected at port *n* by the RFSEL and RCSEL multiplexer settings, respectively. Similarly, in the external direction, port *m* is configured as a 4-wire port; TFSEL selects the FS_obe and FS_out signals. In this mode, the configuration of RFSEL and RCSEL is not used, since the RFS_out and RCLK_out contacts at port *m* are not available.

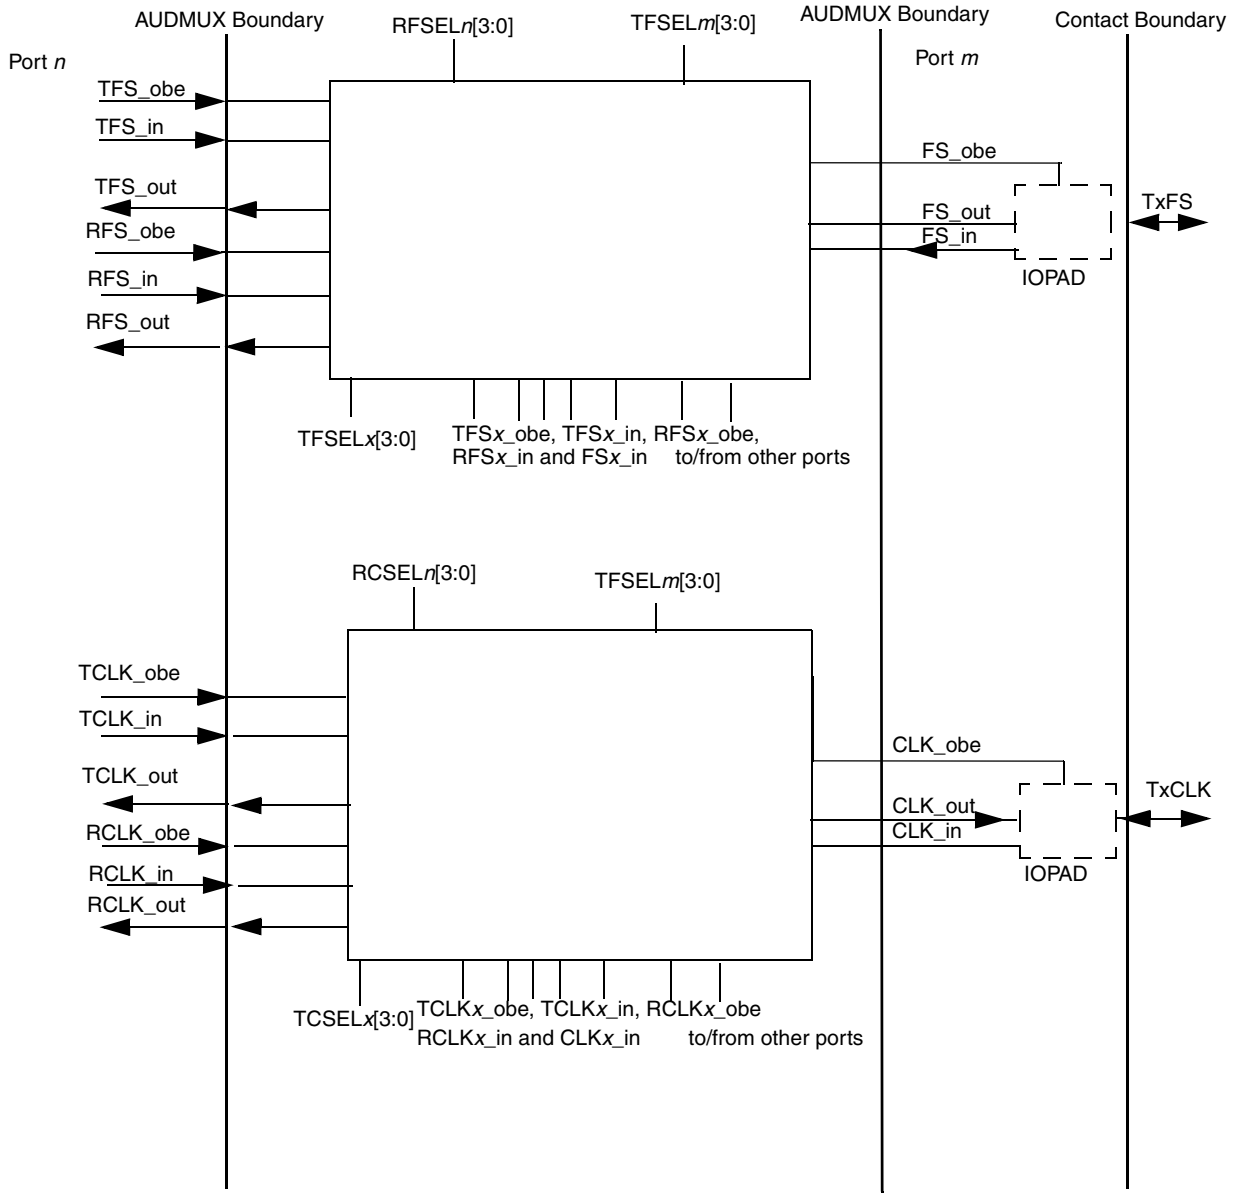

Figure 12-19. Frame Sync and Clock Routing When External Port Is 4-Wire

12.4.2.4.2 Asynchronous Mode (6-Wire Interface)

In asynchronous mode, the port has a 6-wire interface (including RxD, TxD, TxCLK, TxFS, RxCLK, and RxFS). This mode has additional receive clock (RxCLK) and frame sync (RxFS) signals as compared to the synchronous or 4-wire interface.

As shown in Figure 12-20 and Figure 12-18, port *n* signals can be routed to port *m*, producing 6-wire to 6-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are input frame sync and bit clocks from the serial interface (port *n*) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

TFS_out and TCLK_out are selected by the TFSEL and TCSEL multiplexer settings, respectively. RFS_out and RCLK_out are selected by the RFSEL and RCSEL multiplexer settings, respectively. Similarly, in the external direction, the TFSEL selects the TxFS_obe and TxFS_out signals and TCSEL selects the TxCLK_obe and TxClk_out signals. The RFSEL selects the RxFS_obe and RxFS_out signals and RCSEL selects the RxCLK_obe and RxCLK_out signals.

NOTE

Since FS_in and CLK_in from external interfaces are also routed to the TFSEL and TCSEL multiplexers of the external ports, respectively, these signals do not have corresponding buffer enable signals. Consequently, their corresponding inputs to the TFSEL and TCSEL multiplexer of the external ports have to be tied high.

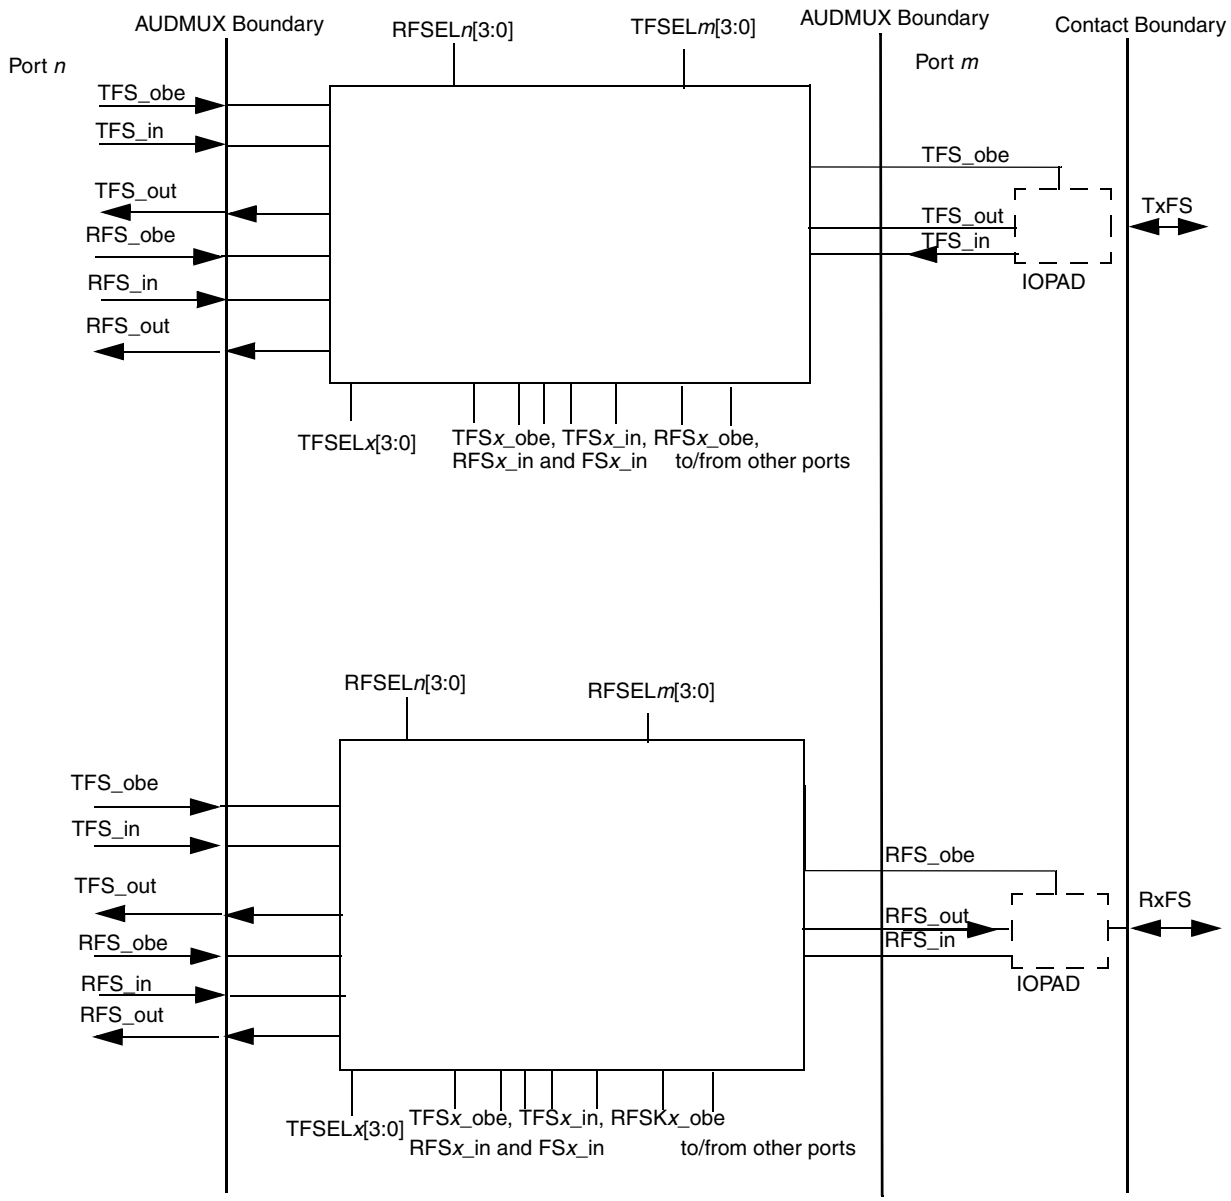

Figure 12-20. Frame Sync Routing When External Port Is 6-Wire

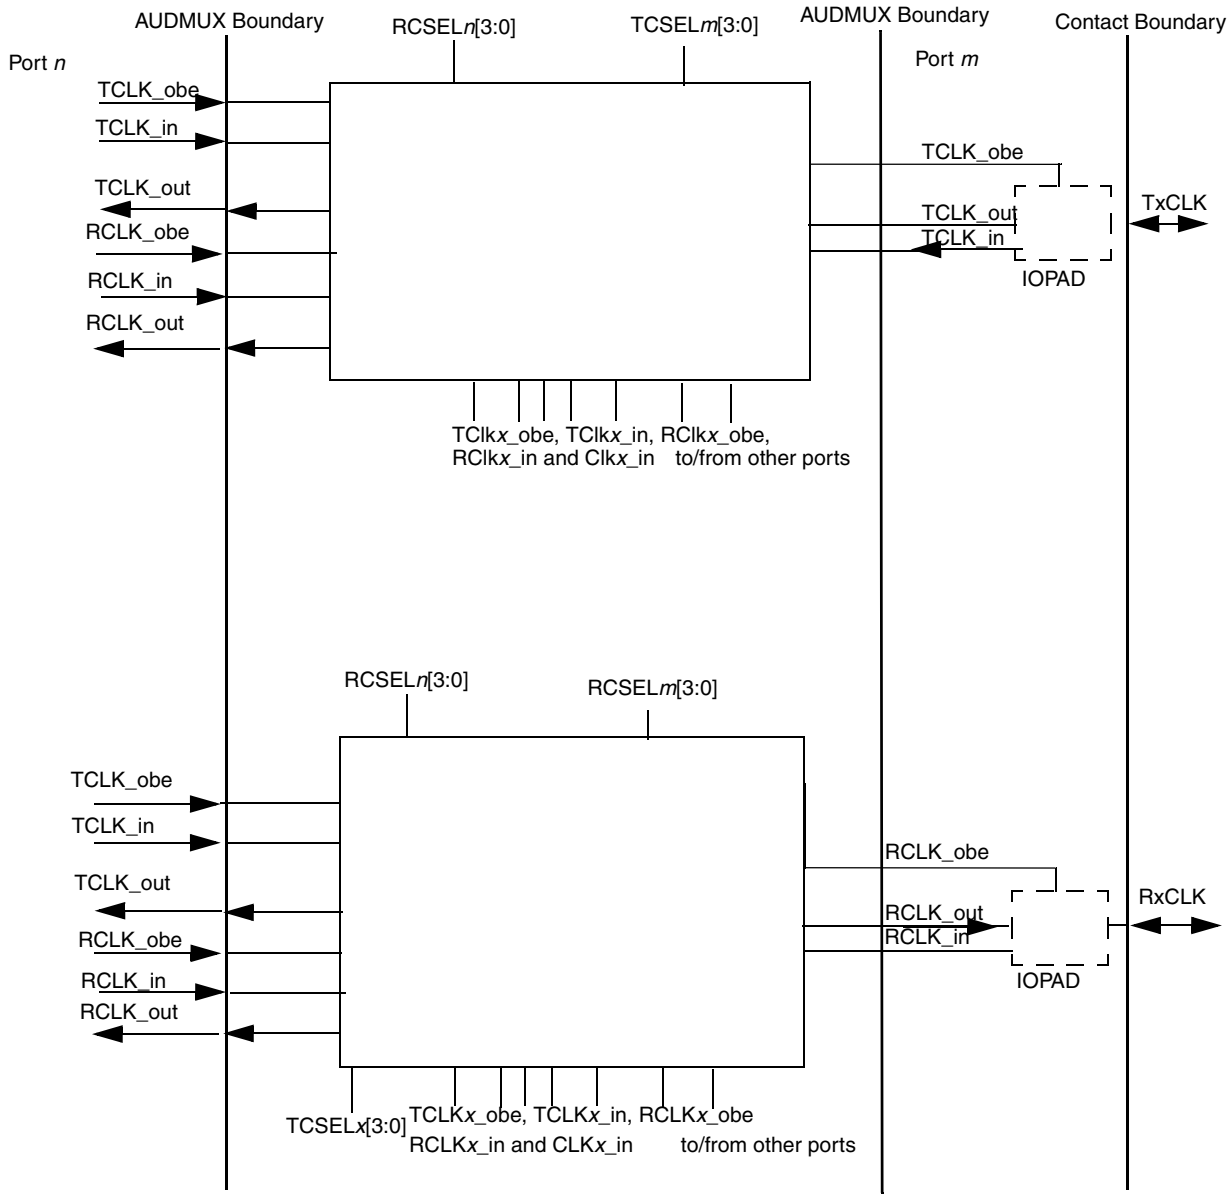

Figure 12-21. Clock Routing When External Port Is 6-Wire

12.4.3 AUDMUX Default Configuration

The AUDMUX reverts back to its default settings following a reset. Section 12.4.3.1, "Default Port Configuration," and Section 12.4.3.2, "Default CE Bus Configuration" describes the default configuration of the ports and CE Bus, respectively.

12.4.3.1 Default Port Configuration

After a reset, each port defaults to normal mode (PDCR*n*[MODE] = 00) with synchronous timing mode (PTCR*n*[SYN] = 1) enabled.

The default port-to-port connections are as follows:

- Port 1 to Port 6
  - Port 6 provides the clock and frame sync.
- Port 2 to Port 5
  - Port 5 provides the clock and frame sync.
- Port 3 to Port 4
  - Port 4 provides the clock and frame sync.
- Port 7 to Port 7 (in data loopback mode)
  - Clock and frame syncs are inputs.

12.4.3.2 Default CE Bus Configuration

The default configuration of all the ports is to set the MODE field to normal mode (that is, no port selects CE Bus network mode). Correspondingly, the default configuration of the CEN field in the CNMCR is clear. To minimize AUDMUX setup for audio testing, the rest of the CNMCR fields default to the following configuration:

- FSPOL is set.
- CLKPOL is set.
- CNTHI is set to 16.
- CNTLOW is set to 16.

This configuration uses a frame sync that is logic high when asserted.

The clock is driven by the transmitter on the rising edge and is sampled by the receiver on the falling edge. The AUDMUX switches between devices on the rising edge; this provides a buffer of one-half clock period between the moment data is sampled and when the AUDMUX switches between devices. See Figure 12-16 for a timing diagram where FSPOL and CLKPOL are both set.

CNTHI and CNTLOW are set to 16 to allow CE Bus to drive data during timeslot 1 and the other device to drive data during timeslots 0, 2, …, N-1 where N is the number of timeslots used and each timeslot has 16 bits.

12.4.4 Connectivity Between Ports

Four basic types of connections are provided by the AUDMUX:

- Internal port to external port
- External port to external port
- Internal port to internal port
- Loopback

12.4.4.1 Internal Port to External Port Connectivity

The internal port is connected to a processor's serial interface. TxD_obe is the buffer enable signal from the serial interface, TxD_in is the input transmit data from the serial interface to the AUDMUX, and RxD_out is the receive data output from the AUDMUX to the serial interface.

RXDSEL[2:0] of the external port selects the buffer enable signal (TxD_obe) and transmit data output (TxD_out) signal from the TxD_obe and RxD_in signals. RXDSEL[2:0] is a common signal to both selection MUXes.

NOTE

Since buffer TxD_in signals from external interfaces do not have corresponding buffer enable signals, their buffer enable signals into the selection multiplexer are tied high. This ensures that selection of TxD_in, as RxD_out also drives the RxD_obe output high.

Transmit Data from the serial interface goes into the RXDSEL data multiplexer and comes out as RxD_out. RxD_out is routed to Da_TxRx when TXRXEN is disabled and to D_RxTx when TXRXEN is enabled. Similarly, D_RxTx is routed to TxD_in when TXRXEN is disabled and D_TxRx is routed to TxD_in when TXRXEN is enabled. The routing of frame syncs is shown in Figure 12-20 and the routing of interface clocks is shown in Figure 12-18.

If internal network mode is disabled, then RXDSEL selects the TxD_in, which is sent from the AUDMUX to the serial interface connected at port *n*. When the internal network mode is selected, RxD_out is constructed by ANDing selected TxD_in signals from the ports (as determined by INMMASK).

If there is more than one device attached to the external port at D_TxRx and D_RxTx and one of the devices is a network master, then following conditions must be observed:

1. When the external master is enabled in network mode, then the serial interface at port *n* must be configured as a slave (normal or network mode). No Tx/Rx switching is required.
2. When the external master is disabled and the serial interface at port *n* and other slave devices must communicate, then the serial interface at port *n* must be configured as a network mode master and the Tx/Rx switch at port *m* must be enabled (TXRXEN=1). This ensures that the transmit and receive paths are connected appropriately.

To communicate with more than one port, internal network mode can be enabled at port *n*. In internal network mode, it is possible to communicate with any device attached to the other ports. Internal network mode shall be enabled at the port that is the SSI network mode master.

It is also possible for a port to communicate with two (and only two) ports by enabling CE Bus network mode at Port *n*. It is then possible to communicate with any device attached to two enabled ports; one of which is Port 7 and the other is selected by RXDSEL*n*[2:0]. CE Bus network mode is enabled at the port that is the SSI network mode master.

12.4.4.2 External Port to External Port Connectivity

External ports can communicate with external ports directly. External ports can communicate together in the following ways:

1. Each port's receive logic is configured in normal mode (MODE = 00). Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 01). All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. Since an external port is being used as the internal network mode master, all other devices on the same AUDMUX port as the internal network mode master must be disabled. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.
3. One port is configured in CE Bus network mode (MODE[0:1] = 10) to receive and/or transmit data from and to the CE Bus connected to Port 7 and one other port. The ce_bus_dis signal is generated by the AUDMUX depending upon the CNMCR register configuration. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any of the three ports can be the master.

12.4.4.3 Internal Port to Internal Port Connectivity

Internal ports can communicate with other internal ports directly, thereby providing a means for synchronous interprocessor communication. Internal ports can communicate together in three ways:

1. Each port's receive logic is configured in normal mode (MODE = 00). Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 01). All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.
3. One port is configured in CE Bus network mode (MODE[0:1] = 10) to receive and/or transmit data from and to the CE Bus connected at Port 7 and one other port. The ce_bus_dis signal is generated by the AUDMUX depending upon the CNMCR register configuration. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any of the three ports can be the master.

12.4.4.4 Loopback Connectivity

AUDMUX ports can communicate with themselves in order to provide loopback functionality. Port *n* can route its TxDATA signal to its own RxD_out signal by setting RXDSEL*n*[2:0] to its own port number. This is supported by all ports in the AUDMUX.

In addition, ports can provide loopback support in internal network mode as well as CE Bus network mode. With internal network mode, the internal network mode master can loop its TxDATA signal (combined with those of other ports, if desired) back into its RxD_out signal. Port *n*'s INMMASK must be set such that bit (*n* - 1) is clear in order to enable the loopback.

With CE Bus network mode, the CE Bus network mode master can loop its TxDATA signal (combined with CE Bus's TxDATA) back into its RxD_in signal. RXDSEL*n*[2:0] must be set to select port *n*.

12.4.5 AUDMUX Clocking

This section provides information about AUDMUX clocking including clock inputs and the clock diagram.

12.4.5.1 AUDMUX Clock Inputs

The IP Bus read/write clock— peripheral clock—is an input to the AUDMUX. It is used for all AUDMUX register accesses. It is driven only when there is an AUDMUX access on the IP bus.

The AUDMUX uses the selected Tx/Rx bit clock to drive the synchronous switching of the CE Bus Network mode. Specifically, this clock is used to drive the ce_bus_dis signal generation logic. The bit clock used for this function can come from either internal serial interfaces or external codecs. The clock used for CE bus network mode is determined by PTCR7. See "ce_bus_dis Signal Generation" for more details of the clock selection for CE bus network mode.

12.4.5.2 AUDMUX Clock Diagram

Figure 12-22 shows the clocking used in the AUDMUX.

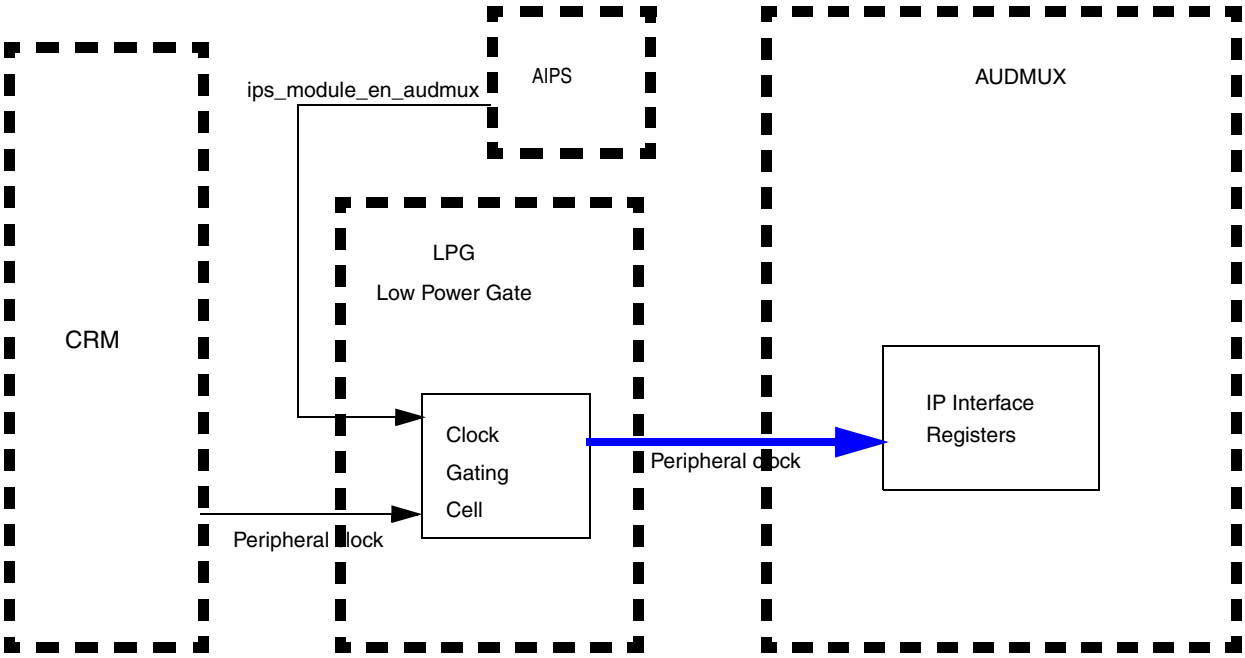

Figure 12-22. AUDMUX Clocking Scheme

12.4.5.3 Clocking Restrictions

Since the AUDMUX requires only peripheral clock, the AUDMUX places no restrictions on the bus frequency. All registers in the AUDMUX are control registers so their values do not change frequently. Their values are programmed when changing between use cases (not during use cases).

Chapter 13
ARM1136JF-S Interrupt Controller (AVIC)

The ARM1136JF-S interrupt controller (AVIC) is a 32-bit peripheral which collects interrupt requests from up to 64 sources and provides an interface to the ARM1136JF-S core. The simplified block diagram of the AVIC is shown in Figure 13-1.

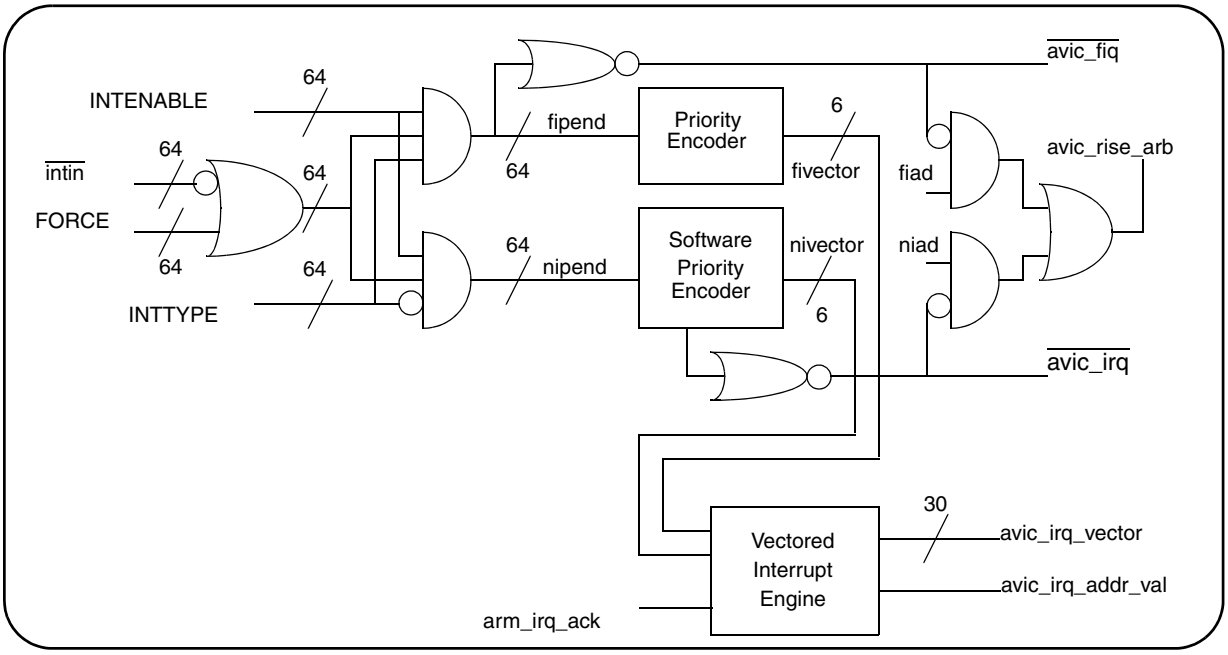

Figure 13-1. AVIC Block Diagram

13.1 Overview

The AVIC includes hardware acceleration of normal interrupts. The AVIC also includes software controlled priority levels for normal interrupts. The following sections describe the operation and configuration of the AVIC.

13.1.1 Features

The AVIC performs the following functions:

- Supports up to 64 interrupt sources
- Supports fast and normal interrupts
- Selects normal or fast interrupt request for any interrupt source
- Supports hardware accelerated vectoring to service routines for all normal interrupts

- Indicates pending interrupt sources via a register for normal and fast interrupts
- Indicates highest priority interrupt number via register (can be used as a table index)
- Independently enable or disable any interrupt source
- Provides a mechanism for software to schedule an interrupt
- Provides integrated vector table for hardware acceleration of normal interrupt service routine entry
- Supports up to 16 software controlled priority levels for normal interrupts and priority masking
- Single-bit disabling of all normal interrupts and of all fast interrupts, used in enabling of secure operations

13.1.2 Modes of Operation

The interrupt controller consists of a set of control registers and associated logic to perform interrupt masking, priority support, and hardware acceleration of normal interrupts.

The interrupt source registers (INTSRCH / INTSRCL) are a pair of 32-bit status registers with a single interrupt source associated with each of the 64 bits. An interrupt line or set of interrupt lines are routed from each interrupt source to the INTSRCH or INTSRCL register. This allows up to 64 distinct interrupt sources in an implementation. Interrupt requests may be forced to be asserted by way of the interrupt force registers (INTFRCH / INTFRCL). Each bit in this register is logically “OR-ed” with the corresponding hardware request line prior to feeding the INTSRCH or INTSRCL register inputs.

There is a corresponding set of interrupt enable registers (INTENABLEH / INTENABLEL), also 32 bits wide, which allow individual bit masking of the INTSRCH / INTSRCL registers. There is also a corresponding set of interrupt type registers (INTTYPEH / INTTYPEL) which select whether an interrupt source will generate a normal or fast interrupt to the ARM1136JF-S core.

There is a corresponding set of normal interrupt pending registers (NIPNDH / NIPNDL) which indicate pending normal interrupt requests. These registers are equivalent to the logical AND of the interrupt source registers (INTSRCH / INTSRCL), the interrupt enable registers (INTENABLEH / INTENABLEL), and the NOT of the interrupt type registers (INTTYPEH / INTTYPEL) (see Figure 13-1). The NIPNDH / NIPNDL register bits are bit-wise “NOR-ed” together to form the nIRQ signal routed to the ARM1136JF-S core. This core input signal is maskable by the normal interrupt disable bit (I bit) in the processor status register (CPSR). The normal interrupt vector register (NIVECSR) indicates the vector index of highest priority pending normal interrupt.

There is a corresponding set of fast interrupt pending registers (FIPNDH / FIPNDL) which indicate pending fast interrupt requests. These registers are equivalent to the logical AND of the interrupt source registers (INTSRCH / INTSRCL), the interrupt enable registers (INTENABLEH / INTENABLEL), and the interrupt type registers (INTTYPEH / INTTYPEL) (see Figure 13-1). The FIPNDH/FIPNDL register bits are bit-wise “NOR-ed” together to form the nFIQ signal routed to the ARM1136JF-S core. This core input signal is maskable by the fast interrupt disable bit (F bit) in the CPSR. The fast interrupt vector register (FIVECSR) indicates the vector index of highest priority pending fast interrupt.

The AVIC includes hardware acceleration of normal interrupt service routine entry. If enabled and a normal interrupt occurs, the ARM1136JF-S core will use the integrated vector table and the ARM1136JF-S’s VIC interface to quickly jump to the interrupt service routine.

All interrupt controller registers are readable and writable in privileged mode only. Writes attempted to read-only registers are ignored. These registers can only be modified using 32-bit writes.

The INTFRCH/INTFRCL registers are provided for software generation of interrupts. By enabling interrupts for these bit positions, software can force an interrupt request. This register can also be used to debug hardware interrupt service routines by providing an alternate method of interrupt assertion.

The interrupt requests are prioritized in the following sequence:

1. Fast interrupt requests, in order of highest number
2. Normal interrupt requests, in order of highest priority level, then highest source number with the same priority

The AVIC provides 16 software controlled priority levels for normal interrupts. Every interrupt can be placed in any priority level. The AVIC also provides a normal interrupt priority level mask (NIMASK) which disables any interrupt with a priority level lower than or equal to the mask. If a level 0 normal interrupt and a level 1 normal interrupt are asserted at the same time, the level 1 normal interrupt is selected, assuming that NIMASK has not disabled level 1 normal interrupts. If two level 1 normal interrupts are asserted at the same time, the level 1 normal interrupt with the highest source number is selected, also assuming that NIMASK has not disabled level 1 normal interrupts.

13.2 Memory Map and Register Definition

The AVIC module has 26 registers. All of these registers are single-cycle access as the AVIC sits on the native bus of the ARM1136JF-S core. Section 13.2.3, “Register Descriptions,” provides the detailed descriptions for all of the AVIC registers.

13.2.1 Memory Map

Table 13-2 shows the AVIC memory map.

13.2.2 Register Summary

Figure 13-2 shows the key to the register fields and Table 13-3 shows the register figure conventions.

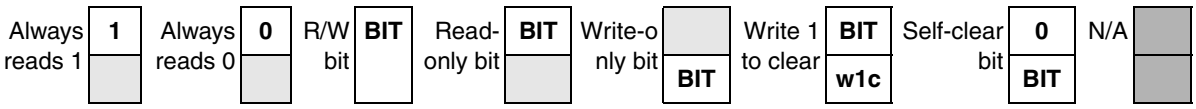

Figure 13-2. Key to Register Fields

Table 13-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

13.2.3 Register Descriptions

This section contains the detailed register descriptions for the AVIC registers.

13.2.3.1 Interrupt Control Register

The interrupt control register (INTCNTL), shown in Figure 13-3, controls the hardware acceleration done by the AVIC. Both normal interrupts and fast interrupts can be enabled to jump directly to the interrupt service routine.

This register is located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. This register can be only modified using 32-bit writes.

0x6800_0000 (INTCNTL) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	ABFLAG	ABFEN	0	NIDIS	FIDIS	NIAD	FIAD	NM	0	0
W							w1c

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 13-3. Interrupt Control (INTCNTL) Register

Table 13-5 provides field descriptions for the INTCNTL register.

Table 13-5. INTCNTL Register Field Descriptions

Field	Description
31–26	Reserved
25 ABFLAG	Core Arbitration Prioritization Risen Flag. This status bit indicates that the AVIC is asserting the avic_rise_arb signal to raise the priority level of the ARM core in the bus arbitration logic. This signal is directly tied to the avic_rise_arb output signal. When the ABFEN bit is cleared, this bit indicates the current value of the avic_rise_arb signal to the ARM core. This bit is set if the nFIQ is asserted and the FIAD bit is set, or if the nIRQ is asserted and the NIAD bit is set. When the ABFEN bit is set, this bit keeps the “1” until written to with a “1”. This bit remains set on both of the normal settings of the ABFLAG bit. 0 AVIC does not affect the bus arbitration priority levels 1 AVIC raises the ARM core priority level in bus arbitration logic.
24 ABFEN	ABFLAG Sticky Enable. This bit controls whether the ABFLAG bit is “sticky.” This allows the arbitration logic to keep the ARM core at the higher priority level until the ABFLAG bit is written. 0 ABFLAG bit is normal 1 ABFLAG bit is “sticky” and requires a write of “1” to clear the bit.
23	Reserved
22 NIDIS	Normal Interrupt Disable. This bit, when set, disables the generation of the normal interrupt signal. This bit is similar to the I bit of the ARM1136JF-S core. This bit, along with the FIDIS bit, is used to enable secure operations. 0 Does not affect the normal interrupt generation 1 Disable all normal interrupts
21 FIDIS	Fast Interrupt Disable. This bit, when set, disables the generation of the fast interrupt signal. This bit is similar to the F bit of the ARM1136JF-S core. This bit, along with the NIDIS bit, is used to enable secure operations. 0 Does not affect the fast interrupt generation 1 Disable all fast interrupts

Table 13-5. INTCNTL Register Field Descriptions (Continued)

Field	Description
20 NIAD	Normal Interrupt Arbiter Rise ARM Level. This bit, when asserted, increases the bus arbitration priority of the ARM core when the normal interrupt signal (nIRQ) is asserted. If an alternate master has ownership of the bus when a normal interrupt occurs, the bus will be given back to the processor core *after* the DMA device has completed its accesses. The NIAD bit does not affect alternate master accesses that are in progress. In order to prevent an alternate master from accessing the bus during an interrupt service routine, the interrupt flag should not be cleared until the end of the service routine. Another option is to use the ABFEN and ABFLAG bits. 0 Disregard the normal interrupt flag when evaluating bus requests 1 Normal interrupt flag increases the bus arbitration priority of the ARM core to decrease the latency of the interrupt service routine.
19 FIAD	Fast Interrupt Arbiter Rise ARM Level. This bit functions the same as the NIAD bit except for the fast interrupts (nFIQ). 0 Disregard the fast interrupt flag when evaluating bus requests 1 Fast interrupt flag increases the bus arbitration priority of the ARM core to decrease the latency of the interrupt service routine.
18 NM	Normal Interrupt Mode Control. Selects the hardware acceleration mode for normal interrupt. 0 AVIC will not accelerate nIRQ servicing, i.e. complete software control 1 Normal interrupt hardware acceleration enabled, i.e. enable VIC interface for Normal interrupts
17–0	Reserved

13.2.3.2 Normal Interrupt Mask Register

The normal interrupt mask (NIMASK) register, shown in Figure 13-4, controls the normal interrupt mask level. All normal interrupts with a priority level lower than or equal to the NIMASK will be disabled. The priority level of normal interrupts are determined by the normal interrupt priority level registers (NIPRIORITY7, NIPRIORITY6, NIPRIORITY5, NIPRIORITY4, NIPRIORITY3, NIPRIORITY2, NIPRIORITY1, and NIPRIORITY0). The reset state of this register does not disable any normal interrupts.

Writing all ones, or -1, to the NIMASK sets the normal interrupt mask to -1 which will not disable any normal interrupt priority levels.

This hardware mechanism can be used to create reentrant normal interrupt routines by disabling lower priority normal interrupts. See Section 13.3.8, “Writing Reentrant Normal Interrupt Routines,” for more details on the use of the NIMASK register.

This register is located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. This register can be only modified using 32-bit writes.

0x6800_0004 (NIMASK) Access: User read-write

Figure 13-4. Normal Interrupt Mask (NIMASK) Register

Table 13-6 provides field descriptions of the NIMASK register.

Table 13-6. NIMASK Register Field Descriptions

Field	Description
31–5	Reserved
4–0 NIMASK	Normal Interrupt Mask. Controls normal interrupt mask level. All normal interrupts of priority level lower than or equal to the NIMASK will be disabled. -1 Do not disable any normal interrupts 0 Disable priority level 0 normal interrupts 1 Disable priority level 1 and lower normal interrupts ... 15 Disable all normal interrupts 16+ Do not disable any normal interrupts

13.2.3.3 Interrupt Enable Number Register

The interrupt enable number register (INTENNUM), shown in Figure 13-5, provides a hardware accelerated enabling of interrupts. Any write to this register will enable one interrupt source. If the 6 LSBs are equal to 000000, then interrupt source 0 is enabled; if the 6 LSBs equal 000001, then interrupt source 1 is enabled; and so forth. This register is decoded into a one-hot mask which will be logically OR-ed with the INTENABLEH / INTENABLEL register.

This hardware mechanism alleviates the need for an atomic read/modify/write sequence to enable an interrupt source. To enable interrupts 10 and 20, the software only needs to perform two writes to the AVIC: a write of 10 to the INTENNUM register, and a write of 20 to the INTENNUM register (the order of the writes is irrelevant).

This register is located on the ARM1136JF-S native bus, is accessible in 1 cycle, and can only be accessed in privileged mode. This register can only be modified using 32-bit writes. This register always reads back all 0s.

0x6800_0008 (INTENNUM) Access: User read-write

Table 13-7. INTENNUM Register Field Descriptions

Field	Description
31–6	Reserved
5–0 ENNUM	Interrupt Enable Number. Writing to this register enables the interrupt source associated with this value. 0 Enable interrupt source 0 1 Enable interrupt source 1 ... 63 Enable interrupt source 63

13.2.3.4 Interrupt Disable Number Register

The interrupt disable number (INTDISNUM) register, shown in Table 13-6, provides a hardware accelerated disabling of interrupts. Any write to this register will disable one interrupt source. If the 6 LSBs are equal 000000, then interrupt source 0 is disabled; if the 6 LSBs equal 000001, then interrupt source 1 is disabled; and so forth. This register is decoded into a one hot mask which will be inverted and logically AND-ed with the INTENABLEH / INTENABLEL register.

This hardware mechanism alleviates the need for an atomic read/modify/write sequence to disable an interrupt source. To disable interrupts 10 and 20, the software need only preform two writes to the AVIC: first write 10 to INTDISNUM register, then write 20 to INTDISNUM register (the order of the writes is irrelevant).

This register is located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. This register can be only modified using 32-bit writes. This register will always read back all 0s.

5–0 DISNUM	Interrupt Disable Number. Writing to this register will disable the interrupt source associated with this value. 0 Disable interrupt source 0 1 Disable interrupt source 1 ... 63 Disable interrupt source 63

13.2.3.5 Interrupt Enable Registers

The interrupt enable register high (INTENABLEH) and the interrupt enable register low (INTENABLEL), shown in Figure 13-7 and Figure 13-8 respectively, are used to enable pending interrupt requests to the core. Each bit in this register corresponds to an interrupt source available in the system. The reset state of these registers are all interrupts masked.

This register can be updated by various methods: writing directly to the INTENABLEH / INTENABLEL registers, setting bits with the INTENNUM register, or clearing bits with the INTDISNUM register.

These registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. These registers can be only modified using 32-bit writes.

Figure 13-8. Interrupt Enable Register Low (INTENABLEL)

Table 13-9 shows the INTENABLEH/L register field descriptions.

Table 13-9. INTENABLEH/L Register Field Descriptions

Field	Description
31–0 INTENABLEH 31–0 INTENABLEL	Interrupt Enable. This bit enables the corresponding interrupt source to request a normal interrupt or a fast interrupt. A reset operation clears this bit. If an enable bit is set and the corresponding interrupt source is asserted, the interrupt controller asserts a normal or a fast interrupt request depending on associated INTTYPEH / INTTYPEL setting. 0 Interrupt disabled 1 Interrupt enabled and will generate a normal or fast interrupt upon assertion

13.2.3.6 Interrupt Type Registers

The interrupt type register high (INTTYPEH) and the interrupt type register low (INTTYPEL), shown in Figure 13-9 and Figure 13-10 respectively, are used to select whether a pending interrupt source, when enabled with the INTENABLEH/INTENABLEL, will create a normal interrupt or a fast interrupt to the

core. Each bit in this register corresponds to an interrupt source available in the system. The reset state of these registers will cause all enabled interrupt sources to generate a normal interrupt.

These registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. These registers can be only modified using 32-bit writes.

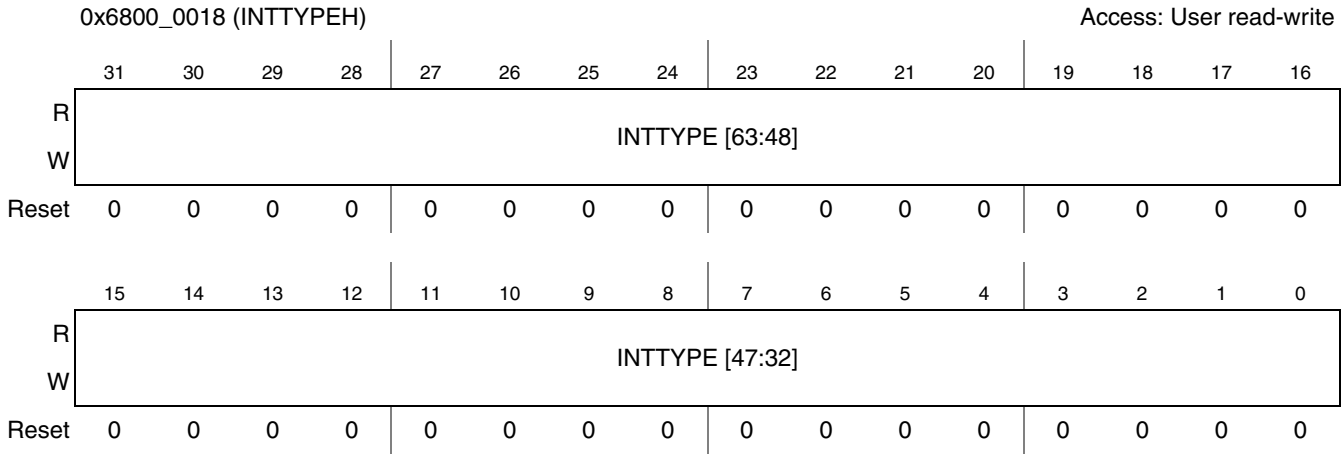

Figure 13-9. Interrupt Type Register High (INTTYPEH)

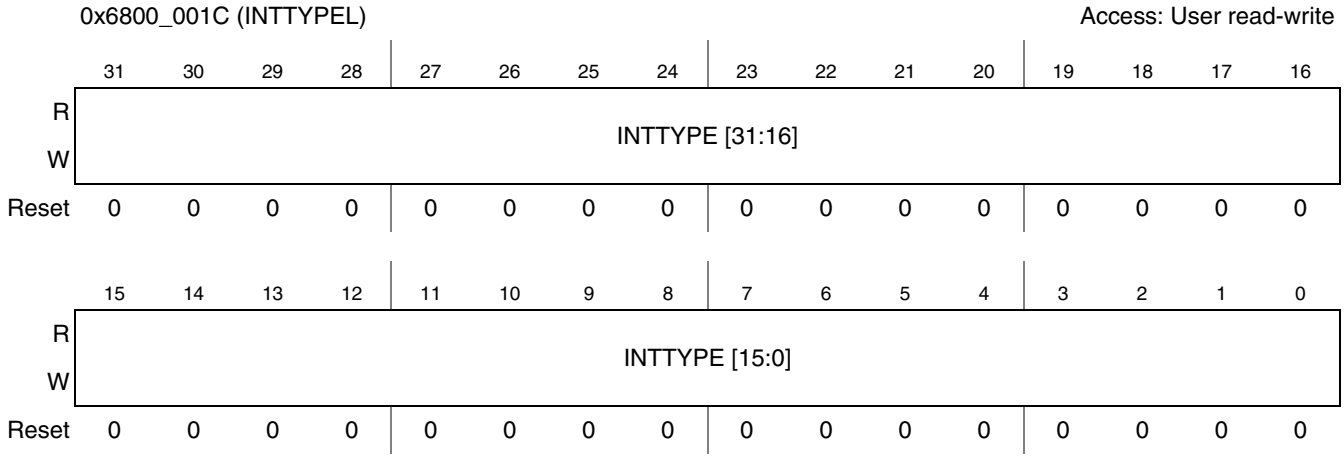

Figure 13-10. Interrupt Type Register Low (INTTYPEL)

Table 13-10 provides field descriptions of the INTTYPEH and INTTYPEL registers.

Table 13-10. INTTYPEH/INTTYPEL Field Descriptions

Field	Description
31–0 INTTYPEH 31–0 INTTYPEL	Interrupt Type. This bit controls whether the corresponding interrupt source will request a normal interrupt or a fast interrupt. If a INTTYPE bit is set and the corresponding interrupt source is asserted, the interrupt controller will assert a fast interrupt request. 0 Interrupt source will generate a normal interrupt (nIRQ) 1 Interrupt source will generate a fast interrupt (nFIQ)

13.2.3.7 Normal Interrupt Priority Level Registers

The normal interrupt priority level registers (NIPRIORITY7, NIPRIORITY6, NIPRIORITY5, NIPRIORITY4, NIPRIORITY3, NIPRIORITY2, NIPRIORITY1, and NIPRIORITY0) are shown in Figure 13-11 through Figure 13-18. Table 13-11 through Table 13-18 provide field descriptions for these registers. The NIPRIORITY*n* registers provide a software controllable prioritization of normal interrupts. Normal interrupts with a higher priority level will preempt normal interrupts with a lower priority. The reset state of these registers forces all normal interrupts to the lowest priority level.

If a level 0 normal interrupt and a level 1 normal interrupt are asserted at the same time, the level 1 normal interrupt will be selected assuming that NIMASK has not disabled level 1 normal interrupts. If two level 1 normal interrupts are asserted at the same time, the level 1 normal interrupt with the highest source number will be selected, also assuming that NIMASK has not disabled level 1 normal interrupts.

These registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. These registers can be only modified using 32-bit writes.

13.2.3.8 Normal Interrupt Vector and Status Register

The normal interrupt vector and status register (NIVECSR), shown in Figure 13-19, provides the priority of the highest pending normal interrupt and provides the vector index of the interrupt's service routine. This hardware mechanism replaces the previous necessity for core support of the FF1 command. This number can be directly used as an index into a vector table to select the highest pending normal interrupt source.

This read-only register is located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode.

0x6800_0040 (NIVECSR) Access: User read-only

Table 13-19. NIVECSR Register Field Descriptions

Field	Description
31–16 NIVECTOR	Normal Interrupt Vector. Indicates vector index for the highest pending normal interrupt. -1 No normal interrupt request pending 0 Interrupt 0 highest priority pending normal interrupt 1 Interrupt 1 highest priority pending normal interrupt ... 63 Interrupt 63 highest priority pending normal interrupt 64+ (not -1)unused, will not occur
15–0 NIPRILVL	Normal Interrupt Priority Level. Indicates the priority level of the highest priority normal interrupt. This number can be written to the NIMASK to disable the current priority normal interrupts to build a reentrant normal interrupt system. -1 No normal interrupt request pending 0 Highest priority normal interrupt is level 0 1 Highest priority normal interrupt is level 1 ... 15 Highest priority normal interrupt is level 15 16+ (not -1)unused, will not occur

13.2.3.9 Fast Interrupt Vector and Status Register

The fast interrupt vector and status register (FIVECSR), shown in Figure 13-20, provides the vector index for the highest priority active fast interrupt's service routine (the higher the source number of the fast interrupt, the higher the priority level). This hardware mechanism replaces the previous necessity for core support of the FF1 command. This number can be directly used as an index into a vector table to select the highest pending fast interrupt source.

This read-only register is located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode.

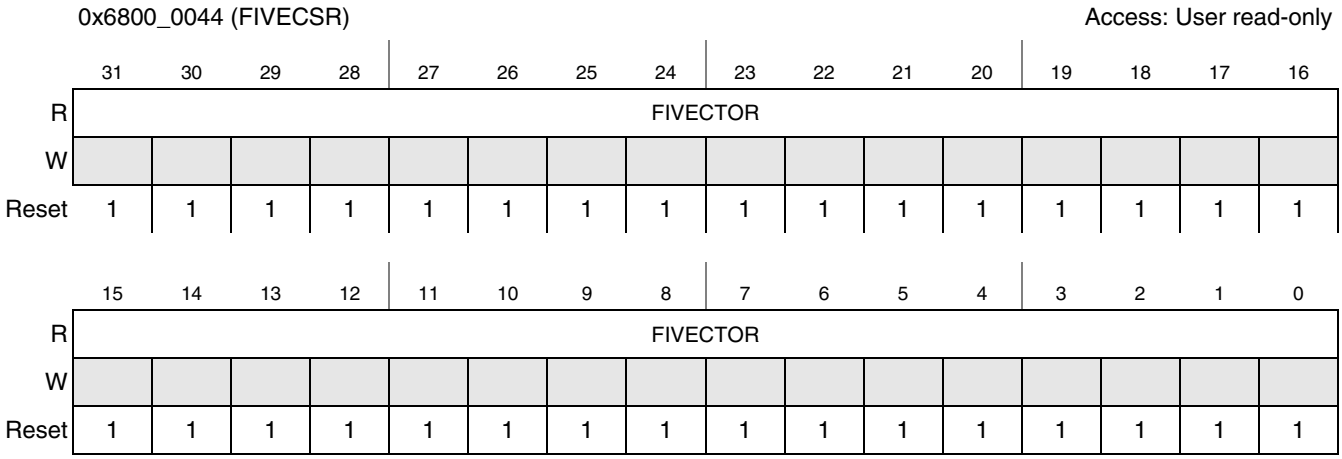

Figure 13-20. Fast Interrupt Vector and Status Register (FIVECSR)

Table 13-20 provides a field description for the FIVECSR.

Table 13-20. FIVECSR Field Descriptions

Field	Description
31–0 FIVECTOR	Fast Interrupt Vector. Indicates vector index for the highest pending fast interrupt. -1 No fast interrupt request pending 0 Interrupt 0 highest pending fast interrupt 1 Interrupt 1 highest pending fast interrupt ... 63 Interrupt 63 highest pending fast interrupt 64+ (not -1)unused, will not occur

13.2.3.10 Interrupt Source Registers

The interrupt source register high (INTSRCH) and the interrupt source register low (INTSRCL), shown in Figure 13-21 and Figure 13-22 respectively, are each 32-bits wide. INTSRCH and INTSRCL reflect the status of all interrupt request inputs into the interrupt controller. Unused bit positions always read zero (no request pending). The state of this register out of reset is determined by the peripheral circuits generating the requests; normally, the requests would be inactive.

These read-only registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode.

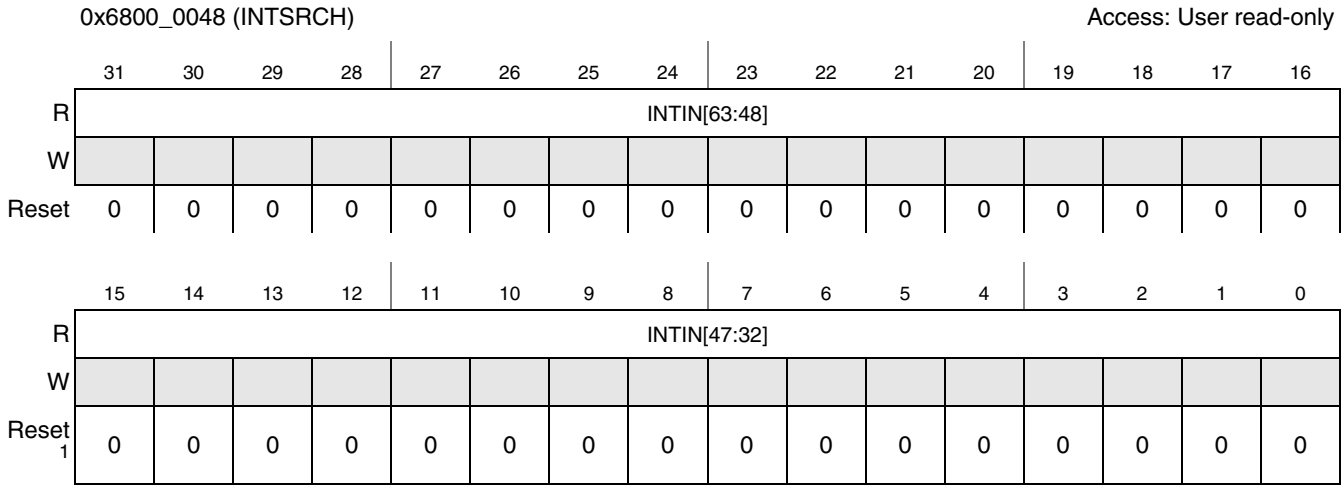

Figure 13-21. Interrupt Source Register High (INTSRCH)

1 The state of the register out of reset is determined by the peripheral circuits generating the requests; normally, the requests would be inactive. This read-only register should be only accessed with 32-bit reads.

Table 13-21 provides field descriptions for the INTSRCH and INTSRCL registers.

Table 13-21. INTSRCH/INTSRCL Field Descriptions

Field	Description
31–16 INTIN[63:48] INTIN[31:16] 15–0 INTIN[47:32] INTIN[15:0]	Interrupt Source. Indicates the state of the corresponding hardware interrupt source. 0 Interrupt source negated 1 Interrupt source asserted

13.2.3.11 Interrupt Force Registers

The interrupt force register high (INTFRCH) and the interrupt force register low (INTFRCL), shown in Figure 13-23 and Figure 13-24 respectively, are each 32-bits wide. The interrupt force registers allow for software generation of interrupts for each of the possible interrupt sources for functional or debug purposes. The system level design may reserve one or more sources for software purposes to allow software to self-schedule interrupts by forcing one or more of these “sources” in the appropriate interrupt force register(s).

These registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. These registers can be only modified using 32-bit writes.

13.2.3.12 Normal Interrupt Pending Register

The normal interrupt pending register high (NIPNDH) and the normal interrupt pending register low (NIPNDL), shown in Figure 13-25 and Figure 13-26 respectively, are 32-bit wide registers used to monitor the outputs of the enable and masking operations. These registers are actually only a set of buffers; therefore, the reset state of these registers are determined by the normal interrupt enable registers, the

interrupt mask register, and the interrupt source registers. The value reflected in these registers is unaffected by the value of the NIMASK register.

These read-only registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode.

13.2.3.14 AVIC Vector Registers

The AVIC vector registers (VECTOR0 through VECTOR63), shown in Figure 13-29, store the memory addresses where the interrupt service routine for the associated interrupt source is located. The vector registers are each 30 bits wide and can point to any memory location.

These registers are located on the ARM1136JF-S native bus, accessible in 1 cycle, and can only be accessed in privileged mode. These registers can be only modified using 32-bit writes.

Table 13-25. VECTOR0–VECTOR63 Field Descriptions

Field	Description
31–2 VECTOR0 through VECTOR63	AVIC Vector Registers. These control registers contain the address of the interrupt service routine for the associated interrupt source. These addresses are used to vector the ARM1136JF-S core to the interrupt service routine quickly. The two LSBs are always 0 because all interrupt service routines are WORD aligned.
1–0	Reserved

13.3 ARM1136JF-S Interrupt Controller Operation

13.3.1 ARM1136JF-S Prioritization of Exception Sources

The ARM1136JF-S core imposes the following priority among the various exceptions:

- Reset (highest priority)
- Data abort
- Fast interrupt
- Normal interrupt
- Prefetch abort
- Undefined instruction and SWI (lowest priority)

13.3.2 AVIC Prioritization of Interrupt Sources

The AVIC module prioritizes the various interrupt sources by source number where higher source numbers have higher priority. Fast interrupt always have higher priority over normal interrupts.

The interrupt requests are prioritized in the following sequence:

1. Fast interrupt requests, in order of highest source number
2. Normal interrupt requests, in order of highest priority level, then in order of highest source number with the same priority level

13.3.3 Assigning and Enabling Interrupt Sources

The interrupt controller provides for flexible assignment of any interrupt source to either of the two core interrupt request inputs. This is done by setting the appropriate bits in the INTENABLEH / INTENABLEL registers and the INTTYPEH / INTTYPEL registers. Usually, interrupt assignment is done once during system initialization and does not affect interrupt latency.

Interrupt assignment is the first of three steps required to enable an interrupt source, and this is done at chip integration. The second step is to program the source to generate interrupt requests. The final step is to enable the interrupt inputs in the core by clearing the normal interrupt disable (I) and/or the fast interrupt disable (F) bits in the program status register (CPSR).

13.3.4 Enabling Interrupts Sources

There are two methods of enabling or disabling interrupts in the AVIC. The first method is directly reading the INTENABLEH / INTENABLEL registers, logically OR or BIT CLEAR these registers with a generated masks, then writing back to the INTENABLEH / INTENABLEL registers.

The second method is performing an atomic write to the source number to INTENNUM register. The AVIC will decode this 6 bit register and enable one of the 64 interrupt sources. The AVIC will automatically generate a “one hot” enable mask and logically OR this mask to the correct INTENABLEH or INTENABLEL register. To disable interrupts is exactly the same except the source number is written to the INTDISNUM register.

13.3.5 Controlling Bus Arbitration With AVIC

The AVIC has some logic to raise the priority level of the ARM core when either a fast or normal interrupt occurs. When a fast interrupt occurs and the FIAD bit is set, the AVIC will assert the avic_rise_arb signal. When a normal interrupt occurs and the NIAD bit is set, the AVIC will assert the avic_rise_arb signal. This signal will raise the priority level of the ARM core, so that it has priority of all other alternate masters. This signal will not stop the current alternate master transfer instead will prevent/limit future bus arbitration away from the ARM core.

The AVIC includes some logic in the ABFLAG and ABFEN bits. The ABFLAG bit indicates the AVIC is currently asserted the avic_rise_arb signal to the bus arbitration logic. The ABFEN bit changes the ABFLAG from a read-only status bit to a “sticky” write-1-to-clear status bit.

13.3.6 The VIC Interface To The ARM1136JF-S Core

The AVIC utilizes the VIC interface of the ARM1136JF-S core to vector the processor quickly to the interrupt service routine. The interface consists of four controls which follow to the sequence:

1. The AVIC asserts IRQ to the ARM1136JF-S core.
2. The ARM1136JF-S acknowledges interrupt and requests the vector via the “arm_irq_ack” signal.
3. The AVIC latches the current vector source and selects an interrupt service routine vector to place on the “avic_irq_vector[31:2]” bus.
4. The AVIC then asserts the “avic_irq_addr_val” signal indicating that the “avic_irq_vector[31:2]” bus is stable.
5. The ARM1136JF-S captures the vector information and negates the “arm_irq_ack” signal
6. The AVIC then negates the “avic_irq_addr_val” signal.

13.3.7 VIC Interface and Fast Interrupts

The VIC interface of the ARm1136JF-S core does not support hardware acceleration of fast interrupts, therefore software must determine how to process the incoming fast interrupt requests. Below is a sample piece of assembly code which will read the FIVECSR register, then read the vector out of the VECTORx register, and then jump to the interrupt service routine.

```
ldr       r10, =0x6C000000              @ load AVIC base address
ldr       r9, [r10,#0x44]               @ read FIVECSR of AVIC
add       r10, r10, #100                @ move pointer to base of VECTOR table
ldr       r8, [r10,r9,lsl #2]           @ read FIQ vector from VECTOR table
bx        r8                            @ jump to FIQ service routine
```

13.3.8 Writing Reentrant Normal Interrupt Routines

The AVIC can be used to create a reentrant normal interrupt system. This enables preempting of lower priority level interrupts by higher priority level interrupts. This requires a small amount of software support and overhead.

1. Push the link register (LR_irq) on to the stack (SP_irq)

2. Push the saved status register (SPSR_irq) on to the stack
3. Read the current value of NIMASK and push this value on to the stack
4. Read current priority level via NIVECSR
5. Interrupts of the equal or lesser priority than the current priority level should be masked via the NIMASK register by writing value from NIVECSR
6. Clear the I bit in the ARM1136JF-S core via a MSR / MRS command sequence (now a higher priority normal interrupt can preempt a lower priority one)
   Also change the operating mode of the core to System Mode from IRQ mode
7. Push System Mode link register (LR) on to the stack (SP_user)
8. The traditional interrupt service routine is now included
9. Pop System Mode link register (LR) from the stack (SP_user)
10. Set I bit in the ARM1136JF-S core via a MSR / MRS command sequence (thus disabling all normal interrupts)
    Also change the operating mode of the core to IRQ Mode from System mode
11. Pop the original value of normal interrupt mask and write to the NIMASK register
12. The saved status register should be popped from the stack (SP_irq)
13. The link register should be popped from the stack into the PC
14. Return from nIRQ

NOTE: *Steps 1, 2, 13, and 14 are automatically done by most C compilers and are included for completeness.*

Chapter 14
Clock Controller Module (CCM)

14.1 Introduction

The CCM performs the following functions:

- Controls the system frequency
- Distributes clocks to various parts of the chip
- Controls the chip reset mechanism
- Provides advanced low-power management

14.1.1 Overview

The CCM contains four functional parts:

- Clock control and gating logic
- Reset control logic
- Boot control logic
- Low-power control logic

14.1.2 Features

The CCM includes these distinctive features:

- PLL with divide generation (DIVGEN) and PLL control
- Clock distributions—division of PLLs output clock and clock source selectors
- Reset controller—generates reset signals to the core and to the peripherals
- Boot controller—generates boot mode and boot address
- Power manager—controls power modes and minimize power consumption via techniques such as AWB, power gating, DPTC, and DVFS.

14.1.3 Modes of Operation

There are three modes of operation:

- Normal operation mode
- Low-power mode
- Debug mode

14.1.3.1 Normal Operating Mode

The normal operating mode is run mode. Clocks are generated by PLLs (or alternatively, PLLs can be bypassed).

14.1.3.2 Low-Power Modes

There are three system low-power modes:

- Wait
- Doze
- Stop

14.2 External Signal Description

Table 14-1 describes all signals that connect off chip.

Table 14-1. External Signal Properties

Name	Port	Function	I/O	Reset	Pull Up
OSC24M_XTAL	ipp_din_osc24m_xtal	OSC24M xtal input	I	—	—
OSC24M_EXTAL	ipp_din_osc24m_extal	OSC24M extal input	I	—	—
OSCAUDIO_XTAL	ipp_din_osc_audio_xtal	OSCAUDIO xtal input	I	—	—
OSCAUDIO_EXTAL	ipp_din_osc_audio_extal	OSCAUDIO extal input	I	—	—
CLK_MODE[1:0]	clk_mode	Clock mode input	I	—	—
BOOTIN[1:0]	ipp_boot_in	Boot mode pins	I	—	—
POR_B	ipp_por_reset_in_b	Power-on reset signal from external contact	I	—	Enabled
RESET_IN_B	ipp_reset_in_b	External reset signal. All modules are reset except for the PLL, FUSE, and CCM.	I	—	Enabled
PMIC_INT	ipp_pmic_rdy	PMIC ready signal, shows the PMIC voltage change is finished and the voltage is stable (this input needs to be configured before use).	I	—	—
EXT_ARMCLK	ipp_ind_clk_arm	Bypass arm clock input from the contact for function test.	I	—	—
CAPTURE/CSPI1_SS1	ipp_32k_muxed_in	Muxed input for 32 kHz clock while internal OSC24M is powered off.	I	—	—
CLKO	ipp_clko	CKO clockout pin. Because of pin limitations, configure the CLKO output frequency < 90 MHz.	O	0	—
VSTBY	ccm_vstby_pmic	IO signal to PMIC. Requests that the supply voltage change to state retention value	O	0	—

14.3 Memory Map and Register Definition

This section provides memory maps and detailed descriptions of all registers.

14.3.1 Memory Map

See the system memory map for the complete listing of memory map offset addresses. Table 14-2 shows the CCM memory map.

14.3.2 Register Summary

The conventions in Figure 14-1 and Table 14-3 serve as a key for the register summary and individual register diagrams.

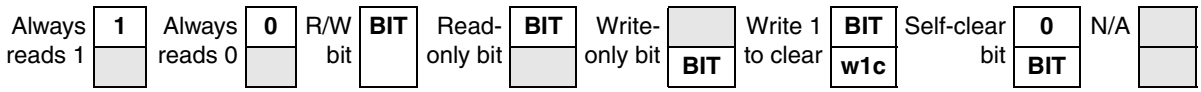

Figure 14-1. Key to Register Fields

Table 14-3 provides a key for register figures and tables and the register summary.

Table 14-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero (previously designated slfclr).
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 14-4 shows the CCM register summary table.

Table 14-4. CCM Registers Summary

R	LPM		0	0	0	0	UPE	0	0	0	0	0	MPE	0	0	0
W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	1	0	0	0

Figure 14-2. Clock Control Module Register (CCMR)

Table 14-5. CCMR Field Descriptions

Field	Description
31	Reserved
30 WFI	This bit is for-low power mode entry. If set, the ccm_int_holdoff asserts first to block the ARM interrupt before the low-power mode really begins. In a normal process, clearing this bit also clears the ccm_int_holdoff bit.

Table 14-5. CCMR Field Descriptions

Field	Description
29 STBY_EXIT_SRC	Power-ready detection by: 1 Voltage-ready counter CCMR[VOL_RDY_CNT] has finished. 0 Signal input PMIC_RDY=1 assertion. PMIC_RDY must be asserted by external PMIC after power is ready (default)]
28 VSTBY	VSTBY defines the state of the VSTBY output signal after the core enters a low-power state defined in the LPM field. The VSTBY output signal is used to notify an external PMIC to enter standby mode and/or reduce the core voltage to state-retention voltage. 0 No assertion of VSTBY in low-power state. 1 Assertion of VSTBY in low-power state
27 WBEN	ARM/EMI domain well bias enable bit. This bit enables the well biasing of modules in the ARM11P and EMI. Well biasing can be activated only after the core has entered standby mode and the max_halted signal is asserted. 1 Well Bias is enabled for ARM/EMI 0 Well Bias is disabled for ARM/EMI
26–24	Reserved
23–20 VOL_RDY_CNT	These four bits define the value of the counter that needs to wait for power-supply ready while exiting from state-retention mode. The counter is driven by the async CKIL (32 kHz) clock input.
19–18 ROMW	Wait-state control bit for the ARM ROM 00 0 wait states for both ARM and alternate masters. 01 0 wait states and 1 wait state for alternate masters. Not recommended for this device. 10 1 wait state for ARM and 0 wait states for alternate masters. Not recommended for this device. 11 1 wait state for both ARM and alternate masters.
17–16 RAMW	Wait-state control bits for the ARM RAM 00 0 wait states for both ARM and alternate masters. 01 Reserved 10 Reserved 11 Reserved
15–14 LPM	These bits define which low-power mode the device will enter when the WFI command is next executed by the core. 00 Run mode 01 Wait mode 10 Doze mode 11 Sleep mode
13–10	Reserved
9 UPE	Peripheral PLL (also denoted as PPLL) enable bit. This bit cannot be set when the selected clock source is disabled. 1 PPLL enabled 0 PPLL disabled
8–4	Reserved
3 MPE	Core PLL (also called MPLL) enable bit. 1 Core PLL enabled 0 Core PLL disabled CAUTION: The core PLL can only be disabled while the clock mode input signal CLK_MODE is 11, so that the PLL is bypassed and an external clock is used. Otherwise disabling the core PLL crashes the system.
2–0	Reserved

14.3.3.2 Post Divider Register 0 (PDR0)

Offset 0x0004 (PDR0) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	PER_SEL	0	0	IPU_HND_BYP	0	HSP_PODF		CON_MUX_DIV			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

R	CKIL_SEL	CCM_PER_AHB			0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Figure 14-3. Post Divider Register 0 (PDR0)

Table 14-6. PDR0 Field Descriptions

Field	Description
31–27	Reserved
26 PER_SEL	This bits select the synch perclk source. See Figure 14-25. 0 Perclk from the AHB divided clock (default) 1 Perclk from the ARM high-frequency clock and synched with the AHB clk. **Note:** If this bit is set, PDR4[21:16] should be configured to divide the ARM clock to be lower than 1/2 the AHB clk frequency.
25–24	Reserved
23 IPU_HND_BYP	This bit controls the IPU handshake process bypass. 0 Bypass 1 Not bypass **Note:** If the IPU is not configured for frequency change handshake, IPU_HND_BYP should remain 0, or the frequency will not change.
22	Reserved.
21–20 HSP_PODF	These two bits define the HSP clock-divider value from the ARM clock. For an ARM clock at 532 MHz: 00 Divide by 4. HSP_clock is 133 Mhz. 01 Divide by 8. HSP_clock is 66.5 Mhz. 10 Divide by 3. HSP_clock is 178 Mhz. For an ARM clock at 400 MHz: 00 Divide by 3. HSP_clock is 133 Mhz. 01 Divide by 6. HSP_clock is 66.5 Mhz. 10 Divide by 3. HSP_clock is 133 Mhz.

Figure 14-8. Reset Control and Source Register (RCSR)

Table 14-11. RCSR Field Descriptions

Name	Description
31–30 BT_USB_SRC	BT_USB_SRC. Read only bit. Represents the USB PHY selection boot mode. 00 Internal PHY used on USBOTG (UTMI PHY) 00 External PHY used on USBOTG (ULPI PHY) 10 Serial PHY used (ATLAS) 11 Serial PHY used (PHILIPS ISP1301)
29 BUS_WIDTH	This read-only bit shows the NAND bus width from the contact or fuse value. 0 8-bit width 1 16-bit width
28–27 PAGE_SIZE	These two read-only bits show the NAND flash page size from the contact or fuse value. 00 512 bytes 01 2 Kbytes 10 4 Kbytes, 128 bytes spare 11 4 Kbytes, 218 bytes spare
26–25 MEM_CTRL	These two bits show the boot memory type from the contact or fuse value. (read only) 00 WEIM 01 NAND flash 10 Reserved 11 SD/MMC

Table 14-11. RCSR Field Descriptions

Name	Description
24–23 MEM_TYPE	These read-only bits show the boot-memory type from the contact or fuse value. BT_MEM_CTL Boot Memory Control Type (memory device) 00 WEIM 01 NAND flash 10 ATA HDD 11 Expansion Device (SD/MMC, support high storage, EEPROMs. See BT_MEM_TYPE[1:0] settings for details). BT_MEM_TYPE Boot Memory Type. Interpreted by boot ROM software according to BT_MEM_CTL setting. Signals could also be interpreted by hardware to alter delays and timing in support of direct boot. If BT_MEM_CTL = WEIM then 00 NOR 01 Reserved 10 Samsung OneNAND 11 Reserved If BT_MEM_CTL = NAND Flash 00 3 address cycles 01 4 address cycles 10 5 address cycles 11 Reserved If BT_MEM_CTL = ATA HDD 00 CE-ATA HDD 01 P-ATA HDD 10 Reserved 11 Reserved If BT_MEM_CTL = Expansion Card Device 00 SD/MMC 01 Reserved 10 Serial ROM via I2C 11 Serial ROM via SPI
22 BT_ECC	Boot ECC value 0 4-bit ECC 1 8-bit ECC
21–15	Reserved
14 NFC_16bit_SEL0	This bit is configured by software to set the NAND Flash width. It should not be used while booting from NAND: nf8_boot_b and nf16_boot_b should both be high (negated). 0 8-bit width 1 16-bit width
13–12	Reserved
11–10 BOOT_REG	These two read-only bits show the boot mode as read from the BOOT_MODE[1:0] pins when the device comes out of reset. 00 Internal Boot 01 Function Test (including DTE mode) 10 External Boot 11 Boot Strap

Table 14-11. RCSR Field Descriptions

Name	Description
9 NFC_4K	This bit is used to configure the NAND Flash page size. It is defined by PAGE_SIZE while booting, and can be configured by software after booting up. 0 Not a 4-Kbyte page 1 4-Kbyte page If NFC_FMS and NFC_4K are both set, the page size is 4 Kbyte.
8 NFC_FMS	This bit is used to configure the NAND Flash page size. It is defined by PAGE_SIZE while booting, and can be configured by software after booting up. 0 Not a 2-Kbyte page 1 2-Kbyte page If NFC_FMS and NFC_4K are both set, the page size is 4 Kbytes.
7–4 GPF	General purpose flag bits. This bits are reset by the reset_in_por_b input pin. This bits can be used as warm-start parameters or for debug purposes. For example, the user can write a value to these bits before turning off the voltage. This value can then be used by the wake-up routine for wake-up scenario purposes.
3–0 REST	Reset status bits. Shows cause of most recent reset to the system. If the signals are released during the same CLK32 cycle (which also causes the assertion of the RESET_OUT signal), only the highest-priority event is registered by the REST field using the following priority order: • POR external reset signal • Qualified external reset signal • Watchdog signal • JTAG reset Otherwise, the last signal that is released is honored. 0000 POR external reset 0100 Qualified external reset 1000 Watchdog timeout 0010 JTAG reset

14.3.3.8 Core PLL (MPLL) Control Register (MPCTL)

This register controls the core PLL (also called MPLL).

Offset 0x001C (MPCTL) Access: User read-write

Figure 14-9. Core PLL (MPLL) Control Register (MPCTL)

The core PLL output frequency (F_{VCO}) is determined by Equation 14-1 below:

$$2 \times F_{ref} \times \frac{MF_I + \frac{MF_N}{MF_D}}{PD} = Fvco$$

MCU Core PLL Output Frequency ***Eqn. 14-1***

Where:

F_{ref}: Reference clock (input frequency) of MCU core PLL
MFx: Various multiplication factors, whose value is set using the MPCTL register (see the bit descriptions below)
PD: Pre-Divider factor, whose value is also set in the MPCTL register

NOTE

In Equation 14-1, the absolute value of MF_N/MF_D must be smaller than 1, and the MF part must not exceed 15.

Table 14-12. MPCTL Field Descriptions

Name	Description
31 BRMO	Binary Rate Multiplier (BRM) Order bit. Determines if the BRM is first or second order. The first-order BRM is used if the MF fractional part is between 1/10 and 9/10 or if MF_I > 13. Otherwise the second-order BRM is used. 1 BRM is second order. 0 BRM is first order.
30	Reserved

Table 14-12. MPCTL Field Descriptions (Continued)

Name	Description
29–26 PD	Predivider factor bits. Define the predivider factor (PD) applied to the PLL input frequency, as specified in Equation 14-1. PD is an integer between 1 and 16 (inclusive). The PD is selected to ensure that the resulting output frequency remains within the specified range. When a new value is written into PD bits, the PLL loses its lock; after a frequency lock time delay, the PLL relocks. 0000 1 0001 2 ... 1111 16
25–16 MFD	Multiplication factor denominator. Defines the denominator part of the BRM value for the MF, as specified in Equation 14-1. When a new value is written into the MFD bits, the PLL loses its lock; after a frequency lock time delay, the PLL relocks. 000000000 1 000000001 2 ... 1111111111 1024
15–14	Reserved
13–10 MFI	Multiplication factor, integer part. Defines the integer part of the BRM value for the MF. See Equation 14-2. The MFI is encoded so that MFI < 5 results in MFI = 5. When a new value is written into the MFI bits, the PLL loses its lock: after a frequency lock time delay, the PLL relocks. 0000–0101 5 0110 6 ... 1111 15
9–0 MFN	Multiplication factor numerator. Defines the numerator of the BRM value for the MF. See Equation 14-2. When a new value is written into the MFN bits, the PLL loses its lock; after a frequency lock time delay, the PLL relocks. This value is a 2's complements number. 0000000000 0 0000000001 1 ... 0111111111 511 1000000000 –512 ... 1111111111 –1

14.3.3.9 Peripheral PLL Control Register (PPCTL)

This register controls the peripheral PLL (also denoted PPLL).

Offset 0x0020 (PPCTL) Access: User read-write

Table 14-16. CGR0 - CGR3 Field Descriptions

Name	Description
31–30 CG15 … CG(i)[(2i+1): 2i]	The clock gating registers define the clock gating for power reduction of each clock (CG(i) bits). There are *n* CGR registers. The number of registers required is according to the number of peripherals (*n*) in the system. CG(i) bits These bits are used to turn on/off the clock to each module independently. The following list details the possible clock activity conditions for each module. 00 Clock is off during all modes. 01 Clock is on in run mode, but off in wait and doze modes 10 Clock is on in run and wait modes, but off in doze mode 11 Clock is on during all modes, except when PLL clock is off.

Note: Before writing 00 to these bits (shutting off the clock to the module), the module to which it is connected must first be stopped. If this is not done, the module's behavior can be adversely affected.

Table 14-17, Table 14-18, and Table 14-19 describe the mapping of modules and the CGR registers bits.

27–25	Reserved
24 DVFS_UPD_FINISH	This bit shows DVFS UPDATE finish by software 0 Not finished 1 Finished
23 DVFEV	Always trigger a DVFS event (interrupt or DMA reguest) 0 Do not always trigger a DVFS event 1 Alway trigger a DVFS event
22 DVFIS	DVFS Interrupt select. These bits define destination of DVFS interrupts. 1 Core interrupt will be generated for DVFS events. 0 SDMA interrupt will be generated for DVFS events.
21 LBMI	Load buffer full mask interrupt. This bit masks the generation of this interrupt. 1 Load buffer full interrupt is masked. 0 Load buffer full interrupt is enabled.
20 LBFL	Load buffer full status bit. This bit indicates that log buffer registers are full. An interrupt is generated if LBMI bit is set to 0. Software can write only 0 in to this bit. 1 Load buffer is full. 0 Load buffer is not full.

Table 14-28. PMCR0 Field Descriptions (Continued)

Name	Description
19–18 LBCF	DVFS load buffer programmable size 00 Load buffer size is 4 01 Load buffer size is 8 10 Load buffer size is 12 11 Load buffer size is 16
17 PTVIS	DPTC Interrupt select. These bits define destination of DPTC interrupts. 1 Core interrupts will be generated for DPTC events 0 SDMA interrupts will be generated for DPTC events.
16 DVFS_START	DVFS update start bit, configured by software. Assertion shows update is ongoing. 0 DVFS freq/vol update has not started 1 DVFS freq/vol update is ongoing.
15 FSVAIM	DVFS Frequency adjustment interrupt mask. This bit masks the DVFS frequency adjustment interrupt. FSVAI status bits will be still asserted in relevant cases. 1 interrupt is masked. 0 interrupt is enabled.
14–13 FSVAI[1:0]	FSVAI DVFS Frequency adjustment interrupt. These status bits indicate that the system frequency should be changed. 00 No interrupt 01 Frequency should be increased. Low priority interrupt. Interrupt is asserted, if FSVAIM=0. Interrupt is masked if DVLV = 00 (highest frequency). 10 Frequency should be decreased. Interrupt is asserted, if FSVAIM = 0. Interrupt is masked if DVLV = 11 (lowest frequency). 11 Frequency should be increased immediately. High priority interrupt. Interrupt is asserted, if FSVAIM = 0. Interrupt is masked if DVLV = 00 (highest frequency).
12 DPVCR	DPTC voltage change request 0 Disabled 1 Enabled
11 DPVV	DPTC voltage valid edge detect. Can be updated by SW. If written by SW, it's possible to assert it only after DPVCR is asserted. 0 Voltage is not valid 1 Received a voltage valid acknowledge
10 WFIM	DVFS Wait for Interrupt mask bit 0 Wait for interrupt not masked 1 Wait for interrupt masked.
9 DRCE3	DPTC reference circuit3 enable bit. This bit defines if reference circuit3 is enabled during DPTC operation. 1 DPTC reference circuit3 enabled. 0 DPTC reference circuit3 disabled.
8 DRCE2	DPTC reference circuit2 enable bit. This bit defines if reference circuit2 is enabled during DPTC operation. 1 DPTC reference circuit2 enabled. 0 DPTC reference circuit2 disabled.
7 DRCE1	DPTC reference circuit1 enable bit. This bit defines if reference circuit1 is enabled during DPTC operation. 1 DPTC reference circuit1 enabled. 0 DPTC reference circuit1 disabled.
6 DRCE0	DPTC reference circuit0 enable bits. This bit defines if reference circuit0 is enabled during DPTC operation. 1 DPTC reference circuit0 enabled. 0 DPTC reference circuit0 disabled.

Table 14-28. PMCR0 Field Descriptions (Continued)

Name	Description
5 SCR	DPTC counting range. This bit determines the number of system clocks during which the reference circuits remain active (and their output signals are counted). 1 512 system clock count 0 256 system clock count
4 DVFEN	DVFS enable. This bit enables the DVFS block. 1 DVFS enabled 0 DVFS disabled **Note:** There must be at least three div_3_clk cycles between disable and enable.
3 PTVAIM	DPTC Voltage adjustment interrupt mask. This bit masks the DPTC voltage adjustment interrupt. PTVAI status bits will be still asserted in relevant case. 1 interrupt is masked 0 interrupt is enabled
2–1 PTVAI[1:0]	DPTC Voltage adjustment interrupt. These status bits indicate that the supply voltage should be changed. 00 No interrupt 01 Voltage should be decreased. Interrupt is asserted, if PTVAIM=0 10 Voltage should be increased. Low priority interrupt. Interrupt is asserted, if PTVAIM=0 11 Voltage should be increased immediately. High priority interrupt. Interrupt is asserted, if PTVAIM=0
0 DPTEN	DPTC enable. This bit enables the DPTC block and starts the reference circuit clock counting and compares this to look-up table values. 1 DPTC enabled. 0 DPTC disabled.

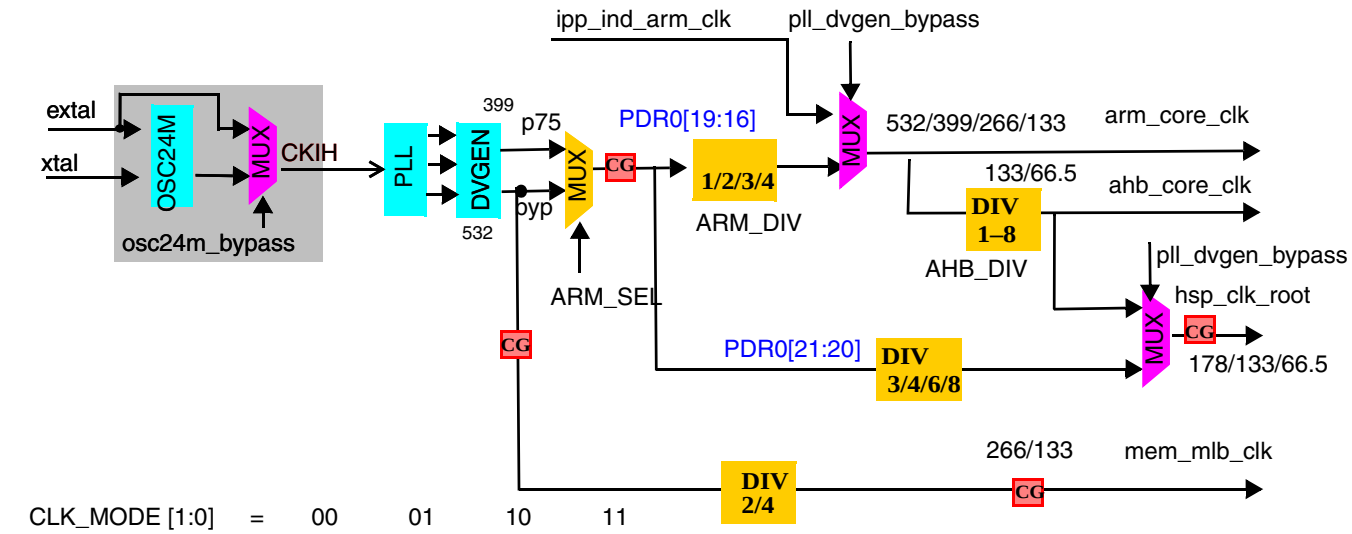
31–23 OSC_RDY_CNT	These bits define how many CKIL(32 kHz) cycles are required for the OSC 24 Mhz to be stable while exiting from stop mode.
22	Reserved
21 M1_GAS	Control bit for gasket onEMI port1. 0 Gasket is used. 1 Gasket is bypassed.
20 M4_GAS	Control bit for gasket onEMI port4. 0 Gasket is used. 1 Gasket is bypassed.
19 M3_GAS	Control bit for gasket onEMI port3. 0 Gasket is used. 1 Gasket is bypassed.
18 IPU_GAS	This bit is used to select the gasket between IPU and EMI. 0 IPU gasket is used. 1 IPU gasket is bypassed.
17 OSC_AUDIO_DOWN	This bit is used to control the osc audio power supply. 0 osc audio power is on 1 osc audio power is off
16 OSC24M_DOWN	This bit is used to control the osc 24 MHz power supply. It can only be powered down in stop mode. 0 osc 24 MHz will not be powered off in stop mode. 1 osc 24 MHz will be powered off in stop mode.
15–5 REF_COUNTER_OUT	DPTC reference circuit counter value which can be read through ipbus. Read-only.
4-2	Reserved

1 DVFS_REQ	This bit is used to control the dvfs req signal to request EMI M3IF for design change.This bit will be cleared by dvfs_ack signal automatically. 0 No request 1 Request
0 DVFS_ACK	This bit is read only and shows the status of EMI has closed the access for SDRAM or not. 0 No ack signal 1 Acked

14.4 Functional Description

14.4.1 Clock Control And Gating

The general clock generation scheme is shown in Figure 14-24 through Figure 14-26.



CLK_MODE [1:0]	=	00	01	10	11
OSC_24m_bypass	=	0	1	1	1
OSC_audio_bypass	=	0	1	1	1
pll_dvgen_bypass	=	0	1	0	1
per_pll_bypass	=	0	1	0	1
div_32k_bypass	=	0	0	0	1

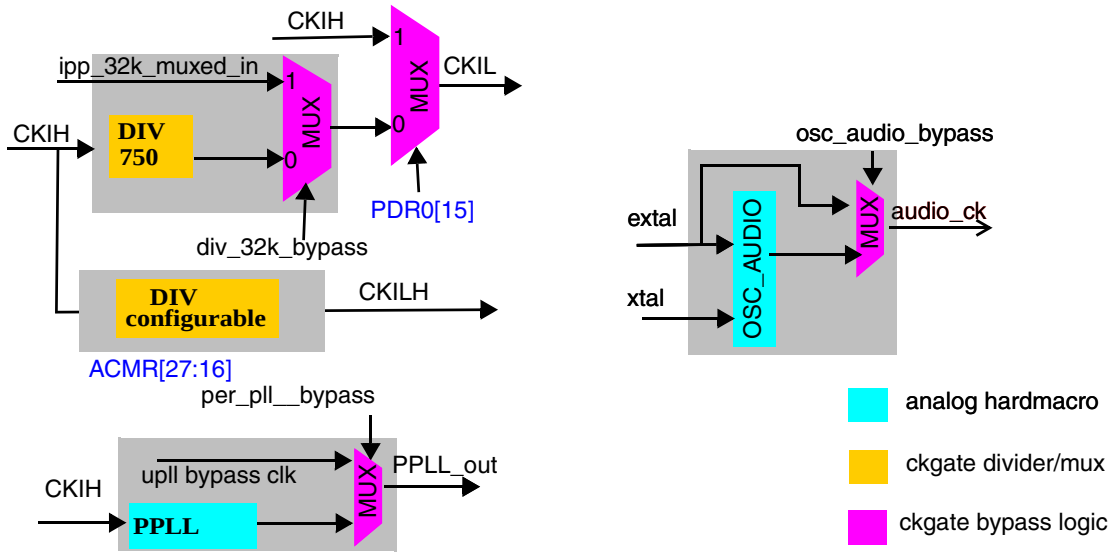


Figure 14-24. MCIMX35 Clock Generation Scheme 1

[1] This figure does not show scan mux and clock gating.

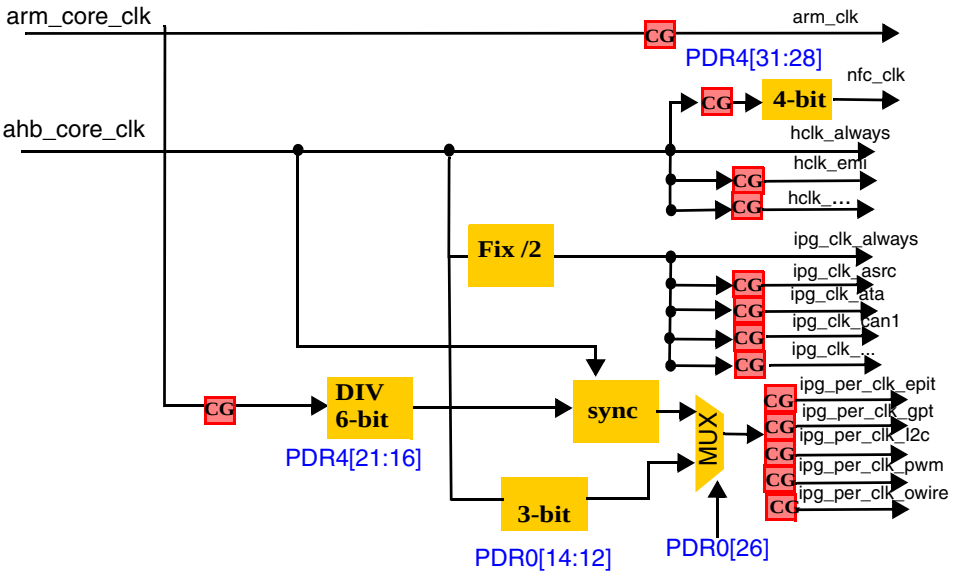

Figure 14-25. MCIMX35 Clock Generation Scheme 2

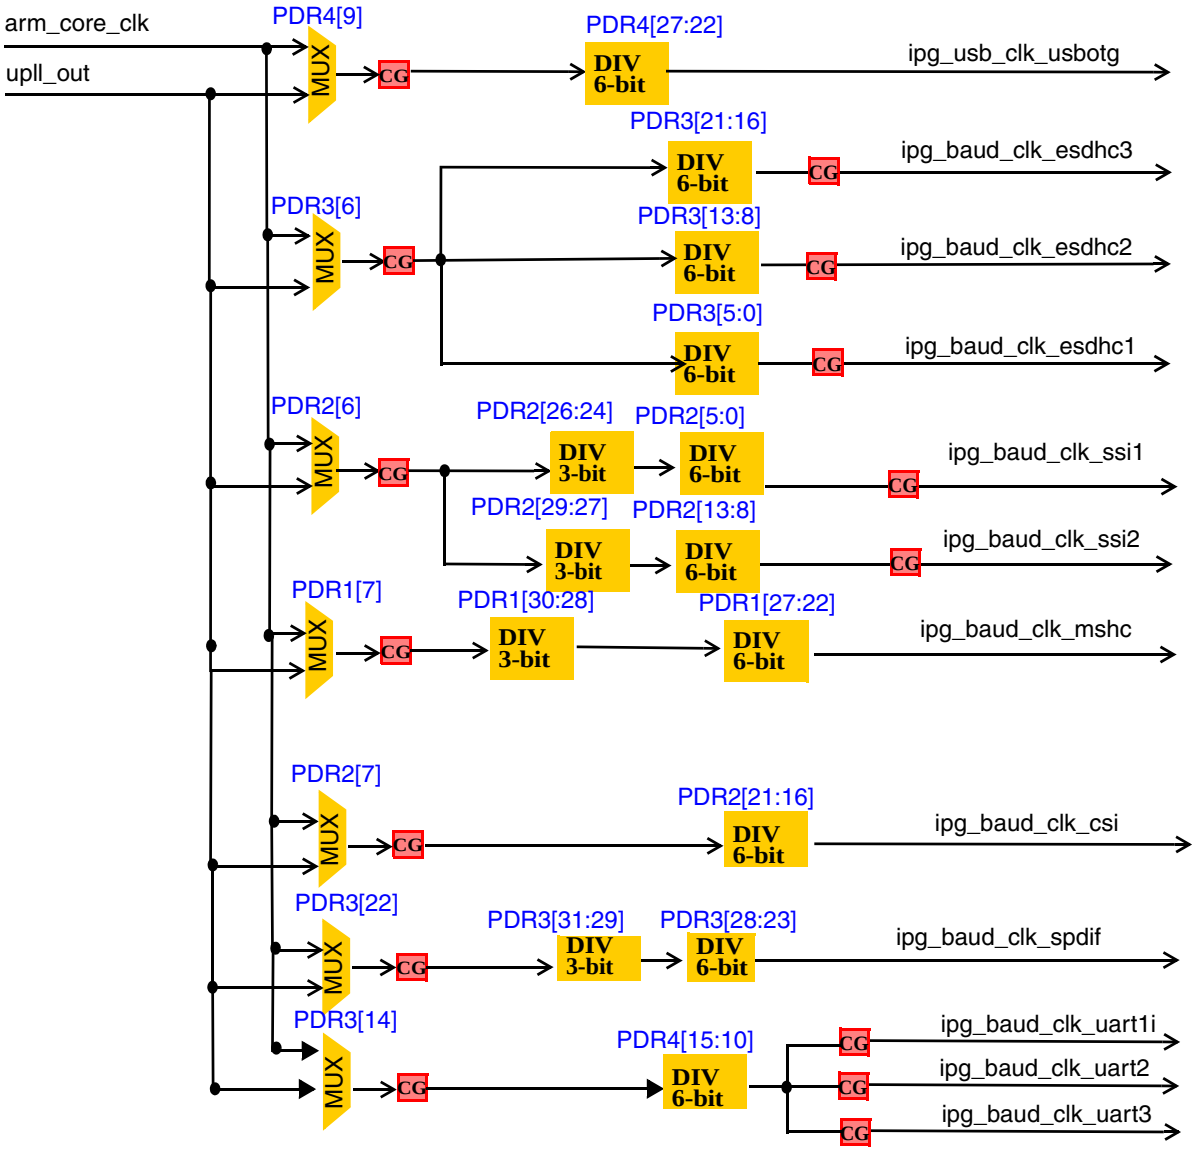

Figure 14-26. MCIMX35 Clock Generation Scheme 3

14.4.1.1 Clock Sources

There are three clock sources:

- 24 MHz external crystal (mandatory)
- 32 kHz clock input (mandatory)
- External crystal audio (optional)

14.4.1.1.1 24 MHz External Crystal

The device needs an external 24 MHz crystal to work with the internal oscillator. The 24 MHz signal is used as a core PLL and peripheral PLL reference clock, and is also divided by 750 to generate a 32 kHz clock after power-on reset.

The internal 24 MHz oscillator can be bypassed through the CLK_MODE[1:0] pins, so that the external 24 MHz clk can enter the device directly. Figure 14-24 describe these functions.

14.4.1.1.2 32 kHz Clock Input

The device requires a 32 kHz clock for USB, EMI, and so on. The 32 kHz clock is divided from the external input 24 MHz clock, synched with the IPG clock, then sent to each module.

As shown in Figure 14-24, the device has another 32 kHz input muxed from one contact. This can be used to enable the 32 kHz clock when the internal 24 MHz oscillator is be powered down.

14.4.1.1.3 External Crystal Audio

The device has an audio clock input source from an external crystal. Through an internal oscillator, the device can generate two possible frequencies (24.576 Mhz or 22.528 Mhz) for audio modules such as SPDIF. The frequency depends on the external crystal and system requirements. If the audio system requires a 48 kHz (respectively 44 kHz) audio clock, the device should be connected to a 24.576 Mhz (respectively 22.528 MHz) external crystal.

The internal OSC AUDIO can be bypassed by CLK_MODE[1:0] pins, so that the external audio clk passes directly into the device.

14.4.1.2 PLLs and Clock Generation

The core PLL and peripheral PLL generate all high-frequency clocks for ARM and each module. These PLLs are described in the following subsections

14.4.1.2.1 Core PLL (MPLL) Domain Clock Generation

The core PLL is configured by the MPCTL register. It generates three clocks simultaneously with relative frequencies 1x, 2x and 0.75x. For example, if the DPLL_DIVGEN is locked at 532 MHz then the 1x, 2x and 0.75x ports provide signals of 532 MHz, 1064 MHz, and 399 MHz respectively.

Figure 14-24 shows the generation of clocks from the PLLs. For the core PLL, it has 1x and 0.75x ports, which generate two edge-aligned clocks. The configuration of the clock switch is defined in the PDR0 register map. The actual divider value for ARM and AHB does not matter; PDR0[19:16] should be configured according to the register description to determine the frequency. The ARM clock frequency is 133–532 MHz, and the AHB clock frequency ranges from 66.5–133 MHz. Internal logic guarantees that the ARM or AHB clock switches concurrently at the ARM or AHB aligned rising edge.

The core PLL generates clocks in the following order:

1. arm_core_clk and ahb_core_clk
2. Generated ARM clock (through a gating cell)
3. All AHB clocks for AHB modules (through gating cells)
4. All IPG clocks for all modules (through gating cells)
5. All ipg_per clocks for special modules (these modules may require different frequencies from ipg_clk, but must be synched with the AHB clock through gating cells).

14.4.1.2.2 Peripheral PLL (PPLL) Domain Clock Generation

The PPLL is configured by the PPCTL register. It is based on the same design as MPLL, but only connects the 1x port to output. The typical PPLL frequency is 300 MHz.

The PPLL is used for USB/SSI/MSHC/SPDIF/UART baud-rate clock generation. The baud clocks of these modules do not need to be synched with the AHB/IPG clock (which is used to generate data to communicate externally to the device). The baud-rate clocks can also be derived from the core PLL (as shown in Figure 14-26), if the PPLL value does not meet the requirements or if the PPLL is disabled.

14.4.1.3 MLB Clock Generation

The MLB requires an hclk_mlb frequency of 133 MHz, and a mem_mlb frequency of 266 MHz. Because of the MLB design, the relationship between hclk_mlb and mem_mlb must be maintained after system reset, and gating of the hclk_mlb or mem_mlb, or changing the frequencies, should be done carefully. The logic guarantees clock switch and a fixed relationship between mem_mlb and hclk_mlb. A clock gating control signal driven by the ipg clk is first synched with ckgate hclk, and then used to gate or open hclk_mlb and mem_mlb. In this way, the relationship between hclk_mlb and mem_mlb clocks is maintained whether gated or open.

14.4.1.4 HSP Clock Generation

The HSP clock is the clock for IPU. This clock must always be synched with the AHB and IPG clocks. The HSP clock can run up to 178 MHz when ARM is at 532 MHz and core voltage is above 1.45 V–1.6 V. Otherwise, the HSP clock is the same frequency as the AHB clock at 133 MHz or 66.5 MHz. However, the HSP clock cannot be slower than the AHB clock.

the HSP clock has a separate divider from MPLL output. The field PDR0[21:20] informs the CCM as to which frequency (178 MHz, 133 MHz, or 66.5 MHz) is to be used by the HSP. The CCM logic calculates the actual divider value for the HSP clock based on this information and the ARM divider value.

An HSP clock change triggers the handshake process between the CCM and IPU. For details, see the IPU block guide.

14.4.1.5 Clock Generation: ipg_ckil_sync Clock

This clock is generated by synchronization of the CKIL clock to ipg_clk when the system is not in deep sleep mode. When the system is in deep sleep mode, the synchronizer is bypassed.

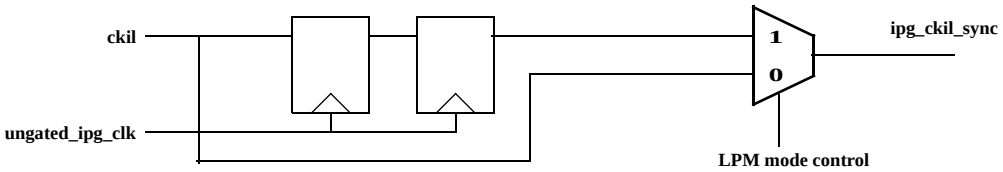

Figure 14-27. ckil_mcu_sync_ipg Clock Generation

14.4.2 Reset Controller

This section includes the following:

- A description of the reset module
- The reset negation sequence from POR
- A description of other reset events

14.4.2.1 Functional Description of the Reset Module

The reset module controls or distributes all of the system reset signals used by the device.

The device has four system reset inputs.

- POR: mandatory power on reset
- RESET_IN_B: optional warm reset
- WDOG_RST: optional reset input from the watchdog timer
- TRSTB: mandatory JTAG reset input

A simplified block diagram of the reset module is shown in Figure 14-28.

- The mcu_reset_out_b signal is connected to ARM1136, TMAX, GPU2D, WBCP, SCC and WDOG.
- The per_reset_out_b signal is connected to most of the peripheral modules such as ATA, ASRC, AUDMUX and so on.
- The ccm_fuse_reset signal is inverted and connected to RTC and FSH module, the laser fuses in the L2 cache data array through the FSH module.
- The ccm_por_reset_b signal is connected to the fusebox, IIM, USBPHY, and WDOG modules.
- The ccm_pll_reset signal is connected to two PLLS.
- The ccm_emi_reset_b signal is connected to the EMI.
- The ccm_reset_b is connected to the CCM module.

Normally POR_B is connected to PMIC or the dedicated RESET monitor that generates the Power ON Reset signal after power is on, while RESET_IN_B is connected to the Manual/Warm RESET button or the output of external MCU/Watchdog.

During the power-on stage, only POR_B needs to be asserted (active low); RESET_IN_B does not need to be asserted. If RESET_IN_B is not used, it can be tied with POR_B, or just pulled up.

POR_B resets everything; while RESET_IN_B resets the ARM core and peripherals except PLL, CCM, FUSEBOX, and IIM. If you want to assert both RESET_IN_B and POR_B while powering on, it's better to release RESET_IN_B before POR_B,

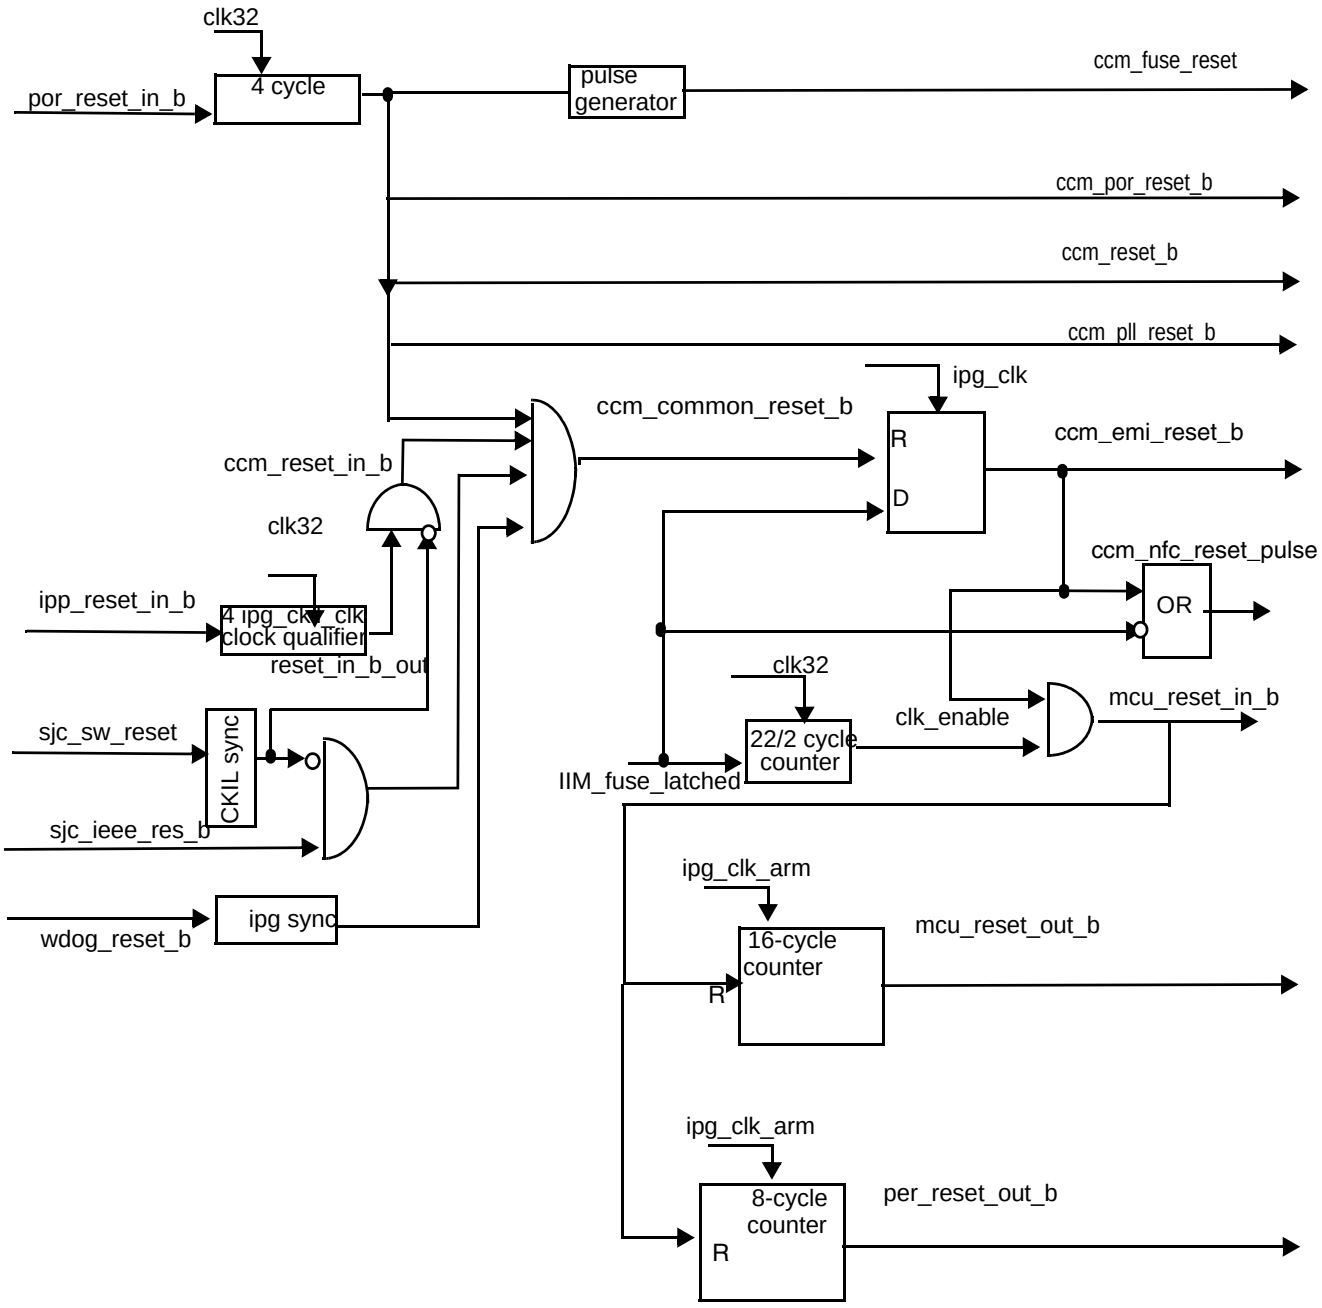

Figure 14-28. Reset Module Clock Diagram

14.4.2.2 Reset Negation Sequence from POR

The reset exit sequence is driven by the CKIL (32 kHz) clock:

1. After POR reset, Boot mode pins are sampled.
2. After 300 32 kHz clock cycles (four 32 kHz clock cycles, if OSC24M is bypassed), Fuse reset is generated (after POR reset only).
3. PLL reset released, CCM reset released (after POR reset only).

4. After the core PLL is locked, the IIM ipg clock is generated, and IIM begins to latch the fuse value. After the IIM fuse is latched and the signal asserted, the pins or fuse value for boot such as boot_type and mem_ctrl are sampled. And then ccm_emi_reset_b is released.
5. After 22 32 kHz clock cycles (after 2 32 kHz clock cycles in function-test mode), the ccm_clk_enable signal is asserted. This provides time for the NAND flash controller to download data from the device to an internal 512-byte/2-kbyte/4-kbyte buffer.
6. After the 8 mcu_clk cycles, per_reset_out_b will be released, after 16 mcu_clk cycles, mcu_reset_out_b will be released.
7. ARM11 processor begins fetching code from the internal bootstrap ROM, sync flash or CS0 space. The memory location of the fetch depends on the configuration of the BOOT pins and the value of the fuse/GPIO pins value latched in step 4.

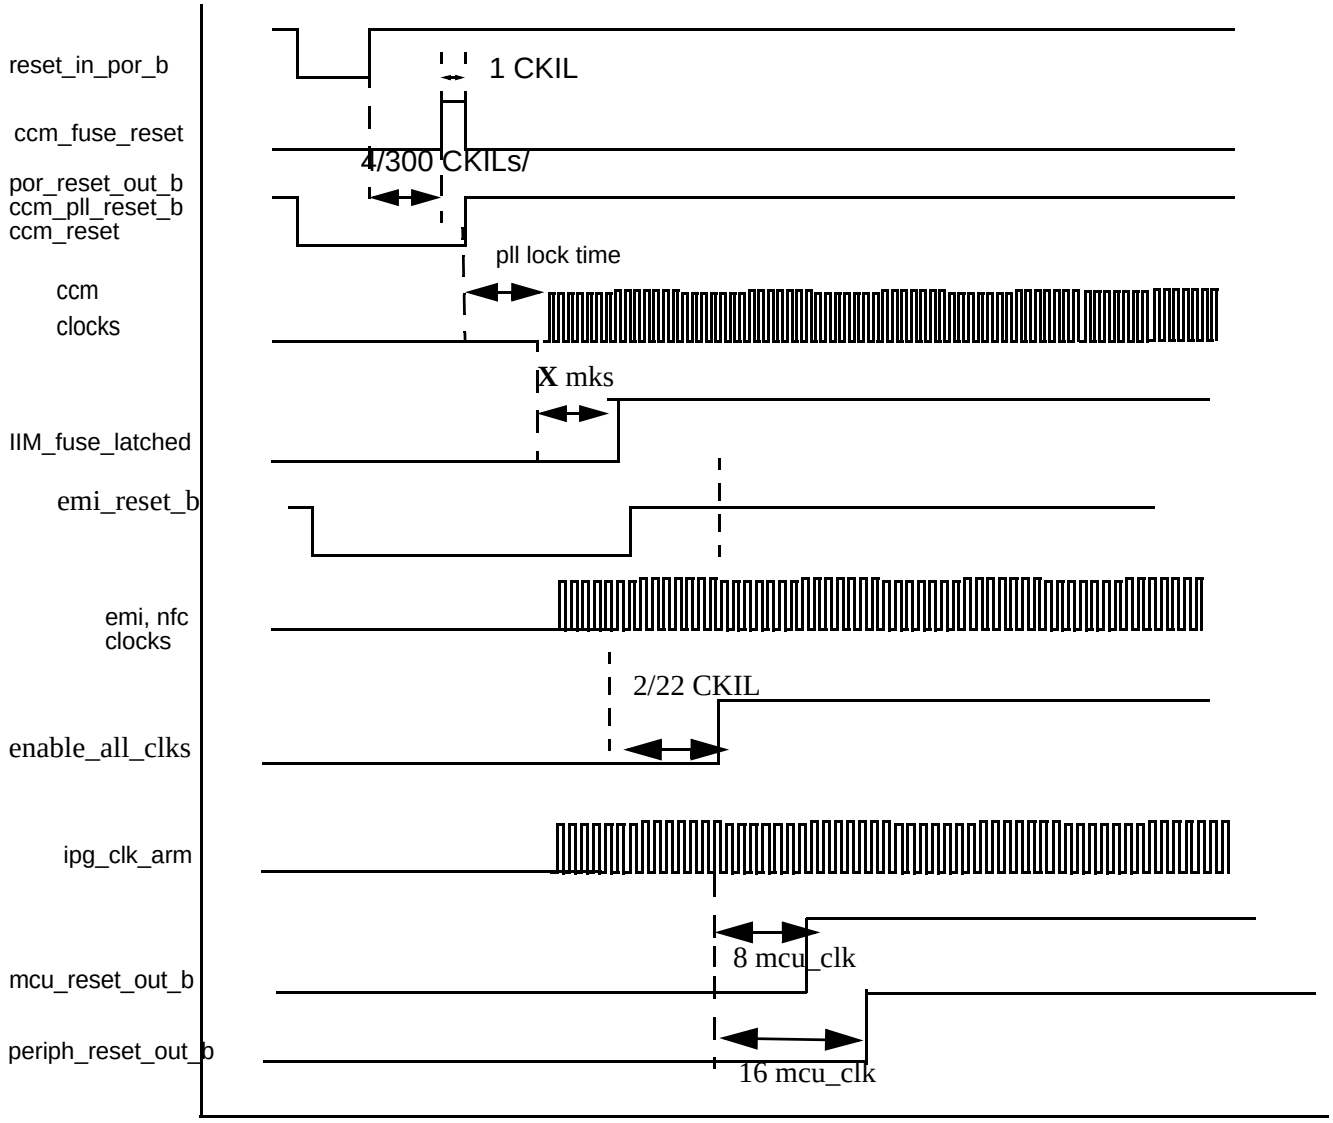

Figure 14-29. Reset Timing Diagram from Power-on Reset

14.4.2.3 Other Reset Events

Other reset events include the following:

- Watchdog resets
- RESET_IN_B source
- JTAG software reset

These events are described in the following subsections.

14.4.2.3.1 Watchdog Resets

There are two different watchdog reset events: a time-out event or a software reset. For more information, see the watchdog specification.

A watchdog module reset causes a reset of the chip, and the CCM generates a reset pulse. When the core comes out of reset, it can check the reset source bits in the CCM module.

The watchdog reset negation sequence is as follows:

1. A reset is received from the watchdog timer.
2. The reset is triggered and the ccm_common_reset_b asserted.
3. After one ipg clk, ccm_emi_reset_b is released.
4. After 8 mcu_clk cycles, per_reset_out_b is released, and after 16 mcu_clk cycles, mcu_reset_out_b is released.

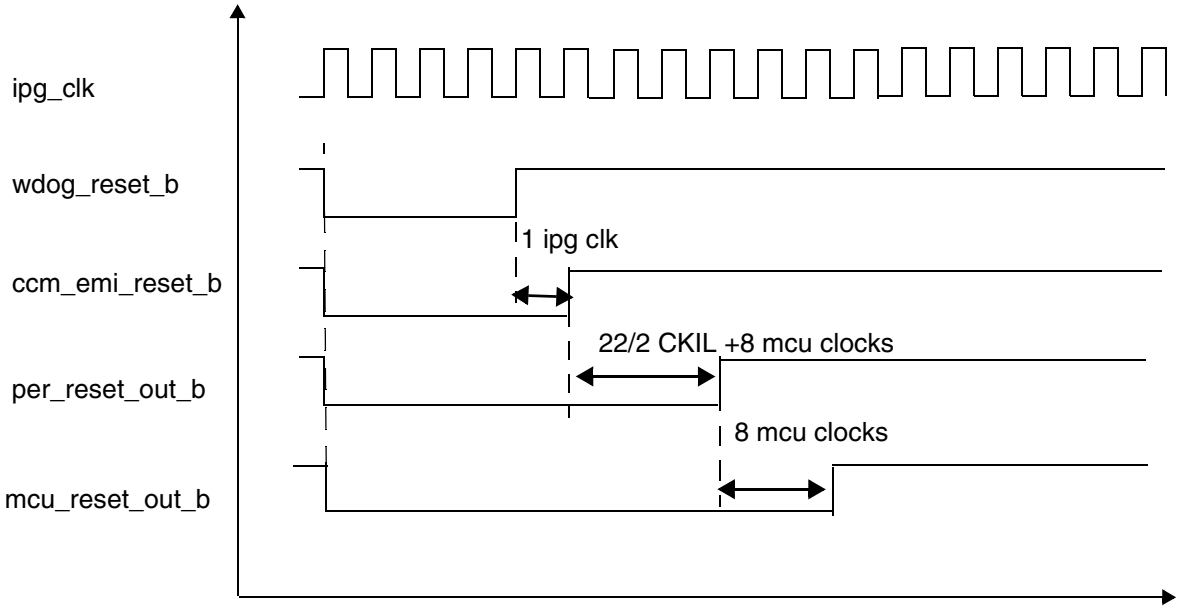

Figure 14-30. Watchdog Software Reset Diagram

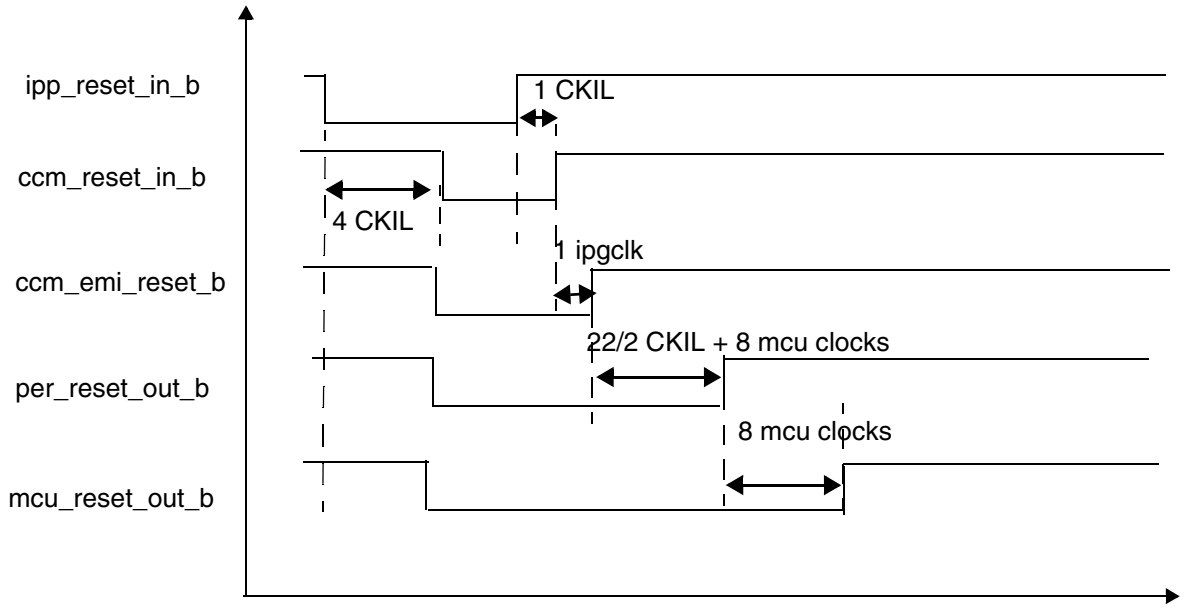

Figure 14-31. Reset_IN_B Diagram

14.4.2.3.2 RESET_IN_B Source

RESET_IN_B is a warm reset input and has the same function as the WDOG_RTS input. It is normally used to connect a reset button. The RESET_IN_B signal can trigger the EMI, peripheral and core resets, but does not reset the PLL, fusebox, IIM, or CCM. The reset sequence is the same as for the WDOG reset.

14.4.2.3.3 JTAG Software Reset

The device can be reset via software from a JTAG module, either by a signal or by a general-purpose bit.

14.4.3 Power Management

The CCM supports several power management techniques that reduce active and static power consumption:

- **Clock Gating** reduces the active power if the module is not active. CCM has low power mode power gating to gate the source clocks, and has register control the clock gating of each module.
- **Dynamic Voltage Frequency Scaling** (DVFS) reduces active power consumption by scaling voltage and frequency accordingly to required MIPs.
- **Dynamic Process Temperature Compensation** (DPTC) reduces active power consumption by adjusting supply voltage according to part-specific characteristics, the manner in which the chip was fabricated, and the ambient temperature.
- **State Retention Voltage** (SRV) reduces static power consumption by decreasing supply voltage to minimum State Retention level. Chip is not functional in this mode.
- **Active Well Bias** (AWB) reduces static power consumption by applying back bias on transistors. AWB can be applied on ARM11P. ARM11P is not functional when AWB is applied.

14.4.3.1 Power Domains

The device is partitioned into several power domains, but all digital logics are included in one common power domain.

14.4.3.2 Power Modes

The device supports a versatile definition of power modes, including power and clock domains status and applied power techniques. The power modes described in the following sections were defined taking into account static and dynamic power consumption of blocks in different operational modes, the power consumption of clock sources, and the time required to exit low power modes.

14.4.3.2.1 Run Mode

This is the normal/functional operating mode of ARM11. The ARM clock frequency can vary between fmax (532 MHz) and fmin(133 MHz), and the voltage between Vmax(1.47 V) and Vmin(1.22 V).

14.4.3.2.2 Wait Mode

In this mode, the core clock is gated, but the ARM1136 MAX and all peripherals clocks are available. This mode is entered by the core executing a STANDBY FOR INTERRUPT command. The arm_clk_off output of ARM11P is asserted and the clock to the core arm_clk is gated by the CCM. The core exits the wait mode and enters the run mode by receiving of any interrupt (depending on the mask bits) and negation of the arm_clk_off signal. Clocks for specific modules can be gated off automatically in wait mode by programming CGR registers. The wait mode entry process is as follows:

1. The ARM1136 executes the STANDBY FOR INTERRUPT instruction.
2. If the SDMA/IPU clocks are configured to be gated in wait mode, the CCM sends a standby request, and waits for the stby_ack signal from each module.
3. If the EMI is configured to be gated in wait mode, the CCM sends the sd_lpmd to EMI, and waits to receive the sd_lpack signal.
4. If all acknowledgements listed above are received, the 4-bit IPG clock counter is started.
5. If the FlexCAN is configured to stay open in wait mode, the CCM sends out the doze_request to the FlexCAN; if the FlexCAN is configured to be gated in wait mode, the CCM sends a stop_request to the FlexCAN.
6. If an acknowledgement is received from the FlexCAN, and the 4-bit counter finishes counting 9 IPG clock cycles, the lpm_sm signal is in wait mode.

The wait mode exit process is as follows:

- When the arm_clk_off signal is negated, the system immediately returns to run mode.

14.4.3.2.3 Doze Mode

The core and MAX clocks are gated. The clock source is available and peripherals that do not require MAX and core functionality can be active.

Doze mode is entered by programming the CCMR LPM bits. The next time the core executes the STANDBY FOR INTERRUPT command, the CCM asserts a signal for the MAX clock halt request and the clock to MAX is gated off upon acknowledgement of the signal assertion.

The core exits from doze mode and enters run mode by receiving any enabled interrupt and negation of the arm_clk_off signal. If active well biasing is enabled (CCMR[WBEN]=1), the CKIL well bias counter must complete until clocks are provided to the core and peripherals.

Clocks for specific modules can be gated off automatically in doze mode by programming the CGR register. Some modules trigger the handshake process while trying to close the clock. For example, SDMA, IPU, and EMI. This process is handled automatically by the CCM and by each module.

Doze mode is entered as follows:

1. The ARM1136 executes the STANDBY FOR INTERRUPT instruction.
2. If the IPU/SDMA modules are configured to be clock-gated in doze mode, the CCM sends the stby_req signal for each module.
3. The CCM sends a MAX halt request.
4. If a standby acknowledgement is received from the IPU/SDMA modules and a MAX halted acknowledgement is received, the CCM sends out the EMI lpm_sd request if the EMI is configured to be clock gated.
5. If all acknowledgement signals (IPU/SDMA/MAX/EMI) are received, the CCM sends the can_doze request or can_stop request. If the FlexCAN is configured to keep the clock in doze mode, the CCM sends out the can_doze request. If the FlexCAN is configured to be clock-gated in doze mode, the CCM sends out a can_stop request.
6. If an acknowledgement signal from is received from the FlexCAN and the 4-bit counter is finished counting nine IPG clock cycles, the lpm_sm signal change into real doze mode, and the ccm_int_holdoff signal is negated.
7. The ARM1136 enters well bias mode if well biasing is enabled (CCMR[WBEN]=1).

Doze mode is exited as follows:

1. If the wb_en bit is not asserted, the system returns to run mode immediately.
2. If the wb_en bit is asserted, mcu_mem_pwrdn and mcu_wb_en(emi_wb_en) are immediately negated. After wb_counter_finished asserts, then mcu_mem_on is asserted, mcu_wbcp_fbd_b(emi_wbcp_fbd_b) is negated, and the system returns to run mode.

14.4.3.2.4 Stop Mode

Stop mode stops the PLL and all clocks that are generated from the PLL. In some cases, if the VSTBY bit is set to 1, the CCM informs the external PMIC to lower the core power supply to 1.0 V after all PLLs are closed. If the OSC24M_DOWN bit (PMCR2 register) is set, CCM powers down the OSC24M to reduce the system power to minimum. If the 32 kHz CKIL clock is still required while the OSC24M is powered down, an external 32 kHz source can be muxed into the CCM, and the CKIL_SEL bit can be set so that the external 32 kHz source is used instead of the internal OSC24M divided source.

Stop mode is entered by programming the LPM bits in the CCMR register the next time the STANDBY FOR INTERRUPT command is issued.

The sequence below is implemented by the CCM upon entering the stop mode:

1. IPU, SDMA, MAX, FlexCAN and EMI standby requests are sent if each module is not clock-gated before entering stop mode.
2. After all acknowledgement signals are received, the CCM waits eight IPG clock cycles and the request for CKIL to switch from IPG synched to not synched is sent. sm_mode changes to stop, and the ARM clock is gated.
3. After the sync_back_ack from CKIL to confirm that the CKIL is switched from synched to asynched, the CCM sends a signal to request to stop the core PLL and peripheral PLL.
4. If the PLL lock flag is negated, interrupts are allowed.
5. If CCMR[VSTBY]=1 (standby voltage enable), the VSTBY output signal is asserted. This requests PMIC to lower the core voltage to 1.0 V for state retention.
6. The internal 24 MHz oscillator OSC24M is switched to power-down if PMCR2[OSC24M_DOWN]=1, and so the internal 32 kHz clock divided from OSC24M is closed. If the device wants to keep the CKIL (32 kHz) and power down the OSC24M at the same time, it can configure first the ckil_sel bit to select the CKIL clock source from external muxed in 32 kHz, not the internal divided CKIL (32 kHz).

The device exits state-retention mode by any internal or external interrupt. The figure shows the external GPIO interrupt wake-up flow from state-retention mode or stop mode.

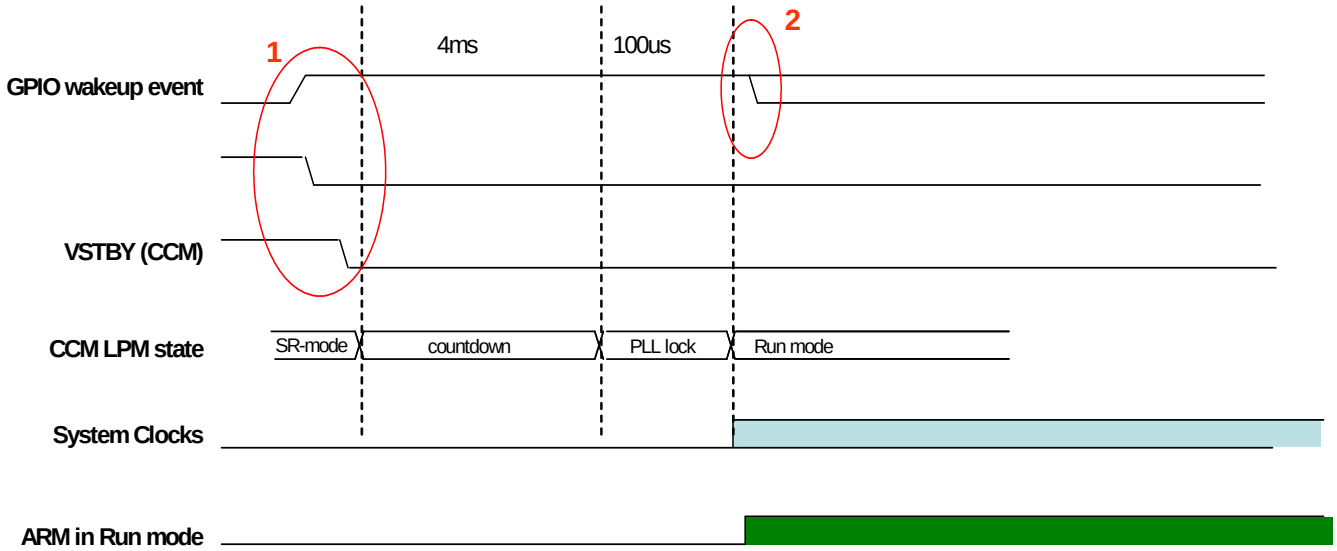

Figure 32. External GPIO Interrupt Wake-up flow from State-Retention mode (SR) / Stop Mode

In the figure, 1 indicates that the combinational logic is used from the interrupt event until VSTBY negation. 2 indicates GPIO wake-up. That is, an external interrupt event signal must remain asserted until run mode as has been entered.

VSTBY output is a combination of an input interrupt wake-up event (GPIO) going through the ARM Vector Interrupt Controller (AVIC) until the the system clocks are running. Any possible de-assertion of this wake-up event signal should last until all system clocks are running and stable. Any toggle of an input interrupt wake-up event (GPIO) before the system reaches normal operation mode can cause the CCM

internal low-power mode state machine to be set to an undetermined state. To ensure that the wake-up event is handled correctly, the GPIO event stays asserted until software can read the GPIO status register and confirm the event is valid. Else the system returns to state-retention mode (low-power mode).

Stop mode is exited as follows:

1. If the system is in state retention mode, the VSTBY signal is negated, and requests that the external PMIC restore the voltage supply from 1.0 V to normal voltage.
2. If OSC24M is powered down, OSC24M is activated.
3. If the OSC24M used to power down is now powered up, the CCM needs to wait for the 32 kHz clock counter to finish to confirm that the OSC24M output is stable.
4. If the system is used to configure state-retention mode, the CCM waits for the 32 kHz clock counter to finish or PMIC_RDY signal ack from PMIC. This can be selected by the register configuration signal, CCMR[STBY_EXIT_SRC].
5. After the OSC24M is stable and PMIC is ready, the CCM begins to request PLL restart. If well biasing is enabled, the existing well biasing counter starts.
6. After the PLL is ready, and the well biasing counter is finished, CCM sends out the sync request for the CKIL switch from asynched to synched.
7. After the sync ack signal comes back, the CCM switches back to run mode, and the ARM clock begins.

14.4.3.3 Dynamic Voltage Frequency Scaling Support

The CCM allows simple software dynamic voltage frequency scaling (DVFS). The frequency of the core clock domain and the voltage of the chip can be changed on the fly while all modules (including the core) continue their normal operation. The voltage of the chip can be changed by software through the CSPI/I2C port between the MCIMX35 and external PMIC. The frequency of the core clock domain can be changed only by configuring the con_mux_div bits in PDR0.

The system bus frequency (AHB, IP) can also be changed according to the core clock. The AHB frequency is configured by con_mux_div. And the IP frequency is fixed as 1/2 of the AHB frequency.

The DVFS scheme relies on software configuration. Figure 14-33 shows the DVFS flow in the MCIMX35. This flow describes the software routine flow after the DVFS interrupt is triggered or the DVFS DMA event is triggered.

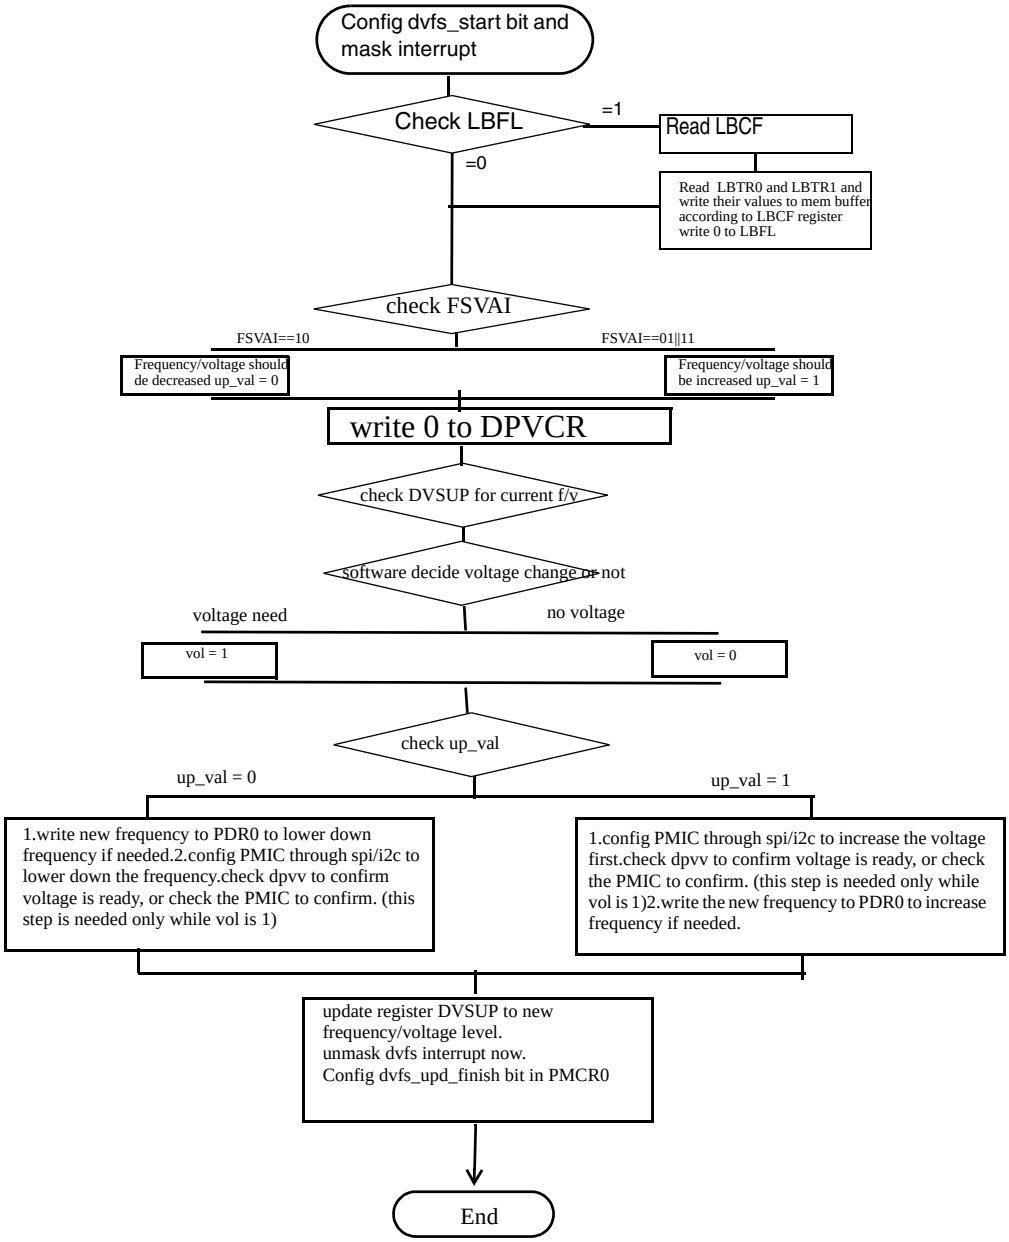

Figure 14-33. DVFS Frequency/Voltage Change Process

The DVFS load-tracking block allows hardware tracking on the core load and generation of an interrupt when a frequency change is requested.

14.4.3.4 Dynamic Process and Temperature Compensation (DPTC) Support

The DPTC module is a power management module. The purpose of the DPTC module is to detect the minimum operation voltage for the IC, taking into account the extrema of processing activity and ambient temperature for a given frequency. It inputs predefined values for processor speed performance measurements.

Figure 14-34 is a block diagram of the DPTC module.

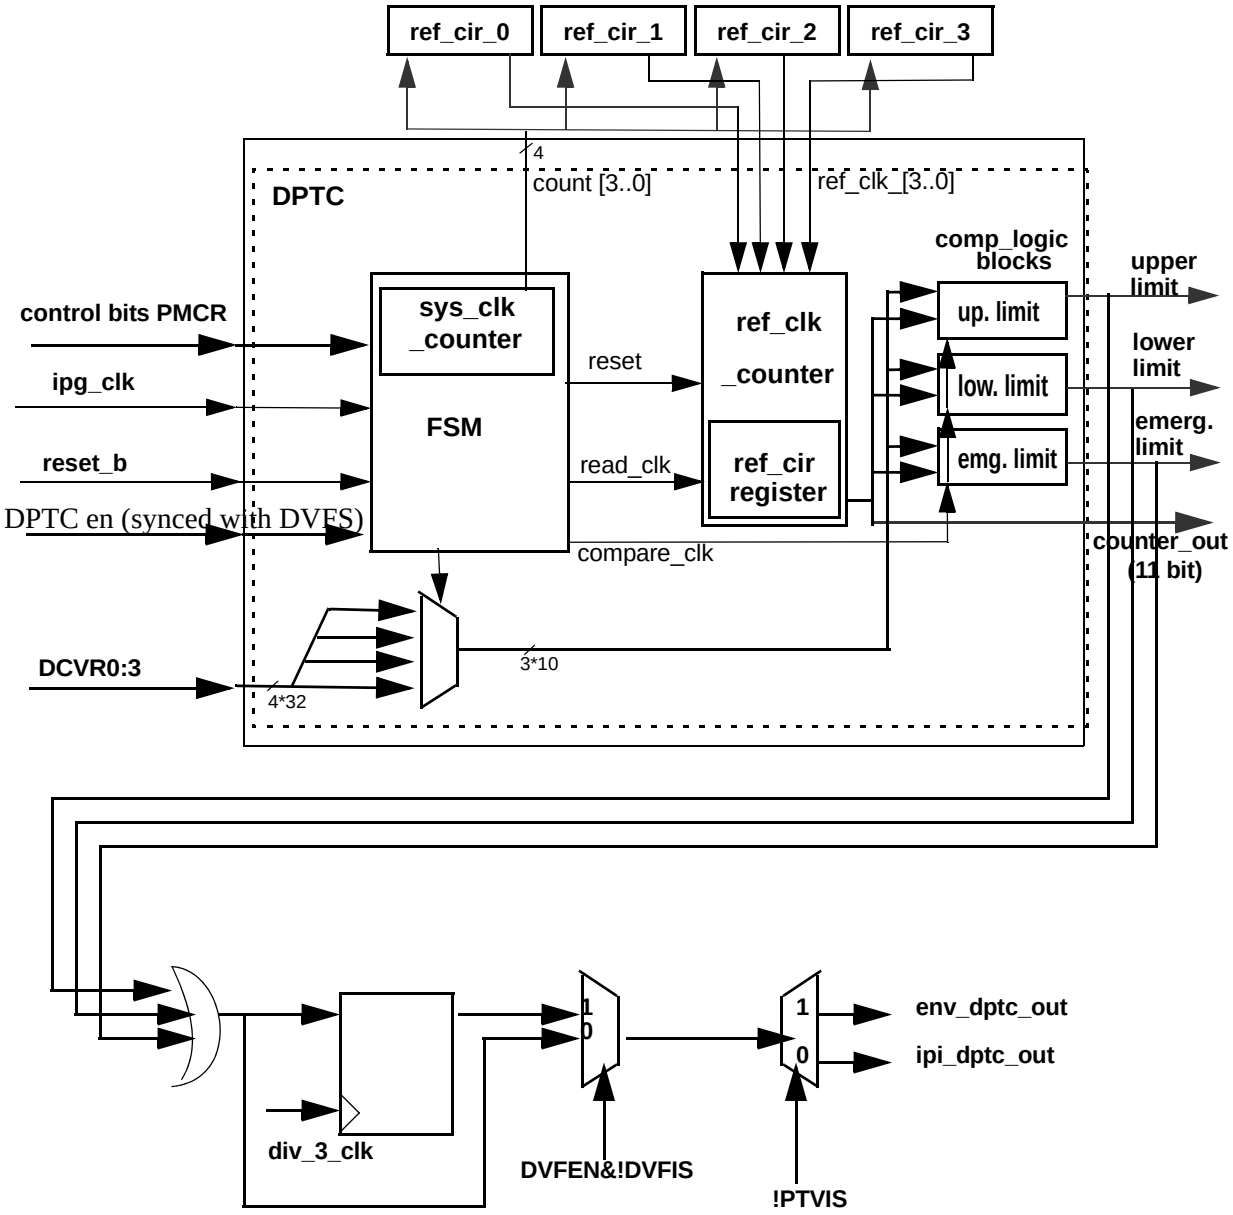

Figure 14-34. DPTC Block Diagram

14.4.3.4.1 Block Description

This section describes the DPTC blocks:

- FSM block
- ref_clk_counter block
- comp_logic blocks
- ref_cir blocks

The FSM Block

The FSM block is responsible for generation of internal control signals and includes a sys_clk_counter sub-block that creates a long-interval count-enable signal, based on the system clock signal, and received from the sys_clk input pin.

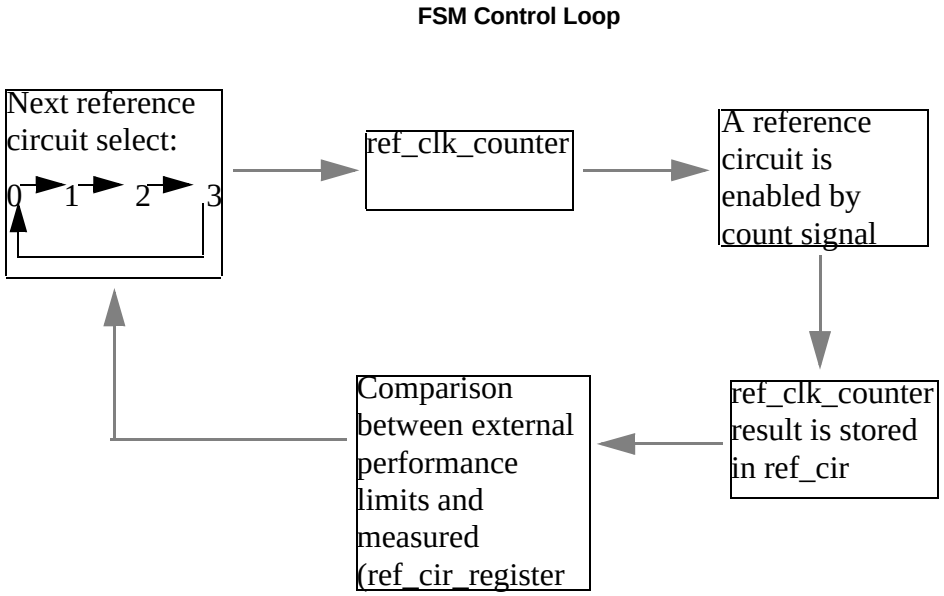

Figure 14-35. FSM Control Loop

Table 14-3. FSM Control Loop Stages

Operation	Explanation	Active Signals	Level	Misc.
reference circuit select	Reference circuit 0-3 is selected	ref_circuit_select	2 bits value	
ref_clk_counter reset	Previous reference circuit counting result is deleted from ref_circuit_counter	ref_count_reset_b	low	counter_out value is reset
reference circuit performance evaluation	Amount of ref circuit clock cycles is counted by ref_clk_counter during defined number of sys clock	count	high	
read reference circuit count result	value of ref_circuit_counter is read to register	read_enable_clk	posedge	counter_out value is valid
performance comparison: measured to limits	reference circuit performance is compared to the limits from input register	comp_enable_clk	posedge	

Signal diagrams are described in Figure 14-36.

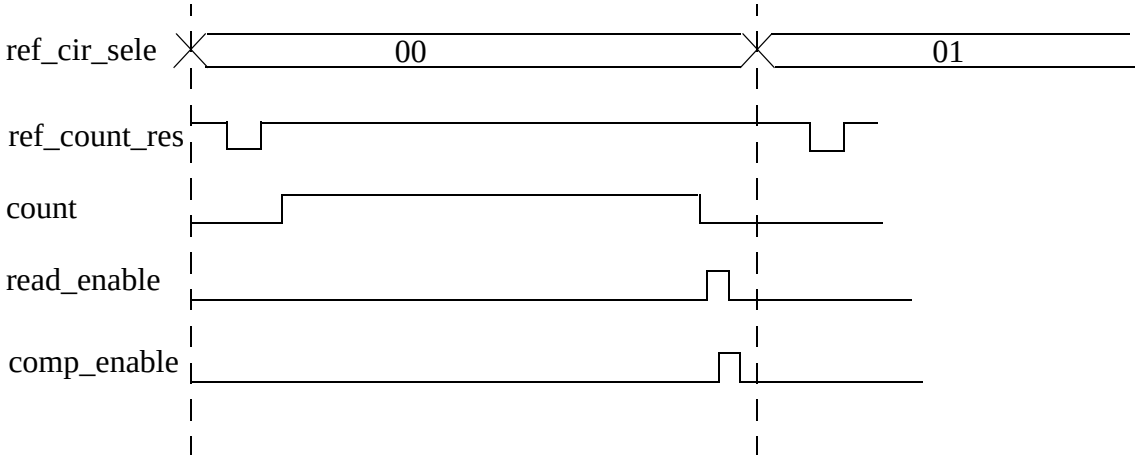

Figure 14-36. FSM Control Signals Waveforms

All signals are generated based on sys_clk. A sub-block sys_clk_counter is used to create a long count signal. The sys_clk_counter counts the system clock and stops when the max value is reached. The max value for the sys_clk_counter is set by the SCR bit in the status control register: 1 is equivalent to 512 system clocks and 0 is equivalent to 256 system clocks.

The ref_clk_counter Block

The ref_clk_counter block acts as a counter for the reference clocks. These clocks are generated by ref_cir blocks and includes the ref_cir_register (11-bit) for storing the last valid value of the counter.

The ref_cir_counter receives the following signals: ref_clk_reset_b, read_enable_clk, ref_clk_0, ref_clk_1, ref_clk_2, ref_clk_3. The output (11 bits) is sent to the counter_out bus.

As long as the ref_clk_counter is not in the reset state (defined by the ref_clk_reset_b active-low signal), counting is enabled. The counter is an 11-bit counter, stored in the ref_cir_register.

comp_logic Blocks

The comparison blocks are responsible for the comparison between performance values from performance limit registers and the actual performance as measured by the ref_clk_counter block. Each one of the compared signals are 11 bits (due to the fact that the input performance limits are extended by a “0” as the MSB).

The comp_logic block inputs include the following:

- Performance limit value (10 bits)—the desired performance limit value
- Actual performance limit value (11 bits)—the measured performance limit value
- ref_cir_select (2 bits)—index of currently active reference circuit
- Reference circuits selective enable (RCSE) (4 bits)—to get information about enabled/disabled reference circuits from the status control register
- comp_enable_clk—comparison enable clock
- Limit type (1 bit)—hard configuration bit, connected to ground or supply

The RCSE data is essential for taking in or not taking in the account the result of comparison of the currently active reference circuit. For the disabled reference circuit, the comparison result should be considered as “right.”

The comp_logic block includes flip-flops (one for a single reference circuit), saving the comparison result for each reference circuit. The flip-flop data is used to generate the output signal of the comp_logic block. The data in the flip-flop is continuously renewed so long as the appropriate reference circuit has completed its cycle and the data is valid. The flip-flop data is reset when the DPTC block is disabled or the external reset signal is activated.

The comp_logic blocks can be operated as high_limit or low_limit type. For the high_limit type active output, the comparison of ALL reference circuits should exceed the high performance limit. For the low_limit type active output, ONE or more reference circuit comparison should exceed the low_limit or emergency_limit value.

ref_cir Blocks

The ref_cir blocks are reference circuit units, constructed using a ring oscillator with an integrated clock-gating cell. The inverting stages components and their values vary according to the type of ring oscillator. Ref_cir blocks are built to optimize speed and performance of the most critical paths in the chip for a given process/temperature.

Initialization Information

In the control status register, at least one of the RCSE bits should be set to 1. Otherwise, the error bit is activated and the output limit signals are atrophied.

14.4.3.4.2 Synchronization Between DVFS and DPTC

A synchronization scheme has been created to avoid a situation where DPTC tries to update events during a voltage update done by DVFS.

The DPTC machine can work in case the DPTC is enabled and the voltage is valid (DPVV = 1) and there is no voltage change request (DPVCR = 1).

14.4.3.5 Well Bias Support

Well bias is implemented with an on-chip charge pump. When well bias is activated, the voltage of wells will be pumped to optimal values to allow minimum leakage. Parameters of the charge pump can be controlled in software by configuring the PMCR1 register. The device has both ARM1136 and EMI well bias.

14.4.3.5.1 ARM Platform Well Bias Activating

Well bias of the ARM power domain can be activated in doze or state retention modes by asserting CCMR[WBEN]. The ARM Platform contains memory blocks with stdVt transistors in its interface sector. Well bias eliminates the leakage from these transistors by power-gating this interface—there is no need for any data saving or restoring. The memory interface is power-gated by asserting the ccm_mcu_mem_pwrdn signal and negating the ccm_mcu_mem_on signal.

14.4.3.5.2 ARM Platform Well Bias Deactivating

When ARM receives an interrupt the clock is provided to the ARM1136 after the well bias counter has finished. The well bias counter runs with 32KHz clock. The counter threshold can be selected in CCMR[WBCN].

14.4.3.6 State Retention Voltage Support

In stop mode, the device's supply voltage can be reduced to a state retention value, which allows a reduction of chip-leakage current while the embedded memory state is dormant. Cores and modules using embedded memory are not functional in this mode. Voltage is reduced by PMIC after assertion (active high) of the VSTBY output signal. Voltage will be restored to the previous value upon negation of this signal. Valid voltage is indicated when the PMIC asserts PMIC_RDY signal to high.

Chapter 15
ARM1136P Clock Control (ARM1136)

15.1 Introduction

The clock control module is used to turn on or off the clocks to various peripherals on the platform. The general registers interface with the AHB to IP-bus interface gaskets (AIPS). The clock control module contains the logic to determine when the ARM11’s clock can be turned off.

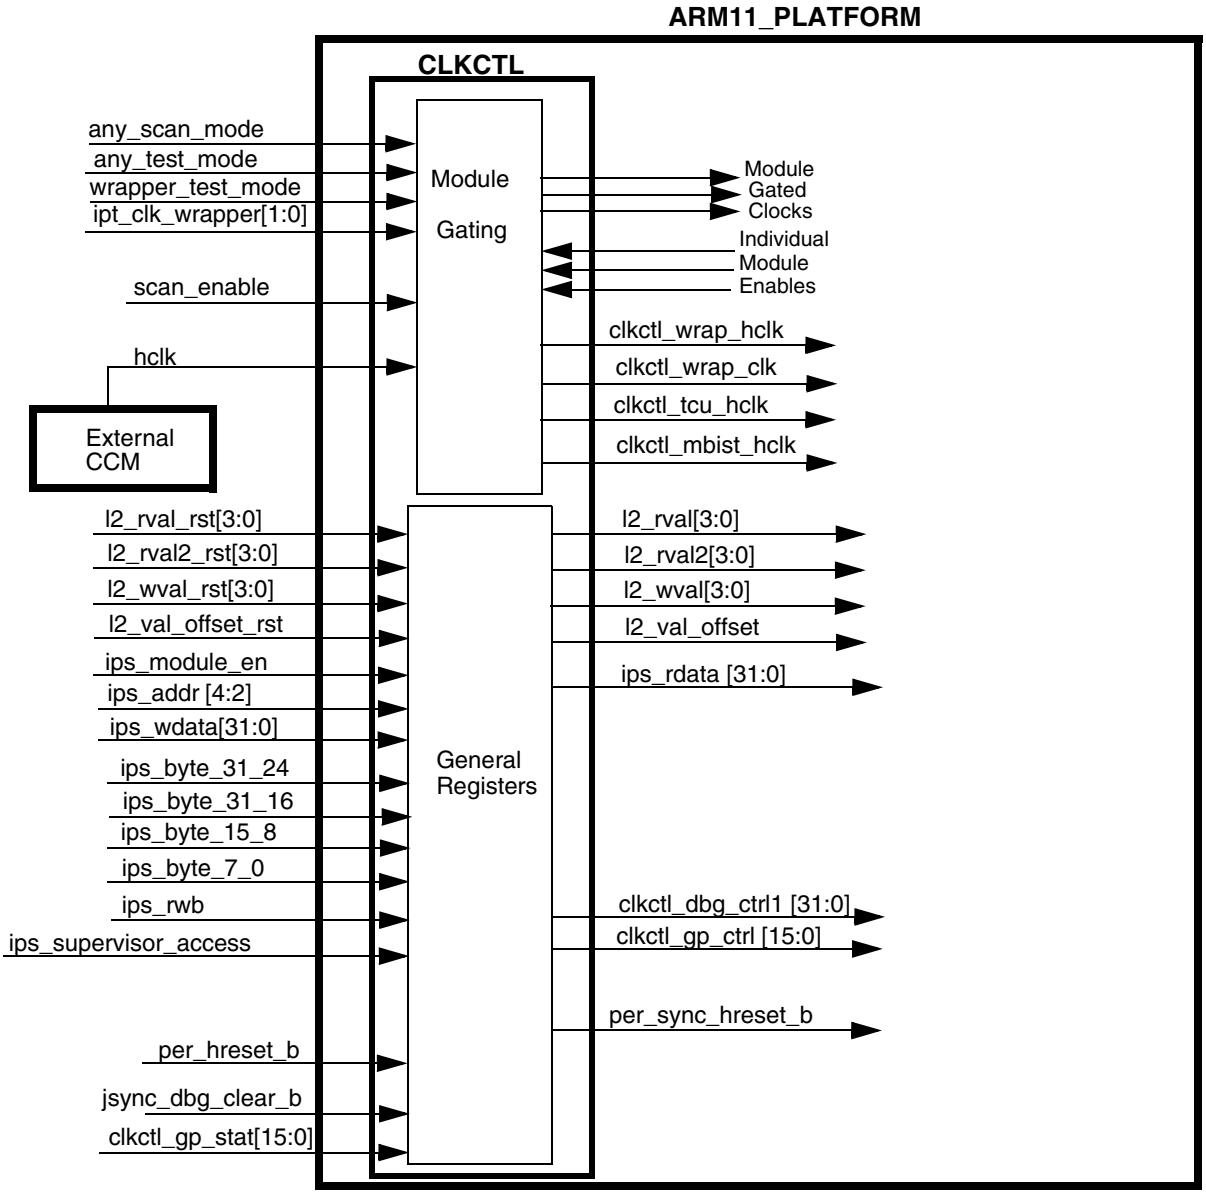

Figure 15-1. Clock Control Module Diagram

15.2 Clock Gating

Clock gating is supported for the modules listed in Table 15-1. The clock to each of the above modules is controlled by a hardware-enable that comes from outside of the CLKCTL. The gated clock is provided by the CLKCTL for synthesis purposes.

Table 15-1. Supported Modules and Method of Clock Gating

Module	Module Enable Logic	Scan Enable	Clock
ROMC	romc_hclk_en	any_test_mode	hclk
RAMC	ram_hclk_en	any_test_mode	hclk
ROMPATCH rompatch_hclk	rompatch_hclk_en	any_scan_mode	hclk
ROMPATCH REGISTERS rompatch_hclk_reg	rompatch_hclk_reg_en	any_scan_mode	hclk
AVIC avic_hclk	avic_hclk_en	any_scan_mode	hclk
AVIC REGISTERS avic_hclk_reg	avic_hclk_reg_en	any_scan_mode	hclk
MAX REGISTERS	ipg_clk_max_en	any_scan_mode	hclk
AIPSA	aipsa_hclk_en | aipsa_active	any_scan_mode	hclk
AIPSB	aipsb_hclk_en | aipsb_active	any_scan_mode	hclk
AHBDIV2_DATA	dahbdiv2_hclk_en	any_scan_mode	hclk
AHBDIV2_INST	iahbdiv2_hclk_en	any_scan_mode	hclk
MBIST	any_test_mode	any_test_mode	hclk
Wrapper Cells for hclk & clk	any_scan_mode	wrapper_test_mode	ipt_clk_wrapper
TCU	any_scan_mode	any_scan_mode	hclk

The hardware clock control works as shown in Table 15-2:

Table 15-2. Hardware Clock Control Truth Table

Scan Enable	Module Enable	Gated Hclk
0	0	OFF
0	1	ON
1	0	ON
1	1	ON

A possible clock control circuit is show Figure 15-2.

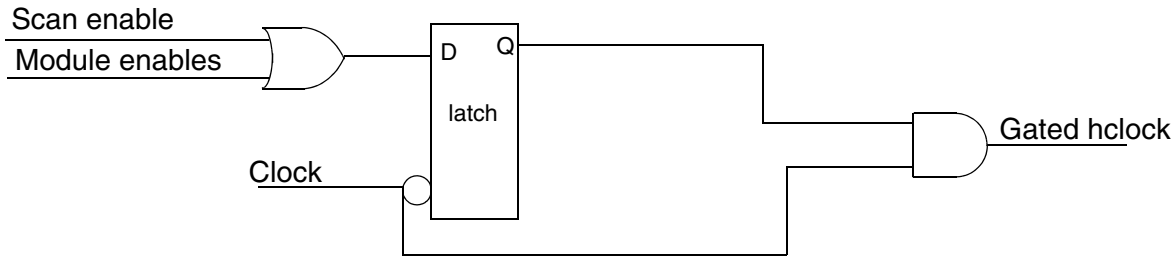

Figure 15-2. Clock Control Circuit

15.3 AHB to IP-Bus Interface Gaskets (AIPS) Interface Signals

15.3.1 IP Address Bus (ips_addr[4:2])

These inputs from the AIPS provide the address to access the CLKCTL registers.

15.3.2 IP Read Data Bus (ips_rdata[31:0])

This output bus is the read data path from the CLKCTL to the AIPS.

15.3.3 IP Write Data Bus (ips_wdata[31:0])

This input bus is the write data path from the AIPS to the CLKCTL.

15.3.4 ips_module_en

The AIPS asserts one (and only one) module-enable at a time. The module-enable is driven off the rising edge of **hclk** and remains valid until the rising edge of **hclk** when the **ips_xfr_wait** signal is negated.

The **haddr**[25:0] bits of the R-AHB-Lite address are decoded to determine which module-select is to be generated. If the selected IP-bus peripheral location is occupied, then the corresponding **ips_module_en** is asserted, otherwise an error response is returned to the R-AHB-Lite and no IP bus activity will occur.

The **ips_module_en** signal is not available externally, as this peripheral location is occupied by the CLKCTL registers.

15.3.5 ips_rwb

This signal is used to indicate to the peripheral that current access is either a read or write access. A logic-high indicates a read and a logic-low indicates a write. It is asserted after the rising edge of **hclk** along with the **ips_module_en**. This signal remains asserted for the duration of the peripheral-access byte-strobe signal.

Byte-enables are generated based on the **hsize**[1:0] bits and lower bits of address. That is, **haddr**[1:0]. These byte-enables are used to select the corresponding bytes.

15.3.6 ips_supervisor_access

This signal is asserted at the positive edge of **hclk** to indicate to the peripheral that the current access is in supervisor mode.

15.3.7 per_hreset_b

This signal is the system reset for the peripheral domain.

15.3.8 clkctl_ips_xfr_err

This signal asserts if a non-word size access is attempted to the internal CLKCTL registers.

15.4 CLKCTL Registers

The CLKCTL registers are 32-bit and can only be accessed in supervisor mode. Only word-sized accesses are allowed. Halfword and byte accesses cause an abort.

15.4.1 CLKCTL Registers Overview

The CLKCTL module includes the following registers:

- Two general purpose registers inside the CLKCTL—a control register and a status register. The control register is read/write any time. All bits in the control register are cleared on reset. The status register is read-only; all bits are cleared on reset.
- Two support registers to clear and set the control register. To clear a bit in the control register, write a one to the relative bit inside the clear register. To set a bit in the control register, write a one to the relative bit inside the set register. Reading the clear and set locations returns all zeros. The advantage of a clear/set register is the ability to clear/set a bit(s) without affecting the state of the other bits within the same register.
- A debug control register for controlling features related to debug hardware on the ARM11 platform.

The CLKCTL module has to be enabled to access these registers; that is, the ips_module_en signal must be asserted.

15.4.2 Memory Map

Table 15-3 shows the CLKCTL memory map. For the base address of a particular module instantiation, see the system memory map.

Table 15-3. CLKCTL Memory Map

Base Address Offset (Name Abbreviation)	Register Name	Access	Reset Value	Section/Page
0x0000 (GP_CTRL)	General Purpose Control Register	R/W	0x0000_3600	15.4.4.1/15-7
0x0004 (GP_SER)	Set Register	W	0x0000_0000	15.4.4.2/15-8

Table 15-3. CLKCTL Memory Map (Continued)

Base Address Offset (Name Abbreviation)	Register Name	Access	Reset Value	Section/Page
0x0008 (GP_CER)	Clear Register	W	0x0000_0000	15.4.4.3/15-9
0x000C (GP_STAT)	General Purpose Status Register	R/W	0x0000_0000	15.4.4.4/15-9
0x0010 (L2_MEM_VAL)	L2 Data Memory Val Register	R/W	0x0000_0515	15.4.4.5/15-10
0x0014 (DBG_CTRL1)	Debug Control Register 1	R/W	0x0000_0000	15.4.4.6/15-11
0x0020 (PLAT_ID)	Platform ID Register	R	0x3200_0000	15.4.4.7/15-12

15.4.3 Register Summary

Table 15-4 shows a summary of the CLKCTL registers.

Table 15-4. ARM1136 Register Summary

15.4.4 Register Descriptions

15.4.4.1 General Purpose Control Register (GP_CTRL)

Figure 15-3 shows the general purpose control register. The register can be read/written in supervisor mode only. User mode reads return all zeros.

Offset:	0x0000 (GP_CTRL)										Access: Supervisor read/write					
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read:	0	0	1	[12]	0	GP_CTRL										
Write:																
Reset:	0	0	1	1	0	1	1	0	0	0	0	0	0	0	0	0

Figure 15-3. General Purpose Control Register

The values for these bits are defined in Chapter 38, "ARM1136 Platform." They are currently defined as shown in Table 15-8.

Table 15-5. General Purpose Control Register Field Descriptions

Field	Description
31–13	Reserved
12	Enables the a11p_clk_off signal in the JSYNC. This bit resets to 1.
11	Reserved

Table 15-5. General Purpose Control Register Field Descriptions (Continued)

Field	Description
10	Drives the signal that controls the state of aips_byte_config[0] on AIPSB. This bit is reset to a one.
9	Drives the signal that controls the state of aips_byte_config[0] on AIPSA. This bit is reset to a one.
8	Enables clock GATING in the Level 2 Cache Controller. Clocks are not gated out of reset.
7	Enables the high speed DVFS signals to propagate through the platform boundary flip-flop. It also allows a11p_clk_off to assert (to allow the SOC to shut off arm_clk to the platform) even when the ARM1136 platform debug sticky bit is set, which would normally prevent the a11p_clk_off from asserting since arm_clk must run for debug activity to occur.
6	Enables clocks to the ETB.
5	Enables clocks to the CTI module.
4	Enables the peripheral bus time-out monitors.
3–0	Driven off platform for use at SoC level.

15.4.4.2 Set Control Register (GP_SER)

Figure 15-4 shows the set control register. Reads of this register always return 0, and writes can only be performed in supervisor mode.

Offset:	0x0004 (GP_SER)												Access: Supervisor write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:				w1s		GP_SER										
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 15-4. Set Control Register

Table 15-6. Set Control Register Field Descriptions

Field	Description
31–13	Reserved
12	Write 1 to this bit to set bit 12 of the general-purpose control register.
11	Reserved
10–0 GP_SER	Writing 1 to any of these bits sets the corresponding bit in the general purpose control register.

15.4.4.3 Clear Control Register (GP_CER)

Figure 15-5 shows the clear control register. Reads of this register always return 0, and writes can only be performed in supervisor mode.

Offset:	0x0008 (GP_CER)												Access: Supervisor write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:				w1c		GP_CER										
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 15-5. Clear Control Register

Table 15-7. Clear Control Register Field Descriptions

Field	Description
31–13	Reserved
12	Write 1 to this bit to set bit 12 of the general-purpose control register.
11	Reserved
10–0 GP_CER	Writing 1 to any of these bits clears the corresponding bit in the general purpose control register.

15.4.4.4 General Purpose Status Register (GP_STAT)

Figure 15-6 shows the general purpose status register. The register can only be read in supervisor mode—user mode reads return all zeros. Writes have no effect.

Offset:	0x000C (GP_STAT)												Access: Supervisor read			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Read:	GP_STAT[15:0]															
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 15-6. General Purpose Status Register

Table 15-8. General Purpose Status Register Field Descriptions

Bits	Description
31–16	Reserved
15–0 GP_STAT	Reads of these bits while reset is negated the values on the ARM11 platform's clkctl_gp_stat[15:0] inputs

15.4.4.5 L2_MEM_VAL Register (L2_MEM_VAL)

The L2_MEM_VAL register enables the user to modify the L2 data memory's default VAL settings. The L2_MEM_VAL register resets to the values on the l2_val_offset_rst, l2_rval_rst[3:0], l2_rval2_rst[3:0], and l2_wval_rst[3:0] inputs. Subsequent to system reset, this register may be written to change the VAL settings driven to the L2 data memory.

Figure 15-7 shows the L2_MEM_VAL register. The register can only be accessed in supervisor mode—user mode reads return all zeros.

Offset:	0x0010 (L2_MEM_VAL)												Access: Supervisor read/write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Read:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read:	0	0	0	offset _ rst	l2_wval_rst[3:0]				l2_rval2_rst[3:0]				l2_rval_rst[3:0]			
Write:																
Reset:	0	0	0	0	0	1	0	1	0	0	0	1	0	1	0	1

Figure 15-7. L2_MEM_VAL Register

Table 15-9. L2_MEM_VAL Register Field Descriptions

Bits	Description
31–13	Reserved.
12 offset_rst	Controls the VAL_OFFSET parameter in the level 2 cache RAM. Signals memory that Vdd will be reduced and self-timed delays will be increased by memory on subsequent accesses.
11–8 l2_wval_rst[3:0]	These bits are reset to the value of the l2_wval_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's WVAL inputs. After reset, these bit may be written by the user to modify the reset value. Programmable write time.

Table 15-9. L2_MEM_VAL Register Field Descriptions

Bits	Description
7–4 l2_rval2_rst[3:0]	These bits are reset to the value of the l2_rval2_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's RVAL2 inputs. After reset, these bit may be written by the user to modify the reset value. Programmable global sense time.
3–0 l2_rval_rst[3:0]	These bits are reset to the value of the l2_rval_rst[3:0] platform inputs. The register's outputs are driven directly to the L2 data memory's RVAL inputs. After reset, these bit may be written by the user to modify the reset value. Programmable bit sense time.

15.4.4.6 Debug Control Register 1 (DBG_CTRL1)

Figure 15-8 shows the debug control register 1.The register can be accessed in supervisor mode only—user mode reads return all zeros.

The implemented bits in this register get their reset values from tie-offs at the SoC level. They are used to control multiplexers and gate ECT trigger outputs. Because these bits controls debug functionality this register is reset with jsync_dbg_clear_b, which is a combination of power-on-reset and JTAG trst.

Offset:	0x0014 (DBG_CTRL1)												Access: Supervisor read/write			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 15-8. Debug Control Register 1

Table 15-10 provides field descriptions of the debug control register.

Table 15-10. Debug Control Register 1 Field Descriptions

Bits	Description
31–25	Reserved
24 EPS	ETM11 ext_etm_extin3 Pulse Select. When set, ext_etm_extin3 is forced to a single arm_clk pulse on its rising edge (this is done after the signal is synchronized). When the bit is not set, default, the signal is routed straight to the EXTIN[3] pin of the ETM11 (after ext_etm_extin3 has gone through a synchronizer).
23–20	Reserved
19–16 TIMS[7:4]	Controls trigger input multiplexors in the ECTCTI wrapper. By default the multiplexors allow ARM's recommended triggers to pass through to the ECTCTI.
15–14	Reserved.

Table 15-10. Debug Control Register 1 Field Descriptions (Continued)

Bits	Description
13–12 TIMS[1:0]	Controls trigger input multiplexors in the ECTCTI wrapper. By default the multiplexors allow ARM's recommended triggers to pass through to the ECTCTI.
11–8 TOMS[7:4]	TOMS[7:4],[1]: Controls trigger output multiplexors in the ECTCTI wrapper. When set, the trigger outputs from the ECTCTI wrapper are single arm clock pulses. These pulses are created on the rising edge of the trigger output. Each bit in the field (7-4 and 2) corresponds to the same ECTCTI trigger bit. Bit 0,2,3 do not need a pulse, thus they do not get a bit in the register. When negated, the trigger outputs pass through the ECTCTI wrapper un-effected.
7–0	Reserved

15.4.4.7 Platform ID Register (PLAT_ID)

Figure 15-9 shows the platform ID register. These register bits are tied off in the ARM11 platform.

Offset:	0x0020 (PLAT_ID)												Access: Supervisor read only			
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Read:	ECO[15:8]								0	0	0	0	0	0	0	0
Write:																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 15-9. Platform ID Register

Table 15-11 shows the platform ID register fields.

Table 15-11. Platform ID Register

Bits	Description
31–28 SPEC	Describes the IP specification and definition revision. An IP specification and definition revision occurs when there is significant deviation from a previous definition, such as the addition or removal of a module or major architectural changes.
27–24 IMPL	Describes the IP implementation revision. This field is similar to the freeze designation used in the past where a change in implementation occurs such as a further refinement of a specification or implementation process
23–16 MINOR	Two-digit (binary-coded decimal (BCD)) field that describes the IP revision level. This field is used to identify minor refinements of a specification such as a bug fix or additional or removal of some signals
15–8 ECO	Two-digit (BCD) field that describes changes to the implementation that occur after an implementation has hardened.
7–0	Reserved

15.5 Synchronized Resets

The CLKCTL module generates a synchronized reset for the per_hreset_b signals. This synchronized reset has asynchronous assertion and synchronous negation using a 2-flop synchronizer.

Chapter 16
Configurable Serial Peripheral Interface (CSPI)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

16.1 Overview

The configurable serial peripheral interface (CSPI) module is a full-duplex, synchronous, four-wire serial communication module. The CSPI module contains a 8 × 32 receive buffer (RXFIFO) and a 8 × 32 transmit buffer (TXFIFO). With data FIFOs, the CSPI module allows rapid data communication with fewer software interrupts. Figure 16-1 shows a block diagram of the CSPI.

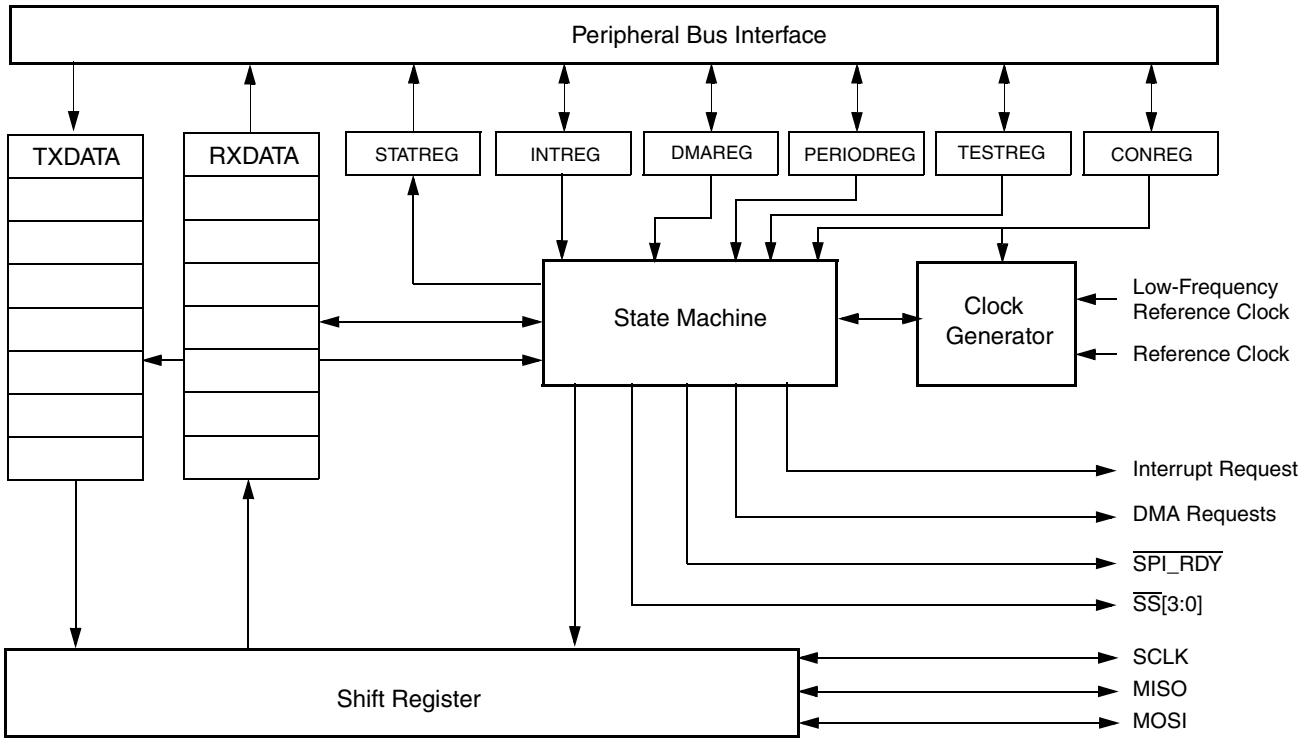

Figure 16-1. CSPI Block Diagram

16.1.1 Features

Key features of the CSPI module include:

- Full-duplex synchronous serial interface

- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 8-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to one-quarter of the reference clock frequency.

16.1.2 Modes and Operations

The CSPI supports the modes described in the indicated sections:

- Section 16.4.1, “Operating Modes”:
  - Section 16.4.1.1, “Master Mode
  - Section 16.4.1.2, “Slave Mode
- Section 16.4.2, “Low Power Modes”

As described in Section 16.4.3, “Operations,” the CSPI supports the operations described in the indicated sections:

- Section 16.4.3.1, “Typical Master Mode
  - Section 16.4.3.1.1, “Master Mode with SPI_RDY
  - Section 16.4.3.1.2, “Master Mode with Wait States
  - Section 16.4.3.1.3, “Master Mode with SSCTL Control
  - Section 16.4.3.1.4, “Master Mode with Phase Control
- Section 16.4.3.2, “Typical Slave Mode

16.2 External Signals

Conventions: Table 16-1 lists conventions for representing signals.

Table 16-1. Module Signal Conventions

Category	Convention	Example(s)
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

1 Internal signals are for reference only in descriptions of internal module or SoC functionality.

Table 16-2 describes all CSPI signals that connect off-chip.

Table 16-2. Off-Chip Module Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
$\overline{SS}$[3:0]	I/O	Chip selects	1	—
SCLK	I/O	SPI clock	0	Active
MISO	I/O	Master data in; slave data out	0	Passive
MOSI	I/O	Master data out; slave data in	0	—
$\overline{SPI\_RDY}$	I	Master data out; slave data in	0	Active

1 The reset state values and pull-up/down requirements provided in this table are from the module-level perspective. To understand how the module is integrated at the SoC level, the system software developer must see discussions of the module in the appropriate SoC-level chapter(s). For example, a module signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

Figure 16-2 shows the CSPI module in master mode connected to four external devices in a one-way communication link.

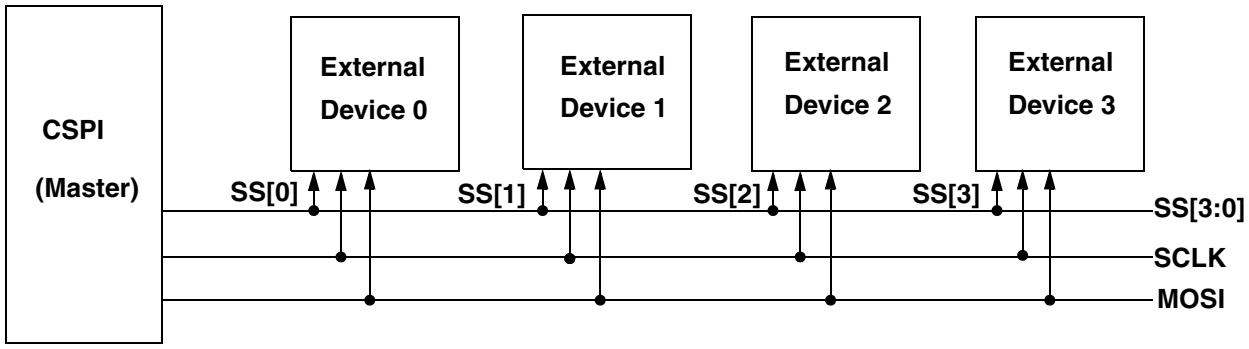

Figure 16-2. Example Connection Diagram

16.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers. For the base address of a particular module instantiation, see the system memory map.

16.3.1 Memory Map

Table 16-3 is the module memory map.

Table 16-3. Module Memory Map

16.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 16-3 and Table 16-5 explain conventions used in register diagrams and tables.

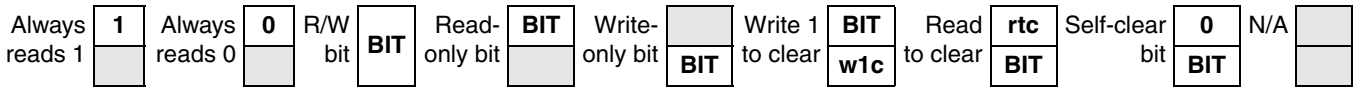

Figure 16-3. Register Field Conventions

Table 16-5. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.

Table 16-5. General Register Conventions (Continued)

Convention	Description
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

16.3.3.1 Receive Data Register (RXDATA)

The receive data register (RXDATA) is a read-only register that forms the top word of the 8 × 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed. Figure 16-4 shows the register. Table 16-6 describes the register fields.

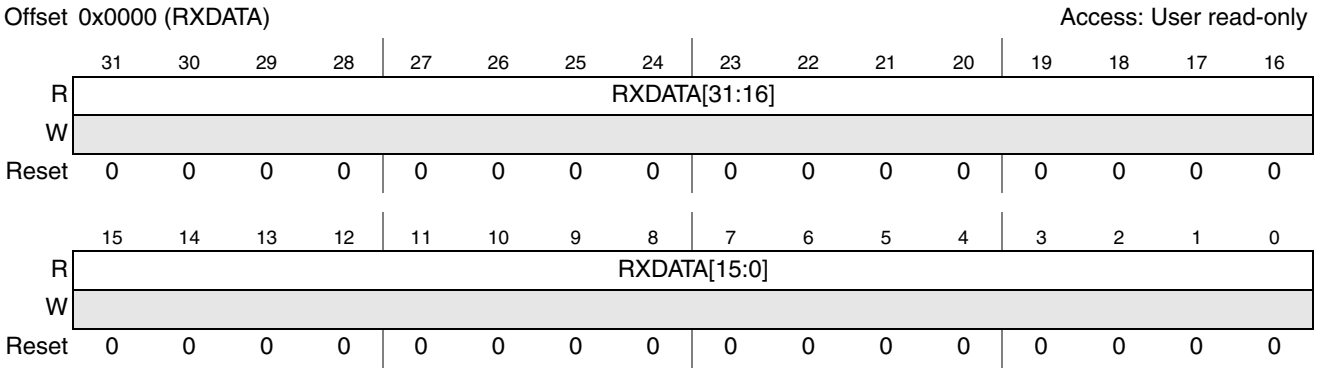

Figure 16-4. RXDATA Register Diagram

Table 16-6. RXDATA Register Field Description

Field	Description
31–0 RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when CSPI is disabled.

16.3.3.2 Transmit Data Register (TXDATA)

The transmit data (TXDATA) register is a write-only data register that forms the bottom word of the 8 × 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the CSPI module is disabled (CONREG[EN] bit is cleared). Figure 16-5 shows the register. Table 16-7 describes the register fields.

Offset 0x0004 (TXDATA) Access: User write-only

Figure 16-5. TXDATA Register Diagram

Table 16-7. TXDATA Register Field Description

Field	Description
31–0 TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the CSPI module is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when CSPI is disabled.

16.3.3.3 Control Register (CONREG)

The control register (CONREG) allows software to enable the CSPI module, configure its operating modes, specify the divider value, phase, and polarity of the clock, configure the Chip Select (SS) and SPI_RDY control signal, and define the transfer length.

Figure 16-6 shows the register. Table 16-8 describes the register fields.

Offset 0x0008 (CONREG) Access: User read/write

Figure 16-6. CONREG Register Diagram

Table 16-8. CONREG Register Field Description

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. In slave mode, only when SSCTL is cleared, this field will take effect in the transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. ..... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. ..... 0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19	Reserved
18–16 DATA RATE	SPI Data Rate Control. This field selects the baud rate of the SCLK based on a division of the reference clock. These bits allow the CSPI to synchronize with different external SPI devices. The max frequency is one quarter of the reference clock. The divide ratio is determined according to the following table using the equation: $2^{(n+2)}$. SPI Data Rate Control (Master Mode only) 000 Divide by 4. 001 Divide by 8. 010 Divide by 16. 011 Divide by 32. 100 Divide by 64. 101 Divide by 128. 110 Divide by 256. 111 Divide by 512.
15 –14	Reserved

Table 16-8. CONREG Register Field Description (Continued)

Field	Description
13 –12 CHIP SELECT	CHIP SELECT. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. Chip Select 00 Chip Select 0 (SS0) will be asserted. 01 Chip Select 1 (SS1) will be asserted. 10 Chip Select 2 (SS2) will be asserted. 11 Chip Select 3 (SS3) will be asserted.
11–10	Reserved
9–8 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. CSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
7 SSPOL	SPI SS Polarity Select. In both Master and Slave modes, this bit selects the polarity of the Chip Select (SS) signal. 0 Active low. 1 Active high.
6 SSCTL	SPI SS Wave Form Select. In master mode, this bit controls the output wave form of the Chip Select (SS) signal when SMC is cleared. The SSCTL bit will be ignored if the SMC (Start Mode Control) bit is set. 0 Only one SPI burst will be transmitted. 1 Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. In slave mode, this bit controls when the SPI burst is completed. 0 A SPI burst is completed when the number of bits received in the shift register is equal to BURST LENGTH + 1. Only n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 A SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data.
5 PHA	SPI Clock/Data Phase Control. This bit controls the clock/data phase relationship. See Figure 16-19 for more information. 0 Phase 0 operation. 1 Phase 1 operation.
4 POL	SPI Clock Polarity Control. This bit controls the polarity of the SCLK signal. See Figure 16-19 for more information. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3 SMC	Start Mode Control. This bit applies only when the module is configured in Master mode (MODE = 1). It controls how the CSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SSCTL) bit. See the XCH and SSCTL bit descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.

Table 16-8. CONREG Register Field Description (Continued)

Field	Description
2 XCH	SPI Exchange Bit. This bit applies only when the module is configured in Master mode (MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SSCTL bit). The XCH bit remains set while either the data exchange is in progress, or when the CSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 MODE	SPI Function Mode Select. This bit selects the operating mode of the CSPI. 0 Slave mode. 1 Master mode.
0 EN	SPI Module Enable Control. This bit enables the CSPI module. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the module and resets the internal logic with the exception of the CONREG. The module's internal clocks are gated off whenever the module is disabled. 0 Disable the module. 1 Enable the module.

16.3.3.4 Interrupt Control Register (INTREG)

The interrupt control register (INTREG) enables the generation of interrupts to the host processor. If the CSPI is disabled, this register reads zero. Figure 16-7 shows the register. Table 16-9 describes the register fields.

Offset 0x000C (INTREG) Access: User read/write

16.3.3.5 DMA Control Register (DMAREG)

The direct memory access control register (DMAREG) provides software a way to use an on-chip DMA controller for CSPI data. Internal DMA request signals enable direct data transfers between the CSPI FIFOs and system memory. The CSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the CSPI is disabled, this register is read as 0. Figure 16-8 shows the register. Table 16-10 describes the register fields.

5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RH	RXFIFO Half Full. This bit is set when the RXFIFO reaches half full. 0 Less than 4 words are stored in RXFIFO. 1 Four or more words are available in RXFIFO.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TH	TXFIFO Half empty. This bit is set when the TXFIFO reaches half empty. 0 TXFIFO holds more than 4 words. 1 TXFIFO holds 4 or fewer words.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

16.3.3.7 Sample Period Control Register (PERIODREG)

The sample period control register (PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the module is configured in Master mode (CONREG[MODE] = 1).

Figure 16-10 shows the register. Table 16-12 describes the register fields.

Offset 0x0018 (PERIODREG) Access: User read/write

16.3.3.8 Test Control Register (TESTREG)

The test control register (TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the CSPI module, swap the byte order for receive data, and monitor the contents of the receive and transmit FIFO.

Figure 16-11 shows the register. Table 16-13 describes the register fields.

Offset 0x001C (TESTREG) Access: User read/write

16.4 Functional Description

This section provides a complete functional description of the CSPI. Figure 16-12 shows the relationship of SCLK and data lines while CSPI has been configured with different POL and PHA settings.

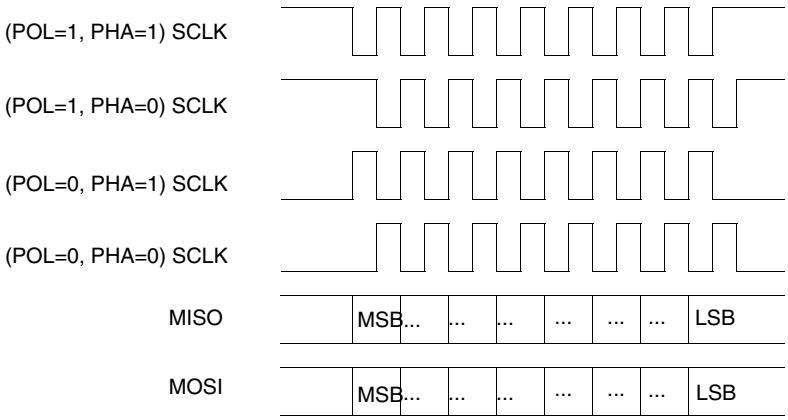

Figure 16-12. CSPI SCLK, MISO, and MOSI Relationship

16.4.1 Operating Modes

CSPI has two operating modes, master mode and slave mode. This section describes all functional operation modes of the CSPI.

16.4.1.1 Master Mode

When the CSPI module is configured as a master, it uses a serial link to transfer data between the CSPI and an external slave device. One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the CSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

16.4.1.2 Slave Mode

When the CSPI module is configured as a slave, software can configure the CSPI Control register to match the external SPI master's timing. In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

16.4.2 Low Power Modes

The CSPI module does not operate under low power mode. It holds its operation when its clock is gated off in master mode. In slave mode, the CSPI module does not respond when its clock is gated off.

16.4.3 Operations

This section describes the CSPI's operations.

16.4.3.1 Typical Master Mode

The CSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register. The SPI_RDY enables fast data communication with fewer software interrupts. By programming the PERIODREG register accordingly, the CSPI can be used for a fixed data transfer rate.

When the CSPI module is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input. Figure 16-13 shows a typical SPI burst.

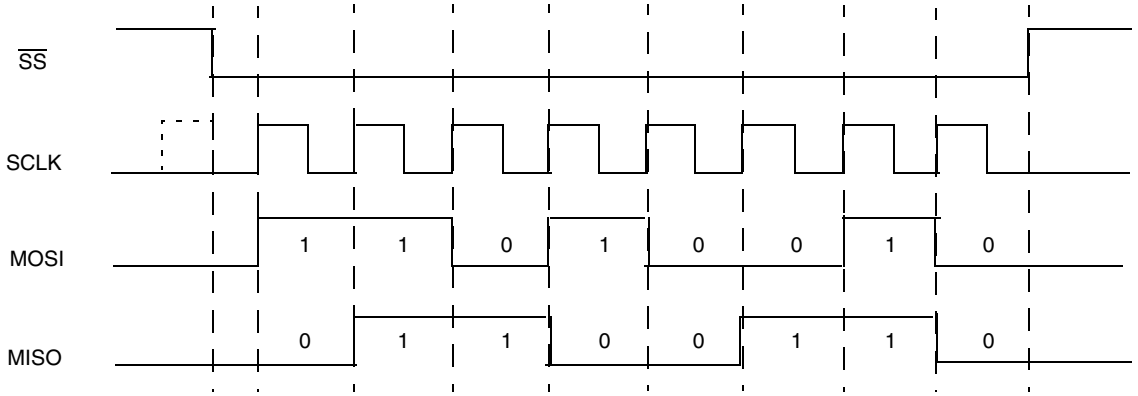

Figure 16-13. Typical SPI Burst (8-bit Transfer)

In Figure 16-13, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. Figure 16-13 shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

16.4.3.1.1 Master Mode with SPI_RDY

By default, the CSPI does not use the SPI_RDY signal in master mode (MODE =1). A SPI burst begins when the following events happen:

- The CSPI is enabled, TXFIFO has data in it, and CONREG[XCH] bit or the CONREG[SMC] bit is set.
- When the SPI Data Ready Control (CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected. Figure 16-14 shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

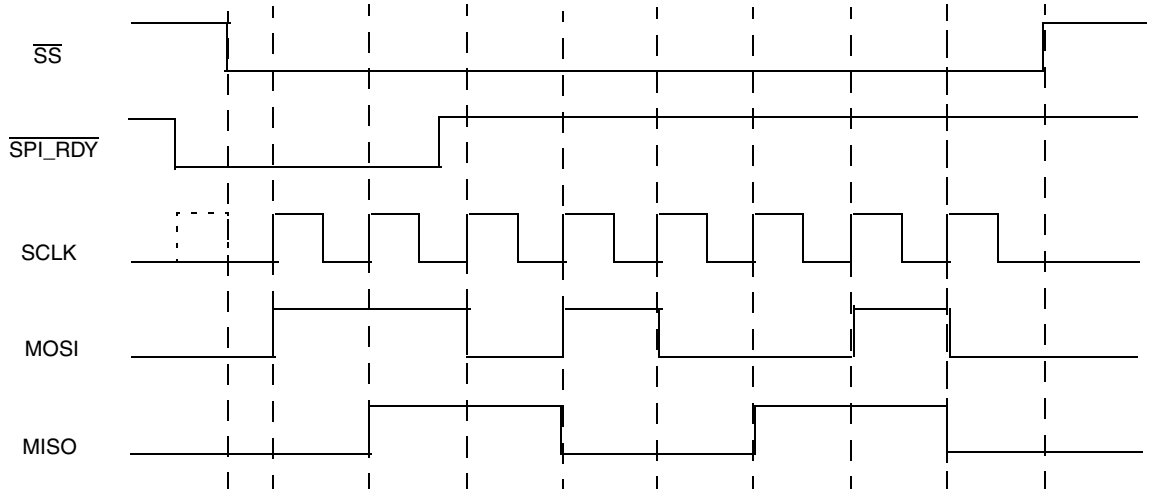

Figure 16-14. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low. Figure 16-15 shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The CSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

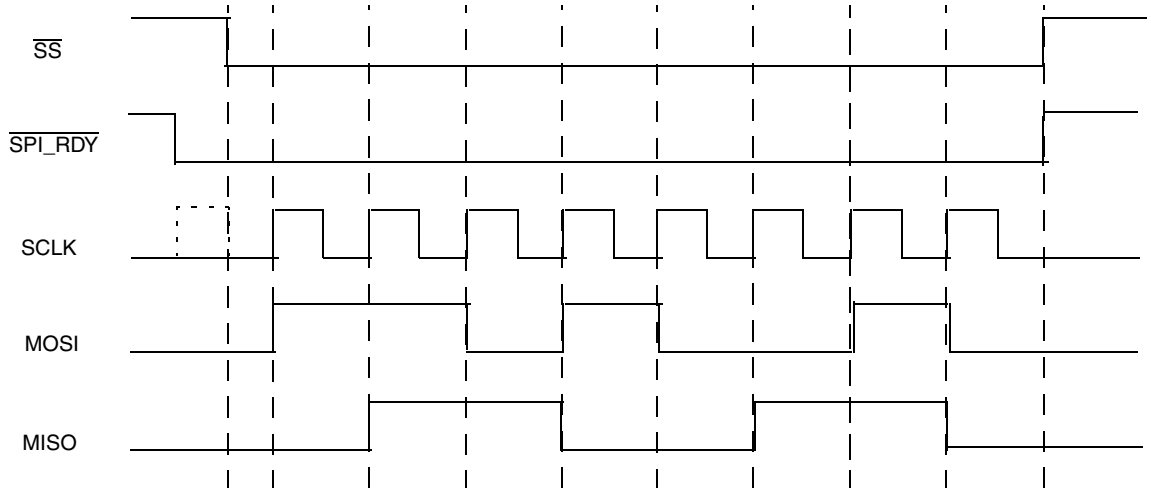

Figure 16-15. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

16.4.3.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device. Figure 16-16 shows wait states inserted between SPI bursts.

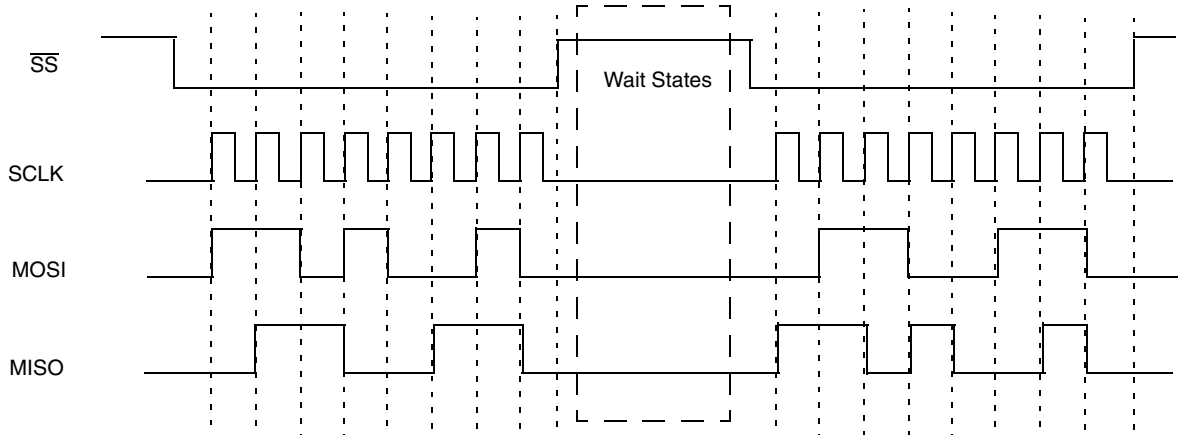

Figure 16-16. SPI Bursts with Wait States

In this case, the number of wait states is controlled by PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by PERIODREG[CSRC].

16.4.3.1.3 Master Mode with SSCTL Control

The SPI SS Control (SSCTL) bit controls whether the current operation is single burst or multiple bursts. When the SPI SS Wave Form Select (SSCTL) bit is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SSCTL) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the CONREG register.

Figure 16-17 shows one SPI burst while SSCTL is clear.

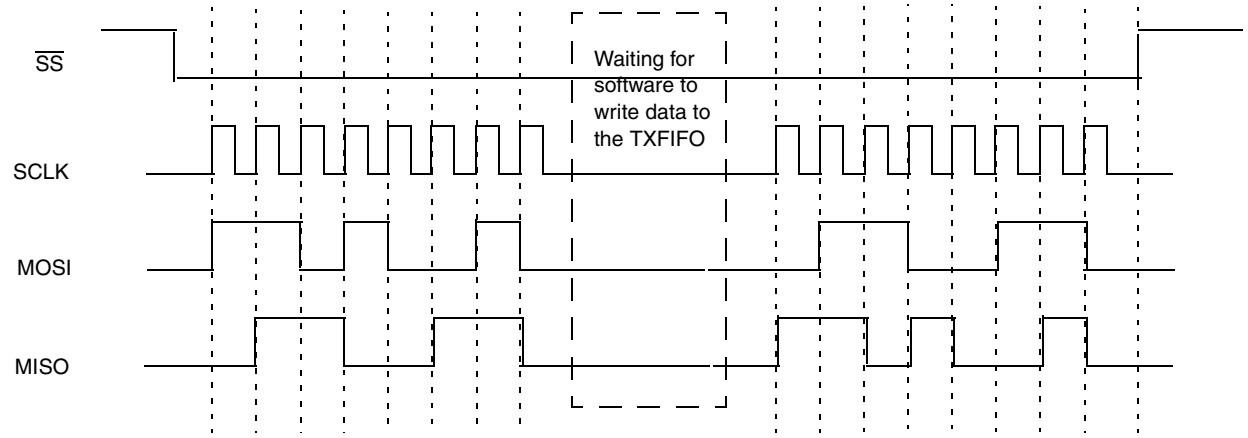

Figure 16-17. SPI Burst While SSCTL is Clear

In Figure 16-17, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the CONREG control register. (Figure 16-17 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the CSPI is transmitting.

Figure 16-18 shows two SPI bursts are transmitted while SSCTL is set.

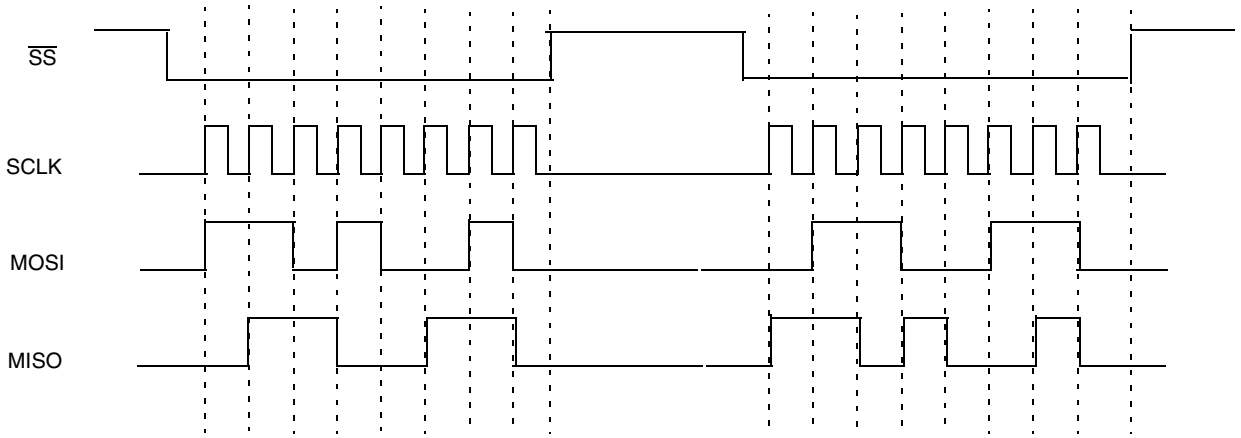

Figure 16-18. SPI Bursts While SSCTL is Set

In Figure 16-18, two FIFO entries are transmitted, one entry with each SPI burst. The CSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

16.4.3.1.4 Master Mode with Phase Control

The Phase Control (CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 16-19 shows a SPI burst using different POL and PHA configurations.

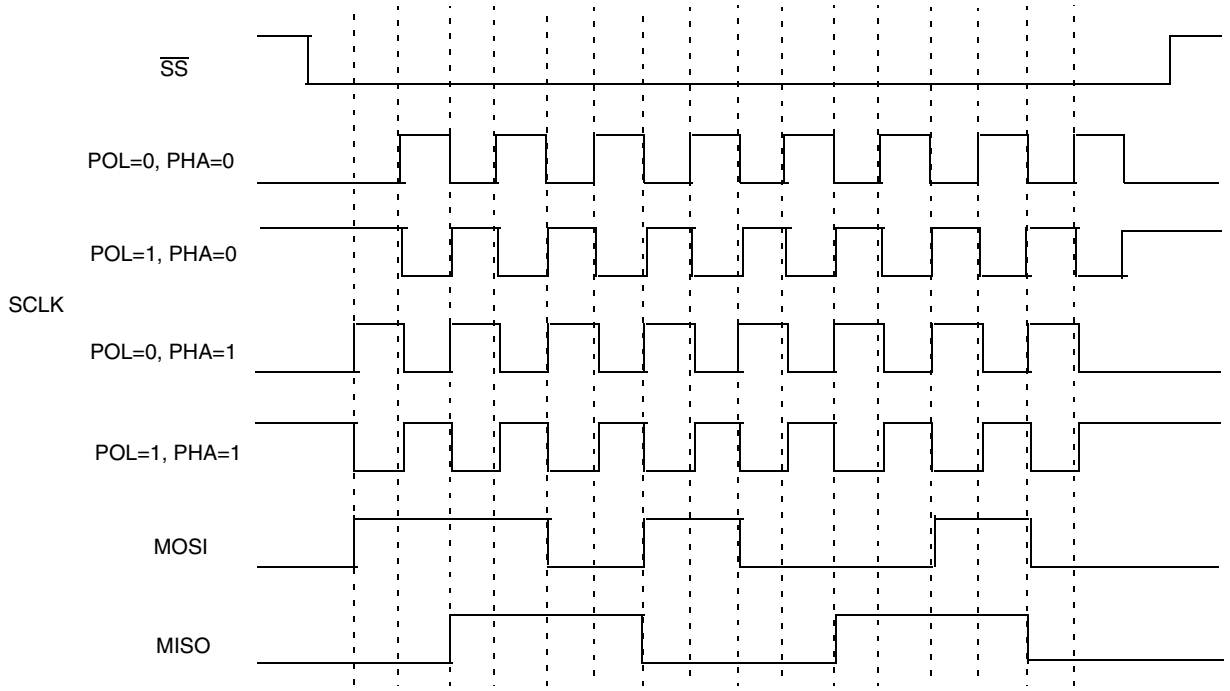

Figure 16-19. SPI Burst with Different POL and PHA Configurations

16.4.3.2 Typical Slave Mode

When the CSPI module is configured as a slave (Mode = 0), software can configure the CSPI control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SSCTL is set while the CSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SSPOL = 1), the data FIFO will advance on the falling edge of the SS signal.

Figure 16-20 shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

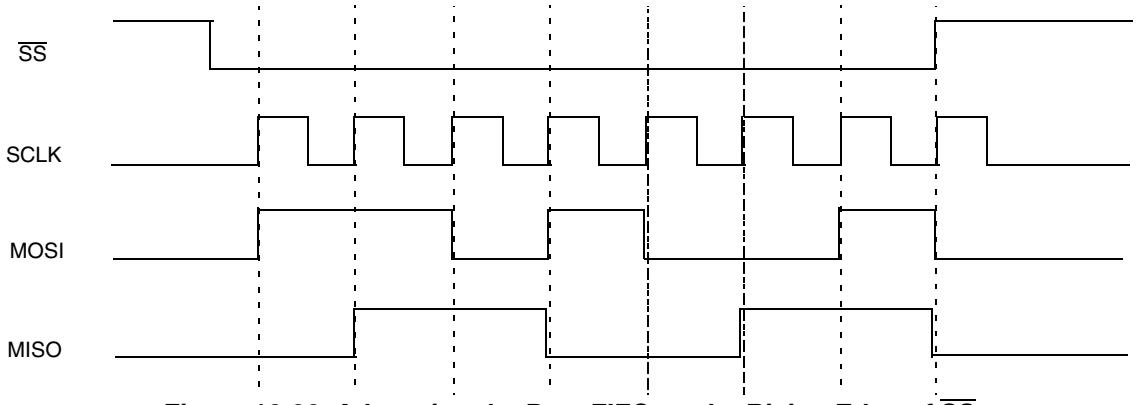

Figure 16-20. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

16.4.4 Clocks

This section describes clocks and special clocking requirements of the module.

CSPI has the following clock inputs:

- Reference Clock is the reference clock.
- Low-Frequency Reference Clock is a 32KHz input clock optionally used for counting wait states.

16.4.5 Reset

Whenever a device reset occurs, a reset is performed on the CSPI module, resetting all registers to their default values.

Software can reset the module using the CONREG[EN] bit; see Section 16.3.3.3, “Control Register (CONREG).”

16.4.6 Interrupts

Interrupt control provides a way to manage the CSPI FIFOs:

- For transmitting data, software can enable the *TXFIFO empty*, *TXFIFO half*, and *TXFIFO full* interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the *RXFIFO ready*, *RXFIFO half*, and *RXFIFO full* interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The *transfer-completed* interrupt means that there is no data left in the TXFIFO and that the data in the shift register has been shifted out.
- The *RXFIFO overflow* interrupt means that the RXFIFO received more than8 words and will not accept any other words.

Figure 16-21 shows a program sequence of SPI bursts using interrupt control.

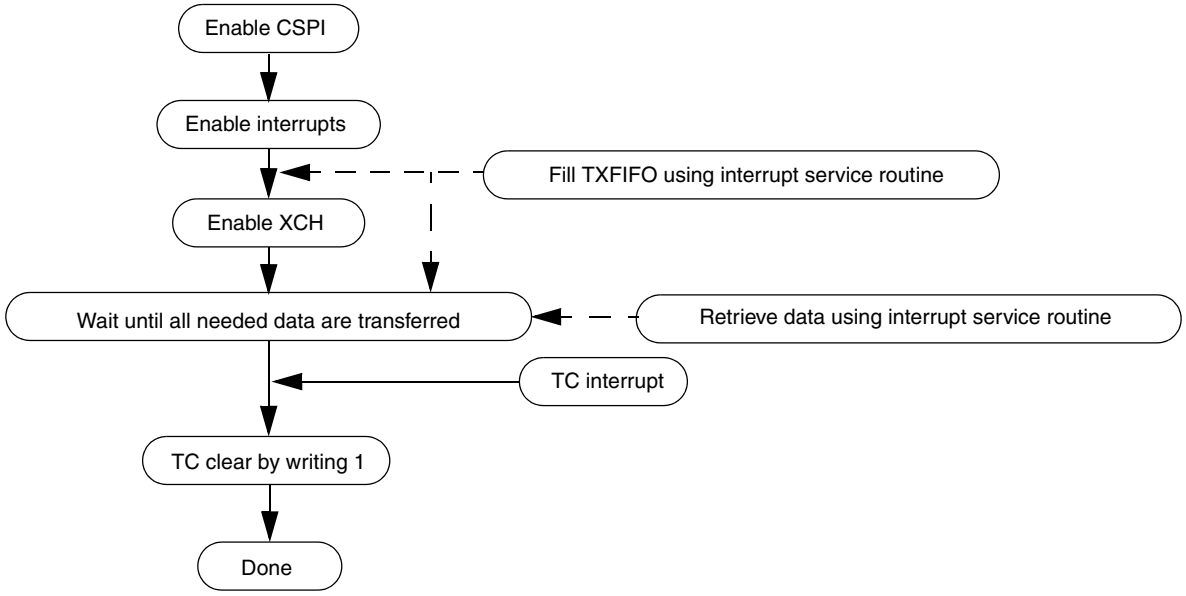

Figure 16-21. Program Sequence of SPI Burst Using Interrupt Control

16.4.7 DMA

DMA control provides another method to utilize the FIFOs in the CSPI module. By using DMA request and acknowledge signals, larger amounts of data can be transferred and reduce interrupts and host processor loading. When the appropriate conditions are matched, the module sends out a DMA request, and the DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO half
- RXFIFO half
- RXFIFO full

Figure 16-22 shows a program sequence of SPI bursts using DMA control.

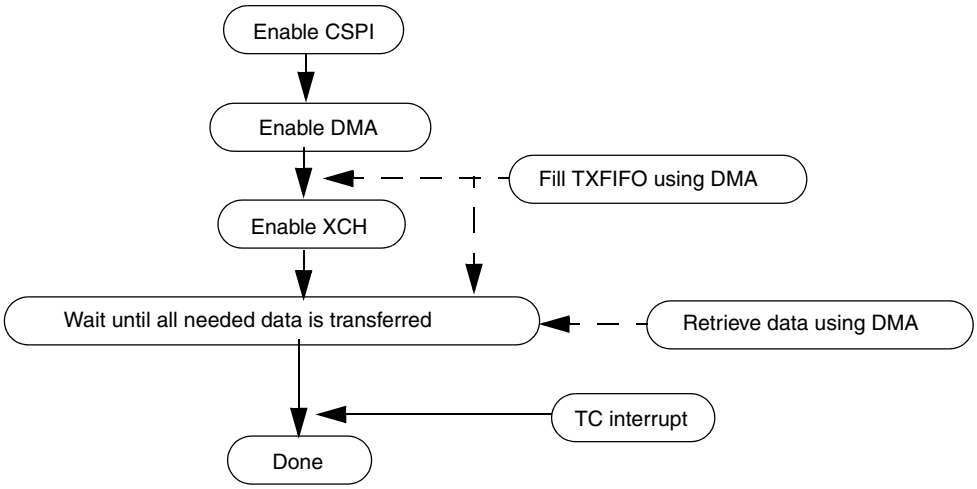

Figure 16-22. Program Sequence of SPI Burst Using DMA

16.4.8 Byte Order

Software can swap bytes for receive data using the TESTREG[SWAP] bit; see Section 16.3.3.8, "Test Control Register (TESTREG)."

16.5 Initialization

This section provides initialization information for CSPI.

To initialize the module:

1. Clear the EN bit in CONREG to reset the module.
2. Enable the clocks for CSPI.
3. Set the EN bit in CONREG to put CSPI out of reset.
4. Configure corresponding IOMUX for CSPI external signals.
5. Configure registers of CSPI properly according to the specifications of the external SPI device.

16.6 Applications

Figure 16-23 shows two flowcharts for the master and slave mode of operations supported by the CSPI module.

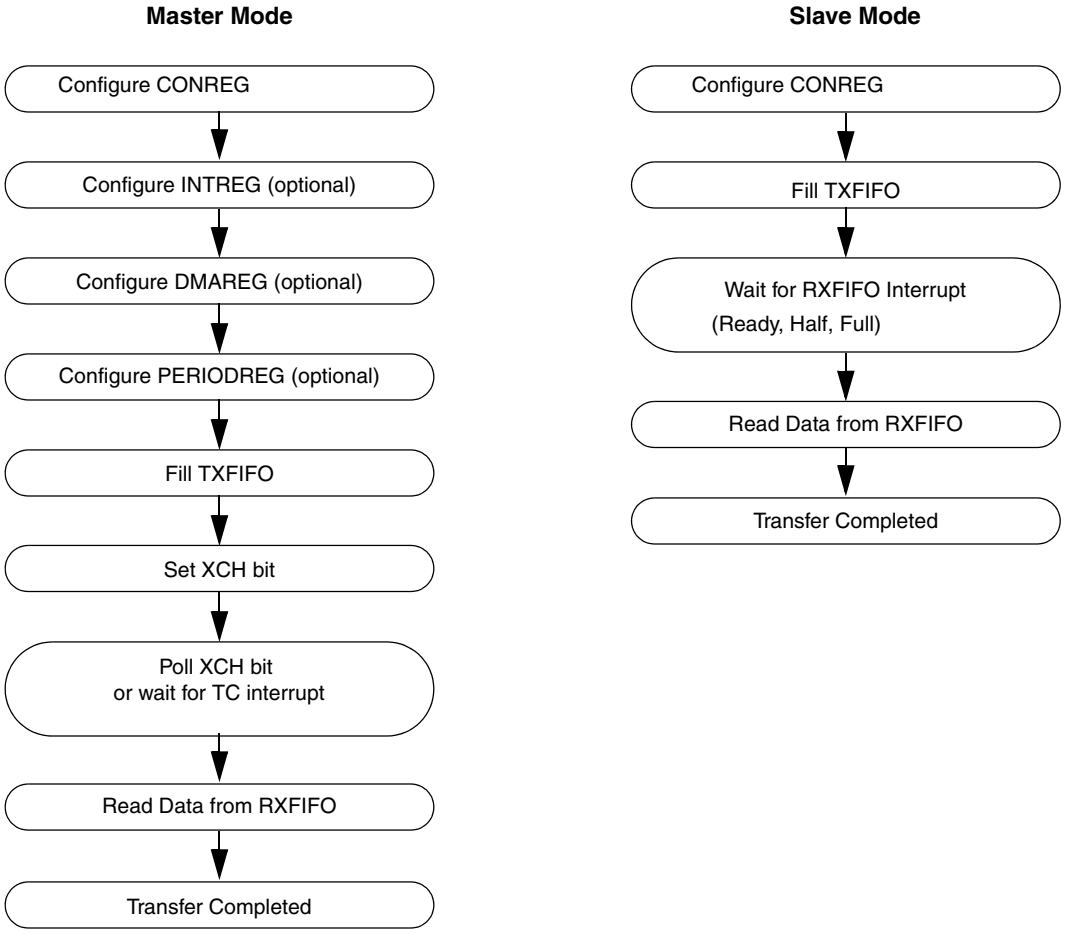

Figure 16-23. Flowchart of the CSPI Operation

Example 16-1 shows example code of CSPI operation using ARM instructions.

Example 16-1. CSPI Operation using ARM Instructions

```
LDR R0, =CSPI_BASE_ADDRESS; Load CSPI Base Address to R0
LDR R1, =0x01F00003; Master Mode, 32-bit transaction
STR R1, [R0, #0x08]
LDR R1, =0x00000011; Enable RXFIFO half and TXFIFO empty
STR R1, [R0, #0x0C]; interrupt (Alternatively with DMA Mode)
LDR R1, =0x00000011; Enable RXFIFO half and TXFIFO empty
STR R1, [R0, #0x10]; DMA (Alternatively with interrupt)
LDR R5, =0x05     ; R5 as number of words to be transferred.
```

```
        LDR R1, =0x11111111; R1 as increment to generate the data.
        LDR R2, =0x12345678; R2 load the data to be transferred.
Loop_00
        STR R2, [R2,#0x04]; Store data into TXFIFO.
        ADD R2, R2, R1    ; Generating next data to be transferred.
        SUB R5, R5, #1    ; Decrease the R5.
        CMP R5, #0x00     ; Check R5 if it is zero.
        BNE Loop_00       ; Loop until R5 is zero.
        LDR R1, =0x01F00007; set XCH bit to start transaction.
        STR R1, [R0, #0x08]
Loop_01
        LDR R1, [R0, #0x08]; check XCH bit if it is cleared.
        LDR R2, =0x00000004
        AND R1, R2, R1
        CMP R1, #0x00
        BEQ PASS_00       ; if XCH bit is cleared then finish.
        B Loop_01         ; if it isn't cleared then continue loop
        LDR R1, [R0, #0x00]; Read data from RXFIFO.
```

Chapter 17
External Memory Interface (EMI)

The EMI provides the ability to connect the system to a wide variety of memory devices. This chapter contains technical information about the operation and configuration of the chip's EMI module, to allow the designer to quickly integrate external memory devices into new and existing designs. The chapter covers the following topics:

17.1 Overview

The EMI controls all IC external memory accesses (read/write/erase/program) from all the masters in the system to different external memories. All accesses are arbitrated by the multi-master memory interface (M3IF) submodule and controlled by the respective memory controller.

The EMI contains the following external memory controllers to support different types of memory devices:

- Enhanced SDRAM/LPDDR memory controller (ESDRAMC, also known as ESDRAMC/MDDRC, or ESDCTL/MDDRC). The ESDRAMC and ESDCTL mnemonics are equivalent; for historical reasons they are alternately used throughout the document.
- NAND Flash memory controller (NFC).
- Wireless external interface module (WEIM), which supports SRAM, PSRAM, and NOR Flash memory devices.

Figure 17-1 is a top-level diagram of the EMI that shows the functional organization of the block.

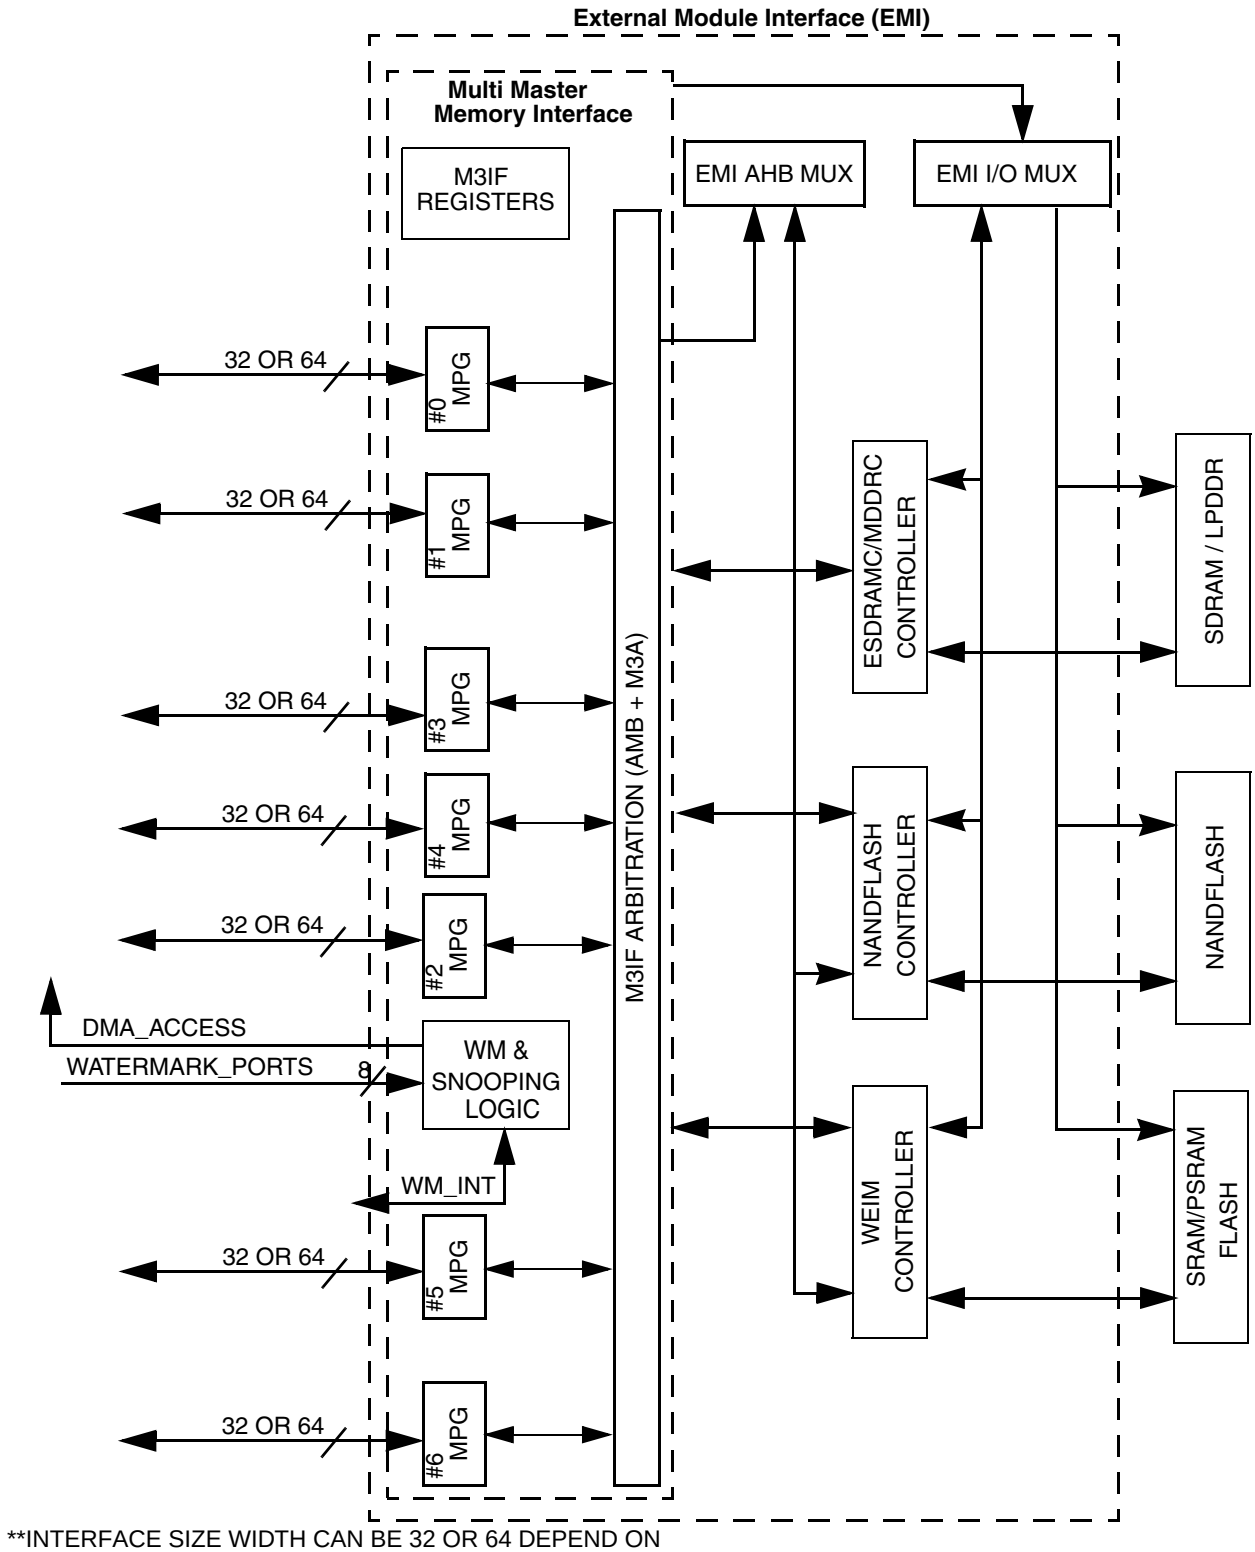

Figure 17-1. EMI System Block Diagram

17.1.1 Features

The EMI includes the following features:

- Multimaster memory interface (M3IF)
  - Supports multiple requests from up to 8 masters through input ports interface.
  - Supports memory snooping: monitors a region of size 2 Kbytes–16 Mbytes in external memory for write accesses.
  - Supports memory watermark protection for up to 8 different chip selects for hardware-preselected masters.
- Enhanced SDRAM controller (ESDRAMC) / LPDDR controller (MDDRC)
  - Up to 2 chip selects (due to sharing of pins, 2 chip selects are supported only when the WEIM CS2 and CS3 are not is use).
  - Support x32/x16 SDR SDRAM (up to 2 Gb @133 MHz)
  - Support x32/x16 LPDDR SDRAM (up to 2 Gb @ 266 MHz)
- NAND Flash controller (NFC)
  - Supports 8- and 16-bit NAND FLASH (up to 2 GB address space)
  - Internal 4.5 Kbyte RAM buffer.
- Wireless external interface memory controller (WEIM)
  - Up to five chip selects (due to sharing of pins, five chip selects are supported only when both ESDCTL/MDDRC and NAND FLASH chip selects are not in use).
  - Supports x16/x32 multiplexed/non-multiplexed mode for PSRAM and NOR Flash memory devices.
- Different memory controllers are accessible via AHB
- Pins are shared among memory controllers via the EMI AHB multiplexer and the EMI I/O multiplexer

17.2 EMI Input/Output Signals

Table 17-1 lists all of the EMI input and output signals. For the detailed description of each signal function, see the relevant module chapter in this document.

Table 17-1. EMI Signal Properties

Name	Port	Function	Reset State
AHB Interface Outputs			
M3IF_HREADY_M0	O	AHB access completion strobe to master #0	1
M3IF_HREADY_M1	O	AHB access completion strobe to master #1	1
M3IF_HREADY_M2	O	AHB access completion strobe to master #2	1
M3IF_HREADY_M3	O	AHB access completion strobe to master #3	1
M3IF_HREADY_M4	O	AHB access completion strobe to master #4	1

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
M3IF_HREADY_M5	O	AHB access completion strobe to master #5	1
M3IF_HREADY_M6	O	AHB access completion strobe to master #6	1
M3IF_HREADY_M7	O	AHB access completion strobe to master #7	1
M3IF_HRESP_M0	O	AHB error response to master #0	0
M3IF_HRESP_M1	O	AHB error response to master #1	0
M3IF_HRESP_M2	O	AHB error response to master #2	0
M3IF_HRESP_M3	O	AHB error response to master #3	0
M3IF_HRESP_M4	O	AHB error response to master #4	0
M3IF_HRESP_M5	O	AHB error response to master #5	0
M3IF_HRESP_M6	O	AHB error response to master #6	0
M3IF_HRESP_M7	O	AHB error response to master #7	0
M3IF_HRDATA_M0	O	AHB read data bus to master #0 (bus size is determined by system configuration)	0
M3IF_HRDATA_M1	O	AHB read data bus to master #1 (bus size is determined by system configuration)	0
M3IF_HRDATA_M2	O	AHB read data bus to master #2 (bus size is determined by system configuration)	0
M3IF_HRDATA_M3	O	AHB read data bus to master #3 (bus size is determined by system configuration)	0
M3IF_HRDATA_M4	O	AHB read data bus to master #4 (bus size is determined by system configuration)	0
M3IF_HRDATA_M5	O	AHB read data bus to master #5 (bus size is determined by system configuration)	0
M3IF_HRDATA_M6	O	AHB read data bus to master #6 (bus size is determined by system configuration)	0
M3IF_HRDATA_M7	O	AHB read data bus to master #7 (bus size is determined by system configuration)	0
M3IF and ESDRAMC/MDDRC Outputs			
IPP_DO_SDRC_SDCKE[1:0]	O	SDRAM/LPDDR clock enable	0
IPP_DO_EMI_DQM[3:0]	O	SDRAM data mask strobes. DQM0 corresponds to DQ0–DQ7, DQM1 corresponds to DQ8–DQ15, DQM2 corresponds to DQ16–DQ23 and DQM3 corresponds to DQ24–DQ31.	0
IPP_DO_DQS[3:0]	O	LPDDR data sample strobes for write accesses. DQS0 corresponds to DQ0–DQ7, DQS1 corresponds to DQ8–DQ15, DQS2 corresponds to DQ16–DQ23 and DQS3 corresponds to DQ24–DQ31.	0
IPP_OBE_DQS	O	DQS output enable strobe	0
IPP_DO_E M I _ADDR[25:0]	O	WEIM Address [25:0] multiplexed with SDR[13:0] (except for SDR[10])	0

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
IPP_DO_SDBA[1:0]	O	SDRAM/LPDDR bank address bits	0
IPP_DO_M3IF_MA10	O	SDRAM/LPDDR address bit A10	0
IPP_DO_M3IF_CAS_B	O	SDRAM/LPDDR CAS strobe	1
IPP_DO_M3IF_RAS_B	O	SDRAM/LPDDR RAS strobe	1
IPP_DO_SDRC	O	SDRAM/LPDDR WE strobe	1
M3IF_CHOOSEN_MASTER[2:0]	O	M3IF arbitration chosen master (for debug)	3
IPP_DO_SDRC_SDCLK	O	SDRAM/LPDDR clock (up to 133MHz)	0
LPACK	O	Low power mode acknowledge; toward CCM	1
SDRC_SF_WACK	O	Memory wakeup acknowledge indication to WDOG	0
NFC Ouputs			
IPI_INT_NFC_B	0	NFC interrupt (indicating an access completion)	1
IPP_NFC_ALE_OUT	O	NFC out NF_ALE	0
IPP_NFC_CE0_OUT	O	NFC out NF_CE0	0
IPP_NFC_CE1_OUT	O	NFC out NF_CE1	0
IPP_NFC_CE2_OUT	O	NFC out NF_CE2	0
IPP_NFC_CE3_OUT	O	NFC out NF_CE3	0
IPP_NFC_CLE_OUT	O	NFC out NF_CLE	0
IPP_NFC_RE_OUT	O	NFC out NF_RE	0
IPP_NFC_WE_OUT	O	NFC out NF_WE	0
IPP_NFC_WP_OUT	O	NFC out NF_WP	0
WEIM Outputs			
IPP_DO_WEIM_CS_B0	O	WEIM CS0 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_CS_B1	O	WEIM CS1 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_CS_B2_CSD0	O	WEIM CS2 or ESDRAMC/MDDRC CSD0 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_CS_B3_CSD1	O	WEIM CS2 or ESDRAMC/MDDRC CSD1 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_CS_B4	O	WEIM CS4 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_CS_B5	O	WEIM CS5 chip select toward I/O multiplexer/pins	1
IPP_DO_WEIM_BCLK	O	WEIM Burst Clock	0
IPP_DO_WEIM_LBA_B	O	WEIM Load Burst Address (LBA)	1
IPP_DO_WEIM_RW_B	O	WEIM read/write strobe	1

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
Global Ouputs			
M3IF_DMA_ACCESS	O	Snooping detection indication toward IPU module	0
IPP_OBE_DDR_EN	O	LPDDR active indication to ESDRAMC/MDDRC DATA pins	0
IPP_DO_EMI_ADDR[25:0]	O	EMI address out toward I/O multiplexer/pins	0
IPP_DO_NFC_WEIM_IO_DATA_OUT[15:0]	O	EMI WEIM/NFC data out toward I/O multiplexer/pins	0
IPP_DO_EMI_DATA[31:0]	O	EMI SDRAM/DDR data out toward I/O multiplexer/pins	0
IPP_OBE_EMI_DATA_DIR	O	EMI SDRAM/DDR data direction toward I/O multiplexer/pins	0
IPP_OBE_NFC_DIR_HIGH	O	EMI (NFC, WEIM) data direction toward I/O multiplexer/pins	0
IPP_OBE_NFC_DIR_LOW	O	EMI (NFC, WEIM) data direction toward I/O multiplexer/pins	0
IPP_DO_EMI_EB_B[1:0]	O	WEIM enable byte out toward I/O multiplexer/pins	0
IPP_DO_EMI_OE_B	O	EMI output enable toward I/O multiplexer/pins	0
IPP_OBE_IO_ADDR_DIR[1:0]	O	EMI output enable (dir) toward I/O ADDR/WEIM multiplexed DATA multiplexer/pins	0
AHB Interface Inputs			
M3IF_HADDR_M0[31:0]	I	AHB address bus from master #0	0
M3IF_HADDR_M1[31:0]	I	AHB address bus from master #1	0
M3IF_HADDR_M2[31:0]	I	AHB address bus from master #2	0
M3IF_HADDR_M3[31:0]	I	AHB address bus from master #3	0
M3IF_HADDR_M4[31:0]	I	AHB address bus from master #4	0
M3IF_HADDR_M5[31:0]	I	AHB address bus from master #5	0
M3IF_HADDR_M6[31:0]	I	AHB address bus from master #6	0
M3IF_HADDR_M7[31:0]	I	AHB address bus from master #7	0
M3IF_HWDATA_M0	I	AHB write data bus from master #0 (bus size is determined by system configuration). In case this master is a read only-master this signal is not routed as an EMI output.	0
M3IF_HWDATA_M1	I	AHB write data bus from master #1 (bus size is determined by system configuration)	0
M3IF_HWDATA_M2	I	AHB write data bus from master #2 (bus size is determined by system configuration)	0
M3IF_HWDATA_M3	I	AHB write data bus from master #3 (bus size is determined by system configuration)	0
M3IF_HWDATA_M4	I	AHB write data bus from master #4 (bus size is determined by system configuration)	0

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
M3IF_HWDATA_M5	I	AHB write data bus from master #5 (bus size is determined by system configuration)	0
M3IF_HWDATA_M6	I	AHB write data bus from master #6 (bus size is determined by system configuration)	0

M3IF_HUNALIGN_M4	I	Unalign access signal from master #4	0
M3IF_HUNALIGN_M5	I	Unalign access signal from master #5	0
M3IF_HUNALIGN_M6	I	Unalign access signal from master #6	0

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
M3IF_HUNALIGN_M7	I	Unalign access signal from master #7	0
M3IF and ESDRAMC/MDDRC Inputs			
M3IF_HCLK	I	M3IF AHB system clock up to 133MHz	0
HCLK32	I	32 KHz clock for ESDRAMC refresh counter	0
IPP_IND_SDRC_SDCLK_FB	I	SDRAM/LPDDR feedback clock (up to 133MHz)	0
LPMD	I	Low power mode indication signal, “0”=STOP, “1”=RUN.	1
IPP_IND_DQS[3:0]	I	LPDDR data sample strobes for read accesses. DQS0 corresponds to DQ0–DQ7, DQS1 corresponds to DQ8–DQ15, DQS2 corresponds to DQ16–DQ23 and DQS3 corresponds to DQ24–DQ31.	0
SDCTL_CSD0_SEL_B	I	SDRAM/LPDDR CSD0 select multiplexed with CS2 (configurable via the system control register, FMCR)	0
SDCTL_CSD1_SEL_B	I	SDRAM/LPDDR CSD1 select multiplexed with CS3 (configurable via the system control register, FMCR)	0
NFC Inputs			
NF16_BOOT_B	I	Boot mode source is 16 bit NAND Flash memory.	Application dependent
NF8_BOOT_B	I	Boot mode source is 8-bit NAND Flash memory.	Application dependent
NF_16BIT_SEL	I	16-bit NAND Flash memory is use indication.	0
NFC_HCLK	I	NFC AHB input clock	0
NFC_RD_OE	I	NFC read output enable controls the direction of data bus	0
IPP_IND_FLASH_CLK	I	NAND Flash side clock with period of 40 nS	0
IPP_IND_NFC_RB_IN	I	NFC in NF_RB	0
WEIM Inputs			
WEIM_BOOT_CFG[2:0]	I	WEIM boot mode select (from ccm) For detailed boot description see the WEIM specification	Application dependent
IPP_IND_WEIM_ECB_B	I	WEIM end current burst	1
WEIM_HCLK	I	WEIM AHB input clock	0
IPP_IND_WEIM_DTACK_B	I	External DTACK acknowledge	1
Global Inputs			
IPP_IND_RESETB	I	Reset signal	1
IPP_IND_NFC_READ_DATA_IN [15:0]	I	External memories (non SDRAM) read data in from I/O multiplexer/pins	0
IPP_IND_EMI_DATA_IN [31:0]	I	EMI SDRAM/DDR data in from I/O multiplexer/pins	0

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
IPP_IND_ADDR_IN[15:0]	I	EMI WEIM multiplexed data in from I/O multiplexer/pins.	0
M3IF_BIGEND_M0	I	Endian mode signal from master #0	Master dependent
M3IF_BIGEND_M1	I	Endian mode signal from master #1	Master dependent
M3IF_BIGEND_M2	I	Endian mode signal from master #2	Master dependent
M3IF_BIGEND_M3	I	Endian mode signal from master #3	Master dependent
M3IF_BIGEND_M4	I	Endian mode signal from master #4	Master dependent
M3IF_BIGEND_M5	I	Endian mode signal from master #5	Master dependent
M3IF_BIGEND_M6	I	Endian mode signal from master #6	Master dependent
M3IF_BIGEND_M7	I	Endian mode signal from master #7	Master dependent
WATERMARK_PORT[7:0]	I	Selects the watermark ports. If watermark is not enabled this port is not routed as EMI port.	0
IPI_INT_WATERMARK		Watermark interrupt. If watermark is not enabled this port is not routed as EMI port.	0
WARM_RESET	I	Warm reset indication. If ESDRAMC doesn't support warm_reset, than this port is not routed as EMI port.	0
M3IF_HMASTLOCK_M0	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M1	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M2	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M3	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M4	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M5	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M6	—	Master arbitration locking signal	0
M3IF_HMASTLOCK_M7	—	Master arbitration locking signal	0
DMA_REQ	—	NFC DMA request	0
HRESET_B	—	Reset signal	1
HRESET_NEG_B	—	Reset signal	1
IPP_DO_EMI_OE_B	—	WEIM Data pads direction	0
IPP_IND_WEIM_BCLK_FB	—	WEIM feedback clock	0
IPT_MODE	—	Scan signal	0

Table 17-1. EMI Signal Properties (Continued)

Name	Port	Function	Reset State
IPT_MODE_BURNIN	—	Scan signal	0
IPT_RAM_SE	—	Scan signal	0
IPT_SE	—	Scan signal	0
IPT_SE_ASYNC	—	Scan signal	0
IPT_SE_GATEDCLK	—	Scan signal	0
JTA_OR_IOB_BIST_BITMAPPING	—	NFC JTAG signal	0
JTAGC_BIST_NAND_CLOCK_DR	—	NFC JTAG signal	0
JTAGC_BIST_NAND_TDI	—	NFC JTAG signal	0
NAND_JTAGC_BIST_TDO	—	NFC JTAG signal	0
NFC_FMS	—	NFC 512-byte / 2-Kbyte page size	
NF_4K	—	8-bit ECC signal	
NF_BOOT_WITH_RESET	—	Flash memory is MLC type	
EMI_SPARE_PORT_IN[9:0]	—	Spare inputs	0
EMI_SPARE_PORT_OUT[9:0]	—	spare outputs	0
IPT_SI[59:0]	—	Scan inputs	0
IPT_SO[59:0]	—	Scan outputs	0
DELAY_LINE_REF_CLK	—	Reference clock to the delay line	0
DVFS_REQ	—	DVFS request signal	0
DVFS_GRANT	—	DVFS acknowledge signal	0
VNW	—	WT_SHORT signal	0
VPW	—	WT_SHORT signal	0
WT_EN_DNW	—	WT_SHORT signal	0
WT_EN	—	WT_SHORT signal	0
NON_MOBILE_DDR_FUSE	—	DDR Type select	0

17.3 Memory Map/Register Definition

Table 17-2 shows the address ranges for the four different controllers' registers (M3IF plus three external memory controllers). See the separate memory controller chapters for detailed descriptions of the memory controllers' registers.

Table 17-2. EMI Registers Address Ranges

Address Range	Use	Access
0xB800_3000 – 0xB800_3FFF	M3IF registers space (4 Kbytes)	Read/write

Table 17-2. EMI Registers Address Ranges (Continued)

0xB800_1000 – 0xB800_1FFF	ESDRAMC/MDDRC registers space (4 Kbytes)	Read/write
0xB800_2000 – 0xB800_2FFF	WEIM registers space (4 Kbytes)	Read/write
0xBB00_1E00 – 0xBB00_1EFF	NFC registers space (4 Kbytes)	Read/write

Table 17-3 shows the memory map, including memory spaces allocated to the three different external controllers.

Table 17-3. EMI Memory Map

Address Range	Use	Access
ESDRAMC/MDDRC Memory Space		
0x8000_0000 – 0x8FFF_FFFF	CSD0 SDRAM/LPDDR memory region (256 Mbytes)	Read/write
0x9000_0000 – 0x9FFF_FFFF	CSD1 SDRAM/LPDDR memory region (256 Mbytes)	Read/write
WEIM Memory Space		
0xA000_0000 – 0xA7FF_FFFF	WEIM CS0 memory region[1] (128 Mbytes)	Read/write
0xA800_0000 – 0xAFFF_FFFF	WEIM CS1 memory region (128 Mbytes)	Read/write
0xB000_0000 – 0xB1FF_FFFF	WEIM CS2 memory region (32 Mbytes)7	Read/write
0xB200_0000 – 0xB3FF_FFFF	WEIM CS3 memory region (32 Mbytes)	Read/write
0xB400_0000 – 0xB5FF_FFFF	WEIM CS4 memory region (32 Mbytes)	Read/write
0xB600_0000 – 0xB7FF_FFFF	WEIM CS5 memory region (32 Mbytes)	Read/write
NFC Memory Space		
0xBB00_0000 – 0xBB00_11FF	NFC memory region[1] (4.5 Kbytes, NAND Flash)	Read/write

1. Can be used as a boot memory region.

17.4 Functional Description

This section provides a functional description of the multi-master memory interface (M3IF), the three external memory controllers, and the EMI's AHB and I/O multiplexers.

17.4.1 Multi-Master Memory Interface (M3IF)

When a master requests a memory access, the access is immediately taken by the M3IF if no other access is in progress. The M3IF forwards the access to the respective memory controller (slave). When the access execution is completed, HREADY is asserted and a new request can be processed.

The interface between M3IF and ESDRAMC is optimized to reduce access latency by generating multiple accesses through the dedicated ESDRAMC arbitration (MAB) module, which controls the access to/from the ESDRAMC.

For the other memory interfaces, the M3IF receives masters' requests through the master port gasket (MPG) interfaces, performs arbitration, and forwards each request to the appropriate memory controller.

17.4.2 NAND Flash Controller (NFC)

The NFC provides an interface between standard NAND Flash devices and the IC and hides the complexities of accessing a NAND Flash memory device. It provides a glueless interface to 8- or 16-bit SLC or MLC NAND Flash devices with different page size. Figure 17-2 is a simplified block diagram of the NFC.

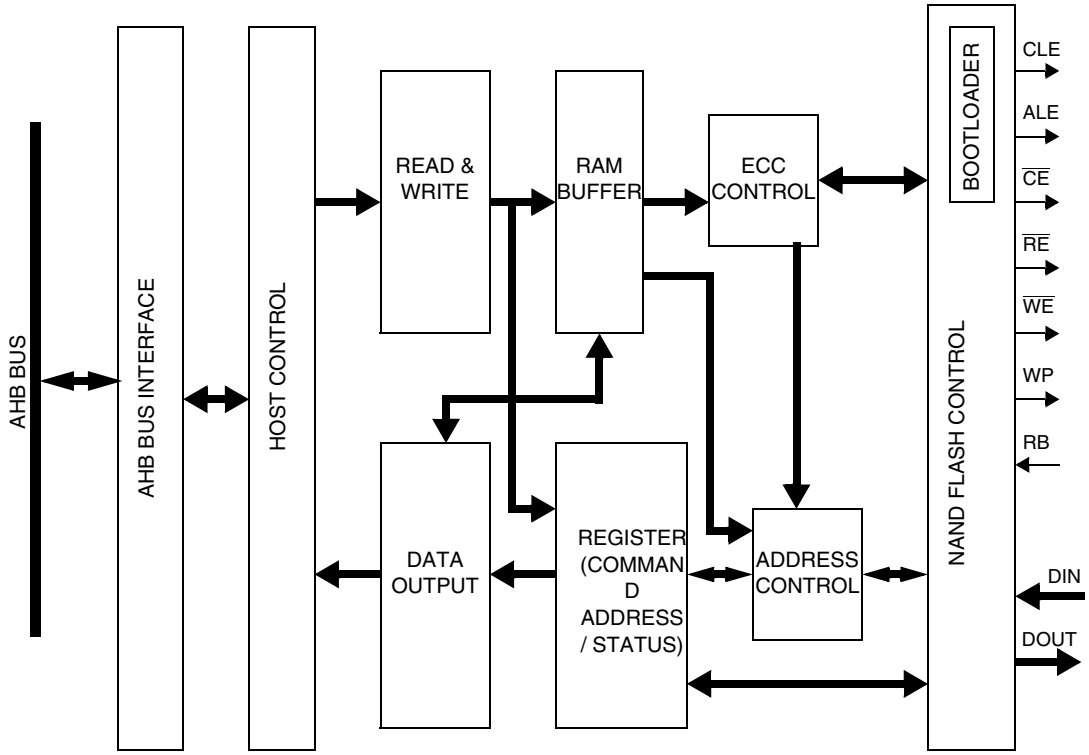

Figure 17-2. NAND Flash Controller Simplified Block Diagram

17.4.2.1 NFC Operation

Communication with a Flash memory device begins by the AHB host initiating a read from the NFC. This is accomplished by configuring the NFC and then waiting for an interrupt from the Flash memory device to be generated. When the NFC receives the interrupt, it inputs a page from the Flash memory device, and upon completion generates an interrupt to the AHB host.

When the AHB host receives the NFC interrupt, it reads the content from the internal RAM buffer of the NFC. To complete the operation the AHB host checks the status of the operation by reading the NFC status registers.

Data that is exchanged with the Flash memory device is temporarily maintained in the RAM buffer. This buffer is used as the boot RAM during a cold reset (if the IC is configured to boot from the NAND Flash device). After the boot load completes, the RAM is available as buffer RAM for normal Flash memory operations.

17.4.2.2 NFC Internal and External Communications

To ensure the greatest degree of flexibility, the NFC provides an internal interface to the AHB bus allowing 16-bit or 32-bit bus transfers, and a signal-selectable 8- or 16-bit interface to the external NAND Flash memory device.

All communication between the NFC and the ARM11 platform passes through the AHB host. The host configures and controls the NFC via the NFC registers.

Data integrity of the NAND Flash is maintained by the NFC. The NFC automatically generates the ECC for verification during a read or program operation.

17.4.2.3 NFC Sharing of I/O Pins

The NFC provides necessary logic to share I/O pins with other memory controllers. For example, when interfacing with a PSRAM, the 16 I/O signals of the NAND Flash controller share the same I/O pins with the data signals of the wireless external interface module (WEIM).

When a request to free the pins is asserted, the NFC state machine halts and the NAND Flash signals when it finishes the current transfer. The other memory controller is then able to gain control of the pins.

Since the NAND Flash memory accesses are typically long and relatively slow, priority is given to the other memory controller sharing the pins. The NFC waits until the other memory controller is finished with its operation and the pins are free before it continues its accesses.

17.4.3 Enhanced SDRAM Controller (ESDRAMC)

The ESDRAMC (equivalently denoted as ESDCTL) provides interface, configuration and control for many different types of synchronous SDRAM and low power mobile DDR (LPDDR) memories. Figure 17-3 shows the functional organization of the enhanced SDRAM controller.

The enhanced SDRAM controller consists of nine major blocks:

- SDRAM command state machine controller,
- Bank register (page and bank address comparators),
- Row/column address multiplexer,
- Configuration registers,
- Refresh request counter,
- Command sequencer,
- Size logic (splitting access),
- Data path (data aligner/multiplexer),
- LPDDR interface
- Power-down timer.

Figure 17-3. Enhanced SDR/LPDDR SDRAM Controller Block Diagram

17.4.4 EMI AHB Multiplexer

The EMI AHB multiplexer controls the traffic on the AHB bus (address and controls) between the memory controllers and the internal peripherals (via the M3IF). The EMI uses several muxes/glue logic to control the traffic on the AHB bus.

Only a few AHB signals/buses are routed through the EMI AHB multiplexer to the memory controllers. Most of the AHB buses (data, address and controls) are directly routed from the M3IF to the memory controllers.

17.4.4.1 Overview of EMI AHB Multiplexer Operation

Figure 17-4 illustrates the EMI AHB multiplexer block diagram. The interface is compatible with the ARM 11 AMBA-AHB lite standard (for instance, it does not support RETRY and SPLIT transfers). All AHB signals that are not shown in Figure 17-4 are directly routed between the M3IF and the relevant memory controllers. For the entire list of AHB signals see Table 17-1 and to the relevant memory controller specification document.

The EMI AHB multiplexer generates the HSEL signals for all memory controllers, excluding the ESDRAMC (which is generated within the M3IF due to latency-hiding logic).

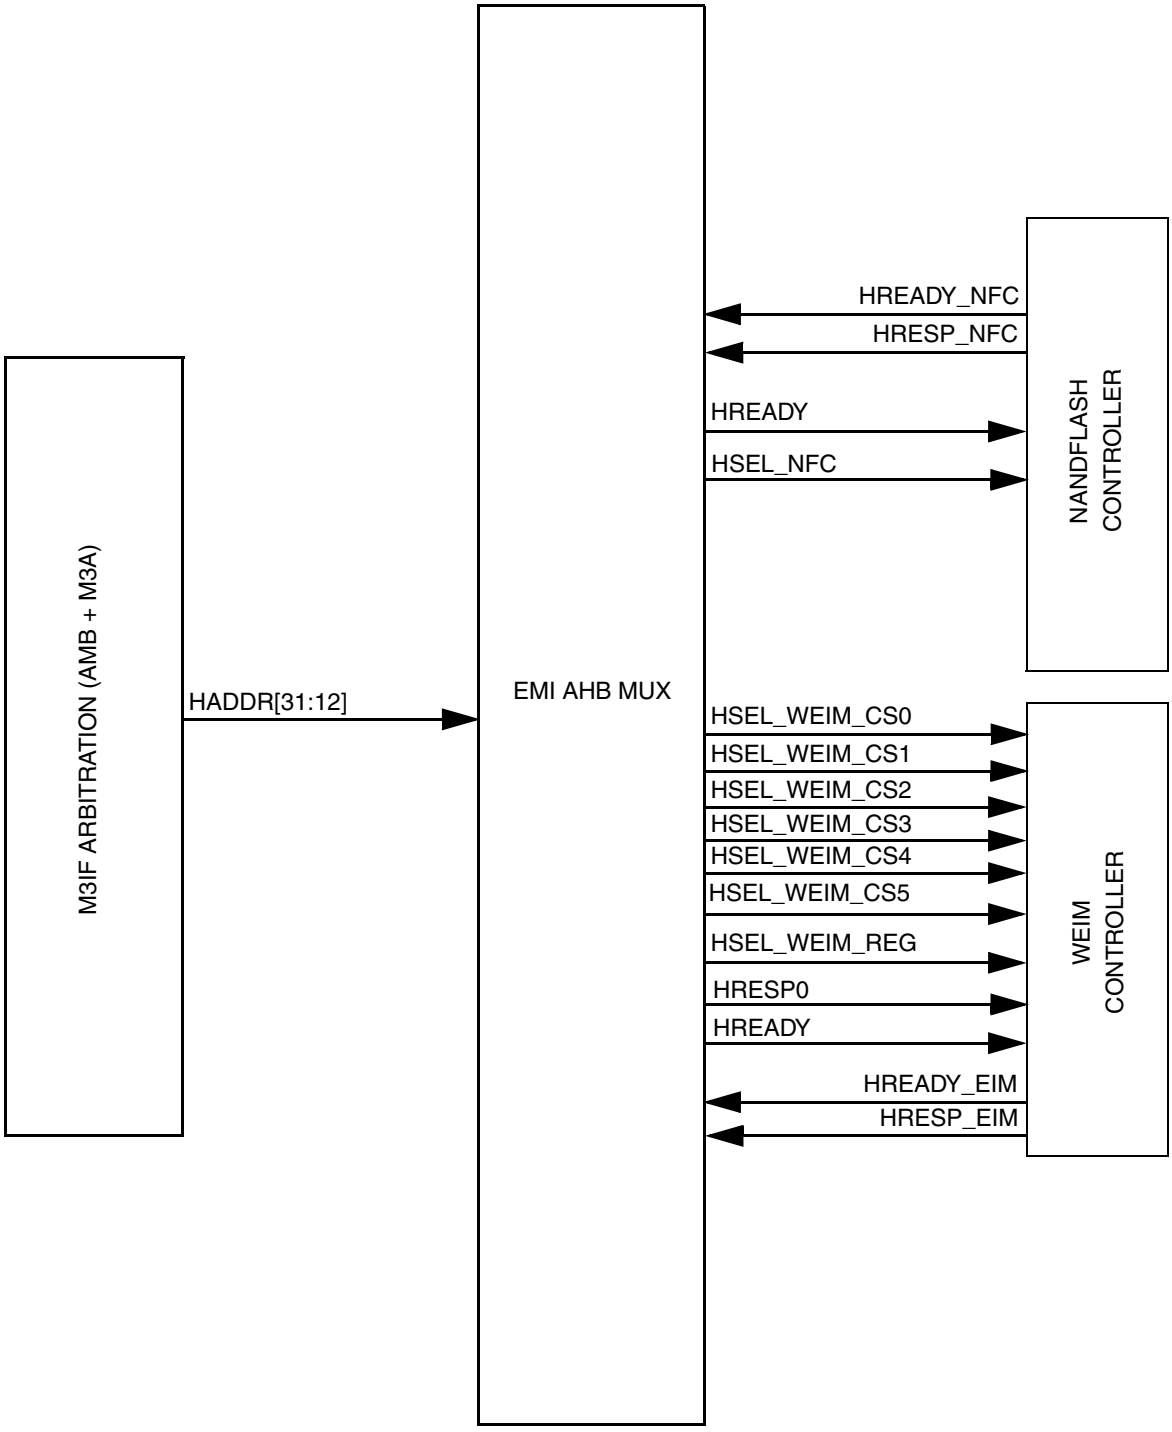

Figure 17-4. EMI AHB Multiplexer Interface Diagram

17.4.5 EMI I/O Multiplexer

The EMI I/O multiplexer controls the traffic (data, address and control signals) between the memory controllers and the external devices (via the IC IOMUX pins).

Figure 17-5 provides a top-level diagram of the EMI I/O multiplexer. Signals that share IC pins are routed through the EMI I/O multiplexer to the external devices. Signals that have dedicated pins (such as control signals) are not shown in Figure 17-5: these are directly routed from the memory controllers to the external devices. For a complete list of signals see Table 17-1 and the relevant memory controller section.

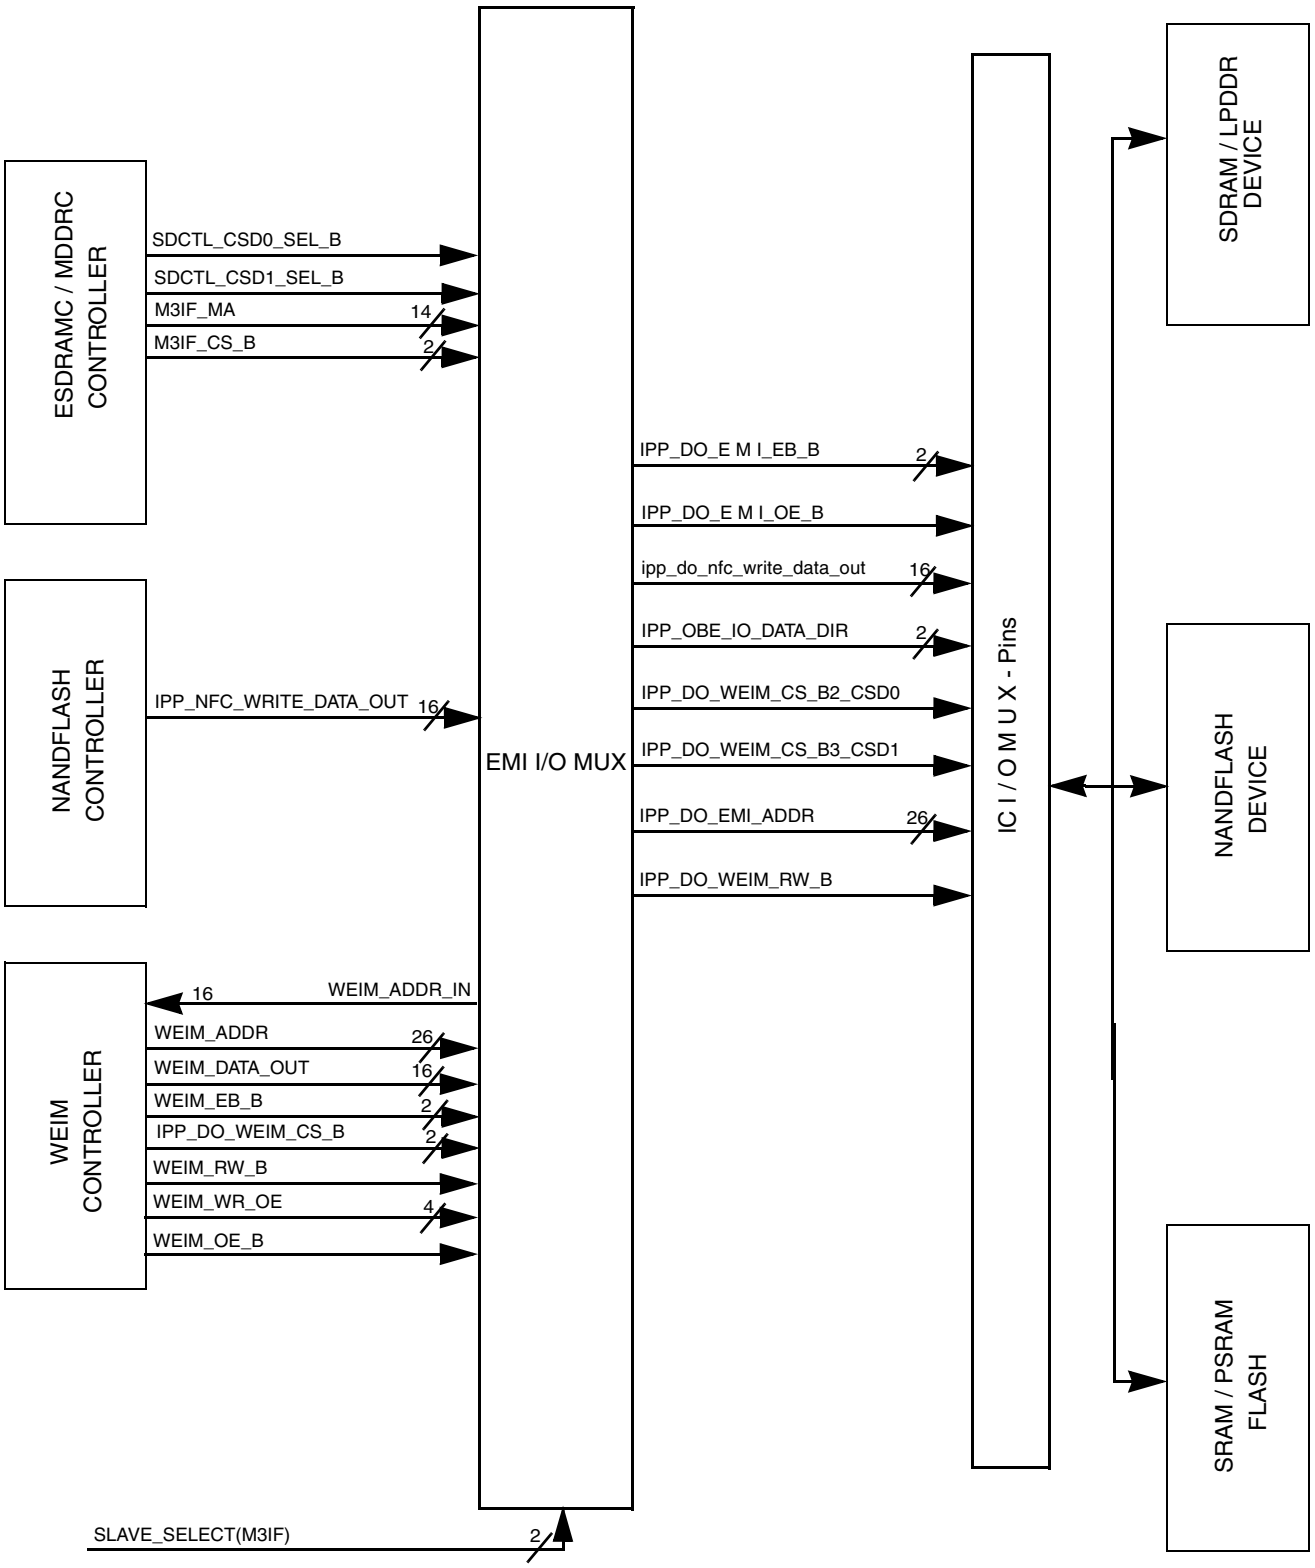

Figure 17-5. EMI I/O Multiplexer Interface Diagram

17.4.5.1 Overview of EMI I/O Multiplexer Operation

The active memory controller is determined by the SLAVE_SELECT[1:0] signal driven by the M3IF. Table 17-4 lists the memory controllers associated with different SLAVE_SELECT values.

Table 17-4. SLAVE_SELECT Memory Controller Selection

SLAVE_SELECT Value	Selected Memory Controller
00	ESDRAMC/MDDRC
01	WEIM
10	Reserved
11	NFC

Table 17-1 summarizes the EMI outputs to IC pins, including dedicated pins and pins which are shared between controllers.

Table 17-5. EMI Outputs to IC Pins

Chapter 18
Enhanced Periodic Interrupt Timer (EPIT)

18.1 Overview

The enhanced periodic interrupt timer (EPIT) is a 32-bit set-and-forget timer that begins counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention. Figure 18-1 illustrates the block diagram of the EPIT.

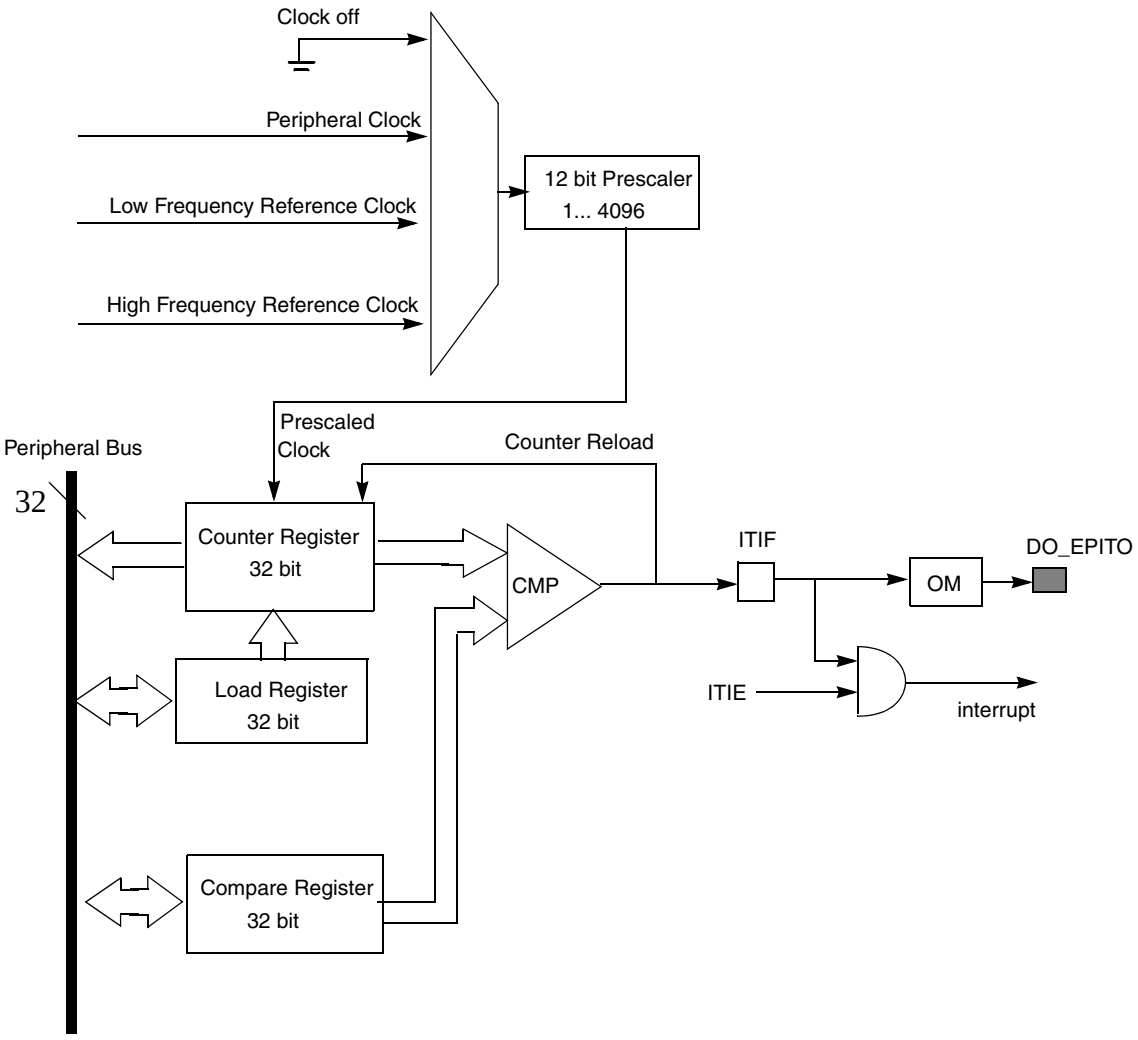

Figure 18-1. Enhanced Periodic Interrupt Timer Block Diagram

18.1.1 Features

Key features of the EPIT include:

- 32-bit down counter with clock source selection
- 12-bit prescaler for division of input clock frequency
- Counter value can be programmed on the fly
- Can be programmed to be active during low-power and debug modes
- Interrupt generation when counter reaches the Compare value

18.1.2 Modes and Operations

The EPIT supports the modes described in the indicated sections:

- Section 18.4.1, “Operating Modes”
  - Section 18.4.1.1, “Set-and-Forget Mode”
  - Section 18.4.1.2, “Free-Running Mode”

The EPIT supports the operations as described in Section 18.4.2, “Operations.”

18.2 External Signals

Table 18-1 describes all EPIT signals that connect off-chip.

Table 18-1. Off-Chip Module Signals

Name	I/O	Description	Reset State	Pull Up
DO_EPITO	O	Output pin at chip boundary for indication of occurrence of output compare event through a specified transition.	0	—

18.3 Memory Map and Register Definitions

The EPIT module includes five user-accessible 32-bit registers. Table 18-2 summarizes these registers and their addresses.

Peripheral bus write access to the EPIT control register (EPITCR) and the EPIT load register (EPITLR) results in one cycle of wait state, while other valid peripheral bus accesses are with 0 wait state.

18.3.1 Memory Map

For the base address of a particular module instantiation, see the system memory map. Table 18-2 shows the memory map for the EPIT registers.

Table 18-2. EPIT Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0004 (EPITSR)	Control register	R/W	0x0000_0000	18.3.3.1/18-4
0x0004 (EPITSR)	Status register	R/W	0x0000_0000	18.3.3.2/18-6
0x0008 (EPITLR)	Load register	R/W	0xFFFF_FFFF	18.3.3.3/18-7
0x000C (EPITCMPR)	Compare register	R/W	0x0000_0000	18.3.3.4/18-8
0x0010 (EPITCNR)	Counter register	R	0xFFFF_FFFF	18.3.3.5/18-8

18.3.2 Register Summary

The EPIT registers are summarized in Table 18-3.

Table 18-3. EPIT Register Summary

Base Address Offset (Register Abbreviation)		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

18.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers. Figure 18-2 and Table 18-4 explain conventions used in register diagrams and tables.

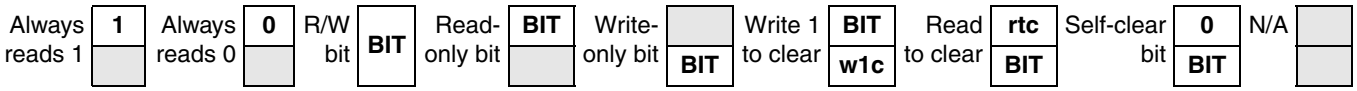

Figure 18-2. Register Field Conventions

Table 18-4. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

18.3.3.1 EPIT Control Register

The EPIT control register (EPITCR) is used to configure the operating settings of the EPIT. It contains the clock division prescaler value and also the interrupt enable bit. Additionally it contains other control bit which are outlined below.

Peripheral Bus Write access to EPIT Control Register (EPITCR) results in one cycle of the wait state, while other valid peripheral bus accesses are with 0 wait state.

Figure 18-3 shows the register. Table 18-5 describes the register fields.

Offset 0x0000 (EPITCR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	PRESCALER[15:4]												RLD	OCIE N	ENM OD	EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-3. EPIT Control Register

Table 18-5. EPIT Control Register Field Description

Field	Description
31–26	Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
25-24 CLKSRC	Select clock source These bits determine which clock input is to be selected for running the counter. This field value should only be changed when the EPIT is disabled by clearing the EN bit in this register. For other programming requirements while changing clock source, see Section 18.5.1, “Change of Clock Source.” 00 Clock is off 01 Peripheral clock 10 High-frequency reference clock 11 Low-frequency reference clock
23–22 OM	EPIT output mode.This bit field determines the mode of EPIT output on the output pin. 00 EPIT output is disconnected from pad 01 Toggle output pin 10 Clear output pin 11 Set output pin
21 STOPEN	EPIT stop mode enable. This read/write control bit enables the operation of the EPIT during stop mode. This bit is reset by a hardware reset and unaffected by software reset. 0 EPIT is disabled in stop mode 1 EPIT is enabled in stop mode
20	Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
19 WAITEN	This read/write control bit enables the operation of the EPIT during wait mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled in wait mode 1 EPIT is enabled in wait mode
18 DBGEN	This bit is used to keep the EPIT functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode.This bit is reset by hardware reset. A software reset does not affect this bit. 0 Inactive in debug mode 1 Active in debug mode

Table 18-5. EPIT Control Register Field Description (Continued)

Field	Description
17 IOVW	EPIT counter overwrite enable. This bit controls the counter data when the modulus register is written. When this bit is set, all writes to the load register overwrites the counter contents and the counter starts subsequently counting down from the programmed value. 0 Write to load register does not result in counter value being overwritten. 1 Write to load register results in immediate overwriting of counter value.
16 SWR	Software reset. The EPIT module is reset when this bit is set to 1. It is a self clearing bit. This bit is set when the module is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values, except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register 0 EPIT is out of reset 1 EPIT is undergoing reset
15–4 PRESCALER	Counter clock prescaler value. This bit field determines the prescaler value by which the clock is divided before it goes to the counter 0x000 Divide by 1 0x001 Divide by 2 … 0xFFFF Divide by 4096
3 RLD	Counter reload control This bit is cleared by hardware reset. It decides the counter functionality, whether to run in free-running mode or set-and-forget mode. 0 When the counter reaches zero it rolls over to 0xFFFF_FFFF (free-running mode) 1 When the counter reaches zero it reloads from the modulus register (set-and-forget mode)
2 OCIEN	Output compare interrupt enable This bit enables the generation of interrupt on occurrence of compare event. 0 Compare interrupt disabled 1 Compare interrupt enabled
1 ENMOD	EPIT enable mode When EPIT is disabled (EN=0), then both main counter and prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit that determines the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and prescaler counter is reset, when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT/DEBUG), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 Counter starts counting from the value it had when it was disabled. 1 Counter starts count from load value (RLD=1) or 0xFFFF_FFFF (If RLD=0)
0 EN	This bit enables the EPIT. EPIT counter and prescaler value when EPIT is enabled (EN =1), is dependent upon ENMOD and RLD bit as described for ENMOD bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled 1 EPIT is enabled

18.3.3.2 EPIT Status Register

The EPIT status register (EPITSR) has a single status bit for the output compare event. The bit is a write 1 to clear bit.

Figure 18-4 shows the register. Table 18-6 describes the register fields.

Offset 0x0004 (EPITSR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	OCIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-4. EPIT Status Register

Table 18-6. EPIT Status Register Field Description

Field	Description
31–1	Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
0 OCIF	Output compare interrupt flag. This bit is the interrupt flag that is set when the content of counter equals the content of the compare register (EPITCMPR). The bit is a write 1 to clear bit. 0 Compare event hasn't occurred 1 Compare event occurred

18.3.3.3 EPIT Load Register

The EPIT load register (EPITLR) contains the value that is to be loaded into the counter when EPIT counter reaches zero if the RLD bit in EPITCR is set. If the IOVW bit in the EPITCR is set then a write to this register overwrites the value of the EPIT counter register in addition to updating this registers value. This overwrite feature is active even if the RLD bit is not set.

Figure 18-5 shows the register. Table 18-7 describes the register fields.

Offset 0x0008 (EPITLR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	LOAD[31:16]															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LOAD[15:0]															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Figure 18-5. EPIT Load Register

Table 18-7. EPIT Load Register Field Description

Field	Description
31–0 LOAD	Load value. Value that is loaded into the counter at the start of each count cycle.

18.3.3.4 EPIT Compare Register

The EPIT compare register (EPITCMPR) holds the value that determines when a compare event is generated.

Figure 18-6 shows the register. Table 18-8 describes the register fields.

Offset 0x000C (EPITCMPR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	COMPARE[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COMPARE[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-6. EPIT Compare Register

Table 18-8. EPIT Compare Register Field Description

Field	Description
31–0 COMPARE	Compare Value. When the counter value equals this bit field value a compare event is generated.

18.3.3.5 EPIT Counter Register

The EPIT counter register (EPITCNR) contains the current count value and can be read at any time without disturbing the counter. This is a read-only register and any attempt to write into it generates a transfer error. But if the IOVW bit in EPITCR is set, the value of this register can be overwritten with a write to EPITLR. This change is reflected when this register is subsequently read.

Figure 18-7 shows the register. Table 18-9 describes the register fields.

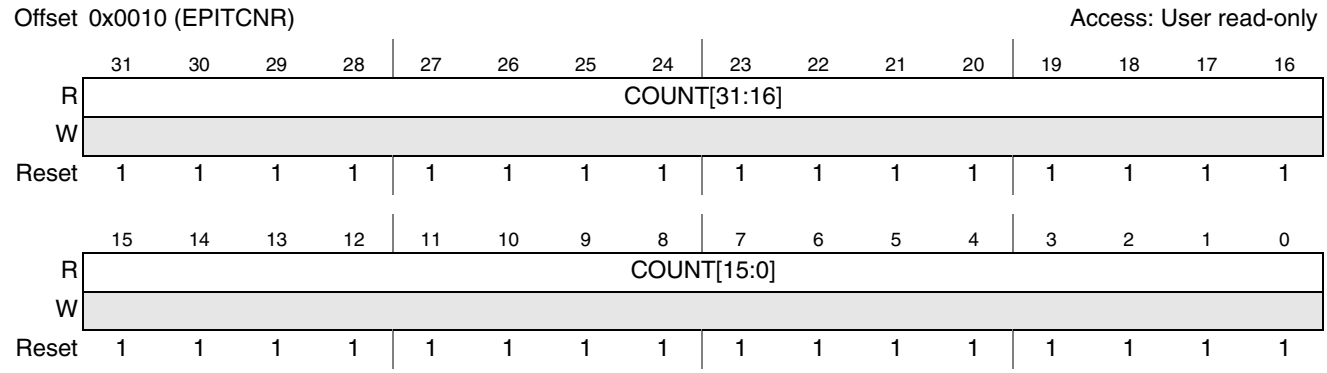

Figure 18-7. EPIT Counter Register

Table 18-9. EPIT Counter Register Field Description

Field	Description
31–0 COUNT	Counter value. This contains the current value of the counter.

18.4 Functional Description

This section provides a complete functional description of the module.

18.4.1 Operating Modes

This section describes all functional operation modes of the module. The EPIT can be programmed to function in set-and-forget or free-running modes.

18.4.1.1 Set-and-Forget Mode

This mode of operation is selected when the RLD bit in control register (EPITCR) is set to a value of one. The counter cannot be directly written from the module data bus. Instead, it gets its data from the load register (EPITLR). Whenever the counter reaches a count of zero, the value in EPITLR is loaded into the counter to be decremented toward zero. The counter may by directly initialized, without having to wait for the count to reach zero, when the EPITLR is written with the IOVW bit in EPITCR set.

18.4.1.2 Free-Running Mode

This mode of operation is selected when the RLD bit is cleared. In this mode, the counter rolls over from 0x0000_0000 to 0xFFFF_FFFF without reloading from the modulus register and continues to count down. In this mode when writing to EPITLR with the required initialization value after having set the IOVW bit, the counter can also be directly initialized.

18.4.2 Operations

The EPIT has a single 32-bit down counter which starts counting when the module is enabled by software. The start value of the counter is loaded from the EPIT load register which can be written to at any time by the processor. The value in the compare register determines the time of occurrence of the interrupt.

When EPIT is disabled (EN=0), then both main counter and prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit which decides the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and prescaler counter is reset (0x000), when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values, when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

A hardware reset resets all EPIT registers to their respective reset values. There is a software reset which has the same effect on all registers except for the EN, ENMOD, STOPEN and WAITEN bits in the control register. The state of these bits are not affected by software reset. A software reset can be asserted even when the EPIT is disabled.

18.4.3 Clocks

The clock that feeds the prescaler can be selected from among the following sources:

- High-frequency reference clock

  This clock is provided by the clock controller module (CCM). This clock remains on during low-power mode when the peripheral clock is turned off, allowing EPIT to use this clock in low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version.
- Low-frequency reference clock

  This 32 kHz reference clock is provided by the CCM. This clock remains on in low-power mode when the peripheral clock is turned off, so EPIT can use this clock during low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version. This clock is derived from the external 32kHz crystal.
- Peripheral clock

  This is the peripheral clock (PER Clock) which is provided (and optionally gated) by the CCM. This clock is typically used in normal operations. In low-power modes, if the EPIT is programmed to be disabled (via STOPEN or WAITEN), then the peripheral clock can be switched off.

The clock input source is determined by the CLKSRC field in the control register. The clock input to the prescaler can also be disabled by setting CLKSRC to 0b00. This field value should only be changed after first disabling the EPIT by clearing the EN bit in the EPITCR. For other programming requirements that apply while changing clock source, refer section Section 18.5.1, “Change of Clock Source.”

The PRESCALER field in the control register is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value between 1 and 4096. A change in the

value of the PRESCALER field is immediately reflected on its output clock frequency. Figure 18-8 shows the timing for a change in the prescaler value.

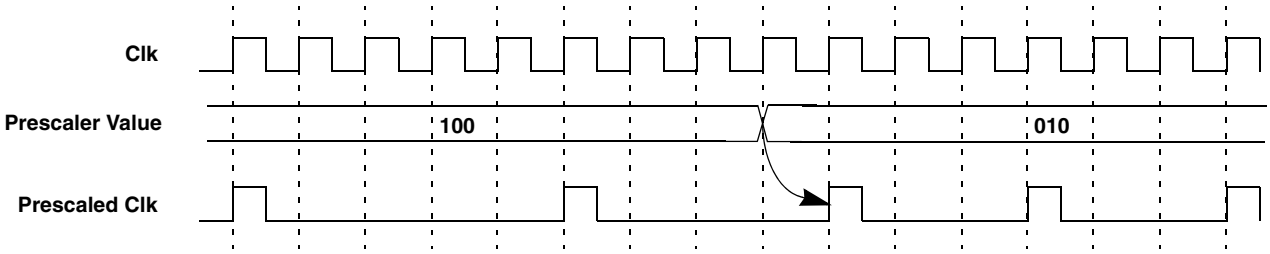

Figure 18-8. Prescaler Value Change Diagram

18.4.4 Compare Event

When the programmed value of EPITCMPR matches the value in EPITCNR a compare status flag is set, and an interrupt is generated if the OCIEN bit is set in the control register. The compare output pin is set, cleared, toggled, or not affected at all depending on the setting of the output mode (OM) bits in the control register. If an interrupt is required at rollover (when the counter value reaches 0x0000_0000 and the new value is loaded) then the compare register value should be set equal to the load register value in set-and-forget mode, or equal to 0xFFFF_FFFF in free-running mode.

Figure 18-9 shows the timing for a compare event and interrupt.

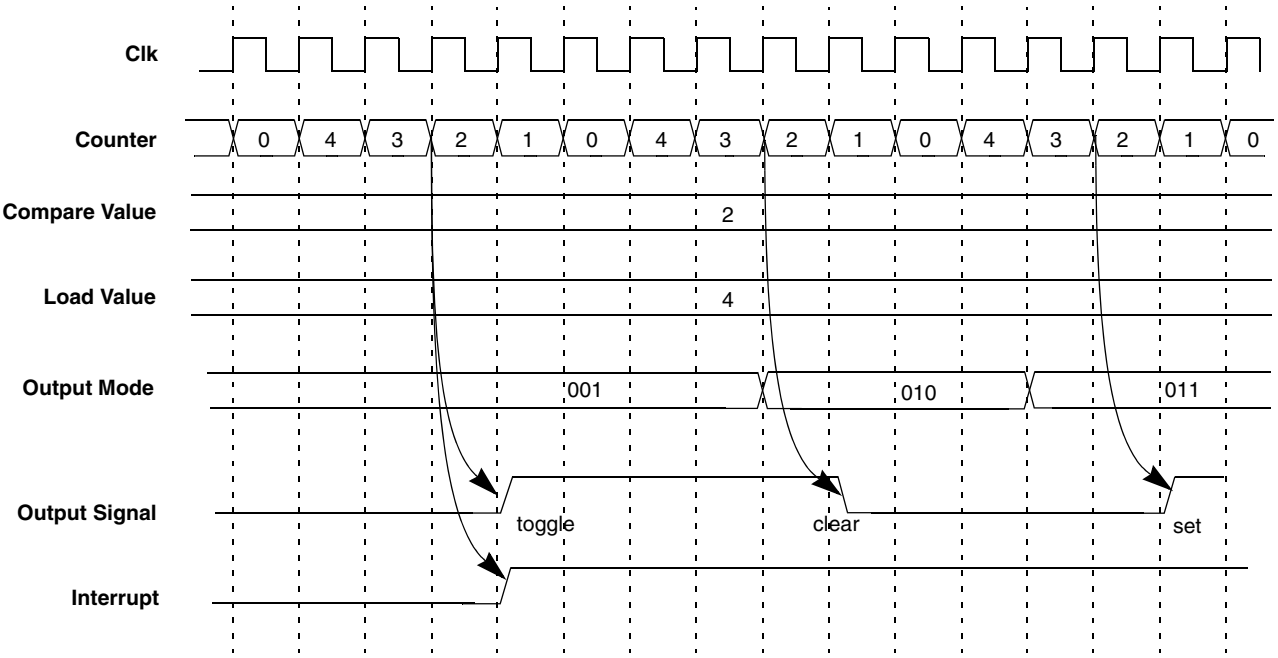

Figure 18-9. Compare Event and Interrupt Timing Diagram

18.4.4.1 Counter Value Overwrite

The EPIT counter value can be overwritten to acquire a desired value at any point of time. The procedure for this is to set the IOVW bit in the control register and then write the desired value into the load register. This results in the load register acquiring that value and also the counter being overwritten with it. If the EPIT is running the counter resumes counting from the overwritten value.

18.4.4.2 Low-Power Mode Behavior

The EPIT timer's behavior in low-power modes depends on which clock source is being used. If the selected clock source is available and the corresponding low-power enable bit is set, then the EPIT continues to function in the low-power mode. If the EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then main counter and the prescaler counter freeze at the current count values when the EPIT enters low-power mode. When the EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

18.4.4.3 Debug Mode Behavior

In debug mode, the user has the option to run or halt the EPIT timers. If the DBGEN bit is reset in the EPIT control Register, the timer is halted. When debug mode is exited, the timer operation reverts to what it was prior to entering debug mode.

18.5 Initialization/ Application Information

18.5.1 Change of Clock Source

The CLKSRC field in EPITCR determines the clock source. This field value should be changed only after disabling the EPIT (EN = 0). Below is the software sequence which must be followed while changing clock source.

1. Disable the EPIT by setting EN=0 in EPITCR.
2. Program OM=00 in the EPITCR.
3. Disable the EPIT interrupts.
4. Program CLKSRC to desired clock source in EPITCR.
5. Clear the EPIT status register (EPITSR) i.e. (w1c).
6. Enable the EPIT interrupts.
7. Set ENMOD= 1 in the EPITCR, to bring the EPIT Counter to defined state (EPITLR value or 0xFFFF_FFFF).
8. Enable EPIT (EN=1) in the EPITCR.

Chapter 19
Enhanced Serial Audio Interface (ESAI)

19.1 Introduction

The enhanced serial audio interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other DSPs. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator.

The ESAI block diagram is shown in Figure 19-1. The ESAI is named synchronous because all serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is similar in that it is also intended for periodic transfers; however, it supports up to 32 words (time slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

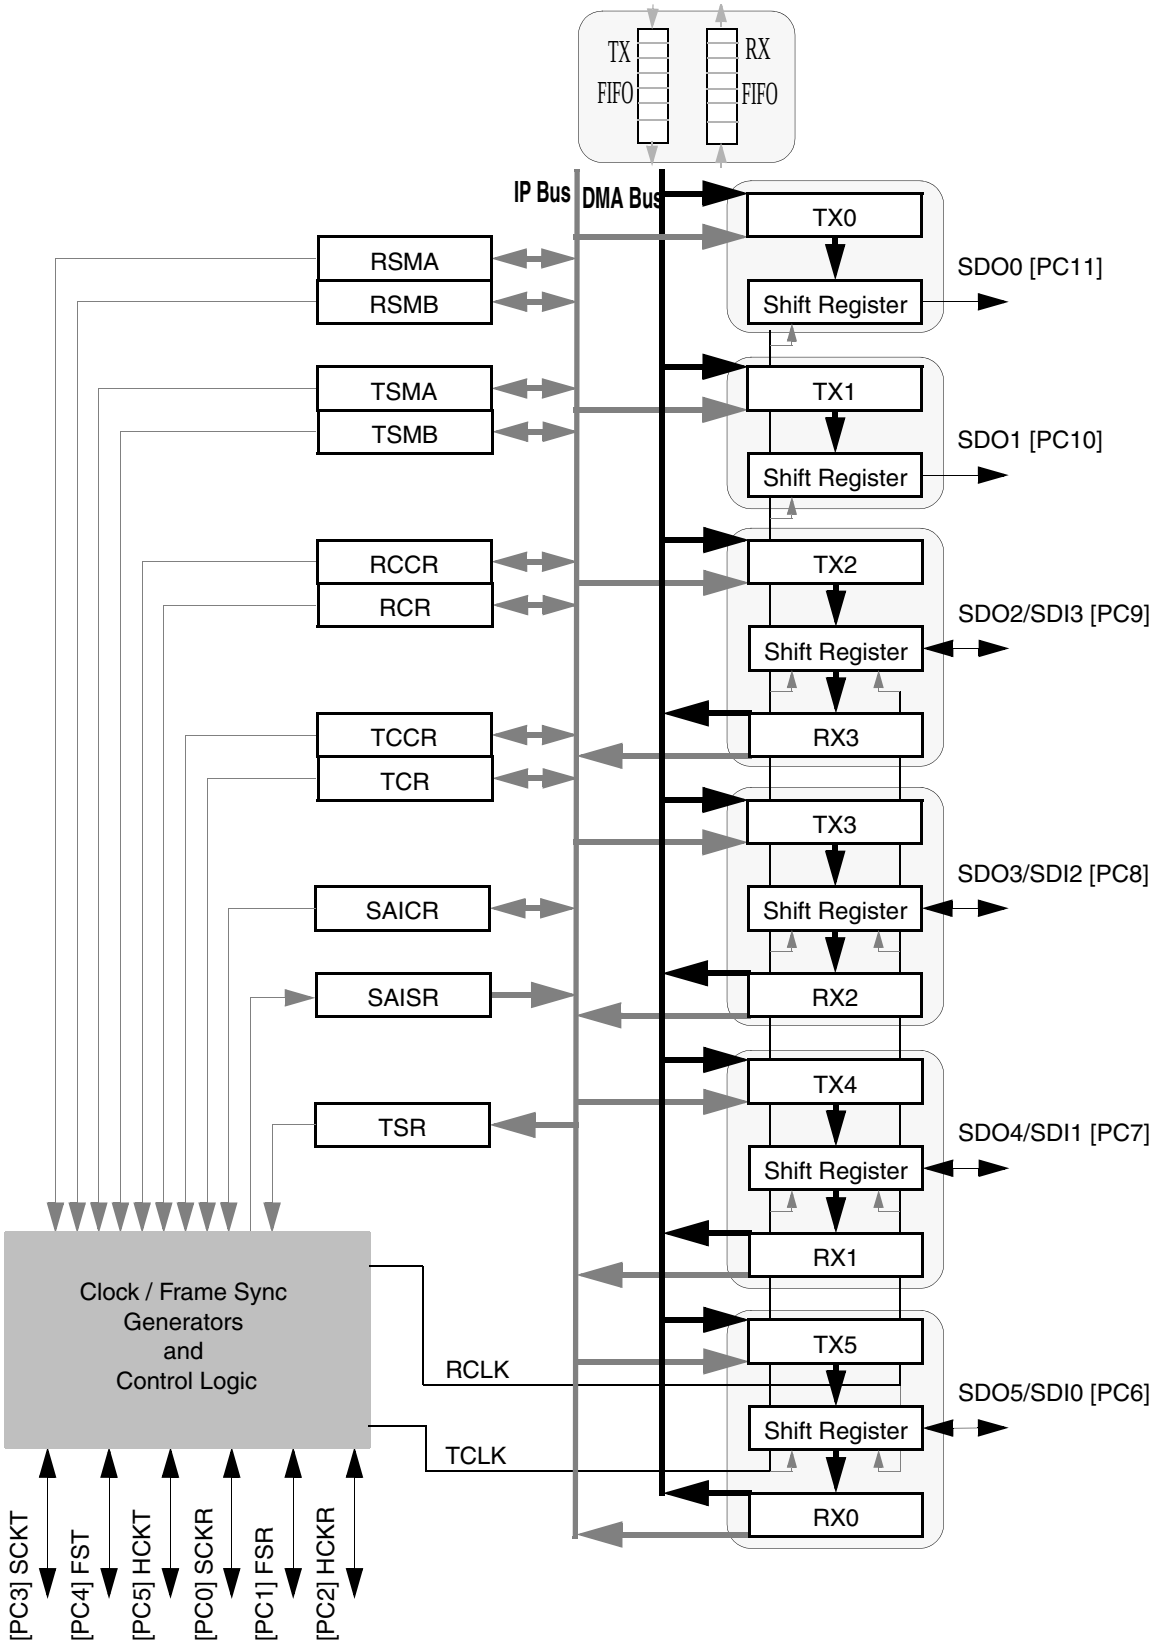

Figure 19-1. ESAI Block Diagram

19.1.1 Features

- Independent (asynchronous mode) or shared (synchronous mode) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Up to 6 transmitters and 4 receivers with SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins shared by transmitters 2 to 5 and receivers 0 to 3. SDO0 and SDO1 pins are used by transmitters 0 and 1 only.
- Programmable data interface modes supported are I2S, LSB aligned, MSB aligned
- Programmable word length (8, 12, 16, 20 or 24bits)
- Flexible selection between system clock or external oscillator as input clock source, programmable internal clock divider and frame sync generation
- AC97 support
- Time Slot Mask Registers for reduced CPU overhead (both transmit and receive)
- 128-word Transmit FIFO shared by six transmitters
- 128-word Receive FIFO shared by four receivers

19.1.2 Modes of Operation

ESAI has three basic operating modes and many data/operation formats. ESAI operating mode are selected by the ESAI control registers (TCCR, TCR, RCCR, RCR, and SAICR). The main operating modes are described in the following paragraphs.

19.1.2.1 Normal/Network/On-Demand Mode Selection

Selecting between the normal mode and network mode is accomplished by clearing or setting the TMOD0-TMOD1 bits in the TCR register for the transmitter section, as well as in the RMOD0-RMOD1 bits in the RCR register for the receiver section.

For normal mode, the ESAI functions with one data word of I/O per frame (per enabled transmitter or receiver). The normal mode is typically used to transfer data to/from a single device.

For the network mode, 2 to 32 time slots per frame may be selected. During each frame, 0 to 32 data words of I/O may be received/transmitted. In either case, the transfers are periodic. The frame sync signal indicates the first time slot in the frame. Network mode is typically used in time division multiplexed (TDM) networks of codecs, DSPs with multiple words per frame, or multi-channel devices.

Selecting the network mode and setting the frame rate divider to zero (DC=00000) selects the on-demand mode. This special case does not generate a periodic frame sync. A frame sync pulse is generated only when data is available to transmit. The on-demand mode requires that the transmit frame sync be internal (output) and the receive frame sync be external (input). Therefore, for simplex operation, the synchronous mode could be used; however, for full-duplex operation, the asynchronous mode must be used. Data transmission that is data driven is enabled by writing data into each TX. Although the ESAI is double buffered, only one word can be written to each TX, even if the transmit shift register is empty. The receive and transmit interrupts function as usual using TDE and RDF; however, transmit underruns are impossible for on-demand transmission and are disabled.

19.1.2.2 Synchronous/Asynchronous Operating Modes

The transmit and receive sections of the ESAI may be synchronous or asynchronous; that is, the transmitter and receiver sections may use common clock and synchronization signals (synchronous operating mode), or they may have their own separate clock and sync signals (asynchronous operating mode). The SYN bit in the SAICR register selects synchronous or asynchronous operation. Since the ESAI is designed to operate either synchronously or asynchronously, separate receive and transmit interrupts are provided.

When SYN is cleared, the ESAI transmitter and receiver clocks and frame sync sources are independent. If SYN is set, the ESAI transmitter and receiver clocks and frame sync come from the transmitter section (either external or internal sources).

Data clock and frame sync signals can be generated internally by the ARM-core or may be obtained from external sources. If internally generated, the ESAI clock generator is used to derive high frequency clock, bit clock and frame sync signals from the ARM-core internal system clock.

19.1.2.3 Frame Sync Selection

The frame sync can be either a bit-long or word-long signal. The transmitter frame format is defined by the TFSL bit in the TCR register. The receiver frame format is defined by the RFSL bit in the RCR register.

1. In the word-long frame sync format, the frame sync signal is asserted during the entire word data transfer period. This frame sync length is compatible with codecs, SPI serial peripherals, serial A/D and D/A converters, shift registers and telecommunication PCM serial I/O.
2. In the bit-long frame sync format, the frame sync signal is asserted for one bit clock immediately before the data transfer period. This frame sync length is compatible with Intel and National components, codecs and telecommunication PCM serial I/O.

The relative timing of the word length frame sync as referred to the data word is specified by the TFSR bit in the TCR register for the transmitter section and by the RFSR bit in the RCR register for the receive section. The word length frame sync may be generated (or expected) with the first bit of the data word, or with the last bit of the previous word. TFSR and RFSR are ignored when a bit length frame sync is selected.

Polarity of the frame sync signal may be defined as positive (asserted high) or negative (asserted low). The TFSP bit in the TCCR register specifies the polarity of the frame sync for the transmitter section. The RFSP bit in the RCCR register specifies the polarity of the frame sync for the receiver section.

The ESAI receiver looks for a receive frame sync leading edge (trailing edge if RFSP is set) only when the previous frame is completed. If the frame sync goes high before the frame is completed (or before the last bit of the frame is received in the case of a bit frame sync or a word length frame sync with RFSR set), the current frame sync is not recognized, and the receiver is internally disabled until the next frame sync. Frames do not have to be adjacent, that is, a new frame sync does not have to immediately follow the previous frame. Gaps of arbitrary periods can occur between frames. Enabled transmitters are tristated during these gaps.

When operating in the synchronous mode (SYN=1), all clocks including the frame sync are generated by the transmitter section.

19.1.2.4 Shift Direction Selection

Some data formats, such as those used by codecs, specify MSB first while other data formats, such as the AES-EBU digital audio interface, specify LSB first. The MSB/LSB first selection is made by programming RSHFD bit in the RCR register for the receiver section and by programming the TSHFD bit in the TCR register for the transmitter section.

19.2 External Signal Description

Three to twelve pins are required for operation, depending on the operating mode selected and the number of transmitters and receivers enabled. The SDO0 and SDO1 pins are used by transmitters 0 and 1 only. The SDO2/SDI3, SDO3/SDI2, SDO4/SDI1 and SDO5/SDI0 pins are shared by transmitters 2 to 5 with receivers 0 to 3. The actual mode of operation is selected under software control. All transmitters operate fully synchronized under control of the same transmitter clock signals. All receivers operate fully synchronized under control of the same receiver clock signals.

19.2.1 Serial Transmit 0 Data Pin (SDO0)

SDO0 is used for transmitting data from the TX0 serial transmit shift register. SDO0 is an output when data is being transmitted from the TX0 shift register. In the on-demand mode with an internally generated bit clock, the SDO0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO0 may be programmed as a disconnected pin (PC11) when the ESAI SDO0 function is not being used. (See Table 19-38.)

19.2.2 Serial Transmit 1 Data Pin (SDO1)

SDO1 is used for transmitting data from the TX1 serial transmit shift register. SDO1 is an output when data is being transmitted from the TX1 shift register. In the on-demand mode with an internally generated bit clock, the SDO1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO1 can be programmed as a disconnected pin (PC10) when the ESAI SDO1 function is not being used. (See Table 19-38.)

19.2.3 Serial Transmit 2/Receive 3 Data Pin (SDO2/SDI3)

SDO2/SDI3 is used as the SDO2 for transmitting data from the TX2 serial transmit shift register when programmed as a transmitter pin, or as the SDI3 signal for receiving serial data to the RX3 serial receive shift register when programmed as a receiver pin. SDO2/SDI3 is an input when data is being received by the RX3 shift register. SDO2/SDI3 is an output when data is being transmitted from the TX2 shift register. In the on-demand mode with an internally generated bit clock, the SDO2/SDI3 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO2/SDI3 may be programmed as a disconnected pin (PC9) when the ESAI SDO2 and SDI3 functions are not being used. (See Table 19-38.)

19.2.4 Serial Transmit 3/Receive 2 Data Pin (SDO3/SDI2)

SDO3/SDI2 is used as the SDO3 signal for transmitting data from the TX3 serial transmit shift register when programmed as a transmitter pin, or as the SDI2 signal for receiving serial data to the RX2 serial receive shift register when programmed as a receiver pin. SDO3/SDI2 is an input when data is being received by the RX2 shift register. SDO3/SDI2 is an output when data is being transmitted from the TX3 shift register. In the on-demand mode with an internally generated bit clock, the SDO3/SDI2 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO3/SDI2 may be programmed as a disconnected pin (PC8) when the ESAI SDO3 and SDI2 functions are not being used. (See Table 19-38.)

19.2.5 Serial Transmit 4/Receive 1 Data Pin (SDO4/SDI1)

SDO4/SDI1 is used as the SDO4 signal for transmitting data from the TX4 serial transmit shift register when programmed as transmitter pin, or as the SDI1 signal for receiving serial data to the RX1 serial receive shift register when programmed as a receiver pin. SDO4/SDI1 is an input when data is being received by the RX1 shift register. SDO4/SDI1 is an output when data is being transmitted from the TX4 shift register. In the on-demand mode with an internally generated bit clock, the SDO4/SDI1 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO4/SDI1 may be programmed as a disconnected pin (PC7) when the ESAI SDO4 and SDI1 functions are not being used. (See Table 19-38.)

19.2.6 Serial Transmit 5/Receive 0 Data Pin (SDO5/SDI0)

SDO5/SDI0 is used as the SDO5 signal for transmitting data from the TX5 serial transmit shift register when programmed as transmitter pin, or as the SDI0 signal for receiving serial data to the RX0 serial shift register when programmed as a receiver pin. SDO5/SDI0 is an input when data is being received by the RX0 shift register. SDO5/SDI0 is an output when data is being transmitted from the TX5 shift register. In the on-demand mode with an internally generated bit clock, the SDO5/SDI0 pin becomes high impedance for a full clock period after the last data bit has been transmitted, assuming another data word does not follow immediately. If a data word follows immediately, there is no high-impedance interval.

SDO5/SDI0 may be programmed as a disconnected pin (PC6) when the ESAI SDO5 and SDI0 functions are not being used. (See Table 19-38.)

19.2.7 Receiver Serial Clock (SCKR)

SCKR is a bidirectional pin providing the receivers serial bit clock for the ESAI interface. The direction of this pin is determined by the RCKD bit in the RCCR register.The SCKR operates as a clock input or output used by all the enabled receivers in the asynchronous mode (SYN=0), or as serial flag 0 pin in the synchronous mode (SYN=1).

When this pin is configured as serial flag pin, its direction is determined by the RCKD bit in the RCCR register. When configured as the output flag OF0, this pin reflects the value of the OF0 bit in the SAICR register, and the data in the OF0 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When this pin is configured as the input flag IF0, the data value at the pin is stored in the IF0 bit in the SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

SCKR may be programmed as a disconnected pin (PC0) when the ESAI SCKR function is not being used. (See Table 19-38.)

NOTE

Although the external ESAI serial clocks can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25 MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

For SCKR pin mode definitions, see Table 19-29.

Table 19-1 provides a list of asynchronous-mode receiver clock sources. For more information about EXTAL/ESAI clocking control bits (ERI,ERO), see Table 19-8.”

Table 19-1. Receiver Clock Sources (Asynchronous Mode Only)

RHCKD	RFSD	RCKD	ERI	ERO	Receiver Bit Clock Source	Outputs		
0	0	0	N/A	N/A	SCKR			
0	0	1	N/A	N/A	HCKR			SCKR
0	1	0	N/A	N/A	SCKR		FSR	
0	1	1	N/A	N/A	HCKR		FSR	SCKR
1	0	0	0	0	SCKR	HCKR		
1	0	0	0	1	SCKR	HCKR		
1	0	0	1	0	SCKR	HCKR		
1	0	0	1	1	SCKR	HCKR		
1	0	1	0	0	Fsys[1]	HCKR		SCKR
1	0	1	0	1	Fsys	HCKR		SCKR
1	0	1	1	0	EXTAL[2]	HCKR		SCKR

Table 19-1. Receiver Clock Sources (Asynchronous Mode Only) (Continued)

RHCKD	RFSD	RCKD	ERI	ERO	Receiver Bit Clock Source	Outputs		
1	0	1	1	1	EXTAL	HCKR		SCKR
1	1	0	0	0	SCKR	HCKR	FSR	
1	1	0	0	1	SCKR	HCKR	FSR	
1	1	0	1	0	SCKR	HCKR	FSR	
1	1	0	1	1	SCKR	HCKR	FSR	
1	1	1	0	0	Fsys	HCKR	FSR	SCKR
1	1	1	0	1	Fsys	HCKR	FSR	SCKR
1	1	1	1	0	EXTAL	HCKR	FSR	SCKR
1	1	1	1	1	EXTAL	HCKR	FSR	SCKR

Note:
1. Fsys = 133MHz for i.MX35.
2. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock. It is the 24.576MHz EXTAL_AUDIO clock in i.MX35 system.

19.2.8 Transmitter Serial Clock (SCKT)

SCKT is a bidirectional pin providing the transmitters serial bit clock for the ESAI interface. The direction of this pin is determined by the TCKD bit in the TCCR register. The SCKT is a clock input or output used by all the enabled transmitters in the asynchronous mode (SYN=0) or by all the enabled transmitters and receivers in the synchronous mode (SYN=1).

Table 19-2 provides a list of asynchronous-mode transmitter clock sources.

Table 19-2. Transmitter Clock Sources (Asynchronous Mode Only)

THCKD	TFSD	TCKD	ETI	ETO	Transmitter Bit Clock Source	Outputs		
0	0	0	N/A	N/A	SCKT			
0	0	1	N/A	N/A	HCKT			SCKT
0	1	0	N/A	N/A	SCKT		FST	
0	1	1	N/A	N/A	HCKT		FST	SCKT
1	0	0	0	0	SCKT	HCKT		
1	0	0	0	1	SCKT	HCKT		
1	0	0	1	0	SCKT	HCKT		
1	0	0	1	1	SCKT	HCKT		
1	0	1	0	0	Fsys[1]	HCKT		SCKT

Table 19-2. Transmitter Clock Sources (Asynchronous Mode Only) (Continued)

THCKD	TFSD	TCKD	ETI	ETO	Transmitter Bit Clock Source	Outputs		
1	0	1	0	1	Fsys	HCKT		SCKT
1	0	1	1	0	EXTAL[2]	HCKT		SCKT
1	0	1	1	1	EXTAL	HCKT		SCKT
1	1	0	0	0	SCKR	HCKT	FST	
1	1	0	0	1	SCKR	HCKT	FST	
1	1	0	1	0	SCKR	HCKT	FST	
1	1	0	1	1	SCKR	HCKT	FST	
1	1	1	0	0	Fsys	HCKT	FST	SCKT
1	1	1	0	1	Fsys	HCKT	FST	SCKT
1	1	1	1	0	EXTAL	HCKT	FST	SCKT
1	1	1	1	1	EXTAL	HCKT	FST	SCKT

Note:
1. Fsys = 133MHz for i.MX35.
2. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock. It is the 24.576MHz EXTAL_AUDIO clock in i.MX35 system.

SCKT may be programmed as a disconnected pin (PC3) when the ESAI SCKT function is not being used. (See Table 19-38.)

For more information about EXTAL/ESAI clocking control bits (ETI, ETO), see the Table 19-8."

NOTE

Although the external ESAI serial clock can be independent of and asynchronous to the internal 133 MHz ESAI system clock, the external ESAI serial clock frequency cannot exceed 133MHz/4 = 33.25MHz and each external ESAI serial clock phase must exceed the minimum of 2 x 1/133MHz = 15.04ns.

19.2.9 Frame Sync for Receiver (FSR)

FSR is a bidirectional pin providing the receivers frame sync signal for the ESAI interface. The direction of this pin is determined by the RFSD bit in RCR register. In the asynchronous mode (SYN=0), the FSR pin operates as the frame sync input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as either the serial flag 1 pin (TEBE=0), or as the transmitter external buffer enable control (TEBE=1, RFSD=1). For FSR pin mode definitions, see Table 19-30; for receiver clock signals, see Table 19-1.

When this pin is configured as serial flag pin, its direction is determined by the RFSD bit in the RCCR register. When configured as the output flag OF1, this pin reflects the value of the OF1 bit in the SAICR

register, and the data in the OF1 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF1, the data value at the pin is stored in the IF1 bit in the SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

FSR may be programmed as a disconnected pin (PC1) when the ESAI FSR function is not being used. (See Table 19-38.)

19.2.10 Frame Sync for Transmitter (FST)

FST is a bidirectional pin providing the frame sync for both the transmitters and receivers in the synchronous mode (SYN=1) and for the transmitters only in asynchronous mode (SYN=0) (see Table 19-2). The direction of this pin is determined by the TFSD bit in the TCR register. When configured as an output, this pin is the internally generated frame sync signal. When configured as an input, this pin receives an external frame sync signal for the transmitters (and the receivers in synchronous mode).

FST may be programmed as a disconnected pin (PC4) when the ESAI FST function is not being used. (See Table 19-38.)

19.2.11 High Frequency Clock for Transmitter (HCKT)

HCKT is a bidirectional pin providing the transmitters high frequency clock for the ESAI interface. The direction of this pin is determined by the THCKD bit in the TCCR register. In the asynchronous mode (SYN=0), the HCKT pin operates as the high frequency clock input or output used by all enabled transmitters. In the synchronous mode (SYN=1), it operates as the high frequency clock input or output used by all enabled transmitters and receivers. When programmed as input this pin is used as an alternative high frequency clock source to the ESAI transmitter rather than the ARM-core main clock. When programmed as output it can serve as a high frequency sample clock (to external DACs for example) or as an additional system clock (see Table 19-2).

HCKT may be programmed as a disconnected pin (PC5) when the ESAI HCKT function is not being used. (See Table 19-38.)

19.2.12 High Frequency Clock for Receiver (HCKR)

HCKR is a bidirectional pin providing the receivers high frequency clock for the ESAI interface. The direction of this pin is determined by the RHCKD bit in the RCCR register. In the asynchronous mode (SYN=0), the HCKR pin operates as the high frequency clock input or output used by all the enabled receivers. In the synchronous mode (SYN=1), it operates as the serial flag 2 pin. For HCKR pin mode definitions, see Table 19-31; for receiver clock signals, see Table 19-1.

When this pin is configured as serial flag pin, its direction is determined by the RHCKD bit in the RCCR register. When configured as the output flag OF2, this pin reflects the value of the OF2 bit in the SAICR register, and the data in the OF2 bit shows up at the pin synchronized to the frame sync being used by the transmitter and receiver sections. When configured as the input flag IF2, the data value at the pin is stored in the IF2 bit in the SAISR register, synchronized by the frame sync in normal mode or the slot in network mode.

HCKR may be programmed as a disconnected pin (PC2) when the ESAI HCKR function is not being used. (See Table 19-38.)

19.2.13 Serial I/O Flags

Three ESAI pins (FSR, SCKR and HCKR) are available as serial I/O flags when the ESAI is operating in the synchronous mode (SYN=1). Their operation is controlled by RCKD, RFSD, TEBE bits in the RCR, RCCR and SAICR registers.The output data bits (OF2, OF1 and OF0) and the input data bits (IF2, IF1 and IF0) are double buffered to/from the HCKR, FSR and SCKR pins. Double buffering the flags keeps them in sync with the TX and RX data lines.

Each flag can be separately programmed. Flag 0 (SCKR pin) direction is selected by RCKD, RCKD=1 for output and RCKD=0 for input. Flag 1 (FSR pin) is enabled when the pin is not configured as external transmitter buffer enable (TEBE=0) and its direction is selected by RFSD, RFSD=1 for output and RFSD=0 for input. Flag 2 (HCKR pin) direction is selected by RHCKD, RHCKD=1 for output and RHCKD=0 for input.

When programmed as input flags, the SCKR, FSR and HCKR logic values, respectively, are latched at the same time as the first bit of the receive data word is sampled. Because the input was latched, the signal on the input flag pin (SCKR, FSR or HCKR) can change without affecting the input flag until the first bit of the next receive data word. When the received data words are transferred to the receive data registers, the input flag latched values are then transferred to the IF0, IF1 and IF2 bits in the SAISR register, where they may be read by software.

When programmed as output flags, the SCKR, FSR and HCKR logic values are driven by the contents of the OF0, OF1 and OF2 bits in the SAICR register respectively, and they are driven when the transmit data registers are transferred to the transmit shift registers. The value on SCKR, FSR and HCKR is stable from the time the first bit of the transmit data word is transmitted until the first bit of the next transmit data word is transmitted. Software may change the OF0-OF2 values thus controlling the SCKR, FSR and HCKR pin values for each transmitted word. The normal sequence for setting output flags when transmitting data is as follows: wait for TDE (transmitter empty) to be set; first write the flags, and then write the transmit data to the transmit registers. OF0, OF1, and OF2 are double buffered so that the flag states appear on the pins when the transmit data is transferred to the transmit shift register, that is, the flags are synchronous with the data.

19.3 Memory Map and Register Definition

Section 19.3, “Memory Map and Register Definition” provides the detailed descriptions for all of the ESAI registers.

19.3.1 Memory Map

For the base address of a particular module instantiation, see the system memory map.Table 19-3 shows the ESAI memory map.

Table 19-3. ESAI Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (ETDR)	ESAI Transmit Data Register	W	0x0000_0000	19.3.3.1/19-18

19.3.2 Register Summary

Figure 19-2 shows the key to register tables and Table 19-4 shows the register figure conventions.

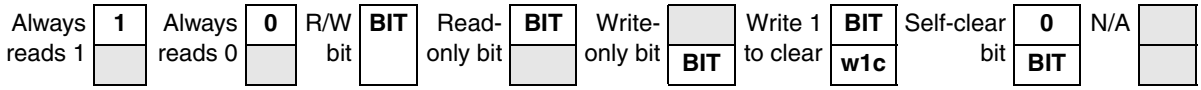

Figure 19-2. Key to Register Fields

Table 19-4. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 19-5 summarizes the ESAI registers.

19.3.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams in bit order.

19.3.3.1 ESAI Transmit Data Register (ETDR)

Offset 0x0000 (ETDR) Access: User write only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W	ETDR[31:16]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W	EDTR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 19-3. ESAI Transmit Data Register

Table 19-6. ESAI Transmit Data Register Field Descriptions

Field	Description
31–0 ETDR [31:0]	ESAI Transmit Data Register. Writing to this register stores the data written into the ESAI Transmit FIFO. Writing to this register when the Transmit FIFO is full causes the data written to be lost (the existing data within the FIFO is not overwritten). When multiple ESAI transmitters are enabled, the data for each transmitter must be interleaved from lowest transmitter to highest transmitter (for example, if transmitters 0, 2 and 3 are enabled then data must be written as follows: transmitter #0, transmitter #2, transmitter #3, transmitter #0, transmitter #2, transmitter #3, transmitter #0, ...). Data within the ESAI Transmit FIFO is passed to the ESAI transmit shifter registers as defined by the Transmit Word Alignment configuration bits.

19.3.3.2 ESAI Receive Data Register (ERDR)

Offset 0x0004 (ERDR) Access: User read only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ERDR[31:16]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ERDR[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 19-4. ESAI Receive Data Register

Table 19-7. ESAI Receive Data Register Field Descriptions

Field	Description
31–0 ERDR [31:0]	ESAI Receive Data Register. Reading this register returns the data within the ESAI Receive FIFO. Reading this register when the Receive FIFO is empty returns the last valid data word. When multiple ESAI receivers are enabled, the data for each receiver is interleaved from lowest receiver to highest receiver (for example, if receivers 0, 2 and 3 are enabled then data is returned as follows: receiver #0, receiver #2, receiver #3, receiver #0, receiver #2, receiver #3, receiver #0, and so on). Data is passed from the ESAI receive shift registers to the ESAI Receive FIFO as defined by the Receiver Word Alignment configuration bits either zero or sign-extended based on the Receive Extension control bit.

19.3.3.3 ESAI Control Register (ECR)

Offset 0x0008 (ECR) Access: User read/write only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	ETI	ETO	ERI	ERO
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	ERST	ESAI EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 19-5. ESAI Control Register

Table 19-8. ESAI Control Register Field Descriptions

Field	Description
31–20	Reserved
19 ETI	EXTAL Transmitter In. Mux EXTAL in place of the High Frequency Transmitter Clock input pin. HCKT can still be used to drive a divided down EXTAL or as GPIO. 0 HCKT pin has normal function. 1 EXTAL muxed into HCKT input.
18 ETO	EXTAL Transmitter Out. Drive the EXTAL input on the High Frequency Transmitter Clock pin. 0 HCKT pin has normal function. 1 EXTAL driven onto HCKT pin.
17 ERI	EXTAL Receiver In. Mux EXTAL in place of the High Frequency Receiver Clock input pin. HCKR can still be used to drive a divided down EXTAL or as GPIO. 0 HCKR pin has normal function. 1 EXTAL muxed into HCKR input.
16 ERO	EXTAL Receiver Out. Drive the EXTAL input on the High Frequency Receiver Clock pin. 0 HCKR pin has normal function. 1 EXTAL driven onto HCKR pin.
15–2	Reserved
1 ERST	ESAI Reset. Reset the ESAI core logic (including configuration registers) but not the ESAI FIFOs. 0 ESAI not reset. 1 ESAI reset.
0 ESAIEN	ESAI Enable. Enables/disables the ESAI logic clock. Enable the ESAI before reading or writing other ESAI registers. 0 ESAI disabled. 1 ESAI enabled.

19.3.3.4 ESAI Status Register (ESR)

Offset 0x000C (ESR) Access: User read only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 19-6. ESAI Status Register

Table 19-9. ESAI Status Register Field Descriptions

Field	Description
31–11	Reserved
10 TINIT	Transmit Initialization. Indicates that the Transmit FIFO is writing the first word for each enabled transmitter into the Transmit Data Registers. This bit sets when the Transmit FIFO is enabled (provided Transmit Initialization is enabled) and clears after the Transmit Data Registers have been initialized. The Transmit Enable bits in the Transmit Control Register should not be set until this flag has cleared. 0 Transmitter has finished initializing the Transmit Data Registers (or Transmit FIFO is not enabled or Transmit Initialization is not enabled). 1 Transmitter has not finished initializing the Transmit Data Registers.
9 RFF	Receive FIFO Full. Indicates that the number of data words in the Receive FIFO has equaled or exceeded the Receive FIFO Watermark. This flag also drives the ESAI Receiver DMA request line. ESAI FIFO DMA requests see Section 19.4.3, “ESAI DMA Requests from the FIFOs”. 0 Number of words in Receive FIFO less than Receive FIFO watermark. 1 Number of words in Receive FIFO is equal to or greater than Receive FIFO watermark.
8 TFE	Transmit FIFO Empty. Indicates that the number of empty slots in the Transmit FIFO has met or exceeded the Transmit FIFO Watermark. This flag also drives the ESAI Transmitter DMA request line. ESAI FIFO DMA request see Section 19.4.3, “ESAI DMA Requests from the FIFOs”. 0 Number of empty slots in Transmit FIFO less than Transmit FIFO watermark. 1 Number of empty slots in Transmit FIFO is equal to or greater than Transmit FIFO watermark.
7 TLS	Transmit Last Slot. Reading this register when TLS is set will negate the Transmit Last Slot interrupt. 0 TLS is not the highest priority active interrupt. 1 TLS is the highest priority active interrupt.
6 TDE	Transmit Data Exception. 0 TDE is not the highest priority active interrupt. 1 TDE is the highest priority active interrupt.
5 TED	Transmit Even Data. 0 TED is not the highest priority active interrupt. 1 TED is the highest priority active interrupt.

Table 19-9. ESAI Status Register Field Descriptions (Continued)

Field	Description
4 TD	Transmit Data. 0 TD is not the highest priority active interrupt. 1 TD is the highest priority active interrupt.
3 RLS	Receive Last Slot. Reading this register when RLS is set will negate the Receive Last Slot interrupt. 0 RLS is not the highest priority active interrupt. 1 RLS is the highest priority active interrupt.
2 RDE	Receive Data Exception. 0 RDE is not the highest priority active interrupt. 1 RDE is the highest priority active interrupt.
1 RED	Receive Even Data. 0 RED is not the highest priority active interrupt. 1 RED is the highest priority active interrupt.
0 RD	Receive Data. 0 RD is not the highest priority active interrupt. 1 RD is the highest priority active interrupt.

19.3.3.5 Transmit FIFO Configuration Register (TFCR)

Offset 0x0010 (TFCR) Access: User read/write only

R	TFWM[7:0]								TE5	TE4	TE3	TE2	TE1	TE0	TFR	TFEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 19-7. Transmit FIFO Configuration Register

Table 19-10. Transmit FIFO Configuration Register Field Descriptions

Field	Description
31–20	Reserved
19 TIEN	Transmitter Initialization Enable. Enables the initialization of the Transmit Data Registers when the Transmitter FIFO is enabled. 0 Transmit Data Registers are not initialized from the FIFO once the Transmit FIFO is enabled. Software must manually initialize the Transmit Data Registers separately. 1 Transmit Data Registers are initialized from the FIFO once the Transmit FIFO is enabled.

Table 19-10. Transmit FIFO Configuration Register Field Descriptions (Continued)

Field	Description
18–16 TWA [2:0]	Transmit Word Alignment. Configures the alignment of the data written into the ESAI Transmit Data Register and then passed to the relevant 24 bit Transmit shift register. 000 MSB of data is bit 31. Data bits 7–0 are ignored when passed to transmit shift register. 001 MSB of data is bit 27. Data bits 3–0 are ignored when passed to transmit shift register. 010 MSB of data is bit 23. 011 MSB of data is bit 19. Bottom 4 bits of transmit shift register are zeroed. 100 MSB of data is bit 15. Bottom 8 bits of transmit shift register are zeroed. 101 MSB of data is bit 11. Bottom 12 bits of transmit shift register are zeroed. 110 MSB of data is bit 7. Bottom 16 bits of transmit shift register are zeroed. 111 MSB of data is bit 3. Bottom 20 bits of transmit shift register are zeroed.
15–8 TFWM [7:0]	Transmit FIFO Watermark. These bits configure the threshold at which the Transmit FIFO Empty flag will set. The TFE is set when the number of empty slots in the Transmit FIFO equal or exceed the selected threshold.
7 TE5	Transmitter #5 FIFO Enable. This bit enables transmitter #5 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #5 is not using the Transmit FIFO. 1 Transmitter #5 is using the Transmit FIFO.
6 TE4	Transmitter #4 FIFO Enable. This bit enables transmitter #4 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #4 is not using the Transmit FIFO. 1 Transmitter #4 is using the Transmit FIFO.
5 TE3	Transmitter #3 FIFO Enable. This bit enables transmitter #3 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #3 is not using the Transmit FIFO. 1 Transmitter #3 is using the Transmit FIFO.
4 TE2	Transmitter #2 FIFO Enable. This bit enables transmitter #2 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #2 is not using the Transmit FIFO. 1 Transmitter #2 is using the Transmit FIFO.
3 TE1	Transmitter #1 FIFO Enable. This bit enables transmitter #1 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #1 is not using the Transmit FIFO. 1 Transmitter #1 is using the Transmit FIFO.
2 TE0	Transmitter #0 FIFO Enable. This bit enables transmitter #0 to use the Transmit FIFO. Do not change this bit when the Transmitter FIFO is enabled. 0 Transmitter #0 is not using the Transmit FIFO. 1 Transmitter #0 is using the Transmit FIFO.
1 TFR	Transmit FIFO Reset. This bit resets the Transmit FIFO pointers. 0 Transmit FIFO not reset. 1 Transmit FIFO reset.
0 TFE	Transmit FIFO Enable. This bit enables the use of the Transmit FIFO. 0 Transmit FIFO disabled. 1 Transmit FIFO enabled.

19.3.3.6 Transmit FIFO Status Register (TFSR)

Offset 0x0014 (TFSR) Access: User read only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 19-9. Receive FIFO Configuration Register

Table 19-12. Receive FIFO Configuration Register Field Descriptions

Field	Description
31–20	Reserved
19 REXT	Receive Extension. Enables the receive data to be returned sign extended when the Receive Word Alignment is configured to return data where the MSB is not aligned with bit 31. 0 Receive data is zero extended. 1 Receive data is sign extended.
18–16 RWA [2:0]	Receive Word Alignment. Configures the alignment of the data passed from the relevant 24 bit Receive shift register and read out the ESAI Receive Data Register. 000 MSB of data is at bit 31. Data bits 7–0 are zeroed. 001 MSB of data is at bit 27. Data bits 3–0 are zeroed. 010 MSB of data is at bit 23. 011 MSB of data is at bit 19. Data bits 3–0 from receive shift register are ignored. 100 MSB of data is at bit 15. Data bits 7–0 from receive shift register are ignored. 101 MSB of data is at bit 11. Data bits 11–0 from receive shift register are ignored. 110 MSB of data is at bit 7. Data bits 15–0 from receive shift register are ignored. 111 MSB of data is at bit 3. Data bits 19–0 from receive shift register are ignored.
15–8 RFWM [7:0]	Receive FIFO Watermark. These bits configure the threshold at which the Receive FIFO Full flag will set. The RFF is set when the number of words in the Receive FIFO equal or exceed the selected threshold. It can be set to a non-zero value.
7–6	Reserved
5 RE3	Receiver #3 FIFO Enable. This bit enables receiver #3 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #3 is not using the Receive FIFO. 1 Receiver #3 is using the Receive FIFO.
4 RE2	Receiver #2 FIFO Enable. This bit enables receiver #2 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #2 is not using the Receive FIFO. 1 Receiver #2 is using the Receive FIFO.

Table 19-12. Receive FIFO Configuration Register Field Descriptions (Continued)

Field	Description
3 RE1	Receiver #1 FIFO Enable. This bit enables receiver #1 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #1 is not using the Receive FIFO. 1 Receiver #1 is using the Receive FIFO.
2 RE0	Receiver #0 FIFO Enable. This bit enables receiver #0 to use the Receive FIFO. Do not change this bit when the Receiver FIFO is enabled. 0 Receiver #0 is not using the Receive FIFO. 1 Receiver #0 is using the Receive FIFO.
1 RFR	Receive FIFO Reset. This bit resets the Receive FIFO pointers. 0 Receive FIFO not reset. 1 Receive FIFO reset.
0 RFE	Receive FIFO Enable. This bit enables the use of the Receive FIFO. 0 Receive FIFO disabled. 1 Receive FIFO enabled.

Field	Description
9–8 NRFO [1:0]	Next Receiver FIFO Out. Indicates which receiver returns the top word of the Receive FIFO. 00 Receiver #0 returns next word from the Receive FIFO. 01 Receiver #1 returns next word from the Receive FIFO. 10 Receiver #2 returns next word from the Receive FIFO. 11 Receiver #3 returns next word from the Receive FIFO.
7–0 RFCNT [7:0]	Receive FIFO Counter. These bits indicate the number of data words stored in the Receive FIFO.

19.3.3.9 ESAI Transmit Data Registers (TX5, TX4, TX3, TX2,TX1,TX0)

TX5, TX4, TX3, TX2, TX1 and TX0 are 32-bit write-only registers. Data to be transmitted is written into these registers and is automatically transferred to the transmit shift registers (Figure 19-12 and Figure 19-13). The data written (8, 12, 16, 20, or 24 bits) should occupy the most significant portion of the TXx according to the ALC control bit setting. The unused bits (least significant portion and the 8 most significant bits when ALC=1) of the TXx are don't care bits. The Core is interrupted whenever the TXx becomes empty if the transmit data register empty interrupt has been enabled.

Offset 0x0080–0x0094 (TX0 - TX5) Access: User write only

Figure 19-11. ESAI Transmit Data Registers

Table 19-14. ESAI Transmit Data Registers

Field	Description
31-24	Reserved
23–0 TXx [23:0]	Stores the data to be transmitted and is automatically transferred to the transmit shift registers.

19.3.3.10 ESAI Transmit Shift Registers

The transmit shift registers contain the data being transmitted (Figure 19-12 and Figure 19-13). Data is shifted out to the serial transmit data pins by the selected (internal/external) bit clock when the associated

frame sync I/O is asserted. The number of bits shifted out before the shift registers are considered empty and may be written to again can be 8, 12, 16, 20, 24 or 32 bits (determined by the slot length control bits in the TCR register). Data is shifted out of these registers MSB first if TSHFD=0 and LSB first if TSHFD=1.

Figure 19-14. ESAI Transmit Slot Register

Table 19-15. ESAI Transmit Slot Register

Field	Description
31-24	Reserved
23–0 TSR [23:0]	The write-only Transmit Slot Register (TSR) is effectively a null data register that is used when the data is not to be transmitted in the available transmit time slot. The transmit data pins of all the enabled transmitters are in the high-impedance state for the respective time slot where TSR has been written. The Transmitter External Buffer Enable pin (FSR pin when SYN=1, TEBE=1, RFSD=1) disables the external buffers during the slot when the TSR register has been written.

19.3.3.12 ESAI Receive Data Registers (RX3, RX2, RX1, RX0)

RX3, RX2, RX1, and RX0 are 32-bit read-only registers that accept data from the receive shift registers when they become full (Figure 19-12 and Figure 19-13). The data occupies the most significant portion of the receive data registers, according to the ALC control bit setting. The unused bits (least significant portion and 8 most significant bits when ALC=1) read as zeros. The Core is interrupted whenever RXx becomes full if the associated interrupt is enabled.

Offset 0x00A0–0x00AC (RX0 - RX3) Access: User read only

Field	Description
31–24	Reserved
23-0 RXx [23:0]	Accept data from the receive shift registers when they become full

19.3.3.13 ESAI Receive Shift Registers

The receive shift registers (Figure 19-12 and Figure 19-13) receive the incoming data from the serial receive data pins. Data is shifted in by the selected (internal/external) bit clock when the associated frame sync I/O is asserted. Data is assumed to be received MSB first if RSHFD=0 and LSB first if RSHFD=1. Data is transferred to the ESAI receive data registers after 8, 12, 16, 20, 24, or 32 serial clock cycles were counted, depending on the slot length control bits in the RCR register.

19.3.3.14 ESAI Status Register (SAISR)

The Status Register (SAISR) is a read-only status register used by the ARM-Core to read the status and serial input flags of the ESAI. The status bits are described in the following paragraphs.

Offset 0x00CC (SAISR) Access: User read only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 19-16. ESAI Status Register

Table 19-17. ESAI Status Register Field Descriptions

Field	Description
31–18	Reserved.
17 TODFE	SAISR Transmit Odd-Data Register Empty. When set, TODFE indicates that the enabled transmitter data registers became empty at the beginning of an odd time slot. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TODFE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (TSR). TODE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TODFE is set. Hardware, software, ESAI individual reset clear TODFE.
16 TEDE	SAISR Transmit Even-Data Register Empty. When set, TEDE indicates that the enabled transmitter data registers became empty at the beginning of an even time slot. Even time slots are all even-numbered slots (0, 2, 4, 6, etc.). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. This flag is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TEDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (TSR). TEDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TEDE is set. Hardware, software, ESAI individual reset clear TEDE.
15 TDE	SAISR Transmit Data Register Empty. TDE is set when the contents of the transmit data register of all the enabled transmitters are transferred to the transmit shift registers; it is also set for a TSR disabled time slot period in network mode (as if data were being transmitted after the TSR was written). When set, TDE indicates that data should be written to all the TX registers of the enabled transmitters or to the transmit slot register (TSR). TDE is cleared when the Core writes to all the transmit data registers of the enabled transmitters, or when the Core writes to the TSR to disable transmission of the next time slot. If TIE is set, an ESAI transmit data interrupt request is issued when TDE is set. Hardware, software, ESAI individual reset clear TDE.

Table 19-17. ESAI Status Register Field Descriptions (Continued)

Field	Description
14 TUE	SAISR Transmit Underrun Error Flag. TUE is set when at least one of the enabled serial transmit shift registers is empty (no new data to be transmitted) and a transmit time slot occurs. When a transmit underrun error occurs, the previous data (which is still present in the TX registers that were not written) is retransmitted. If TEIE is set, an ESAI transmit data with exception (underrun error) interrupt request is issued when TUE is set. Hardware, software, ESAI individual reset clear TUE. TUE is also cleared by reading the SAISR with TUE set, followed by writing to all the enabled transmit data registers or to TSR.
13 TFS	SAISR Transmit Frame Sync Flag. When set, TFS indicates that a transmit frame sync occurred in the current time slot. TFS is set at the start of the first time slot in the frame and cleared during all other time slots. Data written to a transmit data register during the time slot when TFS is set is transmitted (in network mode), if the transmitter is enabled, during the second time slot in the frame. TFS is useful in network mode to identify the start of a frame. TFS is cleared by hardware, software, ESAI individual reset. TFS is valid only if at least one transmitter is enabled, that is, one or more of TE0, TE1, TE2, TE3, TE4 and TE5 are set. (In normal mode, TFS always reads as a one when transmitting data because there is only one time slot per frame – the “frame sync” time slot)
12-11	Reserved.
10 RODF	SAISR Receive Odd-Data Register Full. When set, RODF indicates that the received data in the receive data registers of the enabled receivers have arrived during an odd time slot when operating in the network mode. Odd time slots are all odd-numbered slots (1, 3, 5, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. RODF is set when the contents of the receive shift registers are transferred to the receive data registers. RODF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets.
9 REDF	SAISR Receive Even-Data Register Full. When set, REDF indicates that the received data in the receive data registers of the enabled receivers have arrived during an even time slot when operating in the network mode. Even time slots are all even-numbered slots (0, 2, 4, 6, and so on). Time slots are numbered from zero to N-1, where N is the number of time slots in the frame. The zero time slot is considered even. REDF is set when the contents of the receive shift registers are transferred to the receive data registers. REDF is cleared when the Core reads all the enabled receive data registers or cleared by hardware, software, ESAI individual resets. If REDIE is set, an ESAI receive even slot data interrupt request is issued when REDF is set.
8 RDF	SAISR Receive Data Register Full. RDF is set when the contents of the receive shift register of an enabled receiver is transferred to the respective receive data register. RDF is cleared when the Core reads the receive data register of all enabled receivers or cleared by hardware, software, ESAI individual reset. If RIE is set, an ESAI receive data interrupt request is issued when RDF is set.
7 ROE	SAISR Receive Overrun Error Flag. The ROE flag is set when the serial receive shift register of an enabled receiver is full and ready to transfer to its receiver data register (RXx) and the register is already full (RDF=1). If REIE is set, an ESAI receive data with exception (overrun error) interrupt request is issued when ROE is set. Hardware, software, ESAI individual reset clear ROE. ROE is also cleared by reading the SAISR with ROE set, followed by reading all the enabled receive data registers.
6 RFS	SAISR Receive Frame Sync Flag. When set, RFS indicates that a receive frame sync occurred during reception of the words in the receiver data registers. This indicates that the data words are from the first slot in the frame. When RFS is clear and a word is received, it indicates (only in the network mode) that the frame sync did not occur during reception of that word. RFS is cleared by hardware, software, ESAI individual reset. RFS is valid only if at least one of the receivers is enabled (REx=1). (In normal mode, RFS always reads as a one when reading data because there is only one time slot per frame – the “frame sync” time slot)
5-3	Reserved.

Table 19-17. ESAI Status Register Field Descriptions (Continued)

Field	Description
2 IF2	SAISR Serial Input Flag 2. The IF2 bit is enabled only when the HCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RHCKD=0, indicating that HCKR is an input flag and the synchronous mode is selected. Data present on the HCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF2 bit is updated with this data when the receive shift registers are transferred into the receiver data registers. IF2 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF2.
IF1	SAISR Serial Input Flag 1. The IF1 bit is enabled only when the FSR pin is defined as ESAI in the Port Control Register, SYN =1, RFSD=0 and TEBE=0, indicating that FSR is an input flag and the synchronous mode is selected. Data present on the FSR pin is latched during reception of the first received data bit after frame sync is detected. The IF1 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF1 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF1.
IF0	SAISR Serial Input Flag 0. The IF0 bit is enabled only when the SCKR pin is defined as ESAI in the Port Control Register, SYN=1 and RCKD=0, indicating that SCKR is an input flag and the synchronous mode is selected. Data present on the SCKR pin is latched during reception of the first received data bit after frame sync is detected. The IF0 bit is updated with this data when the receiver shift registers are transferred into the receiver data registers. IF0 reads as a zero when it is not enabled. Hardware, software, ESAI individual reset clear IF0.

19.3.3.15 ESAI Common Control Register (SAICR)

The read/write Common Control Register (SAICR) contains control bits for functions that affect both the receive and transmit sections of the ESAI.

Offset 0x00D0 (SAICR) Access: User read/write only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 19-17. Receive Common Control Register

Table 19-18. Common Control Register Field Descriptions

Field	Description
31–9	Reserved
8 ALC	SAICR Alignment Control. The ESAI is designed for 24-bit fractional data, thus shorter data words are left aligned to the MSB (bit 23). Some applications use 16-bit fractional data. In those cases, shorter data words may be left aligned to bit 15. The Alignment Control (ALC) bit supports these applications. If ALC is set, transmitted and received words are left aligned to bit 15 in the transmit and receive shift registers. If ALC is cleared, transmitted and received word are left aligned to bit 23 in the transmit and receive shift registers. While ALC is set, 20-bit and 24-bit words may not be used, and word length control should specify 8-, 12-, or 16-bit words; otherwise, results are unpredictable.
7 TEBE	SAICR Transmit External Buffer Enable. The Transmitter External Buffer Enable (TEBE) bit controls the function of the FSR pin when in the synchronous mode. If the ESAI is configured for operation in the synchronous mode (SYN=1), and TEBE is set while FSR pin is configured as an output (RFSD=1), the FSR pin functions as the transmitter external buffer enable control to enable the use of an external buffers on the transmitter outputs. If TEBE is cleared, the FSR pin functions as the serial I/O flag 1. See Table 19-30 for a summary of the effects of TEBE on the FSR pin.
6 SYNC	SAICR Synchronous Mode Selection. The Synchronous Mode Selection (SYN) bit controls whether the receiver and transmitter sections of the ESAI operate synchronously or asynchronously with respect to each other (see Figure 19-18). When SYN is cleared, the asynchronous mode is chosen and independent clock and frame sync signals are used for the transmit and receive sections. When SYN is set, the synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals. When in the synchronous mode (SYN=1), the transmit and receive sections use the transmitter section clock generator as the source of the clock and frame sync for both sections. Also, the receiver clock pins SCKR, FSR and HCKR now operate as I/O flags. See Table 19-29, Table 19-30, and Table 19-31 for the effects of SYN on the receiver clock pins.
5-3	Reserved.
2 OF2	SAICR Serial Output Flag 2. The Serial Output Flag 2 (OF2) is a data bit used to hold data to be send to the OF2 pin. When the ESAI is in the synchronous clock mode (SYN=1), the HCKR pin is configured as the ESAI flag 2. If the receiver high frequency clock direction bit (RHCKD) is set, the HCKR pin is the output flag OF2, and data present in the OF2 bit is written to the OF2 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
1 OF1	SAICR Serial Output Flag 1. The Serial Output Flag 1 (OF1) is a data bit used to hold data to be send to the OF1 pin. When the ESAI is in the synchronous clock mode (SYN=1), the FSR pin is configured as the ESAI flag 1. If the receiver frame sync direction bit (RFSD) is set and the TEBE bit is cleared, the FSR pin is the output flag OF1, and data present in the OF1 bit is written to the OF1 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.
0 OF0	SAICR Serial Output Flag 0. The Serial Output Flag 0 (OF0) is a data bit used to hold data to be send to the OF0 pin. When the ESAI is in the synchronous clock mode (SYN=1), the SCKR pin is configured as the ESAI flag 0. If the receiver serial clock direction bit (RCKD) is set, the SCKR pin is the output flag OF0, and data present in the OF0 bit is written to the OF0 pin at the beginning of the frame in normal mode or at the beginning of the next time slot in network mode.

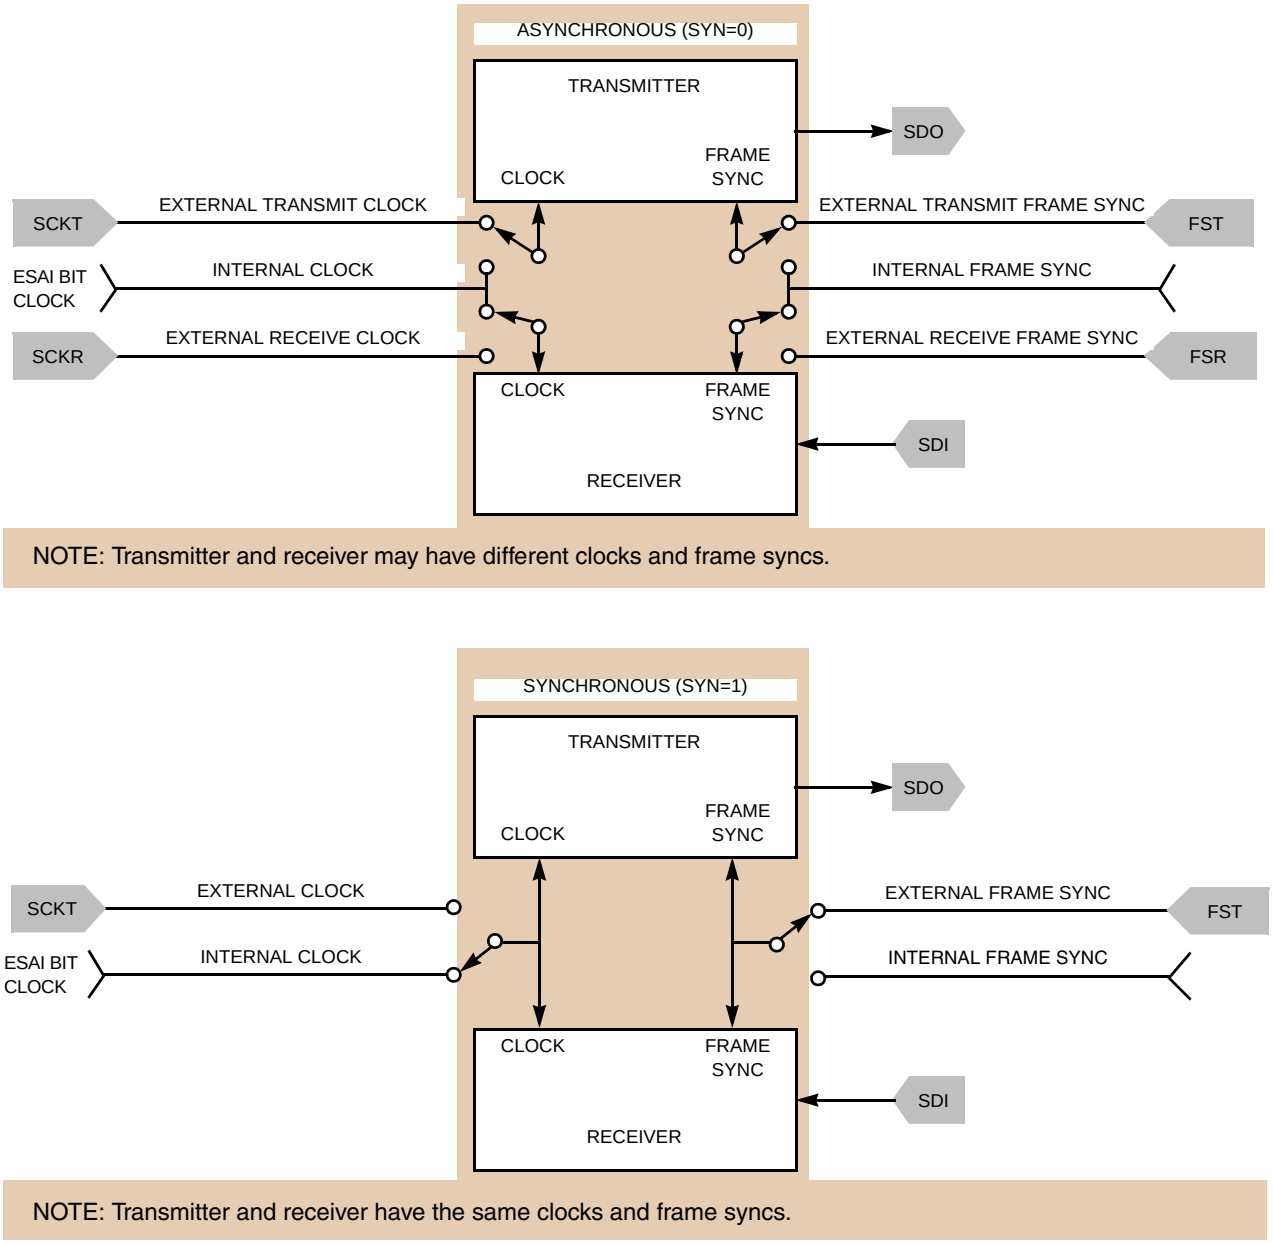

Figure 19-18. SAICR SYN Bit Operation

19.3.3.16 ESAI Transmit Control Register (TCR)

The read/write Transmit Control Register (TCR) controls the ESAI transmitter section. Interrupt enable bits for the transmitter section are provided in this control register. Operating modes are also selected in this register.

Offset 0x00D4 (TCR) Access: User read/write only

Figure 19-19. ESAI Transmit Control Register

Table 19-19. ESAI Transmit Control Register Field Descriptions

Field	Description
31-24	Reserved.
23 TLIE	TCR Transmit Last Slot Interrupt Enable. TLIE enables an interrupt at the beginning of last slot of a frame in network mode. When TLIE is set the Core is interrupted at the start of the last slot in a frame in network mode regardless of the transmit mask register setting. When TLIE is cleared the transmit last slot interrupt is disabled. TLIE is disabled when TDC[4:0]=0x00000 (on-demand mode). The use of the transmit last slot interrupt is described in Section 19.4.2, “ESAI Interrupt Requests”.
22 TIE	TCR Transmit Interrupt Enable. The Core is interrupted when TIE and the TDE flag in the SAISR status register are set. When TIE is cleared, this interrupt is disabled. Writing data to all the data registers of the enabled transmitters or to TSR clears TDE, thus clearing the interrupt. Transmit interrupts with exception have higher priority than normal transmit data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
21 TEDIE	TCR Transmit Even Slot Data Interrupt Enable. The TEDIE control bit is used to enable the transmit even slot data interrupts. If TEDIE is set, the transmit even slot data interrupts are enabled. If TEDIE is cleared, the transmit even slot data interrupts are disabled. A transmit even slot data interrupt request is generated if TEDIE is set and the TEDE status flag in the SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot in the frame is marked by the frame sync signal and is considered to be even. Writing data to all the data registers of the enabled transmitters or to TSR clears the TEDE flag, thus servicing the interrupt. Transmit interrupts with exception have higher priority than transmit even slot data interrupts, therefore if exception occurs (TUE is set) and TEIE is set, the ESAI requests an ESAI transmit data with exception interrupt from the interrupt controller.
20 TEIE	TCR Transmit Exception Interrupt Enable. When TEIE is set, the Core is interrupted when both TDE and TUE in the SAISR status register are set. When TEIE is cleared, this interrupt is disabled. Reading the SAISR status register followed by writing to all the data registers of the enabled transmitters clears TUE, thus clearing the pending interrupt.

Table 19-19. ESAI Transmit Control Register Field Descriptions (Continued)

Field	Description
19 TPR	TCR Transmit Section Personal Reset. The TPR control bit is used to put the transmitter section of the ESAI in the personal reset state. The receiver section is not affected. When TPR is cleared, the transmitter section may operate normally. When TPR is set, the transmitter section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset. The control bits are not affected by the personal reset state. The transmitter data pins are tristated while in the personal reset state; if a stable logic level is desired, the transmitter data pins should be defined as GPIO outputs, or external pull-up or pull-down resistors should be used. The transmitter clock outputs drive zeroes while in the personal reset state. Note that to leave the personal reset state by clearing TPR, the procedure described in Section 19.5.2, "ESAI Initialization Examples" should be followed.
18	Reserved.
17 PADC	TCR Transmit Zero Padding Control. When PADC is cleared, zero padding is disabled. When PADC is set, zero padding is enabled. PADC, in conjunction with the TWA control bit, determines the way that padding is done for operating modes where the word length is less than the slot length. See the TWA bit description in bit 7 for more details. Since the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: 1. If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted. 2. If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
16 TFSR	TCR Transmit Frame Sync Relative Timing. TFSR determines the relative timing of the transmit frame sync signal as referred to the serial data lines, for a word length frame sync only (TFSL=0). When TFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When TFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 TFSL	TCR Transmit Frame Sync Length. The TFSL bit selects the length of frame sync to be generated or recognized. If TFSL is cleared, a word-length frame sync is selected. If TFSL is set, a 1-bit clock period frame sync is selected. See Figure 19-21 for examples of frame length selection.
14-10 TSWS [14:10]	TCR Tx Slot and Word Length Select (TSWS4-TSWS0). The TSWS4–TSWS0 bits are used to select the length of the slot and the length of the data words being transferred via the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 19-21. See also the ESAI data path programming model in Figure 19-12 and Figure 19-13.
9-8 TMOD [9:8]	TCR Transmit Network Mode Control (TMOD1-TMOD0). The TMOD1 and TMOD0 bits are used to define the network mode of ESAI transmitters, as shown in Table 19-20. In the normal mode, the frame rate divider determines the word transfer rate – one word is transferred per frame sync during the frame sync time slot, as shown in Figure 19-20. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 19-20. For further details, see Section 19.1.2, "Modes of Operation." In order to be compatible with AC-97 specifications, TSWS4-TSWS0 should be set to 00011 (20-bit slot, 20-bit word length), TFSL and TFSR should be cleared, and TDC4-TDC0 should be set to 0x0C (13 words in frame). If TMOD[1:0]=0x11 and the above recommendations are followed, the first slot and word will be 16 bits long, and the next 12 slots and words will be 20 bits long, as required by the AC97 protocol.

Table 19-19. ESAI Transmit Control Register Field Descriptions (Continued)

Field	Description
7 TWA	TCR Transmit Word Alignment Control. The Transmitter Word Alignment Control (TWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If TWA is cleared, the data word is left-aligned in the slot frame during transmission. If TWA is set, the data word is right-aligned in the slot frame during transmission. Since the data word is shorter than the slot length, the data word is extended until achieving the slot length, according to the following rule: 1. If the data word is left-aligned (TWA=0), and zero padding is disabled (PADC=0), the last data bit is repeated after the data word has been transmitted. If zero padding is enabled (PADC=1), zeroes are transmitted after the data word has been transmitted. 2. If the data word is right-aligned (TWA=1), and zero padding is disabled (PADC=0), the first data bit is repeated before the transmission of the data word. If zero padding is enabled (PADC=1), zeroes are transmitted before the transmission of the data word.
6 TSHFD	TCR Transmit Shift Direction. The TSHFD bit causes the transmit shift registers to shift data out MSB first when TSHFD equals zero or LSB first when TSHFD equals one (see Figure 19-12 and Figure 19-13.).
5 TE5	TCR ESAI Transmit 5 Enable. TE5 enables the transfer of data from TX5 to the transmit shift register #5. When TE5 is set and a frame sync is detected, the transmit #5 portion of the ESAI is enabled for that frame. When TE5 is cleared, the transmitter #5 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to TX5 when TE5 is cleared but the data is not transferred to the transmit shift register #5. The SDO5/SDI0 pin is the data input pin for RX0 if TE5 is cleared and RE0 in the RCR register is set. If both RE0 and TE5 are cleared, the transmitter and receiver are disabled, and the pin is tristated. Both RE0 and TE5 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE5 and setting it again disables the transmitter #5 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO5/SDI0 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE5 can be left enabled.
4 TE4	TCR ESAI Transmit 4 Enable. TE4 enables the transfer of data from TX4 to the transmit shift register #4. When TE4 is set and a frame sync is detected, the transmit #4 portion of the ESAI is enabled for that frame. When TE4 is cleared, the transmitter #4 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to TX4 when TE4 is cleared but the data is not transferred to the transmit shift register #4. The SDO4/SDI1 pin is the data input pin for RX1 if TE4 is cleared and RE1 in the RCR register is set. If both RE1 and TE4 are cleared, the transmitter and receiver are disabled, and the pin is tristated. Both RE1 and TE4 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE4 and setting it again disables the transmitter #4 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO4/SDI1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE4 can be left enabled.

Table 19-19. ESAI Transmit Control Register Field Descriptions (Continued)

Field	Description
3 TE3	TCR ESAI Transmit 3 Enable. TE3 enables the transfer of data from TX3 to the transmit shift register #3. When TE3 is set and a frame sync is detected, the transmit #3 portion of the ESAI is enabled for that frame. When TE3 is cleared, the transmitter #3 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to TX3 when TE3 is cleared but the data is not transferred to the transmit shift register #3. The SDO3/SDI2 pin is the data input pin for RX2 if TE3 is cleared and RE2 in the RCR register is set. If both RE2 and TE3 are cleared, the transmitter and receiver are disabled, and the pin is tristated. Both RE2 and TE3 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE3 and setting it again disables the transmitter #3 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO3/SDI2 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE3 can be left enabled.
2 TE2	TCR ESAI Transmit 2 Enable. TE2 enables the transfer of data from TX2 to the transmit shift register #2. When TE2 is set and a frame sync is detected, the transmit #2 portion of the ESAI is enabled for that frame. When TE2 is cleared, the transmitter #2 is disabled after completing transmission of data currently in the ESAI transmit shift register. Data can be written to TX2 when TE2 is cleared but the data is not transferred to the transmit shift register #2. The SDO2/SDI3 pin is the data input pin for RX3 if TE2 is cleared and RE3 in the RCR register is set. If both RE3 and TE2 are cleared, the transmitter and receiver are disabled, and the pin is tristated. Both RE3 and TE2 should not be set at the same time. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE2 and setting it again disables the transmitter #2 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO2/SDI3 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE2 can be left enabled.
1 TE1	TCR ESAI Transmit 1 Enable. TE1 enables the transfer of data from TX1 to the transmit shift register #1. When TE1 is set and a frame sync is detected, the transmit #1 portion of the ESAI is enabled for that frame. When TE1 is cleared, the transmitter #1 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO1 output is tristated, and any data present in TX1 is not transmitted, that is, data can be written to TX1 with TE1 cleared, but data is not transferred to the transmit shift register #1. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE1 and setting it again disables the transmitter #1 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO1 pin remains in the high-impedance state. The on-demand mode transmit enable sequence can be the same as the normal mode, or TE1 can be left enabled.
0 TE0	TCR ESAI Transmit 0 Enable. TE0 enables the transfer of data from TX0 to the transmit shift register #0. When TE0 is set and a frame sync is detected, the transmit #0 portion of the ESAI is enabled for that frame. When TE0 is cleared, the transmitter #0 is disabled after completing transmission of data currently in the ESAI transmit shift register. The SDO0 output is tristated, and any data present in TX0 is not transmitted, that is, data can be written to TX0 with TE0 cleared, but data is not transferred to the transmit shift register #0. The normal mode transmit enable sequence is to write data to one or more transmit data registers before setting TEx. The normal transmit disable sequence is to clear TEx, TIE and TEIE after TDE equals one. In the network mode, the operation of clearing TE0 and setting it again disables the transmitter #0 after completing transmission of the current data word until the beginning of the next frame. During that time period, the SDO0 pin remains in the high-impedance state.The on-demand mode transmit enable sequence can be the same as the normal mode, or TE0 can be left enabled.

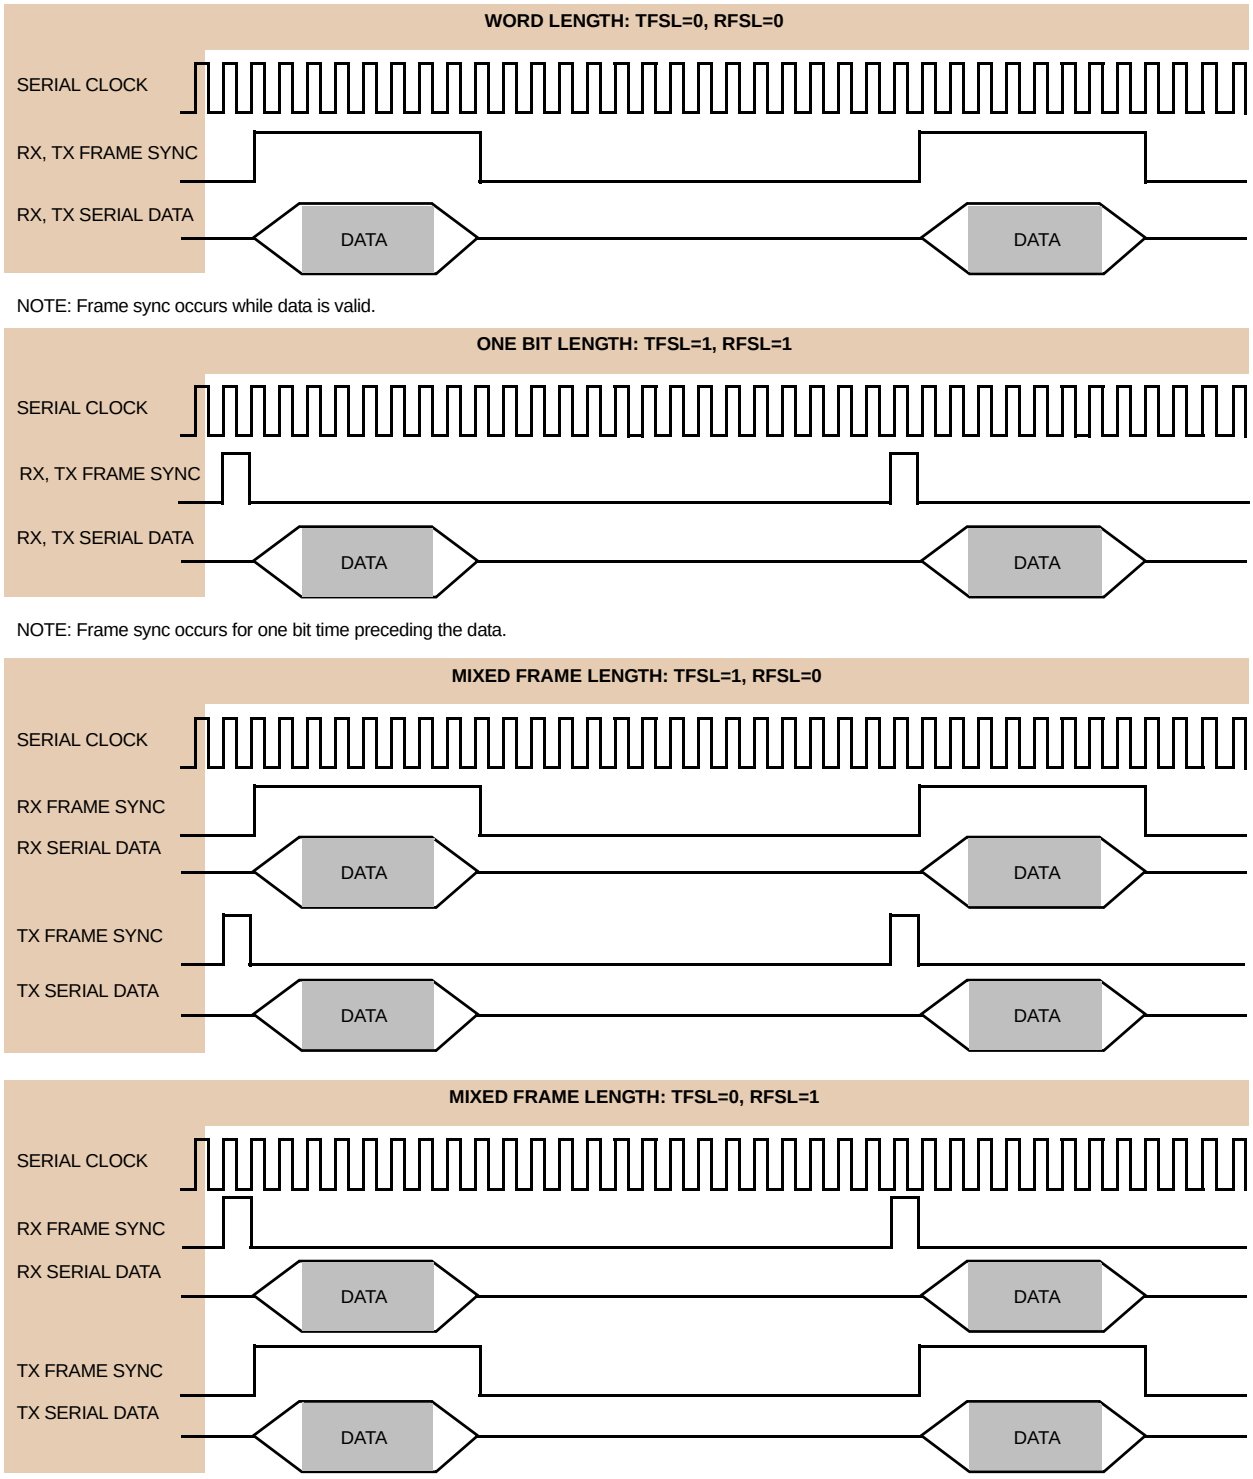

Figure 19-21. Frame Length Selection

19.3.3.17 ESAI Transmitter Clock Control Register (TCCR)

The read/write Transmitter Clock Control Register (TCCR) controls the ESAI transmitter clock generator bit and frame sync rates, the bit clock and high frequency clock sources and the directions of the HCKT, FST and SCKT signals. In the synchronous mode (SYN=1), the bit clock defined for the transmitter determines the receiver bit clock as well. TCCR also controls the number of words per frame for the serial data. Hardware and software reset clear all the bits of the TCCR register. Figure 19-22 shows the register. (Care should be taken in asynchronous mode whenever the frame sync clock (FSR, FST) is not sourced directly from its associated bit clock (SCKR,SCKT). Proper phase relationships must be maintained between these clocks in order to guarantee proper operation of the ESAI)

Offset 0x00D8 (TCCR) Access: User read/write only

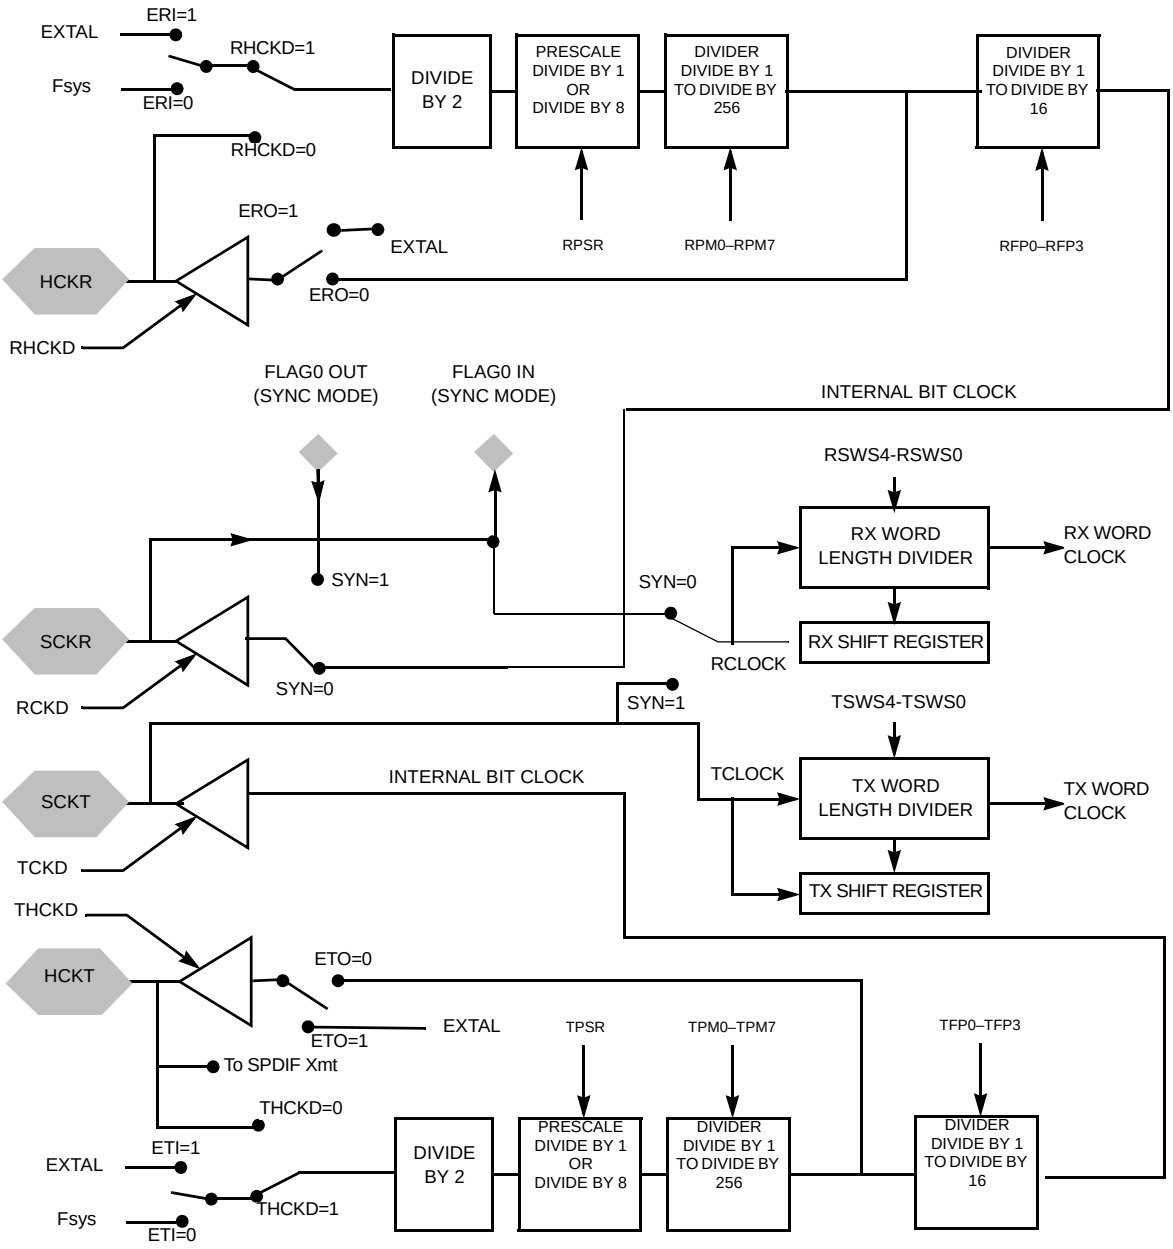
Figure 19-22. ESAI Transmitter Clock Control Register

Table 19-22. ESAI Transmitter Clock Control Register Field Descriptions

Field	Description
31-24	Reserved.
23 THCKD	TCCR Transmit High Frequency Clock Direction. THCKD controls the direction of the HCKT pin. When THCKD is cleared, HCKT is an input; when THCKD is set, HCKT is an output (see Table 19-2.).
22 TFSD	TCCR Transmit Frame Sync Signal Direction. TFSD controls the direction of the FST pin. When TFSD is cleared, FST is an input; when TFSD is set, FST is an output (see Table 19-2.).
21 TCKD	TCCR Transmit Clock Source Direction. The Transmitter Clock Source Direction (TCKD) bit selects the source of the clock signal used to clock the transmit shift registers in the asynchronous mode (SYN=0) and the transmit shift registers and the receive shift registers in the synchronous mode (SYN=1). When TCKD is set, the internal clock source becomes the bit clock for the transmit shift registers and word length divider and is the output on the SCKT pin. When TCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKT pin, and an external clock source may drive this pin (see Table 19-2.).
20 THCKP	TCCR Transmit High Frequency Clock Polarity. The Transmitter High Frequency Clock Polarity (THCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If THCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit high frequency bit clock and latched in on the falling edge of the transmit bit clock. If THCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.

Table 19-22. ESAI Transmitter Clock Control Register Field Descriptions (Continued)

Field	Description
19 TFSP	TCCR Transmit Frame Sync Polarity. The Transmitter Frame Sync Polarity (TFSP) bit determines the polarity of the transmit frame sync signal. When TFSP is cleared, the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When TFSP is set, the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 TCKP	TCCR Transmit Clock Polarity. The Transmitter Clock Polarity (TCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If TCKP is cleared the data and the frame sync are clocked out on the rising edge of the transmit bit clock and latched in on the falling edge of the transmit bit clock. If TCKP is set the falling edge of the transmit clock is used to clock the data out and frame sync and the rising edge of the transmit clock is used to latch the data and frame sync in.
17-14 TFP [3:0]	TCCR Tx High Frequency Clock Divider. The TFP3–TFP0 bits control the divide ratio of the transmitter high frequency clock to the transmitter serial bit clock when the source of the high frequency clock and the bit clock is the internal ARM-core clock. When the HCKT input is being driven from an external high frequency clock, the TFP3-TFP0 bits specify an additional division ratio in the clock divider chain. Table 19-23 shows the specification for the divide ratio. Figure 19-23 shows the ESAI high frequency clock generator functional diagram.
13-9 TDC [4:0]	TCCR Tx Frame Rate Divider Control. The TDC4–TDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the transmitter frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (TDC[4:0]=00001 to 11111) for network mode. A divide ratio of one (TDC[4:0]=00000) in network mode is a special case (on-demand mode). In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (TDC[4:0]=00000 to 11111) for normal mode. In normal mode, a divide ratio of 1 (TDC[4:0]=00000) provides continuous periodic data word transfers. A bit-length frame sync (TFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 19-24.
8 TPSR	TCCR Transmit Prescaler Range. The TPSR bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When TPSR is set, the fixed prescaler is bypassed. When TPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 19-23). The maximum internally generated bit clock frequency is Fsys/4; the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256)=Fsys/4096. (Do not use the combination TPSR=1, TPM7–TPM0=0x00, and TFP3–TFP0=0x0 which causes synchronization problems when using the internal ARM-core clock as source (TCKD=1 or THCKD=1))
7-0 TPM [7:0]	TCCR Transmit Prescale Modulus Select. The TPM7–TPM0 bits specify the divide ratio of the prescale divider in the ESAI transmitter clock generator. A divide ratio from 1 to 256 (TPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the transmit serial bit clock (SCKT) pin. The bit clock output is also available internally for use as the bit clock to shift the transmit and receive shift registers. The ESAI transmit clock generator functional diagram is shown in Figure 19-23.



Notes:
1. ETI, ETO, ERI and ERO bit descriptions are covered in Table 19-8."
2. Fsys is the ESAI system 133 MHz clock.
3. EXTAL is the on-chip clock sources other than ESAI system 133MHz clock. In i.MX35 it is connected to the EXTAL_AUDIO clock.

19.3.3.18 ESAI Receive Control Register (RCR)

The read/write Receive Control Register (RCR) controls the ESAI receiver section. Interrupt enable bits for the receivers are provided in this control register. The receivers are enabled in this register (0,1,2 or 3 receivers can be enabled) if the input data pin is not used by a transmitter. Operating modes are also selected in this register.

Offset 0x00DC (RCR) Access: User read/write only

Figure 19-25. ESAI Receive Control Register

Table 19-24. ESAI Receive Control Register Field Descriptions

Field	Description
31-24	Reserved.
23 RLIE	RCR Receive Last Slot Interrupt Enable. RLIE enables an interrupt after the last slot of a frame ended in network mode only. When RLIE is set the Core is interrupted after the last slot in a frame ended regardless of the receive mask register setting. When RLIE is cleared the receive last slot interrupt is disabled. Hardware and software reset clear RLIE. RLIE is disabled when RDC[4:0]=00000 (on-demand mode). The use of the receive last slot interrupt is described in Section 19.4.2, “ESAI Interrupt Requests”
22 RIE	RCR Receive Interrupt Enable. The Core is interrupted when RIE and the RDF flag in the SAISR status register are set. When RIE is cleared, this interrupt is disabled. Reading the receive data registers of the enabled receivers clears RDF, thus clearing the interrupt. Receive interrupts with exception have higher priority than normal receive data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
21 REDIE	RCR Receive Even Slot Data Interrupt Enable. The REDIE control bit is used to enable the receive even slot data interrupts. If REDIE is set, the receive even slot data interrupts are enabled. If REDIE is cleared, the receive even slot data interrupts are disabled. A receive even slot data interrupt request is generated if REDIE is set and the REDF status flag in the SAISR status register is set. Even time slots are all even-numbered time slots (0, 2, 4, etc.) when operating in network mode. The zero time slot is marked by the frame sync signal and is considered to be even. Reading all the data registers of the enabled receivers clears the REDF flag, thus servicing the interrupt. Receive interrupts with exception have higher priority than receive even slot data interrupts, therefore if exception occurs (ROE is set) and REIE is set, the ESAI requests an ESAI receive data with exception interrupt from the interrupt controller.
20 REIE	RCR Receive Exception Interrupt Enable. When REIE is set, the Core is interrupted when both RDF and ROE in the SAISR status register are set. When REIE is cleared, this interrupt is disabled. Reading the SAISR status register followed by reading the enabled receivers data registers clears ROE, thus clearing the pending interrupt.
19 RPR	RCR Receiver Section Personal Reset. The RPR control bit is used to put the receiver section of the ESAI in the personal reset state. The transmitter section is not affected. When RPR is cleared, the receiver section may operate normally. When RPR is set, the receiver section enters the personal reset state immediately. When in the personal reset state, the status bits are reset to the same state as after hardware reset.The control bits are not affected by the personal reset state.The receiver data pins are disconnected while in the personal reset state. Note that to leave the personal reset state by clearing RPR, the procedure described in Section 19.5.2, “ESAI Initialization Examples” should be followed.

Table 19-24. ESAI Receive Control Register Field Descriptions (Continued)

Field	Description
18-17	Reserved.
16 RFSR	RCR Receiver Frame Sync Relative Timing. RFSR determines the relative timing of the receive frame sync signal as referred to the serial data lines, for a word length frame sync only. When RFSR is cleared the word length frame sync occurs together with the first bit of the data word of the first slot. When RFSR is set the word length frame sync starts one serial clock cycle earlier, that is, together with the last bit of the previous data word.
15 RFSL	RCR Receiver Frame Sync Length. The RFSL bit selects the length of the receive frame sync to be generated or recognized. If RFSL is cleared, a word-length frame sync is selected. If RFSL is set, a 1-bit clock period frame sync is selected. See Figure 19-21 for examples of frame length selection.
14-10 RSWS [4:0]	RCR Receiver Slot and Word Select. The RSWS4–RSWS0 bits are used to select the length of the slot and the length of the data words being received via the ESAI. The word length must be equal to or shorter than the slot length. The possible combinations are shown in Table 19-26. See also the ESAI data path programming model in Figure 19-12 and Figure 19-13.
9-8 RMOD [1:0]	RCR Receiver Network Mode Control. The RMOD1 and RMOD0 bits are used to define the network mode of the ESAI receivers, as shown in Table 19-25. In the normal mode, the frame rate divider determines the word transfer rate – one word is transferred per frame sync during the frame sync time slot, as shown in Figure 19-20. In network mode, it is possible to transfer a word for every time slot, as shown in Figure 19-20. For more details, see Section 19.1.2, “Modes of Operation.” In order to be compatible with AC–97 specifications, RSWS4–RSWS0 should be set to 00011 (20-bit slot, 20-bit word); RFSL and RFSR should be cleared, and RDC4–RDC0 should be set to 0x0C (13 words in frame).
7 RWA	RCR Receiver Word Alignment Control. The Receiver Word Alignment Control (RWA) bit defines the alignment of the data word in relation to the slot. This is relevant for the cases where the word length is shorter than the slot length. If RWA is cleared, the data word is assumed to be left-aligned in the slot frame. If RWA is set, the data word is assumed to be right-aligned in the slot frame. If the data word is shorter than the slot length, the data bits which are not in the data word field are ignored. For data word lengths of less than 24 bits, the data word is right-extended with zeroes before being stored in the receive data registers.
6 RSHFD	RCR Receiver Shift Direction. The RSHFD bit causes the receiver shift registers to shift data in MSB first when RSHFD is cleared or LSB first when RSHFD is set (see Figure 19-12 and Figure 19-13).
5-4	Reserved.
3 RE3	RCR ESAI Receiver 3 Enable. When RE3 is set and TE2 is cleared, the ESAI receiver 3 is enabled and samples data at the SDO2/SDI3 pin. TX2 and RX3 should not be enabled at the same time (RE3=1 and TE2=1). When RE3 is cleared, receiver 3 is disabled by inhibiting data transfer into RX3. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the RX3 data register. If RE3 is set while some of the other receivers are already in operation, the first data word received in RX3 will be invalid and must be discarded.
2 RE2	RCR ESAI Receiver 2 Enable. When RE2 is set and TE3 is cleared, the ESAI receiver 2 is enabled and samples data at the SDO3/SDI2 pin. TX3 and RX2 should not be enabled at the same time (RE2=1 and TE3=1). When RE2 is cleared, receiver 2 is disabled by inhibiting data transfer into RX2. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the RX2 data register. If RE2 is set while some of the other receivers are already in operation, the first data word received in RX2 will be invalid and must be discarded.

Table 19-24. ESAI Receive Control Register Field Descriptions (Continued)

Field	Description
1 RE1	RCR ESAI Receiver 1 Enable. When RE1 is set and TE4 is cleared, the ESAI receiver 1 is enabled and samples data at the SDO4/SDI1 pin. TX4 and RX1 should not be enabled at the same time (RE1=1 and TE4=1). When RE1 is cleared, receiver 1 is disabled by inhibiting data transfer into RX1. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the RX1 data register. If RE1 is set while some of the other receivers are already in operation, the first data word received in RX1 will be invalid and must be discarded.
0 RE0	RCR ESAI Receiver 0 Enable. When RE0 is set and TE5 is cleared, the ESAI receiver 0 is enabled and samples data at the SDO5/SDI0 pin. TX5 and RX0 should not be enabled at the same time (RE0=1 and TE5=1). When RE0 is cleared, receiver 0 is disabled by inhibiting data transfer into RX0. If this bit is cleared while receiving a data word, the remainder of the word is shifted in and transferred to the RX0 data register. If RE0 is set while some of the other receivers are already in operation, the first data word received in RX0 will be invalid and must be discarded.

19.3.3.19 ESAI Receiver Clock Control Register (RCCR)

The read/write Receiver Clock Control Register (RCCR) controls the ESAI receiver clock generator bit and frame sync rates, word length, and number of words per frame for the serial data. The RCCR control bits are described in the following paragraphs.

Offset 0x00E0 (RCCR) Access: User read/write only

Figure 19-26. ESAI Receiver Clock Control Register

Table 19-27. ESAI Receiver Clock Control Register Field Descriptions

Field	Description
31-24	Reserved.
23 RHCKD	RCCR Receiver High Frequency Clock Direction. The Receiver High Frequency Clock Direction (RHCKD) bit selects the source of the receiver high frequency clock when in the asynchronous mode (SYN=0) and the IF2/OF2 flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RHCKD is set, the internal clock generator becomes the source of the receiver high frequency clock and is the output on the HCKR pin. In the asynchronous mode, when RHCKD is cleared, the receiver high frequency clock source is external; the internal clock generator is disconnected from the HCKR pin, and an external clock source may drive this pin. When RHCKD is cleared, HCKR is an input; when RHCKD is set, HCKR is an output. In the synchronous mode when RHCKD is set, the HCKR pin becomes the OF2 output flag. If RHCKD is cleared, the HCKR pin becomes the IF2 input flag. See Table 19-1 and Table 19-31.
22 RFSD	RCCR Receiver Frame Sync Signal Direction. The Receiver Frame Sync Signal Direction (RFSD) bit selects the source of the receiver frame sync signal when in the asynchronous mode (SYN=0) and the IF1/OF1/Transmitter Buffer Enable flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RFSD is set, the internal clock generator becomes the source of the receiver frame sync and is the output on the FSR pin. In the asynchronous mode, when RFSD is cleared, the receiver frame sync source is external; the internal clock generator is disconnected from the FSR pin, and an external clock source may drive this pin. In the synchronous mode when RFSD is set, the FSR pin becomes the OF1 output flag or the Transmitter Buffer Enable, according to the TEBE control bit. If RFSD is cleared, the FSR pin becomes the IF1 input flag. See Table 19-1 and Table 19-30.
21 RCKD	RCCR Receiver Clock Source Direction. The Receiver Clock Source Direction (RCKD) bit selects the source of the clock signal used to clock the receive shift register in the asynchronous mode (SYN=0) and the IF0/OF0 flag direction in the synchronous mode (SYN=1). In the asynchronous mode, when RCKD is set, the internal clock source becomes the bit clock for the receive shift registers and word length divider and is the output on the SCKR pin. In the asynchronous mode when RCKD is cleared, the clock source is external; the internal clock generator is disconnected from the SCKR pin, and an external clock source may drive this pin. In the synchronous mode when RCKD is set, the SCKR pin becomes the OF0 output flag. If RCKD is cleared, the SCKR pin becomes the IF0 input flag. See Table 19-1 and Table 19-29.

Table 19-27. ESAI Receiver Clock Control Register Field Descriptions (Continued)

Field	Description
20 RHCKP	RCCR Receiver High Frequency Clock Polarity. The Receiver High Frequency Clock Polarity (RHCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RHCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive high frequency bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RHCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
19 RFSP	RCCR Receiver Frame Sync Polarity. The Receiver Frame Sync Polarity (RFSP) determines the polarity of the receive frame sync signal. When RFSP is cleared the frame sync signal polarity is positive, that is, the frame start is indicated by a high level on the frame sync pin. When RFSP is set the frame sync signal polarity is negative, that is, the frame start is indicated by a low level on the frame sync pin.
18 RCKP	The Receiver Clock Polarity (RCKP) bit controls on which bit clock edge data and frame sync are clocked out and latched in. If RCKP is cleared the data and the frame sync are clocked out on the rising edge of the receive bit clock and the frame sync is latched in on the falling edge of the receive bit clock. If RCKP is set the falling edge of the receive clock is used to clock the data and frame sync out and the rising edge of the receive clock is used to latch the frame sync in.
17-14 RFP 34:0]	RCCR Rx High Frequency Clock Divider. The RFP3–RFP0 bits control the divide ratio of the receiver high frequency clock to the receiver serial bit clock when the source of the receiver high frequency clock and the bit clock is the internal Core clock. When the HCKR input is being driven from an external high frequency clock, the RFP3–RFP0 bits specify an additional division ration in the clock divider chain. Table 19-28 provides the specification of the divide ratio. Figure 19-23 shows the ESAI high frequency generator functional diagram.
13-9 RDC [4:0]	RCCR Rx Frame Rate Divider Control. The RDC4–RDC0 bits control the divide ratio for the programmable frame rate dividers used to generate the receiver frame clocks. In network mode, this ratio may be interpreted as the number of words per frame minus one. The divide ratio may range from 2 to 32 (RDC[4:0]=00001 to 11111) for network mode. A divide ratio of one (RDC[4:0]=00000) in network mode is a special case (on-demand mode). In normal mode, this ratio determines the word transfer rate. The divide ratio may range from 1 to 32 (RDC[4:0]=00000 to 11111) for normal mode. In normal mode, a divide ratio of one (RDC[4:0]=00000) provides continuous periodic data word transfers. A bit-length frame sync (RFSL=1) must be used in this case. The ESAI frame sync generator functional diagram is shown in Figure 19-24.
8 RPSP	RCCR Receiver Prescaler Range. The RPSR controls a fixed divide-by-eight prescaler in series with the variable prescaler. This bit is used to extend the range of the prescaler for those cases where a slower bit clock is desired. When RPSR is set, the fixed prescaler is bypassed. When RPSR is cleared, the fixed divide-by-eight prescaler is operational (see Figure 19-23). The maximum internally generated bit clock frequency is Fsys/4, the minimum internally generated bit clock frequency is Fsys/(2 x 8 x 256)=Fsys/4096. (Do not use the combination RPSR=1 and RPM7-RPM0=0x00, which causes synchronization problems when using the internal Core clock as source (RHCKD=1 or RCKD=1))
7-0 RPM [7:0]	RCCR Receiver Prescale Modulus Select. The RPM7–RPM0 bits specify the divide ratio of the prescale divider in the ESAI receiver clock generator. A divide ratio from 1 to 256 (RPM[7:0]=0x00 to 0xFF) may be selected. The bit clock output is available at the receiver serial bit clock (SCKR) pin. The bit clock output is also available internally for use as the bit clock to shift the receive shift registers. The ESAI receive clock generator functional diagram is shown in Figure 19-23.

19.3.3.20 ESAI Transmit Slot Mask Register A (TSMA)

The Transmit Slot Mask Register A together with Transmit Slot Mask Register B (TSMA and TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tristate the transmitter data pins. TSMA and TSMB should each be considered as containing half a 32-bit register TSM. Bit number N in TSM (TS**) is the enable/disable control bit for transmission in slot number N.

Offset 0x00E4 (TSMA) Access: User read/write only

Figure 19-27. ESAI Transmit Slot Mask Register A

Table 19-32. ESAI Transmit Slot Mask Register A Field Descriptions

Field	Description
31–16	Reserved
15-0 TS [15:0]	When bit number N in TSMA is cleared, all the transmit data pins of the enabled transmitters are tristated during transmit time slot number N. The data is still transferred from the transmit data registers to the transmit shift registers but neither the TDE nor the TUE flags are set. This means that during a disabled slot, no transmitter empty interrupt is generated. The Core is interrupted only for enabled slots. Data that is written to the transmit data registers when servicing this request is transmitted in the next enabled transmit time slot. When bit number N in TSMA register is set, the transmit sequence is as usual: data is transferred from the TX registers to the shift registers and transmitted during slot number N, and the TDE flag is set. Using the slot mask in TSMA does not conflict with using TSR. Even if a slot is enabled in TSMA, the user may chose to write to TSR instead of writing to the transmit data registers TXx. This causes all the transmit data pins of the enabled transmitters to be tristated during the next slot. Data written to the TSMA affects the next frame transmission. The frame being transmitted is not affected by this data and would comply to the last TSMA setting. Data read from TSMA returns the last written data. After hardware or software reset, the TSMA register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data transmission. When operating in normal mode, bit 0 of the TSMA register must be set, otherwise no output is generated.

19.3.3.21 ESAI Transmit Slot Mask Register B (TSMB)

The Transmit Slot Mask Register B together with Transmit Slot Mask Register A (TSMA and TSMB) are two read/write registers used by the transmitters in network mode to determine for each slot whether to transmit a data word and generate a transmitter empty condition (TDE=1), or to tristate the transmitter data pins. TSMA and TSMB should each be considered as containing half a 32-bit register TSM. Bit number N in TSM (TS**) is the enable/disable control bit for transmission in slot number N.

Field	Description
31–16	Reserved
15-0 TS [31:16]	When bit number N in TSMB is cleared, all the transmit data pins of the enabled transmitters are tristated during transmit time slot number N. The data is still transferred from the transmit data registers to the transmit shift registers but neither the TDE nor the TUE flags are set. This means that during a disabled slot, no transmitter empty interrupt is generated. The Core is interrupted only for enabled slots. Data that is written to the transmit data registers when servicing this request is transmitted in the next enabled transmit time slot. When bit number N in TSMB register is set, the transmit sequence is as usual: data is transferred from the TX registers to the shift registers and transmitted during slot number N, and the TDE flag is set. Using the slot mask in TSMB does not conflict with using TSR. Even if a slot is enabled in TSMB, the user may chose to write to TSR instead of writing to the transmit data registers TXx. This causes all the transmit data pins of the enabled transmitters to be tristated during the next slot. Data written to the TSMB affects the next frame transmission. The frame being transmitted is not affected by this data and would comply to the last TSMB setting. Data read from TSMB returns the last written data. After hardware or software reset, the TSMB register is preset to 0x0000FFFF, which means that all 16 possible slots are enabled for data transmission.

19.3.3.22 ESAI Receive Slot Mask Register A (RSMA)

The Receive Slot Mask Register A together with Receive Slot Mask Register B (RSMA and RSMB) are two read/write registers used by the receiver in network mode to determine for each slot whether to receive a data word and generate a receiver full condition (RDF=1), or to ignore the received data. RSMA and RSMB should be considered as each containing half of a 32-bit register RSM. See Bit number N in RSM (RS**) is an enable/disable control bit for receiving data in slot number N.

19.3.3.24 ESAI Personal Reset Registers

There are two registers to control the ESAI personal reset status - Port C Direction Register (PRRC) and Port C Control Register (PCRC). Their register bits are described in the following paragraphs.

19.3.3.25 Port C Direction Register (PRRC)

The read/write 32-bit Port C Direction Register (PRRC) in conjunction with the Port C Control Register (PCRC) controls the functionality of the ESAI personal reset state. Table 19-38 provides the port pin configurations. Hardware and software reset clear all PRRC bits.

Table 19-38. PCRC and PRRC Bits Functionality

PDC[i]	PC[i]	Port Pin[i] Function
0	0	Disconnected
1	1	ESAI

19.4 Functional Description

19.4.1 ESAI After Reset

Hardware or software reset clears the port control register bits and the port direction control register bits, which configure all ESAI I/O pins as disconnected and both ESAI FIFOs are also in reset state. The ESAI is in personal reset state while all ESAI pins are programmed as disconnected, and it is active only if at least one of the ESAI I/O pins is programmed as an ESAI pin.

19.4.2 ESAI Interrupt Requests

The ESAI can generate eight different interrupt requests (ordered from the highest to the lowest priority)**:**

1. **ESAI Receive Data with Exception Status**:
   Occurs when the receive exception interrupt is enabled (REIE=1 in the RCR register), at least one of the enabled receive data registers is full (RDF=1) and a receiver overrun error has occurred (ROE=1 in the SAISR register). ROE is cleared by first reading the SAISR and then reading all the enabled receive data registers.
2. **ESAI Receive Even Data**:
   Occurs when the receive even slot data interrupt is enabled (REDIE=1), at least one of the enabled receive data registers is full (RDF=1), the data is from an even slot (REDF=1) and no exception has occurred (ROE=0 or REIE=0).
   Reading all enabled receiver data registers clears RDF and REDF.
3. **ESAI Receive Data**:
   Occurs when the receive interrupt is enabled (RIE=1), at least one of the enabled receive data registers is full (RDF=1), no exception has occurred (ROE=0 or REIE=0) and no even slot interrupt has occurred (REDF=0 or REDIE=0).
   Reading all enabled receiver data registers clears RDF.
4. **ESAI Receive Last Slot Interrupt**:
   Occurs, if enabled (RLIE=1), after the last slot of the frame ended (in network mode only) regardless of the receive mask register setting. The receive last slot interrupt may be used for resetting the receive mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the receive last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum receive last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).
5. **ESAI Transmit Data with Exception Status**:
   Occurs when the transmit exception interrupt is enabled (TEIE=1), at least one transmit data register of the enabled transmitters is empty (TDE=1) and a transmitter underrun error has occurred (TUE=1). TUE is cleared by first reading the SAISR and then writing to all the enabled transmit data registers, or to the TSR register.
6. **ESAI Transmit Last Slot Interrupt**:
   Occurs, if enabled (TLIE=1), at the start of the last slot of the frame in network mode regardless of the transmit mask register setting. The transmit last slot interrupt may be used for resetting the transmit mask slot register, reconfiguring the DMA channels and reassigning data memory pointers. Using the transmit last slot interrupt guarantees that the previous frame was serviced with the previous setting and the new frame is serviced with the new setting without synchronization problems. Note that the maximum transmit last slot interrupt service time should not exceed N-1 ESAI bits service time (where N is the number of bits in a slot).
7. **ESAI Transmit Even Data**:
   Occurs when the transmit even slot data interrupt is enabled (TEDIE=1), at least one of the enabled transmit data registers is empty (TDE=1), the slot is an even slot (TEDE=1) and no exception has occurred (TUE=0 or TEIE=0).
   Writing to all the TX registers of the enabled transmitters or to TSR clears this interrupt request.

8. **ESAI Transmit Data**:
   Occurs when the transmit interrupt is enabled (TIE=1), at least one of the enabled transmit data registers is empty (TDE=1), no exception has occurred (TUE=0 or TEIE=0) and no even slot interrupt has occurred (TEDE=0 or TEDIE=0).
   Writing to all the TX registers of the enabled transmitters, or to the TSR clears this interrupt request.

19.4.3 ESAI DMA Requests from the FIFOs

The ESAI can generate two different DMA requests:

1. ESAI Transmit FIFO Empty
   Asserts when the number of empty slots in the ESAI transmit FIFO exceeds the threshold programmed in the ESAI Transmit FIFO Configuration Register (TFCR). Automatically negates when the number of empty slots is less than the threshold programmed in the ESAI Transmit FIFO Configuration Register.
2. ESAI Receive FIFO Full
   Asserts when the number of data words in the ESAI receive FIFO exceeds the threshold programmed in the ESAI Receive FIFO Configuration Register (RFCR). Automatically negates when the number of words is less than the threshold programmed in the ESAI Receive FIFO Configuration Register.

19.5 Initialization Information

19.5.1 ESAI Initialization

The correct way to initialize the ESAI is as follows:

1. Enable the ESAI logic clock by asserting bit 0 of ESAI Control Register (ECR[0]).
2. Hardware, software, ESAI individual reset. (Note that asserting bit 1 of ESAI Control Register only reset the ESAI core logic (including configuration registers) but not the ESAI FIFOs)
3. Reset ESAI FIFOs by asserting bit 1 of TFCR and RFCR.
4. Program ESAI control and time slot registers.(The transmit/receive enable bits of TCR/RCR should not be set)
5. Program ESAI FIFOs via TFCR and RFCR. (enable Transmit/Receive FIFO, enable transmitters/receivers, transmit initialization and set Transmit FIFO/Receive FIFO watermark)
6. Write initial words to ESAI Transmit Data Register (ETDR) (at least one word per enabled transmitter but as many as you want) if Transmit FIFO is used. If not, just write initial words to all the enabled transmitters.
7. Remove ESAI personal reset by configuring PCRC and PRRC.
8. Enabled Transmitters/Receivers in TCR/RCR.

During program execution, all ESAI pins may be defined disconnected, causing the ESAI to stop serial activity and enter the individual reset state. All status bits of the interface are set to their reset state; however, the control bits are not affected. This procedure allows the programmer to reset the ESAI

separately from the other internal peripherals. During individual reset, internal DMA accesses to the data registers of the ESAI are not valid and data read is undefined.

The programmer must use an individual ESAI reset when changing the ESAI control registers (except for TEIE, REIE, TLIE, RLIE, TIE, RIE, TE0-TE5, RE0-RE3) to ensure proper operation of the interface.

NOTE

If the ESAI receiver section is already operating with some of the receivers, enabling additional receivers on the fly, that is, without first putting the ESAI receiver in the personal reset state, by setting their REx control bits will result in erroneous data being received as the first data word for the newly enabled receivers.

19.5.2 ESAI Initialization Examples

19.5.2.1 Initializing the ESAI Using Personal Reset

1. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ECR[0]).
2. The ESAI should be in its personal reset state (PCRC = 0x000 and PRRC = 0x000). In the personal reset state, both the transmitter and receiver sections of the ESAI are simultaneously reset. The TPR bit in the TCR register may be used to reset just the transmitter section. The RPR bit in the RCR register may be used to reset just the receiver section.
3. Configure the control registers (TCCR, TCR, RCCR, RCR) and ESAI FIFOs configuration Registers (TFCR, RFCR) according to the operating mode, but do not enable transmitters (TE5–TE0 = 0x0) or receivers (RE3–RE0 = 0x0). It is possible to set the interrupt enable bits which are in use during the operation (no interrupt occurs).
4. Enable the ESAI by setting the PCRC and PRRC register bits according to pins which are in use during operation.
5. Write initial words to ESAI Transmit Data Register (ETDR) (at least one word per enabled transmitter but as many as you want) if Transmit FIFO is used. If not, just write initial words to all the enabled transmitters which are in use during operation.
   This step is needed even if DMA is used to service the transmitters.
6. Enable the transmitters and receivers.
7. From now on ESAI can be serviced either by polling, interrupts, or DMA.

Operation proceeds as follows:

- For internally generated clock and frame sync, these signals are active immediately after ESAI is enabled (step 4 above).
- Data is received only when one of the receive enable (REx) bits is set and after the occurrence of frame sync signal (either internally or externally generated).
- Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tristated after TEx bit is set until the frame sync occurs.

19.5.2.2 Initializing Just the ESAI Transmitter Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ECR[0])
3. The transmitter section should be in its individual reset state (TPR = 1) and also reset the ESAI Transmit FIFO (TFCR[1] = 1).
4. Configure the control registers TCCR and TCR according to the operating mode, configure the Transmit FIFO Configuration Register (bring transmit FIFO out of reset, enable Transmit FIFO, enable transmitters, transmit initialization and set watermark). Make sure to clear the transmitter enable bits (TE0–TE5). TPR must remain set.
5. Take the transmitter section out of the individual reset state by clearing TPR.
6. Write initial words to ESAI Transmit Data Register (ETDR) (at least one word per enabled transmitter but as many as you want) if Transmit FIFO is used. If not, just write first words to all the enabled transmitters which are in use during operation.
   This step is needed even if DMA is used to service the transmitters.
7. Enable the transmitters by setting their TE bits.
8. Data is transmitted only when the transmitter enable (TEx) bit is set and after the occurrence of frame sync signal (either internally or externally generated). The transmitter outputs remain tristated after TEx bit is set until the frame sync occurs.
9. From now on the transmitters are operating and can be serviced either by polling, interrupts, or DMA.

19.5.2.3 Initializing Just the ESAI Receiver Section

1. It is assumed that the ESAI is operational; that is, at least one pin is defined as an ESAI pin.
2. Enable the ESAI logic clock by setting bit 0 of ESAI Control Register (ECR[0])
3. The receiver section should be in its individual reset state (RPR = 1) and also reset the ESAI Receive FIFO (RFCR[1] = 1).
4. Configure the control registers RCCR and RCR according to the operating mode, configure the Receive FIFO Configuration Register (bring receive FIFO out of reset, enable Receive FIFO, receivers, and set watermark). Making sure to clear the receiver enable bits (RE0–RE3). RPR must remain set.
5. Take the receiver section out of the individual reset state by clearing RPR.
6. Enable the receivers by setting their RE bits.
7. From now on the receivers are operating and can be serviced either by polling, interrupts, or DMA.

Chapter 20
Enhanced Secured Digital Host Controller Version 2 (eSDHCv2)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

20.1 Overview

The enhanced secured digital host controller Version 2 (eSDHCv2, referred to as eSDHC hereafter) provides the interface between the host system and MMC/SD/SDIO/CE-ATA cards, including cards with reduced size or mini cards.

Figure 20-1 shows the eSDHC and its connections within the device. The eSDHC acts as a bridge, passing host bus transactions to the MMC/SD/SDIO/CE-ATA cards by sending commands and performing data accesses to and from the cards. It handles the MMC/SD/SDIO/CE-ATA protocols at the transmission level.

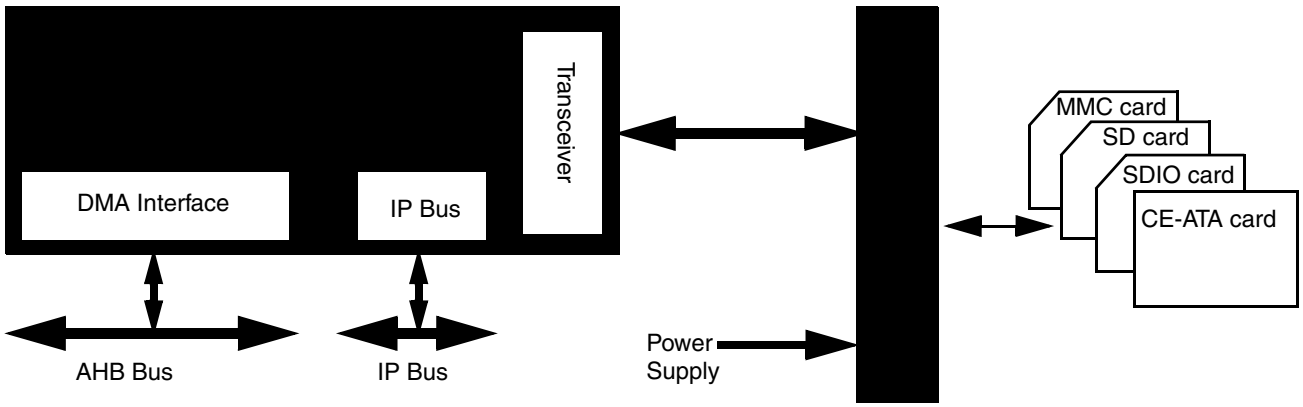

Figure 20-1. eSDHC System Connection

The different cards supported by the eSDHC are described as follows:

- The MultiMediaCard (MMC) is a universal low-cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming both on pre-loaded MMC cards and downloadable from cellular phone, WLAN or other wireless networks. Old MMC cards are based on 7-pin serial bus with a single data pin, while the newer high-speed MMC communication is based on an advanced 11-pin serial bus designed to operate at lower voltage.
- The Secure Digital (SD) card is an evolution of earlier MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with MMC, with some additions. Under the SD protocol, an SD card can be categorized as memory card, I/O card, or combo card (having both

memory and I/O functions). The memory card invokes a copyright protection mechanism that complies with the SDMI security standard. The I/O card provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 20-1 does not show cards with reduced size or mini cards.

- Consumer electronics ATA (CE-ATA) is a hard drive interface that is optimized for embedded applications. The device is layered on the top of the MMC protocol stack using the same physical interface. The interface electrical and signaling definition follows the MMC specification. For more details, see the CE-ATA Specification.

20.1.1 Features

The features of the eSDHC module include the following:

- Designed to work with MMC, MMC plus, MMC RS, SD memory, miniSD memory, SDIO, miniSDIO, SD Combo, and CE-ATA cards. Compatible with the following specifications:
  - MMC System Specification Version 4.2
  - SD Host Controller Standard Specification Version 2.0, including test event register support
  - SD Memory Card Specification Version 2.0: supports High-Capacity SD Memory Cards
  - SDIO Card Specification Version 2.0
  - CE-ATA Card Specification Version 1.0
- Supports 1-, 4-, or 8-bit MMC modes, 1- or 4-bit SD and SDIO modes, and 1-, 4-, or 8-bit CE-ATA devices
  - Card bus clock frequency up to 52 MHz
  - Up to 416 Mbps of data transfer for MMC cards in 8-bit mode
  - Up to 200 Mbps of data transfer for SD/SDIO cards in 4-bit mode
  - Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Supports single-block and multi-block read and write
  - Block sizes of 1–4096 bytes
  - Supports pause during the data transfer at block gap
  - Supports Auto CMD12 for multi-block transfer
- Supports read/write features:
  - Write protection switch for write operations
  - SDIO read wait and suspend/resume operations
  - Includes a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
  - Supports Advanced DMA to perform linked memory access
- Supports both synchronous and asynchronous abort
- Host can initiate non-data transfer command while data transfer is in progress
- Support voltage selection by configuring vendor-specific register bit

20.1.2 Data Transfer Modes

The eSDHC can select the following modes for data transfer:

- MMC 1-, 4-, or 8-bit transfers in full-speed mode (up to 20 MHz) or high-speed mode (up to 52 MHz)
- SD 1- or 4-bit transfers in full-speed mode (up to 25 MHz) or high-speed mode (up to 50 MHz)
- CE-ATA 1-, 4-, or 8-bit transfers
- Identification Mode (up to 400 kHz)

20.2 External Signals

This section includes an overview of the external signals and also their descriptions.

20.2.1 Overview

Figure 20-2 shows the eSDHC I/O signals:

- SD_CLK is an internally-generated clock used to drive the MMC, SD, SDIO, or CE-ATA cards.
- CMD I/O is used to send commands and receive responses to/from the card.
- Eight data lines (DAT7–DAT0) are used to perform data transfers between the eSDHC and the card.
- SD_CD# and SD_WP are card-detection and write-protection signals directly routed from the socket. A low on SD_CD# indicates that a card is inserted, and a high on SD_WP indicates that the write-protect switch is active.
- SD_OD is an output signal generated at the SoC level outside eSDHC, and is used to select the external open-drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- SD_VS is used to control the voltage at the SD_ pins listed above. When asserted, voltage is high (around 3.0 V); when negated, voltage is low (around 1.8 V).

SD_CD#, SD_WP, SD_OD, SD_LCTL, and SD_VS are all optional for system implementation. If the eSDHC is desired to support a 4-bit data transfer, DAT7–DAT4 are optional and can be tied to high.

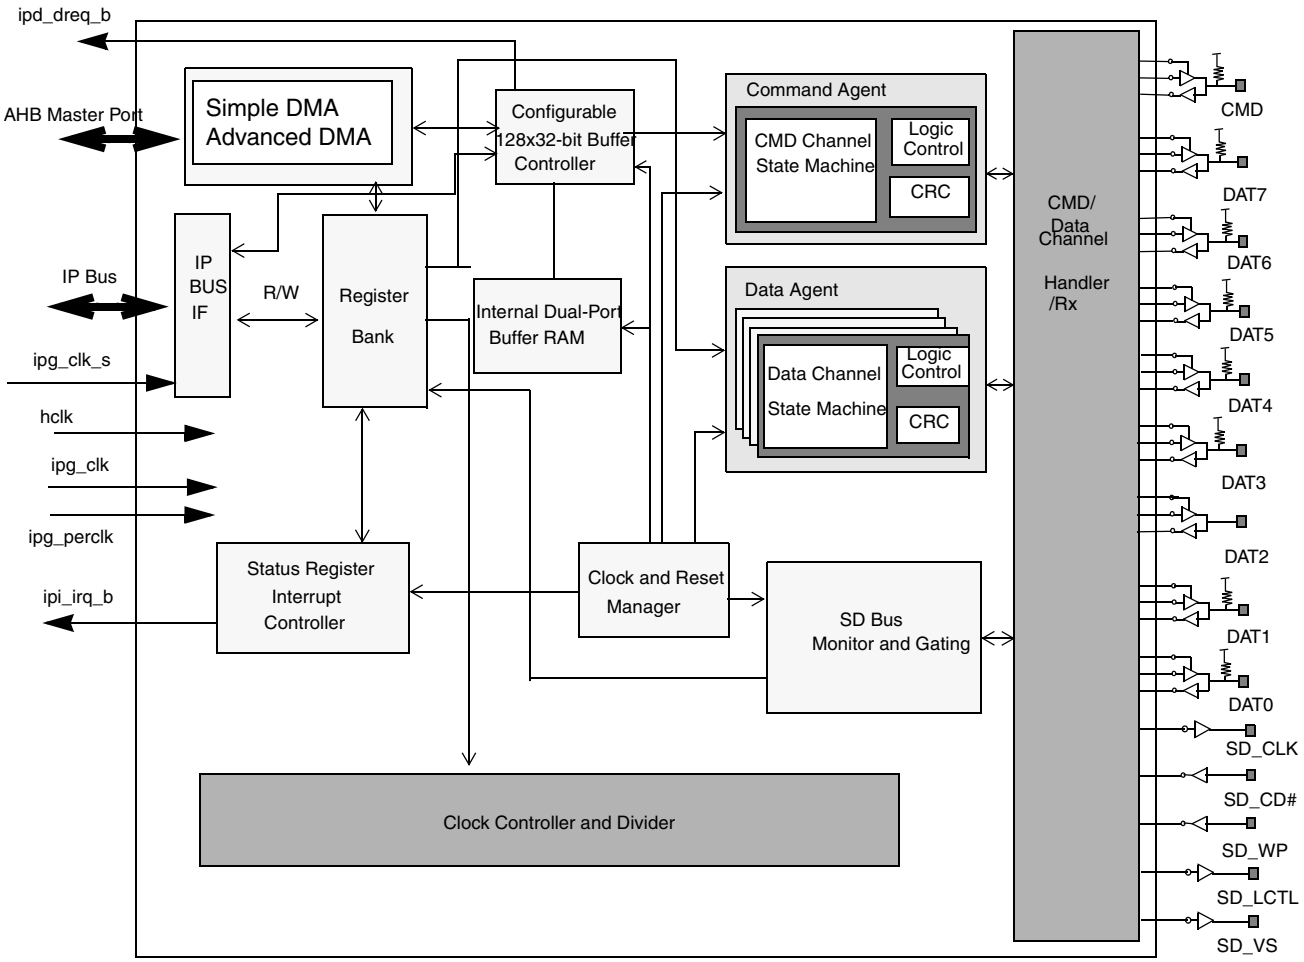

Figure 20-2. enhanced Secure Digital Host Controller (eSDHC) Block Diagram

20.2.2 Signal Descriptions

Table 20-1 shows properties of the I/O signals.

Table 20-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connected to card	1	Pull up
SD_DAT7	I/O	DAT7 line (MSB) in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up

Table 20-1. Properties of I/O Signals (Continued)

Name	Port	Function	Reset State	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Pull-up/pull-down configurable
SD_DAT2	I/O	DAT2 line or read wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 (LSB) line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection signal If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the eSDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A
SD_VS	O	Controls the voltage at SD_ pins. When asserted, voltage is high (around 3.0 V); when negated, voltage is low (around 1.8 V) Optional output	0	N/A

20.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

20.3.1 Memory Map

Table 20-2 shows the eSDHC memory map. For the base address of a particular module instantiation, see the system memory map.

All registers support 32-bit accesses only. Addresses greater than 0x0044, except for 0x0050, 0x0054, 0x0058, and 0x00FC, are reserved and read as all zeros. Writes to these registers are ignored.

Table 20-2. eSDHCv2 Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Section
BASE +0000 (DSADDR)	DMA system address register	R/W	20.3.3.1/20-12

Table 20-3. eSDHC Register Summary (Continued)

20.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 20-3 and Table 20-4 explain conventions used in register diagrams and tables.

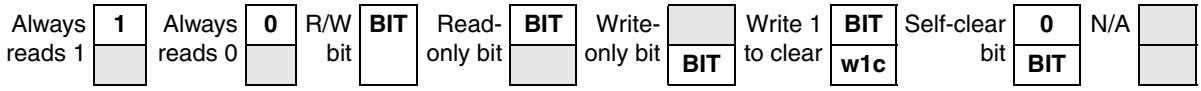

Figure 20-3. Register Field Conventions

Table 20-4. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that can be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

NOTE

The term reset refers to power-on-reset (POR). The reset values given are POR reset values: these may differ from software reset values.

20.3.3.1 DMA System Address Register (DSADDR)

The DSADDR register contains the physical system memory address used for DMA transfers.Figure 20-4 shows the register. Table 20-6 describes the register fields.

Offset BASE +0000 (DSADDR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20-5.

Figure 20-4. DMA System Address Register Diagram (DSADDR)

Table 20-6. DMA System Address Register Field Descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA system address. This register contains the 32-bit system memory address for a DMA transfer. Since the address must be (4-byte) word-aligned, the last 2 bits are always read as 0. When the eSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, writes to this register are ignored. The host driver waits until the DLA bit in the present state register is cleared before writing to this register. The eSDHC internal DMA only supports continuous physical memory access, and does not support a virtual memory system. Due to AHB burst limitations, if a burst of type SEQ crosses the 1 KB boundary, eSDHC I automatically changes the burst type to NSEQ. This register supports dynamic address reflection: when TC bit is set, it automatically alters the value of internal address counter. Software cannot change this register when TC bit is set.
1–0	Reserved, read as 0

20.3.3.2 Block Attributes Register (BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Figure 20-5 shows the register. Table 20-7 describes the register fields.

Offset BASE +0004 (BLKATTR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BLKCNT[15:0][1]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Figure 20-5. Block Attributes Register (BLKATTR)

Table 20-7. Block Attributes Register Field Descriptions

Field	Description
31–16 BLKCNT	Block count for current transfer. This field is enabled when the block count enable (BCEN) bit in the transfer mode register is set to 1, and is valid only for multi-block transfers. For single block transfers, the register always reads as 1. For multi-block transfers, the host driver sets this register to a value between 1 and the maximum block count. The eSDHC decrements the block count after each block transfer, and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions are stopped). Read operations on this register during data transfers can return an invalid value, and write operations are ignored. When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register after transfer is paused by a stop at block gap operation, and before sending the Suspend command. After the Suspend command is sent the eSDHC regards the current transfer as aborted and changes the BLKCNT register back to its original value. When restoring transfer content prior to issuing a Resume command, the host driver is responsible to restore the previously-saved block count. 0x0000Stop count 0x0001 1 block 0x0002 2 blocks ..... 0xFFFF 65535 blocks **Note:** Although the BLKCNT field is 0 after reset, the read value after reset is 0x0001. This is because reset clears the MSBSEL bit to indicate a single-block transfer, so that BLKCNT reads as 0x0001.

Table 20-7. Block Attributes Register Field Descriptions (Continued)

Field	Description
15–13	Reserved, read as 0
12–0 BLKSIZE[12:0]	Transfer block size. This register specifies the block size (in bytes) for block data transfers. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0x000) No data transfer 0x001) 1 Byte 0x002) 2 Bytes … 0x1000) 4096 Bytes 0x1001–0xFFFF Reserved

20.3.3.3 Command Argument Register (CMDARG)

Figure 20-6 shows the register. Table 20-8 describes the register fields.

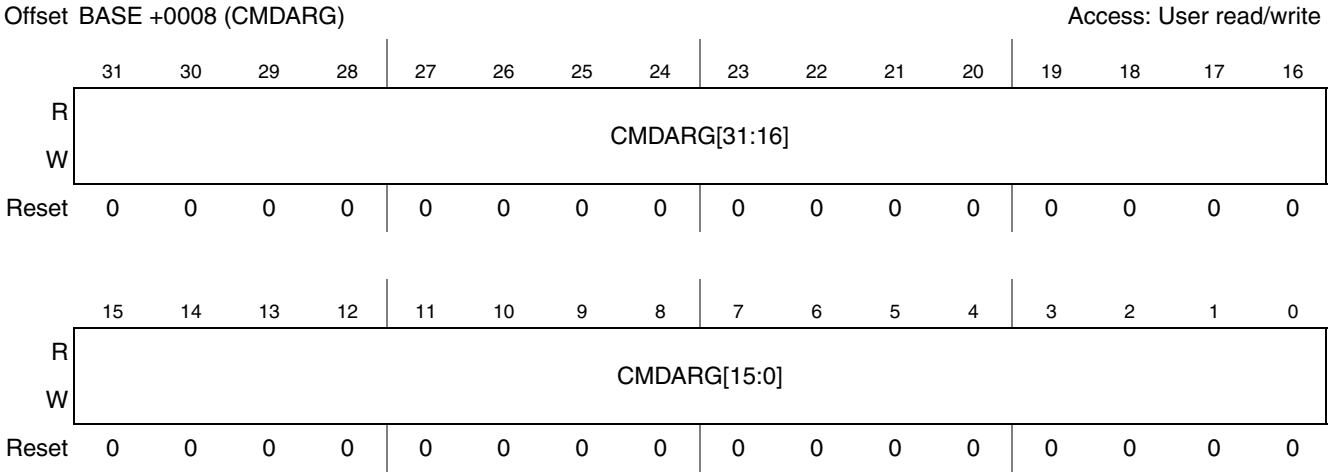

Figure 20-6. Command Argument Register (CMDARG)

Table 20-8. Command Argument Register Field Descriptions

Field	Description
31–0 CMDARG[31:0]	Command argument. The SD/MMC command argument is specified as bits 39-8 of the command format in the SD and MMC specifications.This register is write-protected when the CIHB bit is set in the present state register.

20.3.3.4 Transfer Type Register (XFERTYP)

The XFERTFYP register is used to control the operation of data transfers. The host driver is responsible to set this register before issuing a command followed by a data transfer, or before issuing a Resume command. During data transfers, to prevent data loss the eSDHC prevents writing to the following bits: DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The host driver is responsible to check the command inhibit bits (CDIHB and CIHB) in the present state register before writing to this register. When the CDIHB bit is set, any attempt to send a command with data transfer by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

When sending commands followed by data transfer, the command is ignored unless the following conditions are met:

- Block size is nonzero (specified by the BLKSIZE field in the BLKATTR register).
- At least one of the following conditions holds:
  - Block count is nonzero (specified by the BLKCNT field in the BLKATTR register).
  - Single-block transfer is indicated (MSBSEL bit in XFERTYP register is cleared)
  - Block count is disabled (BCEN bit in XFERTYP register is cleared)
- (Write commands only) Write protect switch is inactive (WPSPL bit in present state register is set to 1).

After the command followed by data transfer is sent, if no response is received within 64 clock cycles (the response timeout period) then the eSDHC aborts the data transfer. Response timeout occurs for instance in the following cases:

- The card responds to the command, but eSDHC does not receive the response
- An internal DMA (either simple DMA or ADMA) read operation occurs, so that external system memory is overwritten by the internal DMA with data sent back from the card.

If the command times out, the driver is responsible to reissue the command.

Figure 20-7 shows the register. Table 20-9 describes the register fields.

Offset BASE +000C (XFERTYP) Access: User read/write

Figure 20-7. Transfer Type Register (XFERTYP)

Table 20-9. Transfer Type Register Field Descriptions

Field	Description
31–30	Reserved, read as 0
29–24 CMDINX[5:0]	Command index. These bits are set to the command number that is specified in bits 45-40 of the command format in the SD Memory Card Physical Layer Specification and the SDIO Card Specification.
23–22 CMDTYP[1:0]	Command type. There are three types of special commands: Suspend, Resume and Abort (for all other commands, CMDTYP is set to 0b00). The three special commands are described as follows: • Suspend command: If a Suspend command is sent, the eSDHC assumes that the card bus has been released and that it can issue the next command which uses the DAT line. However, the eSDHC does not monitor the content of command response, so it does not know if the Suspend command succeeds or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the eSDHC that a Suspend command was successfully issued. Refer to Section 20.5.3.3.1, "Suspend Operation" for more details. After the end bit of the command is sent, the eSDHC negates read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the eSDHC maintains its current state, and the host driver restarts the transfer by setting the continue request bit in the protocol control register. • Resume command: The host driver restarts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The eSDHC checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, the eSDHC stops reads to the buffer. If this command is set when executing a write transfer, the eSDHC stops driving the DAT line. After issuing the Abort command, the host driver should issue a software reset (Abort transaction). 00 Normal— all other commands 01 Suspend CMD52 for writing bus suspend in CCCR 10 Resume CMD52 for writing function select in CCCR 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select. This bit is set to 1 to indicate that data is ready to be transferred using the DAT line. It is set to 0 in the following cases: • Commands using only the CMD line (such as CMD52). • Commands that transfer no data but use the busy signal on DAT[0] line (R1b or R5b, such as CMD38) 0 No data present 1 Data present **Note:** • The Resume command requires this bit be set to 1, while the other XFERTYP fields (except for CMDTYP) are the same as when the transfer was initially launched. • When the write protect switch is on, (WPSPL bit is cleared in the present state register), all writes to the transfer type register with DTDSEL = 0 and DPSEL = 1 are ignored.
20 CICEN	Command index check enable. When this bit is set to 1, the eSDHC checks the index field in the response to see if it has the same value as the command index. If not, the eSDHC reports a command index error. The Index field is not checked if the bit is cleared. 0 Disable command index check 1 Enable command index check
19 CCCEN	Command CRC check enable. If this bit is set to 1, the eSDHC checks the CRC field in the response. If an error is detected, the eSDHC reports a command CRC error. The CRC field is not checked if this bit is cleared. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Table 20-11.) 0 Disable command CRC check 1 Enable command CRC check
18	Reserved

Table 20-9. Transfer Type Register Field Descriptions (Continued)

Field	Description
17–16 RSPTYP[1:0]	Response type select: 00 No response 01 Response length 136 10 Response length 48 11 Response length 48, check busy after response
15–6	Reserved, read as 0
5 MSBSEL	Multi / single-block select: This bit enables multi-block DAT line data transfers. For any other commands, this bit is set to 0. If this bit is 0, it is not necessary to set the block count register. Table 20-10 shows MSBSEL settings corresponding to different transfer types. 0 Single-block transfer 1 Multi-block transfer
4 DTDSEL	Data transfer direction select. This bit defines the direction of DAT line data transfers. The host driver sets this bit to 1 to transfer data from the SD card to the eSDHC. This bit is cleared for all other commands. 0 Write (host to card) 1 Read (card to host)
3	Reserved, read as 0
2 AC12EN	Auto CMD12 enable. Multi-block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the eSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver does not set this bit to issue commands that do not require CMD12 to stop a multi-block data transfer. In particular, secure commands defined in the file security specification do not require CMD12. In single-block transfers, the eSDHC ignores this bit. 0 Disable auto CMD12 1 Enable auto CMD12
1 BCEN	Block count enable. This bit enables the block count register, which is only relevant for multi-block transfers. When this bit is cleared, the internal block counter is disabled: this setting is used for infinite transfers.Table 20-10 shows BCEN settings corresponding to different transfer types. 0 Disable block count register 1 Enable block count register
0 DMAEN	DMA enable. This bit enables internal DMA functionality. If this bit is set to 1, an internal DMA operation begins when the host driver sets the DPSEL bit of this register. Whether the simple DMA, or the advanced DMA, is active depends on the DMA select field of the protocol control register. 0 Disable DMA 1 Enable DMA

Table 20-10 shows multi/single-block select (MSBSEL) and block count enable (BCEN) settings for different data transfer types.

Table 20-10. MSBSEL and BCEN Bit Settings for Different Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Table 20-11 shows the settings for responses type select (RSPTYP), index check enable (CICEN), and command CRC check enable (CCCEN) fields in the XFERTYP register corresponding to different response types.

Table 20-11. RSPTYP, CICEN, and CCCEN Settings for Different Response Types

Response Type Select (RSPTYP)	Index Check Enable (CICEN)	CRC Check Enable (CCCEN)	Response Type
00	0	0	No response
01	0	1	R2
10	0	0[1]	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b[2]

1 The CRC field for R3 and R4 is expected to be all 1's. The CRC check is disabled for these response types.

2 The SDIO Specification does not distinguish between R5 and R5b. The notation R5b here indicates the case where eSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.

20.3.3.5 Command Response *n* Register (CMDRSP0–CMDRSP3)

The CMDRSP*n* registers are used to store parts *n* of the response bits from the card (*n* = 0,1,2,3).

Figure 20-8 shows the register. Table 20-12 describes the register fields.

Offset BASE +0010 (CMDRSP0)
BASE +0014 (CMDRSP1)
BASE +0018 (CMDRSP2)
BASE +001C (CMDRSP3)

Access: User read

Figure 20-8. Command Response *n* Register (CMDRSP0-CMDRSP3)

Table 20-12. Command Response *n* Register Field Description

Field	Description
31–0 CMDRSP*n*[31:0]	Command response *n*. Refer to Table 20-13 for the mapping of command responses from the SD bus to this register for each response type.

Table 20-13 describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R[*x*:*y*] refers to a bit range within the response data as transmitted on the SD bus.

Table 20-13. Response Field Definitions for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O and others	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

The eSDHC only stores part of the response data in the command response registers. This enables the host driver to efficiently read 32 bits of response data in one read cycle on a 32-bit bus system. The eSDHC checks the response data's index field and the CRC (as specified by the command index check enable and the command CRC check enable bits in the transfer type register) and generates an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the eSDHC checks R[47:1], and if the response length is 136 the eSDHC checks R[119:1].

Table 20-13 shows that the auto CMD12 and CMD_wo_DAT responses are stored in the CMDRSP3 and CMDRSP0 registers, respectively. This prevents overwriting of the auto CMD12 response with the CMD_wo_DAT (or vice versa) when the corresponding commands are executed concurrently. When the eSDHC modifies part of the command response registers as shown in Table 20-13, it preserves the unmodified bits.

20.3.3.6 Buffer Data Port Register (DATPORT)

This register contains the buffer data port. Figure 20-9 shows the register. Table 20-14 describes the register fields. The 32-bit DATPORT register is used for CPU or external DMA access the internal buffer. When the internal DMA is enabled, writes to this register is ignored, and the register is read as 0.

Offset BASE +0020 (DATPORT) Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 20-9. Buffer Data Port Register (DATPORT)

Table 20-14. Buffer Data Port Register Field Descriptions

Field	Description
31–0 DATCONT[31:0]	Data content. When the internal DMA is enabled, writes to this register are ignored, and the register is read as 0.

20.3.3.7 Present State Register (PRSSTAT)

The 32-bit read-only PRSSTAT register provides the host driver with the eSDHC status.

Figure 20-10 shows the register. Table 20-15 describes the register fields.

Offset BASE +0024 (PRSSTAT) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLSL[7:0]								CLSL	0	0	0	WPSPL	CDPL	0	CINS
W																
Reset	1	1	1	1	n[1]	1	1	1	1	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	BREN	BWEN	RTA	WTA	SDOFF	PEROFF	HCKOFF	IPGOFF	SDSTB	DLA	CDIHB	CIHB
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[1] The reset value of DLSL [3] depends on the pull-up/pull-down configuration of DAT[3] (see Table 20-1). If DAT[3] is pulled down, then DLSL[3] resets to 0; if DAT[3] is pulled up, then DLSL[3] resets to 1.

Figure 20-10. Present State Register (PRSSTAT)

Table 20-15. Present State Register Field Descriptions

Field	Description
31–24 DLSL[7:0]	DAT[7:0] line signal level. These status bits are used to check the DAT line levels to recover from errors, and for debugging.DLSL[0] is especially useful for detecting the busy signal level. The reset value is affected by the external pull-up / pull-down resistors. These bits all reset to 1 except for DLSL[3], whose reset value depends on the pull-up / pull-down configuration of DAT[3]. If DAT[3] is pulled down, then DLSL[3] resets to 0; if DAT[3] is pulled up, then DLSL[3] resets to 1. DAT[*n*]: Data *n* line signal level (*n* = 7…0)
23 CLSL	CMD line signal level. This status bit is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up/pull-down resistor—by default, the read value of this bit after reset is 0b1.
22–20	Reserved, read as 0
19 WPSPL	Write protect switch pin level. The write protect switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 0 Write protected (SD_WP=1) 1 Write enabled (SD_WP=0)

Table 20-15. Present State Register Field Descriptions (Continued)

Field	Description
18 CDPL	Card detect pin level. This bit reflects the inverse value of the SD_CD# signal for the card socket: for instance, when a card is inserted in the socket the SD_CD# input signal is negated, and the CDPL bit is set to 1. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the force event register does not effect this bit. The reset value is effected by the external card detection pin. 0 No card present (SD_CD# = 1) 1 Card present (SD_CD# = 0)
17	Reserved, read as 0
16 CINS	Card inserted. This bit indicates whether a card has been inserted. The eSDHC debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a card insertion interrupt in the interrupt status register. Changing from a 1 to 0 generates a card removal interrupt in the interrupt status register. A write to the force event register does not effect this bit. Setting the software reset for all (RSTA) bit in the system control register does not effect this bit. A software reset does not effect this bit. 0 Power on reset or no card 1 Card inserted
15–12	Reserved, read as 0
11 BREN	Buffer read enable. This read-only flag indicates that valid data exists in the host-side buffer. When this bit is set to 1, valid data in the buffer meets or exceeds the read watermark level. This bit changes from 1 to 0 whenever data is read from the buffer. This bit changes from 0 to 1 when valid data in the buffer meets or exceeds the watermark level, and the buffer read ready interrupt has been generated and enabled. 0 Read disable 1 Read enable This status bit is used for non-DMA read transfers. The eSDHC may implement multiple buffers to transfer data efficiently.
10 BWEN	Buffer write enable. This read-only flag indicates that space is available for write data. If this bit is set to 1, available space in the buffer meets or exceeds the write watermark level]. This bit changes from 1 to 0 when data is written to the buffer. This bit changes from 0 to 1 when the available space in the buffer meets or exceeds the write watermark level, and the buffer write ready interrupt is generated and enabled. 0 Write disable 1 Write enable This status bit is used for non-DMA write transfers. The eSDHC can implement multiple buffers to transfer data efficiently.
9 RTA	Read transfer active. This status bit is used to detect completion of a read transfer. This bit is set in either of the following two cases: • After the end bit of the read command. • When the continue request bit in the protocol control register is set to 1 to restart a read transfer. A transfer complete interrupt is generated when the RTA bit is cleared. The bit is cleared in either of the following two cases: • When the last data block as specified by the block size is transferred to the system, so that all data are read from the eSDHC internal buffer. • When all valid data blocks have been transferred from eSDHC internal buffer to the system and no current block transfers are being sent because the stop at block gap request is set to 1. 0 No valid data 1 Transferring data

Table 20-15. Present State Register Field Descriptions (Continued)

Field	Description
8 WTA	Write transfer active. This status bit indicates a write transfer is active. If this bit is cleared, it means no valid write data exists in the eSDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When the continue request bit in the protocol control register is set to 1 to restart a write transfer. This bit is cleared in either of the following cases: • After receiving the CRC status of the last data block as specified by the transfer count (single-block or multi-block). • After receiving the CRC status of the current block, when data transmission is about to be stopped by a stop at block gap request. A block gap event interrupt is generated when this bit is cleared as result of a stop at block gap request during a write transaction. The host driver can use this status bit to determine when to issue commands during write busy state. 0 No valid data 1 Transferring data
7 SDOFF	SD clock gated off internally. This status bit indicates that the SD clock is internally gated off due to one of the following causes: • Buffer overrun or underrun • Read pause without read wait assertion • The driver has cleared the SDCLKEN bit to stop the SD clock. The host driver can use this bit to debug data transactions on the SD bus. 0 SD clock is active. 1 SD clock is gated off.
6 PEROFF	Peripheral source clock (ipg_perclk) gated off internally. This status bit indicates that the ipg_perclk is internally gated off. The host driver can use this bit for debug purposes during transactions on the SD bus. 0 ipg_perclk is active. 1 ipg_perclk is gated off.
5 HCKOFF	Master clock (hclk) gated off internally. This status bit indicates that the hclk is internally gated off. The host driver can use this bit for debug purposes during data transfers. 0 hclk is active. 1 hclk is gated off.
4 IPGOFF	ipg_clk gated off internally. This status bit indicates that the ipg_clk is internally gated off. The host driver can use this bit for debug purposes. 0 ipg_clk is active. 1 ipg_clk is gated off.
3 SDSTB	SD clock stable. This status bit indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in system control register to remove glitches on the card clock when the frequency is changing. 0 Clock is changing frequency and not stable. 1 Clock is stable.

Table 20-15. Present State Register Field Descriptions (Continued)

Field	Description
2 DLA	Data line active. This status bit indicates whether one of the DAT lines on the SD bus is in use. In the case of read transactions: This bit indicates if a read transfer is executing on the SD bus. A change in this bit from 1 to 0 between data blocks generates a block gap event interrupt in the interrupt status register. This bit is set in either of the following cases: • After the end bit of the read command. • When writing a 1 to the continue request bit in the protocol control register to restart a read transfer. This bit is cleared in either of the following cases: • When the end bit of the last data block is sent from the SD bus to the eSDHC. • When the read wait state is stopped by a suspend command and the DAT2 line is released. The eSDHC waits at the next block gap by driving a read wait signal at the start of the interrupt cycle. If the read wait signal is already driven (indicating that the data buffer cannot receive data), the eSDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait in order to use the suspend / resume function. This bit remains set to 1 during read wait. In the case of write transactions: This bit indicates that a write transfer is executing on the SD bus. Changes in this bit from 1 to 0 generate a transfer complete interrupt in the interrupt status register. This bit is set in either of the following cases: • After the end bit of the write command. • When writing to 1 to the continue request bit in the protocol control register to continue a write transfer. This bit is cleared in either of the following cases: • When the SD card releases write busy of the last data block, the eSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the eSDHC assumes the card drives the not busy signal. • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request. In the case of command with busy pending: This status bit indicates that a busy state follows the command and the data line is in use. This bit is cleared when the DAT0 line is released. 0 DAT line inactive 1 DAT line active

Table 20-15. Present State Register Field Descriptions (Continued)

Field	Description
1 CDIHB	Command inhibit (DAT). This status bit is generated if either the DAT line active (DLA) bit or the read transfer active (RTA) bit in this register is set to 1. If this bit is cleared, it indicates that the eSDHC can issue the next SD/MMC command. Commands with a busy signal (for example, R1b, R5b type) belong to command inhibit (DAT). Except in the case when the command busy is finished, changing this bit from 1 to 0 generates a transfer complete interrupt in the interrupt status register. **Note:** The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 0 Can issue command which uses the DAT line 1 Cannot issue command which uses the DAT line
0 CIHB	Command inhibit (CMD). This status bit is cleared when the CMD line is not in use, indicating that the eSDHC can issue a SD/MMC command using the CMD line. This bit is set immediately after the transfer type register is written. This bit is cleared when the command response is received. Changing this bit from 1 to 0 sets the command complete (CC) bit in the interrupt status register, which generates an interrupt if the CCIEN bit is set in the interrupt signal enable register. Commands using only the CMD line can be issued if this bit is cleared, even when CDIHB (bit 1 of this register) is set. Examples of commands using only the CMD line include CMD0, CMD12, CMD13 (for memory cards) and CMD52 (for SDIO). This bit is remains set (and the CC bit in the interrupt status register remains cleared) in either of the following two cases: • If the eSDHC detects a CMD line conflict when the command is issued (eSDHC drives the CMD line to 1, but detects a 0 at the next SD_CLK edge). In this case, command CRC error and command timeout error bits in the interrupt status register are set to 1. • If the command is not issued due to an auto CMD12 error. 0 Can issue command using only the CMD line 1 Cannot issue command

20.3.3.8 Protocol Control Register (PROCTL)

Figure 20-11 shows the register. Table 20-16 describes the register fields.

Offset BASE +0028 (PROCTL) Access: User read/write

Figure 20-11. Protocol Control Register (PROCTL)

Table 20-16. Protocol Control Register Field Descriptions

Field	Description
31–27	Reserved, read as 0
26 WECRM	Wakeup event enable on SD card removal. This bit enables a wakeup event (via a card removal) in the interrupt status register. FN_WUS (wakeup support) in CIS does not effect this bit. When this bit is set, the card removal status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card removal status and assert the eSDHC interrupt. 0 Disable 1 Enable
25 WECINS	Wakeup event enable on SD card insertion. This bit enables a wakeup event, via a card insertion, in the interrupt status register. FN_WUS (wakeup support) in CIS does not effect this bit. When this bit is set, the card insertion status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card insertion status and assert the eSDHC interrupt. 0 Disable 1 Enable
24 WECINT	Wakeup event enable on card interrupt. This bit enables a wakeup event, via a card interrupt, in the interrupt status register. This bit can be set to 1 if FN_WUS (wakeup support) in CIS is set to 1. When this bit is set, the card interrupt status and the eSDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the card interrupt status and assert the eSDHC interrupt. 0 Disable 1 Enable
23–20	Reserved
19 IABG	Interrupt at block gap. This bit is only valid for SDIO cards in 4-bit mode. It selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multi-block transfer. Clearing the bit disables interrupt detection during a multi-block transfer. If the SDIO card cannot signal an interrupt during a multi-block transfer, this bit should be cleared to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 0 Disabled 1 Enabled
18 RWCTL	Read wait control. The read wait function is optional for SDIO cards. If the card supports read wait, setting this bit enables the read wait protocol to stop read data using the DAT[2] line. Otherwise the eSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit is never set to 1—otherwise DAT line conflicts may occur. If this bit is cleared and the stop at block gap request (SABGREQ) bit is set, the eSDHC stops the SD clock to pause the read operation. 0 Disable read wait control, and stop SD Clock at block gap when SABGREQ bit is set 1 Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set
17 CREQ	Continue request. When a Suspend operation is not accepted by the card, setting this bit restarts the paused transfer. This bit is also used to restart a transaction that was stopped using the stop at block gap request (SABGREQ). To cancel the stop at block gap, the host driver clears the SABGREQ bit and sets this bit to 1 to restart the transfer. If both the SABGREQ bit and this bit are set to 1, the continue request is ignored. The eSDHC automatically clears this bit: the host driver does not need to clear it. 0 No effect 1 Restart

Table 20-16. Protocol Control Register Field Descriptions (Continued)

Field	Description
16 SABGREQ	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. In the case of read transfers, setting the SABREQ bit stops the transaction at the next block gap only if the SDIO card supports read wait, and the read wait control bit (RWCTL) in this register is set to 1. Otherwise, the read operation can be paused at the next block gap by stopping the SD bus clock. In the case of write transfers in which the host driver writes data to the data port register, the host driver sets this bit after all block data is written. If this bit is set to 1, the host driver does not write data to the data port register after a block is sent. If the host driver clears this bit before the transfer complete bit in interrupt status register is set:, then the eSDHC's behavior is unpredictable. Clearing both SABGREQ and CREQ bits does not cause the transaction to restart. This bit affects the read transfer active, write transfer active, DAT line active and command inhibit (DAT) bits in the present state register. 0 Transfer 1 Stop
15–10	Reserved, read as 0
9–8 DMAS	DMA select. This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 Reserved
7 CDSS	Card detect signal selection. This bit selects the source for the card detection. 0 Card detection level is selected (for normal purposes) 1 Card detection test level is selected (for test purposes)
6 CDTL	Card detect test level. This is bit is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0 Card detect test level is 0, no card inserted 1 Card detect test level is 1, card inserted
5–4 EMODE	Endian mode. The eSDHC supports all four endian modes in data transfer. Refer to Section 20.4.1, "Data Buffer" for more details. 00 Big-endian mode 01 Halfword big-endian mode 10 Little-endian mode 11 Reserved
3 D3CD	DAT3 as card detection pin. If this bit is set, DAT3 should be pulled down to act as a card detection pin. 0 DAT3 does not monitor card insertion 1 DAT3 as card detection pin **Note:** Since DAT3 is also a chip select for SPI mode, a pull-down on this pin and CMD0 may set the card into the SPI mode. eSDHC does not support SPI mode.

Table 20-16. Protocol Control Register Field Descriptions (Continued)

Field	Description
2–1 DTW[1:0]	Data transfer width. This bit selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00 1-bit mode 01 4-bit mode 10 8-bit mode 11 Reserved
0 LCTL	LED control. This bit, fully controlled by the host driver, is used to caution the user not to remove the card while the card is being accessed. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands. 0 LED off 1 LED on

There are three ways to restart the transfer after stop at the block gap, depending on the status of the Suspend command.

1. If the host driver does not issue a Suspend command, the continue request is used to restart the transfer.
2. If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
3. If the host driver issues a Suspend command and the SD card does not accept it, the continue request is used to restart the transfer.

When a stop at block gap request stops the data transfer, the host driver waits for the transfer complete bit (interrupt status register) to be set before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver clears the stop at block gap request before, or simultaneously with, issuing the continue request.

20.3.3.9 System Control Register (SYSCTL)

Figure 20-12 shows the register. Table 20-17 describes the register fields.

Offset BASE +002C (SYSCTL) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 20-12. System Control Register (SYSCTL)

Table 20-17. System Control Register Field Descriptions

Field	Description
31–28	Reserved, read as 0
27 INITA	Initialization active. When this bit is set, 80 SD clocks are sent to the card. After the 80 clocks are sent, this bit self clears. This bit is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the present state register are set, writes to this bit is ignored (when the command or data lines are active, writes to this bit is not allowed). However, when this bit is set to 1 (that is, during the initialization active period), it is still possible to issue a command—the command bit stream appears on the CMD signal after the 80 clock cycles are completed. In this way, the driver can ensure that 80 clock cycles have completed before the command is sent out. This is a useful feature in the case where the driver needs to send 80 cycles to the card and does not want to wait until this bit is self-cleared.
26 RSTD	Software reset for DAT line. Resets part of the data circuit and the DMA circuit. Setting this bit clears and initializes the buffer, and also clears the following bits: • Data port register: all bits • Present state register: buffer read enable, buffer write enable, read transfer active, write transfer active, data line active, command inhibit (DAT) • Protocol control register: Continue request, Stop at block gap request • Interrupt status register: buffer read ready, buffer write ready, DMA interrupt, block gap event, transfer complete 0 No reset 1 Reset

Table 20-17. System Control Register Field Descriptions (Continued)

Field	Description
25 RSTC	Software reset for CMD line. Resets part of the command circuit. The following bits are cleared by this bit: • Command inhibit (CMD) bit in present state register • Command complete (CC) bit in interrupt status register 0 No reset 1 Reset
24 RSTA	Software reset for all. This reset effects the entire host controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During initialization, the host driver sets this bit to 1 to reset the eSDHC. The eSDHC resets this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of software reset for all does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset and reinitialize the external card. 0 No Reset 1 Reset
23–20	Reserved, read as 0
19–16 DTOCV	Data timeout counter value. This value determines the interval by which DAT line timeouts are detected. Refer to the data timeout error bit in the interrupt status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SD_CLK frequency by this value. The host driver can clear the data timeout error status enable (in the interrupt status enable register) to prevent inadvertent time-out events. 0000 SD_CLK x 2^{13} 0001 SD_CLK x 2^{14} ..... 1110 SD_CLK x 2^{27} 1111 Reserved
15–8 SDCLKFS	SD clock (SD_CLK) frequency prescale select. This register is used to select the prescaler of the SD_CLK signal. The frequency of the SD clock is set based on SD_CLKF and DVS settings according to the following formula: SD clock frequency = (peripheral source clock frequency) / (SDCLKF x DVS) See Section 20.4.6, “SD Clock Generator” for more information about SD clock generation. Multiple bits in this field must not be set, or the behavior of the prescaler is undefined. 0x00 Base clock (10–63 MHz) divided by 1 0x01 Base clock divided by 2 0x02 Base clock divided by 4 0x04 Base clock divided by 8 0x08 Base clock divided by 16 0x10 Base clock divided by 32 0x20 Base clock divided by 64 0x40 Base clock divided by 128 0x80 Base clock divided by 256 (reset value) Other settings Reserved, not allowed

Table 20-17. System Control Register Field Descriptions (Continued)

Field	Description
7–4 DVS[3:0]	Frequency divisor. The frequency of the SD clock is set based on SDCLKF and DVS settings according to the following formula: SD clock frequency = (peripheral source clock frequency) / (SDCLKF x DVS) DVS provides a finer granularity for the available frequencies. Odd divisors are supported without deterioration of the duty cycle. See Section 20.4.6, “SD Clock Generator” for more information about SD clock generation. 0x0 Divide by 1 0x1 Divide by 2 ... 0xE Divide by 15 0xF Divide by 16
3 SDCLKEN	SD clock (SD_CLK) enable. The host controller stops SD_CLK when this bit is cleared. The SD_CLK frequency can only be changed when this bit is cleared. If the card inserted bit in the present state register is cleared, the host driver saves power by clearing this bit. 0 SD clock is stopped 1 SD clock is enabled
2 PEREN	Peripheral source clock (ipg_perclk) enable. When this bit is set, ipg_perclk is always active and no automatic gating is applied. In this case SD_CLK is active except during auto gating-off in case of buffer danger (pending underrun or overrun). When this bit is cleared, the ipg_perclk is automatically gated off when there is no transaction on the SD bus, and when none of the following conditions are met: • The cmd part is reset • Data part is reset • A soft reset • The cmd is about to be sent • Clock divisor is just updated • Continue request is just set • Card insertion is detected • Card removal is detected • Card external interrupt is detected • 80 clocks for initialization phase is ongoing Since this bit is only a feature-enabling bit, clearing this bit does not stop SD_CLK immediately. 0 ipg_perclk is internally gated off. 1 ipg_perclk is not automatically gated off and is active.

Table 20-17. System Control Register Field Descriptions (Continued)

Field	Description
1 HCKEN	Master clock (hclk) enable. If this bit is set, hclk is always active and no automatic gating is applied. When this bit is cleared, hclk is automatically off when no data transfer is active on the SD bus. 0 hclk is internally gated off 1 hclk is not automatically gated off
0 IPGEN	ipg_clk enable. If this bit is set, ipg_clk is always active and no automatic gating is applied. When this bit is cleared, the ipg_clk is internally gated off if none of the following conditions is met: • The cmd part is reset • Data part is reset • Soft reset • The cmd is about to be sent • Clock divisor is just updated • Continue request is just set • Card insertion is detected • Card removal is detected • Card external interrupt is detected • The ipg_perclk is not gated off (thus clearing this bit has no effect unless the PEREN bit is also cleared) 0 ipg_clk is internally gated off 1 ipg_clk is not automatically gated off

20.3.3.10 Interrupt Status Register (IRQSTAT)

An interrupt is generated when at least one of the status bits in this register is set to 1, and the corresponding interrupt enable bit is set in the interrupt signal enable register. All bits are write 1 to clear: writing zeros has no effect. More than one status bit can be cleared with a single register write.

Figure 20-13 shows the register. Table 20-18 describes the register fields.

Offset BASE +0030 (IRQSTAT) Access: User read/write

Figure 20-13. Interrupt Status Register (IRQSTAT)

Table 20-18. Interrupt Status Register Field Descriptions

Field	Description
31–29	Reserved, read as 0
28 DMAE	DMA error. This bit is set to 1, when some error occurs in the internal DMA data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA system address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the host driver re-starts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0 No DMA error 1 DMA error
27–25	Reserved, read as 0
24 AC12E	Auto CMD12 error. This bit is set to 1 when the eSDHC detects that one of the bits in the auto CMD12 error status register has changed from 0 to 1. This bit is set either when the errors in auto CMD12 occur, or when the auto CMD12 is not executed due to an error in the previous command. 0 No auto CMD12 error 1 Auto CMD12 error
23	Reserved, read as 0
22 DEBE	Data end bit error. Occurs either when the eSDHC detects 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 0 No data end bit error 1 Data end bit error
21 DCE	Data CRC error. Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the write CRC status having a value other than 010. 0 No data CRC error 1 Data CRC error
20 DTOE	Data timeout error. Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b response types • Busy time-out after write CRC status • Read data time-out. 0 No data timeout error 1 Data timeout error
19 CIE	Command index error. Occurs if a command index error occurs in the command response. 0 No command index error 1 Command index error
18 CEBE	Command end bit error. Occurs when detecting that the end bit of a command response is 0. 0 No command end error 1 End bit error generated
17 CCE	Command CRC error. A command CRC error is generated in two cases. • If a CRC error is detected in the command response. In this case, the command timeout error bit in this register remains cleared (indicating no timeout) • If the eSDHC detects a CMD line conflict when the command is issued. This occurs when the eSDHC drives the CMD line to 1, but detects a 0 on the CMD line at the next SD_CLK edge. In this case, the eSDHC aborts the command (stops driving the CMD line), and sets the command timeout error bit in this register to 1. 0 No command CRC error 1 Command CRC error generated.

Table 20-18. Interrupt Status Register Field Descriptions (Continued)

Field	Description
16 CTOE	Command timeout error. This bit is set if no response is returned within 64 SD_CLK cycles from the end bit of the command. If the eSDHC detects a CMD line conflict this bit is set without waiting for 64 SD_CLK cycles (the command CRC error bit (CCE) bit is also set, as shown in Table 20-21). 0 No command timeout error 1 Command timeout error
15–9	Reserved, read as 0
8 CINT	Card interrupt. This status bit is set when an interrupt signal is detected from the external card. Wakeup is supported: in 1-bit mode, the eSDHC detects the card interrupt without the SD clock. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, which may introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing 1 to this bit clears it, but if the interrupt factor from the SDIO card is not cleared then the bit is immediately set again. When CINT has been set to 1, it is the host driver's responsibility to clear the card interrupt signal enable bit in the interrupt signal enable register, so that the eSDHC stops driving the interrupt while it is being serviced. After the card interrupt service is completed, and the interrupt factors in the SDIO card have been reset, then the host driver can write 1 to clear this bit and set the card interrupt signal enable to 1. This causes the eSDHC to restart sampling the interrupt signal. 0 No card interrupt 1 Generate card interrupt
7 CRM	Card removal. This status bit is set if the card inserted bit in the present state register changes from 1 to 0. When writing 1 to this bit to clear it, the host driver is responsible to confirm the value of the card inserted bit in the present state register. This is necessary because it is possible for the card state to change while the host driver clears this bit, and the interrupt event may not be generated. When the CRM bit is cleared, if no card is inserted it is immediately set again: this can be prevented by clearing the card removal status enable bit in interrupt status enable register. 0 Card state unstable or inserted 1 Card removed
6 CINS	Card insertion. This status bit is set when the card inserted bit in the present state register changes from 0 to 1. When writing 1 to this bit to clear it, the host driver is responsible to confirm the value of the card inserted bit in the present state register. This is necessary because it is possible for the card state to change while the host driver clears this bit, and the interrupt event may not be generated. When the CIN bit is cleared, if a card is inserted it is immediately set again: this can be prevented by clearing the card inserted status enable bit in interrupt status enable register. 0 Card state unstable or removed 1 Card inserted
5 BRR	Buffer read ready. This status bit is set when the buffer read enable bit changes from 0 to 1. Refer to the buffer read enable bit in the present state register description for additional information. 0 Not ready to read buffer 1 Ready to read buffer
4 BWR	Buffer write ready. This status bit is set when the buffer write enable bit changes from 0 to 1. Refer to the buffer write enable bit in the present state register description for additional information. 0 Not ready to write buffer 1 Ready to write buffer:
3 DINT	DMA interrupt. Occurs only when the internal DMA (simple DMA or ADMA) finishes the data transfer successfully. When errors occur during data transfer, this bit is not set: the DMAE bit is set instead. 0 No DMA interrupt 1 DMA interrupt is generated

Table 20-18. Interrupt Status Register Field Descriptions (Continued)

Field	Description
2 BGE	Block gap event. If the stop at block gap request bit in the protocol control register is set to 1, this bit is set when a read or write transaction is stopped at a block gap. If the stop at block gap request is not set to 1, this bit is not set to 1. For read transactions, this bit is set at the falling edge of the DAT line active status signal (when the transaction is stopped at SD bus timing). Read wait must be supported in order to use this function. For write transactions, this bit is set at the falling edge of the write transfer active status signal (after getting CRC status at SD bus timing). 0 No block gap event 1 Transaction stopped at block gap
1 TC	Transfer complete. This bit is set when a read or write transfer is completed. For read transactions, this bit is set at the falling edge of the read transfer active status signal. There are two cases in which the transfer complete interrupt is generated: • When a data transfer is completed as specified by the data length (after the last data has been read to the host system). • When data has stopped at the block gap and completed the data transfer by setting the stop at block gap request bit in the Protocol Control register (after valid data has been read to the host system). For write transactions, this bit is set at the falling edge of the DAT line active status signal. There are two cases in which this interrupt is generated: • When the last data is written to the SD card as specified by the data length and the busy signal is released. • When data transfers are stopped at the block gap, by setting the stop at block gap request bit in the protocol control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). 0 Transfer not complete 1 Transfer complete
0 CC	Command complete. This bit is set when the end bit of the command response is received (except auto CMD12). This bit is set to 1 when the command inhibit (CMD) bit in the present state register is cleared. 0 Command not complete 1 Command complete

Table 20-19 shows the eSDHC status associated with different settings of the command timeout error and command complete bits.

Table 20-19. eSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete Bit	Command Timeout Error Bit	eSDHC Status
0	0	—
0 or 1	1	Response not received within 64 SD_CLK cycles
1	0	Response received

Table 20-20 shows the eSDHC status associated with different settings of the transfer complete and the data timeout error bits.

Table 20-20. eSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete Bit	Data Timeout Error Bit	eSDHC Status
0	0	—
0	1	Timeout occurred during transfer
1	0 or 1	Data transfer complete

Table 20-21 shows the eSDHC status associated with different settings of the command CRC error and command timeout error bits.

Table 20-21. eSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command CCR Error Bit	Command Timeout Error Bit	eSDHC Status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

20.3.3.11 Interrupt Status Enable Register (IRQSTATEN)

Setting bits in this register to 1 enables the corresponding interrupt status register bits to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is cleared and remains 0.

Figure 20-14 shows the register. Table 20-22 describes the register fields.

Offset BASE +0034 (IRQSTATEN) Access: User read/write

2 BGESEN	Block gap event status enable 0 Masked 1 Enabled
1 TCSEN	Transfer complete status enable 0 Masked 1 Enabled
0 CCSEN	Command complete status enable 0 Masked 1 Enabled

NOTE

Depending on the setting of the IABG bit in the protocol control register, eSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold this value in the flip-flop. This can cause a delay between the assertion of the card interrupt signal and notification of the host system.

To detect a CMD line conflict, the host driver sets both the command timeout error status enable bit and the command CRC error status enable bit to 1.

20.3.3.12 Interrupt Signal Enable Register (IRQSIGEN)

This register is used to select the events which are signaled to the host system as interrupts (these status bits all share the same interrupt line). When a bit in this register is set to 1, then setting the corresponding interrupt status register bit to 1 generates an interrupt.

Figure 20-15 shows the register. Table 20-23 describes the register fields.

Offset BASE +0038 (IRQSIGEN) Access: User read/write

20.3.3.13 Auto CMD12 Error Status Register (AUTOC12ERR)

When the auto CMD12 error status bit in the status register is set to 1, the host driver checks this register to identify the source of auto CMD12 errors. This register is valid only when the auto CMD12 error status bit in the status register is set to 1.

Figure 20-16 shows the register. Table 20-24 describes the register fields.

Offset BASE +003C (AUTOC12ERR) Access: User read

Figure 20-16. Auto CMD12 Error Status Register (AUTOC12ERR)

Table 20-24. Auto CMD12 Error Status Register Field Descriptions

Field	Description
31–8	Reserved, read as 0
7 CNIBAC12E	Command not issued by auto CMD12 error. This bit is set to 1 when CMD_wo_DAT is not executed due to an auto CMD12 error (D04–D01) in this register. 0 No error 1 Not issued
6–5	Reserved, read as 0
4 AC12IE	Auto CMD12 index error. Indicates that a command index error occurred in response to a command. 0 No error 1 Error, the CMD index in response is not CMD12
3 AC12CE	Auto CMD12 CRC error. Indicates a CRC error in the command response. 0 No CRC error 1 CRC Error Met in auto CMD12 Response
2 AC12EBE	Auto CMD12 end bit error. indicates the end bit of command response is 0 which should be 1. 0 No error 1 End Bit Error Generated

Table 20-24. Auto CMD12 Error Status Register Field Descriptions (Continued)

Field	Description
1 AC12TOE	Auto CMD12 timeout error. Indicates that no response is returned within 64 SD_CLK cycles after the end bit of the command. If this bit is set to1, then the other error status bits (2–4) are not valid. 0 No error 1 Time out
0 AC12NE	Auto CMD12 not executed. This bit is set to 1 when the eSDHC cannot issue the auto CMD12 to stop a memory multi-block data transfer due to some error. In case the memory multi-block data transfer is not started due to a command error, this bit is not set because it is not necessary to issue an auto CMD12. If this bit is set to 1, other error status bits (1-4) have no meaning. 0 Executed 1 Not executed

Table 20-25 shows error types associated with different auto CMD12 CRC error and auto CMD12 command timeout error bit settings.

Table 20-25. Command CRC Error and Command Timeout Error Bit Settings and Error Types

Auto CMD12 CRC Error Bit	Auto CMD12 Timeout Error Bit	Type of Error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

When issuing auto CMD12 commands, the eSDHC sets bits in the auto CMD12 error status register according to the following steps:

1. Before issuing an auto CMD12 command, the eSDHC sets the auto CMD12 not executed bit (bit 0) of the auto CMD12 error status register if the auto CMD12 cannot be issued due to an error in the previous command.
2. If the auto CMD12 is issued, then the auto CMD12 not executed bit (bit 0) is cleared.
3. At the end bit of an auto CMD12 response, the eSDHC checks errors corresponding to bits 0–4 (AC12IE, AC12CE, AC12EBE, and AC12TOE) and sets the bit if the corresponding error is detected.
4. Before reading the command not issued by auto CMD12 error bit (bit 7) the eSDHC sets bit 7 to 1 if there is a command that cannot be issued, and clears bit 7 if there is no command to issue.

Auto CMD12 errors and writes to the command register are asynchronous. After an auto CMD12 command, bit 7 is sampled when the driver is not writing to the command register. The driver can avoid problems by setting the AC12E bit in the interrupt status register before reading this register. An auto CMD12 error interrupt is generated when one of the error bits (0–4) is set to 1. The command not issued by auto CMD12 error does not generate an interrupt.

20.3.3.14 Host Controller Capabilities Register (HOSTCAPBLT)

This register provides the host driver with information specific to the eSDHC implementation. The value in this register is the same as at power-on reset, and does not change during a software reset. Any write to this register is ignored.

Figure 20-17 shows the register. Table 20-26 describes the register fields.

Offset BASE +0040 (HOSTCAPBLT) Access: User read

Figure 20-17. Host Controller Capabilities Register (HOSTCAPBLT)

Table 20-26. Host Capabilities Register Field Descriptions

Field	Description
31–27	Reserved, read as 0
26 VS18	Voltage support 1.8V. This bit's setting depends on the host system ability. 0 1.8V not supported 1 1.8V supported
25 VS30	Voltage support 3.0 V. This bit's setting depends on the host system ability. 0 3.0 V not supported 1 3.0 V supported
24 VS33	Voltage support 3.3 V. This bit's setting depends on the host system ability. 0 3.3 V not supported 1 3.3 V supported
23 SRS	Suspend/Resume support. This bit indicates whether the eSDHC supports Suspend/Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the host driver does not issue either Suspend or Resume commands. 0 Not supported 1 Supported
22 DMAS	DMA support. This bit indicates whether the eSDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 0 DMA not supported 1 DMA supported

Table 20-26. Host Capabilities Register Field Descriptions (Continued)

Field	Description
21 HSS	High-speed mode support. This bit indicates whether the eSDHC supports High-speed mode and the Host System can supply a SD clock frequency from 25 MHz to 50 MHz. 0 High-speed not supported 1 High-speed supported
20 ADMAS	ADMA support. This bit indicates whether the eSDHC supports the ADMA feature. 0 Advanced DMA not supported 1 Advanced DMA supported
19	Reserved, read as 0
18–16 MBL[2:0]	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the eSDHC's buffer. The buffer transfers blocks up to this size without wait cycles. 000512 bytes 0011024 bytes 0102048 bytes 0114096 bytes
15–0	Reserved, read as 0

20.3.3.15 Watermark Level Register (WML)

This register configures watermark levels (FIFO thresholds) and burst lengths for write and read. Watermark levels can range from 1–128 words; burst lengths can range from 1–31 words.

Figure 20-18 shows the register. Table 20-27 describes the register fields.

Offset BASE +0044 (WML) Access: User read/write

Figure 20-18. Watermark Level Register (WML)

Table 20-27. Watermark Level Register Field Descriptions

Field	Description
31–29	Reserved, read as 0
28–24 WR_BRST_LEN[4:0]	Write burst length. The number of words the eSDHC writes in a single burst. The write burst length must not exceed the write watermark level, and all bursts within a watermark level transfer are in back-to-back mode. This field resets to 01000. The field cannot be cleared: writing 0 to this field results in the reset value 01000. **Note:** Due to system restrictions, the actual burst length does not exceed 16.
23–16 WR_WML[7:0]	Write watermark level. The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words in a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 127. The reset write watermark level is 16.
15–13	Reserved, read as 0
12–8 RD_BRST_LEN[4:0]	Read burst length. The number of words the eSDHC reads in a single burst. The read burst length must not exceed the read watermark level, and all bursts within a watermark level transfer are in back-to-back mode. This field resets to 01000. The field cannot be cleared: writing 0 to this field results in the reset value 01000. **Note:** Due to system restrictions, the actual burst length does not exceed 16.
7–0 RD_WML[7:0]	Read watermark level. The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words in a sequence of read bursts in back-to-back mode. The maximum legal value for the read watermark level is 127. The reset read watermark level is 16.

20.3.3.16 Force Event Register (FEVT)

The force event register is not a physically-implemented register, but rather an address where the interrupt status register can be written if the corresponding bit of the interrupt status enable register is set. Writing 1's to this register sets the corresponding bits in the interrupt status register. This register is a write-only register: reads always return zero. Writing zero to the register has no effect.

When writing to this register to change status bits in the interrupt status register, the driver is responsible to ensure that the ipg_clk is active by setting the IPGEN bit in the system control register.

Figure 20-19 shows the register. Table 20-28 describes the register fields.

Offset BASE +0050 (FEVT) Access: User write

20 FEVTDTOE	Force event data time out error. Force the DTOE bit of interrupt status register to be set
19 FEVTCIE	Force event command index error. Forces the CCE bit of interrupt status register to be set
18 FEVTCEBE	Force event command end bit error. Forces the CEBE bit of interrupt status register to be set
17 FEVTCCE	Force event command CRC error. Forces the CCE bit of interrupt status register to be set
16 FEVTCCE	Force event command time out error. Forces the CTOE bit of interrupt status register to be set
15–8	Reserved, read as 0
7 FEVTCNIBAC12E	Force event command not executed by auto CMD12 error. Forces the CNIBAC12E bit in the Auto CMD12 Error Status Register to be set.
6–5	Reserved, read as 0
4 FEVTAC12IE	Force event auto CMD12 Index error. Forces the AC12IE bit in the auto CMD12 error status register to be set.
3 FEVTAC12EBE	Force event auto CMD12 end bit error. Forces the AC12EBE bit in the auto CMD12 error status register to be set.
2 FEVTAC12CE	Force event auto CMD12 CRC error. Forces the AC12CE bit in the auto CMD12 error status register to be set.
1 FEVTAC12TOE	Force event auto CMD12 time out error. Forces the AC12TOE bit in the auto CMD12 error status register to be set.
0 FEVTAC12NE	Force event auto CMD12 not executed. Forces the AC12NE bit in the auto CMD12 error status register to be set.

20.3.3.17 ADMA Error Status Register (ADMAES

When an ADMA error interrupt occurs, the ADMA error status (ADMAES) field in this register indicates the ADMA error state. To recover from the error, the ADMAES field together with the system address register can be used to determine the address of the error descriptor (see the ADMAES field description in Table 20-29).

In case of a write operation, the host driver should use the ACMD22 to get the number of the written blocks, rather than using this information, since unwritten data may exist in the host controller.

The host controller generates the ADMA error interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

Figure 20-20 shows the register. Table 20-29 describes the register fields

Offset BASE +0054 (ADMAES) Access: User read

Figure 20-21. ADMA System Address Register (ADSADDR)

Table 20-32. ADMA System Address Register Field Descriptions

Field	Description
31–2 ADS_ADDR[31:0]	ADMA system address. This register holds the address of the executing command word in the descriptor table. At the start of ADMA transfer, the host driver sets the start address of the descriptor table. The ADMA engine increments this register address ever y fetch of a descriptor command. When the ADMA is stopped at the block gap, this register indicates the address of the next executable descriptor command. When the ADMA error interrupt is generated, this register holds the valid descriptor address or the next executable descriptor command, depending on the ADMA state (see Table 20-29). The lower 2 bits of this register are tied to '0' so the ADMA address is always word aligned. This register supports dynamic address reflection: when the transfer complete (TC) bit is set in the interrupt status register it automatically alters the value of internal address counter, so software cannot change this register when TC bit is set. Additional software restrictions are listed in Section 20.7, "Software Restrictions."
1–0	Reserved, read as 0

20.3.3.19 Vendor Specific Register (VENDOR)

This register contains the vendor-specific control/status settings.

Figure 20-22 shows the register. Table 20-33 describes the register fields.

Offset BASE + 00C0 (VENDOR) Access: User read/write

Table 20-33. Vendor Specific Register Field Descriptions

Field	Description
31–28	Reserved, read as 0
27–24 DBG_SEL[3:0]	Debug select. Select the internal submodule to show its internal state value.

Table 20-33. Vendor Specific Register Field Descriptions (Continued)

Field	Description
23–16 INT_ST_VAL[7:0]	Internal state value. Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.
15–2	Reserved, read as 0
1 VOLT_SEL	Voltage selection. Changes the value of output signal SD_VS, to control the voltage on the pins for an external card. A control circuit outside of the eSDHC is required to change the actual voltage on the pins. 0 Low voltage range (about 1.8 V) 1 High voltage range (about 3.0 V)
0 EXT_DMA_EN	External DMA request enable. Enables requests to external DMA. When the internal DMA (either simple DMA or advanced DMA) is not in use and this bit is set to 1, then the eSDHC sends out a DMA request when the internal buffer is ready. Clearing this bit disables the external DMA request: this can be useful in CPU polling mode. By default, this bit is set. 0 In any scenario, eSDHC does not send out external DMA request. 1 When internal DMA is not active, an external DMA request is sent out (reset value)

20.3.3.20 Host Controller Version (HOSTVER)

This register contains the vendor host controller version information. All bits are read-only with the same value as on power-on reset.

Figure 20-23 shows the register. Table 20-34 describes the register fields.

20.4 Functional Description

The following subsections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank and IP bus interface, dual-port memory wrapper, data/command controller, clock and reset manager and clock generator.

20.4.1 Data Buffer

The eSDHC uses a configurable data buffer to optimize data transfer between the system bus (IP Bus or AHB bus) in the master clock (hclk) domain, and the SD card in the IP peripheral source clock (ipg_perclk) domain

Figure 20-24 shows the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, from 1–128 words inclusive. The burst lengths for read and write are also configurable, from 1–16 words inclusive (the burst length field of the watermark level register can range from 1–31, but actual burst lengths greater than 16 are not supported).

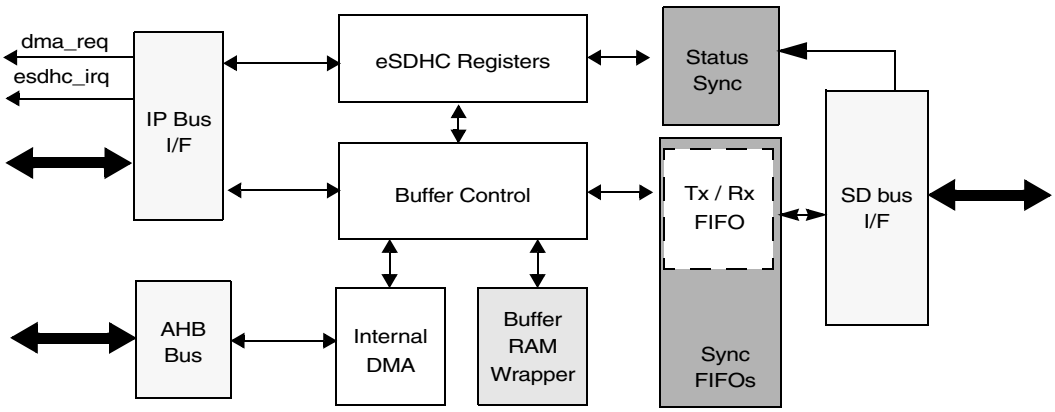

Figure 20-24. eSDHC Buffer Scheme

20.4.1.1 Data Buffer Transfer Modes

There are three transfer modes to access the data buffer:

- External DMA mode
- CPU polling mode
- Internal DMA mode (includes simple and advanced DMA accesses)

These transfer modes are explained in the following subsections

20.4.1.1.1 External DMA Mode

External DMA uses the IP bus. Using external DMA requires that DMAEN bit in the transfer type register be cleared when the DMA request is sent.

For read operations, the eSDHC sends an external DMA request (by asserting the signal esdhc_dreq_b to 0) when the number of words received in the buffer meets or exceeds the read watermark value (RD_WML in the watermark level register). The request is immediately negated when there is an access on the buffer data port register. If the number of words in the buffer after the current burst still meets or exceeds RD_WML value, the DMA request is reasserted, with one idle cycle between successive requests.

Write operations in external DMA mode are similar to read operations, except the write watermark value WR_WML is used instead of RD_WML to determine whether there are sufficiently many empty words in the buffer before the eSDHC sends the external DMA request.

20.4.1.1.2 CPU Polling Mode

CPU polling mode is similar to external DMA mode in that it uses the IP bus, and requires the DMAEN bit in the transfer type register be cleared.

CPU polling mode requires that the BRRIEN bit be set to 1 in the interrupt signal enable register. It differs from external DMA mode in that rather than relying on an external DMA request the host driver polls the BRR bit in the interrupt status register, as follows:

For read operations, when the number of words received in the buffer meets or exceeds the read watermark value (RD_WML field in the watermark level register) the eSDHC sets the BRR bit in the interrupt status register to 1 (this occurs simultaneously with sending the external DMA request). The host driver is responsible to poll the BRR bit, and when it detects that BRR is set it reads the buffer data port register to fetch RD_WML words from the buffer.

Write operation in CPU polling mode requires setting the BWRIEN to 1 in the interrupt signal enable register. Write operations are similar to read operations, except that the write watermark level WR_WML is used instead of RD_WML to determine whether there are sufficiently many empty words in the buffer, and the BWR bit is polled instead of BRR.

20.4.1.1.3 Internal DMA Mode

Internal DMA accesses utilize the AHB bus, and requires that the DMAEN bit in the transfer type register be set to 1 when the DMA request is sent. Unlike external DMA or CPU polling mode, the external DMA request is never sent out.

Internal DMA Read Operations

For internal DMA read operations, when the number of words in the buffer meets or exceeds the watermark level (RD_WML field in the watermark level register) the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8 (for burst lengths 4 and 8, respectively), the burst type is always INCR mode, and the burst length depends on the shortest of following factors:

- Burst length, configured in the burst length field of the watermark level register
- Watermark level boundary
- Remaining number of words in the current block
- Data boundary, configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

When internal DMA is used, if no error is encountered the eSDHC does not inform the system before the required number of bytes are transferred. When an error occurs during the data transfer, the eSDHC aborts the data transfer and abandon the current block. The host driver is responsible to read the contents of the DMA system address register to find the starting address of the abandoned data block. If the current data transfer is in multi block mode, the eSDHC does not automatically send CMD12, even though the AC12EN bit in the transfer type register is set. Instead, it is the host drivers responsibility to send CMD12 and restart the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted after error recovery.

The eSDHC does not start data transmission until the number of words in the buffer meets or exceeds the read watermark level RD_WML. If the buffer is full and the host system does not read data in time, the eSDHC stops SD_CLK to avoid a data buffer overrun.

Internal DMA Write Operations

Write operations in internal DMA mode are similar to read operations, except that the write watermark level WR_WML is used to determine whether there are sufficiently many empty words in the buffer.The eSDHC does not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the host system does not write data in time, the eSDHC stops SD_CLK to avoid a data buffer under-run situation.

20.4.1.2 Data Addressing and Byte Ordering

Sequential and contiguous access is necessary to update the pointer address value correctly. Random or skipped access is not possible. On reset, byte ordering is set to little endian mode. The actually byte order is swapped inside the buffer according to the endian mode configured by software, as shown in Figure 20-25 and Figure 20-26. For a host write operation, byte order is swapped after data is fetched from the buffer and before it is sent to the SD bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

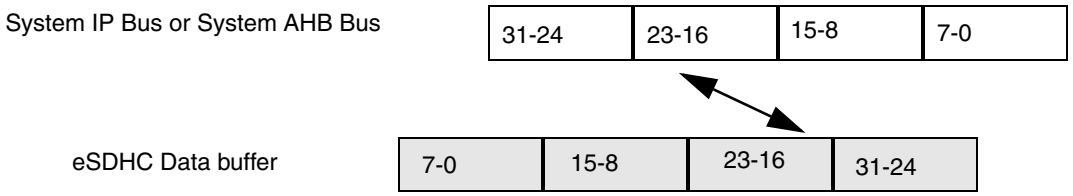

Figure 20-25. Data Swap between System Bus and eSDHC Data Buffer in Byte Little Endian Mode

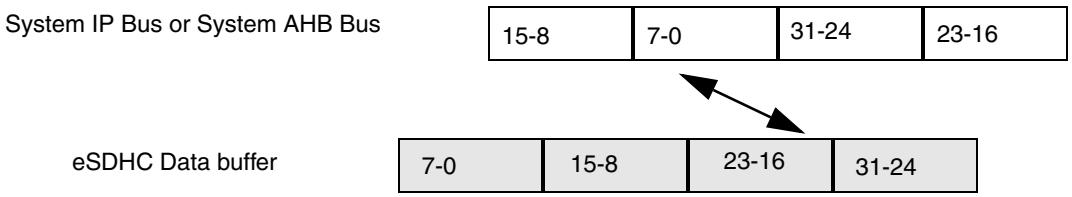

Figure 20-26. Data Swap Between System Bus and eSDHC Data Buffer in Half Word Big Endian Mode

20.4.1.3 Data Transfer Parameter Settings

In the eSDHC, the data buffer holds up to 127 4-byte words. The watermark levels for write and read can be configured from 1–127 words inclusive. For both read and write, the burst length, can be from 1–16 words inclusive (the burst length field in the watermark level ranges from 1–31, but actual burst lengths greater than 16 are not supported). The host driver is responsible to configure these values according to the system situation and requirements.

During a multi-block data transfer, the block size may be set to any value between 1 and 4096 bytes. However, additional restrictions may be imposed by the external card, which may not support large block sizes and/or partial block accesses.

For block size that are not multiples of four (that is, not word-aligned), the eSDHC requires stuff bytes at the end of each block (this is because the eSDHC treats each block individually). For example, if the block size is 7 bytes and the write is 12 blocks, the system side does 2 writes for each block, and the last byte for each block is discarded by eSDHC since it only sends 7 bytes to the card, then picks data from the following system write. Thus in this example there are 24 total beats required for the write.

20.4.1.3.1 Dividing Large Data Transfers

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multi-block transfer must be an integer multiple of the block size. If the total data length is not a multiple of the block size then there are two ways to transfer the data, depending on the function and the card design:

- The host driver splits the transaction, and fractional block portion of data is transferred using a second (single block) transfer.
- Dummy data is added to fill the last block. In this case, the card must manage the removal of the dummy data.

Figure 20-27 shows an example of a large data transfer using a WLAN SDIO card that only supports block sizes up to 64 bytes. In this case, 544 bytes are divided into eight 64-byte blocks plus 32 bytes, which are transferred using two separate CMD53 commands.

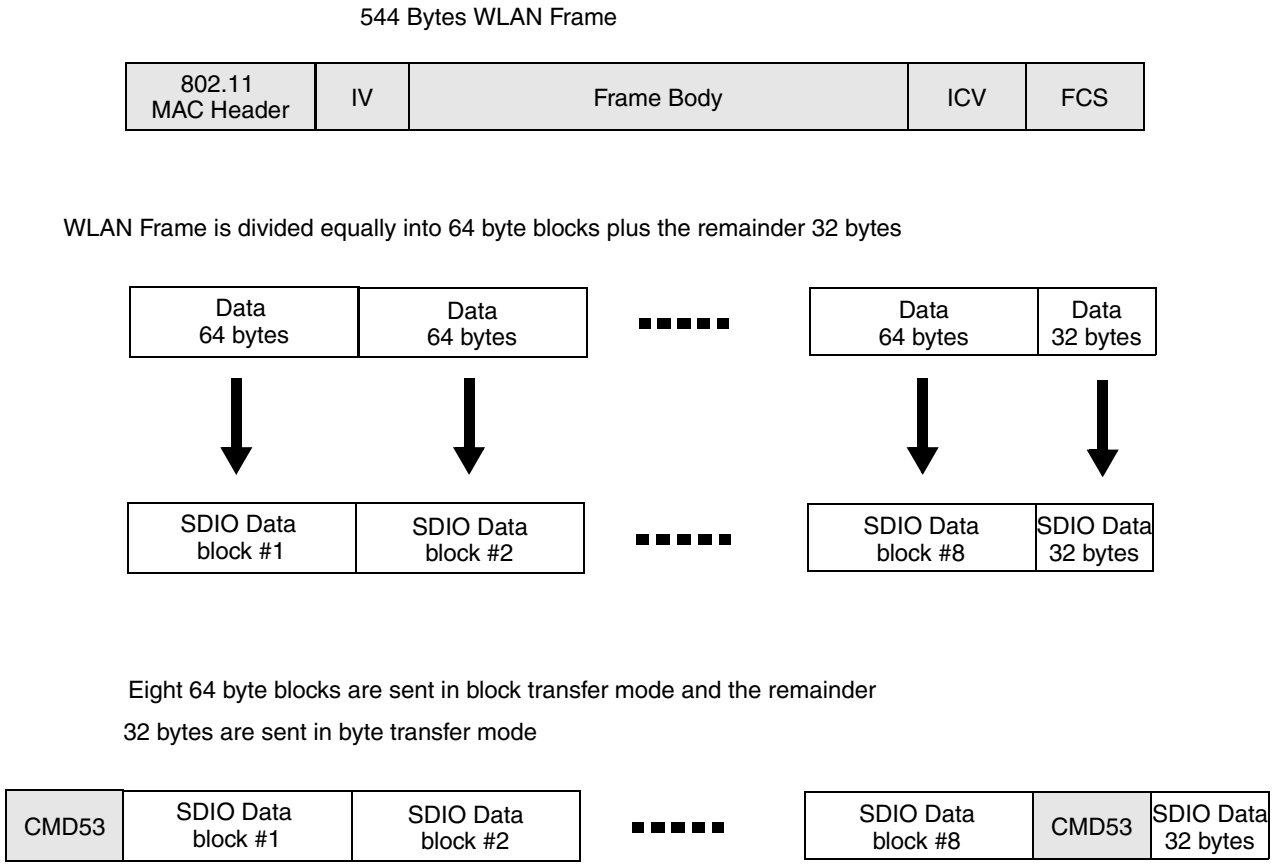

Figure 20-27. Example for Dividing Large Data Transfers

20.4.1.4 Data Transfer Parameters for External DMA Requests

[In external DMA transfer mode, since the DMA burst length cannot change during a data transfer it is necessary that the watermark level (read or write) must be a divisor of the block size (in word units): otherwise, transferring of the block may cause buffer underrun (for reads) or overrun (for writes). This implies for example that a block size of 512 bytes (128 words) requires that read and write watermark levels must be a power of two between 1 and 128 inclusive.

In CPU polling mode there are no such restrictions on the watermark levels, because the last access in the block transfer can be controlled by software. The watermark levels can even be larger than the block size (but no greater than 128 words). The actual number of bytes in each transfer is controlled by software, and does not exceed the block size.

Non-word–aligned block sizes are supported in CPU polling mode, as long as the card supports that block size. For example, the block size can be set at 31 bytes (if supported by the card), and the watermark level and burst length can take any allowed value. This is because the software transfers 8 words, and the eSDHC also sets the BRR or BWR bits (for reads or writes, respectively) when the remaining data satisfies watermark level conditions. Even though 8 words are transferred via the data port register, the eSDHC

transfers only 31 bytes over the SD bus, as required by the BLKSIZE bits. In data transfers with non-word aligned block sizes, the endian mode should be set carefully, or invalid data can be transferred to/from the card.

20.4.1.5 Data Transfer Parameters for Internal DMA Requests

Internal DMA data transfers are in block units, and the host driver is responsible to set the watermark level as the minimum remaining number of words remaining in a block following a series of burst transfers. For instance, consider a multi-block read with block size 31 bytes and burst length set to 6 (4-byte) words. After the first burst transfer, there are 7 (= 31 – 4*6) bytes remaining to be read from the first block: the remaining data occupies 2 words. The host driver sets the read watermark level as 2 words, so that another DMA request is sent if there are 2 or more words in the buffer (which might contain some data from the next block). The eSDHC reads 2 words out of the buffer, which include 7 valid bytes and 1 stuff byte.

The DMA burst length for the internal DMA engine can be from 1 to 16 words inclusive, just as in CPU polling mode. The actual burst length for the DMA depends on the smaller of the configured burst length and the remaining words of the current block. In the above example with block size 31 bytes and burst length set to 6, the actual burst lengths alternate between 6 and 2 words. The host driver is responsible to take this variable burst length into account. One option is to configure the burst length as a divisor of the block size, so that the burst length does not need to vary.

20.4.2 DMA AHB Interface

Figure 20-28 shows the DMA AHB interface block. The internal DMA AHB interface includes a DMA engine and the AHB master.

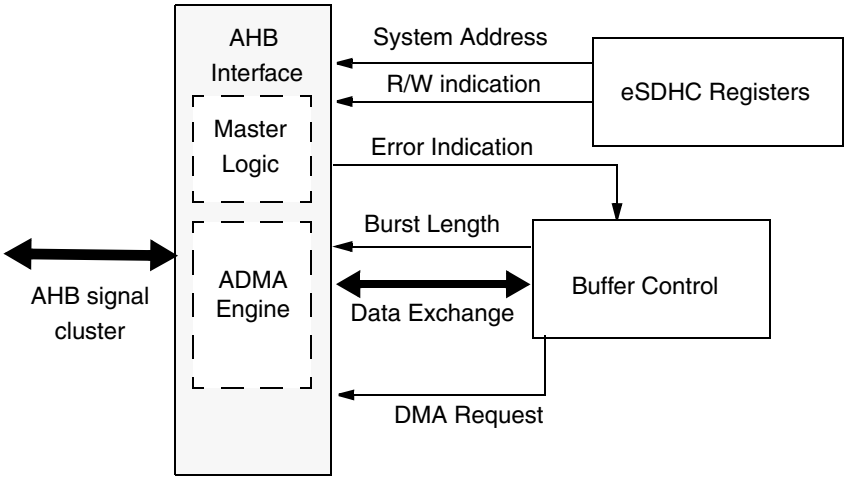

Figure 20-28. DMA AHB Interface Block

20.4.2.1 Internal DMA Requests

Internal DMA transfers are enabled by setting the DMAEN bit in the transfer type register. The external DMA request signal (esdhc_dreq_b) is disabled: however, the BRR and BWR bits in the interrupt status register are still valid, as long as the BRRSEN and BWRSEN bits have been set in the interrupt status

enable register. See Section 20.4.1.1.3, “Internal DMA Mode” for more details about internal DMA transfers.

If the watermark level requirement is met, the data buffer block sends a DMA request to the AHB interface. There is a delay in the internal DMA engine’s response that depends on the system AHB bus loading and the priority assigned to the eSDHC. The DMA engine does not respond to a request during burst transfers, but is ready to serve as soon as the burst is over. The data buffer negates the request after the buffer is accessed. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and if the watermark level requirement is satisfied another DMA request is sent.

20.4.2.2 AHB Master Interface

If the internal AHB DMA engine fails during the data transfer, the following actions occur:

- The DMA engine stops the transfer and goes to the idle state
- The internal data buffer stops accepting incoming data.
- The DMAE bit in the interrupt status register is set to inform the driver.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and reads the DS_ADDR bits of the DMA system address register to get the starting address of the corrupted block. After the DMA error is fixed, the software applies a data reset and restarts the transfer from this address to recover the corrupted block.

20.4.2.3 ADMA Engine

The ADMA (Advanced DMA) transfer algorithm is defined in the SD Host Controller Standard. In contrast with simple DMA transfers, which generate a DMA interrupt at each page boundary so that the host driver can program a new system address, ADMA transfers define a programmable descriptor table in the system memory. The host driver can then calculate the system address at the page boundary and program the descriptor table before executing ADMA. This enables higher speed DMA transfers, because host intervention is not needed during long DMA-based data transfers.

The eSDHC implements two types of ADMA: ADMA1 and ADMA2. ADMA1 supports data transfers of 4-KB–aligned data in system memory. ADMA2 supports data transfers of any size from any location in system memory. ADMA1 and ADMA2 have different descriptor table formats, which are described in Section 20.4.2.3.1, “ADMA1 Descriptor Tables”.

The ADMA engine recognizes all descriptor types defined in the SD Host Controller Standard. The ADMA1 and ADMA2 descriptors are described in Section 20.4.2.3.1, “ADMA1 Descriptor Tables” and Section 20.4.2.3.2, “ADMA2 Descriptor Tables,” respectively.

20.4.2.3.1 ADMA1 Descriptor Tables

ADMA1 includes the following descriptor types:

- No operation (Nop): No operation is performed, pointer passes to the next descriptor
- Set data length (Set): Specifies data length for the next data transfer
- Transfer data (Tran): Initiates data transfer

- Link descriptor (Link): Links to the next descriptor in the table, at a non-consecutive location in system memory

Descriptors also contain interrupt, end, and valid/invalid flag bits which inform the ADMA engine of the descriptor's status.

Figure 20-29 shows the ADMA1 descriptor format. Table 20-35 describes the ADMA1 field settings corresponding to each descriptor type, and Table 20-36 describes the interrupt, end, and valid/invalid flag bits.

Figure 20-29. ADMA1 Descriptor Format

Address/Page Field		Address/Page Field		Attribute Fields					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act2	Act1	0	Int	End	Valid

Table 20-35. ADMA1 Descriptor Type Field Settings

Descriptor Type Abbreviation	Descriptor Type Name	Descriptor Field Settings			
		31:12 Address/Page	27:12 Address/Page	5 Act2	4 Act1
Nop	No Operation	Don't Care		0	0
Set	Set Data Length	0000	Data Length	0	1
Tran	Transfer Data	Data Address		1	0
Link	Link Descriptor	Descriptor Address		1	1

Table 20-36. ADMA1 Descriptor Flag Bit Descriptions

Flag Bit	Description
Int (Bit 2)	Int =1 generates a DMA interrupt when this descriptor is processed.
End (Bit 1)	End = 1 indicates current descriptor is the last one in the table.
Valid (Bit 0)	Valid =1 indicates the descriptor is effective. If Valid = 0, the ADMA engine generates an ADMA error interrupt and stops the ADMA.

Figure 20-30 shows the ADMA1 descriptor table structure and its accesses by the ADMA engine. Every Tran type descriptor triggers a data transfer, with data length specified by the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length from the previous transfer is used. If no Set descriptor has been read, the data length is 0.

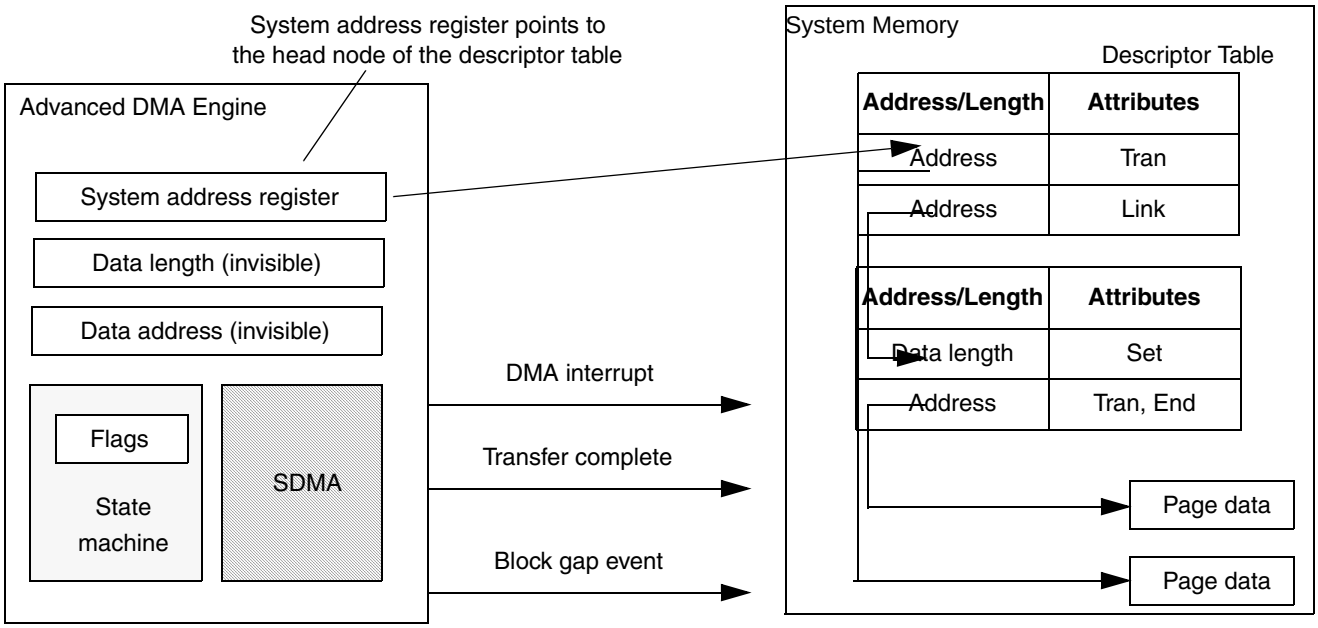

Figure 20-30. ADMA1 Descriptor Table and Access by the ADMA Engine

20.4.2.3.2 ADMA2 Descriptor Tables

ADMA2 includes the following descriptor types:

- No operation (Nop): No operation is performed, pointer passes to the next descriptor
- Reserved (Rsv): No operation is performed, passes to the next descriptor (same as Nop)
- Transfer data (Tran): Transfers data with address and length set in this descriptor line
- Link descriptor (Link): Links to the next descriptor in the table, at a non-consecutive location in system memory

Descriptors also contain interrupt, end and valid/invalid flag bits which inform the ADMA engine of the descriptor's status.

Figure 20-31 shows the ADMA2 descriptor format. Table 20-35 describes the ADMA2 Act*n* bit settings corresponding to each descriptor type, and Table 20-36 describes the interrupt, end, and valid/invalid flag bits.

Figure 20-31. ADMA2 Descriptor Format

Address Field		Length Field		Reserved		Attribute Fields					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit address		16-bit length		0000000000		Act2	Act1	0	Int	End	Valid

Table 20-37. ADMA2 Descriptor Type Field Settings

Descriptor Type Abbreviation	Descriptor Type Name	Act*n* Bit Settings		Descriptor Operation
		5 Act2	4 Act1	
Nop	No Operation	0	0	No operation: read this line and go on to the next
Rsv	Reserved	0	1	No operation: read this line and go on to the next
Tran	Transfer data	1	0	Transfer data with address and length set in this descriptor line
Link	Link descriptor	1	1	Links to the next descriptor in the table, at a non-consecutive location in system memory

Table 20-38. ADMA2 Descriptor Flag Bit Descriptions

Flag Bit	Description
Int (Bit 2)	Int =1 generates a DMA interrupt when this descriptor is processed.
End (Bit 1)	End = 1 indicates current descriptor is the last one in the table.
Valid (Bit 0)	Valid =1 indicates the descriptor is effective. If Valid = 0, the ADMA engine generates an ADMA error interrupt and stops the ADMA.

Figure 20-32 shows the ADMA2 descriptor table structure and its accesses by the ADMA engine. The ADMA engine first processes the descriptor's lower 32 bits, before reading the upper 32 bits. If the Valid flag (bit 0) of the descriptor is 0, the upper 32 bits are ignored. The address field contains word-aligned addresses, so the lowest 2 bits are always set to 0. The data length is specified in bytes.

ADMA2 read/write operations are initiated by Tran descriptors, and use the data length and address specified in the descriptor itself.

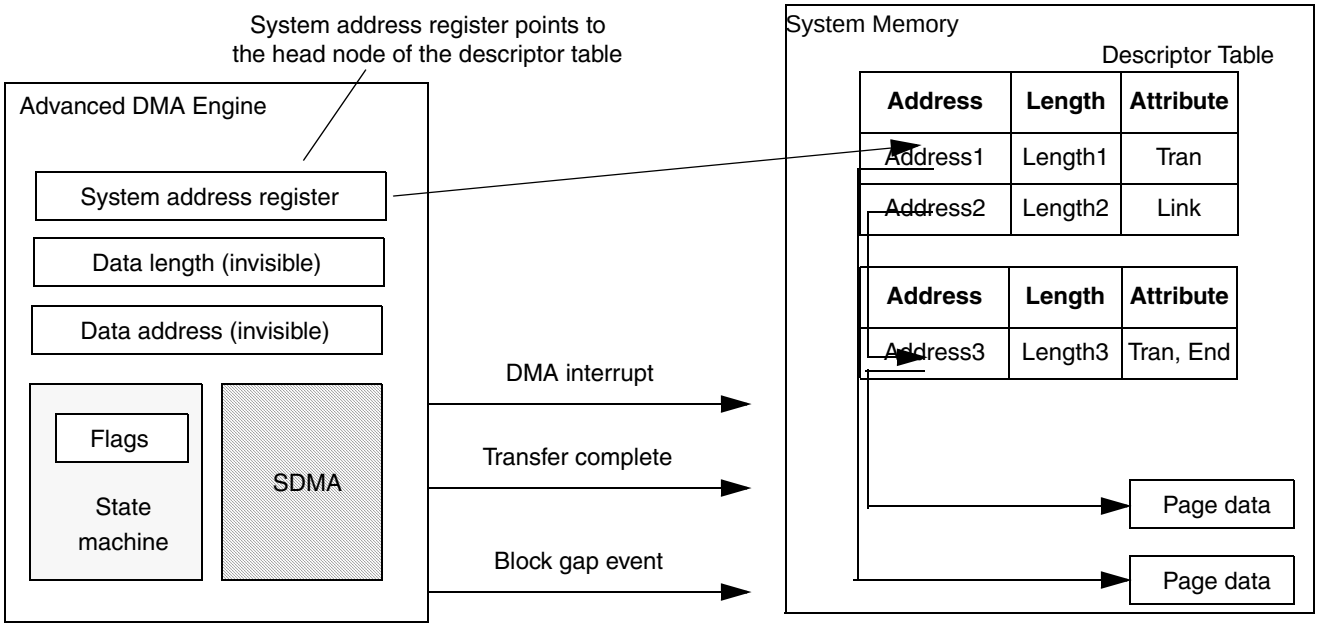

Figure 20-32. ADMA2 Descriptor Table and Access by the ADMA Engine

20.4.2.3.3 ADMA Interrupts

If the Interrupt flag (bit 2) of a descriptor is set, the ADMA engine generates an interrupt according to descriptor type, as follows:

- Nop descriptor: interrupt is generated after the descriptor is fetched
- Rsv descriptor (ADMA2 only): interrupt is generated after the descriptor is fetched
- Set descriptor (ADMA1 only): interrupt is generated after the data length is set
- Tran descriptor: interrupt is generated after this transfer is completed
- Link descriptor: interrupt is generated after the new descriptor address is set.

20.4.2.3.4 ADMA Errors

The ADMA stops execution when the following errors are encountered:

- Descriptor error, generated when the valid flag in the descriptor is cleared. If an ADMA descriptor error occurs, no interrupt is generated, even if the Interrupt flag of this descriptor is set.
- AHB response error
- Data length mismatch error, generated under either of the following conditions:
  - The block count enable bit (BCEN) in the transfer type register is set, and the total data length specified by the descriptor table is different from that specified by the block count and block size.
  - The BCEN bit is cleared, and the total data length is not a multiple of the block size

20.4.3 Register Bank Access Via IP Bus Interface

The IP bus-accessible registers are contained in the register bank. Figure 20-33 is a block diagram of the register bank. Only 32-bit accesses are allowed, and no partial read/writes are supported. All accesses are word aligned (the lowest two address bits are tied to 0).

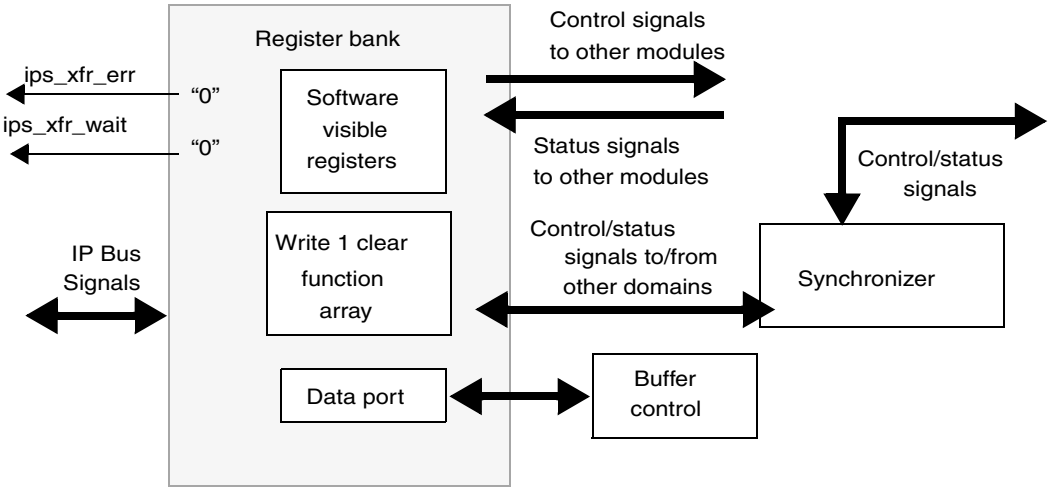

Figure 20-33. Register Bank Diagram

20.4.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs, and performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors interrupts from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when the buffer announces danger status
- Detects the write-protect state

The SD protocol unit consists of four submodules:

- SD transceiver
- SD clock and monitor
- Command agent
- Data agent

20.4.4.1 SD Transceiver

The transceiver is the main control submodule in the SD protocol unit. It consists of a finite state machine (FSM) and a control module, from which the control signals for the other three submodules are generated.

20.4.4.2 SD Clock and Monitor

This submodule monitors the signal level on all 8 data lines and the command lines, and directly routes the level values into the register bank. The driver can use these values for debug purposes.

This submodule detects the card detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the protocol control register is set.

In addition this submodule detects the write protect (WP) line, and informs the register bank when the WP switch is on. When the WP switch is on, the register bank ignores commands involving a write operation.

If the internal data buffer is in danger of overrun or underrun, this submodule asserts the gates off the SD clock. The SD clock is gated on again when the system access of the buffer catches up.

This submodule also drives the LED control output signal (SD_LCTL) when the LCTL bit is set by the driver.

20.4.4.3 Command Agent

The command agent deals with the transactions on the CMD line. Figure 20-34 shows the command CRC shift register.

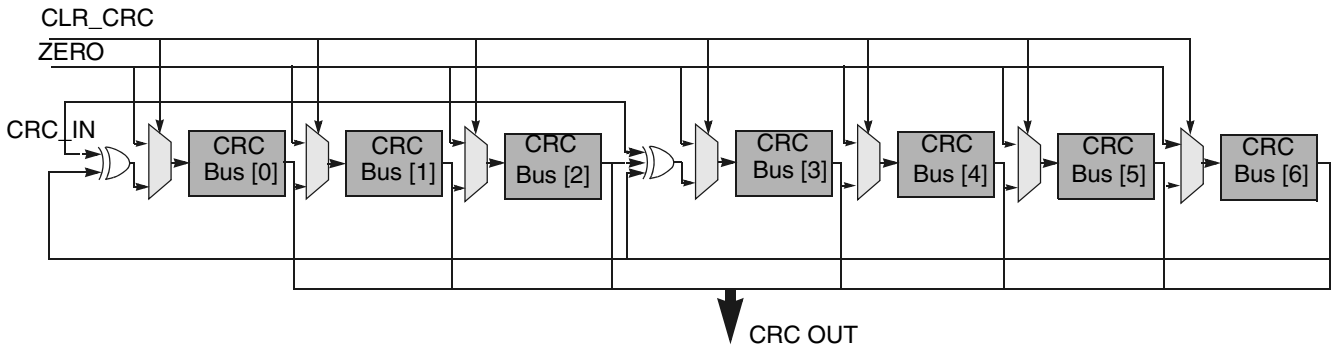

Figure 20-34. Command CRC Shift Register

The CRC polynomial for CMD is computed as follows:

$$\text{Generator polynomial: } G(x) = x^7 + x^3 + 1$$
$$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$$
$$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$$

20.4.4.4 Data Agent

The data agent deals with the transactions on the eight data lines. This module also detects the busy state from the DAT[0] line, and generates the read wait state when requested by the transceiver.

The CRC polynomials for DAT are computed as follows:

$$\text{Generator polynomial: } G(x) = x^{16} + x^{12} + x^5 + 1$$
$$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$$
$$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$$

20.4.5 Clock and Reset Manager Submodule (CRM)

The CRM controls all the reset signals within the eSDHC, which can be classified as four types:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

Reset signals are fed into the CRM, and stable signals are generated inside the CRM to reset all other modules.

The CRM also monitors the activities of all other eSDHC submodules, supplies the clocks for them and (when enabled) automatically gates off the corresponding clocks. Clocks used by the eSDHC include IPG clock (ipg_clk), peripheral source clock (ipg_perclk), and master clock (hclk).

20.4.6 SD Clock Generator

The SD clock generator generates the SD clock (SD_CLK) signal from the peripheral source clock by dividing in two stages. Refer to Figure 20-35 for the structure of the divider.

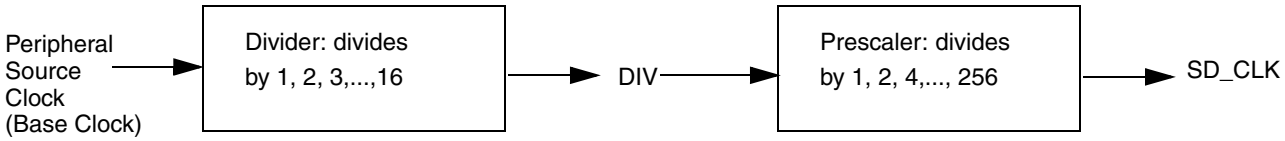

Figure 20-35. Two Stages of the Clock Divider

The SD_CLK signal which is output from the clock divider drives the clocks for all submodules of the SD protocol unit, and for the sync FIFOs to synchronize with the data rate in the internal data buffer (see Figure 20-24).

The divider and prescaler values are determined by the DVS and the SDCLKF bits in the system control register. For example, if the peripheral source clock frequency (ipg_perclk) is 96 MHz, and the target SD_CLK frequency is 25 MHz, then choosing SDCLKF as 0x01 (divide by 2) and DVS as 0x1 (divide by 2) yields an SD_CLK frequency 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to obtain a SD_CLK frequency of 400 kHz, SDCLKF = 0x08 and DVS = 0xE yields the exact clock value of 400 kHz. The highest SD_CLK frequency is equal to the base clock's (peripheral source clock); the second highest frequency is base/2; the lowest frequency is base/4096. The ipg_perclk is about 96 MHz: the reset values of SDCLKFS and DVS correspond to divides of 256 and 1 respectively, so the SD clock frequency after reset is 375 kHz.

According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and must never exceed this limit.

If the peripheral source clock has duty cycle of 50% (which is usually true), then the duty cycle of SD_CLK is also 50%.

20.4.7 SDIO Card Interrupts

20.4.7.1 Interrupts in 1-Bit Mode

In 1-bit mode the DAT[1] signal is dedicated to providing the interrupt function. An interrupt is asserted by pulling DAT[1] low from the SDIO card, until the interrupt service routine clears the interrupt.

20.4.7.2 Interrupts in 4-Bit Mode

In 4-bit mode the interrupt and data line 1 share pin 8. To accommodate this sharing, the eSDHC treats pin 8 as an interrupt only during specified time intervals known as interrupt periods. At all other times, the level on pin 8, is treated as a data signal.

The definition of the interrupt period is different for single-block and multi-block data transfers:

- For single-block transfers, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until the card has received the end bit of the next command that has a data block transfer associated with it.

- For multi-block data transfers, the interrupt period is limited to two clock cycles, due to the limited time between blocks. The interrupt period begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line is held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the interrupt period, the card releases the DAT[1] line into the high Z state. The eSDHC samples the DAT[1] during the interrupt period when the IABG bit in the protocol control register is set.

Refer to SDIO Card Specification v1.10f for further information about SDIO card interrupts.

20.4.7.3 Card Interrupt Handling

Before servicing a card interrupt, the host driver is responsible to clear the card interrupt interrupt enable (CINTIEN) bit in the interrupt signal enable register. This prevents inadvertent interrupts from occurring while the interrupt is being serviced. After all interrupt requests from the card are cleared, it is the host driver's responsibility to reset this bit to 1.

The SDIO status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the eSDHC will detect the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the host driver needs to start the interrupt service routine, the SDIO bit in the Interrupt Control Register. of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the eSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO interrupt enable bit is set to 1, and the eSDHC starts sampling the interrupt signal again.

Figure 20-36 shows the system's interrupt-handling features, and also shows a flowchart that summarizes the interrupt detection and handling procedure.

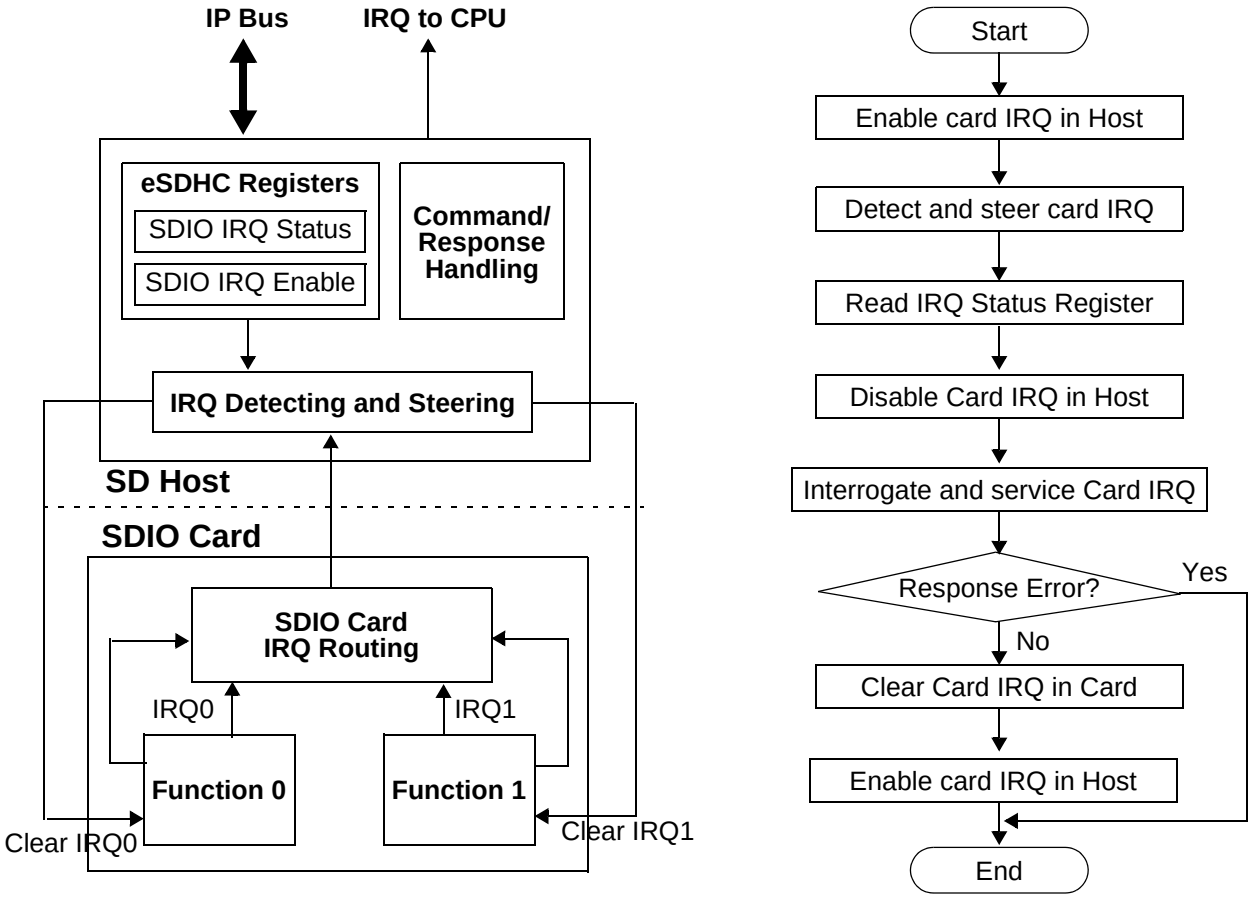

Figure 20-36. Card Interrupt-Handling Features and Card Interrupt-Detection and Handling Procedure

20.4.8 Card Insertion and Removal Detection

The eSDHC uses either the DAT[3] or the SD_CD signal to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] is pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the eSDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. Whether DAT[3] signal is used for card detection or not, the SD_CD pin must be connected for card detection. It may be implemented by a GPIO. The SD_CD pin is always used as a reference for card detection. If either the DAT[3] or SD_CD signal reports card inserted, the eSDHC informs the host system that a card is inserted and an interrupt is sent if it is enabled.

20.4.9 Power Management and Wakeup Events

The eSDHC offers a power management feature: by clearing the PEREN, HCKEN or IPGEN bits in the system control register, the peripheral source clock, master clock, or IPG clocks are gated in the low position to the eSDHC. For maximum power saving, the user can disable all the clocks to the eSDHC when no operation is in progress.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- The internal data buffer is empty

Even when the system is in low power mode and the clocks to the eSDHC are disabled, there are some events for which the clocks must be enabled to handle the event. There are three events (denoted as wakeup events or wakeup interrupts) that can be used to wake up the eSDHC by re-enabling the clocks, even if there are no clocks enabled. These three wakeup interrupts are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from the SDIO card

In order to enable these interrupts to wake up the eSDHC, the corresponding wakeup enabled bits need to be set in the protocol control register, before the CPU enters sleep mode. See Section 20.3.3.8, “Protocol Control Register (PROCTL)” for more details.

20.5 Initialization/Application Information

All communication between system and cards is controlled by the host. See Section 20.6, “MMC/SD/SDIO/CE-ATA Card Commands for a complete list of the commands that the host can issue. There are two types of commands:

- Broadcast commands are intended for all cards: examples include “GO_IDLE_STATE”, “SEND_OP_COND”, “ALL_SEND_CID” and so on. In broadcast mode, all cards are in open-drain mode to avoid bus contention.
- Addressed commands can be issued after the broadcast command CMD3 has been sent, causing the cards to enter standby mode. In standby mode, the CMD and DAT I/O pads are in push-pull mode, which provides the driving capability for maximum frequency operation.

20.5.1 Command Send and Response Receive Basic Operation

The following pseudocode indicates the procedure for sending a command to the card(s). The data type WORD here denotes unsigned 32-bit integer.

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into transfer type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as ‘00’+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
        set MSBSEL bit;
        if (finite block number) {
                set BCEN bit;
```

```
                if (auto12 command is to use) set AC12EN bit;
        }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set transfer type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

In this example the function wait_for_response is implemented by means of polling for the sake of simplicity. For an effective and formal way, the response is checked after the command complete interrupt is received. By doing this, the corresponding interrupt status bits are verified.

In some scenarios, a response timeout is expected after a command is issued. For example, after the host issues a CMD3 command and all cards enter the standby state, then when CMD2 is sent the cards send no response to the host. The host driver is responsible to deal with these ‘fake’ errors.

20.5.2 Card Identification Mode

When a card is inserted into the socket, or when the card is reset by the host, the host is responsible for performing a sequence of operations on the card including the following:

- Card detection (when the card is inserted) or card reset (when the card is reset by the host)
- Voltage validation (also determines whether the card is MMC, SD, SDIO, or CE-ATA)
- Card registration (including card identification and determination of relative card address (RCA))

20.5.2.1 Card Detection

Figure 20-37 shows a flowchart for the detection of MMC, SD and SDIO cards using the eSDHC.

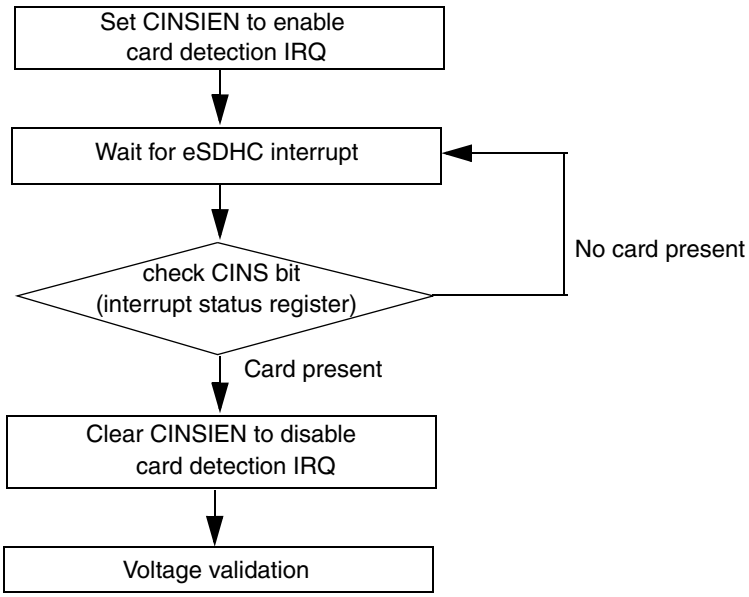

Figure 20-37. Flow Diagram for Card Detection

20.5.2.2 Reset

There are three types of resets involving the eSDHC:

- Hardware reset (card and host), which is driven by POR (power on reset)
- Software reset (host only). There are three types of software reset, which are effected by writes to bits in the system controller register as follows:
  - — Setting the RSTD bit to 1 resets the data part of the eSDHC
  - — Setting the RSTC bit to 1 resets the command part of the eSDHC
  - — Setting the RSTA bit to 1 resets all parts of the eSDHC.
- Card reset (Card Only). The command, “Go_Idle_State” (CMD0), is the software reset command for all types of MMC, SD Memory, and CE-ATA cards. This command sets each card into the idle state regardless of the current card state. For SD I/O Cards, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host is responsible to validate the voltage range of the card. See Figure 20-38 for a pseudocode to reset both the eSDHC and the card.

For CE-ATA devices that support ATA mode, two CMD39 commands should be issued back-to-back to the ATA control register before issuing CMD0 to reset the MMC layer. The first CMD39 has the SRST bit set to one, and the second has the SRST bit cleared.

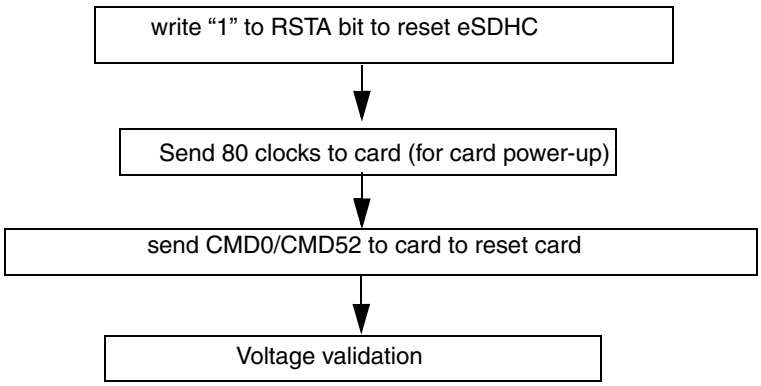

Figure 20-38. Flowchart for Reset of the eSDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the host
set DTOCV and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

20.5.2.3 Voltage Validation

The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host.

A card’s supported minimum and maximum values for Vdd are defined in the card’s operating conditions register (OCR). The supported range may not cover the maximum allowed voltage range specified in the card specification. Cards that store the card identification (CID) and card-specific data (CSD) in preloaded memory are only able to communicate this information under data transfer Vdd conditions: so if the host and card have non-overlapping Vdd ranges, then the card is not able to complete the identification cycle, nor is it be able to send CSD data.

Voltage validation makes use of the special commands listed in Table 20-39 as follows:

- The host can send a command in Table 20-39 with the desired Vdd voltage window as operand. Then cards of the corresponding type that cannot perform the data transfer in the specified range disqualify themselves from further bus operations, and go into the inactive state.
- Alternatively, the host can send a command in Table 20-39 and omits the voltage range in the command. By this means the host can query each card and determine the common voltage range before sending out-of-range cards into the inactive state. This query can be used to enable the host to select a common voltage range, or to enable notification of the system when an unusable card is detected in the stack.

Table 20-39. Voltage Validation Commands for Different Card Types

Card Type	Command Name	CMD #
MMC, CE-ATA	Send_Op_Cont	CMD1
SD	SD_Send_Op_Cont	ACMD41
SDIO	IO_Send_Op_Cont	CMD5

The following pseudocode outlines the voltage validation procedure when a card is inserted:

```
voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operating voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
                label the card as SDIO;
                IORDY = 0;
                while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                        send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                        wait_for_response(IO_SEND_OP_COND);
                } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
for memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN) label the card as SD;
        return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refused, it must be MMC card or CE-ATA card
        if (card is already labelled as SDCombo) { // change label
                re-label the card as SDIO;
                ignore the error or report it;
                return; // card is identified as SDIO card
        } // of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
                label the card as UNKNOWN;
                return;
        } // of if (RESP_TIMEOUT ...
        if (check for CE-ATA signature succeeded) { // the card is CE-ATA
                store CE-ATA specific info from the signature;
                label the card as CE-ATA;
```

```
        } // of if (check for CE-ATA ...
        else label the card as MMC;
} // of else
}
```

The host detects a CE-ATA device by issuing a CMD 60 to check for a CE-ATA signature, after completing all other MMC voltage validation and identification steps. If the device responds to CMD 60 with the CE-ATA signature, then a CE-ATA device has been found.

It is possible that the CE-ATA device does not support the ATA mode, so the driver cannot issue ATA command to the device. In order to check this, the driver queries the EXT_CSD register byte 504 (S_CMD_SET) in the MMC register space. If the ATA bit (bit 4) is set, then ATA commands are supported, and the driver sets the ATA bit (bit 4) of the EXT_CSD register byte 191 (CMD_SET) to activate the ATA command set for use. To choose the ATA command set, the driver issues CMD6.

20.5.2.4 Card Identification and Registration

The card identification and registration process establishes a relative card address (RCA), which is used to address the card for future data transfer operations. The registration processes for different card types are described in Section 20.5.2.4.1, “Card Identification and Registration for MMC Cards,” Section 20.5.2.4.2, “Card Registration for SD, SDIO, and SD Combo Cards,” and Section 20.5.2.4.3, “Card Identification and Registration for CE-ATA Cards” respectively. A pseudocode which outlines the entire registration process is given in Section 20.5.2.4.4, “Card Registration Pseudocode”.

20.5.2.4.1 Card Identification and Registration for MMC Cards

For MMC cards, the relative card address (RCA) is set by the host. The procedure for identifying the cards and setting their RCAs is described below.

Card identification mode for MMC cards uses a clock frequency of less than 400 kHz and a power voltage greater than 2.7 V. The process begins in open-drain mode: the open-drain driver stages on the CMD line allow parallel card operation during card identification. The host sends the following sequence of commands:

1. After the bus is activated, the host broadcasts a CMD1 command requesting the cards to send their valid operating conditions. The response to CMD1 is the “wired OR” operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the inactive state.
2. The host then broadcasts an All_Send_CID (CMD2) command, asking all cards for their unique card identification (CID) number. All unidentified cards (in ready state) simultaneously start sending their CID numbers serially, while bitwise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods stop sending their CID immediately, and must wait for the next identification cycle. Since the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the identification state.
3. Next, the host issues a point-to-point Set_Relative_Addr command (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received, the card state changes to the standby state, and the card does not participate in further identification cycles. The card’s output driver switches from open-drain to push-pull.

4. The host repeats steps 2 and 3 above until the host sends a CMD2 which times out, signifying the completion of the identification process.

20.5.2.4.2 Card Registration for SD, SDIO, and SD Combo Cards

For SD, SDIO, and SD Combo cards, the RCA is published by the cards at the host's request. The procedure for identifying the cards and setting their RCAs is described below.

Card identification mode for SD cards uses a clock frequency of less than 400 kHz and a power voltage greater than 2.7 V (as defined in the SD card specification). The CMD line output drivers are in push-pull mode. The host sends the following sequence of commands:

1. After the bus is activated, the host broadcasts a ACMD41 (for SD) or CMD5 (for SDIO) command to all new cards in the system, requesting them to send their valid operating conditions. The card responds by sending the contents of its operating conditions register. Incompatible cards are put into the inactive state.
2. The host then broadcasts an All_Send_CID (CMD2) command, asking all cards for their unique card identification (CID) number. All unidentified cards (in ready state) simultaneously start sending their CID numbers serially, while bitwise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods stop sending their CID immediately, and must wait for the next identification cycle. Since the CID is unique for each card, only one card can successfully send its full CID to the host. This card then goes into the identification state.
3. Next, the host issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. Once the RCA is received, the card changes its state to the standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.
4. The host repeats steps 2 and 3 above until the host sends a CMD2 which times out, signifying the completion of the identification process.

20.5.2.4.3 Card Identification and Registration for CE-ATA Cards

CE-ATA operation has the same interface as MMC cards. However, CE-ATA devices are connected in a point-to-point manner, and no RCA is needed. All data communications in card identification mode use the command line (CMD) only. See CE-ATA Digital Protocol, Revision 1.1 for more details.

CE-ATA enters the tran state after reset is completed.

20.5.2.4.4 Card Registration Pseudocode

The following pseudocode outlines the card registration process for all cards (corresponding to steps 2 through 4 in the procedures shown in Section 20.5.2.4.1, "Card Identification and Registration for MMC Cards" and Section 20.5.2.4.2, "Card Registration for SD, SDIO, and SD Combo Cards").

```
card_registry()
{
do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
```

```
                send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its
RCA
                retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
                send_command(ALL_SEND_CID, <...>);
                if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                send_command(SET_RELATIVE_ADDR, <...>);
                retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                send_command(ALL_SEND_CID, <...>);
                rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also the
relative address to access the CE-ATA card
                send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16
bits
        } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

20.5.3 Card Accesses

This section describes write, read, suspend/resume, and ADMA card accesses.

20.5.3.1 Block Write

Normal writes and writes with pause are described in Section 20.5.3.1.1, “Normal Write” and Section 20.5.3.1.2, “Write With Pause,” respectively.

20.5.3.1.1 Normal Write

During a block write (CMD24–27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates the failure on the DAT line. The transferred data is discarded and not written, and all further transmitted blocks (in multi-block write mode) is ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set, and the CE-ATA card does not support partial block write, either), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, while ignoring all further data transfer, waits in the Receive-data-State for a stop command. For a CE-ATA card, check the CE-ATA card specification for its behavior in block misalignment. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block size setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and not change any register contents.

Different cards may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DAT line low if its

write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO and CE-ATA cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1~0 in the scrControl register
3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the transfer complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

20.5.3.1.2 Write With Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition during a write operation to the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to negate to release the busy state, no suspend command is needed.

Like in the flow described in Section 20.5.3.1.1, “Normal Write,” the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)

b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)

c) For CE-ATA cards, configure bits 1:0 in the scrControl register

3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the transfer complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the transfer complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. The data transfer and the setting of the SABGREQ bit are concurrent, and the delay of the register read and writing, the actual number of blocks left may not be exactly the value read earlier. The driver reads the value of BLKCNT after the transfer is paused and the transfer complete interrupt is received.

It is also possible the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the eSDHC thinks the System switches to another function on the SDIO card, and flush the data buffer. The eSDHC takes the Resume Command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the transfer type register are set as well as the AC12EN bit. However, the eSDHC automatically sends a CMD12 to mark the end of the multi-block transfer.

20.5.3.2 Block Read

Normal reads and reads with pause are described in Section 20.5.3.2.1, “Normal Read” and Section 20.5.3.2.2, “Read with Pause,” respectively.

20.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data

transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi-block read, data blocks is continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA, and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfers, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)
   b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)
   c) For CE-ATA cards, configure bits 1:0 in the scrControl register
3. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the transfer complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

20.5.3.2.2 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the read wait feature can pause during the read operation. If the SDIO card supports read wait (SRW bit in CCCR register is 1), the driver can set the SABGREQ bit in the protocol control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the protocol control register is set, otherwise the eSDHC does not assert the read wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

As in the flow described in Section 20.5.3.2.1, “Normal Read,” the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports read wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   a) For SD/MMC, use SET_BLOCKLEN (CMD16)

b) For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1–7)

c) For CE-ATA cards, configure bits 1~0 in the scrControl register

5. Set the eSDHC block size register to be the same as the block size set for the card in Step 2.
6. Set the eSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the transfer complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the transfer complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the eSDHC ignores the stop at block gap request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. Whether the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, the eSDHC takes the command as a normal one accompanied with data transfer. It is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the transfer type register are set, as well as the AC12EN bit. However, the eSDHC automatically sends the CMD12 to mark the end of multi-block transfer.

20.5.3.3 Suspend/Resume Operations

The eSDHC supports suspend and resume operations for SDIO cards, although the implementation of suspend is slightly different than that suggested in the SDIO Card Specification.

20.5.3.3.1 Suspend Operation

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The eSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it does not negate read wait for a read pause. To solve this problem, the driver first sends the command as if it were a normal command (CMDTYP = 01). After the command succeeds, and the BS bit is set to 1 in the response, the driver then sends another command marked as Suspend to inform the eSDHC that the current transfer is suspended. The following sequence is used for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.

2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field is set as 0b00.
3. Check the BS bit of the CCCR in the response. If it is set, repeat this step until the BS bit is cleared or abandon the Suspend operation according to the driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 0b01, to inform the eSDHC that the paused operation has successfully suspended. If the paused transfer is a read operation, the eSDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA system address register (for internal DMA operation), and the block attribute register.
6. Begin operation for another function on the SDIO card.

20.5.3.3.2 Resume Operation

Data transfer is resumed following a Suspend command according to the following procedure:

1. Resume the suspended function by restoring the context register with the value saved in step #5 of the Suspend operation (see Section 20.5.3.3.1, “Suspend Operation”).
2. Send the Resume command. In the transfer type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP field is set to 0b10).
3. If the Resume command has responded, the data transfer is resumed.

20.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the host driver prepares the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length must be a multiple of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1–3.
4. Repeat steps 1–3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the block attribute register.
6. Set the ADMA system address register to the address of the first descriptor and set the DMAS field in the protocol control register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the transfer type register.

Steps 1–5 are independent of step 6, so step 6 can finish before steps 1–5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

20.5.3.5 Handling of Transfer Errors

20.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the last block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even if AC12EN and BCEND bits are set, the eSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by the eSDHC. In this case, the driver resends or reobtains the last block with a single-block transfer.

20.5.3.5.2 Internal DMA Error

During the data transfer with internal simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA error interrupt is sent to the Host System. When acknowledged by such an interrupt, the driver calculates the start address of data block in which the error occurs. The start address can be calculated by either of the following methods:

1. Read the DMA system address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straightforward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the block attribute register. By the number of blocks left, the total number of blocks to transfer, the start address of transfer, and the size of each block, the start address of the corrupted block can be obtained. When the BCEN bit is not set, the contents of the block attribute register do not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

20.5.3.5.3 ADMA Error

There are 3 types of ADMA errors: AHB transfer, invalid descriptor, and data length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and retransfer from the place of interruption.

1. AHB transfer error—Such errors can occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and retransfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error—For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.

3. Data length mismatch error—Recovery from data length mismatch is similar to recovery from an invalid descriptor error. The host driver polls relating registers to retrieve the transfer context, applies a reset for the data part, configures a new descriptor chain, and makes another transfer if there is data left. As in the case of invalid descriptor error, the data length must match the new transfer.

20.5.3.5.4 Auto CMD12 Error

If the AC12EN bit is set when a multi-block data transfer is initiated by the data command, then the eSDHC automatically sends a CMD12 to the card to stop the transfer after the last block of the transfer is sent or received. It is recommended that the driver respond to errors in the auto CMD12 command as follows:

1. If the error is an auto CMD12 response timeout (indicated by bit 1 of the auto CMD12 error status register (AUTOC12ERR), then it is not certain whether the command has been accepted by the card or not. In this case, the driver can clear the AUTOC12ERR status bits and resend the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error (indicated by bit 3 of AUTOC12ERR). Since the card responds to CMD12, the card aborts the transfer. In this case, the driver can ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The CMD12 command is not sent. In this case, the driver can send a CMD12 manually.

20.5.3.6 Card Interrupts

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. For the CE-ATA card, it can be a pulse on the CMD line to inform the host controller that the command and its response is finished, and it is possible that some additional external interrupt behaviors are defined. The eSDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the eSDHC, and the host system is informed by the eSDHC asserting the eSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by writing 1. Refer to Section 20.4.7.3, “Card Interrupt Handling” for the card interrupt handling flow.

20.5.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC spec. High-speed timing mode for all card devices, is also a recent addition to the various card specifications. To enable these new features in cards of different types the host driver issues commands as follows:

- For MMC cards (and CE-ATA over MMC interface), the high-speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol SWITCH). 4-bit and 8-bit MMC bus widths are also enabled by SWITCH commands, but with a different argument.

- For SD cards, the high-speed mode is queried and enabled by a CMD6 (with the mnemonic symbol SWITCH_FUNC).
- For SDIO cards, the high-speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed.

These new functions can be disabled by a software reset. For SDIO cards this can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

The following subsections provide pseudocodes for enabling/disabling high-speed mode for various card types, and for setting MMC bus width. For the sake of simplicity, the pseudocodes do not show current capability check, which is recommended in the function switch process.

20.5.4.1 Query, Enable and Disable SDIO High-Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is ‘0’) report the SDIO card does not support high-speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

20.5.4.2 Query, Enable and Disable SD High-Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is ‘0’) report the SD card does not support high-speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
```

```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

20.5.4.3 Query, Enable and Disable MMC High-Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high-speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high-speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high-speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

20.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

20.5.5 ADMA Operation

Pseudocodes for ADMA1 and ADMA2 operation are provided in Section 20.5.5.1, "ADMA1 Operation" and Section 20.5.5.2, "ADMA2 Operation" respectively.

20.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 4KB align.
          Set ‘Set’ type descriptor;
          {
               Set Act bits to 01;
               Set [31:12] bits data length (byte unit);
          }
          Set ‘Tran’ type descriptor;
          {
               Set Act bits to 10;
               Set [31:12] bits address (4KB align);
          }
      }
      else if (to fetch descriptor at non-continuous address) {
          Set Act bits to 11;
          Set [31:12] bits the next descriptor address (4KB align);
      }
      else { // other types of descriptor
          Set Act bits accordingly
      }
      if (this descriptor is the last one) {
          Set End bit to 1;
      }
      if (to generate interrupt for this descriptor) {
          Set Int bit to 1;
      }
      Set Valid bit to 1;
}
```

20.5.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
      if (to start data transfer) {
          // Make sure the address is 32-bit boundary (lower 2-bit are always '00').
          Set higher 32-bit of descriptor for this data transfer initial address;
          Set [31:16] bits data length (byte unit);
          Set Act bits to '10';
      }
      else if (to fetch descriptor at non-continuous address) {
          Set Act bits to '11';
          // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
          Set higher 32-bit of descriptor for the next descriptor address;
      }
      else { // other types of descriptor
          Set Act bits accordingly
      }
      if (this descriptor is the last one) {
          Set 'End' bit '1';
      }
      if (to generate interrupt for this descriptor) {
          Set 'Int' bit '1';
      }
```

```
      Set the 'Valid' bit to '1';
}
```

20.6 MMC/SD/SDIO/CE-ATA Card Commands

There are four kinds of commands defined to control MultiMediaCards:

- Broadcast commands (bc), which elicit no response from the cards
- Broadcast commands with response (bcr), which elicit responses from all cards simultaneously
- Addressed (point-to-point) commands (ac), which do not involve data transfer on the DAT lines
- Addressed (point-to-point) data transfer commands (adtc), which involve data transfer

Table 20-40 lists commands for MMC/SD/SDIO/CE-ATA cards. Refer to the corresponding specifications for more details about these commands.

Table 20-40. Commands for MMC/SD/SDIO/CE-ATA Cards

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	—	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	—	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operating conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to “SD Physical Specification V1.1” for more details.

Table 20-40. Commands for MMC/SD/SDIO/CE-ATA Cards (Continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to “The MultiMediaCard System Specification Version 4.0 Final draft 2” for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/DESELECT_CARD	Toggles a card between the standby and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	—	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				

Table 20-40. Commands for MMC/SD/SDIO/CE-ATA Cards (Continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.

Table 20-40. Commands for MMC/SD/SDIO/CE-ATA Cards (Continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				

Table 20-40. Commands for MMC/SD/SDIO/CE-ATA Cards (Continued)

CMD INDEX	Type	Argument	Response	Abbreviation	Description
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	CE-ATA devices contain a set of Status and Control registers that begin at register offset 80h. These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are word (32-bit) in size and are word aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer for the ATA command.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width (‘00’=1bit or ‘10’=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	—	R1	SET_WR_BLK_ERASE_COUNT	—
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating conditions register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	—	R1	SET_CLR_CARD_DETECT	—
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1 CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).

2 CMD6 differs completely between high-speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.

3 Command SWITCH is for high-speed MMC cards as well as for CE-ATA cards over the MMC interface. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 20-41.

[4] ACMDs is preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown in Table 20-41.

Table 20-41. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

20.7 Software Restrictions

20.7.1 Initialization Active

The driver cannot set the INITA bit in the system control register when either of the command line or data lines is active, so the driver is responsible to ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be 1, otherwise no clock signal goes out to the card and INITA never clears.

20.7.1.1 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the watermark level register; moreover, if the block size is not the times of the value in watermark level register (read and write respectively), the software must access exactly the remained number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

20.7.1.2 Suspend Operation

In order to suspend the data transfer, the software must inform eSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as ‘01’) to inform eSDHC that the transfer is suspended.

If the software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such ‘suspend’ command, eSDHC regards that the current transfer is aborted and changes BLKCNT register to its original value, instead of keeping the remained number of blocks.

20.7.1.3 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be times of 4.

20.7.1.4 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

20.7.1.5 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the eSDHC buffer.

20.7.1.6 Change Clock Frequency

eSDHC does not automatically gates off the card clock when the host driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to ‘1’ after SDSTB bit is ‘1’ again.

Chapter 21
Enhanced SDRAM Controller (ESDRAMC)

The enhanced synchronous dynamic RAM controller (ESDRAMC) provides interface and control for synchronous DRAM (SDRAM) memories for the system. SDRAM memories use a synchronous interface with all signals registered on a clock edge. A command protocol is used for initialization, read, write, and refresh operations to the SDRAM and is generated on the signals by the controller when required due to external or internal requests. It has support for both single- and double-data rate SDRAMs. It supports 64-, 128-, 256-, or 512-Mbit and 1- or 2-Gbit 4-bank SDRAM by two independent chip selects and with up to 64 Mbytes addressable memory per chip select.

Figure 21-1 is the enhanced SDRAM controller top-level diagram, showing the functional organization of the module.

NOTE

The ESDRAMC and ESDCTL mnemonics are equivalent. For historical reasons they are alternately used throughout the document.

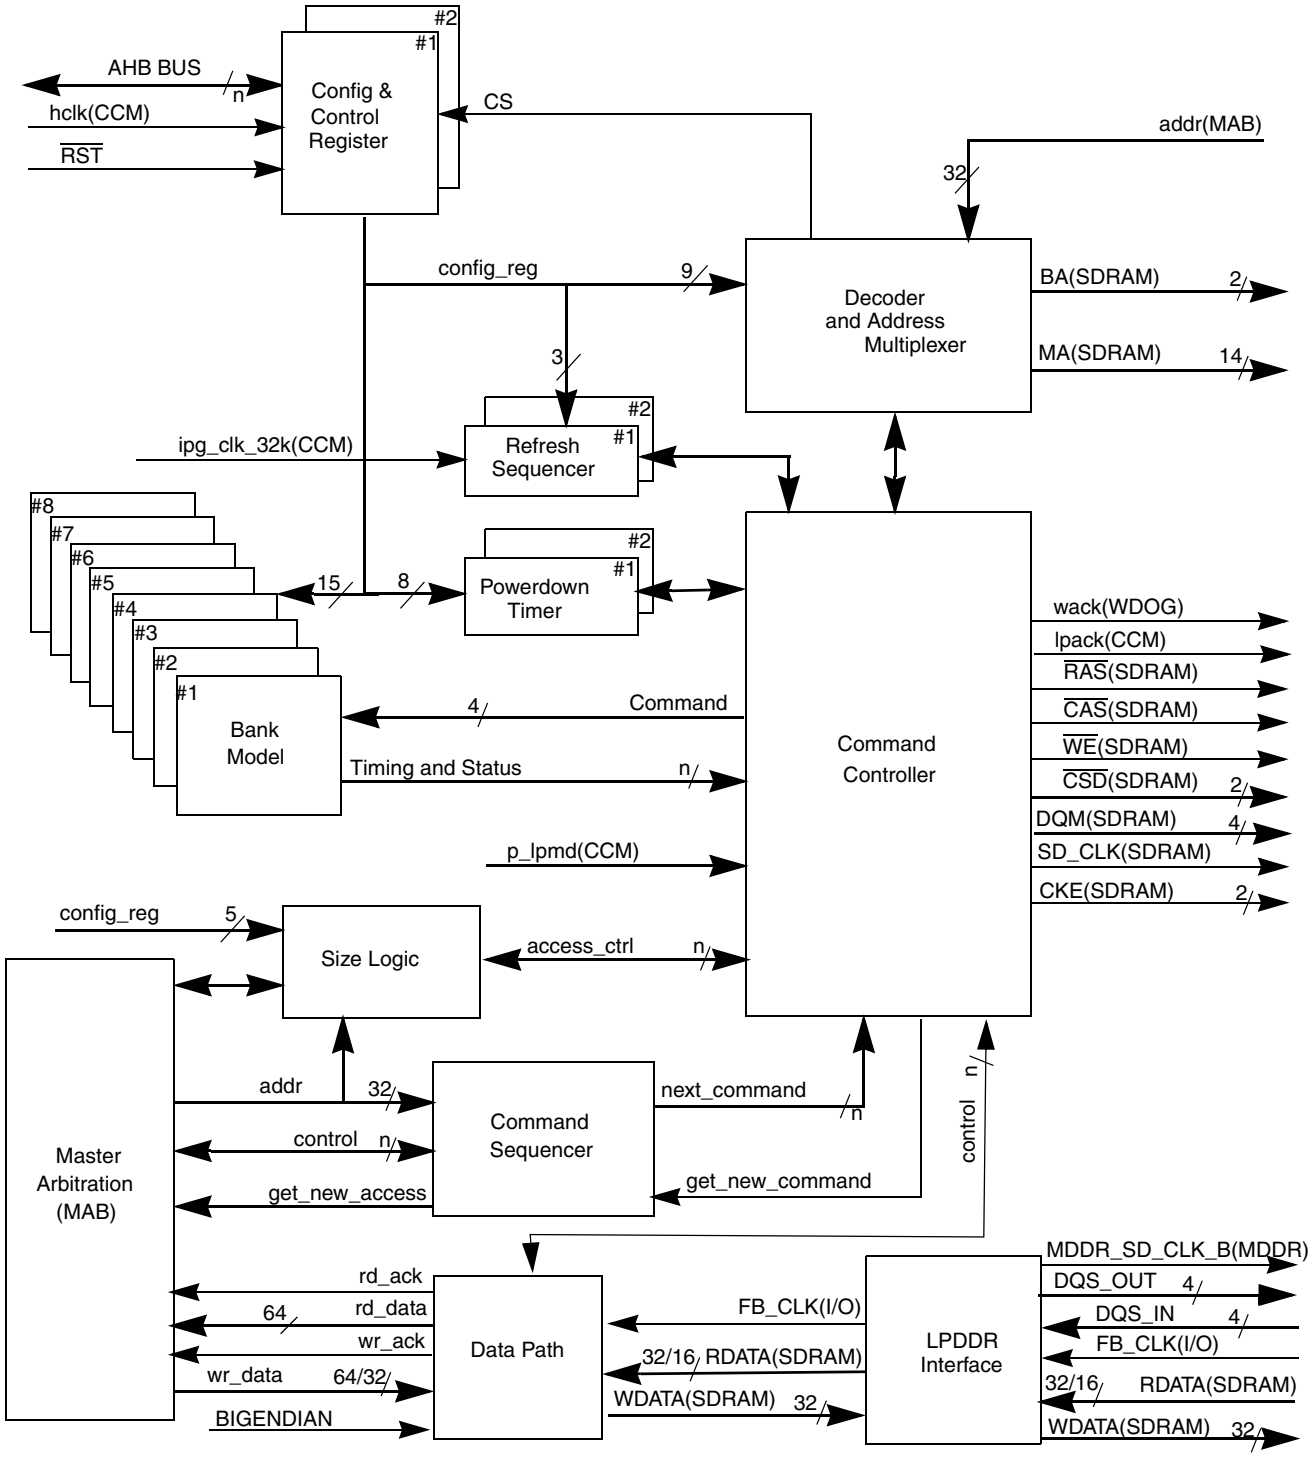

Figure 21-1. Enhanced SDR/LPDDR SDRAM Controller Module Top-Level Diagram

21.1 Overview

The enhanced SDRAM controller consists of nine major submodules:

- SDRAM command controller
- 8 Bank models (page and bank address comparators)
- Row/Column address multiplexer,
- Control and configuration registers
- Refresh request counter
- Command sequencer
- Size logic (splitting access)
- Data aligner/multiplexer (data path)
- LPDDR interface
- Power-down timer

These submodules are described in the following subsections.

21.1.1 SDRAM Command Controller

This submodule controls most of the actions within the ESDRAMC. All commands to the memory are executed through this submodule.

21.1.2 Bank Models

There are a total of 8 address comparators, one comparator for each of the 4 banks within each of the two chip select regions. The comparators are used to determine if a requested access falls within the address range of a currently active SDRAM page. The bank model also includes all timing parameters for the comparators.

21.1.3 Row/Column Address Multiplexer

All synchronous SDRAMs incorporate a multiplexed address bus, although the number of bytes per bank and bytes per page vary according to memory density, number of data I/O, and the processor data bus width. The enhanced SDRAM controller takes these variables into account and provides the proper alignment of the multiplexed address through the combination of the row/column address multiplexer, non-multiplexed address pins, and the connections between the controller and the memory devices.

21.1.4 ESDRAMC Control and Configuration Registers

Control and configuration registers determine the operating mode of the ESDRAMC. Configurable parameters include memory device density and bus width, number of memory devices, CAS latency, row to column delay, and burst length. Enable bits are provided for refresh and the power-down timer. Mode bits provide a mechanism for software initiated SDRAM initialization, setting the device mode register, precharge, and auto-refresh cycles.

21.1.5 Refresh Request Counter

SDRAM memories require periodic refresh to retain data. The refresh request counter generates requests to the SDRAM command controller to perform those refresh cycles. Requests are scheduled according to a 32-kHz clock input. One, 2, 4, 8, or 16 refresh cycles are generated per a 32-kHz clock.

21.1.6 Command Sequencer

The command sequencer submodule sends the commands be executed (including precharge-all, precharge-bank, active, read, write, and burst terminate commands) to the command controller, after taking into account the bank's state of the access, the command controller execution signal and the command busy situation.

21.1.7 Size Logic

The size logic submodule gets as inputs from one side the address, access size, and wrap/incr access, and from the other side the configuration values—burst length and DSIZ. In case of a misaligned access, the size logic splits the access into multiple accesses as a function of the inputs to the submodule.

21.1.8 Mobile/Low Power DDR (LPDDR) Interface

The LPDDR interface provides the device's interface with LPDDR SDRAM. It converts the double–data rate signal that is synchronized to both positive and negative edges of the data strobe (DQS) signals to a pass through a double-width data bus synchronized to the positive edge of the controller internal clock (which is derived from HCLK).

The interface uses a read FIFO which samples the data with delayed DQS in read cycles. Two read FIFOs are used for positive and negative clock edges, respectively. Delay lines are used to generate delayed versions of DQS input signals in order to sample the data at the middle of the data valid window. In write cycles DQS are output signals that are generated using a delay line. The data at the input to the interface has a double width from the memory so it is divided into the memory width but with double frequency. For this purpose a multiplexer is used to pass the upper half and lower half of the data. In read cycles, double-rate data is received with a DQS signal that is edge-aligned with read data; and in write cycles double-rate data is created with a centered DQS signal.

DQS delay lines are based on three functional units:

1. The measurement unit measures one cycle time between successive positive edges. The output of this unit is the number of small delay intervals needed to delay one positive edge of the clock to overlap the following positive edge.
2. The division unit divides the result of the measurement by 4.
3. The delay unit takes the result and selects the correct delay tap.

The delay unit is duplicated 5 times: 4 units for read (one for each byte lane's DQS signal) and one unit for write (to delay overall data sampling).

21.1.8.1 Power-Down Timer

The power-down timer detects periods of inactivity to the SDRAM and disables the clock when the inactive period surpasses the selected timeout. Data is retained during the power-down state. Subsequent requests to the SDRAM incur only a minimal added start-up delay (beyond the normal access time, as specified in Table 21-21). The power-down timer can be disabled, or can be programmed to expire under any one of the following conditions:

- Any time the controller is not actively reading/writing the memory,
- After 64 clocks of inactivity
- After 128 clocks of inactivity

21.1.9 Features

The ESDRAMC includes the following features:

- Optimizes consecutive memory accesses through memory command anticipation (latency hiding)
  - Hides latency by optimization the commands to both chip selects (command anticipation)
  - Keeps track of open memory pages
  - Bankwise memory address mapping
  - SDRAM burst length configuration of 4 or 8 (for 16-bit memory burst length 4 is not supported) or full-page mode
  - LPDDR/DDR burst length configuration of 8
  - Support of different internal burst lengths (1/4/8 words) by using burst truncate commands
  - ARM AMBA AHB-lite compatible
  - Shared address and command bus to SDRAM/LPDDR
- Supports 64-, 128-, 256-, or 512-Mbit and 1- or 2-Gbit sizes of 4-bank, single data rate, synchronous SDRAM, LPDDR and non-mobile DDR1 devices. Limited support for DDR2 devices (4 banks only, no ODT control signal)
  - Two independent chip selects
  - Up to 256 Mbytes per chip select
  - Up to four banks active simultaneously per chip select
  - JEDEC standard pinout/operation
- Support for 16- and 32-bit mobile/low power DDR266 devices
- PC133-compatible interface
  - 133 MHz system clock achievable with “-7” option for PC133-compatible memories
  - Single fixed-length (4/8-word) burst or full-page access
  - Access time of 9-1-1-1-1-1-1-1 at 133 MHz (for read access when memory bus is available, row is open and CAS latency configured to 3 cycles). The access time includes the M3IF delay (assuming no arbitration penalty).
- Software-configurable for different system and memory devices requirements
  - 16- or 32-bit memory data bus width (equal in both chip selects)

  - Number of row and column addresses
  - Row cycle delay (t_{RC})
  - Row precharge delay (t_{RP})
  - Row to column delay (t_{RCD})
  - Column to data delay (CAS Latency)
  - Load mode register to active command (t_{MRD})
  - Write to precharge (t_{WR})
  - Write to read (t_{WTR}) for LPDDR memories only
  - LPDDR exit power-down to next valid command delay (t_{XS})
  - Active to precharge (t_{RAS})
  - Active to active (t_{RRD})
- Built- in auto-refresh timer and state machine
- Hardware- and software-supported self-refresh entry and exit
  - Data remains valid during system reset and low power modes
  - Auto–power-down timer (one per chip select)
  - Auto-precharge timer (one per bank in each chip select)

21.1.10 Modes of Operation

This section provides a high-level description of the ESDRAMC operating modes: see Section 21.4, “Functional Description” for more detailed descriptions.

The ESDRAMC’s different operating modes for each chip select ($\overline{\text{CSD}}n$, n = 0,1) are defined by the 3-bit SMODE field in the corresponding ESDCTL*n* register. In addition to the normal operating mode, the controller is capable of operating in three alternate operating modes primarily used for SDRAM/LPDDR initialization, as follows:

- Normal read/write mode

  This is the normal operating mode used to read/write (single or burst accesses) from/to external SDRAM/LPDDR devices. The ESDRAMC automatically drives the precharge/active/burst/terminate commands during the normal operating mode.
- Precharge mode

  The manual precharge command is used to manually deactivate the open (active) row in a particular bank or the open row in all banks. The bank(s) are available for a subsequent row access at a specified time (tRP) after the precharge command is issued. External memory device input A10 determines whether one or all banks are to be precharged, and in the case that only one bank is to be precharged, inputs BA0 and BA1 select the bank. The manual precharge command is used during SDRAM initialization, load mode register command, and manual refresh cycles
- Auto-refresh mode

  The auto-refresh command is used to retain data in the SDRAM memory devices. This command is non persistent, so it must be issued each time a refresh is required. The ESDRAMC has a refresh counter for each CSD_B (external memory region), and it automatically handles the refresh

commands to the memory. The manual auto-refresh command is used during SDRAM initialization or in case the refresh counters are not enabled.

- Load mode register mode

  The mode register is used to define the specific mode of operation of the SDRAM device. This definition includes the selection of a burst length, a burst type, a CAS latency, an operating mode and a write burst mode. The mode register is programmed via the load mode register command and retains the stored information until it is programmed again or the external memory device loses power. The mode register can only be loaded when all banks are idle (after precharge-all). The ESDRAMC waits a specified period of time (t_{MRD})as configured in the ESDCFG0 or ESDCFG1 register. Violating either of these requirements by an incorrect controller register configuration results in unspecified operation.

Any access to the SDRAM/LPDDR memory space while in one of the alternate modes results in the corresponding special cycle being run. Moving from normal to any other mode does not close (precharge) any banks that may be open (activated). Under most circumstances, software should run a precharge-all cycle when transitioning out of normal read/write mode. Reset initializes the operating mode to normal read/write mode.

21.2 External Signal Descriptions

This section discusses input and output signals between the enhanced SDRAM controller and the external memory devices. Other than the chip select outputs ($\overline{CSD}$0 and $\overline{CSD}$1) and clock enables (CKE0 and CKE1), all signals are shared between the two chip select regions.

Interconnect and timing diagrams are included as part of the detailed discussion on controller operation in Section 21.4, “Functional Description”.

21.2.1 Overview of Signals

Table 21-2 summarizes the interface signals.

Table 21-2. ESDRAMC Signal Properties

Name	Port	Function	Reset State	Direction
SD_CLK	—	Clock to SDRAM (up to 133MHz)	1	Output
FB_CLK_IN	—	Feedback clock	0	Input
CKE0	—	Clock enable to SDRAM 0	0	Output
CKE1	—	Clock enable to SDRAM 1	0	Output
$\overline{CSD}$[0]	—	Chip select to SDRAM Array 0	1	Output
$\overline{CSD}$[1]	—	Chip select to SDRAM Array 1	1	Output
RDATA[31:0]	—	Read data from memories	0	Input
WDATA[31:0]	—	Write data to memories	0	Output
MA[13:0]	—	Multiplexed address	0	Output

Table 21-2. ESDRAMC Signal Properties (Continued)

Name	Port	Function	Reset State	Direction
BA[1:0]	—	Bank address	0	Output
DQM3	—	Data qualifier mask byte 3 (D[31:24])	0	Output
DQM2	—	Data qualifier mask byte 2 (D[23:16])	0	Output
DQM1	—	Data qualifier mask byte 1(D[15:8])	0	Output
DQM0	—	Data Qualifier mask byte 0 (D[7:0])	0	Output
$\overline{WE}$	—	Write enable	1	Output
$\overline{RAS}$	—	Row address strobe	1	Output
$\overline{CAS}$	—	Column address strobe	1	Output
Mobile LPDDR signals				
MDDR_SD_CLK_B	—	Inverted clock to LPDDR SDRAM	0	Output
DQS_OUT3	—	Data strobe byte 3 (D[31:24])	0	Output
DQS_OUT2	—	Data strobe byte 2 (D[23:16])	0	Output
DQS_OUT1	—	Data strobe byte 1 (D[15:8])	0	Output
DQS_OUT0	—	Data strobe byte 0 (D[7:0])	0	Output
DQS_IN3	—	Data strobe byte 3 (D[31:24])	0	Input
DQS_IN2	—	Data strobe byte 2 (D[23:16])	0	Input
DQS_IN1	—	Data strobe byte 1 (D[15:8])	0	Input
DQS_IN0	—	Data strobe byte 0 (D[7:0])	0	Input

21.2.2 Detailed Signal Descriptions

Table 21-3 lists the signals and descriptions of all of the I/O signals that interface with the ESDRAMC.

Table 21-3. ESDRAMC Detailed Signal Description

Signal	I/O	Description
SD_CLK	O	SDRAM clock. The SD_CLK output provides the timing reference for the memory devices. All other SDRAM interface signals are referenced to this clock. SD_CLK is synchronous to the system clock, but is gated off during low power operating modes when both CKE0 and CKE1 are negated.
FB_CLK_IN	I	Feedback clock. The FB_CLK_IN signal is used by the Enhanced SDRAM controller to sample the data during read cycles. The FB_CLK_IN is a delayed SD_CLK, and at a good proximity is identical to the external memory device clock. A delay between SD_CLK and FB_CLK_IN compensates the PAD input/output buffers, chip route.
CKEO CKE1	O	SDRAM/MMDR clock enables. Clock enable outputs to the SDRAM memory devices. CKE0 corresponds to SDRAM/LPDDR array 0 and CKE1 to SDRAM/LPDDR array 1. Activates the memory's clock input when high, indicating a stable clock is being supplied. Deactivates the memory's clock input when low. CKEx low initiates power-down and self-refresh modes to the SDRAM.

Table 21-3. ESDRAMC Detailed Signal Description (Continued)

$\overline{\text{CSD0}}$ $\overline{\text{CSD1}}$	O	SDRAM/LPDDR chip select. $\overline{\text{CSD0}}$ and $\overline{\text{CSD1}}$ are used to select SDRAM/LPDDR array 0 and SDRAM/LPDDR array 1, respectively. The chip select signals are used to indicate when a valid command is present on the other control signals and to which device the command is directed.
RDATA[31:0] WDATA[31:0]	I/O	Read/write data bus. The 32 data pins are used to transfer data between the enhanced SDRAM controller and memory. Data bit 31 is the most significant bit. Bit 0 is the least significant. 16-bit memory alignment is selectable according to the programming of the DSIZ field in the ESDCTL*n* register (See Section 21.3.3, “Register Descriptions”).
MA[13:0]	O	Multiplexed address bus. The multiplexed address bus specifies the SDRAM page and location within the page targeted by the current access. Connections between the enhanced SDRAM Controller and memory varies depending on the SDRAM device density. See Section 21.4.2, “Address Multiplexing” and specifically Table 21-18 and Table 21-19 for details on supported SDRAM configurations.
BA[1:0]	O	Bank address bus. The bank address pins specify to which bank the current command is targeted. Table 21-18 and Table 21-19 document which address pins are used as the bank address bus for given device configuration.
DQM3, DQM2, DQM1, DQM0	O	Data qualifier mask. During read cycles, DQMx controls the SDRAM data output buffers. DQMx asserted high disables the output buffers leaving them in a high-impedance state. DQMx low allows the data buffers to drive normally. During write cycles, DQMx controls which bytes are written in the SDRAM. DQMx driven low enables a write to the corresponding byte, while DQMx asserted high leaves the byte unchanged. DQM0 corresponds to D[7:0] and DQM3 to D[31:24]. Sixteen bit memories require only two DQM connections. Memories aligned to the upper data bus (D[31:16]) connect to DQM2 and DQM3, while memories aligned to the lower data bus (D[15:0]) connect to DQM0 and DQM1. The ESDRAMC takes care of the endian operating mode, and drives the respective DQM strobe required. **Note:** When the controller is used to interface mobile/low power DDR, DQM changes twice each cycle (like the data) and is aligned to DQS edges.
$\overline{\text{WE}}$	O	Write enable. Write enable is part of the three bit command field ($\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ make up the other two bits) used by the SDRAM. Generally, $\overline{\text{WE}}$ is asserted low if a command transfers data to the memory. A detailed summary of the supported SDRAM commands is provided in Table 21-22.
$\overline{\text{RAS}}$	O	Row address strobe. Row address strobe is also part of the SDRAM command field. It is generally used to indicate an operation affecting an entire bank or row. RAS is an active low signal. Table 21-22 provides details on SDRAM command encoding.
$\overline{\text{CAS}}$	O	Column address strobe. The column address strobe is the third signal comprised in the command field. It generally signifies a column oriented command. CAS is an active low signal. Table 21-22 provides details on SDRAM command encoding.
SD_CLK/$\overline{\text{MDDR\_SD\_CLK}}$	O	LPDDR SDRAM inverted clock. SD_CLK and $\overline{\text{MDDR\_SD\_CLK}}$ are mobile/low power DDR differential clocks. All LPDDRs address and control input signals are sampled on the crossing of the positive edge of SD_CLK and negative edge of $\overline{\text{MDDR\_SD\_CLK}}$. Internal clock signals are derived from SD_CLK/$\overline{\text{MDDR\_SD\_CLK}}$.
DQS_OUT3, DQS_OUT2, DQS_OUT1, DQS_OUT0	O	Data strobes outputs. Data strobes are used for data capture for LPDDR memory. During write cycles, they are generated by the SDRAMC controller and are centered with write data. DQS3 corresponds to the most significant byte and DQS0 to the least significant byte.

Table 21-3. ESDRAMC Detailed Signal Description (Continued)

DQS_IN3, DQS_IN2, DQS_IN1, DQS_IN0	I	Data strobes inputs. During read cycles, DQS_INx are generated by the memory devices and are edge aligned with read data. For read data, the controller receives a DQS signal that is edge aligned with the read data. The DQS delay module is used to delay the DQS signal and center it in the data valid window.
non_mobile_ddr_fuse	I	Reset value for DDR_EN bit for non-mobile DDR-based systems. if this wire is tied high, then DDR_EN is 1 by default, thus resulting in CKE signal low at boot. This saves time during initialization of DDR devices (regular DDR require CKE low at boot, while mobile DDR devices require CKE high at boot). If this wire is set at zero and a DDR device is connected externally, then upon register set CKE goes low, and the controller will start counting 200 µsec again. **Note:** This fuse does not control the MDDR_EN bit. Software is responsible to configure the MDDR_EN bit during the initialization procedure.

21.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

All implemented bits in the ESDRAMC registers are fully readable and writable, except for the enhanced MDDR delay line cycle length debug register (ESDCDLYL) register which is read-only. Reserved bit locations are unaffected by writes and always read as zero. All register accesses must be single-word (32-bit) operations through the AHB bus protocol. Accesses of any other size have indeterminate results. All ESDRAMC registers can be only accessed by one master at a time: multiple-master accesses to the registers cause undetermined behavior.

21.3.1 Memory Map

Table 21-4 shows the ESDRAMC memory map. For the base address of a particular module instantiation, see the system memory map.

The ESDRAMC supports memory devices on two independent chip selects. Each chip select defines a specific memory address range: Table 21-5 shows the ESDRAMC memory address ranges for each chip select.

Table 21-4. ESDRAMC Memory Map

Base Address Offset (Name Abbreviation)	Register	Access	Reset	Section/Page
0x0000 (ESDCTL0)	Enhanced SDRAM control register 0	R/W	0x0111_0080	21.3.3.1/21-14
0x0004 (ESDCFG0)	Enhanced SDRAM configuration register 0	R/W	0x0076_EB3A	21.3.3.2/21-18
0x0008 (ESDCTL1)	Enhanced SDRAM control register 1	R/W	0x8112_0080	21.3.3.1/21-14
0x000C (ESDCFG1)	Enhanced SDRAM configuration register 1	R/W	0x007A_C727	21.3.3.2/21-18
0x0010 (ESDMISC)	Enhanced SDRAM miscellaneous register	R/W	0x0000_0000	21.3.3.3/21-32
0x0020 (ESDCDLY1)	Enhanced MDDR Delay Line 1 configuration debug register	R/W	0x00F4_8000	21.3.3.4/21-34
0x0024 (ESDCDLY2)	Enhanced MDDR delay line 2 configuration debug register	R/W	0x00F4_8000	21.3.3.4/21-34

Table 21-4. ESDRAMC Memory Map (Continued)

0x0028 (ESDCDLY3)	Enhanced MDDR delay line 3 configuration debug register	R/W	0x00F4_8000	21.3.3.4/21-34
0x002C (ESDCDLY4)	Enhanced MDDR delay line 4 configuration debug register	R/W	0x00F4_8000	21.3.3.4/21-34
0x0030 (ESDCDLY5)	Enhanced MDDR delay line 5 configuration debug register	R/W	0x00F4_8000	21.3.3.5/21-35
0x0034 (ESDCDLYL)	Enhanced MDDR delay line cycle length debug register	R	N/A	21.3.3.6/21-36

Table 21-5. ESDRAMC Memory Regions

Address Range	Use	Access
CS0_BASE–(CS0_BASE + 0x0FFF_FFFF)	CSD0 SDRAM or LPDDR memory region (256 Mbytes)	Read/write
CS1_BASE–(CS1_BASE + 0x0FFF_FFFF)	CSD1 SDRAM or LPDDR memory region (256 Mbytes)	Read/write

21.3.2 Register Summary

Figure 21-2 shows the key to the register fields and Table 21-6 shows the register figure conventions.

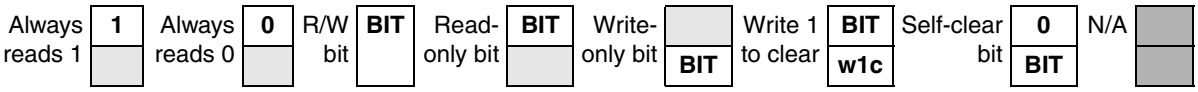

Figure 21-2. Key to Register Fields

Table 21-6. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read-only. Writing this bit has no effect.
W	Write-only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.

Table 21-6. Register Figure Conventions (Continued)

Convention	Description
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 21-7 shows the ESDRAMC register summary. For the base address of a particular module instantiation, see the system memory map.

21.3.3 Register Descriptions

This section consists of register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

NOTE

Memory may be viewed from either a big-endian or little-endian byte ordering perspective depending on the processor configuration (see Figure 21-3). In big-endian mode (the typical default operating mode), the most significant byte (byte 0) of word 0 is located at address 0. For little-endian mode, the most significant byte of word 0 is located at address 3. Within registers, bits are numbered within a word starting with bit 31 as the most significant bit. By convention, byte 0 of a register is the most significant byte regardless of endian mode.

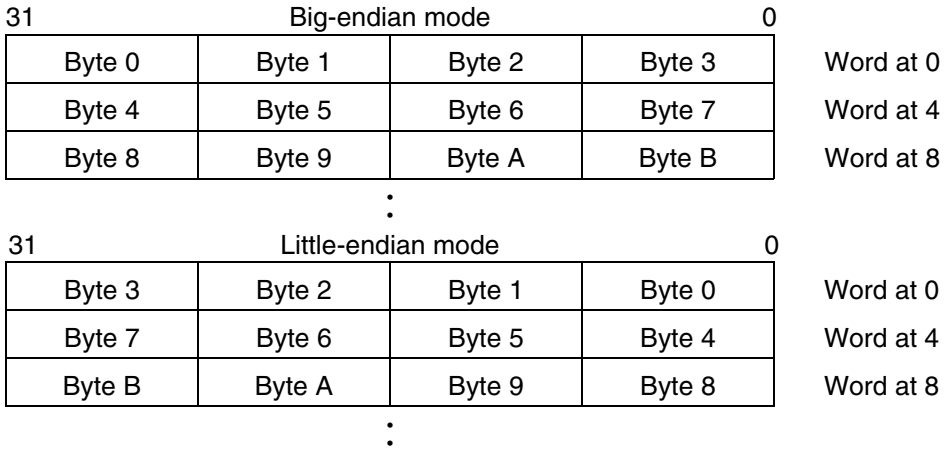

Figure 21-3. Data Organization in Memory

21.3.3.1 Enhanced SDRAM Control Registers (ESDCTL*n*, *n* = 0,1)

These registers configure the memory and control settings for the ESDRAMC for chip selects 0 and 1 respectively. Figure 21-4 and Figure 21-5 show the bit assignments for the registers. Note that bit field assignments are identical for the two registers, but reset values for some fields are different. Table 21-8 provides field descriptions.

Figure 21-5. Enhanced SDRAM Control Register 1 (ESDCTL1)

Table 21-8. Enhanced SDRAM Control Register (ESDCTL*n*) Field Descriptions

Field	Description
31 SDE	Enhanced SDRAM controller enable. This control bit enables/disables the enhanced SDRAM controller. Writing 1 to both control bits enables the module for both chip selects. Clearing both SDE bits disables the module, and all clocks within the module shuts off (with the exception of register accesses). When the value of both SDE bits is 0, the module is disabled. 0 Disabled (reset value for ESDCTL0) 1 Enabled (reset value for ESDCTL1)
30–28 SMODE	SDRAM controller operating mode. This bit field determines the operating mode of the enhanced SDRAM controller. In addition to the normal operating mode, the controller is capable of operating in several alternate operating modes, which are primarily used for SDRAM initialization. Any access to the SDRAM memory space, while in one of the alternate modes, results in the corresponding special cycle being run. Transitioning from normal to any other mode does not close (precharge) any banks that may be open (activated). Under most circumstances, software should run a precharge-all cycle when transitioning out of normal read/write mode. Operating mode details are provided in Section 21.4, “Functional Description.” Reset initializes the operating mode to “normal read/write”. 000 Normal read/write 001 Precharge command 010 Auto-refresh command 011 Load mode register command 100 Manual self-refresh 101 through 111 Reserved
27 SP	Supervisor protect. This control bit is used to restrict user accesses within the chip select region. The default at reset are that both user and supervisor accesses are allowed. 0 User mode accesses are allowed to this chip select region. 1 User mode accesses are prohibited. An attempted access to this chip select region while in user mode will result in a high HRESP[1] being returned back to the CPU. The chip select will not be asserted. An ESDRAMC error response is generated by the M3IF arbitrator.

Table 21-8. Enhanced SDRAM Control Register (ESDCTL*n*) Field Descriptions (Continued)

Field	Description
26–24 ROW	Row address width. This control field specifies the number of row addresses used by the memory array. This number does not include the bank, column, or data qualifier addresses. Parameters affected by the programming of this field include the page-hit address comparators and the bank address bit locations. 000 11 row addresses 001 12 row addresses 010 13 row addresses 011 14 row addresses 100 through 111 Reserved
23–22	Reserved
21–20 COL	Column address width. The COL control field is used to specify the number of column addresses in the memory array and determine the break point in the address multiplexer. Column width is the number of multiplexed column addresses and does not include bank, and row addresses, or addresses used to generate the DQM signals. 00 8 column addresses 01 9 column addresses 10 10 column addresses 11 Reserved
19–18	Reserved, read as 0
17–16 DSIZ	SDRAM memory data width. This field defines the width of the SDRAM memory and its alignment on the external data bus. 16-bit ports may be aligned to either the high or low half word to equalize capacitive loading on the bus. Data qualifier mask control outputs must be matched to the selected data bus alignment. Memories aligned to D[31:16] use DQM2 and DQM3. Memories aligned to D[15:0] use DQM0 and DQM1. 00 16-bit memory width aligned to D[31:16] 01 16-bit memory width aligned to D[15:0] (reset value for CSD0) 10 32-bit memory width (reset value for CSD1) 11 Reserved

Table 21-8. Enhanced SDRAM Control Register (ESDCTL*n*) Field Descriptions (Continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>15–13
SREFR</td><td>SDRAM refresh rate. This control bit field enables/disables SDRAM refresh cycles and controls the refresh rate. Refresh cycles are referenced to a 32 kHz clock. At each falling edge 1, 2, 4, 8 or 16 rows are refreshed as determined by this bit field. Multiple refresh cycles are separated by the row cycle delay specified in the SRC control field. Refresh is disabled by hardware reset. For an example of usage see Table 21-15.
<table>
<tr><th>SREFR[2:0]</th><th>Rows per Refresh Clock</th><th>Rows per 64 ms @ 32 kHz</th><th>Row Rate @ 32 kHz</th></tr>
<tr><td>000</td><td colspan="3">Refresh Disabled (bit field reset value)</td></tr>
<tr><td>001</td><td>1</td><td>2048</td><td>31.25 µs</td></tr>
<tr><td>010</td><td>2</td><td>4096</td><td>15.62 µs</td></tr>
<tr><td>011</td><td>4</td><td>8192</td><td>7.81 µs</td></tr>
<tr><td>100</td><td>8</td><td>16384</td><td>3.91µs</td></tr>
<tr><td>101</td><td>16</td><td>32768</td><td>1.95 µs</td></tr>
<tr><td>110</td><td colspan="3">Reserved</td></tr>
<tr><td>111</td><td colspan="3">Reserved</td></tr>
</table></td></tr>
<tr><td>12</td><td>Reserved, read as 0</td></tr>
<tr><td>11–10
PWDT</td><td>Power-down timer. This field determines whether the SDRAM is placed in a power-down condition after a selectable delay from the last access. The power-down timeout can be triggered on either the absence of an active bank (PWDT=01) or a clock (HCLK) count from the last access (PWDT=10 or 11). Count-based timeouts do not force the SDRAM into an idle condition (for example., any active banks remain open). The power-down timers feature is disabled by hardware reset. See sections Section 21.4.5.3, “Power-Down Modes” and Section 21.4.5.3.2, “Active Power-Down Mode” for a comprehensive description of this operating mode.
<table>
<tr><th>PWDT[1:0]</th><th>Power-Down Timeout</th><th>Memory Device Operating Mode</th></tr>
<tr><td>00</td><td>Disabled (bit field reset value)</td><td>Run mode</td></tr>
<tr><td>01</td><td>Any time no banks are active</td><td>Precharge power-down</td></tr>
<tr><td>10</td><td>64 clocks (HCLK) after completion of last access[1]</td><td>Active power-down</td></tr>
<tr><td>11</td><td>128 clocks (HCLK) after completion of last access[1]</td><td>Active power-down</td></tr>
</table>
[1] This setting cannot be used if the PRCT (precharge timer) is enabled.
Note: When PWDT is enabled, and LPMD or DVFS requests are required by the system, PWDT must be disabled before the requests are granted. PWDT can only be re-enabled after these modes are exited.</td></tr>
<tr><td>9</td><td>Reserved, read as 0</td></tr>
<tr><td>8
FP</td><td>Full page. This bit should be set to 1 if the burst length of the SDRAM connected to the CSD has been configured to full page mode. This bit is needed since ESDRAMC needs to induce a BURST TERMINATE (BT) command to terminate early all accesses that are less than full page.

0 Burst length of the external memory device is not set to full page.
1 Burst length of the external memory device is set to full page.
Note: Full page mode is not supported when LPDDR external devices are used.</td></tr>
</table>

Table 21-8. Enhanced SDRAM Control Register (ESDCTL*n*) Field Descriptions (Continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>7
BL</td><td>Burst length. This bit configures the access burst length. For proper operation the ESDRAMC burst length configuration must match the external SDRAM/LPDDR memory device (configured via special operating load mode register). Setting this bit to 1 means that the external memory device connected to the CSD have been configured to burst length of 8. If this bit is cleared to 0, means that the external memory device connected to the CSD have been configured to burst length of 4.
BL bit settings are given in the following table:
<table>
<tr><th>BL setting</th><th>SDR SDRAM</th><th>LPDDR SDRAM</th></tr>
<tr><td>0</td><td>4 (not supported for 16-bit SDRAM devices</td><td>Reserved</td></tr>
<tr><td>1 (reset value)</td><td>8</td><td>8</td></tr>
</table>
</td></tr>
<tr><td>6</td><td>Reserved, read as 0</td></tr>
<tr><td>5–0
PRCT</td><td>Precharge timer. Banks are precharged after 2xPRCT clocks (HCLK, up to 133 MHz) of no activity.
Using the precharge command to close the last used/open row in any inactive bank within a chip select reduces the power consumption of the external memory device. The power saving is device-dependent: the user may consult the external memory device specification for more details on power consumption reduction.
If PRCT is enabled, the PRCT field specifies the approximately number of HCLK cycles of inactivity to one of the SDRAM/LPDDR banks before the precharge command is issued. The number of cycles before the precharge command is issued depends on command bus (WE, RAS, CAS and CSD) availability (means there is no active access to other bank) and the memory timing parameters.

000000 Disabled (reset value)
000001 2 clocks to precharge
000010 4 clocks to precharge
000011 6 clocks to precharge
000100 8 clocks to precharge
…
100000 64 clocks to precharge
…
111111 126 clocks to precharge</td></tr>
</table>

21.3.3.2 Enhanced SDRAM Configuration Registers (ESDCFG*n*, *n* = 0,1)

Figure 21-6 and Figure 21-7 show the bit assignments for the enhanced SDRMA configuration registers. Bit assignments for the two registers are identical, but reset values for some fields differ. Table 21-9 provides field descriptions for the registers.

NOTE

The ESDRAMC configuration registers reset values define timing parameters that meet memory device optimal timing requirements at 133 MHz. If the external memory device operates at a lower frequency, for optimal performance the user should reconfigure the timing parameters according to the device electrical characteristics and operating conditions.

Table 21-9. ESDCFG*n* Field Descriptions

Field	Description
31–23	Reserved, read as 0
22–21 t_{XP}	LPDDR exit power-down to next valid command delay. This control field determines the minimum delay between a valid command is issued to the LPDDR after exiting power-down mode. The value programmed in t_{XP} is the number of clocks inserted after exiting power-down mode and any subsequent new valid command. An example timing diagram for t_{XP} can be found in Figure 21-19. 00 1 clock delay before new command issued to LPDDR after power-down mode exit 01 2 clock delay before new command issued to LPDDR after power-down mode exit 10 3 clock delay before new command issued to LPDDR after power-down mode exit 11 4 clock delay before new command issued to LPDDR after power-down mode exit

Table 21-9. ESDCFG*n* Field Descriptions (Continued)

Field	Description
20 t_{WTR}	tLPDDR write to read command delay. Data for any write burst may be followed by a subsequent read command. To follow a write without truncating the write burst, t_{WTR} should be set as shown in Figure 21-8. The LPDDRC automatically induces a t_{WTR} number of idle cycles between a write followed by a read command. The t_{WTR} should be configured according to the LPDDR device being used. The t_{WTR} is referenced from the first positive clock edge after the last data-in pair. 0 1 clock 1 2 clocks
19–18 t_{RP}	SDRAM row precharge delay. This control bit determines the number of idle clocks inserted between a precharge command and the next row activate command to the same bank. Hardware reset initializes the controller to insert 3 clocks. Following a precharge command, a subsequent command to the same bank cannot be issued until t_{RP} is met. 00 1 clock 01 2 clocks 10 3 clocks 11 4 clocks
17–16 t_{MRD}	tMRD - SDRAM load mode register to active command. This control bits determines the minimum number of idle clocks required between a load mode register (LMR) command to active. Hardware reset initializes the controller to insert 2 clocks. 00 1 clock 01 2 clocks 10 3 clocks 11 4 clocks
15 t_{WR}	SDRAM write to precharge command. Data for a fixed length write burst may be followed by, or truncated with, a precharge command to the same bank (provided that auto-precharge was not activated), and a full-page write burst may be truncated with a precharge command to the same bank. The precharge command should be issued t_{WR} after the clock edge at which the last desired input data element is registered. t_{WR} control bit determines the number of idle clocks inserted between the last desired input data element and the next precharge command, as shown in Figure 21-11. **Note:** The auto-precharge mode requires a t_{WR} of at least one clock plus time, regardless of frequency.

tWR	Write to Precharge (SDRAM)	Write to Precharge (LPDDR)[1]
0	2 clock	2 clocks
1 (reset value)	3 clocks	3 clocks

[1]Applies in case that MDDR_EN bit is set, that is, the external memory device is a LPDDR.

Table 21-9. ESDCFG*n* Field Descriptions (Continued)

Field	Description
14–12 t_{RAS}	SDRAM active to precharge command. These control bits determine the minimum number of clocks required between a active to precharge command to the same bank. Hardware reset initializes the controller to insert 6 clocks. Following a active command, a subsequent precharge command to the same bank cannot be issued until t_{RAS} is met. Figure 21-12 presents an example of a single read (without auto-precharge). It should be noticed that the precharge command is not allowed at T3 and at T4, since t_{RAS} is violated (for t_{RAS}= 4 clock cycles). Note that t_{RAS} also defines the minimum period of time that the SDRAM must remain in self-refresh mode, as it shown in Figure 21-13. 000 1 clock 001 2 clocks 010 3 clocks 011 4 clocks 100 5 clocks 101 6 clocks 110 7 clocks 111 8 clocks
11–10 t_{RRD}	Active bank A to active bank B command. A subsequent active command to a different row in the same bank can only be issued after the previous active row has been “closed” (precharged). A subsequent active command to another bank can be issued while the first bank is being accessed, which results in a reduction of total row-access overhead. The minimum interval between successive active commands to different banks is defined by t_{RRD} as shown in Figure 21-14 (for t_{RRD}=3). The t_{RRD} bits field encoding is listed below and it determines the number of idle clocks inserted between consecutive active commands to different banks. 00 1 clock active to active (different banks) 01 2 clocks active to active (different banks) 10 3 clocks active to active (different banks) 11 4 clocks active to active (different banks)
9–8 t_{CAS}	SDRAM CAS latency. This field determines the latency between a read command and the availability of data on the bus, as shown in Figure 21-15. This field does not affect the second and subsequent data words in a burst. This control field has no effect on write cycles. CAS latency is initialized to 3 clocks following a hardware reset. 00 3 clocks only for LPDDR and DDR2 CAS latency 01 Reserved 10 2 clocks SDR and LPDDR SDRAM CAS latency 11 3 clocks SDR SDRAM CAS latency
7	Reserved

Table 21-9. ESDCFG*n* Field Descriptions (Continued)

Field	Description
6–4 t_{RCD}	SDRAM row to column delay. This field determines the number of clocks inserted between a row activate command and a subsequent read or write command to the same bank. Hardware reset initializes the delay to 3 clocks. 000 1 clock row to column delay 001 2 clocks row to column delay 010 3 clocks row to column delay 011 4 clocks row to column delay 100 5 clocks row to column delay 101 6 clocks row to column delay 110 7 clocks row to column delay 111 8 clocks row to column delay
3–0 t_{RC}	SDRAM row cycle delay. This control field determines the minimum delay between a refresh and any subsequent refresh or read/write access. This delay corresponds to the minimum row cycle time captured in the t_{RC}/t_{RFC} memory timing specification. The value programmed in t_{RC} is the number of clocks inserted between the refresh and subsequent refresh/activate command. An example timing diagram for t_{RC} can be found in Figure 21-18. 0000 20 clocks 0001 2 clocks 0010 3 clocks 0011 4 clocks … 1111 16 clocks **Note:** The t_{RC} control field is not used to enforce t_{RC} timing for row activate to row activate within the same bank as this is implicitly guaranteed by the sum of t_{RCD} + t_{CAS} + t_{RP}.Use regular paragraphs to summarize register function, then use the following special styles to define bit and field function. **Note:** Since t_{RC} +1 is also used to determine the time between auto-refresh cycles (may be referred to in memories as t_{RFC} or t_{ARFC}) and self-refresh exit time in SDR memories (may be referred to as t_{SREX} or t_{SRFX} for some vendors), and for a specific memory these timings may be worse then t_{RC}, this parameter should be configured to the worst of the three, like so: t_{RC} in controller = max (t_{ARFC} -1, t_{SRFX} -1, t_{RC} in memory). Example: For Samsung K4M51323PC-75 mobile SDR SDRAM, t_{RC} is 72.5 ns, t_{ARFC} is 80 ns, and t_{SRFX} is 120 ns. @133MHz, cycle time is 7.5 ns, so t_{RC} = max (80/7.5 - 1, 120/7.5 - 1, 72.5/7.5) = 15 cycles.

Table 21-10 summarizes the enhanced SDRAM controller configurable set of timing parameters for SDRAM and LPDDR devices.

Table 21-10. Configurable SDRAM/LPDDR Timing Parameters

Symbol	Description	Relevancy	Typical Values at 133 MHz
t_{MRD}	Load mode register command to active or refresh command	Always	2 cycles
t_{WR}	Write recovery time (write to precharge)	Commands to same bank	2 cycles
t_{RAS}	Active to precharge command	Commands to same bank	6 cycles
t_{RRD}	Active bank A to active bank B command	Commands to different banks	2 cycles
t_{CAS}	Read to data out period (known as CAS latency)	Always	3 cycles

Table 21-10. Configurable SDRAM/LPDDR Timing Parameters (Continued)

Symbol	Description	Relevancy	Typical Values at 133 MHz
t_{RP}	Precharge command period	Commands to same bank	3 cycles
t_{RCD}	Active to read or write delay	Commands to same bank	3 cycles
t_{RC}	Active to active command period	Commands to same bank	10 cycles[1]
t_{WTR}	LPDDR read to write command delay	Commands to same bank	2 cycles
t_{XP}	LPDDR exit power-down to next valid command delay	Always	4 cycles

1 Since t_{RC} +1 is also used to determine the time between auto-refresh cycles (may be referred to in memories as t_{RFC} or t_{ARFC}) and self-refresh exit time in SDR memories (may be referred to as t_{SREX} or t_{SRFX} for some vendors), and for a specific memory these timings may be worse then t_{RC}, this parameter should be configured to the worst of the three, like so: t_{RC} in controller = max (t_{ARFC} -1, t_{SRFX} -1, t_{RC} in memory).
Example:
For Samsung K4M51323PC-75 Mobile SDR SDRAM, t_{RC} is 72.5 ns, t_{ARFC} is 80 ns, and t_{SRFX} is 120 ns.@133MHz, cycle time is 7.5 ns, so t_{RC} = max (80/7.5 - 1, 120/7.5 - 1, 72.5/7.5) = 15 cycles.

21.3.3.3 Enhanced SDRAM Miscellaneous Register (ESDMISC)

This register configures various memory and control settings for the ESDRAMC. The bit assignments for the register are shown in Figure 21-20 and the field descriptions for the bit assignments are listed in Table 21-11.

Offset 0x0010 (ESDMISC) Access: User read-write

Table 21-11. Enhanced SDRAM Miscellaneous Register Field Descriptions

Field	Description
31 SDRAM_RDY	External SDRAM/LPDDR device status. This is a read-only status bit, that indicates the state of the external memory device(s). This bit is cleared at reset. This bit is set after the 200 µs SDRAM/LPDDR external memory wakeup period. After the wakeup period the software can start the external memory initialization (as described in Section 21.5.4, “SDRAM/LPDDR Initialization Sequence”). 0 SDRAM/LPDDR external device is not ready for use (reset value). 1 SDRAM/MMDR external device is ready for use.
30-10	Reserved, read as 0
9 DDR2_EN	Regular (non-mobile) DDR2 device is connected. This bit is common for both chip selects. 0 DDR2 device is not used (reset value) 1 DDR2 device is used **Note:** When this bit is asserted, the MDDR_EN bit and the DDR_EN bit must also be asserted.
8 DDR_EN	Regular (non-mobile) device is connected. This bit is common for both chip selects. 0 DDR1/DDR2 device is not being used (reset value) 1 Non-mobile DDR device is used (DDR2 or DDR1) **Note:** When this bit is asserted the MDDR_EN bit must also be asserted.
7 FRC_MSR	Force measurement. When this bit is set the measurement unit will start a new measurement over and over again till this bit is cleared.t

Table 21-11. Enhanced SDRAM Miscellaneous Register Field Descriptions (Continued)

Field	Description
6 MA10_SHARE	MA10 share. Need to be enabled if MA10 address line is shared with other memory controllers address line. If enabled, the ESDRAMC will request the address line from the M3IF before issuing the precharge-all command (during auto-refresh cycles). After the precharge-all command is completed the ESDRAMC will remove the request. If MA10 share is disable, the ESDRAMC will execute the precharge-all command without requesting the MA10 address line, by assuming that MA10 address line is dedicated to ESDRAMC. 0 MA10 share disable 1 MA10 share enable
5 LHD	Latency hiding disable. This bit disables the command anticipation (latency hiding) mechanism. If this bit is set, the M3IF/ESDRAMC will operate in MIF1 (non-optimized) mode as shown in Figure 21-26 and Figure 21-27. The first memory command of a new access is sent to the memory only after the previous access is completed, For example: the last data word of a burst has been read or written. The reset value of this bit is 0, meaning that latency hiding is enabled (M3IF/ESDRAMC works in MIF2 mode) as described in Section 21.4.1, “Enhanced SDRAM Controller Optimization Strategy”). 0 Latency hiding enable 1 Latency hiding disable
4 MDDR_MDIS	LPDDR delay line measure disable. This is a read/write bit, that, if set, disables the delay line measure unit. After reset, this bit is cleared, meaning the delay line measure unit is enabled. The measure time period is estimated to be around 2000 clock cycles of the AHB HCLK. 0 LPDDR delay line measure unit is enabled. 1 LPDDR delay line measure unit is disabled.
3 MDDR_DL_RST	LPDDR delay line soft reset. This is a write only bit, that if set the delay line unit is reset. After reset the delay unit will automatically (if LPDDR_MDIS is cleared) start a new measurement. 0 LPDDR delay line is not reset. 1 LPDDR delay line is reset.
2 MDDR_EN	Enable DDR SDRAM device. 0 SDR SDRAM is used. 1 DDR SDRAM is used (either mobile or non-mobile).
1 RST	Software initiated local module reset. This bit generate local module reset to the ESDRAMC. Writing a 1 to RST bit results in a one cycle reset pulse to the controller. This bit is always read as 0. All ESDRAMC registers are not affected by the software reset, in order to keep the refresh mechanism active as initially configured, so the SDRAM/LPDDR data is not violated. A burst terminate command is issued to the memory after the soft reset (to terminate any active bursts, in order to prevent potential contention on the data pads). During the software reset an error response (HRESP[1]=1) is broadcast to all masters with active access to the ESDRAMC by the multi master memory interface (M3IF) module and the M3IF arbitration pipeline is cleared. For detailed information on error response see theM3IF module specification. **Note:** After soft reset, a precharge-all command must be issued prior to normal usage of the ESDRAMC. 0 Soft reset disabled. 1 Soft reset initiated.
0	Reserved, read as 0

21.3.3.4 MDDR Delay Line *n* Configuration Debug Registers (ESDCDLY*n*, *n* = 1–4)

These debug registers controls the functionality of delay lines 1–4 (signals DQS[0–3]) used during read cycles. It enables software to override the delays of the DQS[*n*] lines that is used during read cycles of byte *n*. The delay line compensates for process variations, and produces a constant delay regardless of the process, temperature and voltage. The bit assignments for the register are shown in Figure 21-21 and the field descriptions for the bit assignments are listed in Table 21-12.

Offset 0x0020 (ESDCDLY1)

Table 21-12. Enhanced MDDR Delay Line *n* Control Register (ESDCDLY*n*) Field Descriptions

Field	Description
31 SEL_DLY_REG_*n*	SEL_DLY_REG_*n* bit selects the delay used by delay line *n*. It selects between the following options: • Delay line *n* value is a quarter of a cycle (measured) plus or minus the delay line *n* offset field (DLY_OFFSET_*n*) • Delay line *n* value is equal to the delay line *n* register value (DLY_REG_*n*). 0 Delay line *n* value is a quarter of a cycle (measured) plus or minus the delay line *n* correction factor field. 1 Bypass mode: Delay line *n* value is the value of delay line *n* register field (skipping the measurement).
30-24	Reserved
23-16 DLY_OFFSET_*n*	Delay line *n* offset value. The offset value is used only if SEL_DLY_REG_*n* is cleared. The offset value is used to compensate process-dependent misalignments between the DQS signal and the corresponding read data (in number of small delay intervals). The field represents positive and negative numbers using twos complement representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay intervals to the measured delay, set this field to 00000011. To subtract 3 delay intervals, set it to 11111101.

Field	Description
15-8 DLY_ABS_OFFSET_*n*	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay line's delay is computed as (DLY_ABS_OFFSET_*n* / 512) * tCK. For example, the default value of 128 causes a quarter cycle delay. In bypass mode (SEL_DLY_REG_*n* = 1), this register has no effect on the delay. **Note:** Not all changes have an effect on the actual delay. If the requested change is smaller then the delay line resolution (1 delay interval, which varies between 20 pSec in the best case to 50 pSec in the worst case), then no change occurs. **Note:** Updating this field requires two cycles to update in the delay line.
7-0 DLY_REG_*n*	This field is the delay (in number of buffer units) that is used by delay line *n*, if the SEL_DLY_REG_*n* bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this field we get different actual delay values. This field contains only positive numbers.

21.3.3.5 MDDR Delay Line 5 Configuration Debug Register (ESDCDLY5)

This debug register controls delay line 5 functionality, that is data bus delay used during write cycles. It allows software to manually set the delay of the data bus, during write cycles. The bit assignments for the register are shown in Figure 21-22 and the field descriptions for the bit assignments are listed in Table 21-13.

Offset 0x0030 (ESDCDLY5) Access: User read-write

Figure 21-22. MDDR Delay Line 5 Configuration Debug Register

Table 21-13. Enhanced MDDR Delay Line 5 Control Register (ESDCDLY5) Field Descriptions

Field	Description
31 SEL_DLY_REG_5	SEL_DLY_REG_5 bit selects the delay used by delay line 5. It selects between a quarter of a cycle (measured) plus or minus the delay line 5 offset field (DLY_OFFSET_5) and delay line 5 register value (DLY_REG_5). 0 Delay line 5 value is a quarter of a cycle (measured) plus or minus the delay line 5 correction factor field. 1 Bypass mode: Delay line 5 value is the value of delay line 5 register field (skipping the measurement).
30-24	Reserved

Field	Description
23-16 DLY_OFFSET_5	This field is the delay line 5 offset value. The offset value is used only if SEL_DLY_REG_5 is cleared. The offset value is used to compensate process-dependent misalignments between the DQS signal and the corresponding read data (in number of small delay intervals). The field represents positive and negative numbers using twos complement representation. This allows positive and negative offsets from the quarter cycle measured value. For example, to add 3 delay units to the measured delay, set this field to 00000011, to subtract 3 delay units, set it to 11111101.
15-8 DLY_ABS_OFFSET_5	Absolute delay offset. This field decides the specific delay line absolute delay in fraction of a cycle terms. The fraction is process and frequency independent. The delay for the delay line would be (DLY_ABS_OFFSET_5 / 512) * tCK. So for the default value of 128 we get a quarter cycle delay. In Bypass mode (SEL_DLY_REG_5 = 1), this register has no effect on the delay. **Note:** Not all changes will have effect on the actual delay. If the requested change is smaller then the delay line resolution (1 delay unit, which varies between 20 pSec in the best case to 50 pSec in the worst case), then no change will occur. Remark: Updating this field requires two cycles to update in the delay line.
7-0 DLY_REG_5	This field is the delay (in number of buffer units) that is used by delay line 5, if the SEL_DLY_REG_5 bit is set. Since the delay is process, temperature and voltage dependent, for a given value of this filed we get different delay values. This field contains only positive numbers.

21.3.3.6 MDDR Delay Line Cycle Length Debug Register (ESDCDLYL)

This read-only register's value represents the number of inverters required to achieve a delay of one clock cycle, as a function of the IC conditions (temperature, voltage, frequency, process). The reset value is unknown, because after reset the register value is updated from the measured delay. The bit assignments for the register are shown in Figure 21-23 and the field descriptions for the bit assignments are listed in Table 21-14.

Figure 21-23. MDDR Delay Line Cycle Length Debug Register

Table 21-14. Enhanced MDDR Delay Line Cycle Length Debug Register (ESDCDLY1) Field Descriptions

Field	Description
31-8	Reserved, read as 0
7-0 QTR_CYCLE_LENGTH	This debug register shows the number of delay intervals that are being used to create the needed delay for Delay Line 5 (for write operations). Changes to the DLY_ABS_OFFSET_5 or DLY_OFFSET_5 fields of the ESDCDLY5 register cause this value to change, as long as the minimal or maximal delay is not reached.

21.4 Functional Description

The ESDRAMC's general operating characteristics are addressed in this section, including the following topics:

- Section 21.4.1, "Enhanced SDRAM Controller Optimization Strategy"
- Section 21.4.2, "Address Multiplexing"
- Section 21.4.3, "Multiplexed Address Bus During Precharge or Load Mode Registers Modes"
- Section 21.4.4, "Refresh"
- Section 21.4.5, "Low Power Operating Modes"
- Section 21.4.6, "SDRAM (SDR and LPDDR) Command Encoding"

In Section 21.4.7, "Normal Read/Write Mode" through Section 21.4.11, "Load Mode Register Mode," the different ESDRAMC operating modes are described. The discussion includes details on basic operation, relationship to SDRAM/LPDDR operating modes, and any special precautions which need to be observed. State and timing diagrams are included where appropriate.

The enhanced SDRAM controller is designed to support a broad range of broad range of JEDEC standard SDRAM/LPDDR configurations including devices of 64-, 128-, 256-, 512-Mbit, 1-Gbit and 2-Gbit densities. Given the physical size constraints of the target applications, the design support memory devices with data widths of 16 and 32 bits. Table 21-15 summarizes the devices supported by the design. Only 4-bank devices are supported. 133-MHz system bus operation is possible with PC133-compatible single– or double–data rate memory devices.

Table 21-15. JEDEC Standard Single/Double–Data Rate SDRAMs

	SDRAM Configurations—4-Bank Devices

[1] Not ratified by JEDEC, row-column organization may change.
[2] 2 -Gbit SDRAM/LPDDR (16-bit) are not supported/available.

21.4.1 Enhanced SDRAM Controller Optimization Strategy

SDRAM (SDR and LPDDR) memories provide high speed access by hiding the latency of consecutive memory accesses through a pipeline interface architecture. The resulting high bandwidth is achieved with a rather complex command interface and a large number of timing constraints that must be kept by the memory controller.

SDRAM, LPDDR and memories are organized in several independent banks. By issuing a row address and bank number to the memory device, the corresponding memory page is activated (opened). Consecutive READ commands (together with the column address) into this memory page (same row address) have a low latency. Accessing another page in the same bank requires closing the open page by a precharge command, followed by the activation (ACTIVE command) of the new memory page (new row address).

Figure 21-24 and Figure 21-25 show examples of SDR and LPDDR SDRAM read bursts. Initially the cell in [COL a, ROW a] is active/open. Accessing the cell position [COL b, ROW b] requires first closing the old cell in [COL a, ROW a], which is done with a PRECHARGE command (P in the figure). Then the access row address (ROW b) can be activated (A in the figure) before the column address (COL b) is passed (READ command R). Timing restrictions are as follows:

- The ACTIVE command can be issued only tRP cycles after the PRECHARGE command.
- The READ command can be issued only tRCD cycles after the ACTIVE command.
- The first data is available only tCAS cycles after the READ command has been issued.

Hence, in those examples a 4-word (8-word in LPDDR is converted to 4-word with twice data width) read burst requires 9 cycles (6 cycles latency from the PRECHARGE command to the first word on the external bus) or 6-1-1-1. A read access from an already-open row is shown as well: the read burst from target cell [ROW b, COL c] onward takes only 5 cycles (2 cycles latency from the READ command to the first word on the external bus) or 2-1-1-1.

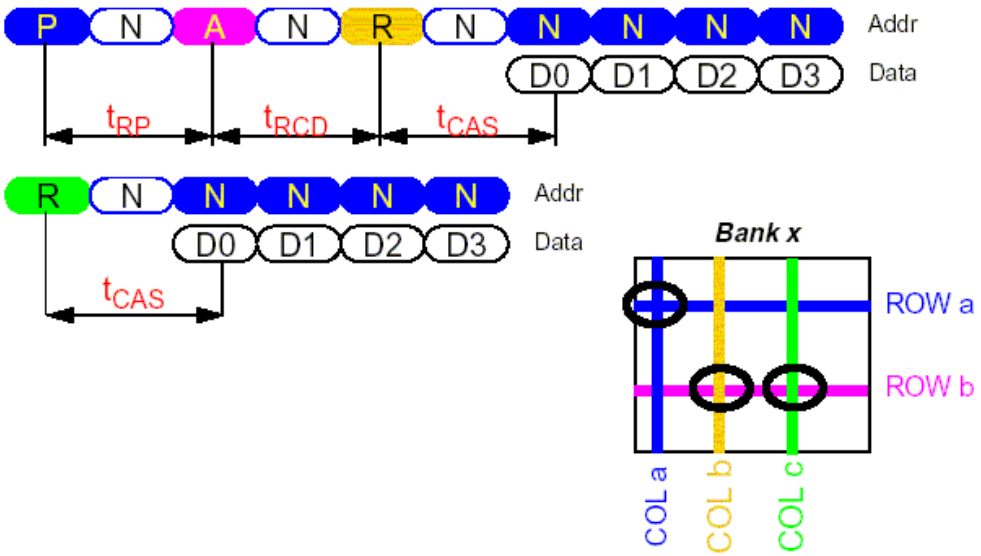

Figure 21-24. SDR SDRAM Read Burst Command Sequence Example

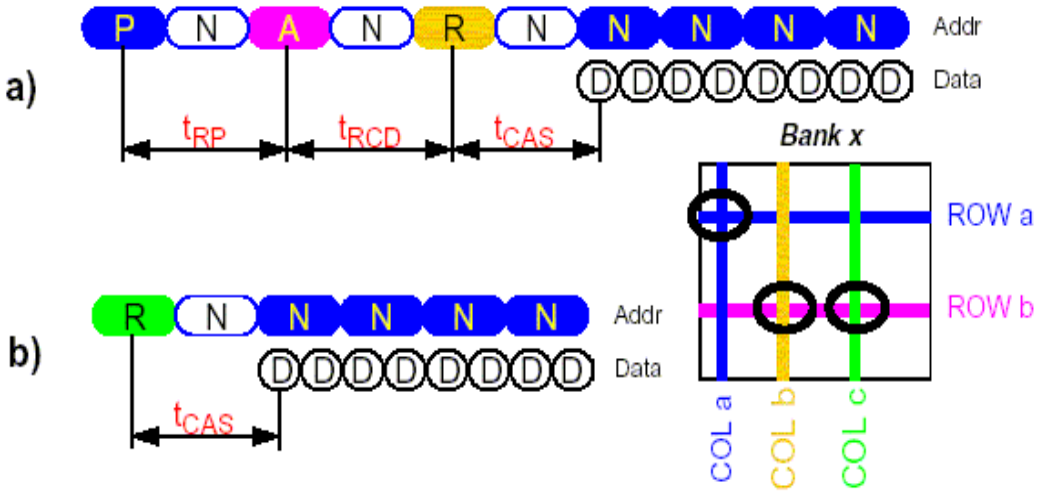

Figure 21-25. LPDDR SDRAM Read Burst Command Sequence Example

Since the ESDRAMC handles two devices that both feature 4 independent memory banks, there are opportunities for the controller to optimize the access timing of consecutive memory accesses by hiding as much as possible the latency of the first data word in a burst. Table 21-16 summarizes cases where latency hiding is possible.

Table 21-16. Possibilities for Latency Hiding

Current Burst Access	Next Burst Access
SDRAM bank *x*	SDRAM bank *y*

Table 21-16. Possibilities for Latency Hiding (Continued)

Current Burst Access	Next Burst Access
SDRAM bank *x* (row *y*, col *z*)	SDRAM bank *x* (row *y*, col *w*)
LPDDR SDRAM bank *x*	LPDDR SDRAM bank *y*

Figure 21-26 (SDR) and Figure 21-27 (LPDDR) show the no-optimization (MIF1) and medium-level optimization (MIF2) strategies, respectively. For SDR SDRAM each strategy, two examples for two consecutive read accesses are given:

- An 8-word burst from the SDRAM with CAS latency of 2 cycles followed by an 8-word burst from the same bank and row (different column) with CAS latency of 2 cycles.
- An 8-word burst from one bank in the SDRAM followed by an 8-word burst from a different bank to the same SDRAM.

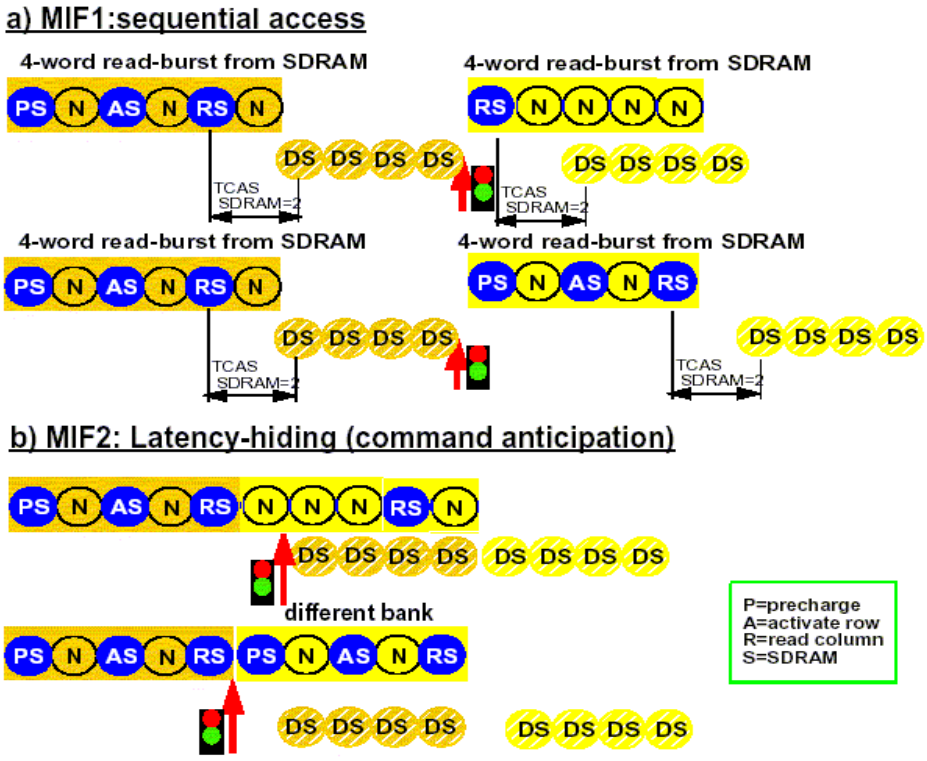

Figure 21-26. SDR SDRAM Optimization Strategies - MIF1 and MIF2 Examples

For LPDDR SDRAM each strategy, one example for two consecutive read accesses is given:

- a 8-word burst from one bank in the LPDDR SDRAM followed by a 8-word burst from a different bank to the same LPDDR SDRAM.

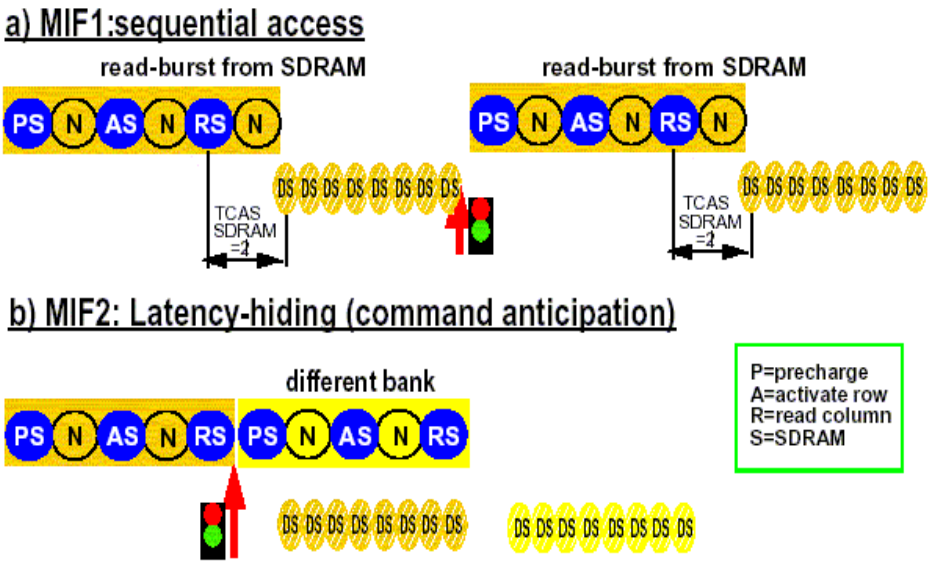

Figure 21-27. Mobile LPDDR SDRAM Optimization Strategies—MIF1 and MIF2 Examples

21.4.1.1 MIF1—No Optimization/Sequential Accesses

This is the non-optimized case shown in Figure 21-26 and Figure 21-27. The first memory command of a new access is sent to the memory only after the previous access is completed, for example, the last data word of a burst has been read or written. It can be seen in this example that although the 2 memory accesses follow with no delay between them, the bandwidth usage for the command (address) and data busses is far from being optimal. This no optimization/ sequential accesses occurs in the following cases;

- Only one master active/present in a given system - in this case only sequential commands are possible since the given master need to receive/send (read/write) all data's for one access before it can proceed to the next access, for example, command anticipation is not possible.
- Low density accesses, such as non-overlapped/consecutive/continuous requests, means that the next SDRAM request starts after the previous request is completed. In this low SDRAM utilization only sequential accesses occurs.
- Large number of SINGLE or INCR (aborted after one data) accesses instead of burst type accesses. SINGLE/INCR see the AMBA AHB bus protocol.
- The LHD (latency hiding disable) bit is set.

21.4.1.2 MIF2—Medium Level Optimization/Command Anticipation

This strategy is shown in Figure 21-26 and Figure 21-27. As soon as the address and command bus (referred to as the SDRAM control bus) is no longer used for issuing the previous memory access command, the controller can use this bus to start issuing the PRECHARGE/ACTIVE commands for the next scheduled memory access while the previous one is still active on the data bus. Two conditions limit the use of this optimization at a given time:

- Memory timing constraints must not be violated.

- The execution of the previous command should not be affected (for example, truncated).

This approach allows for hiding a part of the latency for the first data word or even the complete hiding of the latency in case that the burst length exceeds the maximal command sequence length.

21.4.1.3 Latency Hiding

The ESDRAMC optimization is based on command anticipation (MIF2), so that the next access control phase (memory address and command) is driven during the previous access data phase (data flow from/to the memory). This creates an overlap between accesses which hides part or all of the latency. Additional optimization (not implemented in the ESDRAMC module) can be achieved by control phase interleaving: during idle cycles in the control phase (caused by the memory timing constraints like tRP and tRCD) two accesses' control phases can be interleaved so the latency is fully hidden. The ESDRAMC optimization can occur only in a multi-master system with a high SDRAM utilization (that is, a high density of accesses).

The ESDRAMC module optimizes data bus utilization in accesses to memory according to the system initial configuration. Some examples for different memory/access conditions are as follows.

The timing diagrams in Figure 21-28 and Figure 21-29 show latency hiding for SDR and mobile DDR respectively in the case where a read miss is followed by a read hit. In Figure 21-28, the miss burst read from bank A in SDR memory is followed by a hit burst read request from the same chip select. The second READ command is issued during the first access data phase, so the first data of the second access (D10) is valid immediately after the last data of the first access (D4 for the SDR and D8 for the LPDDR). The CAS latency (tCAS) is set to 2 cycles. The second access latency is fully hidden during the first access data phase.

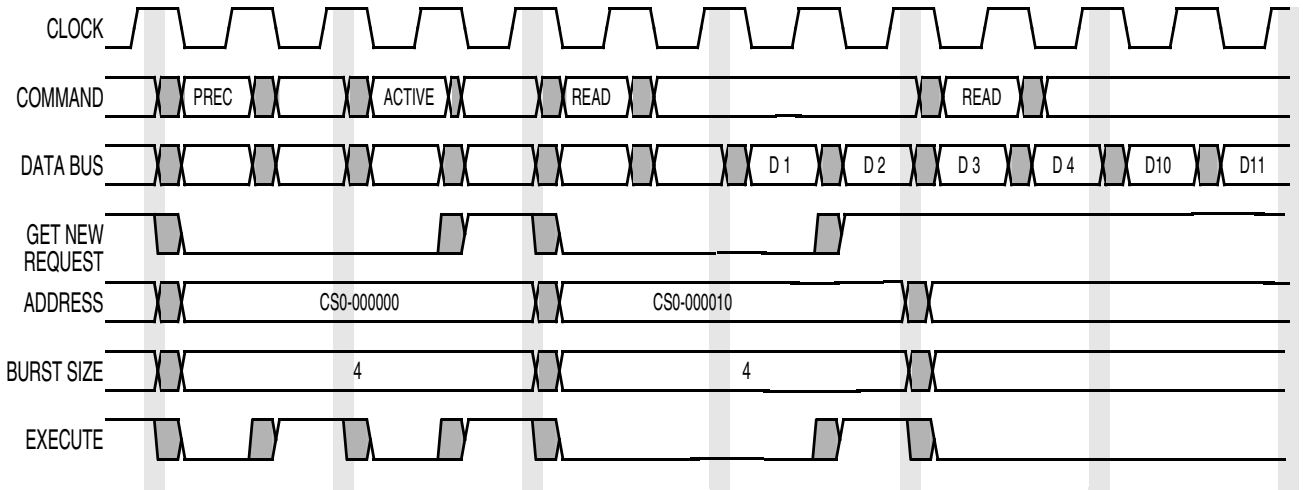

Figure 21-28. SDR Simple Read after Read Latency Hiding Timing Diagram

Figure 21-29 shows the case where a miss burst read from bank A in one mobile / low power DDR memory device is followed by a hit burst read request from another LPDDR on the other chip select. In this case, an empty cycle is needed on the data bus to prevent contention of DQS signals from two different LPDDRs

on two different chip selects (contention between the last two data cycles of the first transfer and the preamble of the second transfer).

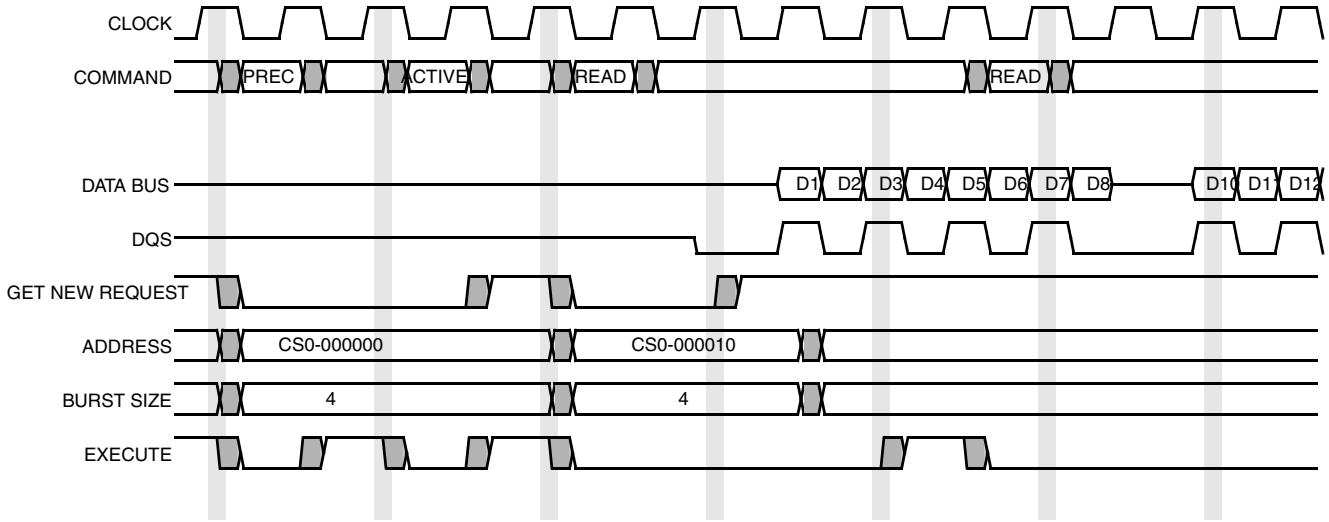

Figure 21-29. Mobile DDR Simple Read After Read Latency Hiding Timing Diagram

The timing diagrams in Figure 21-30 and Figure 21-31 show latency hiding for SDR and mobile DDR memories respectively in case a burst read to CSD0 is followed by a miss burst write access to CSD1. In the SDR case (Figure 21-30), both CSD burst lengths are 4; while in the LPDDR case the burst lengths are 8 but from the system point of view appear as burst length 4 with double bus width. Due to command anticipation the second access latency is fully hidden during the first access data phase. The first WRITE command to CSD1 (D10) is issued immediately after the last data from CSD0 (D4 for SDR and D8 for LPDDR), even though the access to CSD1 is a miss access CSD0 CAS latency is set to 3 cycles in these examples.

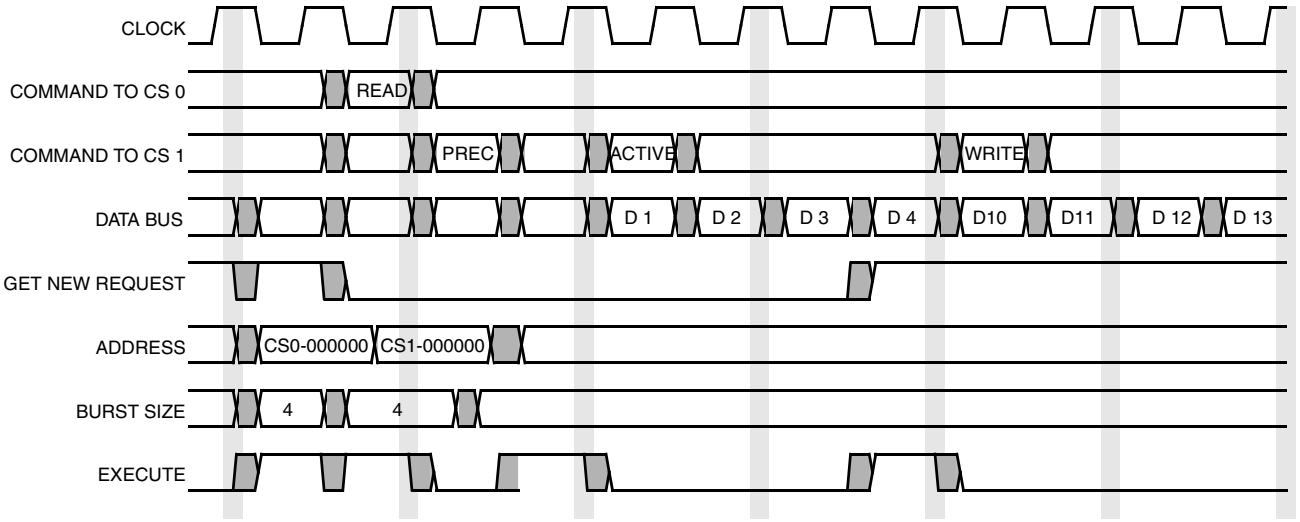

Figure 21-30. SDR Miss Write to CSD1 after Read from CSD0

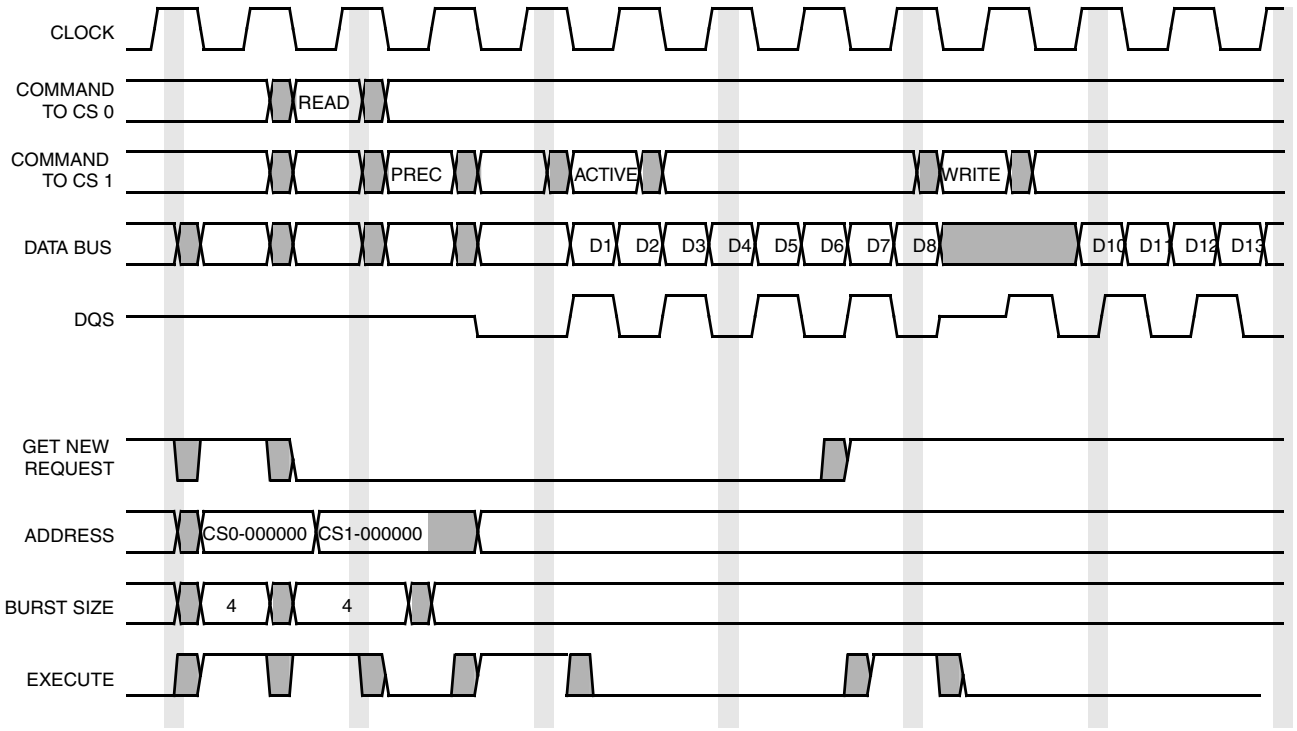

Figure 21-31. Mobile DDR Miss Write to CSD1 after Read from CSD0

21.4.2 Address Multiplexing

21.4.2.1 Multiplexed Address Bus

Table 21-17 illustrates several examples on how a CPU address is scrambled by the enhanced SDRAM controller to implement a contiguous address space.

Table 21-17. CPU to SDRAM/LPDDR Translation

CPU ADDRESS	16-bit SDRAM[1]	32-bit SDRAM[1]
A25	-	BA1
A24	BA1	BA0
A23	BA0	R11
A22	R11	R10
A21	R10	R9
A20	R9	R8
A19	R8	R7
A18	R7	R6
A17	R6	R5
A16	R5	R4

Table 21-17. CPU to SDRAM/LPDDR Translation (Continued)

CPU ADDRESS	16-bit SDRAM[1]	32-bit SDRAM[1]
A15	R4	R3
A14	R3	R2
A13	R2	R1
A12	R1	R0
A11	R0	C9
A10	C9	C8
A9	C8	C7
A8	C7	C6
A7	C6	C5
A6	C5	C4
A5	C4	C3
A4	C3	C2
A3	C2	C1
A2	C1	C0
A1[2]	C0	—
A0[3]	—	—

1 For the SDRAM example a memory configuration with 10 columns and 12 rows is illustrated. The address translation is based on the following concept, COLUMN - ROW - BANK.

2 CPU A1 defines how the data masks are driven—it is used as the byte enable for non-word accesses. This bit has a regular/normal use only in case of 16-bit memory, while CPU A0 defines the 2 bytes (low and high) in the 16-bit word.

3 CPU A0 defines how the data masks are driven— it is used as the byte enable for non-word accesses to 32-bit memory devices. Both CPU A0 and A1 define the 4 bytes in the 32-bit word.

4. Legend: C=COLUMN, S=SEGMENT, R=ROW, BA=BANK

The enhanced SDRAM controller multiplexed address bus is aligned to the column addresses so that address line A1 always appears on pin MA0 for 16-bit memory devices and A2 always appears on MA0 for 32-bit memory devices. With this alignment, the “folding point” in the multiplexer is driven solely by the number of column address bits. Column bus widths of 8 to 11 bits are supported. Table 21-18 summarizes the multiplex options supported by the controller for 16 and 32-bit devices respectively. Column addresses through A10 are driven regardless of the multiplexer configuration, although some of the lines are unused for the smaller page sizes.

Table 21-18. Address Multiplexing by Column/Row Width for 16-bit Devices

21.4.2.2 Bank Addresses

Bank address connections are summarized in Table 21-20. Bank addressing utilizes the most-significant addresses to specify the active bank, the actual bits being dependent on the density of the memory system. Page size and density for a number of potential configurations are documented in Table 21-20. For undocumented configurations, the Equation 21-1 and Equation 21-2 can be used to calculate page size and density.

$$\text{Page Size (bytes)} = 2^{\#\text{ Column address bits}} \times (\text{Memory width in bits} / 8) \qquad \textit{Eqn. 21-1}$$

$$\text{Density (bytes)} = 2^{(\#\text{Column Address Bits} + \#\text{ Row Address Bits})} \times (\text{Memory width in bits} / 2) \qquad \textit{Eqn. 21-2}$$

Table 21-20. Bank Address Bit Assignment

Density (Bytes)	Page Size (Bytes)	BA1	BA0
8 Mbytes	X	A22	A21
16 Mbytes		A23	A22
32 Mbytes		A24	A23
64 Mbytes		A25	A24
128 Mbytes		A26	A25
256 Mbytes		A27	A26

21.4.3 Multiplexed Address Bus During Precharge or Load Mode Registers Modes

During precharge or load mode registers modes (SMODE = 0b001 or 0b010) there is no address shifting, so that CPU address A0 is mapped to MA0 for all memory widths. For example, to drive the MA10 bit (PRECHARGE ALL command) the CPU A10 bit is required to be set (for both 16- or 32-bit external devices). The same logic is valid for the load mode register command, as shown in the initialization routine example in Section 21.5.4.1, “SDRAM Initialization”.

Byte accesses are required during precharge and load mode register modes, since the address can be nonaligned depending on the load mode register data.

21.4.4 Refresh

The ESDRAMC hardware satisfies all SDRAM refresh requirements based on initial configuration by the user software. 0,1,2,4,8 or 16 refresh cycles are scheduled at 31.25 µs (nominal 32 kHz clock) intervals, providing 0,2048,4096,8192,16384 or 32768 refresh cycles every 64 ms. The refresh rate is programmed through the REFR field in the ESDCTL0 and ESDCTL1 registers. Each array can have a different rate, allowing a mix of SDRAM/LPDDR devices, or different SDRAM densities. Refresh is disabled by hardware reset.

A refresh request is made pending at each rising edge on the 32 kHz clock. In response to this request, the hardware gains control of the SDRAM as soon as any in-process bus cycle completes. Once it has gained control of the memory, commands are issued to precharge all banks. Following a row precharge delay (t_{RP}), an AUTO REFRESH command is issued. At t_{RC} intervals, additional auto-refresh cycles are issued until the specified number of cycles have been run. Figure 21-32 illustrates two refresh sequences. Burst transfers in progress when the refresh request arrives are allowed to complete prior to the refresh operation. SDRAM bus accesses queued after the refresh request are held off until the refresh completes.

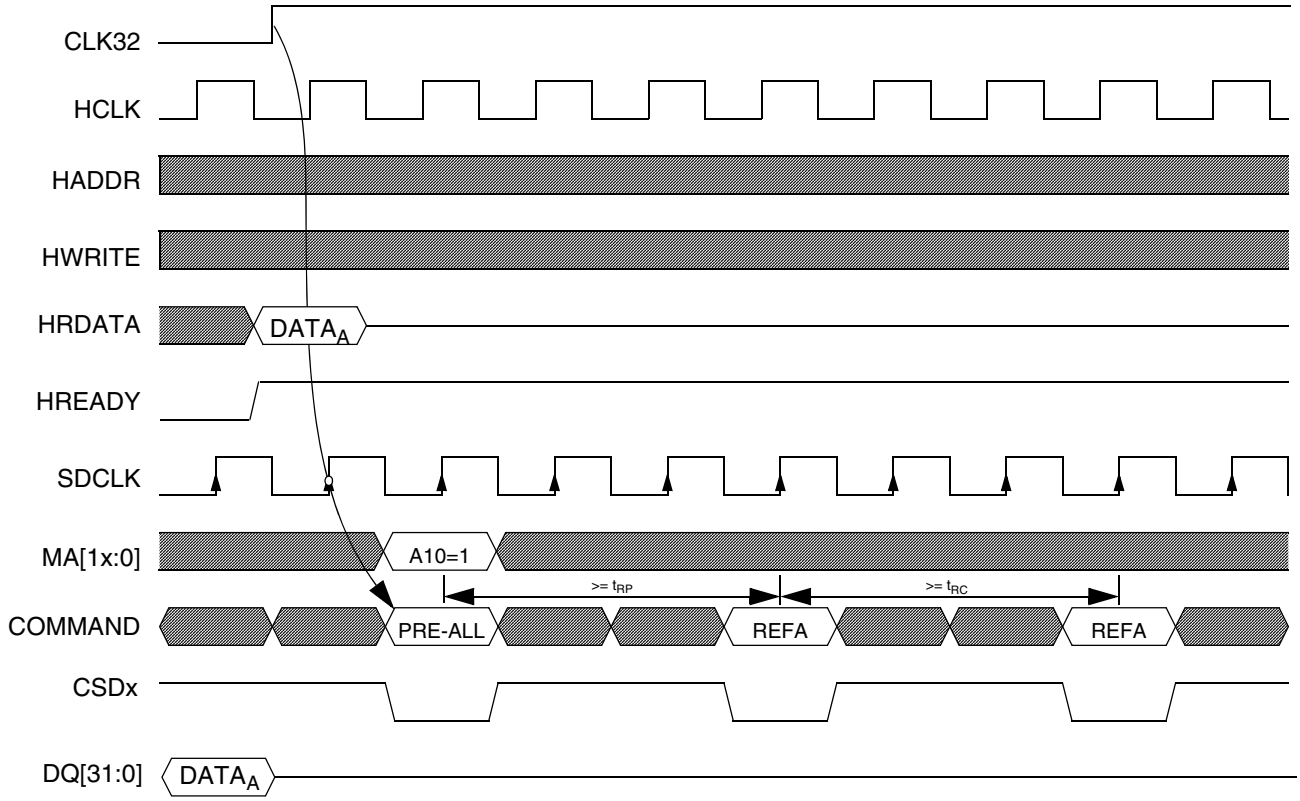

Figure 21-32. Hardware Refresh Timing Diagram

In Figure 21-33, an access is queued just as the refresh begins. This cycle is delayed until the precharge and single refresh (REFR=01) cycles are run. Bus cycles targeted to other memory or peripheral devices are allowed to progress normally while the refresh is in progress. None of the pins shared between the SDRAM and other devices are required for the refresh operation.

NOTE

Because refresh commands (requires all banks to be in idle state, achieved by precharge-all) are issued automatically by the enhanced SDRAM controller at each 32 kHz clock, address bit A10 (for both 16- and 32-bit devices) cannot be shared with other peripherals' address bus in the system.

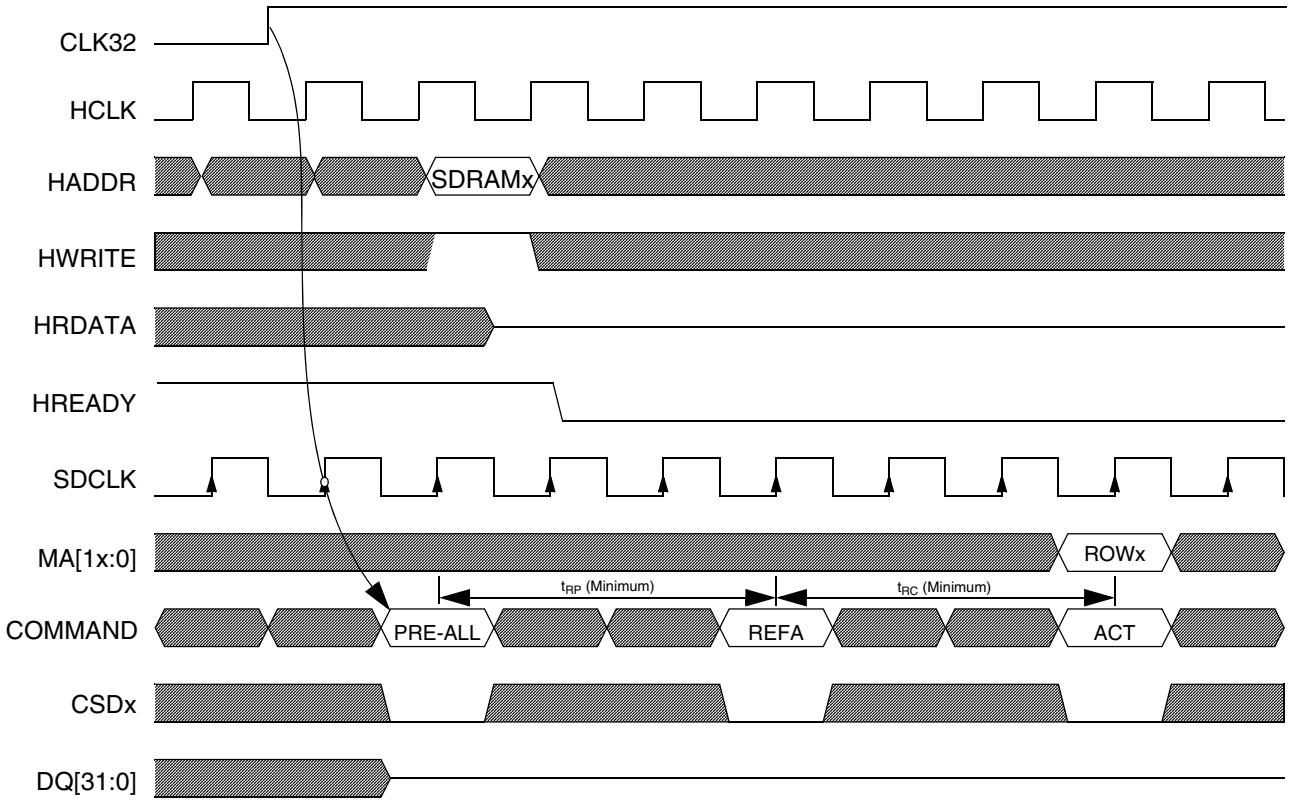

Figure 21-33. Hardware Refresh with Pending Bus Cycle Timing Diagram

21.4.5 Low Power Operating Modes

The following section describes the low power operating modes of the ESDRAMC. Table 21-21 summarizes the low power modes supported by the ESDRAMC for SDRAM and LPDDR devices.

Table 21-21. ESDRAMC Low Power Operating Modes

System Operating Mode	Memory Device Low Power Operating Mode	Wake-Up Penalty (SDRAM Device)	Wake-Up Penalty (LPDDR Device)
Run	Power-down mode	1 clock cycle	tXP
Run	Precharge bank(s)	1 clock cycle	1 clock cycle
Run	Manual self-refresh mode	2 refresh periods	tXS + 2 refresh periods
Stop	Self-refresh mode	2 refresh periods	tXS + 2 refresh periods

21.4.5.1 Self-Refresh Mode for SDRAM/LPDDR Devices

The controller puts external memory in self-refresh mode in response to a p_lpmd request from the clock controller module (CCM). When done, the controller sends a low power acknowledge (lpack) signal to the CCM. If the controller is busy when the p_lpmd request is received, it first finishes the received accesses and then puts the memory in self-refresh mode.

Figure 21-34 and Figure 21-35 show timing for entering and exiting self-refresh mode, respectively.

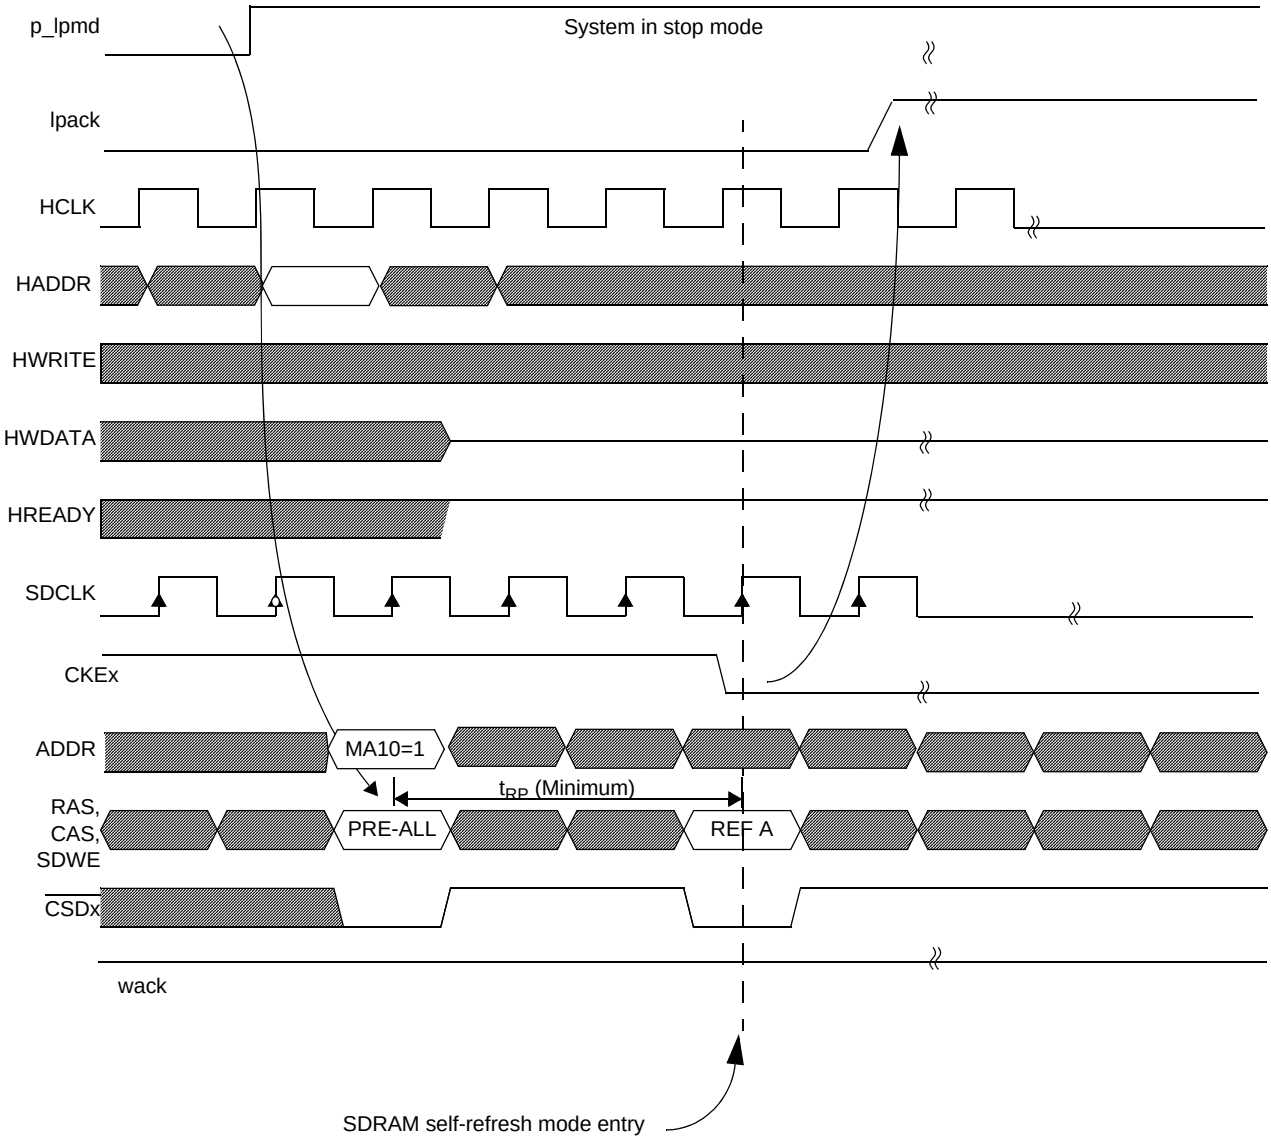

Figure 21-34. SDRAM/LPDDR Enter Self-Refresh Mode During System STOP Mode

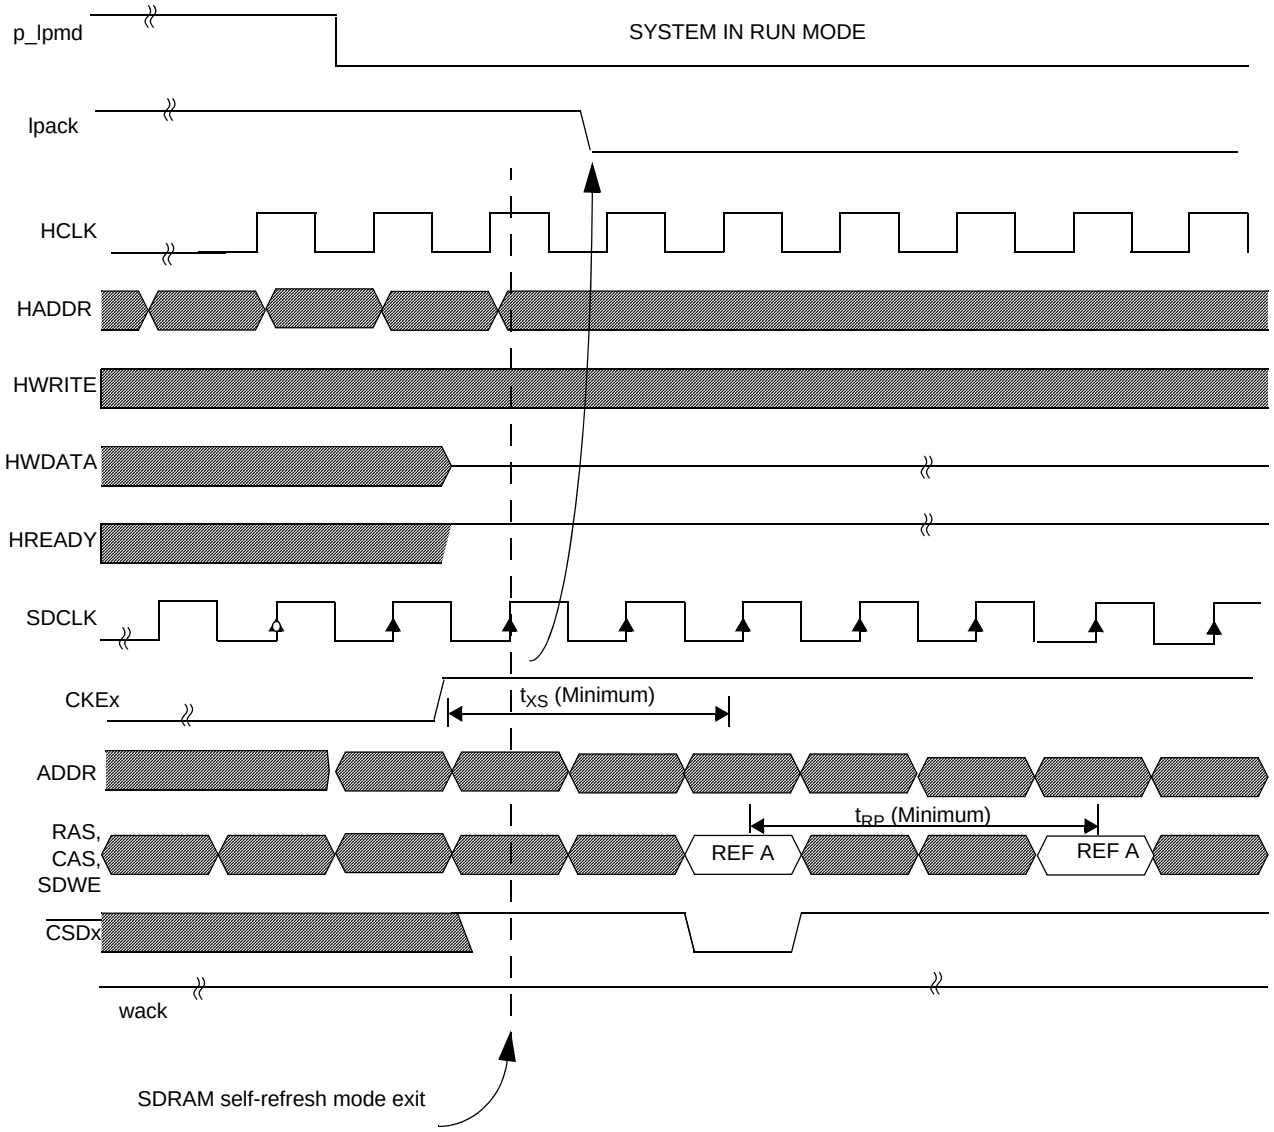

Figure 21-35. SDRAM/LPDDR Exit Self-Refresh Mode during System STOP Mode

21.4.5.2 Manual Self-Refresh Mode for SDRAM/LPDDR Devices

This operating mode allows the software to control a self-refresh mode entry of the external SDRAM/LPDDR device. When this mode is selected (SMODE=100 in the respective CSD control register) and refresh is enabled the enhanced SDRAM controller will complete any active access and a self-refresh command to the external device is issued. No access is allowed to the respective CSD during manual self-refresh mode. If refresh has not been enabled, the enhanced SDRAM controller places the memory in a low power consumption mode known as power-down.

NOTE

- A manual precharge-all should be initiated by the user before a manual self-refresh.

- SDCLK stops only if both chip selects are in manual self-refresh mode, so that one chip select can be used while the other is in manual self-refresh (in case that both chip selects are in use).

Manual self-refresh mode is exited by changing SMODE bits in the respective chip select control register to select a different operating mode. When a different mode is selected, the controller takes the SDRAM device out of self-refresh mode and begins issuing auto-refresh cycles (if refresh has been enabled).

Figure 21-36 and Figure 21-37 show timing for entry and exit from manual self-refresh mode, respectively.

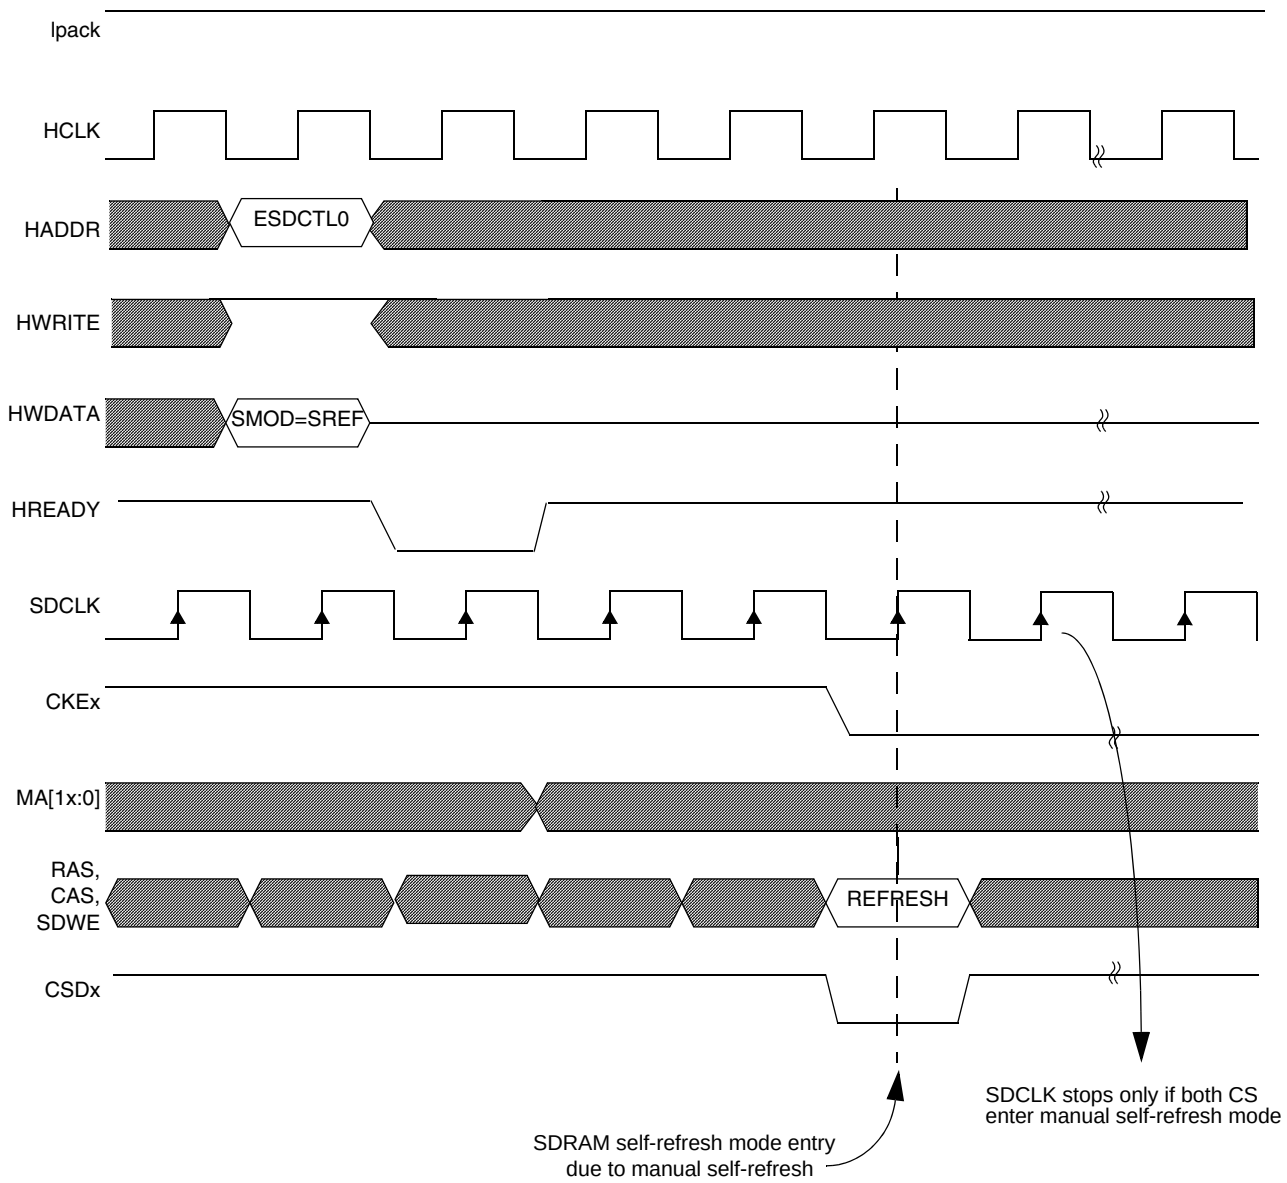

Figure 21-36. Manual Self-Refresh Entry Timing Diagram

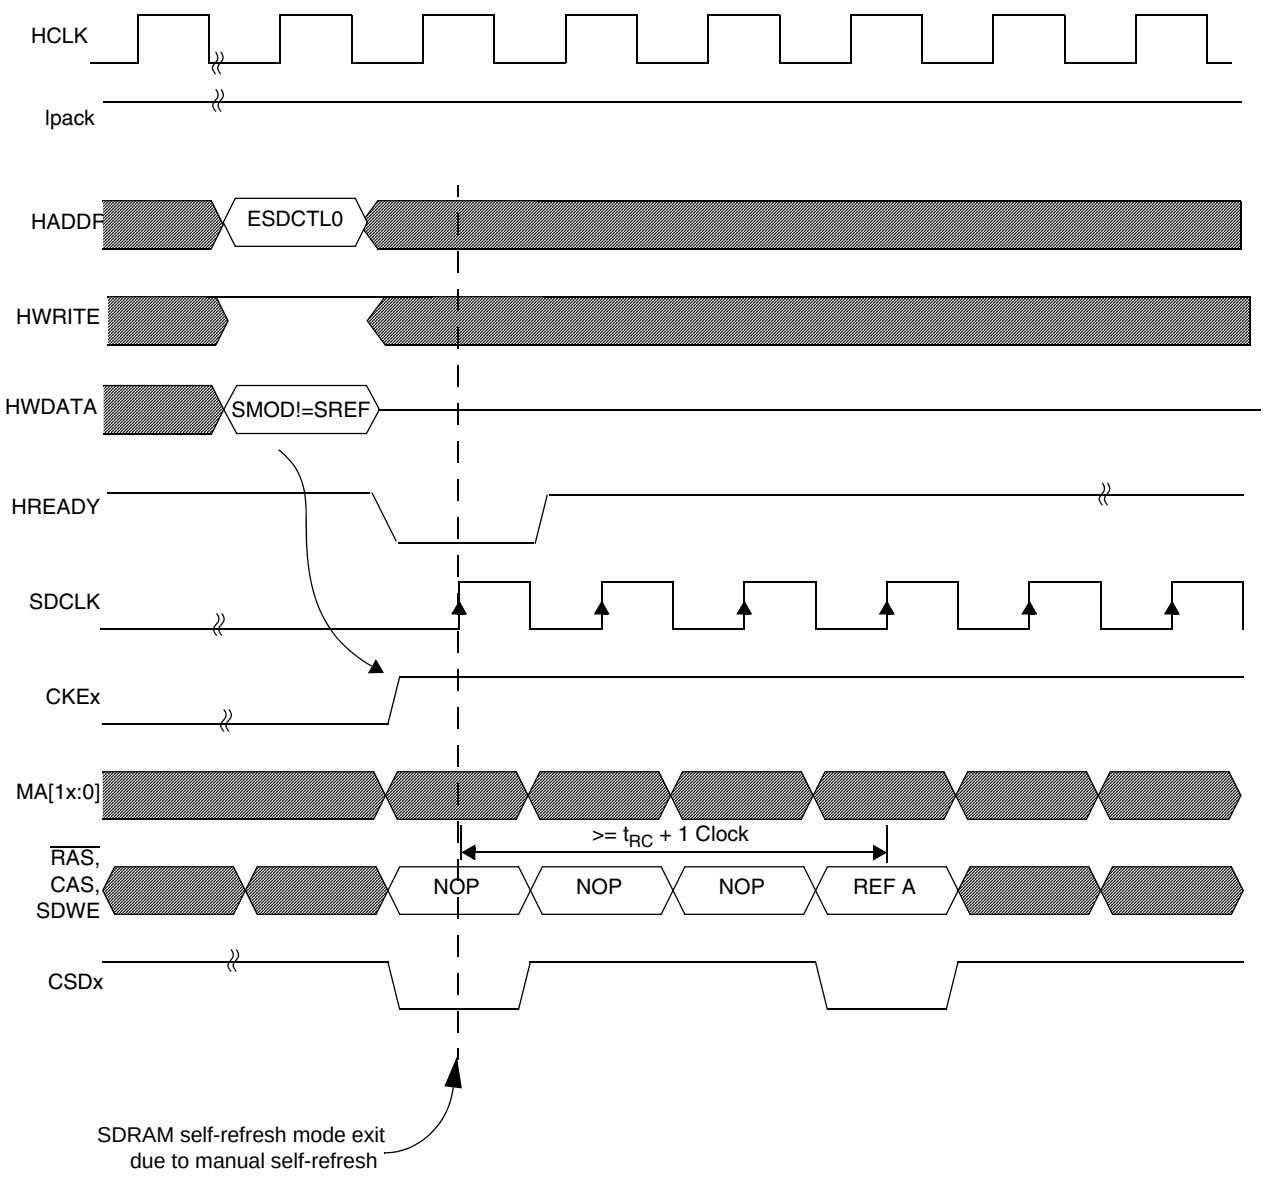

Figure 21-37. Manual Self-Refresh Exit Timing Diagram

21.4.5.3 Power-Down Modes

If the SDRAM/LPDDR memory utilization is low, the ESDRAMC can reduce power consumption by putting the SDRAM/LPDDR into power-down mode. Power-down mode for CSD*n* is activated by programming the PWDT bits in the ESDCTL*n* register (*n* = 0,1). In power-down mode the ESDRAMC automatically issues the refresh commands to the SDRAM/LPDDR memories at the rate defined by the SREFR bits in the corresponding ESDCTL*n* register.

The two power-down modes are discussed in Section 21.4.5.3.1, “Precharge Power-Down Mode’ and Section 21.4.5.3.2, “Active Power-Down Mode,” respectively. The distinguishing factor between the two

is whether banks remain active while the clock is stopped. Active power-down allows banks to remain activated, while precharge power-down does not.

21.4.5.3.1 Precharge Power-Down Mode

Programming PWDT[1:0] = 01 in the ESDCTL*n* register causes the ESDRAMC to place the memories in power-down mode any time the controller detects that no banks are active. This mode is useful in applications where a memory array is accessed infrequently, and the chances of more than one access to the same page are minimal.

Reading or writing to memory activates a page within the addressed bank. Reset, software generated precharge, and hardware initiated refresh are three ways to close an active bank. The periodically occurring refresh is the normal means that invokes the power-down mode. At each refresh interval, all banks are closed by a precharge all command, followed by the refresh operation. The controller then issues the power-down command to the memories. A few cycles of delay are incurred with the first read or write cycle in order to restart the clocks, but only on the first cycle. After that, the clocks continue to run until the next refresh operation or until any active banks are manually precharged.

Page misses on read and write cycles cause the addressed bank to be closed (precharged) and a new page opened within the bank. This operation does not cause the clocks to stop, nor does manually precharging only a single bank within the memory. All banks within the memory must be inactive before the power-down mode is invoked.

Power-down mode occurs if the CKE is registered low coincident with a NOP or COMMAND INHIBIT, when no accesses are in progress. Entering power-down will deactivate the input and output buffers (excluding CKE) of the device. The power-down mode state is exited by registering a NOP or COMMAND INHIBIT and CKE is high at the desired clock edge.

NOTE

Because the ESDRAMC does not issue auto precharge commands to the SDRAM, the software is responsible to issue a precharge all command in order to enter precharge power-down mode, to wait for precharge timer (PRCT) to close/precharge all active banks, or to wait for the next refresh cycle in order to enter this low power mode. (During the refresh cycle, the ESDRAMC automatically issues the precharge all command).

Figure 21-38 and Figure 21-39 illustrate timing for SDR SDRAM power-down mode entry and exit respectively. Figure 21-40 and Figure 21-41 illustrate timing for LPDDR SDRAM power-down mode entry and exit respectively.

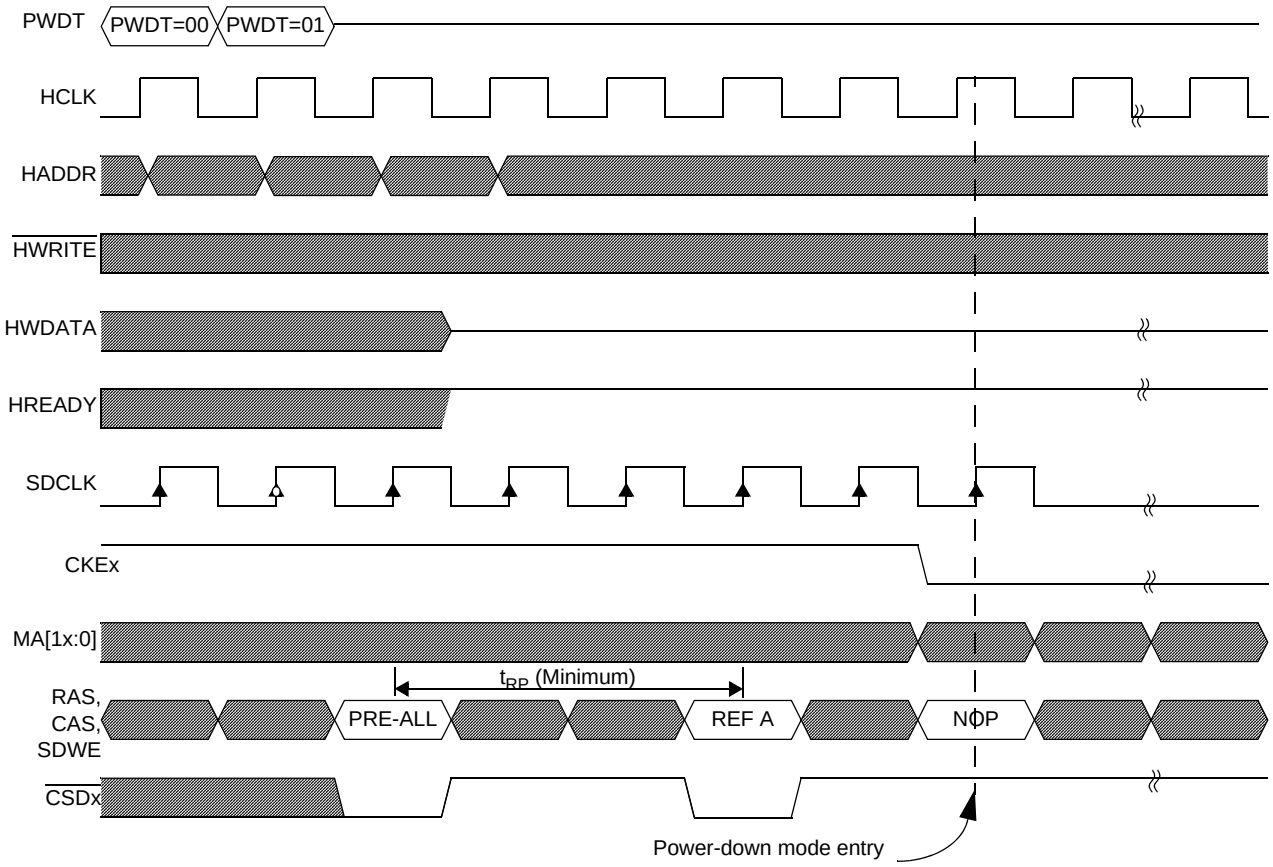

Figure 21-38. SDR SDRAM Precharge Power-Down Mode Entry Timing Diagram

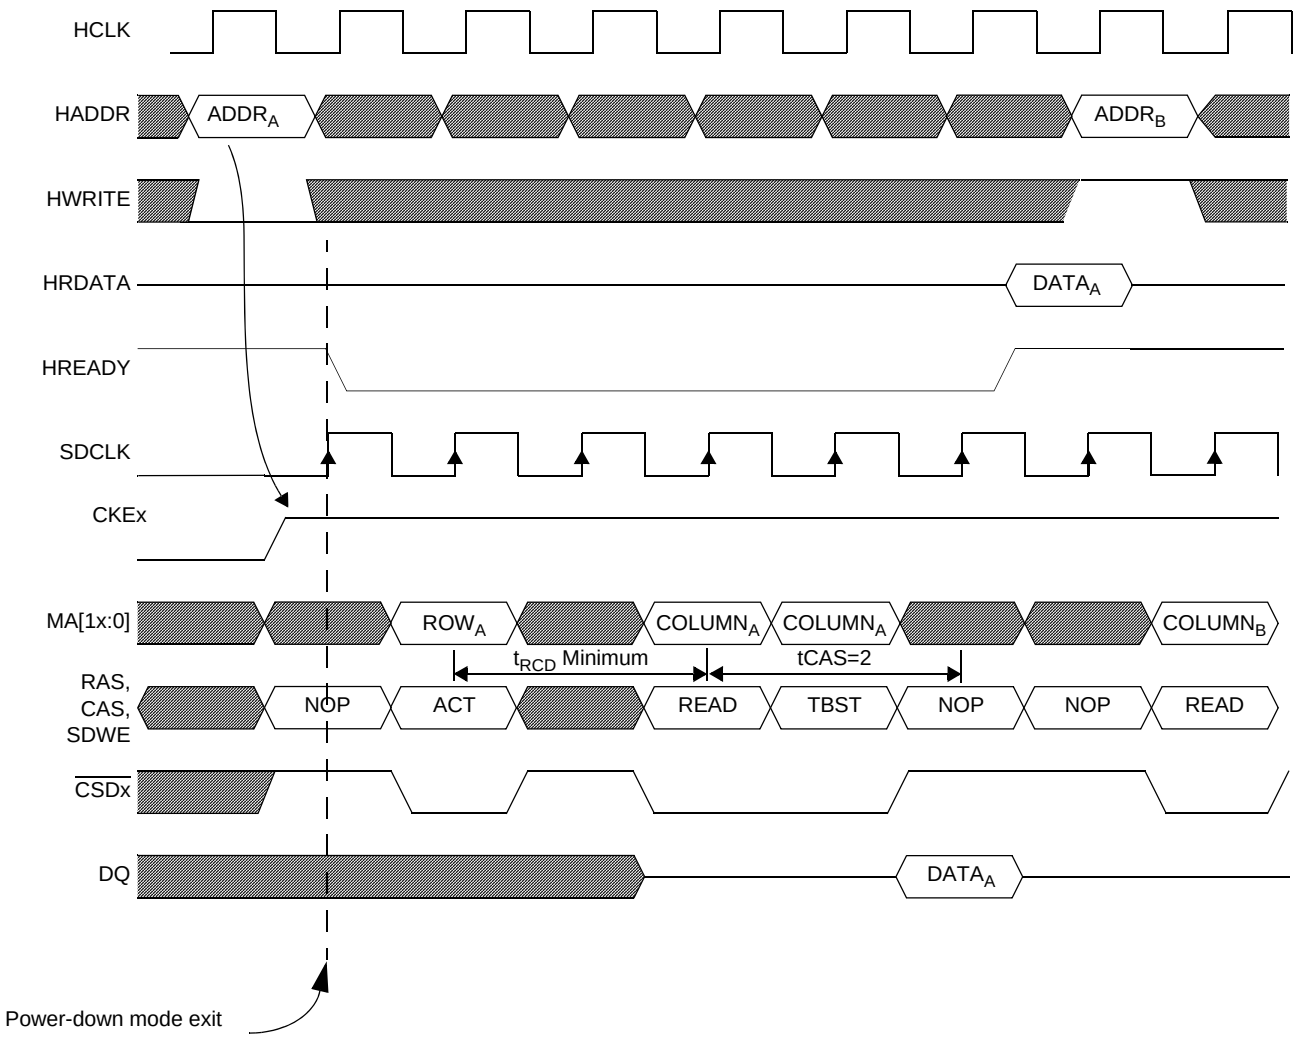

Figure 21-39. SDR SDRAM Precharge Power-Down Mode Exit Timing Diagram

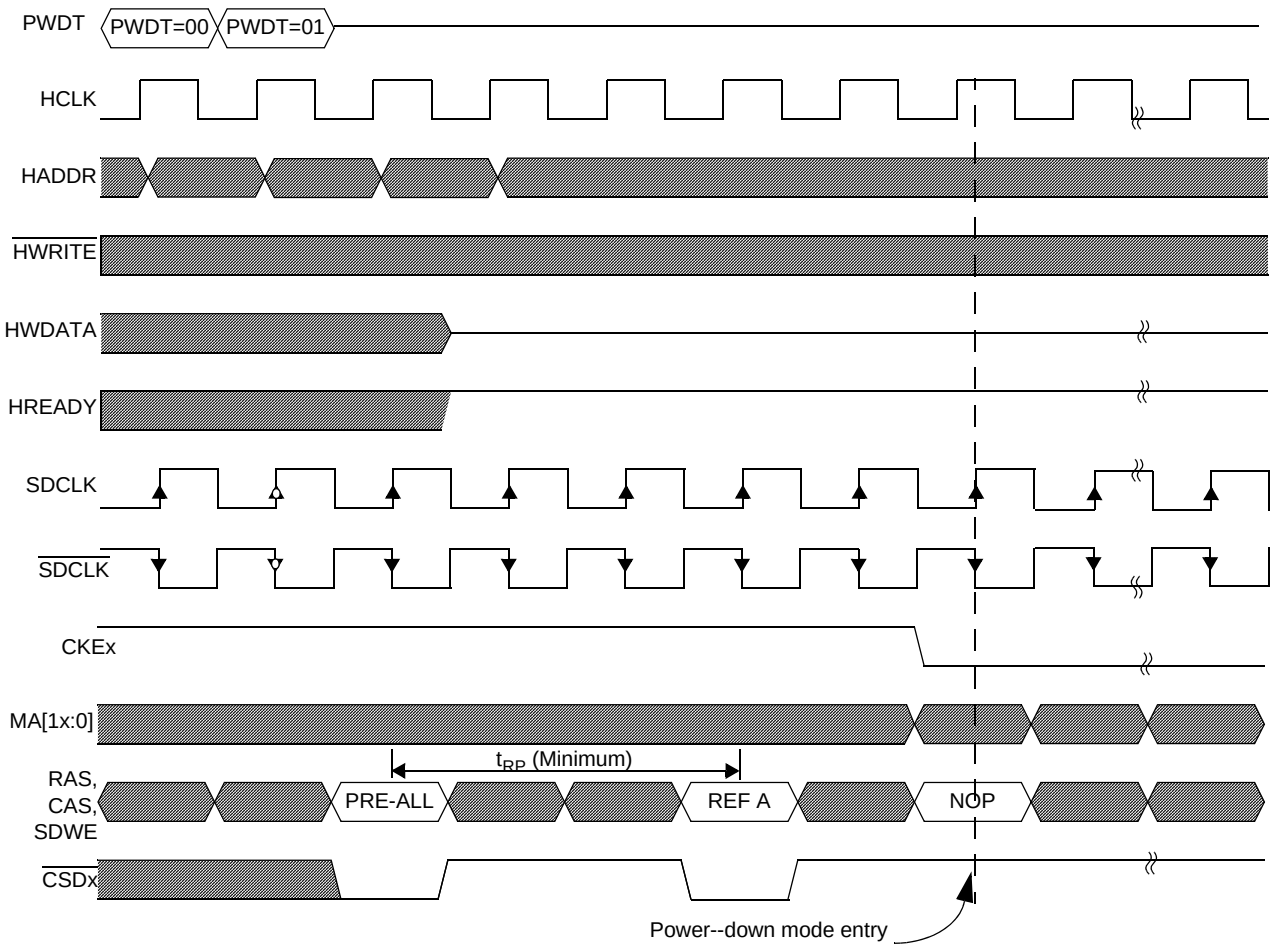

Figure 21-40. Mobile DDR SDRAM Precharge Power-Down Mode Entry Timing Diagram

Power-down mode for several LPDDRs require the clock CK (and $\overline{CK}$) to continue running. (The PWR_CK_EN (power-down clock enable for mobile/low power DDR SDRAM) should be set to 1 in order to enable this option)

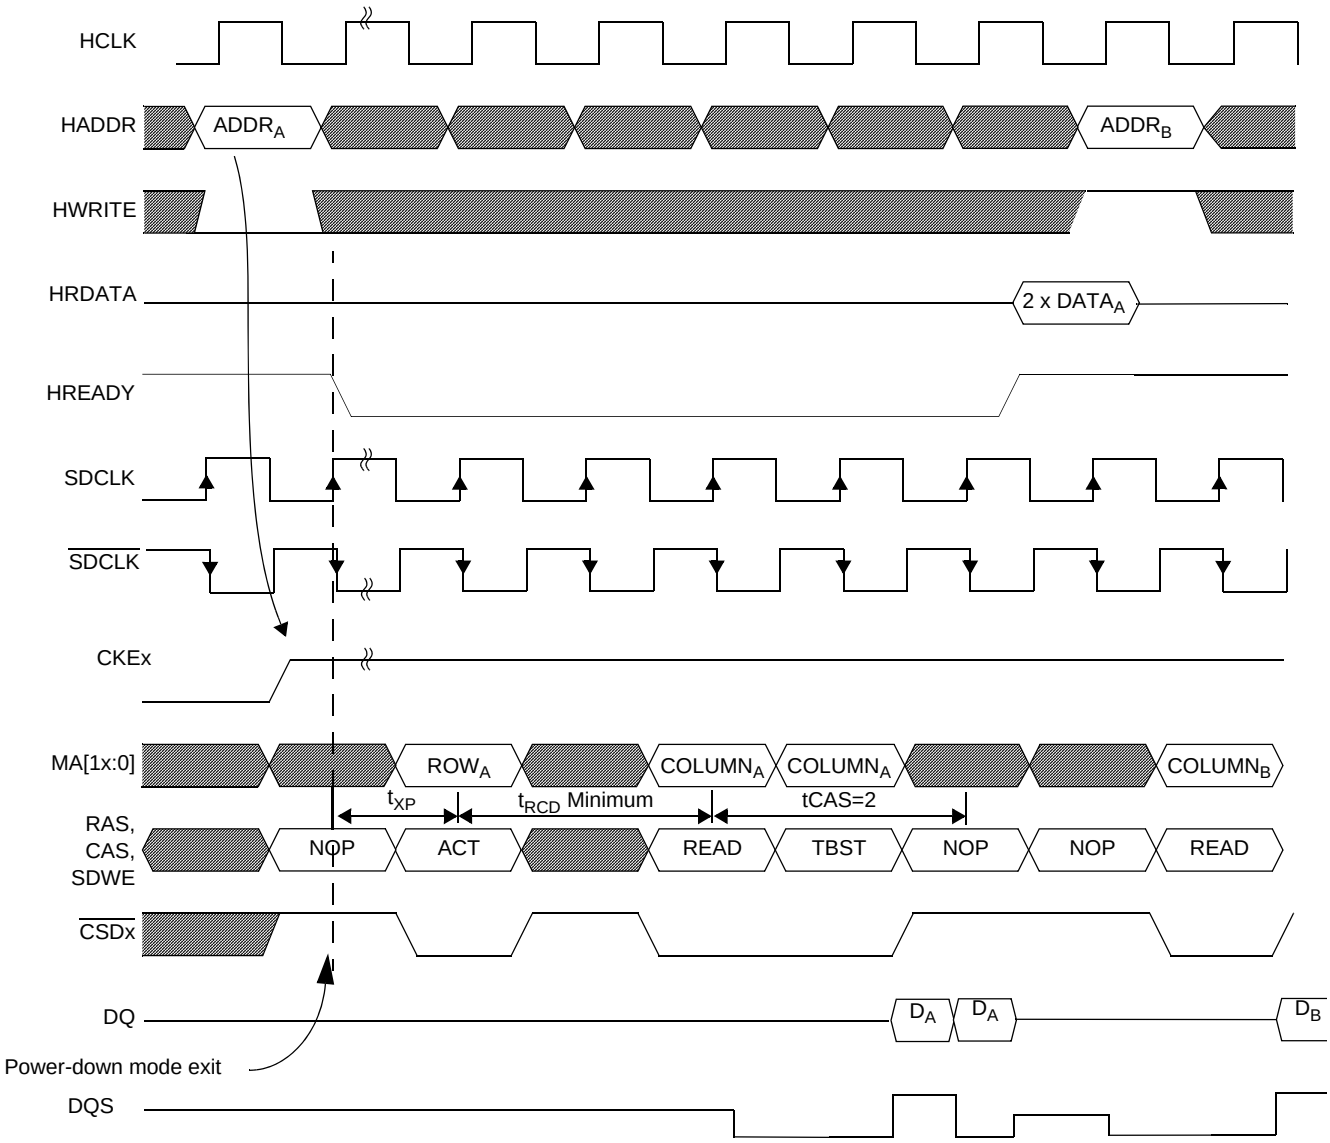

Figure 21-41. Mobile DDR SDRAM Precharge Power-Down Mode Exit Timing Diagram

21.4.5.3.2 Active Power-Down Mode

Active power-down mode is selected whenever PWDT[1:0] = 1*n*. In this mode the SDCLK is stopped after a selectable delay from the last access to the array. Active banks are not closed prior to disabling the SDRAM/LPDDR clock. Either 64 (PWDT[1:0] = 10) or 128 (PWDT[1:0] = 11) cycle delays are possible. SDRAM/LPDDR clocks are counted from the end of the last read or write access. Subsequent read accesses, write accesses, and self-refresh modes reset the counter. Auto-refresh cycles do not affect the counter: however, if the counter expires during a refresh operation the clock is disabled immediately following the refresh.

Figure 21-42 and Figure 21-43 are timing diagrams for entry and exit of SDR and LPDDR SDRAM active power-down modes.

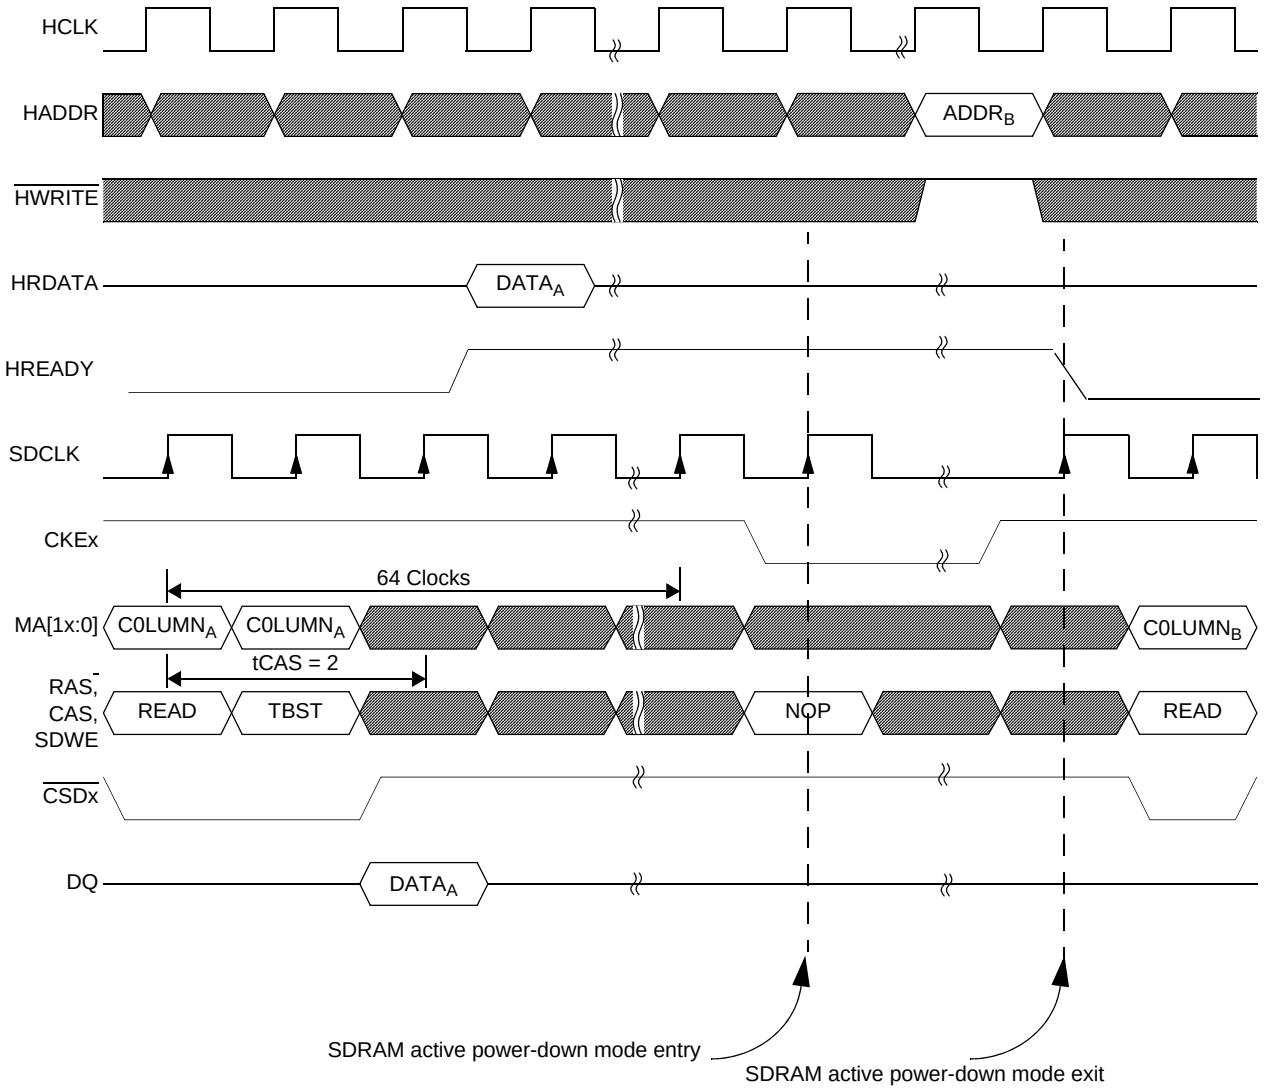

Figure 21-42. SDR SDRAM Active Power-Down Mode Timing Diagram

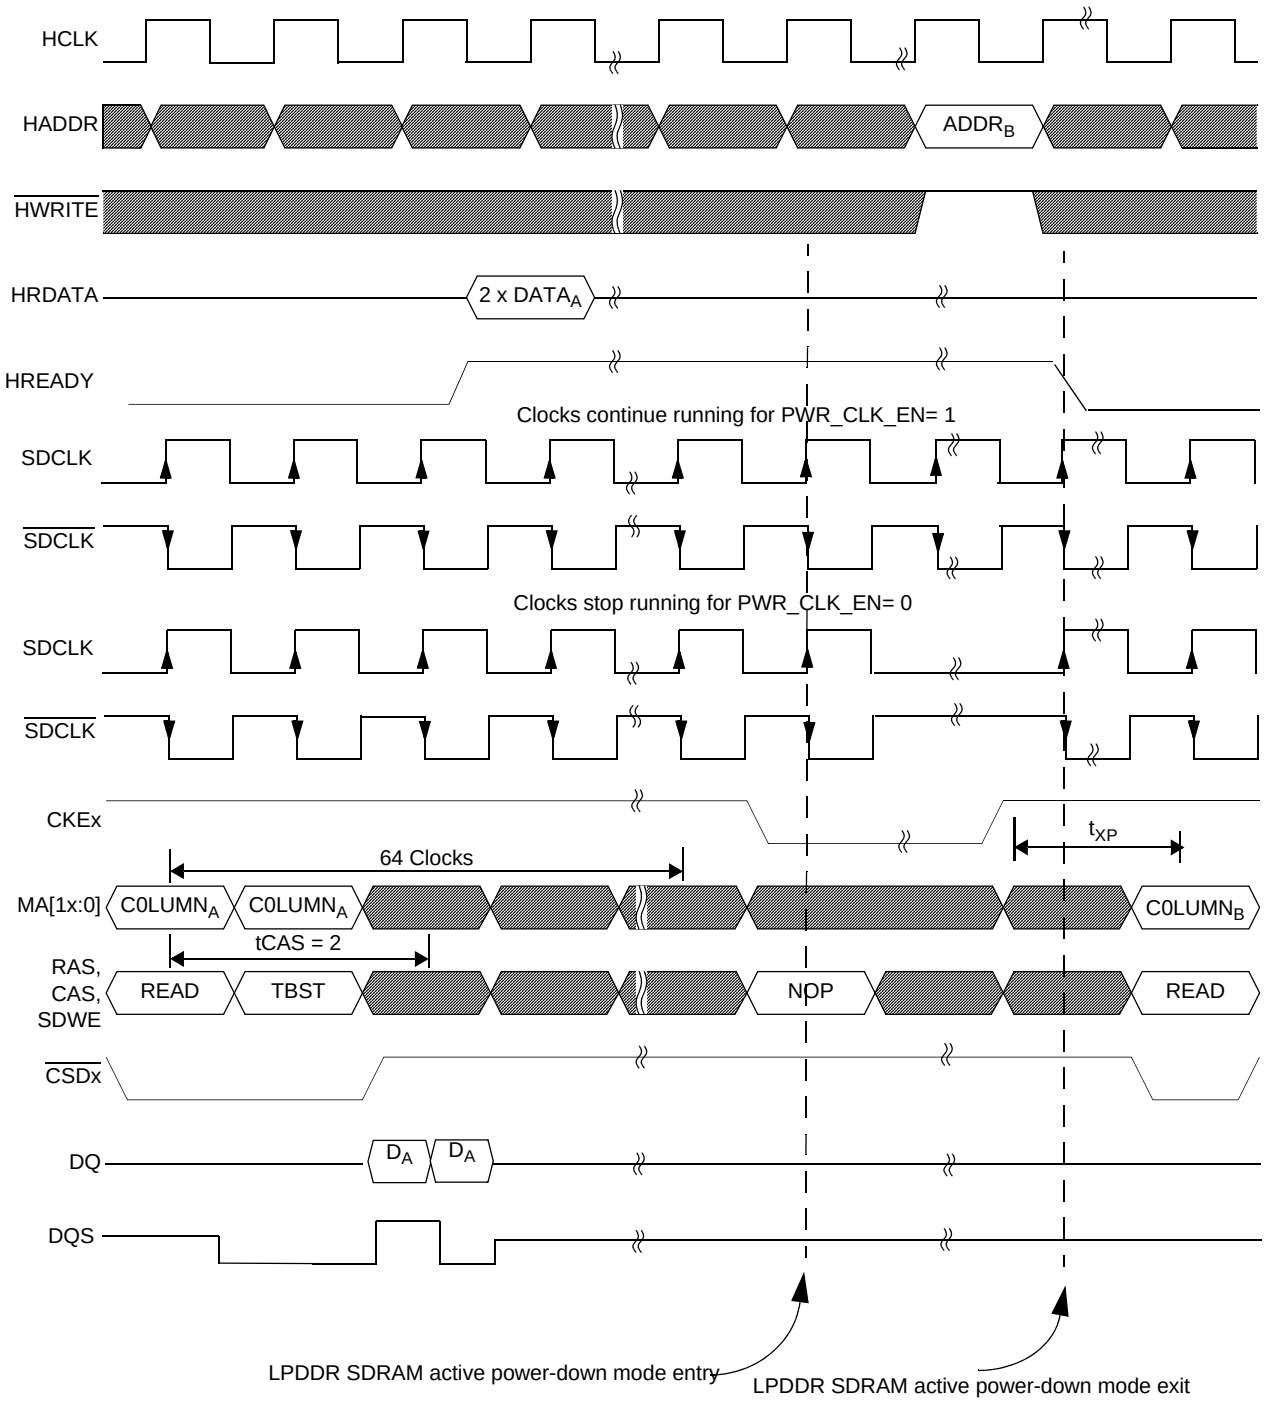

Figure 21-43. Mobile DDR SDRAM Active Power-Down Mode Timing Diagram

Power-down mode for several mobile DDRs require the clock CK (and $\overline{CK}$) to continue running. The PWR_CK_EN (power-down clock enable for mobile DDR SDRAM) should be set to 1 in order to enable this option.

21.4.5.4 Precharge Bank(s)—Low Power Mode

"Closing" (due to PRECHARGE command) the last used/open row in any non active bank within a chip select reduces the power consumption of the external memory device. The power saving is device dependent, and one should consult/examine the external memory device specification for more details on power consumption reduction. The precharge bank is activated if PRCT is enabled. A PRECHARGE command is issued after 2xPRCT HCLK cycles of no activity to one of the SDRAM/LPDDR banks. The number of cycles before the PRECHARGE command is issued depends on the command bus ($\overline{WE}$, $\overline{RAS}$, $\overline{CAS}$ and CSD) availability (meaning there is no active access to other bank) and the memory timing parameters.

21.4.5.5 LPDDR Frequency Change

To change the frequency in a LPDDR-based system the following can be used to ensure the DDRC delay line locks to the new frequency:

1. Issue PRECHARGE ALL command.
2. Put the external memories into self-refresh operating mode.
3. Change the system frequency.
4. Reset the delay line, by setting the MDDR_DL_RST bit in the enhanced SDRAMC miscellaneous register.
5. Wait about 4500 HCLK cycles for the delay line to lock on the new frequency.
6. Exit self-refresh mode.

After the above steps are performed the LPDDR is ready for normal operation at the new frequency.

21.4.6 SDRAM (SDR and LPDDR) Command Encoding

Table 21-22 summarizes the command encoding utilized by this controller. These commands represent a subset of the commands defined by the JEDEC standard.

Table 21-22. SDRAM (SDR and LPDDR) Command Encoding

Function	Symbol	CKE *n*-1	CKE *n*	CS	$\overline{RAS}$	$\overline{CAS}$	$\overline{WE}$	A11	A10	BA[1:0]	A[13:0]

[1]For mobile DDR, applies only to read bursts (with auto-precharge disabled).
[2]BA0-BA1 select either the mode register, the extended mode register or the low power extended mode register.

21.4.6.1 Reset

Assertion of the $\overline{RST}$ signal initializes the controller into the idle state, and disables the module. While disabled, the controller remains in the idle state with the internal clocks stopped. The reset state of the control register allows for basic read/write operations sufficient to fetch the reset vector and execute the initialization code. A complete initialization of the controller should be performed as part of the start-up code sequence.

Read/write cycles, refresh and low-power mode requests, and power-down timeouts will all trigger transitions out of the idle state. As shown in the simplified enhanced SDRAM controller state diagram in Figure 21-44, state transitions due to a read or write request depend on the operating mode. Other transitions require the corresponding function to be enabled in the ESDCTL*n* registers. Some state transitions have been removed from the figure to minimize complexity and allow an easier understanding of the basic controller operation.

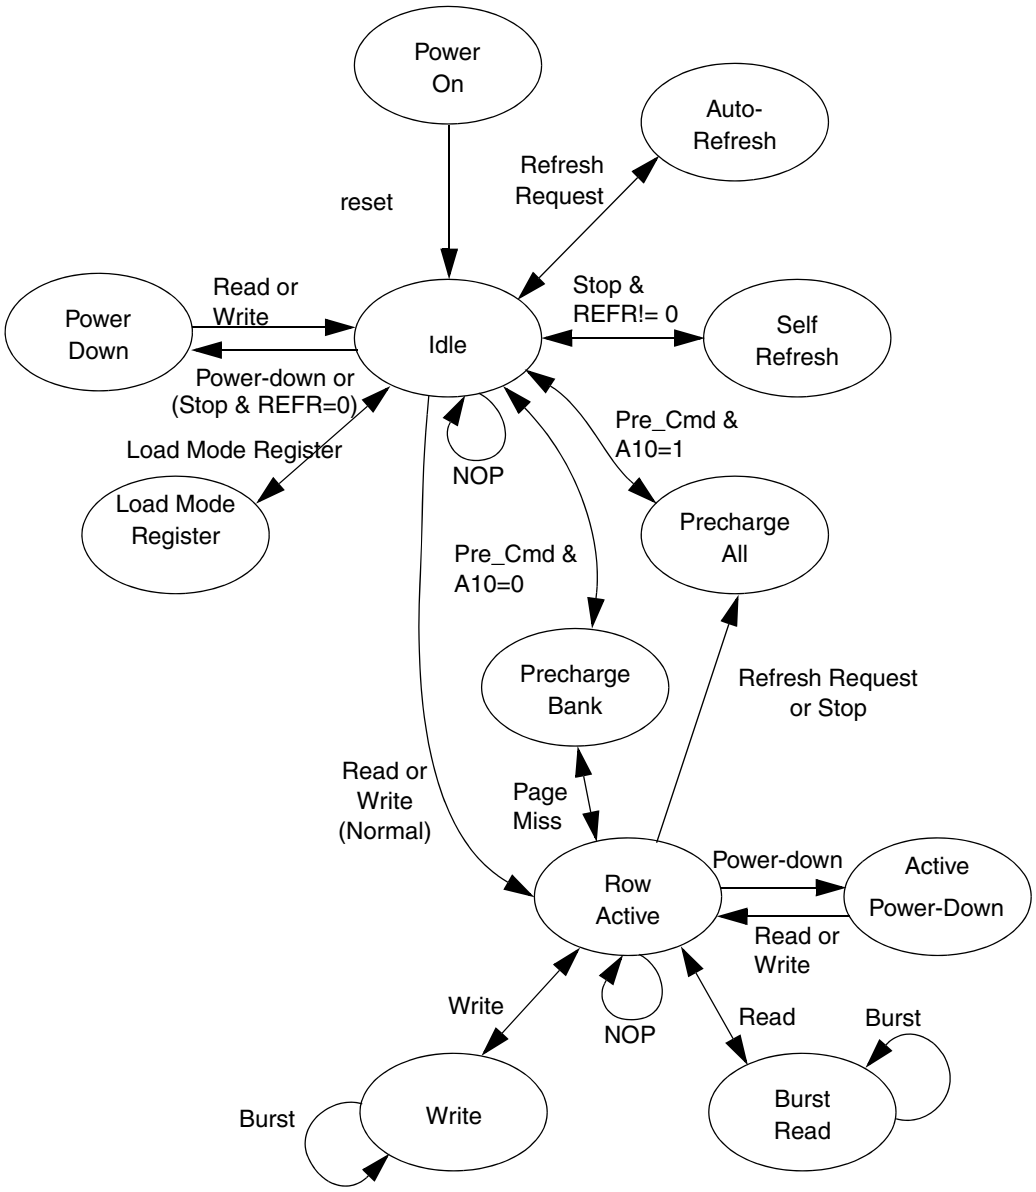

Figure 21-44. Simplified ESDRAMC State Diagram

21.4.6.2 Warm Reset

Warm reset enables the user to reset the ESDRAMC without affecting the data in external SDR/DDR memories. The warm reset is fired by using the warm reset signal (that would be kept high during warm reset inside the ESDRAMC). This signal is latched while exiting reset, which causes ESDRAMC internal logic to keep CKE signals at low level, thus ensuring the self-refresh configuration of the outside device preserved until CS_EN is configured in the ESDCTL*n* registers.

The warm_reset signal to EMI should be driven high before reset is fired. Figure 21-45 shows the signal definitions at the EMI boundary level.

NOTE

The wakeup acknowledge (wack) signal to the watchdog module is set to low after warm reset (that is, the wack reset value is low), and remains low until an internal counter counts 7 CKIL cycles. Access to the DDR external device is blocked during this time interval. This delay of about 220 µsec can be avoided by using regular reset along with warm reset, as shown in Figure 21-45.

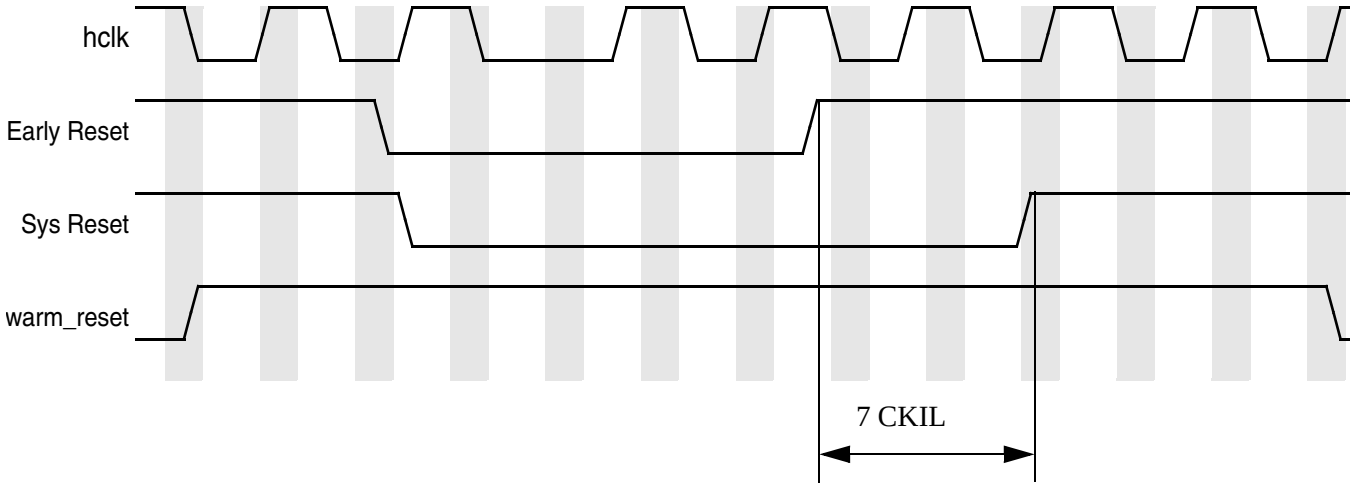

Figure 21-45. Warm Reset Timing Diagram

Figure 21-46 and Figure 21-47 describe the flow to enter self-refresh mode before and during warm reset, as well as ESDRAMC configuration when exiting warm reset.

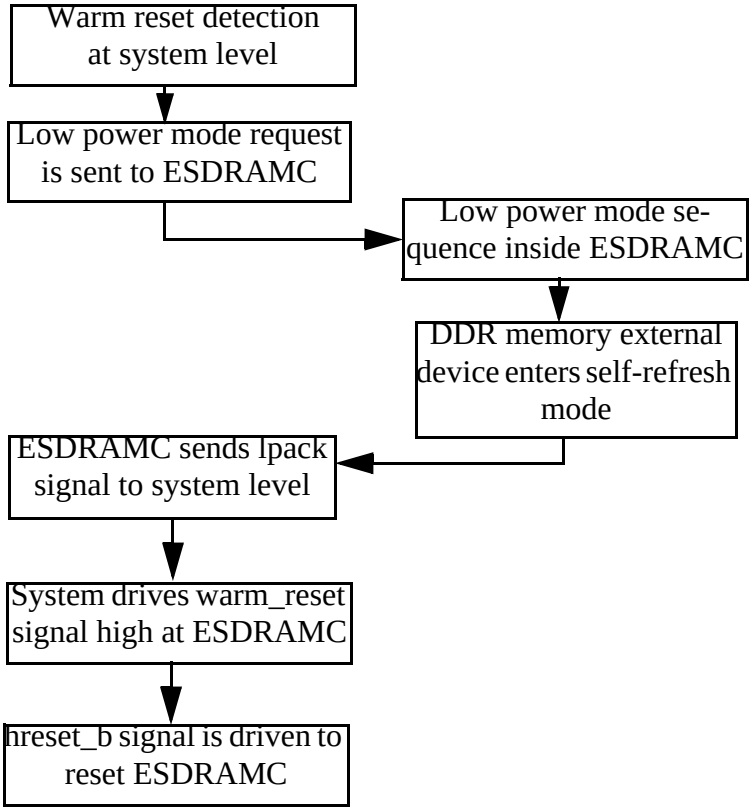

Figure 21-46. Self-Refresh Entry Before warm_reset Assertion

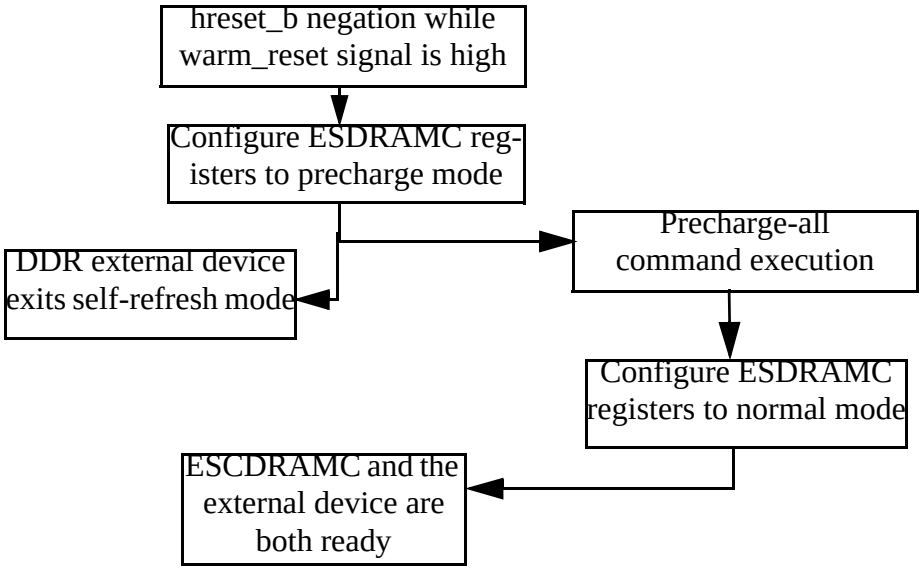

Figure 21-47. Self-Refresh Exit After Warm Reset Assertion

21.4.7 Normal Read/Write Mode

The normal read/write mode (SMODE[2:0] = 000) is used for general read and write accesses (AHB-lite compatible) to the SDRAM/LPDDR. Single and read burst accesses are supported for both SDRAM/LPDDR memories (although bursts requests are limited as shown in Table 21-23). For SDRAM/LPDDR memories single and burst write accesses are supported as well.

Table 21-23. SDRAM/LPDDR Burst Access Support

Internal AHB Word Access (32 bit)		External Memory Device[3]						Description
		16-bit			32-bit			
HBURST	TYPE	BL=4	BL=8	BL=FP	BL=4	BL=8	BL=FP[2]	
000	SINGLE[1,2]	No	Yes	Yes	Yes	Yes	Yes	Single transfer
001	INCR	No	Yes	Yes	Yes	Yes	Yes	Incrementing burst
010	WRAP4	No	Yes	Yes	Yes	Yes	Yes	4-beat wrapping burst
011	INCR4	No	Yes	Yes	Yes	Yes	Yes	4-beat incrementing burst
100	WRAP8	No	Yes	Yes	Yes	Yes	Yes	8-beat wrapping burst
101	INCR8	No	Yes	Yes	Yes	Yes	Yes	8-beat incrementing burst
110	WRAP16	No	No	No	No	No	No	16-beat wrapping burst
111	INCR16	No	No	No	No	No	No	16-beat incrementing burst

1 ESDRAMC only supports bursts of 32-bit (word size). Byte or half-word accesses are only supported for single transfers (HBURST type SINGLE). The ESDRAMC automatically splits the AHB bursts as a function of the external memory device according to the ESDCTL configuration register settings (size and burst length), in such a way that a continuous flow of data is obtained for both read or write bursts (see example in Table 21-24).

2 BL = Burst Length field in device mode register; FP = Full Page (wrap at external memory device ROW boundary). For both LPDDR 16 and 32-bit devices only BL=8 is supported

Read or write requests to the enhanced SDRAM controller initiate a check to see whether the page is already open. This check consists of comparing the requested address against the last row accessed within the corresponding bank. If the rows are different, a precharge has occurred since the last access, or there has never been an access to the bank, then the access must follow the “off-page” sequence. If the requested and last row match, the shorter “on-page” access is used. An off-page sequence must first activate the requested row, an operation which is analogous to a conventional DRAM $\overline{\text{RAS}}$ cycle. An activate cycle is the first operation depicted in Figure 21-48. During the activate cycle, the appropriate chip select is driven low, the row addresses are placed on the multiplexed address pins, the non-multiplexed addresses are driven to their respective values, the write enable signal is driven high, $\overline{\text{CAS}}$ is driven high, and $\overline{\text{RAS}}$ is driven low. These latter three pins form the SDRAM command word. The data bus is unused during the activate command.

Once the selected row has been activated, the read operation begins after the row to column delay (tRCD) has been met. This delay is either 2 or 3 clocks, as determined by the tRCD control field. During the read cycle, the chip select is once again asserted, the column addresses are driven onto the multiplexed address bus, the non-multiplexed addresses remain driven to the value presented during the activate cycle, the write enable signal is driven high (read), $\overline{\text{RAS}}$ is driven high, and $\overline{\text{CAS}}$ is driven low. After the CAS latency

has expired, data is transferred across the data bus. CAS latency is programmable via the tCAS control field. As data is being returned across the AHB, transfer acknowledge is asserted back to the CPU indicating that the CPU should latch data. While data is still on the bus, the enhanced SDRAM controller must begin monitoring transfer request since the CPU is free to issue the next bus request on the same edge that data is being latched.

Data transfers can be either single operand or a burst (WRAP or INCR) of up to a full page. Burst requests are designated as such by the HBURST bus indicating the length of the access, When HBURST equal to 0 a single access is required, otherwise the access is a burst of HBURST words.

SDRAM memories assume that all transfers are burst transfers unless terminated early. Burst transfers can be terminated by a variety of mechanisms: another read or write cycle, a precharge operation, or through a burst terminate command. Burst terminate commands are the general mechanism used by the ESDCTL for early burst termination, The burst terminate command is subject to the CAS latency and must be pipelined similar to the read command, as shown in Figure 21-48 through Figure 21-68.

NOTE

- The signals displayed in Figure 21-48 through Figure 21-68 are internal interface signals between the M3IF and the ESDRAMC.
- Figure 21-48 through Figure 21-68 are not cycle-accurate, and are only meant to show the external pins' activity relative to internal functionality. For cycle-accurate diagrams see Figure 21-70 through Figure 21-72.

SDRAM write cycles are different than read cycles in one important aspect. Whereas read data was delayed by the CAS latency, write data has no delay and is supplied at the same time as the write command. Figure 21-56 illustrates an off-page write cycle followed by one that hits on-page. Note that the write data is driven during the same clock that the write command is issued. A burst terminate command cancels the burst operation, but again without the CAS latency.

NOTE

ESDRAMC handles the HUNALIGN accesses in the following way. The M3IF module converts the original access address to a word align address to the ESDRAMC. The HBSTRB are used by the ESDRAMC to drive the correct value on the DQM signals to the external memory.

21.4.7.1 SDR Cycle Accurate Enhanced SDRAM Controller Accesses

This section provides cycle accurate timing diagrams for several ESDRAMC (AMBA AHB-Lite) supported read and write accesses to both 16 and 32-bit data width SDR memory devices from only one master. This diagrams are provided to emphasis ESDRAMC performance for single master hit (ACTIVE row) requests. The CAS latency for all diagrams is 2 cycles and burst length is set to 4 words for 16-bit memory and 8 words for 32-bit memory.

21.4.7.1.1 Single Read Word Access to 16-bit Memory

The markers in Figure 21-70 marks the request access time, for example, the time period between HREADY goes LOW (the ESDRAMC starts to execute the request) and HREADY goes HIGH (the ESDRAMC request execution is completed).

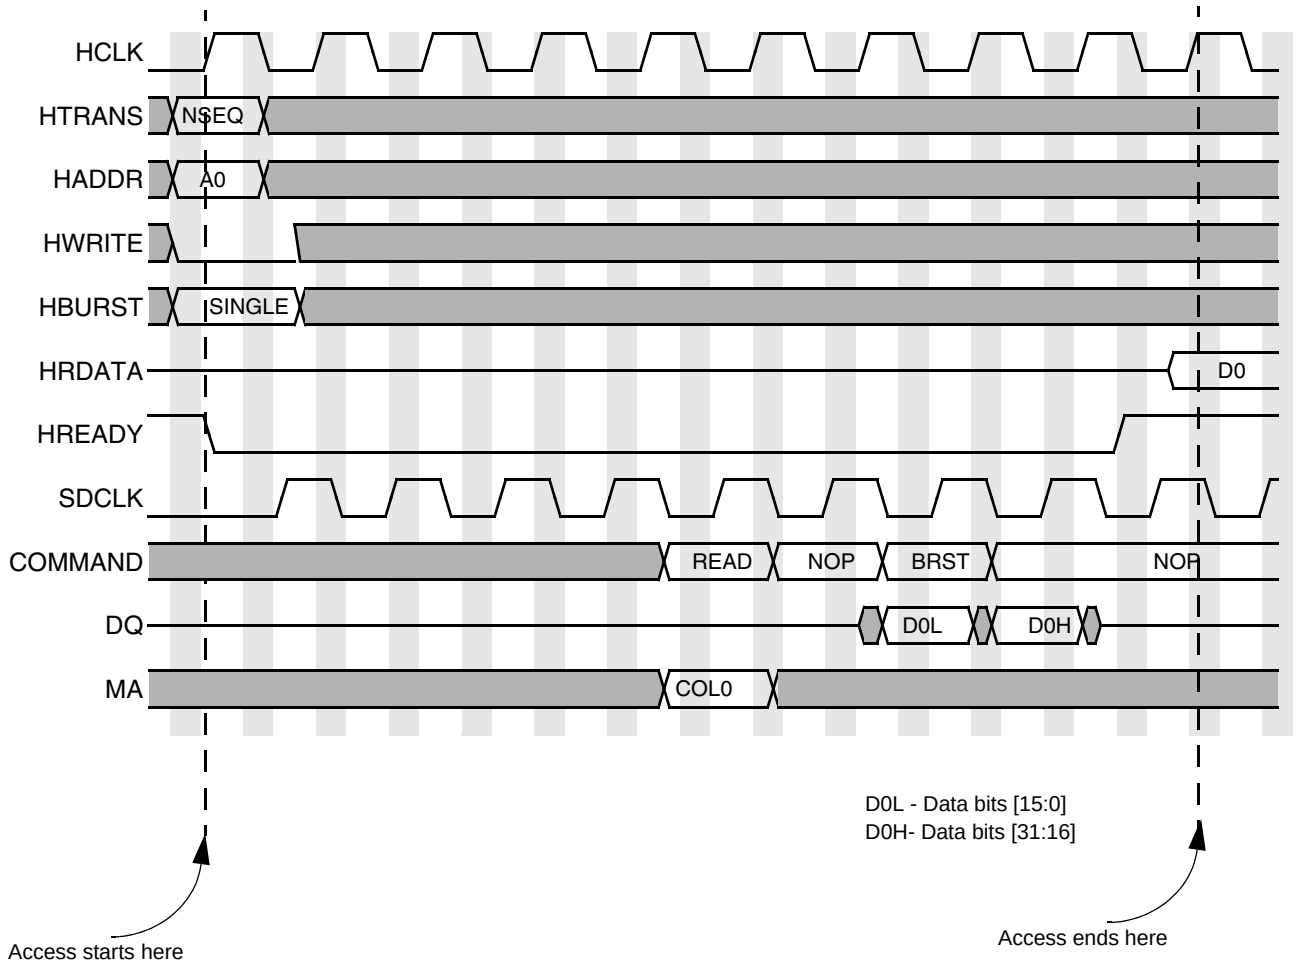

Figure 21-70. Single on Page Read - Word Access to 16-bit Memory (Cycle Accurate)

21.4.7.1.2 Misaligned INCR4 Burst Read Access to 16-bit Memory

The markers in Figure 21-71 marks the request access time, for example, the time period between HREADY goes LOW (the ESDRAMC starts to execute the request) and HREADY goes HIGH (the ESDRAMC request execution is completed).

Two read commands are issued to the SDRAM memory, since the misaligned read burst crosses the 16-bit SDRAM (4 words) memory boundary. The read addresses are 0x04, 0x08, 0x0C, and 0x10. Without issuing the second read the last SDRAM data will come from address 0x00. The ESDRAMC issue the second read command in such a way (at a specific timing) so continuous data flow is obtained. There is no timing difference between an aligned and a misaligned access although the second one requires more commands.

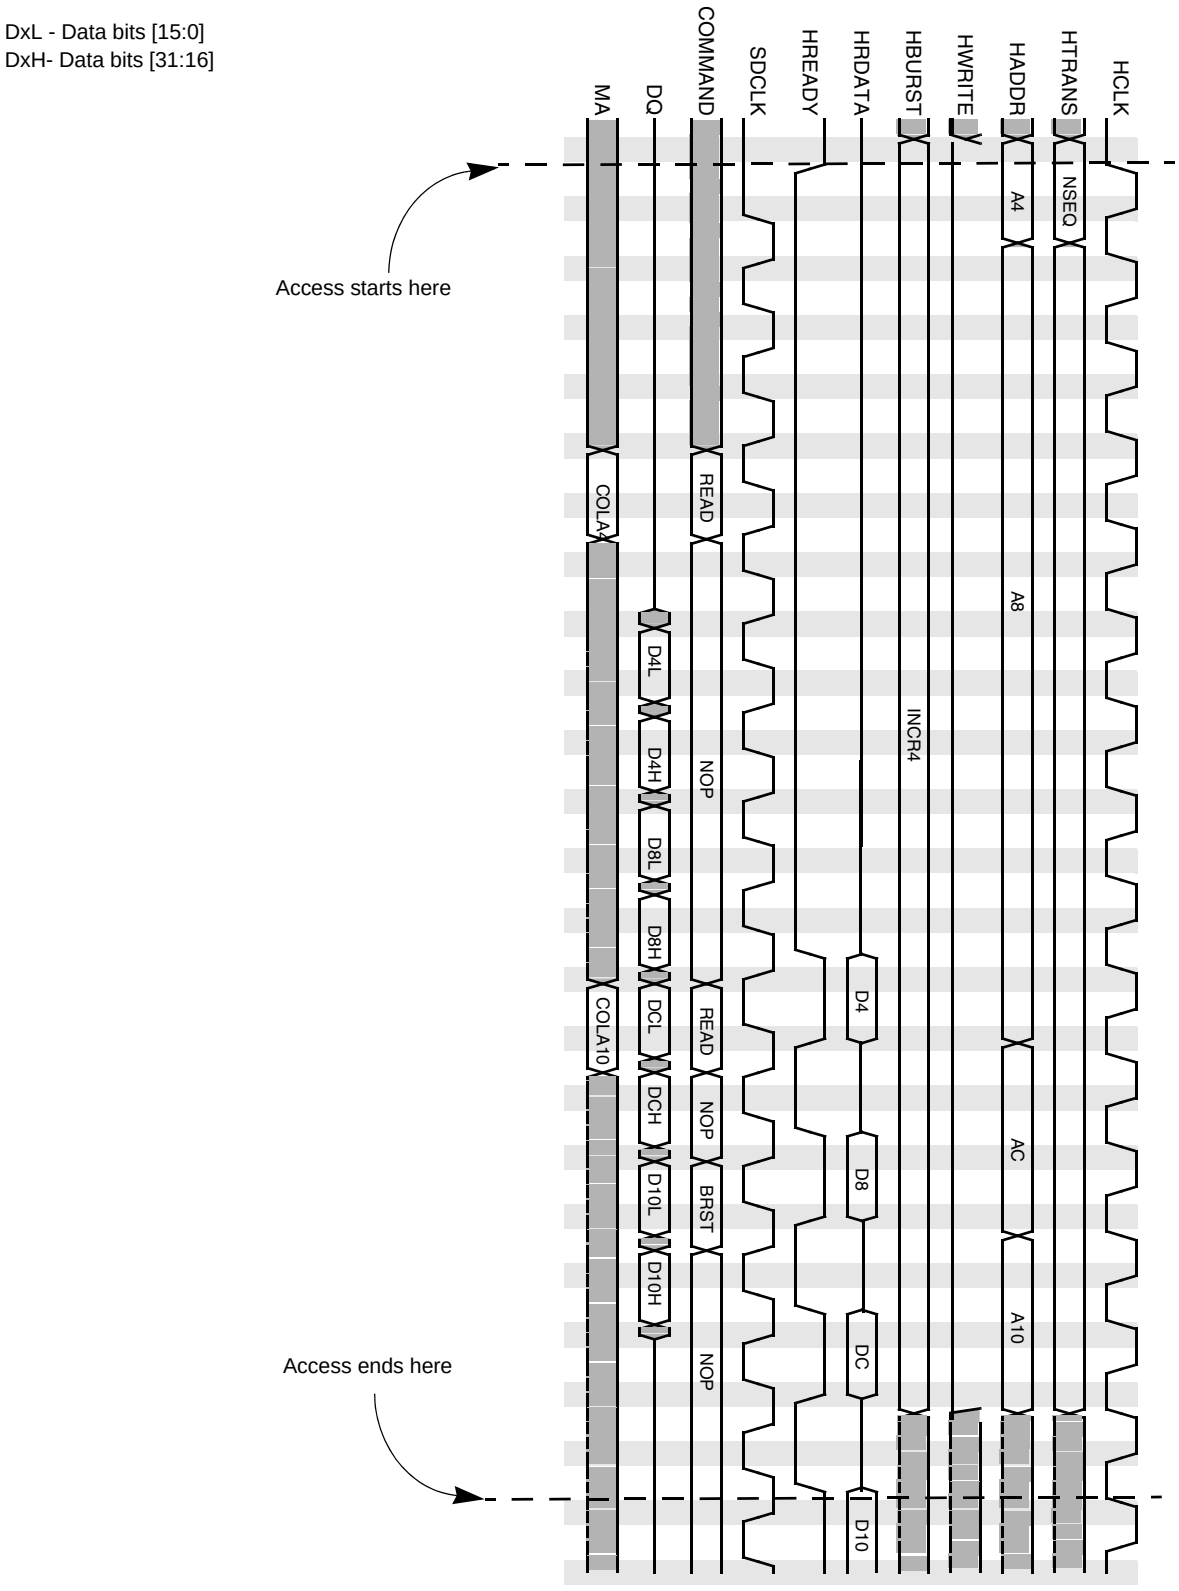

Figure 21-71. Misaligned on Page INCR4 Burst Read Access to 16-bit Memory

21.4.7.1.3 Misaligned WRAP8 Burst Read Access to 32-bit Memory

The markers in Figure 21-72 marks the request access time, that is the time period between HREADY goes low (the ESDRAMC starts to execute the request) and HREADY goes high (the ESDRAMC request execution is completed).

Only one read command is issued to the SDRAM memory, since the misaligned read burst crosses the 32-bit SDRAM memory (8 words) boundary at the memory “natural” boundary. The read addresses are 0x04, 0x08, 0x0C, 0x10, 0x14, 0x18, 0x1C and 0x00. Without issuing the second read the last SDRAM data comes from address 0x00 since this is the “natural” 32-bit memory device boundary as well.

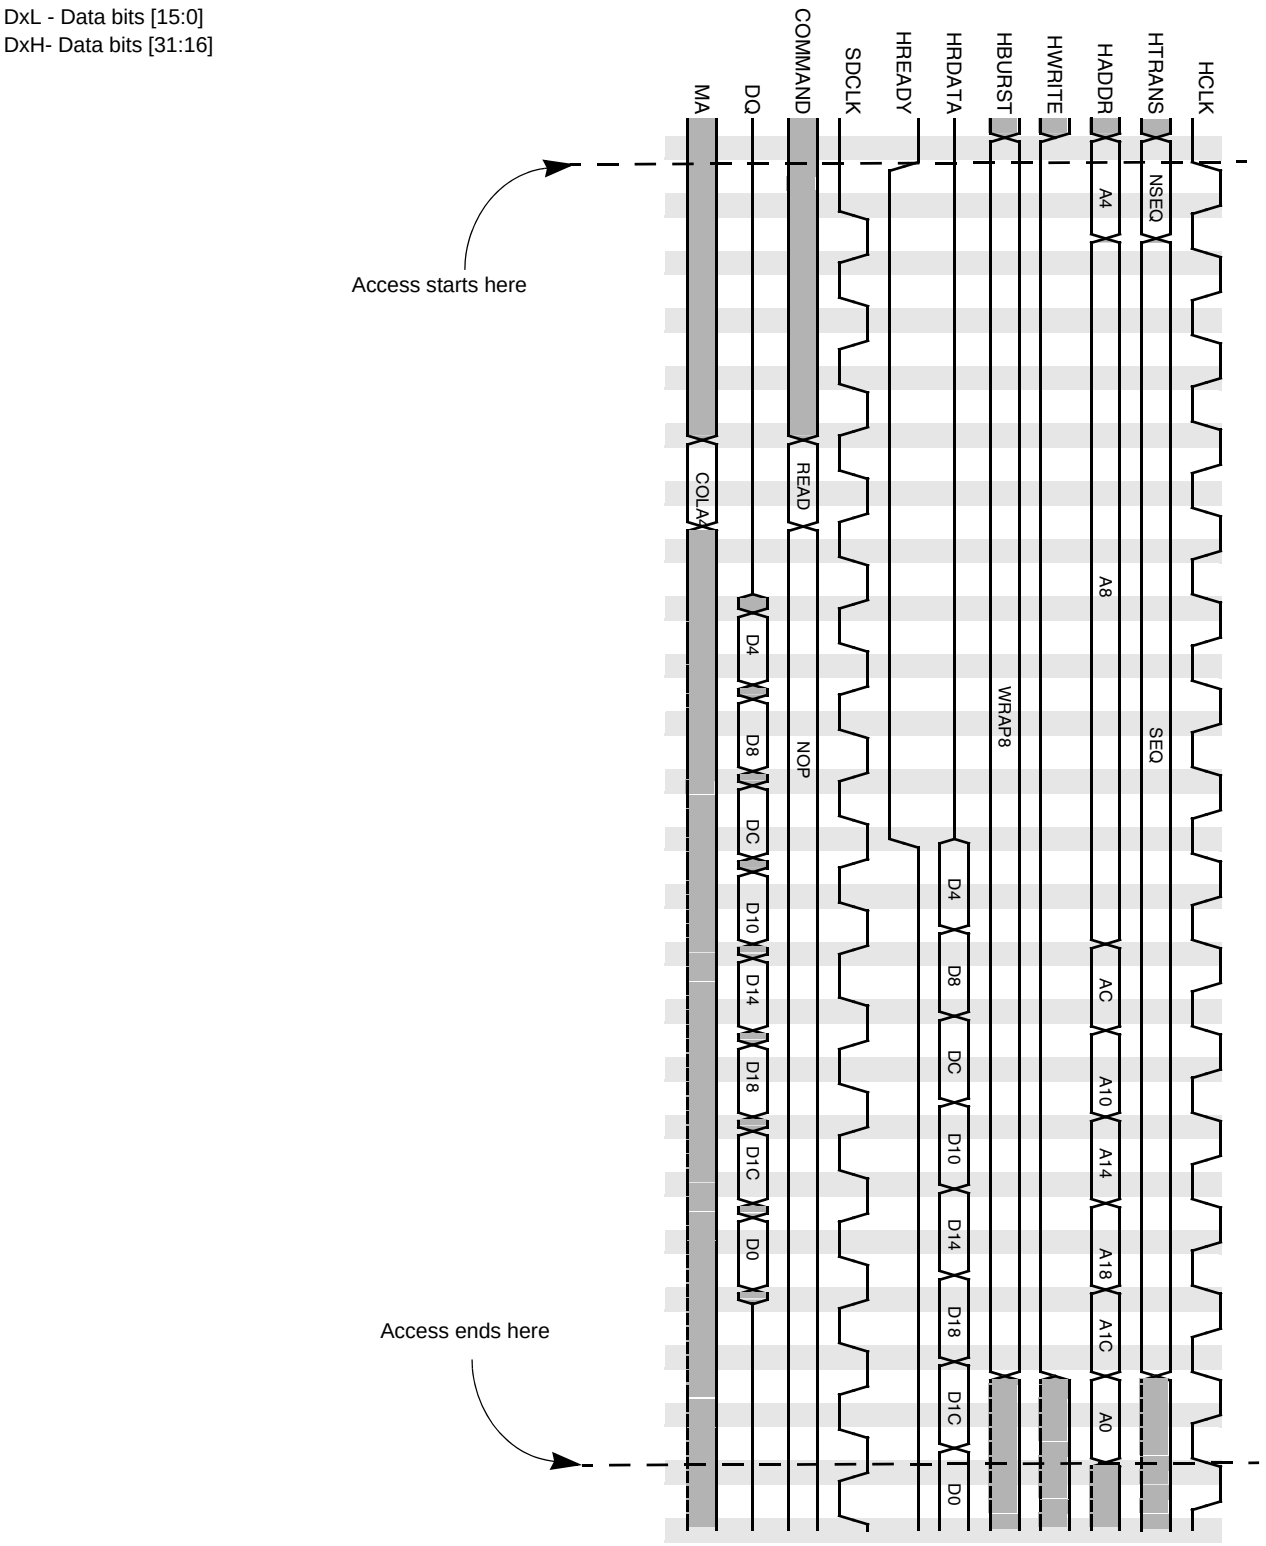

Figure 21-72. Misaligned WRAP8 Burst Read Access to 32-bit Memory

21.4.7.2 Single Write Word Access to 32-bit Memory

The markers in Figure 21-73 mark the request access time, for example, the time period between HREADY goes LOW (the ESDRAMC starts to execute the request) and HREADY goes HIGH (the ESDRAMC request execution is completed).

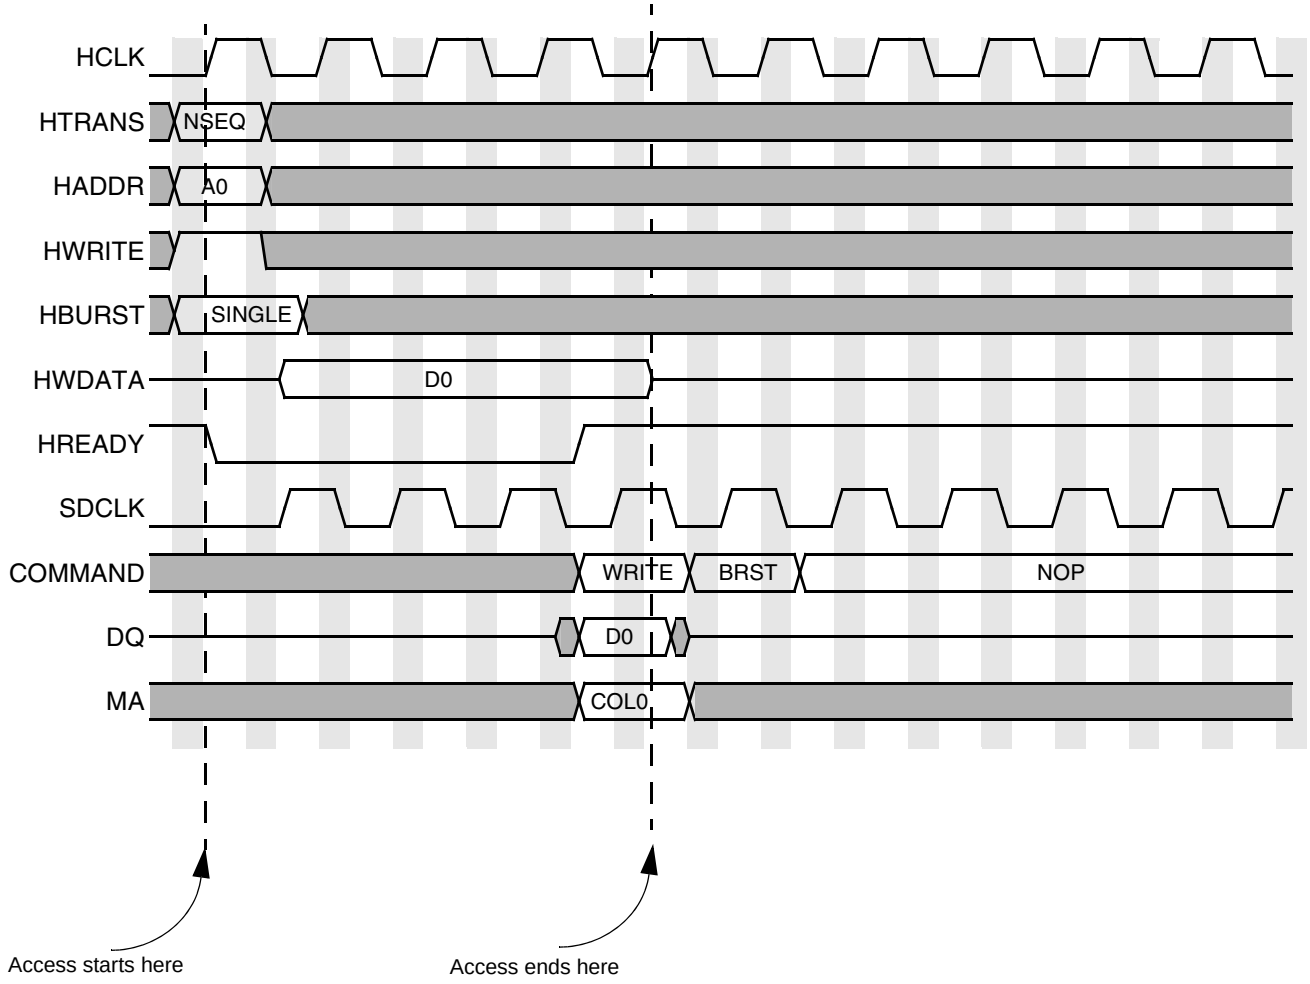

Figure 21-73. Single on Page Write - Word Access to 32-bit Memory (cycle accurate)

21.4.7.2.1 INCR4 Burst Write Word Access to 32-bit Memory

Two write commands are issued to the SDRAM memory, since the misaligned write burst crosses the 32-bit SDRAM (8 words) memory boundary. The write addresses are 0x14, 0x18, 0x1C, and 0x20. Without issuing the second write the last SDRAM data is written to address 0x00. The ESDRAMC issue the second write command in such a way (at a specific timing) so continuous data flow is obtained. There is no timing difference between an aligned and a misaligned access although the second one requires more commands. The markers in Figure 21-74 mark the request access time.

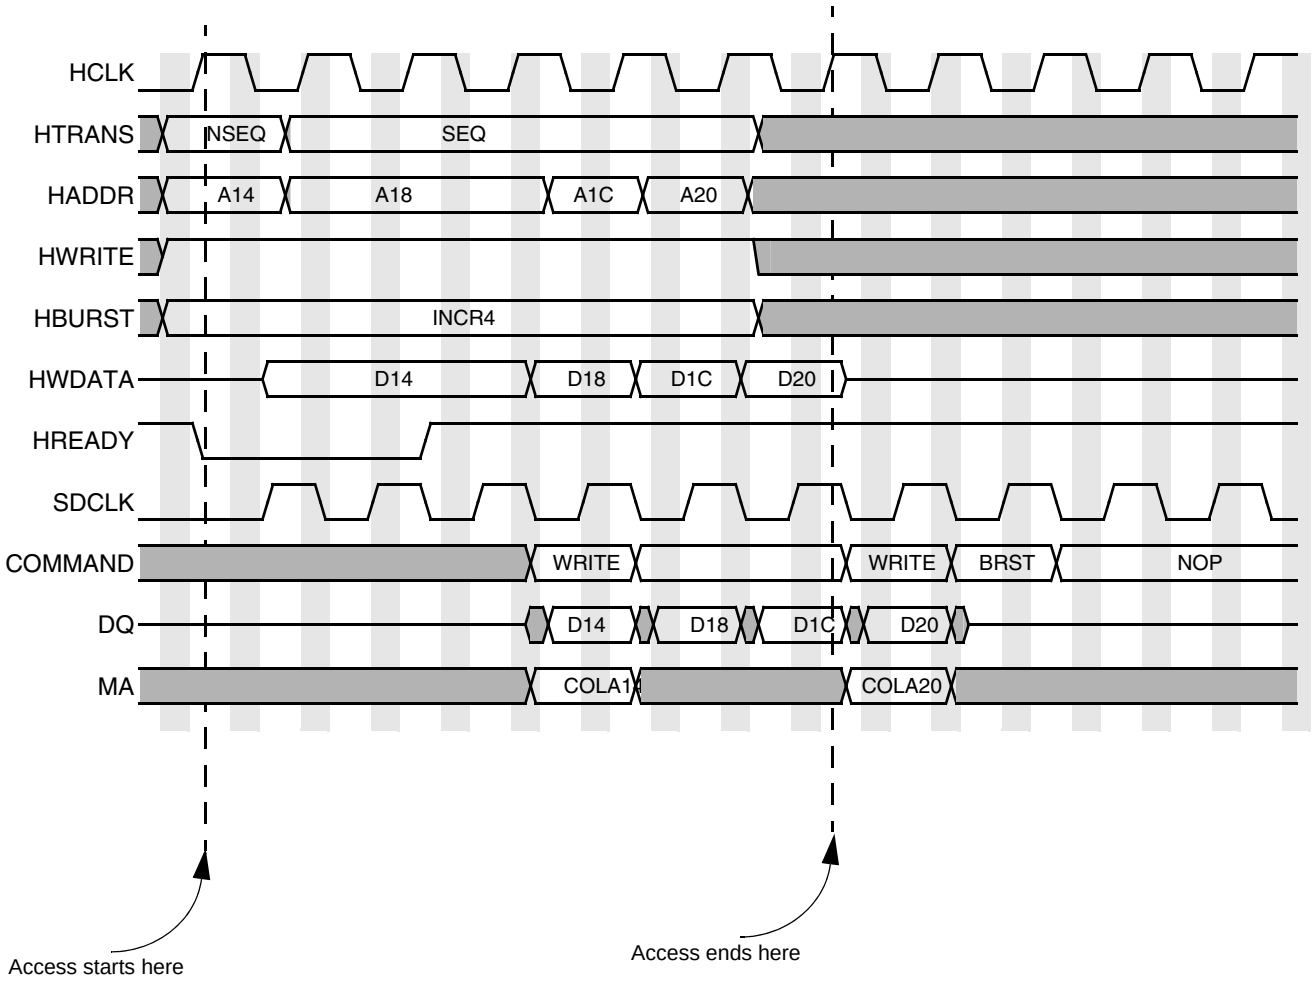

Figure 21-74. INCR4 Burst On Page Write—Word Access to 32-bit Memory (cycle accurate)

21.4.7.3 SDRAM Command Sequence for Burst Accesses

Table 21-24 show the commands that the ESDRAMC performs for WRAP and INCR accesses from the AHB. The controller splits the transaction when needed in cases that the access cross WRAP boundaries of the SDRAM. The memory is configured to 8-beat bursts (BL=8).

Unspecified INCR burst accesses are translated to single accesses to allow the burst to terminate at any length with no additional delays.

The number in the brackets represent the address for read command and the last burst address for BTERM command.

Table 21-24. SDRAM Command Sequence for Burst Accesses

Type	Bus	Address							
		0	4	8	C	10	14	18	1C
WRAP8	16-bit	READ(0) READ(10)	READ(4) READ(10) READ(0) BTERM(0)	READ(8) READ(10) READ(0) BTERM(4)	READ(C) READ(10) READ(0) BTERM(8)	READ(10) READ(0)	READ(14) READ(0) READ(10) BTERM(10)	READ(18) READ(0) READ(10) BTERM(14)	READ(1C) READ(0) READ(10) BTERM(18)
	32-bit	READ(0)	READ(4)	READ(8)	READ(C)	READ(10)	READ(14)	READ(18)	READ(1C)
INCR8	16-bit	READ(0) READ(10)	READ(4) READ(10) READ(20) BTERM(20)	READ(8) READ(10) READ(20) BTERM(24)	READ(C) READ(10) READ(20) BTERM(28)	READ(10) READ(20)	READ(14) READ(20) READ(30) BTERM(30)	READ(18) READ(20) READ(30) BTERM(34)	READ(1C) READ(20) READ(30) BTERM(38)
	32-bit	READ(0)	READ(4) READ(20) BTERM(20)	READ(8) READ(20) BTERM(24)	READ(C) READ(20) BTERM(28)	READ(10) READ(20) BTERM(2C)	READ(14) READ(20) BTERM(30)	READ(18) READ(20) BTERM(34)	READ(1C) READ(20) BTERM(38)
WRAP4	16-bit	READ(0)	READ(4)	READ(8)	READ(C)	READ(10)	READ(14)	READ(18)	READ(1C)
	32-bit	READ(0) BTERM(C)	READ(4) BTERM(10)	READ(8) READ(0) BTERM(4)	READ(C) READ(0) BTERM(8)	READ(10) READ(0) BTERM(C)	READ(14) READ(10) BTERM(10)	READ(18) READ(10) BTERM(14)	READ(1C) READ(10) BTERM(18)
INCR4	16-bit	READ(0)	READ(4) READ(10) BTERM(10)	READ(8) READ(10) BTERM(14)	READ(C) READ(10) BTERM(18)	READ(10)	READ(14) READ(20) BTERM(20)	READ(18) READ(20) BTERM(24)	READ(1C) READ(20) BTERM(28)
	32-bit	READ(0) BTERM(C)	READ(4) BTERM(10)	READ(8) BTERM(14)	READ(C) BTERM(18)	READ(10) BTERM(1C)	READ(14) READ(20) BTERM(20)	READ(18) READ(20) BTERM(24)	READ(1C) READ(20) BTERM(28)

21.4.8 Precharge Command Mode

The precharge command mode (SMODE = 0b001) is used during SDRAM/LPDDR device initialization, and to manually deactivate an active bank(s). While in this mode, an access (either read or write) to the SDRAM/LPDDR address space generate a precharge command cycle. SDRAM/LPDDR address bit A10 determines whether a single bank, or all banks, are precharged by the command. Accessing an address with the SDRAM/LPDDR address A10 low precharges only the bank selected by the bank addresses, as illustrated in Figure 21-75. Conversely, accesses with A10 high precharges all banks regardless of the bank address, as illustrated in Figure 21-76. Note that A10 is the SDRAM pin, not the A10 bit ARM address bus. Translation of the SDRAM A10 to the corresponding ARM address is dependent on the memory

configuration. The precharge command access is two clocks in length on the ARM, and one cycle to the SDRAM/LPDDR.

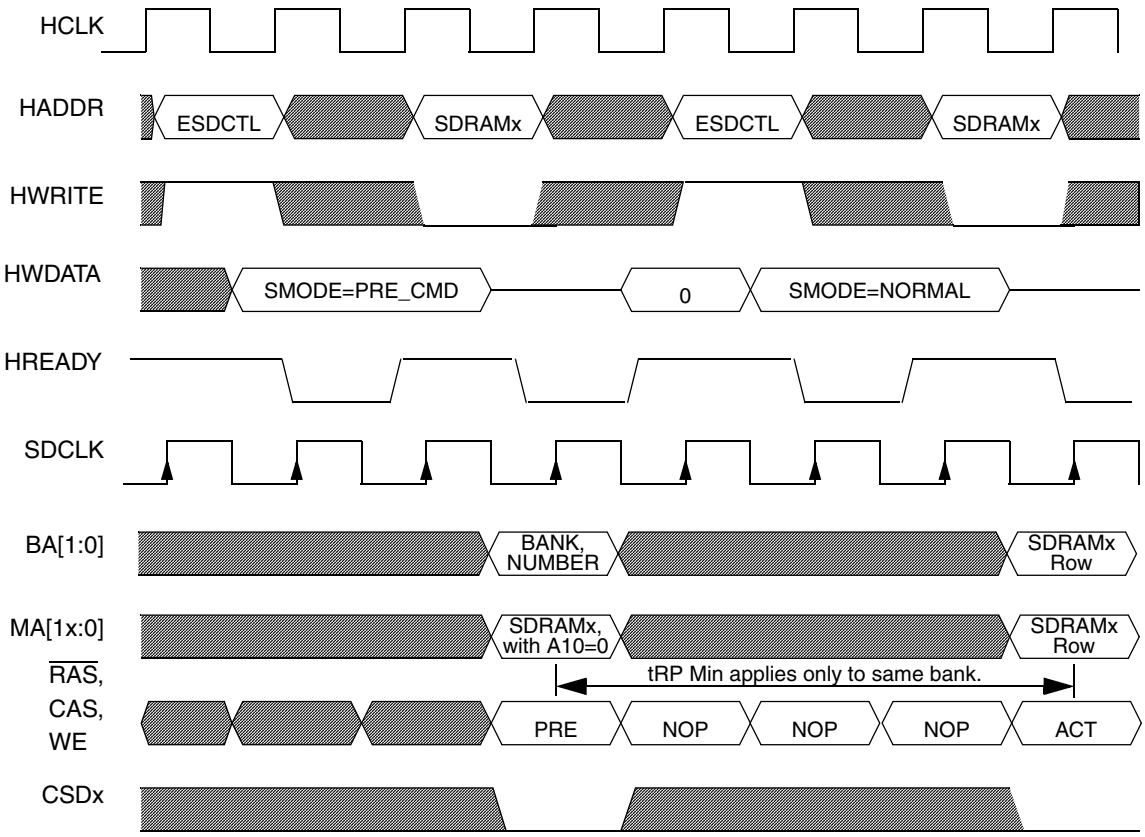

Figure 21-75. Precharge Specific Bank Timing Diagram

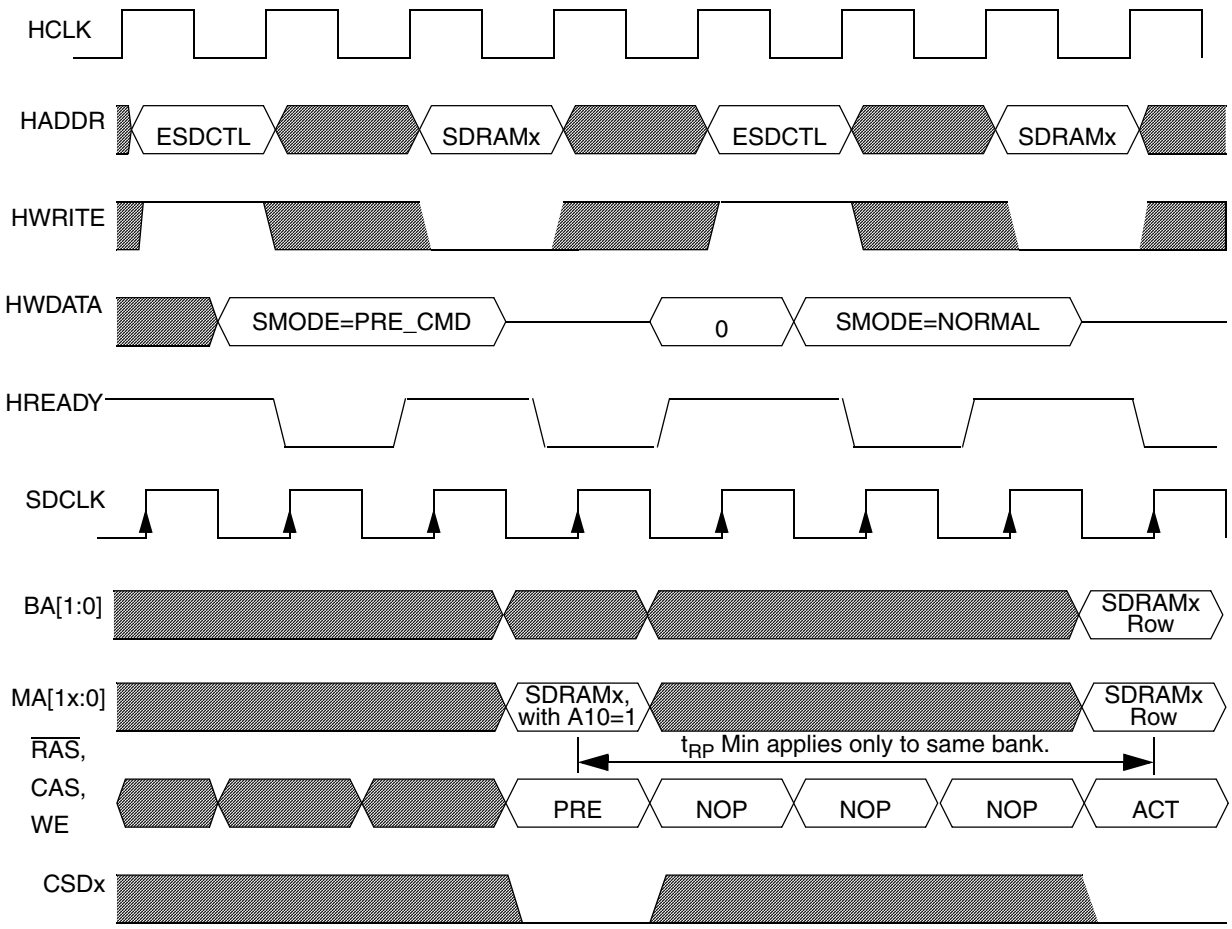

Figure 21-76. Precharge-All Banks Timing Diagram

21.4.9 Auto-Refresh Mode

The auto-refresh mode (SMODE=010) is used to manually request SDRAM/LPDDR refresh cycles and is normally used only during device initialization, since the ESDRAMC automatically generates refresh cycles when properly configured. The auto-refresh command (see Figure 21-77) refreshes all banks in the device, therefore the address supplied during the refresh command need only specify the correct SDRAM/LPDDR device. The lower address lines are a don't care. Either a read or write cycle may be used. If a write is used, the data is ignored and the external data bus is not driven. The cycle is 2 clocks on the ARM and a single clock to the SDRAM/LPDDR device.

The ESDRAMC does not guarantee that the SDRAM/LPDDR is in the idle state before the auto-refresh command is given. If one or more rows are active, a precharge-all command should be issued by the software prior to the auto-refresh command.

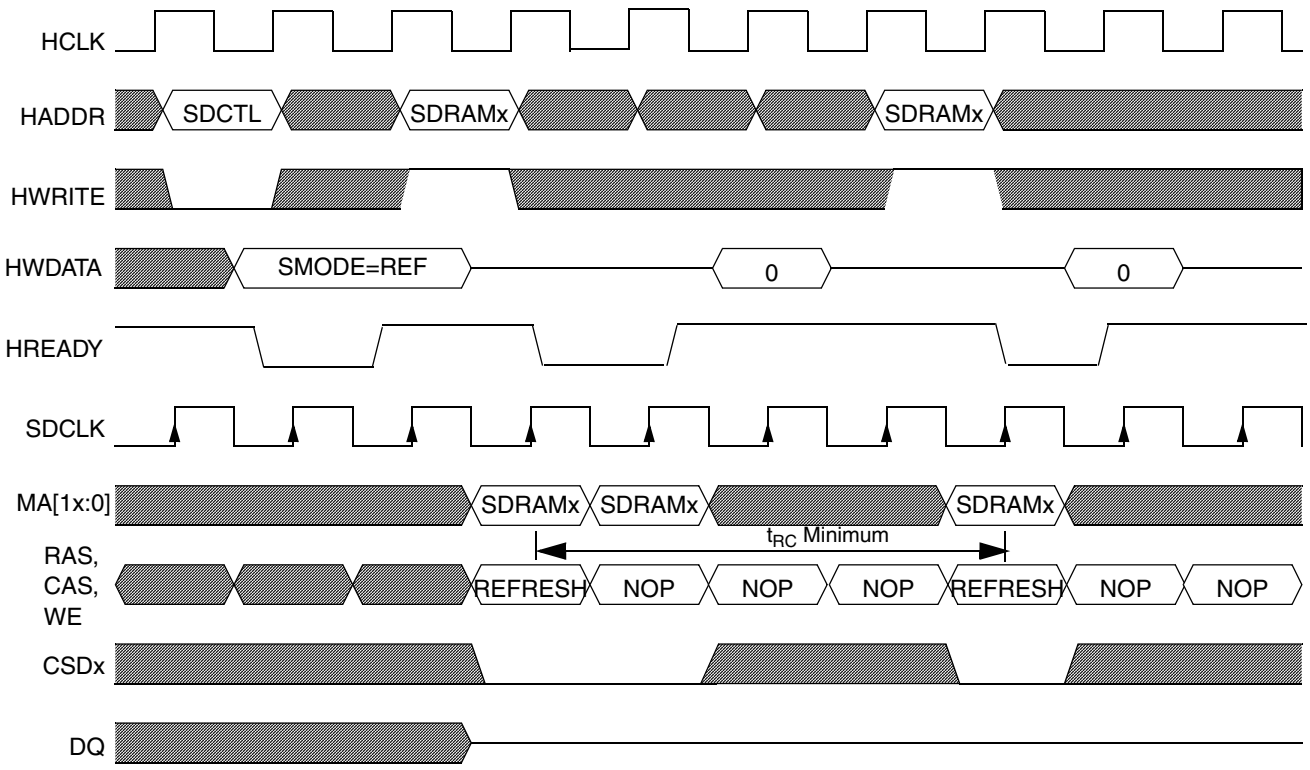

Figure 21-77. Software-Initiated Auto-Refresh Timing Diagram

21.4.10 Manual Self-Refresh Mode

The manual self-refresh mode (SMODE=100) is used to enter the SDRAM/LPDDR external device in self-refresh low power operating mode during the RUN system operating mode. Details regarding this operating mode are provided in Section 21.4.5.2, “Manual Self-Refresh Mode for SDRAM/LPDDR Devices”.

21.4.11 Load Mode Register Mode

Load mode register mode (SMODE=011) is used to program the SDRAM/LPDDR mode register (see Example 21-1 and Section 21.5.4.2, “SDR SDRAM Load Mode Register”). This mode differs from normal SDRAM write cycles because the data to be written is transferred across the address bus. Reads of the mode register are not allowed.

After SMODE bits are set to 011, either a read or write cycle may be used to write the external memory device mode register. In both cases (read or write), the ARM data is ignored and the external data bus is not driven. The row and bank address signals are used to transfer the data to the external memory device mode register (see Example 21-1 and Section 21.5.4.2, “SDR SDRAM Load Mode Register”). The cycle is 2 clocks on the ARM and a single clock to the SDRAM device.

Figure 21-78 illustrates the bus sequence for a load mode register operation. Load mode register commands must be issued while the SDRAM/LPDDR is idle. The enhanced SDRAM controller does not guarantee that the SDRAMs have been returned to the idle state before issuing the load mode register

command. Software is responsible to generate a precharge-all sequence before issuing the load mode register command if there is any possibility that one or more banks could be active. Also note, the row cycle time (t_{RC}) must be met before the load mode register command is issued.

Section 21.5.4.2, "SDR SDRAM Load Mode Register" provides a detailed example of the mode register data value calculation and mapping to the ARM address.

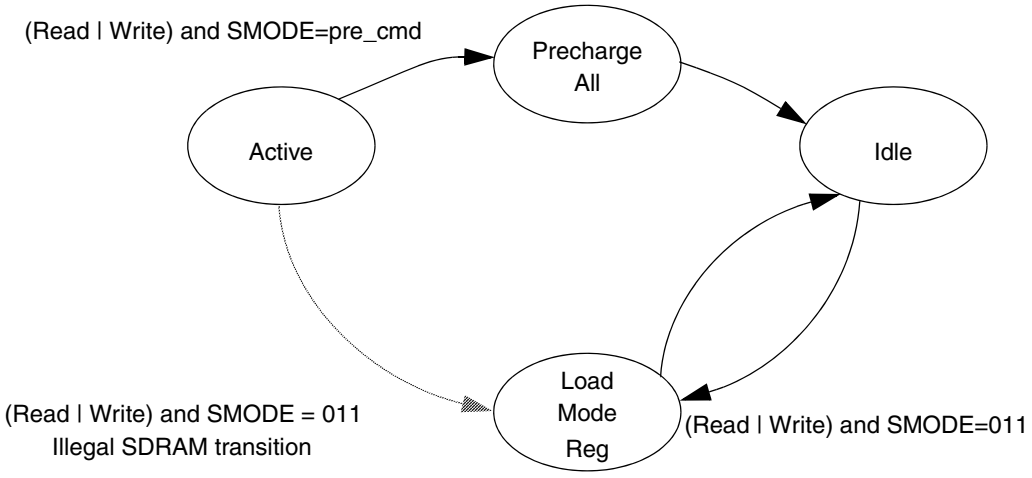

Figure 21-78. Load Mode Register State Diagram

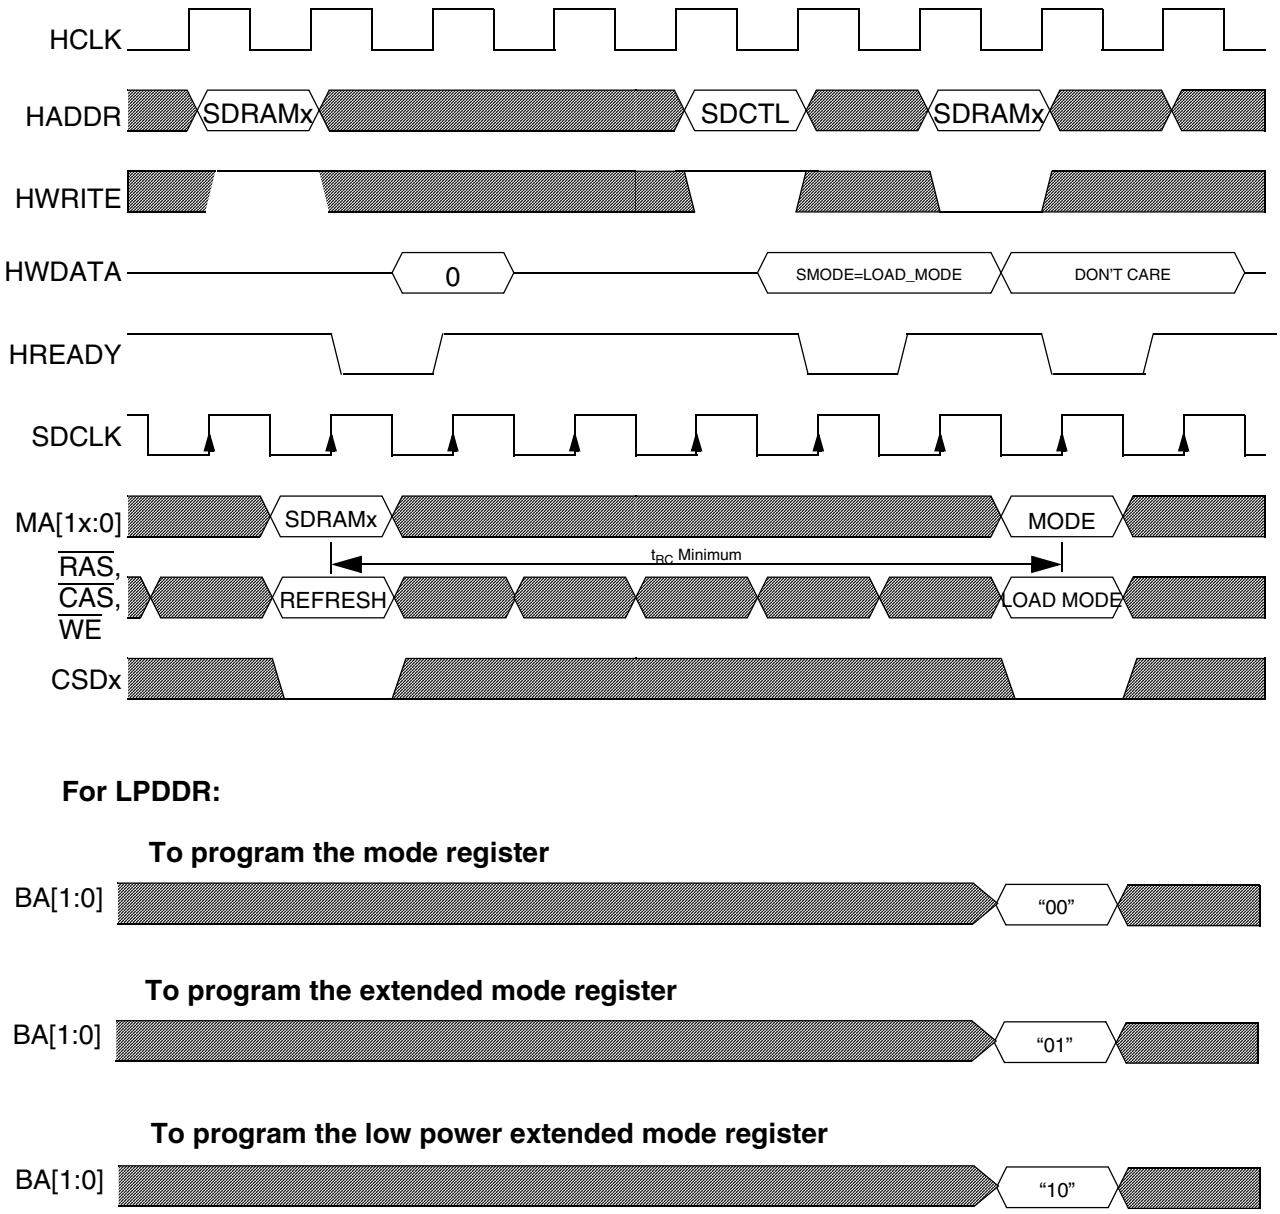

Figure 21-79. SDR and LPDDR Load Mode Register Timing Diagram

21.5 Initialization/Application Information

The following paragraphs provide details on selecting compatible SDRAM memories and configuring the controller to work with the memory system.

21.5.1 Memory Device Selection

Many SDRAM/LPDDR memory types are supported by the enhanced SDRAM controller. Important characteristics to consider when choosing a memory device are:

- The page comparators expect 4-bank memories. 2-bank devices are not supported, and their use results in the memory and controller losing synchronization when crossing page boundaries.
- Page (column) addressing must match one of the supported sizes.
- Memory density can be larger or smaller than those directly supported, although some memory may be inaccessible or redundantly mapped. The bank addresses are the most significant addresses and connecting a memory smaller than the selected density results in one or more banks being inaccessible.
- The controller is designed for memories meeting PC133 timing specifications up to 133 MHz system operation. Use of non-compatible memories require a thorough analysis of all timing parameters.

21.5.2 Configuring the Controller for SDRAM Memory Arrays

Configuration register programming options and controller-to-memory physical connections provide flexibility to accommodate different memory types and system configurations. Options are broadly grouped into 3 categories:

- Physical characteristics: row and column address bus widths and data bus width.
- Timing parameters: CAS latency, row precharge, cycle delays, refresh rate, etc.
- Functional features: clock suspend timer and supervisor/user protection.

Table 21-27– Table 21-37 are provided to assist the designer with the selection of the correct physical parameters for a number of preferred memory configurations. Timing parameters are addressed in the following subsections.

21.5.3 CAS Latency

CAS latency is determined by the operating frequency and access time of the memories. For a 133 MHz system clock frequency and PC133 compatible memories, the CAS latency is generally programmed as 3 clocks, although it is recommended that memory specifications be consulted to confirm this value. CAS latency must be programmed in two places: the chip select Control Register and the device Mode Register. See Table 21-11 for a description of the control register encoding and section Section 21.4.11, “Load Mode Register Mode” for the details on programming the SDRAM mode register.

21.5.4 SDRAM/LPDDR Initialization Sequence

Prior to normal operation (read/write accesses), the external memory device must be initialized. The following paragraphs provide detailed information covering device initialization. Register definition, command descriptions and device operation information has been thoroughly described throughout the chapter.

21.5.4.1 SDRAM Initialization

SDR and LPDDR SDRAMs must be powered up and initialized in a predefined manner. Operational procedures other than those specified by the SDRAM manufacture specification may results in undefined operation.

21.5.4.1.1 SDR SDRAM Initialization

Once power is applied to the device and the clock is stable, the SDRAM requires a 200µs delay prior to issuing any command other than a COMMAND INHIBIT or a NOP. Starting at some point during this 200µs period and continuing at least through the end of this period, COMMAND INHIBIT or NOP commands should be applied.

Once the 200µs delay has been satisfied and at least one COMMAND INHIBIT or NOP command has been applied (the SDRAM_RDY status bit is asserted), a precharge command should be applied. All banks must then be precharged, thereby placing the device in the all banks idle state.

Once in idle state, several (manufacture-dependent) auto-refresh cycles must be performed. After the auto-refresh cycles are complete, the SDRAM is ready for mode register programming. Because the mode register powers up in an unknown state, it is recommended to be loaded prior to applying any operational command. Figure 21-80 illustrates a SDRAM initialization routine with 8 auto-refresh cycles. Table 21-1 shows an initialization SDRAM example code.

It is crucial that the dual parameters (those parameters that are defined both in the SDRAM device register and in ESDRAMC registers, like CAS latency, burst length, etc.) to be identical for proper operation of both SDRAM memory and enhanced SDRAM controller.

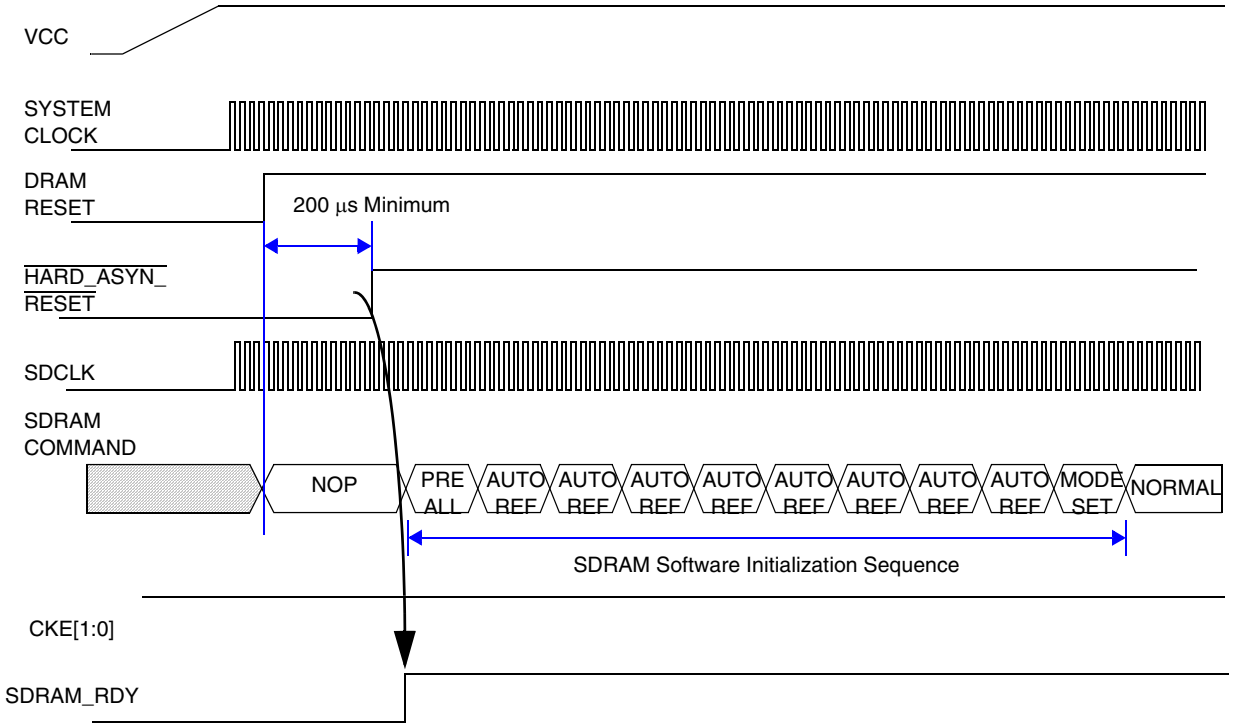

Figure 21-80. SDR SDRAM Initialization and Load Mode Register Sequence

Example 21-1. INIT_SDRAM Example Code (ARM Assembler)

```
init_sdram:
                ldr     r2, =ESD_ESDCTL0        // base address of registers
                ldr     r3, =PRE_ALL_CMD        // SMODE=001
                str     r3,(r2,#0x0)            // put CSD0 in precharge command mode
                ldr     r4, =SDRAM_CSD0         // CSD0 precharge address (A10=1)
                str     r1,(r4,#0x0)            // precharge CSD0 all banks
                ldr     r3, =AUTO_REF_CMD       // SMODE=010
                str     r3,(r2,#0x0)            // put array 0 in auto-refresh mode
                ldr     r4, =SDRAM_CSD0_BASE    // CSD0 base address
                ldr     r6,=0x7                 // load loop counter
0:              ldr     r5,(r4,#0x0)            // run auto-refresh cycle to array 0
                subs    r6,r6,#1                // decrease counter value
                bne     0b
                ldr     r3, =SET_MODE_REG_CMD // SMODE=011
                str     r3,(r2,#0x0)            // setup CSD0 for mode register write
                ldr     r3, =MODE_REG_VAL0      // array 0 mode register value
                ldrb    r5,(r3,#0x0)            // New mode register value on address bus

                ldr     r3, =NORMAL_MODE        // SMODE=000
                str     r3,(r2,#0x0)            // setup CSD0 for normal operation

ESD_ESDCTL0             .long   0xXXXX_XXXX     // system/external device dependent data
SDRAM_CSD0:             .long   0xXXXX_XXXX     // system/external device dependent data
SDRAM_CSD0_BASE:        .long   0xXXXX_XXXX     // system/external device dependent data
PRE_ALL_CMD             .long   0xXXXX_XXXX     // system/external device dependent data (SMODE=001)
AUTO_REF_CMD            .long   0xXXXX_XXXX     // system/external device dependent data (SMODE=010)
SET_MODE_REG_CMD        .long   0xXXXX_XXXX     // system/external device dependent data (SMODE=011)
MODE_REG_VAL0           .long   0xXXXX_XXXX     // system/external device dependent data
NORMAL_MODE             .long   0xXXXX_XXXX     // system/external device dependent data (SMODE=000)
```

NOTE

To load the mode register the address starts from bit 0, so ldrb should be used.

21.5.4.1.2 LPDDR SDRAM Initialization

The DDR mobile SDRAM (LPDDR) must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation. Power must first be applied to VDD and VDDQ according to the LPDDR SDRAM manufacture data sheet. Clock enable mast be driven through the SDRAM controller registers to cs0 and/or cs1.

After all power supply voltages are stable, and the clock is stable, the DDR Mobile-SDRAM requires a 200µs delay prior to applying a command other than DESELECT or NOP.

CKE is driven high by the SDRAM controller on the first edge of the clock.

Once the 200us delay has been satisfied, the following command sequence shall be applied using the SDRAM controller registers:

1. A DESELECT or NOP command.

2. A PRECHARGE ALL command should then be applied, placing the device in the all banks idle state.

3. Once in the idle state, two auto-refresh cycles must be performed (tRFC must be satisfied).

4. Two load mode register commands for the mode register and extended mode register.

Following these cycles, the LPDDR is ready for normal operation.

NOTE

A write access should be performed before the first read access to the LPDDR (in order to assure that a 0 value is driven on the DQS pins and held by the keeper of the DDR pads).

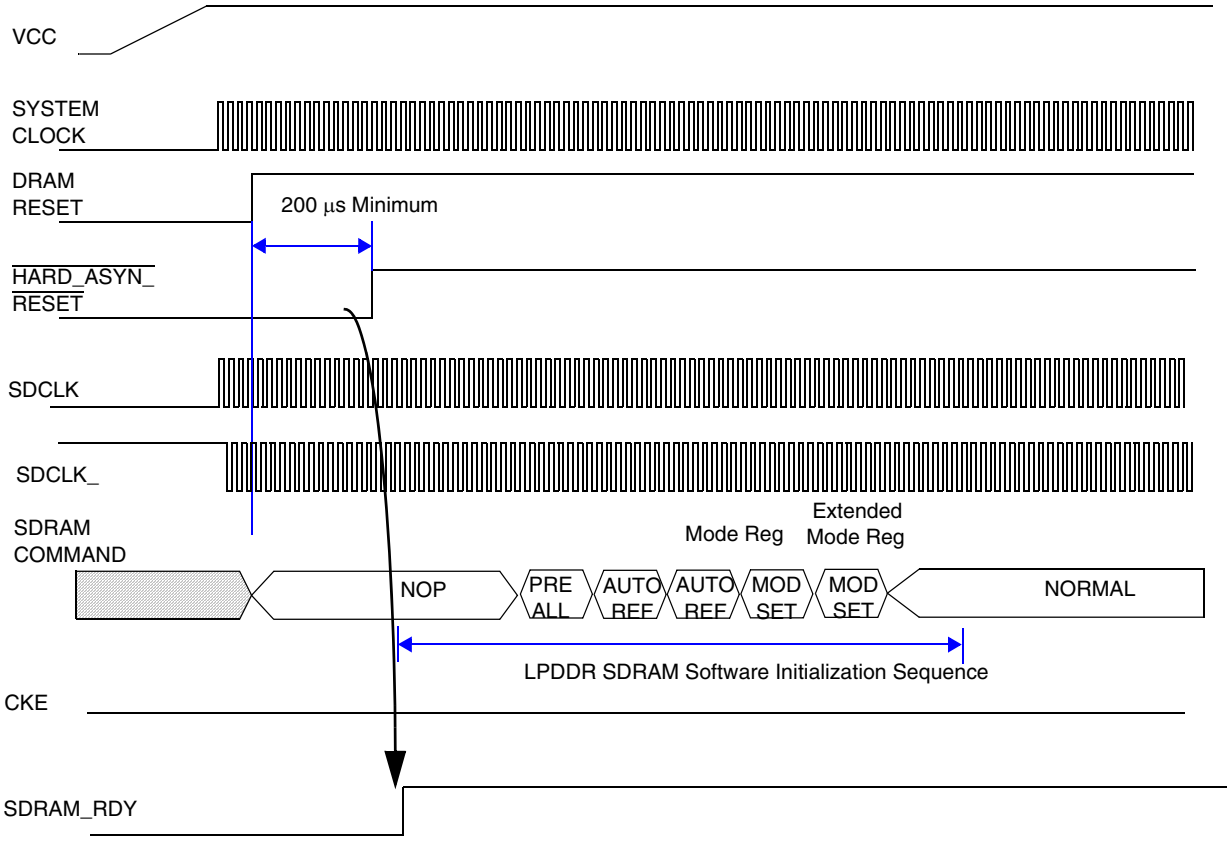

Figure 21-81. Simplified LPDDR SDRAM Initialization and Load Mode Register Sequence

21.5.4.2 SDR SDRAM Load Mode Register

The mode register is used to set the SDRAM operating characteristics including CAS latency, burst length, burst mode, and write data length. The settings depend on system characteristics including the operating frequency, memory device type, burst buffer/cache line length, and bus width. Operating characteristics vary by device type, so the data sheet must be consulted to determine the actual value to be written. In order to demonstrate the procedure, the following system characteristics is used:

- Micron MT48LC4M32B2 128-Mbit (1M x 32 x 4 banks) SDR SDRAMs
- 133-MHz system clock frequency

- Sequential burst, burst length of 8
- Single word writes (for example, no bursting on writes)

Figure 21-82 shows the mode register bit assignments for the Micron 128-Mbit SDRAM. Table 21-25 lists the bit field descriptions.

A9 Write Burst	Write Burst Mode (WB). Selects between burst writes and single location writes. 0 Programmed Burst Length 1 Single Location Access[1]
A8–A7 Op Mode	Operating Mode. Defines operating modes. 00 Standard operation All other states reserved
A6–A4 CAS Latency	CAS Latency (CL). Sets latency between column address and data 000 Reserved 001 1 clock[1] 010 2 clocks 011 3 clocks 1*xx* Reserved
A3 Burst Type	Burst Type (BT). Selects burst type 0 Interleave 1 Sequential
A2–A0 Burst Length	Burst Length (BL). A 16-bit wide SDRAM requires a burst length of eight because the four 32-bit line fill cycles is decomposed into eight 16-bit accesses. 000 = 1[1] 001 = 2[1] 010 = 4[2] 011 = 8 111 = Full Page 10x = Reserved 1x0 = Reserved

1 Not supported by the ESDRAMC

2 Not supported by the ESDRAMC for 16-bit external memory device.

For this example:

- Sequential burst (BT = 0)
- Burst length of 8 (BL = 011)
- Programmed burst length (during writes) (WB = 0)
- 3 Clock Latency (CAS Latency= 011)

Once the mode register value has been determined, it must be converted to an address. The mode register is written via the address bus, and the memory data sheet specifies the SDRAM address bits where the data is to be placed. The enhanced SDRAM controller drives the LSB address bits to the pins, so the memory density and bus width don't need to be taken into account during the conversion. Table 21-26 provides an example conversion using the same system characteristics used in the previous example.

Table 21-26. Example Address Calculation for Mode Register

Mode Register	0	0	WB	0	0	CAS LATENCY			BT	BL		
Program Value	0	0	0	0	0	0	1	1	0	0	1	1
	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓	↓
SDRAM Pin	MA11	MA10	MA9	MA8	MA7	MA6	MA5	MA4	MA3	MA2	MA1	MA0
ARM Address	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0

21.5.4.3 SDRAM Memory Configuration Examples

15 different SDRAM (SDR and LPDDR) configurations are demonstrated. These examples are 64 MByte, 128 MByte, and 256 MByte SDRAM memories in single x16, dual x16, and single x32 configurations.

All single-configuration 16-bit examples are shown connected to the lower half of the data bus. Alternatively, the memory can be connected to the upper half of the data bus by swapping the data connections to D [31:16] and the data qualifier mask connections to DQM3 and DQM2. In this case, it is necessary to program the DSIZ field in the Control Register to a value of 0 (configurations shown require a value of 1).

Chapter 22
Event Monitor (EVTMON)

The ARM1136 Platform Event Monitor (EVTMON) is a 32-bit IP-bus peripheral used for monitoring the level 2 cache controller (L2CC) events via the L2CC event bus interface.

22.1 Overview

The EVTMON contains 6 event counters (EMC0-EMC5), which may be used to count six different events selected from a list of 10 possible external events (through the L2CC event bus) or 7 internal events (overflows or clock edges). Each event counter is a 32-bit counter that has its own interrupt generation logic. By combining different statistics, a variety of useful performance metrics can be obtained.

22.2 L2 Event Monitor Features

The EVTMON has the following features:

- One 32-bit monitor control register (EMMC)
- One 32-bit counter status register (EMCS)
- Six 32-bit counter configuration registers (EMCC0-EMCC5)
- Six 32-bit event counters (EMC0-EMC5)
- IP-Bus interface (for internal register access).
- Ability to track the following events (See the event bus signal descriptions in Table 22-2):
  - CPU instruction read request to level 2
  - CPU instruction read hit in level 2 cache
  - CPU data read request to level 2
  - CPU data read hit in level 2 cache
  - CPU data write request to level 2 (not write through)
  - CPU data write request to level 2 (write through)
  - CPU data write hit in level 2 cache
  - Level 2 buffered write abort
  - L2 cache half-line eviction (2 events for one full-line eviction)
  - Allocation to the L2 cache caused by write transaction (write allocate)
- Intended to run at the same speed as L2CC block

22.3 L2 Event Monitor Register Summary

The EVTMON has 14 registers accessed through the IP-Bus interface. All transactions to these registers must be 32-bit word accesses or else a transfer error will occur. All registers may be accessed in either user or supervisor mode. Table 22-2 shows the EVTMON register summary.

Table 22-2. EVTMON Register Summary

Offset	Register	Access	Reset Value	Section/Page
General Registers				
0x$BASE_00	Event monitor control	R/W	0x0000_0000	22.3.3/22-4
0x$BASE_04	Counter status register	R/W	0x0000_0000	22.3.4/22-6
0x$BASE_08	Counter 0 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_0C	Counter 1 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_10	Counter 2 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_14	Counter 3 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_18	Counter 4 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_1C	Counter 5 configuration	R/W	0x0000_0000	22.3.5/22-7
0x$BASE_20	Counter 0	R/W	0x0000_0000	22.3.6/22-9
0x$BASE_24	Counter 1	R/W	0x0000_0000	22.3.6/22-9
0x$BASE_28	Counter 2	R/W	0x0000_0000	22.3.6/22-9
0x$BASE_2C	Counter 3	R/W	0x0000_0000	22.3.6/22-9
0x$BASE_30	Counter 4	R/W	0x0000_0000	22.3.6/22-9
0x$BASE_34	Counter 5	R/W	0x0000_0000	22.3.6/22-9

The EVTMON module decodes sufficient addresses for the register block to be unique within an 8K memory space. If the select space is larger than 8K, the module registers will alias accordingly.

22.3.1 EVTMON - Detailed Register Summary

The definitions in Figure 22-1 and Table 22-3 serve as a key for the WMSG registers and the detailed register summary.

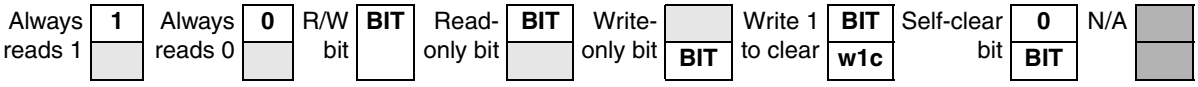

Figure 22-1. Key to Register Field

Table 22-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a 1.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to 0.
1	Resets to 1.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

22.3.2 Detailed Register Summary

All of the user-accessible registers in the EVTMON module are shown in Table 22-4.

Table 22-4. EVTMON Detailed Register Summary

22.3.3 Monitor Control Register (EMMC)

The monitor control (EMMC) register performs the following operations:

- Enables an event monitor block
- Controls interrupt generation
- Resets counters to zero

The EMMC register, shown in Figure 22-2, is accessed using a 32-bit read-modify-write sequence.

0x$BASE_000 (EMMC) Access: User read-write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 22-2. Monitor Control (EMMC) Register

Table 22-5 provides field descriptions of the EMMC register.

Table 22-5. EMMC Register Descriptions

Bits	Description
31–14	Reserved.
13–8	Counter Resets**.** Used for resetting the event counters back to zero. 1 = Clears the corresponding counter register
7–6	Reserved.
5–3	Interrupt Pulse Duration. When configured for Edge Sensitive interrupts, this field encodes how many clocks the interrupt line should remain active. 000: 1 CLK cycle 001: 2 CLK cycles 010: 4 CLK cycles 011: 8 CLK cycles 100: 16 CLK cycles 101: 32 CLK cycles 110: 64 CLK cycles 111: 128 CLK cycles
2	Interrupt Polarity. Configures the interrupt to be either active high or active low. 0 = Interrupt signal is active low (default) 1 = Interrupt signal is active high
1	Interrupt Type. Configures the interrupt to be either level or edge sensitive. 0 = Level sensitive (default), interrupt line remains active until all Counter Flags are cleared 1 = Edge sensitive, interrupt line is active for n CLK cycles (n defined by bits 5-3)
0	Event Monitor Enable. Enable or disable the Event Monitor. 0 = Disabled 1 = Enabled

22.3.4 Counter Status Register (EMCS)

The counter status (EMCS) register, shown in Figure 22-3, contains a flag for each counter and indicates if a counter set condition has occurred. It indicates which counter(s) caused an interrupt, if interrupt generation is enabled. If the interrupt is enabled and programmed as level sensitive, the interrupt remains active until all flags in the counter status register are cleared.

0x$BASE_004 (EMCS) Access: User read-write

Table 22-6 provides field descriptions of the EMCS register.

Table 22-6. EMCS Descriptions

Bits	Description
31–6	Reserved
5 EMC5	Event Counter 5 Flag. Indicates whether or not event counter 5 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred
4 EMC4	Event Counter 4 Flag. Indicates whether or not event counter 4 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred
3 EMC3	Event Counter 3 Flag. Indicates whether or not event counter 3 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred
2 EMC2	Event Counter 2 Flag. Indicates whether or not event counter 2 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred
1 EMC1	Event Counter 1 Flag. Indicates whether or not event counter 1 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred
0 EMC0	Event Counter 0 Flag. Indicates whether or not event counter 0 set condition has occurred. 0 = Counter set condition has not occurred 1 = Counter set condition has occurred

22.3.5 Counter Configuration Registers (EMCCx)

Each counter register has its own counter configuration register (4 total). The purpose of each counter configuration register is to do the following:

- Specify the counter event source.
- Define the counter set condition (the flag is in the counter status register).
- Enable appropriate interrupts.

Figure 22-4 shows the counter configuration (EMCCx) registers.

Figure 22-5. EMCx Registers

Table 22-9 provides the field description for the EMCx register.

Table 22-9. EMCx Descriptions

Bits	Description
31–0	Counter bits. • Reset by writing to the EMMC register (bits 13:8 respectively). • These bits mat may be written to a specific value, which may be useful for de-bugging purposes, or for enabling the EVTMON to interrupt more frequently.

22.4 EVTMON Interrupts

The L2 Cache Controller (L2CC) event monitor can be configured to control how interrupts are generated using the following four steps:

- Interrupt signal setup: the interrupt line can be configured to be level-sensitive (interrupt tied to active level until interrupt is cleared) or edge-sensitive (one pulse to active level lasting a programmable number of CLK cycles). The active level is also configurable for active high or low.
- Counter setup: for each counter, the incrementing trigger is selected from all possible events.
- Counter Flag set condition setup: Counter flags can be set by two conditions, increment or overflow.
- Interrupt enable: An interrupt can only be generated by a counter if the associated Counter Interrupt Generation Enable bit is set in the corresponding Counter Configuration register, see section

Section 22.3.5, “Counter Configuration Registers (EMCCx),” Counter Configuration Registers for details.

- Interrupt frequency: The frequency with which the event monitor may assert the interrupt may be controlled by writing a non-zero value to the counter register each time the interrupt is serviced. For example, writing 0x8000_0000 to a counter register during the interrupt service routine will cause that counter to assert the interrupt 2 times more frequently than letting the counter reset normally during the service routine.

NOTE

This module allows usage of an edge interrupt, but at present, the interrupt controller works only with level interrupts. The user is therefore advised to always select level interrupts.

22.5 Clock Gating

The EVTMON employs module level clock gating on both the high speed clock in the arm_clk domain and the ipg_clk in the per_clk domain.

The l2cc_clken input is used to determine if the L2CC’s clock is running and, thus, if the EVTMON high speed clock must also be running (as long as the EVTMON enable bit is set in the EMMC register). The l2cc_clken is also used to disable the counters in the event that the L2CC clock is gated off.

Note that the l2cc_clken signal can be set to a continuous enabled state by disabling clock gating of the L2CC. This is done by clearing bit 8 of the CLKCTL Control Register, see the ARM11 Platform CLKCTL specification for details.

IP-Bus transactions to the registers can always occur, be it to read, reset the counters or clear status flags, even if l2cc_clken is de-asserted.

Chapter 23
Fast Ethernet Controller (FEC)

This chapter provides a feature-set overview, a functional block diagram, and transceiver connection information for both the 10- and 100-Mbps media independent interface (MII), as well as the 7-wire serial interface. Additionally, detailed descriptions of operation and the programming model are included.

23.1 Overview

The fast Ethernet controller (FEC) is designed to support both 10- and 100-Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports three different standard physical interfaces (MAC-PHY) for connection to an external Ethernet transceiver. The FEC is implemented with a combination of hardware and microcode. Figure 23-1 is a block diagram of the FEC.

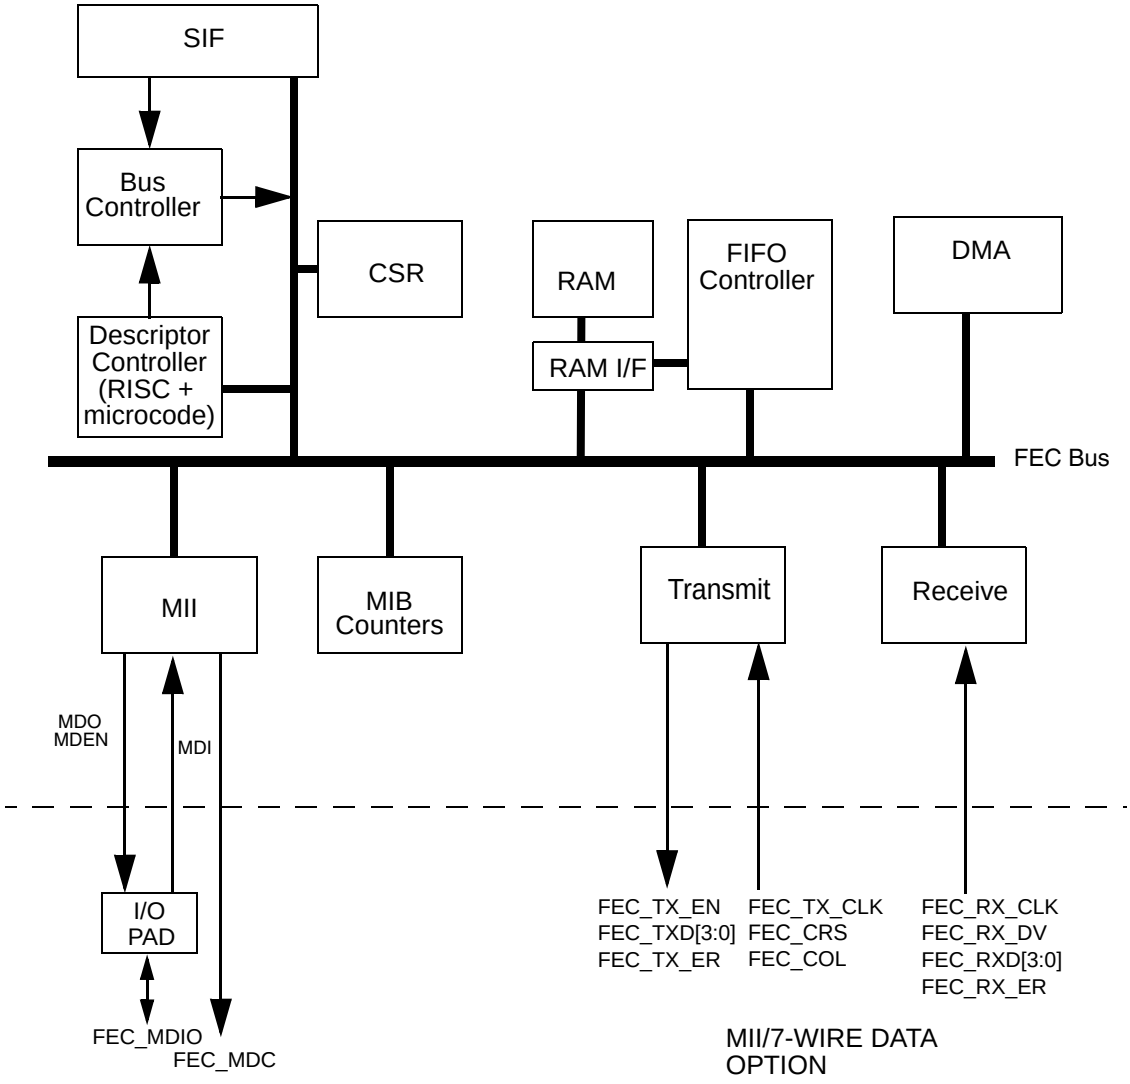

Figure 23-1. FEC Block Diagram

The FEC submodules shown in Figure 23-1 are described as follows:

- The descriptor controller is a RISC-based controller that provides the following functions in the FEC:
  - Initialization (those internal registers not initialized by the user or hardware)
  - High-level control of the DMA channels (initiating DMA transfers)
  - Interpreting buffer descriptors
  - Address recognition for receive frames
  - Random number generation for transmit collision backoff timer

NOTE

This DMA engine is for the transfer of FEC data only and is not related to the system DMA controller.

- The RAM is the focal point of all data flow in the FEC and is divided into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to and from the DMA block, from and to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO to the transmit block, and receive data flows from the receive block to the receive FIFO.
- The user controls the FEC by writing, through the slave interface (SIF) submodule, to control registers located in each block. The control and status register (CSR) block provides global control (for example, Ethernet reset and enable) and interrupt handling registers.
- The MII block provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of the management data clock and management data input/output lines of the MII interface (FEC_MDC and FEC_MDIO, respectively).
- The DMA block provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to run independently.
- The transmit and receive blocks provide the Ethernet MAC functionality (with some assistance from microcode).
- The message information block (MIB) maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC but provides valuable counters for network management. The counters supported are the RMON (RFC 1757) Ethernet statistics group and some of the IEEE 802.3 counters. See Section 23.3.3, “Message Information Block (MIB) Counters Memory Map,” for more information.

23.1.1 Features

The FEC incorporates the following features:

- Support for three different Ethernet physical interfaces:
  - 100-Mbps IEEE 802.3 MII
  - 10-Mbps IEEE 802.3 MII
  - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full-duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200Mbps throughput) with a minimum system clock rate of 50 MHz
- Support for half-duplex operation (100Mbps throughput) with a minimum system clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
  - Frames with broadcast address can be always accepted or always rejected
  - Exact match for single 48-bit individual (unicast) address

— Hash (64-bit hash) check of individual (unicast) addresses
— Hash (64-bit hash) check of group (multicast) addresses
— Promiscuous mode

23.2 Modes of Operation

The primary operational modes are described in this section.

23.2.1 Full- and Half-Duplex Operation

Full-duplex mode is intended for use on point to point links between switches or end node to switch. Half-duplex mode is used in connections between an end node and a repeater or between repeaters. Selection of the duplex mode is controlled by the TCR[FDEN] bit. When configured for full-duplex mode, flow control can be enabled, which is effected by the TCR[RFC_PAUSE], TCR[TFC_PAUSE], and RCR[FCE] bits. See Section 23.4.4, “Full-Duplex Flow Control,” for more details.

23.2.2 Interface Options

The following interface options are supported. A detailed discussion of the interface configurations is provided in Section 23.4.1, “Network Interface Options”.

23.2.2.1 10-Mbps and 100-Mbps Media Independent Interface (MII)

The MII is defined by the IEEE 802.3 standard for 10/100-Mbps operation. The MAC-PHY interface can be configured to operate in MII mode by asserting RCR[MII_MODE].

The speed of operation is determined by the FEC_TX_CLK and FEC_RX_CLK signals which are driven by the external transceiver. The transceiver either autonegotiates the speed or control by software via the serial management interface (FEC_MDC/FEC_MDIO) signals to the transceiver. See the descriptions in Section 23.3.4.6, “MII Management Frame Register (MMFR)” and Section 23.3.4.7, “MII Speed Control Register (MSCR)” respectively, as well as MII documentation for a description of how to read and write registers in the transceiver via this interface.

23.2.2.2 10-Mbps 7-Wire Interface Operation

The FEC supports a 7-wire interface as used by many 10 Mbps ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is cleared, the MII mode is disabled and the 10 Mbps, 7-wire mode is enabled.

23.2.3 Address Recognition Options

The address options supported are promiscuous, broadcast reject, individual address (hash or exact match), and multicast hash match. Address recognition options are discussed in detail in Section 23.4.3.2, “Ethernet Address Recognition”.

23.2.4 Internal Loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in Section 23.4.5, “Internal and External Loopback”.

23.3 Memory Map and Register Definition

This section includes the FEC memory map and detailed descriptions of all the registers, followed by a description of the buffers.

The FEC is programmed by a combination of control and status registers (CSRs) and buffer descriptors. The CSRs are used for mode control and to extract global status information. The descriptors are used to pass data buffers and related buffer information between the hardware and software.

23.3.1 Top Level Module Memory Map

The FEC implementation requires a 1 Kbyte memory space. This space is divided into 2 sections of 512 bytes each. The first is used for control/status registers, and the second contains event/statistics counters held in the MIB block.

Table 23-1 defines the top level memory map.For the base address of a particular module instantiation, see the system memory map.

Table 23-1. Module Memory Map

Base Address Offset	Function
0x0000-01FF	Control/Status Registers
0x0200-03FF	MIB Block Counters

23.3.2 Detailed Memory Map (Control/Status Registers)

Table 23-2 shows the FEC register memory map. For the base address of a particular module instantiation, see the system memory map.

Table 23-2. FEC Registers Memory Map

Base Address Offset (Register Abbreviation	Register	Access	Reset Value	Section/Page

0x0184 (ETDSR)	Transmit buffer descriptor ring start register	R/W	Unaffected by reset	23.3.4.22/23-28
0x0188 (EMRBR)	Maximum receive buffer size register	R/W	Unaffected by reset	23.3.4.23/23-28

23.3.3 Message Information Block (MIB) Counters Memory Map

Table 23-3 shows the MIB counters memory map, which defines the locations in the MIB RAM space where hardware maintained counters reside. It is the responsibility of software to poll the counters often enough to ensure that rollover is detected. For example, on a 100 Mbps channel an octets counter could roll over every 5.7 minutes.

These counters fall in the 0x0200-0x03FF address offset range, and are divided into RMON counters and IEEE counters, as follows:

- RMON counters are included which cover the Ethernet statistics counters defined in RFC 1757. In addition to the counters defined in the Ethernet statistics group, a counter is included to count truncated frames as the FEC only supports frame lengths up to 2047 bytes. The RMON counters are implemented independently for transmit and receive to insure accurate network statistics when operating in full-duplex mode.
- IEEE counters are included which support the mandatory and recommended counter packages defined in section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The IEEE basic package objects are supported by the FEC but do not require counters in the MIB block. In addition, some of the recommended package objects which are supported do not require MIB counters. Counters for transmit and receive full-duplex flow control frames are included as well.

Table 23-3. MIB Counters Memory Map

Base Address Offset	Mnemonic	Description
0x0200	RMON_T_DROP	Count of frames not counted correctly
0x0204	RMON_T_PACKETS	RMON Tx packet count
0x0208	RMON_T_BC_PKT	RMON Tx broadcast packets
0x020C	RMON_T_MC_PKT	RMON Tx multicast packets
0x0210	RMON_T_CRC_ALIGN	RMON Tx packets w CRC/Align error
0x0214	RMON_T_UNDERSIZE	RMON Tx packets < 64 bytes, good crc
0x0218	RMON_T_OVERSIZE	RMON Tx packets > MAX_FL bytes, good crc
0x021C	RMON_T_FRAG	RMON Tx packets < 64 bytes, bad crc
0x0220	RMON_T_JAB	RMON Tx packets > MAX_FL bytes, bad crc
0x0224	RMON_T_COL	RMON Tx collision count
0x0228	RMON_T_P64	RMON Tx 64 byte packets
0x022C	RMON_T_P65TO127	RMON Tx 65 to 127 byte packets
0x0230	RMON_T_P128TO255	RMON Tx 128 to 255 byte packets
0x0234	RMON_T_P256TO511	RMON Tx 256 to 511 byte packets
0x0238	RMON_T_P512TO1023	RMON Tx 512 to 1023 byte packets
0x023C	RMON_T_P1024TO2047	RMON Tx 1024 to 2047 byte packets
0x0240	RMON_T_P_GTE2048	RMON Tx packets w > 2048 bytes
0x0244	RMON_T_OCTETS	RMON Tx octets
0x0248	IEEE_T_DROP	Count of frames not counted correctly
0x024C	IEEE_T_FRAME_OK	Frames transmitted OK
0x0250	IEEE_T_1COL	Frames transmitted with single collision
0x0254	IEEE_T_MCOL	Frames transmitted with multiple collisions
0x0258	IEEE_T_DEF	Frames transmitted after deferral delay
0x025C	IEEE_T_LCOL	Frames transmitted with late collision
0x0260	IEEE_T_EXCOL	Frames transmitted with excessive collisions
0x0264	IEEE_T_MACERR	Frames transmitted with Tx FIFO underrun
0x0268	IEEE_T_CSERR	Frames transmitted with carrier sense error
0x026C	IEEE_T_SQE	Frames transmitted with SQE error
0x0270	IEEE_T_FDXFC	Flow control pause frames transmitted
0x0274	IEEE_T_OCTETS_OK	Octet count for frames transmitted w/o error
0x0284	RMON_R_PACKETS	RMON Rx packet count

Table 23-3. MIB Counters Memory Map (Continued)

Base Address Offset	Mnemonic	Description
0x0288	RMON_R_BC_PKT	RMON Rx broadcast packets
0x028C	RMON_R_MC_PKT	RMON Rx multicast packets
0x0290	RMON_R_CRC_ALIGN	RMON Rx packets w CRC/Align error
0x0294	RMON_R_UNDERSIZE	RMON Rx packets < 64 bytes, good crc
0x0298	RMON_R_OVERSIZE	RMON Rx packets > MAX_FL bytes, good crc
0x029C	RMON_R_FRAG	RMON Rx packets < 64 bytes, bad crc
0x02A0	RMON_R_JAB	RMON Rx packets > MAX_FL bytes, bad crc
0x02A4	RMON_R_RESVD_0	—
0x02A8	RMON_R_P64	RMON Rx 64 byte packets
0x02AC	RMON_R_P65TO127	RMON Rx 65 to 127 byte packets
0x02B0	RMON_R_P128TO255	RMON Rx 128 to 255 byte packets
0x02B4	RMON_R_P256TO511	RMON Rx 256 to 511 byte packets
0x02B8	RMON_R_P512TO1023	RMON Rx 512 to 1023 byte packets
0x02BC	RMON_R_P1024TO2047	RMON Rx 1024 to 2047 byte packets
0x02C0	RMON_R_P_GTE2048	RMON Rx packets w > 2048 bytes
0x02C4	RMON_R_OCTETS	RMON Rx octets
0x02C8	IEEE_R_DROP	Count of frames not counted correctly
0x02CC	IEEE_R_FRAME_OK	Frames received OK
0x02D0	IEEE_R_CRC	Frames received with CRC error
0x02D4	IEEE_R_ALIGN	Frames received with alignment error
0x02D8	IEEE_R_MACERR	Receive FIFO overflow count
0x02DC	IEEE_R_FDXFC	Flow control pause frames received
0x02E0	IEEE_R_OCTETS_OK	Octet count for frames received w/o error

23.3.4 Register Descriptions

This section provides detailed descriptions of the FEC's registers.

23.3.4.1 Ethernet Interrupt Event Register (EIR)

The EIR bit assignments are shown in Figure 23-2 and described in Table 23-4. When an event occurs that sets a bit in the EIR, an interrupt is generated if the corresponding bit in the interrupt mask register (EIMR) is also set. The bit in the EIR is cleared if a one is written to that bit position; writing zero has no effect. This register is cleared upon hardware reset.

Interrupts can be divided into three classes as follows:

- Interrupts that occur in normal operation: these include GRA, TXF, TXB, RXF, RXB, and MII.
- Interrupts that result from errors or problems detected in the network or transceiver: these include HBERR, BABR, BABT, LC, and RL.
- Interrupts that result from internal errors are EBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters. The correspondence between interrupts and counters is shown in Table 23-5. Software can choose to mask off the interrupts since these errors is visible to network management via the MIB counters.

Offset 0x0004 (EIR)
0x0008 (EIMR)

Figure 23-2. Ethernet Interrupt Event Register (EIR)

Table 23-4. EIR Field Descriptions

Bits	Name	Description
31	HBERR	Heartbeat error. This interrupt indicates that HBC is set in the TCR register and that the COL input was not asserted within the Heartbeat window following a transmission.
30	BABR	Babbling receive error. This bit indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29	BABT	Babbling transmit error. This bit indicates that the transmitted frame length has exceeded RCR[MAX_FL] bytes. This condition is usually caused by a frame that is too long being placed into the transmit data buffer(s). Truncation does not occur.
28	GRA	Graceful stop complete. This interrupt is asserted for one of three reasons. Graceful stop means that the transmitter is put into a pause state after completion of the frame currently being transmitted. 1) A graceful stop, which was initiated by the setting of the TCR[GTS] bit is now complete. 2) A graceful stop, which was initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. 3) A graceful stop, which was initiated by the reception of a valid full-duplex flow control “pause” frame is now complete. See the “Full-Duplex Flow Control” section of the Functional Description chapter.

Table 23-4. EIR Field Descriptions (Continued)

Bits	Name	Description
27	TXF	Transmit frame interrupt. This bit indicates that a frame has been transmitted and that the last corresponding buffer descriptor has been updated.
26	TXB	Transmit buffer interrupt. This bit indicates that a transmit buffer descriptor has been updated.
25	RXF	Receive frame interrupt. This bit indicates that a frame has been received and that the last corresponding buffer descriptor has been updated.
24	RXB	Receive buffer interrupt. This bit indicates that a receive buffer descriptor has been updated that was not the last in the frame.
23	MII	MII interrupt. This bit indicates that the MII has completed the data transfer requested.
22	EBERR	Ethernet bus error. This bit indicates that a system bus error occurred when a DMA transaction was underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs software needs to insure that the FIFO controller and DMA are also soft reset.
21	LC	Late collision. This bit indicates that a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame is truncated with a bad CRC and the remainder of the frame is discarded.
20	RL	Collision retry limit. This bit indicates that a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. Can only occur in half-duplex mode.
19	UN	Transmit FIFO underrun. This bit indicates that the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18–0	—	Reserved, read as 0

Table 23-5. Error Interrupts and Block Counters

Interrupt	Counter(s)
HBERR	IEEE_T_SQE
BABR	RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
BABT	RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
LATE_COL	IEEE_T_LCOL
COL_RETRY_LIM	IEEE_T_EXCOL
XFIFO_UN	IEEE_T_MACERR

23.3.4.2 Ethernet Interrupt Mask Register (EIMR)

The EIMR controls which of the interrupt events flagged in the EIR are allowed to generate actual interrupts. If the corresponding bits in both the EIR and EIMR are set, the interrupt is signaled to the CPU. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit. This register is cleared upon a hardware reset.

The EIMR bit assignments are the same as for the EIR: they are shown in Figure 23-2 and described in Table 23-6.

Table 23-6. EIMR Field Descriptions

Bits	Name	Description
31–19	See Table 23-4.	Interrupt mask. Each bit corresponds to an interrupt source defined by the EIR register. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
18–0	—	Reserved, read as 0

23.3.4.3 Receive Descriptor Active Register (RDAR)

RDAR is a user-writeable command register which indicates that the receive descriptor ring has been updated, and that empty receive buffers have been produced by the driver with the empty bit set.

The RDAR[R_DES_ACTIVE] bit is set whenever the register is written, independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (provided ECR[ETHER_EN] is also set to 1). After the FEC polls a receive descriptor whose empty bit is not set, then the FEC clears the RDAR[R_DES_ACTIVE] bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors have been placed into the receive descriptor ring.

The RDAR is cleared at reset, and when ECR[ETHER_EN] is cleared.

The RDAR bit assignments are shown in Figure 23-3 and described in Table 23-7.

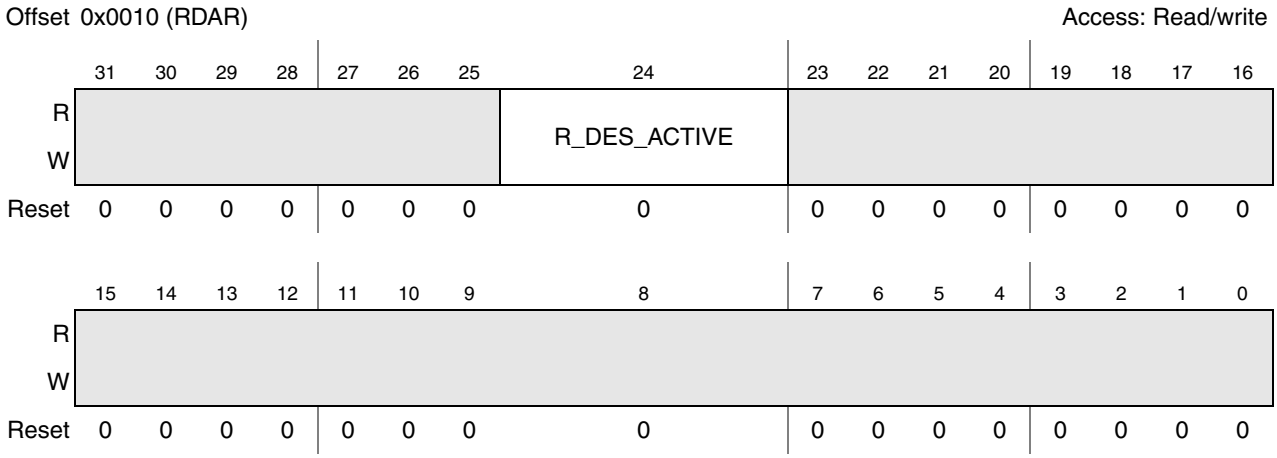

Figure 23-3. Receive Descriptor Active Register (RDAR)

Table 23-7. RDAR Field Descriptions

Bits	Name	Description
31–25	—	Reserved, read as 0
24	R_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device when the FEC polls a receive descriptor whose empty bit is not set. Also cleared when ECR[ETHER_EN] is cleared.
23–0	—	Reserved, read as 0

23.3.4.4 Transmit Descriptor Active Register (TDAR)

The TDAR is a command register, written to by the user, to indicate that the transmit descriptor ring has been updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

Whenever the register is written the TDAR[X_DES_ACTIVE] bit is set to 1, independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and process transmit frames (provided ECR[ETHER_EN] is also set to 1). After the FEC polls a transmit descriptor whose ready bit is not set, then the FEC clears the TDAR[X_DES_ACTIVE] bit and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors have been placed into the transmit descriptor ring.

The TDAR is cleared at reset, when ECR[ETHER_EN] is cleared, or when ECR[RESET] is set to 1.

The TDAR bit assignments are shown in Figure 23-4 and described in Table 23-8.

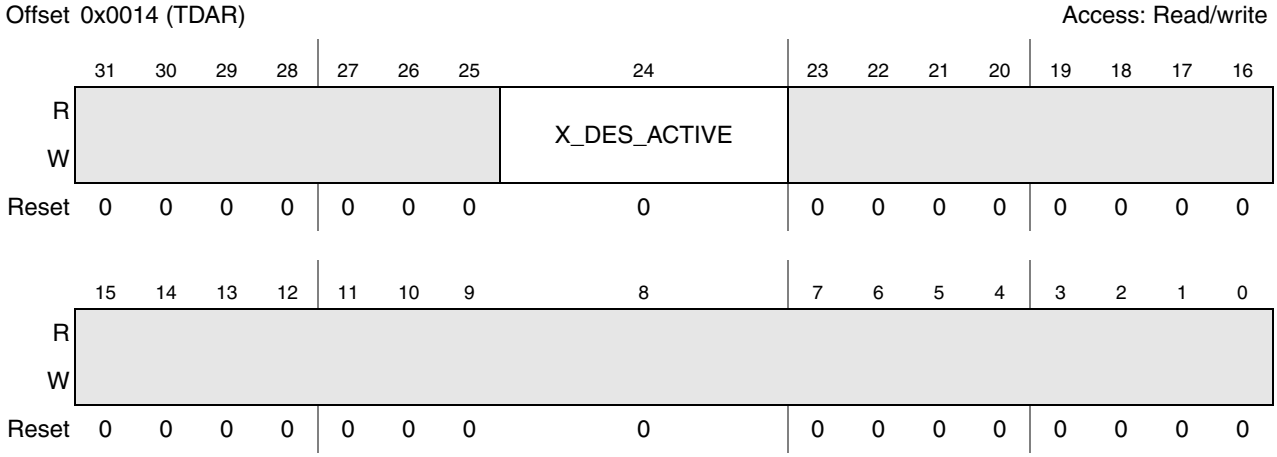

Figure 23-4. Transmit Descriptor Active Register (TDAR)

Table 23-8. TDAR Field Descriptions

Bits	Name	Description
31–25	—	Reserved, read as 0

Table 23-8. TDAR Field Descriptions (Continued)

Bits	Name	Description
24	X_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device when the FEC polls a transmit descriptor whose ready bit is not set. Also cleared when ECR[ETHER_EN] is cleared.
23–0	—	Reserved, read as 0

23.3.4.5 Ethernet Control Register (ECR)

The ECR is used to enable/disable the FEC. ECR is a read/write user register, though both fields in this register can also be altered by hardware.

ECR bit assignments are shown in Figure 23-5 and described in Table 23-9.

Figure 23-5. Ethernet Control Register (ECR)

Table 23-9. ECR Field Descriptions

Bits	Name	Description
31-2	—	Reserved.

Table 23-9. ECR Field Descriptions (Continued)

Bits	Name	Description
1	ETHER_EN	When this bit is set, the FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception is immediately stopped and transmission is stopped after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. The ETHER_EN bit is altered by hardware under the following conditions: • ECR[RESET] is set by software, in which case ETHER_EN is cleared • an error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN isis cleared
0	RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ETHER_EN is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately 8 system clock cycles after RESET is written with a 1.

23.3.4.6 MII Management Frame Register (MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to MMFR causes a management frame to be generated unless the MII-SPEED field of the MSCR has been set to 0, in which case MSCR is set to a non-zero value and an MII frame is generated with the data previously written to MMFR. This allows MMFR and MSCR to be programmed in either order if the MII-SPEED field of MSCR is zero (for further details see Section 23.3.4.7, “MII Speed Control Register (MSCR)”).

The MMFR does not reset to a definite value. MMFR bit assignments are shown in Figure 23-6 and described in Table 23-10.

Offset 0x0040 (MMFR) Access: User read/write

Figure 23-6. MII Management Frame Register (MMFR)

Table 23-10. MMFR Field Descriptions

Bits	Name	Description
31–30	ST	Start of frame delimiter. These bits must be programmed to 01 for a valid MII management frame.
29–28	OP	Operation code. This field must be programmed to 10 (read) or 01 (write) to generate a valid MII management frame. A value of 11 produces “read” frame operation while a value of 00 produces “write” frame operation, but these frames is not MII compatible.
27–23	PA	PHY address. This field specifies one of up to 32 attached PHY devices.
22–18	RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
17–16	TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
15–0	DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

To perform a read or write operation on the MII Management Interface, the MMFR must be written to by the user. To generate a valid read or write management frame, the ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame isis generated but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compatible MII management interface write frame (write to a PHY register), the user must write {01 01 PHYAD REGAD 10 DATA} to the bit fields of the MMFR, as shown in Table 23-10. Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time the contents of the MMFR is altered as the contents are serially shifted and is unpredictable if read by the user. After the write management frame operation has completed, the MII interrupt is generated. At this time the contents of the MMFR matches the original value written.

To generate an MII management interface read frame (read a PHY register) the user must write {01 10 PHYAD REGAD 10 XXXX} to the bit fields of the MMFR shown in Table 23-10 (the contents of the 4-bit DATA field are arbitrary). Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time the contents of the MMFR is altered as the contents are serially shifted, and is unpredictable if read by the user. After the read management frame operation has completed, the MII interrupt is generated. At this time the contents of the MMFR matches the original value written except for the DATA field whose contents have been replaced by the value read from the PHY register.

If the MMFR is written to while frame generation is in progress, the frame contents is altered. Software uses the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

23.3.4.7 MII Speed Control Register (MSCR)

MSCR bit assignments are shown in Figure 23-7 and described in Table 23-11. The MSCR provides control of the frequency of the MII clock (FEC_MDC signal), and allows a preamble drop on the MII management frame.

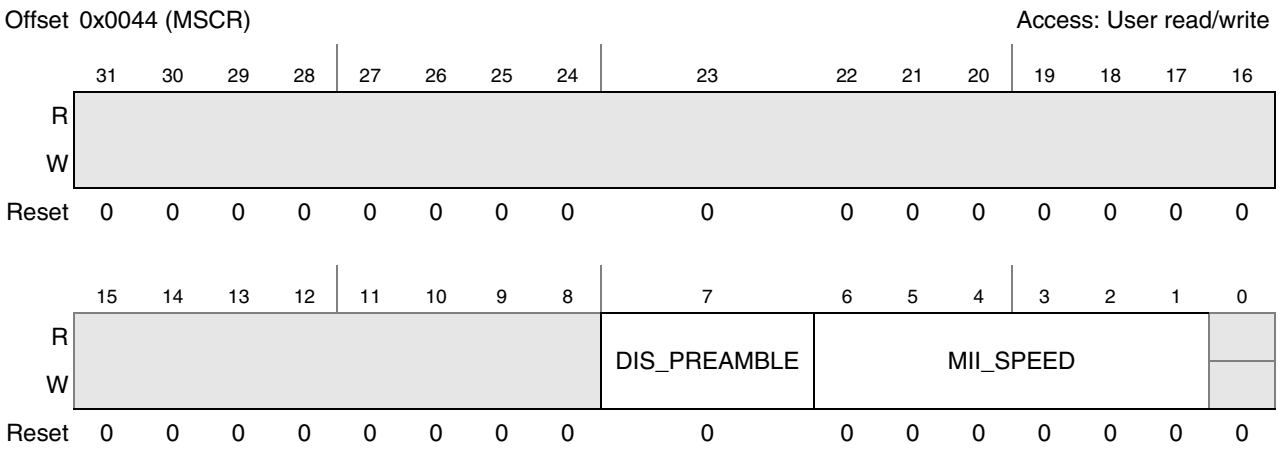

Figure 23-7. MII Speed Control Register (MSCR)

Table 23-11. MSCR Field Descriptions

Bits	Name	Description
31–8	—	Reserved, read as 0
7	DIS_PREAMBLE	Asserting this bit causes preamble (0xFFFF_FFFF) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
6–1	MII_SPEED	MII_SPEED controls the frequency of the MII management interface clock (FEC_MDC) relative to the system clock. A value of 0 in this field “turns off” the FEC_MDC and leave it in low voltage state. Any non-zero value results in the FEC_MDC frequency of 1/(MII_SPEED*2) of the system clock frequency.
0	—	Reserved, read as 0

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compatible with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value in order to generate a read or write management frame. After the management frame is complete the MSCR can optionally be set to zero to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED is changed during operation (change takes effect following either a rising or falling edge of FEC_MDC).

The FEC_MDC frequency depends on both the system clock frequency and the MII_SPEED register. If the system clock is 25 MHz, programming the MII_SPEED register to 0x0000_0005 results in an FEC_MDC frequency of 25 MHz * 1/10 = 2.5 MHz. A table showing optimum values for MII_SPEED for different system clock frequencies is provided below.

Table 23-12. Programming Examples for MSCR

System Clock Frequency	MII_SPEED (field in reg)	FEC_MDC frequency
25 MHz	0x5	2.5 MHz
33 MHz	0x7	2.36 MHz
40 MHz	0x8	2.5 MHz

Table 23-12. Programming Examples for MSCR

System Clock Frequency	MII_SPEED (field in reg)	FEC_MDC frequency
50 MHz	0xA	2.5 MHz
66 MHz	0xD	2.54 MHz

23.3.4.8 MIB Control Register (MIBC)

The MIB control register is a read/write register used to provide control of and to observe the state of the Message Information Block (MIB). This register is accessed by user software if there is a need to disable the MIB operation. For example, in order to clear all MIB counters in RAM the user disables the MIB, then clears all the MIB RAM locations, then enables the MIB. The MIB_DISABLE bit is reset to 1. See Table 23-3 for the locations of the MIB counters.

MIBC bit assignments are shown in Figure 23-8 and described in Table 23-13.

Offset 0x0064 (MIBC) Access: Read/write

Table 23-13. MIBC Field Descriptions

Bits	Name	Description
31	MIB_DISABLE	A read/write control bit. If set, the MIB logic halts and not update any MIB counters.
30	MB_IDLE	A read-only status bit. If set the MIB block is not currently updating any MIB counters.
29–0	—	Reserved.

23.3.4.9 Receive Control Register (RCR)

RCR bit fields are shown in Figure 23-9 and described in Table 23-14. The RCR is programmed by the user, and controls the operational mode of the receive block. It can only be written to when ECR[ETHER_EN] = 0 (that is, during initialization).

Offset 0x0084 (RCR) Access: Read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 23-9. Receive Control Register (RCR)

Table 23-14. RCR Field Descriptions

Bits	Name	Description
31–27	—	Reserved, read as 0
26–16	MAX_FL	Maximum frame length. Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive Frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor. The recommended default value to be programmed by the user is 1518 or 1522 (if VLAN Tags are supported).
15–6	—	Reserved, read as 0
5	FCE	Flow control enable. When FCE is set to 1, the receiver detects pause frames. Upon pause frame detection, the transmitter stops transmitting data frames for a given duration.
4	BC_REJ	Broadcast frame reject. When BC_REJ is set to 1, frames with DA (destination address) = 0xFF_FF_FF_FF_FF_FF are rejected unless the PROM bit is set to 1. If both BC_REJ and PROM are set to 1, then frames with broadcast DA is accepted and the M (MISS) bit is set in the receive buffer descriptor.
3	PROM	Promiscuous mode. All frames are accepted regardless of address matching.
2	MII_MODE	Media independent interface mode. Selects external interface mode. Setting this bit to one selects MII mode, setting this bit equal to zero selects 7-wire mode (used only for serial 10 Mbps). This bit controls the interface mode for both transmit and receive blocks.
1	DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full-duplex or to monitor transmit activity in half-duplex mode). 1 Disable reception of frames while transmitting (normally used for half-duplex mode).
0	LOOP	Internal loopback.When LOOP is set to 1, transmitted frames are looped back internal to the device and the transmit output signals are not asserted. The system clock is substituted for the FEC_TX_CLK when LOOP is set to 1. DRT must be set to zero when setting LOOP to 1.

23.3.4.10 Transmit Control Register (TCR)

TCR bit fields are shown in Figure 23-9 and described in Table 23-14. This register is read/write, and is written by the user to configure the transmit block. Bits [2:1] must only be modified when ECR[ETHER_EN] = 0 (that is, during initialization). This register is cleared at system reset.

Offset 0x00C4 (TCR) Access: Read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 23-10. Transmit Control Register (TCR)

Table 23-15. TCR Field Descriptions

Bits	Name	Description
31–5	—	Reserved read as 0
4	RFC_PAUSE	Receive frame control pause. This read-only status bit is set to 1 when a full-duplex flow control pause frame has been received and the transmitter is paused for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete. 0 Transmitter is not paused 1 Transmitter is paused after reception of full-duplex flow control pause frame
3	TFC_PAUSE	Transmit frame control pause. When this bit is set to 1, a pause frame is transmitted according to the following steps: 1)FEC stops transmission of data frames after the current transmission is complete. 2)The GRA interrupt in the EIR register is asserted. 3)With transmission of data frames stopped, the FEC transmits a MAC control pause frame. 4)The FEC clears the TFC_PAUSE bit and resume transmitting data frames. Note that the FEC can still transmit a MAC control pause frame when the transmitter is paused due to user assertion of GTS or reception of a pause frame. 0 No pause frame is transmitted 1 Pause frame is transmitted
2	FDEN	Full duplex enable. When FDEN is set to 1, frames are transmitted independent of carrier sense and collision inputs. This bit must only be modified when ETHER_EN is cleared. 0 Full duplex is not enabled 1 Full duplex is enabled

Table 23-15. TCR Field Descriptions (Continued)

Bits	Name	Description
1	HBC	Heartbeat control. When HBC is set to 1, the heartbeat check is performed after end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This bit must only be modified when ETHER_EN is cleared. 0 Heartbeat check is not performed after end of transmission 1 Heartbeat check is performed after end of transmission
0	GTS	Graceful transmit stop. When GTS is set to 1, the FEC stops transmission after any frame that is currently being transmitted is complete and the GRA interrupt in the EIR register is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission has completed, a “restart” can be accomplished by clearing the GTS bit. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS = 1, transmission stops after the collision. The frame is transmitted again after GTS is cleared. **Note:** There can be old frames in the transmit FIFO that is transmitted when GTS is reasserted. To avoid this, clear ECR[ETHER_EN] following the GRA interrupt. 0 Graceful transmit stop is not enabled 1 Graceful transmit stop is enabled.

23.3.4.11 Physical Address Low Register (PALR)

The PALR is written by the user, and contains the lower 32 bits (bytes 0,1,2,3) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is also used for bytes 0 through 3 of the 6-byte source address field when transmitting pause frames. This register is unaffected by reset and must be initialized by the user.

PALR bit fields are shown in Figure 23-11 and described in Table 23-16.

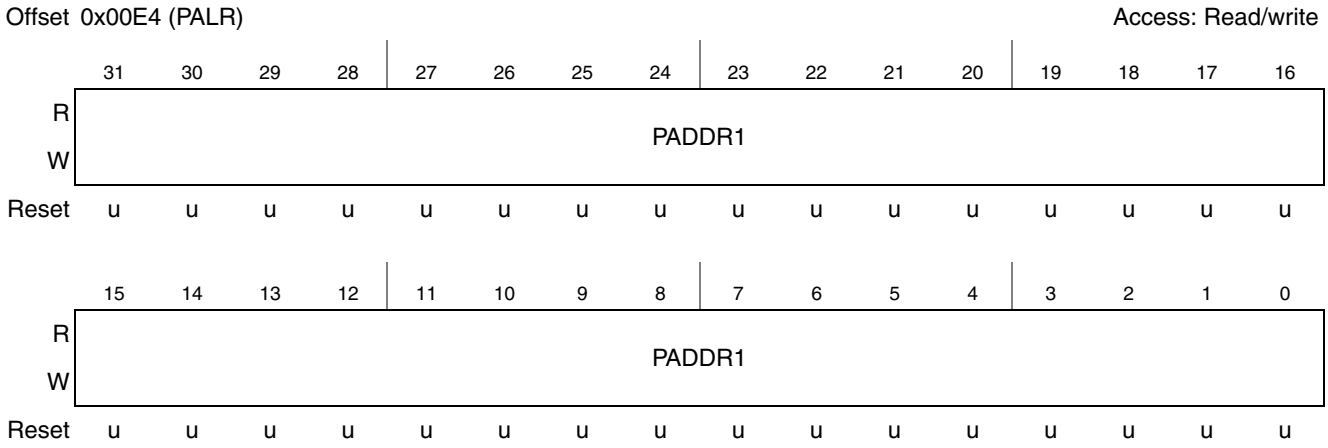

Figure 23-11. Physical Address Low Register (PALR)

Table 23-16. PALR Field Descriptions

Bits	Name	Description
31–0	PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8) and 3 (bits 7:0) of the 6-byte individual address to be used for exact match, and the source address field in pause frames.

23.3.4.12 Physical Address Upper Register (PAUR)

The PAUR is written by the user, and contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte source address field when transmitting pause frames. Bits 15:0 of PAUR contain a constant type field (0x8808) used for transmission of pause frames. This register is unaffected by reset, and bits 31:16 must be initialized by the user.

PAUR bit fields are shown in Figure 23-12 and described in Table 23-17.

Offset 0x00E8 (PAUR) Access: Mixed

15–0	TYPE	Type field in pause frames. This field has a constant value of 0x8808.

23.3.4.13 Opcode/Pause Duration Register (OPDR)

OPDR contains the 16-bit Opcode, and 16-bit pause duration fields used in transmission of a pause frame. The Opcode field is a constant value, 0x0001. When another node detects a pause frame, that node pauses transmission for the duration specified in the pause duration field. This register is not reset and must be initialized by the user.

OPDR bit fields are shown in Figure 23-13 and described in Table 23-18.

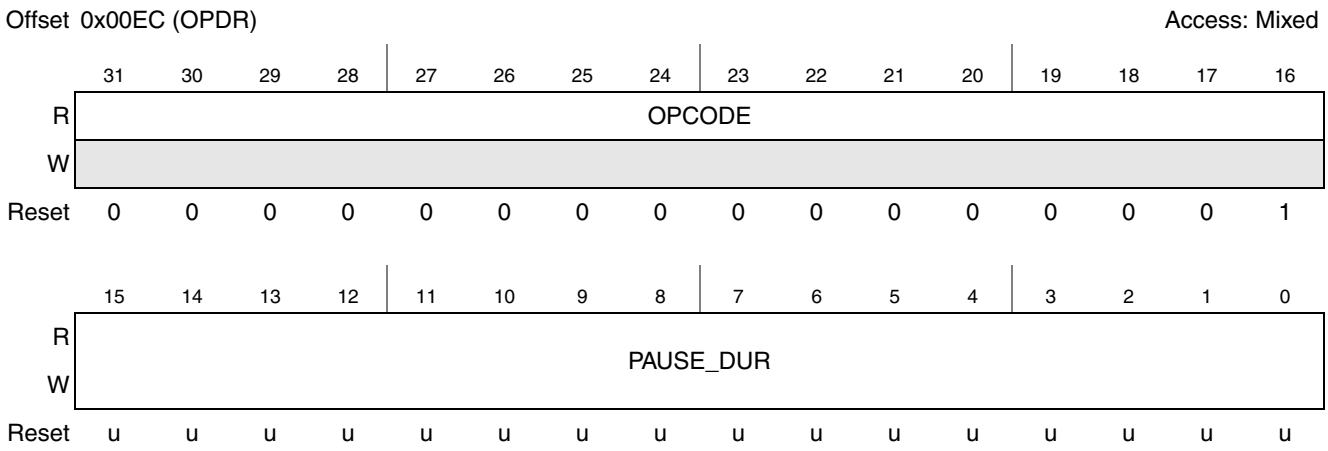

Figure 23-13. Opcode/Pause Duration Register (OPDR)

Table 23-18. OPD Field Descriptions

Bits	Name	Description
31–16	OPCODE	Opcode field used in pause frames. These bits are a constant, 0x0001.
15–0	PAUSE_DUR	Pause duration field used in pause frames.

23.3.4.14 Descriptor Individual Address Upper Register (IAUR)

IAUR bit fields are shown in Figure 23-14 and described in Table 23-19. The IAUR is written by the user, and contains the upper 32 bits of the 64-bit individual address hash table used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is unaffected by reset, and must be initialized by the user.

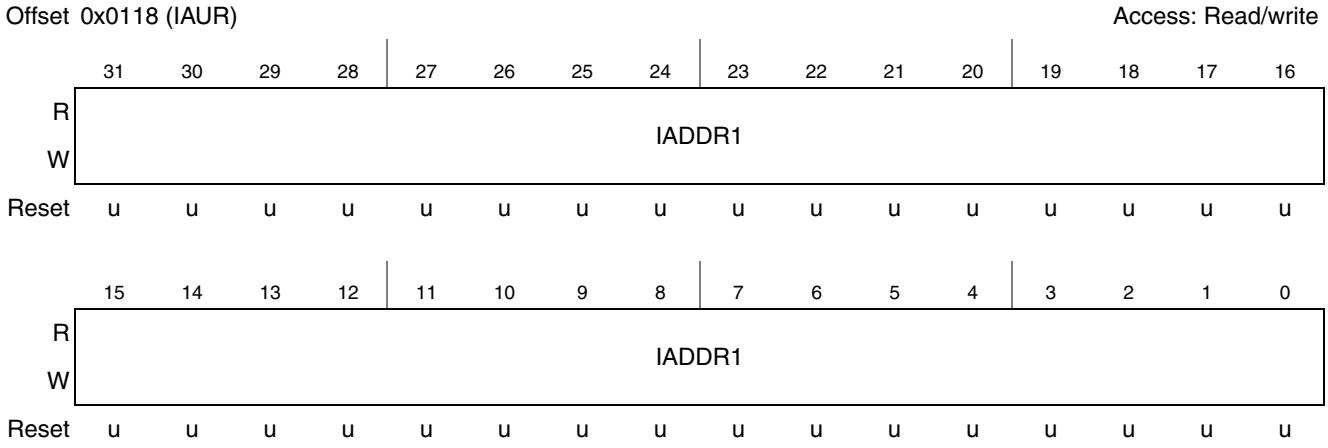

Figure 23-14. Descriptor Individual Upper Address Register (IAUR)

Bits	Name	Description
31–0	IADDR1	The upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

23.3.4.15 Descriptor Individual Address Lower Register (IALR)

The IALR is written by the user, and contains the lower 32 bits of the 64-bit individual address hash table used in the address recognition process to check for possible match with the DA field of receive frames with an individual DA. This register is unaffected by reset, and must be initialized by the user.

IAUR bit fields are shown in Figure 23-15 and described in Table 23-20.

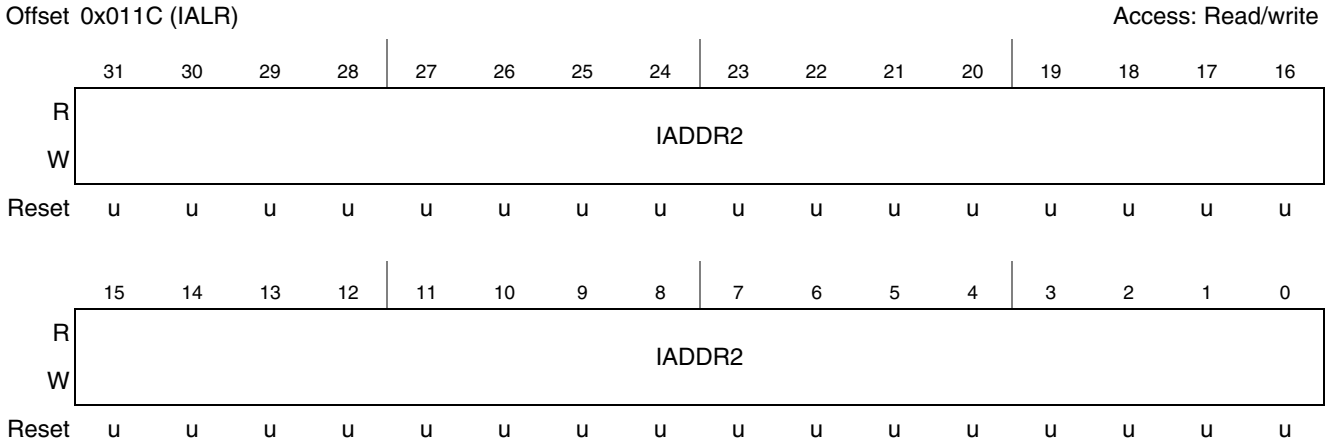

Figure 23-15. Descriptor Individual Address Lower Register (IALR)

31–0	GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

23.3.4.18 Transmit FIFO Watermark Register (TFWR)

The TFWR is programmed by the user to control the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows the user to minimize transmit latency (TFWR[1:0] = 0*n*) or allow for larger bus access latency (TFWR[1:0] = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. In some use cases the byte counts associated with the TFWR field need to be modified to match system requirements, such as the worst-case bus access latency by the transmit data DMA channel.

TFWR bit fields are shown in Figure 23-18 and described in Table 23-23.

Offset 0x0144 (TFWR) Access: Read/write

23.3.4.19 FIFO Receive Bound Register (FRBR)

The FRBR register can be read to determine the upper address bound of the FIFO RAM. Drivers can use this value, along with the FRSR to appropriately divide the available FIFO RAM between the transmit and receive data paths.

FRBR bit fields are shown in Figure 23-19 and described in Table 23-24.

Offset 0x014C (FRBR) Access: Read only

Bits	Name	Description
31–10	—	Reserved, read as 0 (except bit 10, which is read as 1).
9–2	R_BOUND	Read-only. Highest valid FIFO RAM address.
1–0	—	Reserved, read as 0.

23.3.4.20 FIFO Receive Start Register (FRSR)

FRSR is an 8-bit register programmed by the user to indicate the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

The default value of the receive FIFO starting address is 0x40. This is the value assigned by hardware at reset.

FRSR bit assignments are shown in Figure 23-20 and described in Table 23-25.

Offset 0x0150 (FRSR) Access: Read/write

1–0	—	Reserved, read as 0.

23.3.4.21 Receive Buffer Descriptor Ring Start Register (ERDSR)

The register is written by the user, and provides a pointer to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, 128-bit aligned pointers are recommended (that is, evenly divisible by 16).

ERDSR bit assignments are shown in Figure 23-21 and described in Table 23-26.

This register is unaffected by reset and must be initialized by the user prior to operation.

Offset 0x0180 (ERDSR) Access: Read/write

23.3.4.22 Transmit Buffer Descriptor Ring Start Register (ETDSR)

ETDSR bit assignments are shown in Figure 23-21 and described in Table 23-26. The register is written by the user, and provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, 128-bit aligned pointers are recommended (that is, evenly divisible by 16).

This register is unaffected by reset and must be initialized by the user prior to operation.

Bits	Name	Description
31–2	X_DES_START	Pointer to start of transmit buffer descriptor queue.
1–0	—	Reserved, read as 0

23.3.4.23 Maximum Receive Buffer Size Register (EMRBR)

The EMRBR, shown in Figure 23-23 and Table 23-28, is a user-programmable register which dictates the maximum size of all receive buffers. Note that because receive frames is truncated at 2k-1(2047) bytes, bits 31-11 are not used. The programmed value accounts for the fact that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. The EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low, and hence only bits 10-4 are actually used. To minimize bus utilization (descriptor fetches) it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR is unaffected by reset, and must be initialized by the user.

Offset 0x0188 (EMRBR) Access: Read/write

23.4 Functional Description

This section provides a detailed description of the functions of the FEC including:

- Network interface options
- Frame transmission and reception
- Full-duplex flow control
- Internal and external loopback

23.4.1 Network Interface Options

The FEC supports both an MII interface for 10/100 Mbps Ethernet, and a 7-wire serial interface for 10 Mbps Ethernet. The interface mode is selected by the RCR[MII_MODE] bit. In MII mode (RCR[MII_MODE] = 1), there are 18 signals defined by the IEEE 802.3 standard and supported by the FEC. These signals are shown in Table 23-29 below.

Table 23-29. MII Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Transmit clock	FEC_TX_CLK	In
Transmit enable	FEC_TX_EN	Out
Transmit data	FEC_TXD[3:0]	Out
Transmit error	FEC_TX_ER	Out

Table 23-29. MII Mode Signal Configuration (Continued)

Signal Description	FEC Signal Name	Direction
Collision	FEC_COL	In
Carrier sense	FEC_CRS	In
Receive clock	FEC_RX_CLK	In
Receive data valid	FEC_RX_DV	In
Receive data	FEC_RXD[3:0]	In
Receive error	FEC_RX_ER	In
Management data clock	FEC_MDC	Out
Management data input/output	FEC_MDIO	I/O

The 7-wire serial interface (RCR[MII_MODE] = 0) operates in what is generally referred to as AMD mode. 7-wire mode connections to the external transceiver are shown in Table 23-30.

Table 23-30. 7-Wire Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Transmit clock	FEC_TX_CLK	In
Transmit enable	FEC_TX_EN	Out
Transmit data	FEC_TXD[0]	Out
Collision	FEC_COL	In
Receive clock	FEC_RX_CLK	In
Receive data valid	FEC_RX_DV	In
Receive data	FEC_RXD[0]	In

23.4.2 FEC Frame Transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER_EN] is set to 1 and data appears in the transmit FIFO, the FEC is able to transmit onto the network.

When the transmit FIFO fills to the watermark (defined by the TFWR register), the FEC transmit logic asserts FEC_TX_EN and start transmitting the preamble (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller postpones transmission if the network is busy (that is, the carrier sense signal FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense remains inactive for 60 bit periods. If so, the transmission begins after waiting an additional 36 bit periods (96 bit periods after carrier sense originally became inactive). See Section 23.4.2.3, “Transmission Error Handling” for more details.

If a collision occurs during transmission of a frame in half-duplex mode, the Ethernet controller follows the specified backoff procedures (see Section 23.4.2.2, “Collision Handling”) and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit

frame, so that they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data has been transmitted, if the TC bit is set in the transmit frame control word then a 32-bit cyclic redundancy check (CRC) known as the frame check sequence (FCS) is appended. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Short frames are automatically padded by the transmit logic (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set to 1).

Both buffer (TXB) and frame (TXF) interrupts can be generated as determined by the settings in the EIMR.

The transmit error interrupts are HBERR, BABT, LATE_COL, COL_RETRY_LIM, and XFIFO_UN. If the transmit frame length exceeds MAX_FL bytes the BABT interrupt is asserted: however, the entire frame is transmitted (no truncation).

Transmission is paused by setting the graceful transmit stop (GTS) bit in the TCR register. When the TCR[GTS] is set to 1, the FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame either finishes or terminates with a collision. After the transmitter has stopped the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

The Ethernet controller transmits bytes LSB first.

23.4.2.1 Transmit Inter-Packet Gap (IPG) Time

The minimum inter-packet gap (IPG) time for back-to-back transmission is 96 bit periods. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96-bit–period IPG counter. Frame transmission begins 96 bit periods after carrier sense is negated if it stays negated for at least 60 bit periods. If carrier sense is asserted during the last 36 bit periods, it is ignored and a collision occurs.

23.4.2.2 Collision Handling

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit periods, transmitting a jam pattern consisting of 32 ones. If the collision occurs during the preamble sequence, the jam pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit periods, the retry process is initiated. The transmitter waits a random number of slot periods, where one slot period is 512 bit periods. If a collision occurs after 512 bit periods, then no retransmission is performed and the end of frame buffer is closed with a late collision (LC) error indication.

23.4.2.3 Transmission Error Handling

The Ethernet controller reports frame transmission error conditions using the FEC RxBDs, the EIR register, and the MIB block counters

There are four types of transmission errors:

- Transmitter underrun
- Retransmission attempts limit expired
- Late collision
- Heartbeat

The FEC's procedures for handling these errors are described in the following subsections.

23.4.2.3.1 Transmitter Underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error, then stops transmitting. All remaining buffers for that frame are then flushed and closed. The UN bit is set in the EIR and the UN interrupt is asserted (if enabled in the EIMR register). The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

23.4.2.3.2 Retransmission Attempts Limit Expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the RL bit is set in the EIR. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The "RL" interrupt is asserted if enabled in the EIMR register.

23.4.2.3.3 Late Collision

When a collision occurs after the slot time (512 bits starting at the preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the LC bit is set in the EIR register. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The LC interrupt is asserted if enabled in the EIMR register.

23.4.2.3.4 Heartbeat

Some transceivers have a self-test feature called "heartbeat" or "signal quality error." To signify a good self-test, the transceiver indicates a collision to the FEC within 4 microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver still seems to be functioning properly. This is called the heartbeat condition.

If the HBC bit is set in the TCR register and the heartbeat condition is not detected by the FEC after a frame transmission, then a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets the HB bit in the EIR register, and generates the HBERR interrupt if it is enabled.

23.4.3 FEC Frame Reception

The FEC receiver is designed to work with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking.

When the driver enables the FEC receiver by setting ECR[ETHER_EN] to 1, it immediately starts processing receive frames. When FEC_RX_DV asserts, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the frame is processed by the receiver. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit periods of RX_D0 following assertion of FEC_RX_DV are ignored. Following the first 16 bit periods the data sequence is checked for alternating 1/0s. If a 0b11 or 0b00 data sequence is detected during bit periods 17 to 21, the remainder of the frame is ignored. After bit period 21, the data sequence is monitored for a valid SFD (11). If a 0b00 is detected, the frame is rejected. When a 0b11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes can occur, but if a 0b00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame have been received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data has been received and if address recognition has not rejected the frame, the receive FIFO is signaled that the frame is accepted and can be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Thus no collision fragments are presented to the user except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV and TR status bits, and the frame length. See Section 23.4.3.3, “Reception Error Handling” for more details.

Receive Buffer (RXB) and Frame Interrupts (RXF) can be generated if enabled by the EIMR register. The only receive error interrupt is babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See Section 23.5.2.3, “Ethernet Receive Buffer Descriptor (RxBD)” for more details.

When the receive frame is complete, the FEC sets the L bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E bit. The Ethernet controller next generates a maskable interrupt (RXF bit in EIR, maskable by RXF bit in EIMR), indicating that a frame has been received and is in memory. The Ethernet controller then waits for a new frame.

The Ethernet controller receives serial data LSB first.

23.4.3.1 Receive Inter-Packet Gap (IPG) Time

The receiver receives back-to-back frames with a minimum spacing of at least 28 bit periods. If an inter-packet gap between receive frames is less than 28 bit periods, the second frame may be discarded by the receiver.

23.4.3.2 Ethernet Address Recognition

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 23-24 illustrates the address recognition decisions made by the receive block, while Figure 23-25 illustrates the decisions made by the microcontroller.

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the DA field.

If the DA is a broadcast address, and broadcast reject (RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in Figure 23-24. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 23-25.

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame. The hash algorithm is described in Section 23.4.3.2.1, “Hash Algorithm”.

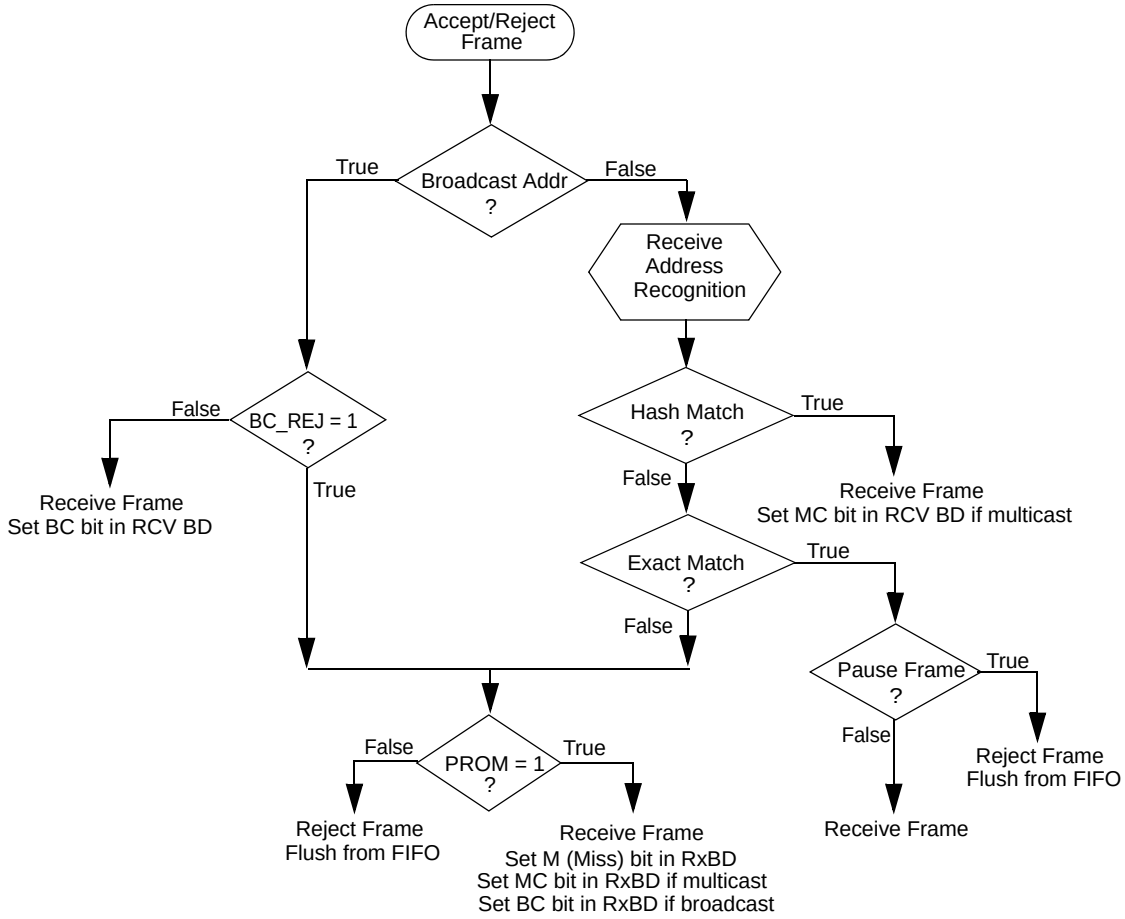
If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines that the received frame is a valid pause frame, then the frame is rejected. Note the receiver detects a pause frame with the DA field set to either the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that the user programs in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR (the hash algorithm is described in Section 23.4.3.2.1, “Hash Algorithm”). In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on pause frame detection, shown in Figure 23-24.

If neither a hash match (group or individual), nor an exact match occur, then if promiscuous mode is enabled (RCR[PROM] = 1), then the frame is accepted and the MISS bit in the receive buffer descriptor is set: otherwise, the frame is rejected.

Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, then the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.



NOTES:

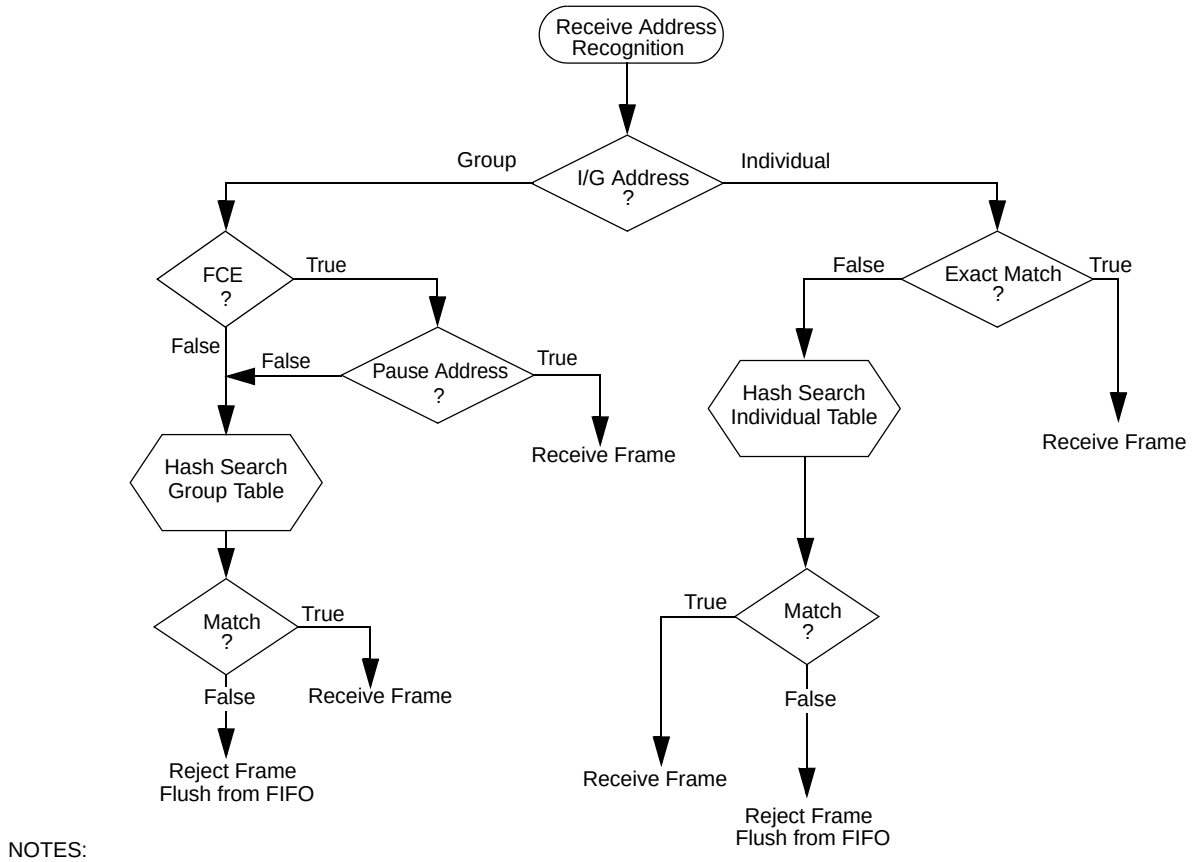
Figure 23-24. Ethernet Address Recognition—Receive Block Decisions



NOTES:
FCE - field in RCR register (Flow Control Enable)
I/G - Individual/Group bit in Destination Address (least significant bit in first byte received in MAC frame)

Figure 23-25. Ethernet Address Recognition—Microcode Decisions

23.4.3.2.1 Hash Algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, which are represented by 64 bits stored in GAUR, GALR (group address hash match) or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The MSB of the CRC result selects GAUR (MSB = 1) or GALR (MSB = 0). The least significant five bits of the hash result select the bit within the selected register. If the CRC generator selects a bit that is set in the hash table, the frame is accepted; otherwise, it is rejected. For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The hash table registers must be initialized by the user. The CRC32 polynomial to use in computing the hash is shown in Equation :

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1$$

Table 23-31 shows example destination addresses and corresponding hash values is included below for reference.

23.4.3.3 Reception Error Handling

The Ethernet controller reports frame reception error conditions using the FEC RxBDs, the EIR register, and the MIB block counters

There are five types of reception errors:

- Overrun
- Non-octet (dribbling bits)
- CRC
- Frame-length violation
- Truncation

These are described in the following subsections.

23.4.3.3.1 Overrun

If the receive block has data to put into the receive FIFO and the receive FIFO is full, the FEC sets the OV bit in the RxBD. All subsequent data in the frame is discarded, and subsequent frames can also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. This frame must be discarded by the driver.

23.4.3.3.2 Non-Octet (Dribbling Bits)

The Ethernet controller handles up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, then the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, then no error is reported.

23.4.3.3.3 CRC

When a CRC error occurs with no dribble bits, the FEC closes the buffer and sets the CR bit in the RxBD. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

23.4.3.3.4 Frame Length Violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and the LG bit in the end of frame RxBD is set. The frame is not truncated unless the frame length exceeds 2047 bytes).

23.4.3.3.5 Truncation

When the receive frame length exceeds 2047 bytes, the frame is truncated and the TR bit is set in the RxBD.

23.4.4 Full-Duplex Flow Control

Full-duplex flow control allows the user to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, FEC data frame transmission stops for a given pause duration.

To enable pause frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] asserted) and flow control enable (RCR[FCE]) must be asserted. The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in Table 23-32. In addition, the receive status associated with the frame indicates that the frame is valid.

Table 23-32. Pause Frame Field Specification

48-bit destination address	0x0180_C200_0001 or physical address
48-bit source address	Any
16-bit type	0x8808
16-bit opcode	0x0001
16-bit pause duration	0x0000–0xFFFF

Pause frame detection is performed by the receiver and microcontroller modules. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is asserted by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. Note that the pause timer makes use of the transmit backoff timer hardware, which is used for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments after every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is cleared allowing FEC data frame transmission to resume. Note that the receive flow control pause (TCR[RFC_PAUSE]) status bit is asserted while the transmitter is paused due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and the user must assert flow control pause (TCR[TFC_PAUSE]). On assertion of transmit flow control pause (TCR[TFC_PAUSE]), the transmitter asserts TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts. Following EIR[GRA] assertion, the pause frame is transmitted. On completion of pause frame transmission, flow control pause (TCR[TFC_PAUSE]) and TCR[GTS] are cleared internally.

The user must specify the desired pause duration in the OPD register.

Note that when the transmitter is paused due to receiver/microcontroller pause frame detection, transmit flow control pause (TCR[TFC_PAUSE]) still can be asserted and causes the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

23.4.5 Internal and External Loopback

Both internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Both internal and external loopback are configured using combinations of the LOOP and DRT bits in the RCR register and the FDEN bit in the TCR register.

For both internal and external loopback set FDEN = 1.

For internal loopback set RCR[LOOP] = 1 and RCR[DRT] = 0. FEC_TX_EN and FEC_TX_ER does not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the internal system clock is used by the transmit and receive blocks instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit and receive data being transferred to and from external memory via DMA. It can be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underrun and receive FIFO overflow.

For external loopback set RCR[LOOP] = 0, RCR[DRT] = 0 and configure the external transceiver for loopback.

23.5 Initialization/Application Information

23.5.1 Initialization Sequence

This section describes which registers are reset due to hardware reset, which are reset by the FEC RISC, and what locations the user must initialize prior to enabling the FEC.

23.5.1.1 Hardware Controlled Initialization

In the FEC, registers and control logic that generate interrupts are reset by hardware. A hardware reset negates output signals and resets general configuration bits.

Other registers are reset when the ECR[ETHER_EN] bit is cleared, as indicated in Table 23-33. ECR[ETHER_EN] is cleared by a hard reset or can be cleared by software to halt operation. By clearing ECR[ETHER_EN], the configuration control registers such as the TCR and RCR do not reset, but the entire data path resets.

Table 23-33. Effect on FEC of Clearing ECR[ETHER_EN]

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated

Table 23-33. Effect on FEC of Clearing ECR[ETHER_EN] (Continued)

Register/Machine	Reset Value
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

23.5.1.2 User Initialization (Prior to Asserting ECR[ETHER_EN])

The user must initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values depend on the particular application. The order of initializations is not important.

The FEC and FEC FIFO/DMA registers requiring initialization are defined in Table 23-34.

Table 23-34. Registers Requiring Initialization before Setting ECR[ETHER_EN]

Register	Location (FEC or FIFO/DMA)	Comments
EIMR	FEC	Requires initialization
EIR	FEC	Must be cleared by writing 0xFFFF_FFFF
TFWR	FEC	Optional
IALR / IAUR	FEC	—
GAUR / GALR	FEC	—
PALR / PAUR	FEC	—
OPD	FEC	Only needed for full-duplex flow control
RCR	FEC	—
TCR	FEC	—
MSCR	FEC	Optional
MIB counters	FEC	Must be cleared
FRSR	FIFO/DMA	Initialization is optional
EMRBR	FIFO/DMA	—
ERDSR	FIFO/DMA	—
ETDSR	FIFO/DMA	—
Transmit Descriptor ring	FIFO/DMA	Must be emptied
Receive Descriptor ring	FIFO/DMA	Must be emptied

23.5.1.3 Microcontroller Initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, the hardware is ready for operation.

The microcontroller initialization sequence follows:

1. Initialize BackOff Random Number Seed
2. Activate Receiver
3. Activate Transmitter

4. Clear Transmit FIFO
5. Clear Receive FIFO
6. Initialize Transmit Ring Pointer
7. Initialize Receive Ring Pointer
8. Initialize FIFO Count Register

23.5.1.4 User Initialization (after asserting ECR[ETHER_EN])

After asserting ECR[ETHER_EN], the user can set up the buffer/frame descriptors and write to the TDAR and RDAR. See Section 23.5.2, “Buffer Descriptors” for more details.

23.5.2 Buffer Descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors (BD). It is followed by a detailed description of the receive and transmit descriptor fields.

23.5.2.1 Driver/DMA Operation with Buffer Descriptors

The data for the FEC frames must reside in memory external to the FEC. The data for a frame is placed in one or more buffers. Associated with each buffer is a buffer descriptor (BD) which contains a starting address (pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read in by the FEC DMA engine.

Software “produces” buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit “produces” the buffer. Software writing to either the TDAR or RDAR tells the FEC that a buffer has been placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and “consumes” the buffers after they have been produced. After the data DMA is complete and the buffer descriptor status bits have been written by the DMA engine, the RxBD[E] or TxBD[R] bit is cleared by hardware to signal the buffer has been “consumed.” Software can poll the BDs to detect when the buffers have been consumed or can rely on the buffer/frame interrupts. These buffers can then be processed by the driver and returned to the free list.

The ECR[ETHER_EN] signal operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is cleared the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before the ECR[ETHER_EN] bit is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The last buffer descriptor in each ring is defined by the Wrap (W) bit. When set, W indicates that the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively.

NOTE

Buffer descriptor rings must start on a 128-bit boundary.

23.5.2.2 Ethernet Transmit Buffer Descriptor (TxBD)

Figure 23-26 shows the transmit buffer descriptor format. Table 23-35 describes the TxBD fields.

Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block. See Section 23.3.3, “Message Information Block (MIB) Counters Memory Map,” for more details.

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x0000	R	TO1	W	TO2	L	TC	ABC									
	Data Length															
0x0004	Tx Data Buffer Pointer A[31:16]															
	Tx Data Buffer Pointer A[15:0]															

Figure 23-26. Transmit Buffer Descriptor (TxBD)

Table 23-35. Transmit Buffer Descriptor Field Definitions

Offset	Field	Description
0x0000	31 R	Ready. Written by the FEC and the user. 0 The data buffer associated with this BD is not ready for transmission. The user is free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, which has been prepared for transmission by the user, has not been transmitted or is currently being transmitted. No fields of this BD can be written by the user after this bit is set.
	30 TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware, nor does its value affect hardware.
	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
	28 TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
	27 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame. 1 The buffer is the last in the transmit frame.
	26 TC	Tx CRC. Written by user (only valid if L = 1). 0 End transmission immediately after the last data byte. 1 Transmit the CRC sequence after the last data byte.
	25 ABC	Append bad CRC. Written by user (only valid if L = 1). 0 No effect 1 Transmit the CRC sequence inverted after the last data byte (regardless of TC value).
	24–16	Reserved.
	15–0 Data Length	Data Length, written by user. Data length is the number of octets the FEC transmits from this BD's data buffer. It is never modified by the FEC. Bits [10:0] are used by the DMA engine, bits[15:11] are ignored.
0x0004	31–0 A	Tx data buffer pointer[1]

[1] The transmit buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

23.5.2.2.1 Driver/DMA Operation with Transmit Buffer Descriptors

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. After the software driver has set up the buffers for a frame, it sets up the corresponding BDs. In the TxBD the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword, and the buffer pointer in the second longword.The last step in setting up the BDs for a transmit frame is to set the R bit in the first BD for the frame. The driver follows that with a write to TDAR which triggers the FEC to poll the next BD in the ring.

The Ethernet controller confirms transmission by clearing the ready bit (R bit) when DMA of the buffer is complete.

Transmit Frame in Multiple Buffers

Typically a transmit frame is divided between multiple buffers. For example, it is possible to have an application payload in one buffer, TCP header in a 2nd buffer, IP header in a 3rd buffer, and Ethernet/IEEE 802.3 header in a 4th buffer. The FEC does not prepend the Ethernet header (Destination Address, Source Address, Length/Type field(s)), so this must be provided by the driver in one of the transmit buffers. The FEC can append the Ethernet CRC to the frame. Whether the CRC is appended by the FEC or by the driver is determined by the TC bit in the transmit BD, which must be set by the driver.

The driver (TxBD software producer) sets up Tx BDs in such a way that a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, first the BD's are initialized with pointer, length and control (W, L, TC, ABC) and then the TxBD[R] bits are set to 1 in *reverse order* (3rd, 2nd, 1st BD) to insure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the 2nd was made available, potentially causing a transmit FIFO underrun.

In the FEC, the DMA is notified by the driver that new transmit frame(s) are available by writing to the TDAR register. When this register is written to (data value is not significant) the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers, until a transmit BD is encountered with the R bit = 0. At this point the FEC polls this BD one more time. If the R bit = 0 the second time, then the RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

23.5.2.3 Ethernet Receive Buffer Descriptor (RxBD)

Figure 23-27 shows the receive buffer descriptor format. Table 23-36 describes the RxBD fields.

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0000	E	RO1	W	RO2	L			M	B	MC	LG	NO		CR	OV	TR
	Data Length															
0x0004	Rx Data Buffer Pointer A[31:16]															
	Rx Data Buffer Pointer A[15:0]															

Figure 23-27. Receive Buffer Descriptor (RxBD)

Table 23-36. Receive Buffer Descriptor Field Definitions

Offset	Field	Description
0x0000	31 E	Empty. Written by the FEC (=0) and user (=1). 0 The data buffer associated with this BD has been filled with received data, or data reception has been aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
0x0000	30 RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ERDSR.
0x0000	28 RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	27 L	Last in frame. Written by the FEC. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
0x0000	26–25	Reserved.
0x0000	24 M	Miss. Written by the FEC. This bit is set by the FEC for frames that were accepted in promiscuous mode, but were flagged as a “miss” by the internal address recognition. Thus, while in promiscuous mode, the user can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
0x0000	23 BC	is set if the DA is broadcast (FF:FF:FF:FF:FF:FF).
0x0000	22 MC	is set if the DA is multicast and not BC.
0x0000	21 LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
0x0000	20 NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set the CR bit is not set.
0x0000	19	Reserved
0x0000	18 CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
0x0000	17 OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and is zero. This bit is valid only if the L-bit is set.
0x0000	16 TR	is set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set the frame is discarded and the other error bits ignored as they can be incorrect.

Table 23-36. Receive Buffer Descriptor Field Definitions (Continued)

Offset	Field	Description
0x0000	15–0 Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L = 0 (the value is equal to EMRBR), or the length of the frame including CRC if L = 1. It is written by the FEC once as the BD is closed.
0x0004	31–0	RX data buffer pointer[1]

[1] The receive buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

23.5.2.3.1 Driver/DMA Operation with Receive Buffer Descriptors

Unlike the transmit case, the length of the receive frame is unknown by the driver ahead of time. Therefore the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) sets up some number of "empty" buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L (1 indicates last buffer in frame) bit, the frame status bits (if L = 1) and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end of frame buffers, the L=1 bit is set in the receive BD, and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame is discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not just the length of the last buffer.

For simplicity the driver can assign the default receive buffer length to be large enough to contain an entire frame, keeping in mind that a malfunction on the network or out-of-specification implementation could result in giant frames. Frames of 2 Kbytes (2048 bytes) or larger are truncated by the FEC at 2047 bytes, so software never sees a receive frame larger than 2047 bytes.

As in the transmit case, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received the FEC fills receive buffers and update the associated BDs, then reads the next BD in the receive descriptor ring. If the FEC reads a receive BD and finds the E bit is cleared, it polls this BD once more. If E is still cleared, then the FEC stops reading receive BDs until the driver writes to RDAR.

NOTE

Whenever the software driver sets an E bit in one or more receive descriptors, the driver follows that with a write to RDAR.

Chapter 24
Controller Area Network (FlexCAN)

The FlexCAN module is a communication controller that implements the CAN protocol according to the CAN 2.0B protocol specification. The CAN protocol was designed primarily (but not solely) to meet requirements suitable for a serial data bus in vehicle applications, including: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and sufficient bandwidth.

References: This document assumes an understanding of the following references:

- Controller Area Network—CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
- ISO International Standard—ISO 11898 First Edition 1993 Road Vehicles—Interchange of Digital Information – Controller Area Network (CAN) for high-speed Communication.

24.1 Introduction

The FlexCAN module is a full implementation of the CAN protocol specification (version 2.0B), which supports both standard and extended message frames.

Figure 24-1 is a block diagram showing the main submodules of the FlexCAN.

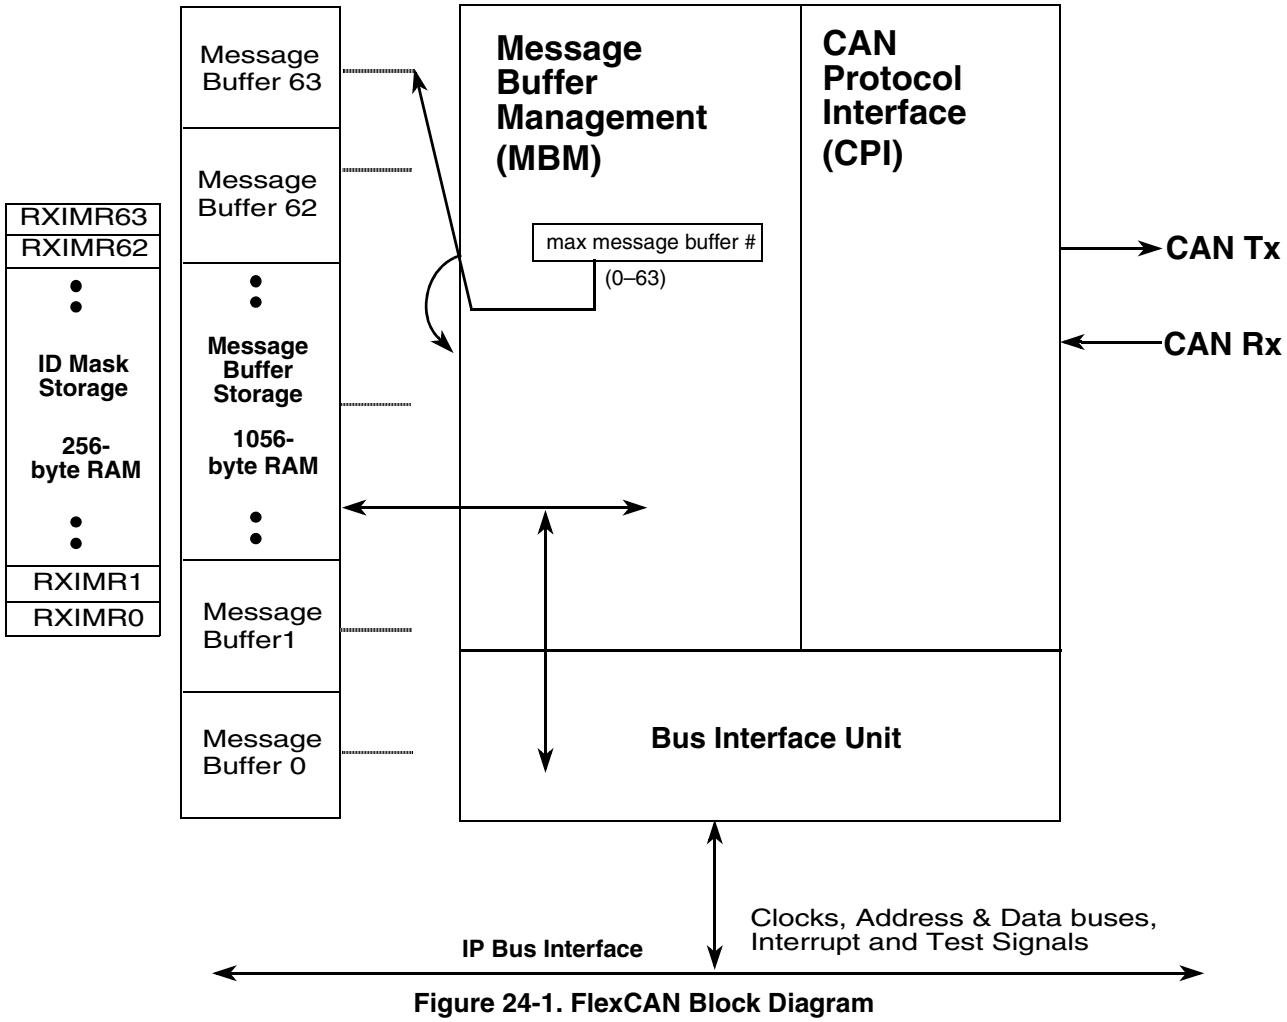

Figure 24-1. FlexCAN Block Diagram

The FlexCAN includes the following submodules:

- An embedded RAM for storing message buffers (64 message buffers are supported)
- An embedded RAM for storing individual Rx mask registers
- A CAN protocol interface (CPI) submodule that manages the serial communication on the CAN bus: requesting RAM access for receiving and transmitting message frames, validating received messages and performing error handling.
- A message buffer management (MBM) submodule which handles message buffer selection for reception and transmission, taking care of arbitration and ID-matching algorithms.
- A bus interface unit (BIU) submodule which controls the access to and from the internal interface bus, in order to establish connection to the ARM and to other blocks. Clocks, address and data buses, interrupt outputs, and test signals are accessed through the bus interface unit.

24.1.1 FlexCAN Module Features

The FlexCAN module includes the following features:

- Full implementation of the CAN protocol specification, version 2.0B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mbyte/sec
  - Content-related addressing
- Flexible message buffers of zero to eight bytes data length
- Each message buffer configurable as Rx or Tx, all supporting standard and extended messages
- Individual Rx mask registers per message buffer
- Includes 1056 bytes of RAM used for message buffer storage (64 message buffers)
- Includes 256 bytes of RAM used for individual Rx mask registers (64 mask registers, one for each message buffer)
- Full-featured Rx FIFO with storage capacity for 6 frames and internal pointer handling
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 8 extended, 16 standard, or 32 partial (8-bit) IDs, with individual masking capability
- Selectable backwards compatibility with previous FlexCAN version
- Selectable clock source to the CAN protocol interface (bus clock or crystal oscillator)
- Unused message buffer and Rx mask register space can be used as general-purpose RAM space
- Listen-only mode capability
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independent of the transmission medium (an external transceiver is assumed)
- Short latency due to an arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity

24.1.2 Modes of Operation

The FlexCAN module has four functional modes: normal mode (user and supervisor), freeze mode, listen-only mode and loopback mode. There are also three low-power modes: disable mode, doze mode and stop mode. These modes are described as follows:

- Normal mode (user or supervisor)—The module receives and/or transmits message frames, errors are handled normally, and all the CAN protocol functions are enabled. User and supervisor modes differ in the access to some restricted control registers.

- Freeze mode—Enabled when the FRZ bit in the module configuration register (MCR) is set to 1. If enabled, freeze mode is entered when the HALT bit in the MCR is set, or when debug mode is requested at the core level. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Section 24.4.9.1, “Freeze Mode,” for more information.
- Listen-only mode—The module enters this mode when the LOM bit in the control register is set to 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN error passive model (see CAN protocol specification). Only messages acknowledged by another CAN station are received. If FlexCAN detects a message that has not been acknowledged, it flags a BIT0 error (without changing the REC), as if it were trying to acknowledge the message.
- Loopback mode—The module enters this mode when the LPB bit in the control register is set to 1. In this mode, FlexCAN performs an internal loopback that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input signal is ignored and the Tx CAN output goes to the recessive state (logic ‘1’). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.
- Module disable mode—This low-power mode is entered when the MDIS bit in the MCR is set to 1. When disabled, the module shuts down the clocks to the CAN protocol interface and message buffer management submodules. This mode is exited by clearing the MDIS bit in the MCR. See Section 24.4.9.2, “Module Disable Mode,” for more information.
- Doze mode—This low-power mode is entered when the DOZE bit in the MCR is set to 1 and doze mode is requested at the core level. When in doze mode, the module shuts down the clocks to the CAN protocol interface and the message buffer management submodules. This mode is exited when the DOZE bit in the MCR is cleared, when the core is removed from doze mode, or when activity is detected on the CAN bus and the self wake-up mechanism is enabled. See Section 24.4.9.3, “Doze Mode” for more information.
- Stop mode—This low-power mode is entered when stop mode is requested at the core level. When in stop mode, the module puts itself in an inactive state and then informs the ARM that the clocks can be shut down globally. This mode is exited when the stop-mode request is removed or when activity is detected on the CAN bus and the self wake-up mechanism is enabled. See Section 24.4.9.4, “Stop Mode,” for more information.

24.2 External Signal Description

24.2.1 Overview

The FlexCAN module has two I/O signals, which are summarized in Table 24-1 and described in more detail in the following subsections.

Table 24-1. FlexCAN External Signals

Signal Name	Direction	Description
CAN Rx	Input	CAN receive signal
CAN Tx	Output	CAN transmit signal

24.2.2 CAN Rx Signal

This is the receive signal from the CAN bus transceiver. The dominant state is represented by logic level 0. The recessive state is represented by logic level 1.

24.2.3 CAN Tx Signal

This is the transmit signal to the CAN bus transceiver. The dominant state is represented by logic level 0. The recessive state is represented by logic level 1.

24.3 Memory Map and Register Definition

This section includes the module memory map, and detailed descriptions of all registers and buffers. For the base address of a particular module instantiation, see the system memory map.

The address space occupied by FlexCAN has 96 bytes for registers starting at the module base address: followed by message buffer storage space in embedded RAM starting at offset 0x0060; and an extra ID mask storage space in a separate embedded RAM starting at offset 0x0880.

24.3.1 Memory Map

Table 24-2 shows the module memory map.

Access type can be supervisor (S) or unrestricted (U). Most registers can be configured to have either supervisor or unrestricted access by programming the SUPV bit in the MCR: these registers are identified as S/U in the Access column of Table 24-2.

The Rx global mask (RXGMASK), Rx buffers 14 mask and 15 mask (RX14MASK and RX15MASK) registers are provided for backwards compatibility, and are not used when the BCC bit in the MCR is set to 1.

The address offsets 0x0060–0x047F (1056 bytes) and 0x0880–0x097F (256 bytes) are occupied by two separate embedded memories. These two ranges are completely occupied by RAM.

Table 24-2. FlexCAN Module Memory Map

Address Offset (Register/Buffer Abbreviation)	Register/Buffer	Access	Affected by Hard Reset	Affected by Soft Reset	Section/Page
0x0000 (MCR)	Module configuration	S R/W	Yes	Yes	24.3.2.1/24-7
0x0004 (CTRL)	Control register	S/U R/W	Yes	No	24.3.2.2/24-10

24.3.2 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 24-2 and Table 24-3 explain conventions used in register diagrams and tables.

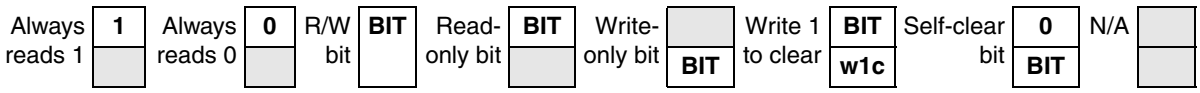

Figure 24-2. Key to Register Fields

Table 24-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	

Table 24-3. Register Conventions (Continued)

Convention	Description
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that can be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

24.3.2.1 Module Configuration Register (MCR)

The MCR defines global system configurations such as the module operation mode (for example, low-power mode) and maximum message buffer configuration. The MAXMB field must only be changed while the module is in freeze mode: all other fields in this register can be accessed at any time.

Offset 0x0000 (MCR) Access: Supervisor read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 24-3. Module Configuration Register (MCR)

Table 24-4. Module Configuration Register Description

Field	Description
31 MDIS	This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN shuts down the clocks to the CAN protocol interface and message buffer management submodules. This is the only bit in the MCR not affected by soft reset. See Section 24.4.9.2, “Module Disable Mode,” for more information. 0 Enable the FlexCAN module 1 Disable the FlexCAN module
30 FRZ	The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR is set or when debug mode is requested at core level. When FRZ is set to 1, FlexCAN is enabled to enter freeze mode. Clearing this bit field causes FlexCAN to exit from freeze mode. 0 Not enabled to enter freeze mode 1 Enabled to enter freeze mode
29 FEN	This bit controls whether the FIFO feature is enabled or not. When FEN is set to 1, message buffers 0 to 7 cannot be used for normal reception and transmission because the corresponding memory region (0x0080-0x00FF) is used by the FIFO engine. See Section 24.3.3.2, “Rx FIFO Description” and Section 24.4.7, “Rx FIFO” for more information. 0 FIFO not enabled 1 FIFO enabled
28 HALT	Setting this bit to 1 puts the FlexCAN module into freeze mode. The ARM clears it after initializing the message buffers and control register. No reception or transmission is performed by FlexCAN before this bit is cleared. While in freeze mode, the ARM has write access to the error counter register, that is otherwise read-only. freeze mode cannot be entered while FlexCAN is in any of the low-power modes. See Section 24.4.9.1, “Freeze Mode” for more information. 0 No freeze-mode request. 1 Enters freeze mode if the FRZ bit is set to 1.
27 NOT_RDY	This read-only bit indicates that FlexCAN is either in disable mode, doze mode, stop mode or freeze mode. It is cleared after FlexCAN has exited these modes. 0 FlexCAN module is either in normal mode, listen-only mode or loopback mode 1 FlexCAN module is either in disable mode, doze mode, stop mode or freeze mode
26 WAK_MSK	This bit enables the wake up interrupt generation. 0 Wake-up interrupt is disabled 1 Wake-up interrupt is enabled
25 SOFT_RST	When this bit is set to 1, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER, ECR, ESR, IMASK1, IMASK2, IFLAG1, IFLAG2. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: • CTRL • RXIMR0–RXIMR63 • RXGMASK, RX14MASK, RX15MASK • All message buffers The SOFT_RST bit can be set to1 directly by the ARM writing to the MCR, but it is also set to 1 when a global soft reset is requested at the core level. Since soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it can take some time to fully propagate its effect. The SOFT_RST bit remains set while reset is pending, and is automatically cleared when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in any of the low-power modes. The module must be first removed from low-power mode, and then soft reset can be applied. 0 No reset request 1 Resets the registers marked as “affected by soft reset” in Table 24-2

Table 24-4. Module Configuration Register Description (Continued)

Field	Description
24 FRZ_ACK	This read-only bit indicates that FlexCAN is in freeze mode and its prescaler is stopped. The freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZ_ACK bit to know when FlexCAN has actually entered freeze mode. If freeze mode request is negated, then this bit is cleared after the FlexCAN prescaler is running again. If freeze mode is requested while FlexCAN is in any of the low-power modes, then the FRZ_ACK bit is only set when the low-power mode is exited. See Section 24.4.9.1, “Freeze Mode” for more information. 0 FlexCAN not in freeze mode, prescaler running 1 FlexCAN in freeze mode, prescaler stopped
23 SUPV	This bit configures some of the FlexCAN registers to be either in supervisor or unrestricted memory space. The registers affected by this bit are marked as S/U in the access type column of Table 24-2. Reset value of this bit is ‘1’, so the affected registers start with supervisor access restrictions. 0 Affected registers are in unrestricted memory space 1 Affected registers are in supervisor memory space. Any access without supervisor permission behaves as though the access was done to an unimplemented register location
22 SLF_WAK	This bit enables the self wake-up feature when FlexCAN is in doze mode or stop mode. If this bit is set to 1 before FlexCAN enters doze mode or stop mode, then FlexCAN looks for a recessive-to-dominant transition on the bus during these modes. If a recessive-to-dominant transition is detected during doze mode, FlexCAN resumes its clocks and, if enabled to do so, generates a wake-up interrupt to the ARM. If a recessive-to-dominant transition is detected during stop mode, then FlexCAN generates, if enabled to do so, a wake-up interrupt to the ARM so that it can resume the clocks globally. This bit cannot be written while the module is in doze mode or stop mode. 0 FlexCAN self wake-up feature is disabled 1 FlexCAN self wake-up feature is enabled
21 WRN_EN	When set to 1, this bit enables the generation of the TWRN_INT and RWRN_INT flags in the error and status register. If WRN_EN is cleared, the TWRN_INT and RWRN_INT flags are always zero, independent of the values of the error counters, and no warning interrupt is ever generated. 0 TWRN_INT and RWRN_INT bits are zero, independent of the values in the error counters. 1 TWRN_INT and RWRN_INT bits are set when the respective error counter transition from <96 to ≥ 96.
20 LPM_ACK	This read-only bit indicates that FlexCAN is either in disable mode, doze mode or stop mode. Either of these low-power modes cannot be entered until all current transmission or reception processes have finished, so the ARM can poll the LPM_ACK bit to know when FlexCAN has actually entered low-power mode. See Section 24.4.9.2, “Module Disable Mode,” Section 24.4.9.3, “Doze Mode,” and Section 24.4.9.4, “Stop Mode,” for more information. 0 FlexCAN not in any of the low-power modes 1 FlexCAN is either in disable mode, doze mode or stop mode
19 WAK_SRC	This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wake-up. See Section 24.4.9.3, “Doze Mode,” and Section 24.4.9.4, “Stop Mode,” for more information. 0 FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus. 1 FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus
18 DOZE	This bit defines whether FlexCAN is allowed to enter low-power mode when doze mode is requested at the core level. This bit is automatically reset when FlexCAN wakes up from doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0 FlexCAN is not enabled to enter low-power mode when doze mode is requested 1 FlexCAN is enabled to enter low-power mode when doze mode is requested
17 SRX_DIS	This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is set to 1, frames transmitted by the module are not stored in any message buffer, regardless if the message buffer is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal is generated due to the frame reception. 0 Self reception enabled 1 Self reception disabled

Table 24-4. Module Configuration Register Description (Continued)

Field	Description
16 BCC	This bit is provided to support backwards compatibility with previous FlexCAN versions. When this bit is cleared, the following configuration is applied: • Individual Rx ID masking is disabled (for cores supporting this feature). Instead of individual ID masking per message buffer, FlexCAN uses the legacy masking scheme with RXGMASK, RX14MASK and RX15MASK. • The reception queue feature is disabled. Upon receiving a message, if the first message buffer with a matching ID that is found is still occupied by a previous unread message, FlexCAN does not look for another matching message buffer. It overrides this message buffer with the new message and set the CODE field to '0110' (OVERRUN). Upon reset this bit is cleared, allowing legacy software to work without modification. 0 Individual Rx masking and queue feature are disabled. 1 Individual Rx masking and queue feature are enabled.
15–14	Reserved
13 LPRIO_EN	This bit is provided for backwards compatibility reasons. It controls whether the local priority feature is enabled or not. It is used to extend the ID used during the arbitration process. With this extended ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11 bits for standard frames and 29 bits for extended frames. 0 Local priority disabled 1 Local priority enabled
12 AEN	This bit is supplied for backwards compatibility reasons. When set to 1, it enables the Tx abort feature. This feature guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. 0 Abort disabled 1 Abort enabled
11–10	Reserved
9–8 IDAM	This 2-bit field identifies the format of the elements of the Rx FIFO filter table, as shown below. All elements of the table are configured at the same time by this field (they are all the same format). See Section 24.3.3.2, "Rx FIFO Description." 00 Format A One full ID (standard or extended) per filter element. 01 Format B Two full standard IDs or two partial 14-bit extended IDs per filter element 10 Format C Four partial 8-bit IDs (standard or extended) per filter element. 11 Format D All frames rejected.
7–6	Reserved
5–0 MAXMB	This 6-bit field defines the maximum number of message buffers that take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to 16 message buffer configuration. Change this field only while the module is in freeze mode. The maximum number of message buffers in use is equal to MAXMB + 1. MAXMB must be programmed with a value smaller or equal to the number of available message buffers, otherwise, FlexCAN does not transmit or receive frames.

24.3.2.2 Control Register (CTRL)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, loopback mode, listen-only mode, bus-off recovery behavior and interrupt enabling (bus-off, error, warning). It also determines the division factor for the clock prescaler. Most of the fields in this register can only be changed while the module is in disable mode or in freeze mode. Exceptions are the BOFF_MSK, ERR_MSK, TWRN_MSK, RWRN_MSK and BOFF_REC bits, that can be accessed at any time.

Offset 0x0004 (CTRL) Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 24-4. Control Register (CTRL)

Table 24-5. Control Register Description

Field	Description
31–24 PRESDIV	This 8-bit field defines the ratio between the CPI clock frequency and the serial clock (SCLK) frequency. The SCLK period defines the time quantum of the CAN protocol. For the reset value, the SCLK frequency is equal to the CPI clock frequency. The maximum value of this register is 0xFF, that gives a minimum SCLK frequency equal to the CPI clock frequency divided by 256. For more information see Section 24.4.8.4, “Protocol Timing”. SCLK frequency = CPI clock frequency / (PRESDIV + 1)
23–22 RJW	This 2-bit field defines the maximum number of time quanta[1] that a bit time can be changed by one re-synchronization. The valid programmable values are 0–3. Resync Jump Width = RJW + 1.
21–19 PSEG1	This 3-bit field defines the length of phase buffer segment 1 in the bit time. The valid programmable values are 0–7. Phase Buffer Segment 1 = (PSEG1 + 1) x Time-Quanta.
18–16 PSEG2	This 3-bit field defines the length of phase buffer segment 2 in the bit time. The valid programmable values are 1–7. Phase Buffer Segment 2 = (PSEG2 + 1) x Time-Quanta.
15 BOFF_MSK	This bit provides a mask for the bus-off interrupt. 0 Bus-off interrupt disabled 1 Bus-off interrupt enabled
14 ERR_MSK	This bit provides a mask for the error interrupt. 0 Error interrupt disabled 1 Error interrupt enabled
13 CLK_SRC	This bit selects the clock source to the CAN protocol interface (CPI) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the SCLK (SCLK). In order to guarantee reliable operation, this bit must only be changed while the module is in disable mode. See Section 24.4.8.4, “Protocol Timing,” for more information. 0 The CAN engine clock source is the oscillator clock (24.576 MHz) 1 The CAN engine clock source is the bus clock (66.5 MHz)

Table 24-5. Control Register Description (Continued)

Field	Description
12 LPB	This bit configures FlexCAN to operate in loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input signal is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. 0 Loopback disabled 1 Loopback enabled
11 TWRN_MSK	This bit provides a mask for the Tx warning interrupt associated with the TWRN_INT flag in the error and status register. This bit has no effect if the WRN_EN bit in the MCR is cleared and it is read as zero when WRN_EN is cleared. 0 Tx warning interrupt disabled 1 Tx warning interrupt enabled
10 RWRN_MSK	This bit provides a mask for the Rx warning interrupt associated with the RWRN_INT flag in the error and status register. This bit has no effect if the WRN_EN bit in the MCR is cleared and it is read as zero when WRN_EN is cleared. 0 Rx warning interrupt disabled 1 Rx warning interrupt enabled
9–8	Reserved
7 SMP	This bit defines the sampling mode of CAN bits at the Rx input. 0 Just one sample is used to determine the bit value 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples, a majority rule is used
6 BOFF_REC	This bit defines how FlexCAN recovers from the bus-off state. If this bit is cleared, automatic recovering from the bus-off state occurs according to the CAN Specification 2.0B. If the bit is set to 1, automatic recovering from bus-off is disabled and the module remains in the bus-off state until the bit is cleared by the user. If the bit is cleared before 128 sequences of 11 recessive bits are detected on the CAN bus, then bus-off recovery happens as if the BOFF_REC bit had never been set to 1. If the bit is cleared after 128 sequences of 11 recessive bits have occurred, then FlexCAN re-synchronizes to the bus by waiting for 11 recessive bits before joining the bus. After it is cleared, the BOFF_REC bit can be set to 1 during bus-off, but it is only effective the next time the module enters bus-off. If BOFF_REC was cleared when the module entered bus-off, setting it to 1 during bus-off is not effective for the current bus-off recovery. 0 Automatic recovering from the bus-off state enabled, according to CAN Specification 2.0 part B 1 Automatic recovering from the bus-off state disabled
5 TSYN	This bit enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message (for example, global network time). If the FEN bit in the MCR is set (FIFO enabled), message buffer 8 is used for timer synchronization instead of message buffer 0. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
4 LBUF	This bit defines the ordering mechanism for message buffer transmission. When set to 1, the LPRIO_EN bit does not affect the priority arbitration. 0 Buffer with highest priority is transmitted first 1 Lowest number buffer is transmitted first

Table 24-5. Control Register Description (Continued)

Field	Description
3 LOM	This bit configures FlexCAN to operate in listen-only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN error passive mode [Ref. 1]. Only messages acknowledged by another CAN station are received. If FlexCAN detects a message that has not been acknowledged, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message. 0 Listen-only mode is deactivated 1 FlexCAN module operates in listen-only mode
2–0 PROP_SEG	This 3-bit field defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. Propagation segment time = (PROPSEG + 1) * Time-Quantum, where Time-Quantum = one SCLK period.

[1] One time quantum is equal to the SCLK period.

24.3.2.3 Free-Running Timer (TIMER)

This register represents a 16-bit free-running counter that can be read and written by the ARM. The timer starts at 0x0000 upon reset, counts linearly to 0xFFFF, then wraps back to 0x0000.

The timer is clocked by the FlexCAN bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments each time a bit is received or transmitted. When there is no message on the bus, it counts using the previously-programmed baud rate. During freeze mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

Writing to the timer is an indirect operation. The data is first written to an auxiliary register and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data takes some time to actually be written to the register. If desired, software can poll the register to discover when the data was actually written.

Offset 0x0008 (TIMER) Access: User read/write

Figure 24-5. Free-Running Timer (TIMER)

Figure 24-6.

24.3.2.4 Rx Global Mask (RXGMASK)

This register is provided for legacy support and for low cost MCUs that do not have the individual masking per message buffer feature. For MCUs supporting individual masks per message buffer, setting the BCC bit in the MCR causes the RXGMASK register to have no effect on the module operation. For MCUs not supporting individual masks per message buffer, this register is always effective.

RXGMASK is used as acceptance mask for all Rx message buffers, excluding message buffers 14–15, which have individual mask registers. When the FEN bit in the MCR is set (FIFO enabled), the RXGMASK also applies to all elements of the ID filter table, except elements 6-7, which have individual masks. Setting the BCC bit in MCR causes the RXGMASK register to have no effect on the module's operation.

The contents of this register must be programmed while the module is in freeze mode, and must not be modified when the module is transmitting or receiving frames.

Offset 0x0010 (RXGMASK)
0x0014 (RX14MASK)
0x0018 (RX15MASK)

Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 24-7. Rx Global Mask Register (RXGMASK)

Table 24-7. Rx Global Mask Register Description

Field	Description
31–0 MI31–MI0	For normal Rx message buffers, the mask bits affect the ID filter programmed on the message buffer. For the Rx FIFO, the mask bits affect all bits programmed in the filter table (ID, IDE, RTR). 0 the corresponding bit in the filter is “don’t care” 1 The corresponding bit in the filter is checked against the one received

24.3.2.5 Rx 14 Mask (RX14MASK)

RX14MASK is used as acceptance mask for the identifier in message buffer 14. When the FEN bit in the MCR is set (FIFO enabled), the RXG14MASK also applies to element 6 of the ID filter table. Setting the BCC bit in the MCR causes the RX14MASK register to have no effect on the module operation.

This register has the same structure as RXGMASK. It must be programmed while the module is in freeze mode, and must not be modified when the module is transmitting or receiving frames.

- Address offset: 0x0014
- Reset value: 0xFFFF_FFFF

24.3.2.6 Rx 15 Mask (RX15MASK)

When the BCC bit is cleared, RX15MASK is used as acceptance mask for the identifier in message buffer 15. When the FEN bit in the MCR is set (FIFO enabled), the RXG14MASK also applies to element 7 of the ID filter table. Setting the BCC bit in the MCR causes the RX15MASK register to have no effect on the module operation

.This register has the same structure as the RXGMASKr. It must be programmed while the module is in freeze mode, and must not be modified when the module is transmitting or receiving frames.

- Address offset: 0x0018

- Reset value: 0xFFFF_FFFF

24.3.2.7 Error Counter Register (ECR)

This register has two 8-bit fields which reflect the value of the transmit error counter (tx_err_counter field) and receive error counter (rx_err_counter field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read only except in freeze mode, where they can be written by the ARM.

Writing to the error counter register while in freeze mode is an indirect operation. The data is first written to an auxiliary register, and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data takes some time to actually be written to the register. If desired, software can poll the register to discover when the data was actually written.

FlexCAN responds to any bus state as described in the protocol, for example, by transmitting an “error active” or “error passive” flag, delaying its transmission start time (“error passive”), and avoiding any influence on the bus when in the bus-off state. The following are the basic rules for FlexCAN bus state transitions:

- If the value of tx_err_counter or rx_err_counter increases to exceed 127, the FLT_CONF field in the error and status register is updated to reflect “error passive” state.
- If the FlexCAN state is “error passive,” and either tx_err_counter or rx_err_counter decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLT_CONF field in the error and status register is updated to reflect “error active” state.
- If the value of tx_err_counter increases to be greater than 255, the FLT_CONF field in the error and status register is updated to reflect the bus-off state, and an interrupt is issued. The value of tx_err_counter is then reset to zero.
- If FlexCAN is in the bus-off state, then tx_err_counter is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, tx_err_counter is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the tx_err_counter. when tx_err_counter reaches the value of 128, the FLT_CONF field in the error and status register is updated to be “error active” and both error counters are reset to zero. at any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the tx_err_counter value.
- If during system start-up, only one node is operating, then its tx_err_counter increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACK_ERR bit in the error and status register). After the transition to “error passive” state, the tx_err_counter does not increment anymore by acknowledge errors. Therefore the device never goes to the bus-off state.
- If the rx_err_counter increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to “error active” state.

Figure 24-8. Error Counter Register (ECR)

24.3.2.8 Error and Status Register (ESR)

This register reflects various error conditions, some general status of the device and it is the source of four interrupts to the ARM. The reported error conditions are those that occurred since the last time the ARM read this register. The ARM read action clears bits. Bits are status bits.

Most bits in this register are read-only, except TWRN_INT, RWRN_INT, BOFF_INT, WAK_INT and ERR_INT, which are interrupt flags that can be cleared by writing 1 to them (writing ‘0’ has no effect). See Section 24.4.10, “Interrupts,” for more details.

Figure 24-9. Error and Status Register (ESR)

Table 24-8. Error and Status Register Description

Field	Description
31–18	Reserved
17 TWRN_INT	If the WRN_EN bit in the MCR is set to 1, the TWRN_INT bit is set when the TX_WRN flag transition from '0' to '1', meaning that the Tx error counter reached 96. If the corresponding mask bit in the control register (TWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. Writing '0' has no effect. 0 No Tx error counter transition detected 1 The Tx error counter has transitioned from < 96 to ≥ 96
16 RWRN_INT	If the WRN_EN bit in the MCR is set to 1, the RWRN_INT bit is set when the RX_WRN flag transition from '0' to '1', meaning that the Rx error counters reached 96. If the corresponding mask bit in the control register (RWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. Writing '0' has no effect. 0 No Rx error counter transition detected 1 The Rx error counter has transitioned from < 96 to ≥ 96
15 BIT1_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 0 No bit inconsistency detected 1 At least one bit sent as recessive is received as dominant This bit is not set by a transmitter in the case of an arbitration field or ACK slot, or in the case of a node sending a passive error flag that detects dominant bits.
14 BIT0_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 0 No bit inconsistency detected 1 At least one bit sent as dominant is received as recessive
13 ACK_ERR	This bit indicates that an acknowledge (ACK) error has been detected by the transmitter node; that is, a dominant bit has not been detected during the ACK SLOT. 0 No ACK error detected 1 An ACK error occurred since last read of this register
12 CRC_ERR	This bit indicates that a CRC error has been detected by the receiver node, in other words the calculated CRC is different from the received. 0 No CRC error detected 1 A CRC error occurred since last read of this register.
11 FRM_ERR	This bit indicates that a form error has been detected by the receiver node, in other words a fixed-form bit field contains at least one illegal bit. 0 No form error detected 1 A form error occurred since last read of this register
10 STF_ERR	This bit indicates that a stuffing error has been detected. 0 No stuffing error detected 1 A stuffing error occurred since last read of this register
9 TX_WRN	This bit indicates when repetitive errors are occurring during message transmission. 0 Repetitive errors not detected 1 tx_err_counter ≥ 96
8 RX_WRN	This bit indicates when repetitive errors are occurring during message reception. 0 Repetitive errors not detected 1 rx_err_counter ≥ 96
7 IDLE	This bit indicates when CAN bus is in IDLE state. 0 CAN bus is not in IDLE state 1 CAN bus is now in IDLE state

Table 24-8. Error and Status Register Description (Continued)

Field	Description
6 TXRX	This bit indicates if FlexCAN is transmitting or receiving a message when the CAN bus is not in IDLE state. This bit has no meaning when IDLE is set to 1. 0 FlexCAN is receiving a message (IDLE=0) 1 FlexCAN is transmitting a message (IDLE=0)
5–4 FLT_CONF	This 2-bit field indicates the confinement state of the FlexCAN module, as follows:. 00 Error active 01 Error passive 1x Bus off If the LOM bit in the control register is set to 1, the FLT_CONF field indicates “Error Passive”. Since the control register is not affected by soft reset, the FLT_CONF field is not affected by soft reset if the LOM bit is set to 1.
3	Reserved
2 BOFF_INT	This bit is set when FlexCAN enters the bus-off state. If the corresponding mask bit in the control register (BOFF_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing a 1 to it. Writing 0 has no effect. 0 FlexCAN has not entered the bus-off state 1 FlexCAN module entered the bus-off state
1 ERR_INT	This bit indicates that at least one of the error bits is set. If the corresponding mask bit in the control register (ERR_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to ‘1’.Writing ‘0’ has no effect. 0 No error bits set in the error and status register 1 Indicates setting of any error bit in the error and status register
0 WAK_INT	When FlexCAN is in doze mode or stop mode and a recessive to dominant transition is detected on the CAN bus and if the WAK_MSK bit in the MCR is set, an interrupt is generated to the ARM. This bit is cleared by writing it to ‘1’. Writing ‘0’ has no effect. 0 No recessive to dominant transition detected 1 Indicates a recessive to dominant transition received on the CAN bus when the FlexCAN module is in doze mode or stop mode

24.3.2.9 Interrupt Masks 2 Register (IMASK2)

This register allows any number of a range of 32 message buffer interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer, enabling the ARM to determine which buffer generates an interrupt after a successful transmission or reception (that is, when the corresponding IFLAG2 bit is set).

Field	Description
31–0 BUF31M–BUF0M	Each bit enables or disables the respective FlexCAN message buffer interrupt (message buffers 0–31). 0 The corresponding buffer interrupt is disabled 1 The corresponding buffer interrupt is enabled

NOTE

Setting or clearing a bit in the IMASK1 register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set.

24.3.2.11 Interrupt Flags 2 Register (IFLAG2)

This register defines the flags for 32 message buffer interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt is generated. The interrupt flag must be cleared by writing a 1; writing 0 has no effect.

When the AEN bit in the MCR is set (abort enabled), while the IFLAG2 bit is set for a message buffer configured as Tx, ARM write access to the corresponding message buffer is blocked.

Offset 0x002C (IFLAG2) Access: User read/write

Figure 24-12. Interrupt Flags 2 Register (IFLAG2)

Table 24-11. Interrupt Flags 2 Register Description

Field	Description
31–0 BUF63I–BUF32I	Each bit flags the respective FlexCAN message buffer interrupt (message buffer 32–63). 0 No such occurrence 1 The corresponding buffer has successfully completed transmission or reception

24.3.2.12 Interrupt Flags 1 Register (IFLAG1)

This register defines the flags for 32 message buffer interrupts and FIFO interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt is generated. The interrupt flag must be cleared by writing a 1 to it. Writing 0 has no effect.

Setting the abort enabled (AEN) bit in the MCR while the IFLAG1 bit is set for a message buffer configured as Tx blocks the ARM's write access to the corresponding message buffer.

Setting the FIFO enable (FEN) bit in the MCR changes the function of the 8 least significant interrupt flags (BUF7I–BUF0I) to support the FIFO's operation. BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO; BUF4I–BUF0I are not used.

Offset 0x0030 (IFLAG1) Access: User read/write

Figure 24-13. Interrupt Flags 1 Register (IFLAG1)

Table 24-12. Interrupt Flags 1 Register Description

Field	Description
31–8 BUF31I–BUF8I	Each bit flags the respective FlexCAN message buffer interrupt (message buffers 8–31). 0 No such occurrence 1 The corresponding message buffer has successfully completed transmission or reception
7 BUF7I	If the FIFO is not enabled, this bit flags the interrupt for message buffer 7. If the FIFO is enabled, this flag indicates an overflow condition in the FIFO (frame lost because FIFO is full). 0 No such occurrence 1 Message buffer 7 completed transmission/reception or FIFO overflow
6 BUF6I	If the FIFO is not enabled, this bit flags the interrupt for message buffer 6. If the FIFO is enabled, this flag indicates that 4 out of 6 buffers of the FIFO are already occupied (FIFO almost full). 0 No such occurrence 1 Message buffer 6 completed transmission/reception or FIFO almost full
5 BUF5I	If the FIFO is not enabled, this bit flags the interrupt for message buffer 5. If the FIFO is enabled, this flag indicates that at least one frame is available to be read from the FIFO. 0 No such occurrence 1 Message buffer 5 completed transmission/reception or frames available in the FIFO
4–0 BUF4I–BUF0I	If the FIFO is not enabled, these bits flag the interrupts for message buffers 0–4. If the FIFO is enabled, these flags are not used and must be considered as reserved locations. 0 No such occurrence 1 Corresponding message buffer completed transmission/reception

24.3.2.13 Rx Individual Mask Registers (RXIMR0–RXIMR63)

These registers are used as acceptance masks for ID filtering in Rx message buffers and the FIFO. If the FIFO is not enabled, one mask register is provided for each available message buffer, providing ID masking capability on a per message buffer basis. When the FIFO is enabled (FEN bit in the MCR is set), the first 8 mask registers apply to the 8 elements of the FIFO filter table (on a one-to-one correspondence), while the rest of the registers apply to the regular message buffers, starting from message buffer 8.

The individual Rx mask registers are implemented in RAM, so they are not affected by reset and must be explicitly initialized prior to any reception. Furthermore, they can only be accessed by the ARM while the module is in freeze mode. Outside of freeze mode, write accesses are blocked and read accesses return “all zeros”. Furthermore, if the BCC bit in the MCR is cleared, any read or write operation to these registers results in an access error.

Table 24-13. Rx Individual Mask Registers Description

Field	Description
31–0 MI31–MI0	For normal Rx message buffers, the mask bits affect the ID filter programmed on the message buffer. For the Rx FIFO, the mask bits affect all bits programmed in the filter table (ID, IDE, RTR). 0 the corresponding bit in the filter is “don’t care” 1 The corresponding bit in the filter is checked against the one received

24.3.3 Buffer Descriptions

The address offset range 0x0080–0x047F is used for message buffers, which store CAN messages for transmission and reception. Table 24-14 shows a standard/extended message buffer (message buffer 0) memory map, using 16 bytes total (0x0080–0x008F space). Each message buffer comprises control and status (C/S), identifier, and data fields, as shown in Table 24-14.

Table 24-14. Message Buffer 0 (MB0) Memory Map

Address Offset	Message Buffer Field
0x0080	Control and Status (C/S)
0x0084	Identifier field
0x0088–0x008F	Data fields 0–7 (1 byte each)

Alternatively, when the MCR's FEN bit is set, the memory area from 0x0080 to 0x00FF (which is normally occupied by message buffers 0 to 7) is used by the reception FIFO engine.

The following subsections describe the structure of the message buffers and the receive FIFO.

24.3.3.1 Message Buffer Description

Figure 24-15 shows the message buffer structure used in FlexCAN. Both extended and standard frames (29-bit and 11-bit identifiers, respectively) used in the CAN specification (Version 2.0, Part B) are represented.

Offset 0x0080–0x017F (MB0–15)

0xC	Data Byte 4		Data Byte 5				Data Byte 6	Data Byte 7

Figure 24-15. Message Buffer Structure

The fields shown in Figure 24-15 are described in Table 24-15.

Table 24-15. Message Buffer Field Descriptions

Field	Description
CODE	Message buffer code. Can be accessed (read or written to) by the ARM core or the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 24-16 and Table 24-17. See Section 24.4, "Functional Description" for additional information.
SRR	Substitute remote request. In the Tx buffers, for transmission of frames in extended format, the bit must be set to 1—a cleared bit is invalid. In the Rx buffers, the bit takes the value received on the CAN bus. A received value of 0 is interpreted as an arbitration loss. 0 Dominant is not a valid value for transmission in extended format frames 1 Recessive value is compulsory for transmission in extended format frames
IDE	ID extended bit. This bit identifies whether the frame format is standard or extended. 0 Extended frame format 1 Standard frame format
RTR	Remote transmission request. Used for requesting transmissions of a data frame. If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 0 Indicates the current message buffer has a data frame to be transmitted 1 Indicates the current message buffer has a remote frame to be transmitted

Table 24-15. Message Buffer Field Descriptions (Continued)

Field	Description
LENGTH	Length of data in bytes of the Rx or Tx data, which is located in offsets 0x0008 through 0x000F of the message buffer space (see Figure 29-2). In reception, this field is copied by the FlexCAN module from the data length code (DLC) field of the received frame. In transmission this field is written by the ARM, and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the value of LENGTH.
TIME STAMP	Free-running counter time stamp. This field is a copy of the free-running timer, captured for Tx and Rx frames when the identifier field first appears on the CAN bus.
PRIO	Local priority. Only used when the LPRIO_EN bit is set in the MCR. Only applies to Tx buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Section 24.4.3, “Arbitration Process”.
ID	Frame identifier. In standard frame format (Tx or Rx), only the 11 most significant bits are used for frame identification—the 18 least significant bits are ignored. In extended frame format (Tx or Rx), all bits are used for frame identification.
DATA	Data field. Up to eight bytes can be used for a data frame. For Rx frames, the data is stored as it is received from the CAN bus. For Tx frames, the ARM prepares the data field to be transmitted within the frame.

Table 24-16. Message Buffer Codes for Rx Buffers

Rx Code Before Rx New Frame	Description	Rx Code After Rx New Frame	Comment
0000	INACTIVE: message buffer is not active.	—	Message buffer does not participate in the matching process.
0100	EMPTY: message buffer is active and empty.	0010	Message buffer participates in the matching process. When a frame is received successfully, the code is automatically updated to FULL.
0010	FULL: message buffer is full.	0010	The act of reading the C/S word followed by unlocking the message buffer does not make the code return to EMPTY. It remains FULL. If a new frame is written to the message buffer after the C/S word is read and the message buffer is unlocked, the code still remains FULL.
		0110	If the message buffer is FULL and a new frame is overwritten to this message buffer before the ARM has time to read it, the code is automatically updated to OVERRUN. See Section 24.4.5, “Matching Process,” for details about overrun behavior.
0110	OVERRUN: a frame was overwritten into a full buffer.	0010	If the code indicates OVERRUN but the ARM reads the C/S word and then unlocks the message buffer, when a new frame is written to the message buffer the code returns to FULL.
		0110	If the code already indicates OVERRUN, yet another new frame must be written, the message buffer is overwritten again, and the code remains OVERRUN. See Section 24.4.5, “Matching Process,” for details about OVERRUN behavior.
0*nm*1[1]	BUSY: FlexCAN is updating the contents of the message buffer. The ARM must not access the message buffer.	0010	An EMPTY buffer was written with a new frame (*nm* was 01).
		0110	A FULL/OVERRUN buffer was overwritten (XY was 11).

[1] For Tx message buffers (see Table 24-17), the BUSY bit should be ignored upon read, except when the AEN bit is set in the MCR.

Table 24-17. Message Buffer Code for Tx Buffers

RTR	Initial Tx Code	Code After Successful Transmission	Description
X	1000	—	INACTIVE: message buffer does not participate in the arbitration process.
X	1001	—	ABORT: message buffer was configured as Tx and ARM aborted the transmission. This code is only valid when the AEN bit in the MCR is set to 1. Message buffer does not participate in the arbitration process.
0	1100	1000	Transmit data frame once unconditionally. After transmission, the message buffer automatically returns to the INACTIVE state.
1	1100	0100	Transmit remote frame once unconditionally. After transmission, the message buffer automatically becomes an Rx message buffer with the same ID.
0	1010	1010	Transmit a data frame whenever a remote request frame with the same ID is received. This message buffer participates simultaneously in both the matching and arbitration processes. The matching process compares the ID of the incoming remote request frame with the ID of the message buffer. If a match occurs, this message buffer is allowed to participate in the current arbitration process and the CODE field is automatically updated to 0b1110 to allow the message buffer to participate in future arbitration runs. When the frame is eventually transmitted successfully, the code automatically returns to 0b1010 to restart the process.
0	1110	1010	This is an intermediate code automatically written to the message buffer by the MBM as a result of a match to a remote request frame. The data frame is transmitted once unconditionally and then the code automatically returns to 0b1010. The ARM can also write this code with the same effect.

24.3.3.2 Rx FIFO Description

When the MCR's FEN bit is set, the memory area from 0x0080 to 0x00FF (which is normally occupied by message buffers 0–7) is used by the reception FIFO engine. Figure 24-16 shows the Rx FIFO data structure. The region 0x0000-0x000C contains an message buffer structure which is the port through which the ARM reads data from the FIFO (the oldest frame received and not read yet). The region 0x0010-0x00DF is reserved for internal use of the FIFO engine. The region 0x00E0-0x00FF contains an 8-entry ID table that specifies filtering criteria for accepting frames into the FIFO. Figure 24-17 shows the three different formats that the elements of the ID table can assume, depending on the IDAM field of the MCR. All elements of the table must have the same format. See Section 24.4.7, "Rx FIFO" for more information.

C	RXIDC_0 (Std/Ext = 31-24)		RXIDC_1 (Std/Ext = 23-16)		RXIDC_2 (Std/Ext = 15-8)		RXIDC_3 (Std/Ext = 7-0)

Table 24-18. Rx FIFO Field Descriptions

Field	Description
REM	Remote frame bit. Specifies if remote frames are accepted into the FIFO if they match the target ID. 0 Remote frames can be accepted and data frames are rejected 1 Remote frames are rejected and data frames can be accepted
EXT	Extended frame bit.Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID. 0 Extended frames can be accepted and standard frames are rejected 1 Extended frames are rejected and standard frames can be accepted
RXIDA	Rx Frame Identifier (Format A). Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (3 to 13)are used for frame identification. In the extended frame format, all bits are used.

Table 24-18. Rx FIFO Field Descriptions (Continued)

Field	Description
RXIDB_0, RXIDB_1	Rx Frame Identifier (Format B). Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (3 to 13)are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	Rx Frame Identifier (Format C). Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

24.4 Functional Description

24.4.1 Overview

The FlexCAN module is a CAN protocol engine with a flexible mailbox system for transmitting and receiving CAN frames. The mailbox system includes a set of up to 64 message buffers that store configuration and control data, time stamp, message ID and data (see Section 24.3.3.1, “Message Buffer Description”). The memory corresponding to the first 8 message buffers can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 8 extended IDs, or 16 standard IDs, or 32 8-bit ID slices), each one with its own individual mask register. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into message buffers that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the message buffer ordering.

A message buffer is said to be active at a given time if it can participate in the currently-active matching and arbitration algorithms. An Rx message buffer with a code of 0b0000 is inactive, as is a Tx message buffer with a 0b1000 or 0b1001 (see Table 24-16 and Table 24-17, respectively). In other cases, a message buffer is temporarily deactivated (that is, it does not participate in the current arbitration or matching run) when the ARM writes to the C/S field of that message buffer (see Section 24.4.6.2, “Message Buffer Deactivation”).

24.4.2 Transmit Process

In order to transmit a CAN frame, the ARM must prepare a message buffer for transmission by executing the following procedure:

1. The first step depends on the state of the message buffer:
   — If the message buffer is active (transmission pending), write an ABORT code (0b1001) to the CODE field of the control and status word to request an abortion of the transmission, then read back the CODE field and the interrupt flag register to check if the transmission was aborted (see Section 24.4.6.1, “Transmission Abort Mechanism).

— Alternatively if backwards compatibility is desired (AEN in MCR is cleared), write 0b1000 to the CODE field to inactivate the message buffer. However, the pending frame may be transmitted without notification (see Section 24.4.6.2, “Message Buffer Deactivation).

2. Write the ID word.
3. Write the data bytes.
4. Write the LENGTH, CODE, and other control fields of the control and status word to activate the message buffer.

After the message buffer is activated by following this procedure, it participates in the arbitration process and eventually is transmitted according to its priority. At the end of the successful transmission, the value of the free running timer is written into the time stamp field, the CODE field in the control and status word is updated, a status flag is set in the interrupt flag register and an interrupt is generated if allowed by the corresponding interrupt mask register bit. The new CODE field after transmission depends on the code that was used to activate the message buffer (see Table 24-16 and Table 24-17 in Section 24.3.3.1, “Message Buffer Description.).

When the abort feature is enabled (AEN in the MCR is set to 1), after the interrupt flag is asserted for a message buffer configured as transmit buffer, the message buffer is blocked: therefore the ARM is not able to update it until the interrupt flag be cleared by ARM. This means that the ARM must clear the corresponding interrupt flag before starting to prepare this message buffer for a new transmission or reception.

24.4.3 Arbitration Process

The arbitration process is an algorithm executed by the message buffer management submodule (MBM) that scans the whole message buffer memory looking for the highest priority message to be transmitted. All message buffers programmed as transmit buffers are scanned to find the lowest ID or the lowest message buffer number or the highest priority, depending on the LBUF and LPRIO_EN bits on the control register. (If LBUF is cleared, the arbitration considers not only the ID, but also the RTR and IDE bits placed inside the ID at the same positions they are transmitted in the CAN frame.) The arbitration process is triggered by any of the following events:

- During the CRC field of the CAN frame
- During the error delimiter field of the CAN frame
- During intermission, if the winner message buffer defined in a previous arbitration was deactivated, or if there was no message buffer to transmit, but the ARM wrote to the C/S word of any message buffer after the previous arbitration finished
- When the MBM is in the idle or bus-off state and the ARM writes to the C/S word of any message buffer
- Upon leaving freeze mode

When LBUF is set to 1, the LPRIO_EN bit has no effect and the lowest number buffer is transmitted first. When LBUF and LPRIO_EN are both cleared, the message buffer with the lowest ID is transmitted first but. If LBUF is cleared and LPRIO_EN is set to 1, the PRIO bits augment the ID used during the arbitration process. With this extended ID concept, arbitration is done based on the full 32-bit ID and the PRIO bits define which message buffer is transmitted first: therefore message buffers with PRIO = 0b000

have higher priority. If two or more message buffers have the same priority, the regular ID determines the priority of transmission. If two or more message buffers have the same priority (3 extra bits) and the same regular ID, the lowest message buffer is transmitted first.

After the highest priority message buffer is selected, it is transferred to a temporary storage space called the serial message buffer (SMB), which has the same structure as a normal message buffer but is not user accessible. After this transfer, write access to the corresponding message buffer is blocked (if the AEN bit in the MCR is set to 1). Write access is restored by any of the following events:

- After the message buffer is transmitted
- FlexCAN enters HALT or BUS OFF
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the DLC (data length code) value is bigger.

24.4.4 Receive Process

To be able to receive CAN frames into the mailbox message buffers, the ARM must prepare one or more message buffers for reception by executing the following steps:

1. The first step depends on the state of the message buffer:
   - If the message buffer has a pending transmission, write an ABORT code (0b1001) to the CODE field of the control and status word to request an abortion of the transmission, then read back the CODE field and the interrupt flag register to check if the transmission was aborted (see Section 24.4.6.1, “Transmission Abort Mechanism”).
   - Alternatively if backwards compatibility is desired (AEN in the MCR is cleared), write 0b1000 to the CODE field to inactivate the message buffer. However, the pending frame may be transmitted without notification (see Section 24.4.6.2, “Message Buffer Deactivation”).
   - If the message buffer already programmed as a receiver, write 0b0000 to the CODE field of the control and status word to keep the message buffer inactive.
2. Write the ID word
3. Write 0b0100 to the CODE field of the control and status word to activate the message buffer

After the message buffer is activated, it is able to receive frames that match the programmed ID. At the end of a successful reception, the message buffer is updated by the MBM as follows:

1. The value of the free running timer is written into the time stamp field
2. The received ID, data (8 bytes at most), and length fields are stored
3. The CODE field in the control and status word is updated (see Table 24-16 and Table 24-17 in Section 24.3.3.1, “Message Buffer Description”)
4. A status flag is set in the interrupt flag register and an interrupt is generated if allowed by the corresponding interrupt mask register bit

Upon receiving the message buffer interrupt, the ARM services the received frame using the following procedure:

1. Read the control and status word (mandatory—activates an internal lock for this buffer)
2. Read the ID field (optional—needed only if a mask was used)
3. Read the data field
4. Read the free-running timer (optional—releases the internal lock)

The ARM's read of the control and status word is necessary to assure data coherence (see Section 24.4.6, "Data Coherence"). After reading the control and status word, if the BUSY bit is set in the CODE field then the ARM postpones the access to the message buffer until this bit is cleared.

Reading the free-running timer is not mandatory. If not executed, the message buffer remains locked, unless the ARM reads the C/S word of another message buffer. Only one message buffer is locked at a time.

The ARM synchronizes to frame reception by the status flag bit for the specific message buffer in one of the interrupt flag registers and not by the CODE field of that message buffer. Polling the CODE field does not work because after a frame is received and the ARM services the message buffer (by reading the C/S word followed by unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 24-16. If the ARM tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the message buffer, then the message buffer is deactivated from any currently ongoing matching process. As a result, a newly-received frame matching the ID of that message buffer can possibly be lost.

NOTE

When polling, do not read directly the C/S word of the message buffers. Instead, read the interrupt flag registers.

The received ID field is always stored in the matching message buffer. The contents of the ID field in a message buffer can possibly change if the match was due to masking.
FlexCAN does receive frames transmitted by itself if there exists an Rx matching message buffer, provided the SRX_DIS bit in the MCR is cleared. If SRX_DIS is set to 1, FlexCAN does not store frames transmitted by itself in any message buffer, even if it contains a matching message buffer, and no interrupt flag or interrupt signal is generated due to the frame reception.

To receive CAN frames through the FIFO, the ARM must first enable and configure the FIFO during freeze mode (see Section 24.4.7, "Rx FIFO"). After receiving the frames available interrupt from FIFO, the ARM services the received frame using the following procedure:

1. Read the control and status word (optional—needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional—needed only if a mask was used)
3. Read the data field
4. Clear the frames available interrupt (mandatory—releases the buffer and allow the ARM to read the next FIFO entry)

24.4.5 Matching Process

The matching process is an algorithm executed by the MBM that scans the message buffer memory looking for Rx message buffers programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the 8-entry ID table from FIFO is scanned first and then, if a match is not found within the FIFO table, the other message buffers are scanned. In the event that the FIFO is full, the matching algorithm always looks for a matching message buffer outside the FIFO region.

When the frame is received, it is temporarily stored in a hidden auxiliary message buffer called serial message buffer (SMB). The matching process takes place during the CRC field of the received frame. If a matching ID is found in the FIFO table or in one of the regular message buffers, the contents of the SMB are transferred to the FIFO or to the matched message buffer during the sixth bit of the end-of-frame field of the CAN protocol. This operation is called “move-in.” If any protocol error (such as CRC or ACK) is detected, than the move-in operation is not performed.

For the regular mailbox message buffers, a message buffer is said to be free to receive a new frame if all of the following conditions are satisfied:

- The message buffer is not locked (see Section 24.4.6.3, “Message Buffer Lock Mechanism”)
- The CODE field is EMPTY; alternatively, the CODE field is FULL or OVERRUN but the ARM has already serviced the message buffer (read the C/S word and then unlocked the message buffer)

If the first message buffer with a matching ID is not free to receive the new frame, then the matching algorithm keeps looking for another free message buffer until it finds one. If no free message buffer can be found, then the last matching message buffer is overwritten (unless it is locked) and the CODE field is set to OVERRUN (see Table 24-16 and Table 24-17). If the last matching message buffer is locked, then the new message remains in the SMB, waiting for the message buffer to be unlocked (see Section 24.4.6.3, “Message Buffer Lock Mechanism”).

Suppose for example that the FIFO is disabled and there are two message buffers with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these message buffers are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in the second message buffer. The code of this message buffer is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds the second message buffer again, but it is not free to receive, so it keeps looking, finds the fifth message buffer, and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching message buffers that are free to receive, so it overwrites the last matched message buffer (fifth message buffer) and sets the CODE field of that message buffer to OVERRUN.

The ability to match the same ID in more than one message buffer can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the ARM to service the message buffers. By programming more than one message buffer with the same ID, received messages are queued into the message buffers. The ARM can examine the time stamp field of the message buffers to determine the order in which the messages arrived.

The matching algorithm described above can be changed to that used in previous versions of the FlexCAN module by clearing the BCC bit in the MCR. In this case, the matching algorithm stops at the first message buffer with a matching ID that it founds, whether this message buffer is free or not. As a result, the message queueing feature does not work if the BCC bit is cleared.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per message buffer. See Section 24.3.2.13, “Rx Individual Mask Registers (RXIMR0–RXIMR63).”. During the matching algorithm, if a mask bit is set to 1 then the corresponding ID bit is compared. If the mask bit is cleared, the corresponding ID bit is “don’t care”. The individual mask registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed if the BCC bit is set to 1 and while the module is in freeze mode.

FlexCAN also supports an alternate masking scheme with only three mask registers (RGXMASK, RX14MASK and RX15MASK) for backwards compatibility. This alternate masking scheme is enabled when the BCC bit in the MCR is cleared.

24.4.6 Data Coherence

In order to maintain data coherence and ensure the proper operation of FlexCAN, the ARM must obey the rules described in Section 24.4.2, “Transmit Process,” and Section 24.4.4, “Receive Process.”. Any ARM access to a message buffer structure within FlexCAN which does not comply with these rules causes FlexCAN to behave in an unpredictable way.

24.4.6.1 Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the ARM if the transmission was aborted or if the frame could not be aborted and was transmitted instead. In order to maintain backwards compatibility, the abort mechanism must be explicitly enabled by setting the AEN bit in the MCR.

In order to abort a transmission, the ARM must write a specific abort code (0b1001) to the CODE field of the control and status word. When the abort mechanism is enabled, the active message buffers configured as transmission must be aborted first before they can be updated. If the abort code is written to an message buffer that is currently being transmitted, or to an message buffer that was already loaded into the SMB for transmission, the write operation is blocked and the message buffer is not deactivated, but the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into freeze mode

If none of conditions above are reached, the message buffer is transmitted correctly, the interrupt flag is set in the interrupt flag register and an interrupt to the ARM is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. In the other hand, if one of the above conditions is reached, the frame is not transmitted, therefore the abort code is written into the CODE field, the interrupt flag is set in the interrupt flag register and an interrupt is (optionally) generated to the ARM.

If the ARM writes the abort code before the transmission begins internally, then the write operation is not blocked, therefore the message buffer is updated and no interrupt flag is set. In this way the ARM just needs to read the abort code to make sure the active message buffer was deactivated. Although the AEN bit is set and the ARM wrote the abort code, in this case the message buffer is deactivated and not aborted, because the transmission did not start yet. One message buffer is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

1. ARM writes 0b1001 into the CODE field of the C/S word
2. ARM reads the CODE field and compares it to the value that was written
3. If the CODE field that is read is different from the value that was written, the ARM must read the corresponding interrupt flag (IFLAG) to check if the frame was transmitted or it is being currently transmitted. If the corresponding IFLAG is set, the frame was transmitted. If the corresponding IFLAG is reset, the ARM must wait for it to be set, and then the ARM must read the CODE field to check if the message buffer was aborted (CODE=0b1001) or it was transmitted (CODE=0b1000).

24.4.6.2 Message Buffer Deactivation

Deactivation is mechanism provided to maintain data coherence when the ARM writes to the control and status word of active message buffers out of freeze mode. Any ARM write access to the control and status word of a message buffer causes that message buffer to be excluded from the transmit or receive processes during the current matching or arbitration round. The deactivation is temporary, affecting only for the current match/arbitration round.

The purpose of deactivation is to maintain data coherence. The match/arbitration process scans the message buffers to decide which message buffer to transmit or receive. If the ARM updates the message buffer in the middle of a match or arbitration process, the data of that message buffer may no longer be coherent. Deactivation of the message buffer prevents this from happening.

Even with the coherency mechanism described above, writing to the control and status word of active message buffers when not in freeze mode can produce undesirable results. Examples are:

- Matching and arbitration are one-pass processes. If message buffers are deactivated after they are scanned, no re-evaluation is done to determine a new match/winner. If an Rx message buffer with a matching ID is deactivated during the matching process after it was scanned, then this message buffer is marked as invalid to receive the frame, and FlexCAN keeps looking for another matching message buffer within those not yet scanned. If no matching buffer is found, then the message is lost. Suppose, for example, that two message buffers have a matching ID to a received frame, and the user deactivated the first matching message buffer after FlexCAN has scanned the second. The received frame is lost even if the second matching message buffer was “free to receive”.
- If a Tx message buffer containing the lowest ID is deactivated after FlexCAN has scanned it, then FlexCAN looks for another winner within the message buffers that it has not scanned yet. Therefore, it can possibly transmit a message buffer with an ID that is not the lowest at the time, if a lower ID is present in one of the message buffers that was already scanned before the deactivation.
- There is a point in time before which the deactivation of a Tx message buffer causes it not to be transmitted (end of move-out). After this time, the message buffer is transmitted but no interrupt is issued and the CODE field is not updated. To avoid this situation, use the abort procedures described in Section 24.4.6.1, “Transmission Abort Mechanism”.

24.4.6.3 Message Buffer Lock Mechanism

Besides message buffer deactivation, FlexCAN has another data coherence mechanism for the receive process. When the ARM reads the control and status word of an “active not empty” Rx message buffer, FlexCAN assumes that the ARM wants to read the whole message buffer in an atomic operation, and thus it sets an internal lock flag for that message buffer. The lock is released when the ARM reads the free running timer (global unlock operation), or when it reads the control and status word of another message buffer. The message buffer locking is done to prevent a new frame to be written into the message buffer while the ARM is reading it.

NOTE

The locking mechanism only applies to Rx message buffers which have a code different than INACTIVE (0b0000) or EMPTY (0b0100). Tx message buffers cannot be locked. In previous FlexCAN versions, reading the C/S word locked the message buffer even if it was empty. This behavior is followed when the BCC bit is cleared.

Suppose, for example, that the FIFO is disabled and the second and the fifth message buffers of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two message buffers. Suppose now that the ARM decides to read message buffer number 5 and at the same time another message with the same ID is arriving. When the ARM reads the control and status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds out that there are no “free to receive” message buffers, so it decides to override message buffer number 5. However, this message buffer is locked, so the new message cannot be written there. It remains in the SMB waiting for the message buffer to be unlocked, and only then is it written to the message buffer. If the message buffer is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there is no indication of lost messages either in the CODE field of the message buffer or in the error and status register.

While the message is being moved-in from the SMB to the message buffer, the BUSY bit on the CODE field is set to 1. If the ARM reads the control and status word and finds out that the BUSY bit is set, the ARM postpones accessing the message buffer until the BUSY bit is cleared.

NOTE

If the BUSY bit is set to 1 or if the message buffer is empty, then reading the control and status word does not lock the message buffer.

Deactivation takes precedence over locking. If the ARM deactivates a locked Rx message buffer, then its lock status is cleared and the message buffer is marked as invalid for the current matching round. Any pending message on the SMB is not transferred to the message buffer.

24.4.7 Rx FIFO

The receive-only FIFO is enabled by setting the FEN bit to 1 in the MCR. The reset value of this bit is zero to maintain software backwards compatibility with previous versions of the module that did not have the FIFO feature. When the FIFO is enabled, the memory region normally occupied by the first 8 message buffers (0x0080-0x00FF) is now reserved for use of the FIFO engine (see Section 24.3.3.2, “Rx FIFO Description”). Management of read and write pointers is done internally by the FIFO engine. The ARM

can read the received frames sequentially, in the order they were received, by repeatedly accessing a message buffer structure at the beginning of the memory.

The FIFO can store up to 6 frames pending service by the ARM. An interrupt is sent to the ARM when new frames are available in the FIFO. Upon receiving the interrupt, the ARM must read the frame (accessing an message buffer in the 0x0080 address) and then clear the interrupt. The act of clearing the interrupt triggers the FIFO engine to replace the message buffer in 0x0080 with the next frame in the queue, and then issue another interrupt to the ARM. If the FIFO is full and more frames continue to be received, an OVERFLOW interrupt is issued to the ARM and subsequent frames are not accepted until the ARM creates space in the FIFO by reading one or more frames. A warning interrupt is also generated when 4frames are accumulated in the FIFO.

A powerful filtering scheme is provided to accept only frames intended for the target application, thus reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of eight 32-bit registers that can be configured to one of the following formats (see also Section 24.3.3.2, “Rx FIFO Description”):

- Format A: 8 extended or standard IDs (including IDE and RTR)
- Format B: 16 standard IDs or 16 extended 14-bit ID slices (including IDE and RTR)
- Format C: 32 standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all 8 registers of the filter table. It is not possible to mix formats within the table.

The eight elements of the filter table are individually affected by the first eight individual mask registers (RXIMR0–RXIMR7), allowing very powerful filtering criteria to be defined. The rest of the RXIMR, starting from RXIM8, continue to affect the regular message buffers, starting from message buffer 8. If the BCC bit is cleared, then the FIFO filter table is affected by the legacy mask registers as follows: element 6 is affected by RX14MASK, element 7 is affected by RX15MASK and the other elements (0–5) are affected by RXGMASK.

24.4.8 CAN Protocol Related Features

24.4.8.1 Remote Frames

The user can program a message buffer to be a remote request frame by writing the message buffer as transmit with the RTR bit set to 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, its ID is compared to the IDs of the transmit message buffers with CODE field 0b1010. If there is a matching ID, then this message buffer frame is transmitted. If the matching message buffer has the RTR bit set, then FlexCAN transmits a remote frame as a response.

A received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame must match.

In the case that a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

If the Rx FIFO is enabled (the FEN bit in the MCR is set to 1), FlexCAN does not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the FIFO and presented to the ARM. For filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID).

24.4.8.2 Overload Frames

FlexCAN transmits overload frames when any of the following conditions on CAN bus are detected:

- Dominant bit in the first or second bit of intermission
- Dominant bit at the 7th (last) bit of end-of-frame field (Rx frames)
- Dominant bit at the 8th (last) bit of the error frame delimiter or the overload frame delimiter

24.4.8.3 Time Stamp

The value of the free-running timer is sampled at the beginning of the identifier field on the CAN bus, and is stored at the end of “move-in” in the time stamp field, providing network behavior with respect to time.

The free-running timer can be reset upon a specific frame reception, enabling network time synchronization. See TSYN description in Section 24.3.2.2, “Control Register (CTRL).”

24.4.8.4 Protocol Timing

Figure 24-18 shows the structure of the clock generation circuitry that feeds the CAN protocol interface (CPI) submodule. The clock source bit (CLK_SRC) in the CTRL register defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock (generally from a PLL). In order to guarantee reliable operation, the clock source must be selected while the module is in disable mode (bit MDIS set in the MCR).

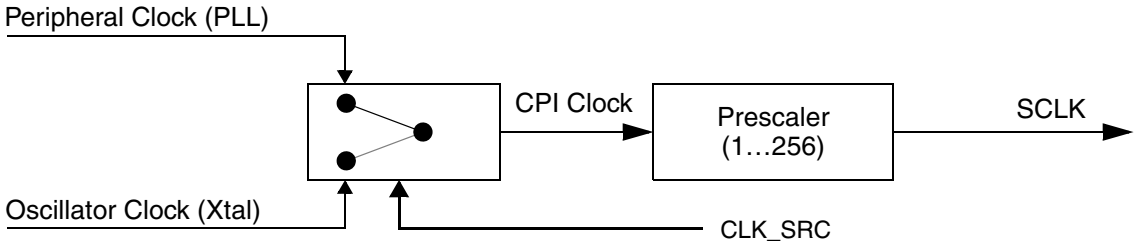

Figure 24-18. CAN Engine Clocking Scheme

The crystal oscillator clock must be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than PLL-generated clocks.

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The control register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. For more details see Section 24.3.2.2, “Control Register (CTRL).”

The PRESDIV field controls a prescaler that generates the SCLK, whose period defines the ‘time quantum’ used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(Prescaler\ \ value)}$$

A bit time is subdivided into three segments[1] (see Figure 24-19 and Figure 24-19):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time segment 2: This segment represents phase segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL register (plus 1) to be 2–8 time quanta long

$$Bit\ \ Rate = \frac{f_{Tq}}{(number\ \ of\ \ Time\ \ Quanta)}$$

1. For further explanation of the underlying concepts see ISO/DIS 11519–1, Section 10.3. See also the Bosch CAN 2.0A/B protocol specification (September 1991) for bit timing.

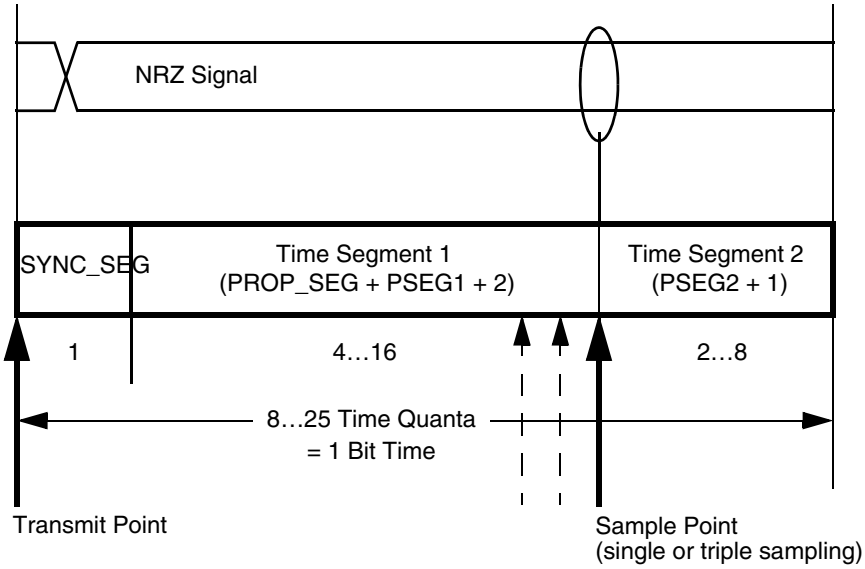

Figure 24-19. Segments Within the Bit Time

Table 24-19. Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

Table 24-20 gives an overview of the CAN-compatible segment settings and the related parameter values.

Table 24-20. CAN Standard Compatible Bit Time Segment Settings

Time Segment 1	Time Segment 2	Resynchronization Jump Width
5…10	2	1…2
4…11	3	1…3
5…12	4	1…4
6…13	5	1…4
7…14	6	1…4
8…15	7	1…4
9…16	8	1…4

NOTE

It is the user's responsibility to ensure the bit time settings are in compliance with the CAN standard. For bit time calculations, use an IPT (information processing time) of 2, which is the value implemented in the FlexCAN module.

24.4.8.5 Arbitration and Matching Timing

During normal transmission or reception of frames, the arbitration, matching, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in Figure 24-20.

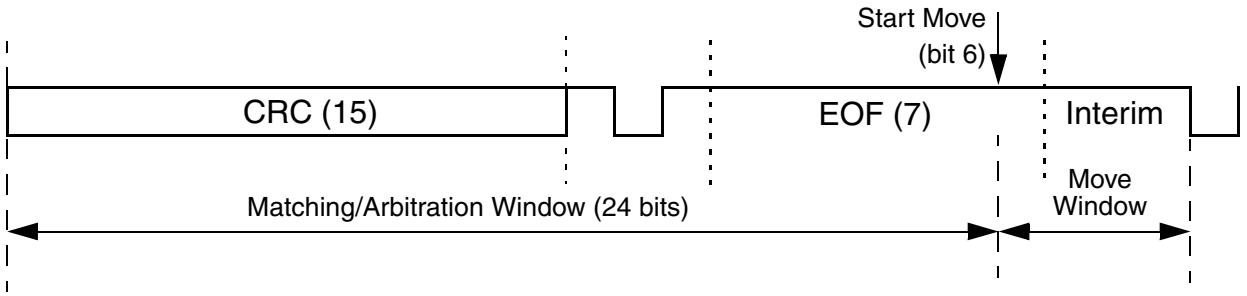

Figure 24-20. Arbitration, Match and Move Time Windows

When performing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in Table 24-20
- The peripheral clock frequency cannot be smaller than the oscillator clock frequency, in other words the PLL cannot be programmed to divide down the oscillator clock
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in Table 24-21

Table 24-21. Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate

Number of Message Buffers	Minimum Ratio
16	8
32	8
64	16

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, so the oscillator clock frequency must be at least 8 times the CAN bit rate. The minimum frequency ratio specified in Table 24-21 can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRESDIV, PROPSEG, PSEG1, PSEG2). As an example, taking the case of 64 message buffers, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRESDIV + 1) must be at least 2. For prescaler factor equal

to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies must be at least 2.

24.4.9 Modes of Operation Detailed Descriptions

24.4.9.1 Freeze Mode

This mode is entered by setting the HALT bit to 1 in the MCR or when the core is put into debug mode. In both cases it is also necessary that the FRZ bit is set in the MCR and the module is not in any of the low-power modes (disable, doze, stop). When freeze mode is requested during transmission or reception, FlexCAN performs the following actions:

- Waits to be in either intermission, passive error, bus-off or idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores the Rx input signal and drives the Tx signal as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the error counter register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in the MCR

After requesting freeze mode, the user must wait for the FRZ_ACK bit to be set in the MCR before executing any other action—otherwise FlexCAN operation is unpredictable. In freeze mode, all memory mapped registers are accessible.

Freeze mode is exited in one of the following ways:

- ARM clears the FRZ bit in the MCR
- The core is removed from debug mode and/or the HALT bit is cleared

Once out of freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

24.4.9.2 Module Disable Mode

This low-power mode is entered when the MDIS bit in the MCR is set to 1. If the module is disabled during freeze mode, it shuts down the clocks to the CPI and MBM submodules, sets the LPM_ACK bit and clears the FRZ_ACK bit. If the module is disabled during transmission or reception, FlexCAN performs the following actions:

- Waits to be in either the idle or bus-off state, or else waits for the third bit of intermission and then checks if it is recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores its Rx input signal and drives its Tx signal as recessive
- Shuts down the clocks to the CPI and MBM submodules
- Sets the NOT_RDY and LPM_ACK bits in the MCR

The bus interface unit continues to operate, enabling the ARM to access memory mapped registers, except the free running timer, the error counter register and the message buffers, which cannot be accessed when

the module is in disable mode. Exiting from this mode is done by clearing the MDIS bit, which resumes the clocks and clears the LPM_ACK bit.

24.4.9.3 Doze Mode

This is a system low-power mode in which the ARM bus is kept alive and a global doze mode request is sent to all peripherals asking them to enter low-power mode. The DOZE bit in the MCR must be set to 1 in order for a global doze mode to trigger doze mode. If doze mode is triggered during freeze mode, FlexCAN shuts down the clocks to the CPI and MBM submodules, sets the LPM_ACK bit and clears the FRZ_ACK bit. If doze mode is triggered during transmission or reception, FlexCAN performs the following actions:

- Waits to be in either the idle or the bus-off state, or else waits for the third bit of intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores its Rx input signal and drives its Tx signal as recessive
- Shuts down the clocks to the CPI and MBM submodules
- Sets the NOT_RDY and LPM_ACK bits in the MCR

The bus interface unit continues to operate, enabling the ARM to access memory mapped registers, except the free-running timer, the error counter register and the message buffers, which cannot be accessed in doze mode.

Doze mode is exited in one of the following ways:

- ARM removes the doze mode request
- ARM clears the DOZE bit of the MCR
- Self wake-up mechanism

In the self wake-up mechanism, if the SLF_WAK bit in the MCR was set at the time FlexCAN entered doze mode, then upon detection of a recessive-to-dominant transition on the CAN bus, FlexCAN clears the DOZE bit and resumes its clocks. It also sets the WAK_INT bit in the ESR and, if enabled by the WAK_MSK bit in the MCR, generates a wake-up interrupt to the ARM. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it does not receive the frame that woke it up. Table 24-22 details the effect of SLF_WAK and WAK_MSK upon wake-up from doze mode.

Table 24-22. Wake-up from Doze Mode

SLF_WAK	WAK_MSK	FlexCAN Clocks Enabled	Wake-up Interrupt Generated
0	0	No	No
0	1	No	No
1	0	Yes	No
1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in doze mode. See the WAK_SRC bit in Section 24.3.2.1, “Module Configuration Register

(MCR).” This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

24.4.9.4 Stop Mode

This is a system low-power mode in which all core clocks are stopped for maximum power savings. If FlexCAN receives the global stop mode request during freeze mode, it sets the LPM_ACK bit, clears the FRZ_ACK bit and then sends a stop acknowledge signal to the ARM, in order to shut down the clocks globally. If stop mode is requested during transmission or reception, FlexCAN performs the following actions:

- Waits to be in either the idle or bus-off state, or else waits for the third bit of intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish
- Ignores its Rx input signal and drives its Tx signal as recessive
- Sets the NOT_RDY and LPM_ACK bits in the MCR
- Sends a Stop Acknowledge signal to the ARM, so that it can shut down the clocks globally

Stop mode is exited in one of the following ways:

- ARM resumes the clocks and removes the stop mode request
- ARM resumes the clocks and stop mode request as a result of the self wake-up mechanism

In the self wake-up mechanism, if the SLF_WAK bit in the MCR was set at the time FlexCAN entered stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAK_INT bit in the ESR and, if enabled by the WAK_MSK bit in the MCR, generates a wake-up interrupt to the ARM. Upon receiving the interrupt, the ARM resumes the clocks and remove the stop mode request. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it does not receive the frame that woke it up. Table 24-23 details the effect of SLF_WAK and WAK_MSK upon wake-up from stop mode. Wake-up from stop mode only works when both bits are set to 1.

Table 24-23. Wake-up from Stop Mode

SLF_WAK	WAK_MSK	Core Clocks Enabled	Wake-up Interrupt Generated
0	0	No	No
0	1	No	No
1	0	No	No
1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in stop mode. See the WAK_SRC bit in Section 24.3.2.1, “Module Configuration Register (MCR). This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

24.4.10 Interrupts

The module can generate up to 70 interrupt sources (64 interrupts due to message buffers and 6 interrupts due to ORed interrupts from message buffers, bus-off, error, Tx warning, Rx warning, and wake-up). Each of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the interrupt flag registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the ARM writes a 1 to it (unless another interrupt is generated at the same time).

NOTE

It must be guaranteed that the ARM only clears the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions can cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (bit FEN of MCR is set to 1), the interrupts corresponding to message buffers 0–7 have a different behavior. Bit 7 of the IFLAG1 becomes the “FIFO Overflow” flag; bit 6 becomes the FIFO warning flag, bit 5 becomes the “Frames Available in FIFO flag” and bits 4–0 are unused. See Section 24.3.2.12, “Interrupt Flags 1 Register (IFLAG1),” for more information.

A combined interrupt for all message buffers is generated by an OR of all the interrupt sources from message buffer 0–7. This interrupt gets generated when any of the message buffers generates an interrupt. In this case the ARM must read the interrupt flag registers to determine which message buffer caused the interrupt.

The other five interrupt sources (bus-off, error, Tx warning, Rx warning, and wake up) generate interrupts like the message buffer ones, and can be read from the error and status register. The bus-off, error, Tx warning, and Rx warning interrupt mask bits are located in the control register, and the wake-up interrupt mask bit is located in the MCR.

24.5 Initialization/Application Information

This section provide instructions for initializing the FlexCAN module.

24.5.1 FlexCAN Initialization Sequence

The FlexCAN module can be reset in two ways:

- Core-level hard reset, which resets all memory mapped registers asynchronously
- SOFT_RST bit in the MCR, which resets some of the memory mapped registers synchronously (see Table 24-2 to see what registers are affected by soft reset)

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it can take some time to fully propagate its effects. The SOFT_RST bit remains set while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft

reset cannot be applied while clocks are shut down in any of the low-power modes. The low-power mode must be exited and the clocks resumed before applying soft reset.

The clock source (CLK_SRC bit) must be selected while the module is in disable mode. After the clock source is selected and the module is enabled (MDIS bit cleared), FlexCAN automatically goes to freeze mode. In freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in the MCR are set, the internal state machines are disabled and the FRZ_ACK and NOT_RDY bits in the MCR are set. The Tx signal is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. The message buffers and the Rx individual mask registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into freeze mode (see Section 24.4.9.1, “Freeze Mode”). The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the module configuration register
   - Enable the individual filtering per message buffer and reception queue features by setting the BCC bit
   - Enable the warning interrupts by setting the WRN_EN bit
   - If required, disable frame self reception by setting the SRX_DIS bit
   - Enable the FIFO by setting the FEN bit
   - Enable the abort mechanism by setting the AEN bit
   - Enable the local priority feature by setting the LPRIO_EN bit
2. Initialize the control register
   - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
   - Determine the bit rate by programming the PRESDIV field
   - Determine the internal arbitration mode (LBUF bit)
3. Initialize the message buffers
   - The control and status word of all message buffers must be initialized
   - If FIFO was enabled, the 8-entry ID table must be initialized
   - Other entries in each message buffer must be initialized as required
4. Initialize the Rx individual mask registers
5. Set required interrupt mask bits in the IMASK registers (for all message-buffer interrupts), in the CTRL register (for bus-off and error interrupts) and in the MCR for wake-up interrupt
6. Clear the HALT bit in the MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

Chapter 25
General Purpose Input/Output Module (GPIO)

This chapter describes a module integrated into an SoC. The chapter is intended for a module driver software developer. It describes module-level operation and programming. To understand how the module is integrated at the SoC level, a system software developer should see discussions of the module in the appropriate SoC-level chapter(s).

25.1 Overview

The general purpose input/output (GPIO) module provides 32 dedicated general-purpose one-bit contacts that can be individually configured as either inputs or outputs. Contacts configured as outputs reflect internal register values, and those configured as inputs can be detected by reading internal registers.

Figure 25-1 is a top-level diagram of the GPIO module.

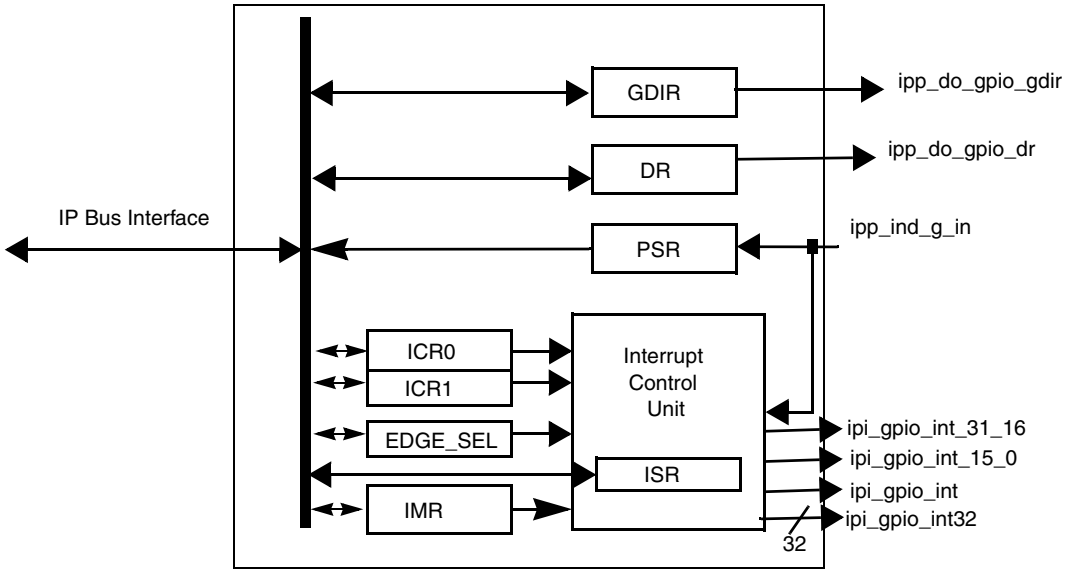

Figure 25-1. GPIO Module Diagram

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic. The eight registers, described in detail in Section 25.3.3, “Register Descriptions”, include the following:

- Data register (DR)
- GPIO direction register (GDIR)
- Pad sample register (PSR)
- Interrupt control registers (ICR1, ICR2)

- Edge select register (EDGE_SEL)
- Interrupt mask register (IMR)
- Interrupt status register (ISR)

Each GPIO input has a dedicated edge-detect circuit that can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. GPIO edge detection is described further in Section 25.4.2, “Interrupt Control Unit”. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (IMR). These qualified outputs are ORed together to generate three one-bit interrupt lines as follows:

- ipi_gpio_int_31_16: OR of 16 high interrupts
- ipi_gpio_int_15_0: OR of 16 low interrupts
- ipi_gpio_int: OR of all 32 interrupts

In addition, the 32-bit signal ipi_gpio_int32 gives the user access to all 32 individual interrupts.

25.1.1 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (DR)
  - Controls the direction of the signal using the GPIO direction register (GDR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

25.2 External Signal Description

In addition to the IP bus interface, the GPIO has the signals listed in Table 25-1.

Table 25-1. External Signal Properties

Name	Function	Reset	Pull Up
ipp_do_gpio_gdir	GPIO direction signal. Controls the direction of the GPIO signal if the I/O multiplexer (IOMUX) is in GPIO mode. 0 GPIO signal is configured as input. 1 GPIO signal is configured as output.	0	—
ipp_do_gpio_dr	GPIO data signal—reflects GPIO data register values. If the IOMUX is in GPIO mode and the corresponding direction bit is set to output, this signal is driven to the I/O interface.	0	—
ipp_ind_g_in	GPIO input line from the IOMUX.	0	—

Table 25-1. External Signal Properties (Continued)

Name	Function	Reset	Pull Up
ipi_gpio_int31_16	GPIO outputs functioning as interrupt—MSB OR'ed interrupts. One-bit interrupt OR of 16 high interrupts.	0	—
ipi_gpio_int15_0	GPIO outputs functioning as interrupt—LSB OR'ed interrupts. One-bit interrupt OR of 16 low interrupts.	0	—
ipi_gpio_int	GPIO outputs functioning as interrupt—OR'ed interrupts. One-bit interrupt OR of 32 interrupts.	0	—
ipi_gpio_int32	GPIO outputs functioning as interrupts—32-bit, all interrupt out.	0	—
ipg_clk_s	Unique GPIO input clock, derived from ipg_clk and gated by the module enable signal. The clock is only active when GPIO is accessed.	—	—

25.3 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers. There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit accesses are supported: non–32-bit read accesses return 32 bits, and non–32-bit write accesses are ignored.

25.3.1 Memory Map

Table 25-2 is the GPIO memory map. For the base address of a particular module instantiation, see the system memory map.

Table 25-2. GPIO Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (DR)	GPIO data register	R/W	0X0000_0000	25.3.3.1/25-5
0x0004 (GDIR)	GPIO direction register	R/W	0X0000_0000	25.3.3.2/25-6
0x0008 (PSR)	GPIO pad status register	Read-only	0X0000_0000	25.3.3.3/25-7
0x000C (ICR1)	GPIO interrupt configuration register1	R/W	0X0000_0000	25.3.3.4/25-8
0x0010 (ICR2)	GPIO interrupt configuration register2	R/W	0X0000_0000	25.3.3.5/25-8
0x0014 (IMR)	GPIO interrupt mask register	R/W	0X0000_0000	25.3.3.6/25-9
0x0018 (ISR)	GPIO interrupt status register	R/W	0X0000_0000	25.3.3.7/25-10
0x001C (EDGE_SEL)	GPIO edge select register	R/W	0X0000_0000	25.3.3.8/25-10

25.3.2 Register Summary

The following definitions serve as a key for the register summary and individual register diagrams.

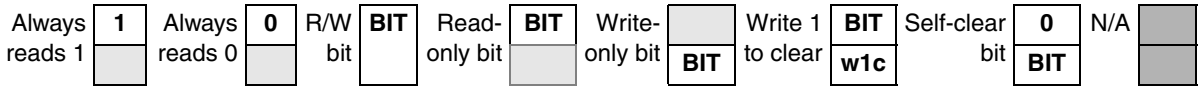

Figure 25-2. Key to Register Fields

Table 25-3 provides a key for register figures and the register summary table.

Table 25-3. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero (previously labeled slfclr).
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 25-4 shows the GPIO register summary.

25.3.3 Register Descriptions

This section contains the detailed descriptions for the GPIO registers.

25.3.3.1 GPIO Data Register (DR)

The 32-bit GPIO DR register stores data that is ready to be driven to the output lines. If the I/O multiplexer (IOMUX) is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of DR reflects the value of the corresponding signal. Read accesses automatically include two wait states to guarantee synchronization.

The results of a read of a DR bit depends on the IOMUX input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set to 1 and the IOMUX input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and the IOMUX input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.
- If GDIR[*n*] is set to 1 and the IOMUX input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and the IOMUX input mode is not GPIO, then reading DR[*n*] always returns zero.

Figure 25-3 shows the DR fields, and Table 25-5 shows the register's field descriptions.

Offset 0x0000 (DR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 25-3. GPIO Data Register (DR)

Table 25-5. DR Field Descriptions

Field	Description
31–0 DR	Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[*n*]=1). Writes to this register are stored in a register. Reading DR returns the value stored in the register if the signal is configured as an output (GDIR[*n*]=1), or the input signal's value if configured as an input (GDIR[*n*]=0). **Note:** The IOMUX must be configured to GPIO mode for the DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

25.3.3.2 GPIO Direction Register (GDIR)

GDIR functions as direction control when the IOMUX is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table; for more details, see Chapter 4, "External Signals and Pin Multiplexing.

Figure 25-4 shows the GDIR fields, and Table 25-6 shows the register's field descriptions.

Offset 0x0004 (GDIR) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	GDIR[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 25-4. GPIO Direction Register (GDIR)

Table 25-6. GDIR Field Descriptions

Field	Description
31–0 GDIR	GPIO direction bits. Bit *n* of this register defines the direction of the GPIO[*n*] signal as follows: 0 GPIO[*n*] is configured as input. 1 GPIO[*n*] is configured as output. **Note:** GDIR only affects the direction of the I/O signal when the corresponding bit in the IOMUX is configured for GPIO.

25.3.3.3 GPIO Pad Status Register (PSR)

Each read-only bit of the PSR stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, so that the input signal is sampled only when accessing this location. PSR reads automatically include two wait states to guarantee synchronization.

Figure 25-5 shows the PSR fields, and Table 25-7 shows the register's field descriptions.

Offset 0x0008 (PSR) Access: User read

Table 25-7. PSR Field Descriptions

Field	Description
31–0 PSR	GPIO pad status bits (status bits). Reading PSR returns the state of the corresponding input signal. **Note:** The IOMUX must be configured to GPIO mode for PSR to reflect the state of the corresponding signal. Otherwise the register shows the default values as set by the IOMUX.

25.3.3.4 GPIO Interrupt Configuration Register1 (ICR1)

ICR1 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal. Figure 25-6 shows the ICR1 fields, and Table 25-8 shows the register's field descriptions.

NOTE

The input signal configurations specified by ICR1 are overridden by setting bits in EDGE_SEL register. For more information, see Section 25.3.3.8, "GPIO Edge Select Register (EDGE_SEL)."

Offset 0x000C (ICR1) Access: User read/write

Table 25-8. ICR1 Field Descriptions

Field	Description
31–0 ICR15–ICR0	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Bits ICR*n*[1:0] determine the interrupt condition for signal *n* as follows: 00 Interrupt *n* is low-level sensitive. 01 Interrupt *n* is high-level sensitive. 10 Interrupt *n* is rising-edge sensitive. 11 Interrupt *n* is falling-edge sensitive.

25.3.3.5 GPIO Interrupt Configuration Register2 (ICR2)

ICR2 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal. Figure 25-7 shows the ICR2 fields, and Table 25-9 shows the register's field descriptions.

NOTE

The input signal configurations specified by ICR2 are overridden by setting bits in EDGE_SEL register. For more information, see Section 25.3.3.8, "GPIO Edge Select Register (EDGE_SEL)."

Figure 25-8. GPIO Interrupt Mask Register (IMR)

Table 25-10. IMR Field Descriptions

Field	Description
31–0 IMR	Interrupt mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Bit IMR[*n*] (n=0...31) controls interrupt *n* as follows: 0 Interrupt *n* is disabled. 1 Interrupt *n* is enabled.

25.3.3.7 GPIO Interrupt Status Register (ISR)

The ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition is met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Read accesses automatically include two wait states to ensure synchronization. One wait state is included for reset. To make sure the ISR register contents can be read out correctly, software should read the register two times. Figure 25-9 shows the ISR fields, and Table 25-11 shows the register's field descriptions.

Offset 0x0018 (ISR) Access: User read/write

Figure 25-9. GPIO Interrupt Status Register (ISR)

Table 25-11. ISR Field Descriptions

Field	Description
31–0 ISR	Interrupt status bits. Bit *n* of this register is set to 1 when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software (by writing 1 to the bit).

25.3.3.8 GPIO Edge Select Register (EDGE_SEL)

EDGE_SEL can be used to override the interrupt configurations specified in the ICR1 and ICR2 registers. If the EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared, so that the ICR registers are not overridden.

Figure 25-7 shows the EDGE_SEL fields, and Table 25-9 shows the register's field descriptions.

Offset 0x001C (EDGE_SEL) Access: User read/write

Figure 25-10. GPIO Edge Select Register (EDGE_SEL)

Table 25-12. EDGE_SEL Field Descriptions

Field	Description
31–0 EDGE_SEL	Edge select. When EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

25.4 GPIO Functional Description

25.4.1 Input/Output Signal Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal can be independently configured as either an input or an output using the GPIO direction register (GDIR). When configured as an output (GDIR bit set to 1), the value in the data bit in the GPIO data register (DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GDIR bit is cleared), the state of the input can be read from the corresponding PSR bit.

25.4.2 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit is cleared). The interrupt control registers (ICR1 and ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about the ICR1 and ICR2 settings, see Section 25.3.3.4, “GPIO Interrupt Configuration Register1 (ICR1)” and Section 25.3.3.5, “GPIO Interrupt Configuration Register2 (ICR2)”.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

25.5 Initialization/Application Information

This section provides initialization and application information for the GPIO.

25.5.1 GPIO Read Mode

The programming sequence for reading input signals is as follows:

1. Configure IOMUX to select GPIO mode (via IOMUXC).
2. Configure the GPIO direction register (GDR) to input.
3. Read value from the data register or pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000 // SET INPUTS TO GPIO MODE.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0 // SET GDIR TO
INPUT.
read DR                                                          // READ INPUT VALUE FROM DR.
read PSR                                                        // READ INPUT VALUE FROM PSR.
```

NOTE

While the GPIO direction is set to input (GDIR[*n*] bit is cleared), a read access to DR[*n*] does not return DR[*n*] data. Instead, it returns the PSR[*n*] data, which is the corresponding input signal value.

25.5.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (via IOMUXC).
2. Configure GPIO direction register (GDR) to output.
3. Write value to data register (DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
write sw_mux_ctl_<output0>_<output1>_<output2>_<output3>, 32'h00000000         // SET OUTPUTS
TO GPIO MODE.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF // SET GDIR
TO OUTPUT.
write DR, 32'hxxxxxxx5                                                  // WRITE OUTPUT VALUE TO DR.
read_cmp PSR, 32'hxxxxxxx5                                          // READ OUTPUT VALUE FROM PSR ONLY.
```

NOTE

While the GPIO direction is set to output (GDIR[*n*] bit is set to 1), the real internal value can only be verified through the PSR[*n*], and not through the DR[*n*].

Chapter 26
General Purpose Timer (GPT)

Figure 26-1 shows the block diagram of the general purpose timer (GPT).

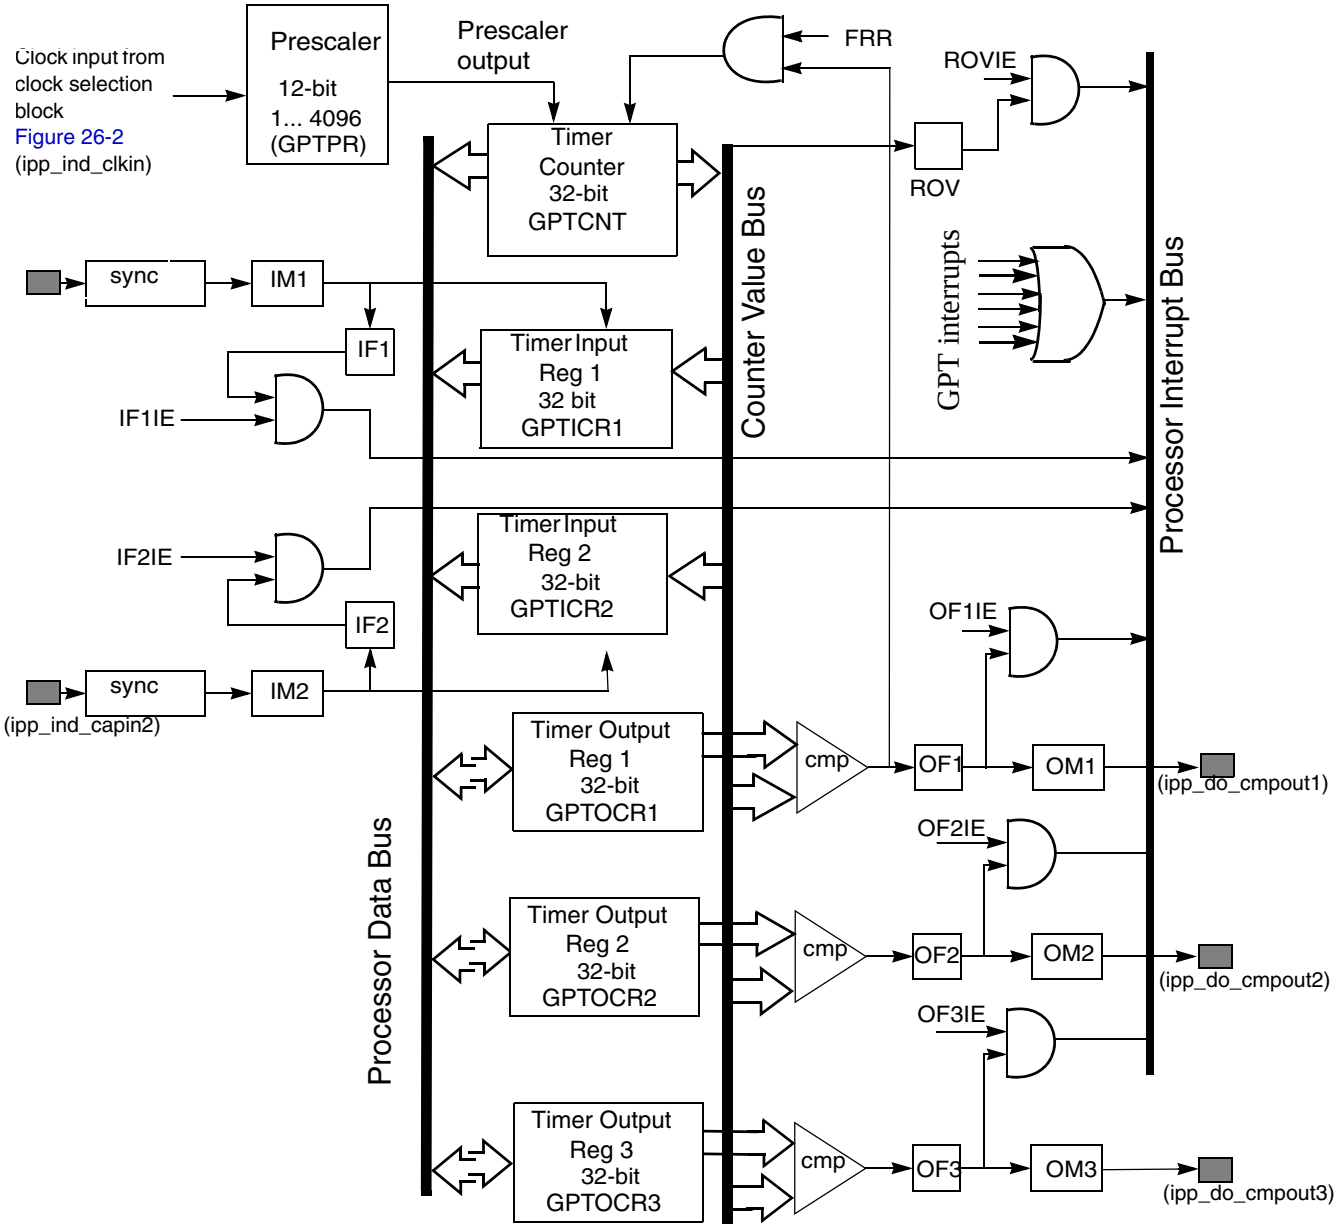

Figure 26-1. General Purpose Timer (GPT) Block Diagram

Figure 26-2 shows the GPT functional clocking scheme.

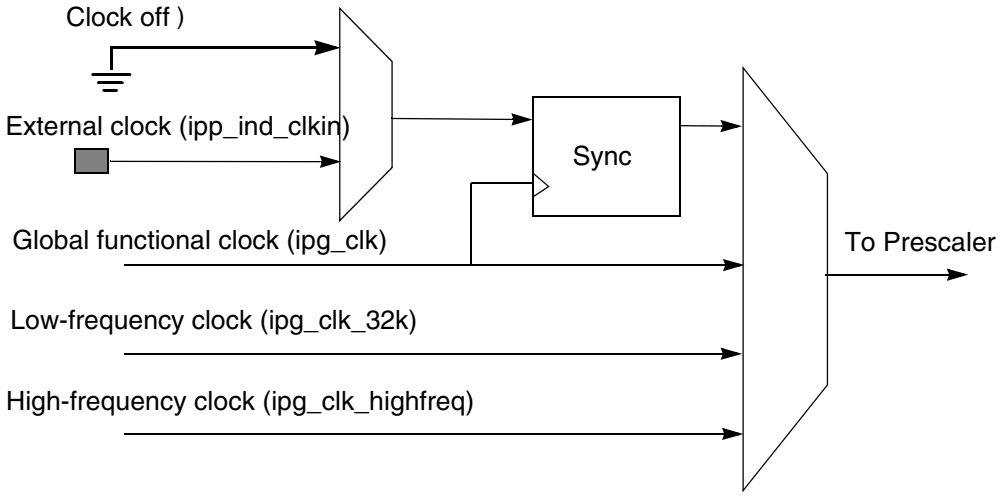

Figure 26-2. GPT Counter Clocks Diagram

26.1 Overview

The general purpose timer (GPT) has a 32-bit upcounter, whose value can be captured when triggered by an external event. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also assert multiple compare event signals and interrupts when the timer reaches a programmed value. A 12-bit prescaler provides a programmable clock frequency derived from multiple clock sources.

26.2 Features

- One 32-bit upcounter with clock source selection, including external clock.
- Two input capture channels with programmable trigger edge.
- Three output compare channels with programmable output mode. Forced compare feature also available.
- Can be programmed to be active in low-power and debug modes
- Interrupt generation at capture, compare, rollover events.
- Free-running or restart modes for counter operation.

26.3 Modes of Operation

The GPT can be programmed (via the control register) to run in free-running or restart modes:

- In free-running mode, the counter is not reset when a compare event occurs on any of the three compare channels (ipp_do_cmp1–3). The counter continues up to 0xFFFF_FFFF, then rolls over to 0x0000_0000.
- In restart mode compare channels 2 and 3 behave as in free-running mode, but channel 1 behaves differently. When the counter reaches the compared value for channel 1 it resets and restarts from 0x0000_0000. Any write access to the compare register of channel 1 results in the GPT counter being reset.

26.4 External Signals

Table 26-1 describes all GPT signals that connect off-chip. These signals are described in the following subsections.

Table 26-1. External Signal Description

Name	Direction	Function	Reset State	Pull up
ipp_ind_clkin	Input	External clock on which counter can be run	-	Passive Hysteresis
ipp_ind_capin1	Input	Capture event for capture channel 1	-	Passive
ipp_ind_capin2	Input	Capture event for capture channel 2	-	Passive
ipp_do_cmpout1	Output	Indicator for compare event occurrence in compare channel 1	0	Passive
ipp_do_cmpout2	Output	Indicator for compare event occurrence in compare channel 2	0	Passive
ipp_do_cmpout3	Output	Indicator for compare event occurrence in compare channel 3	0	Passive

26.4.1 External Clock Input (ipp_ind_clkin)

The GPT counter can be run on an external clock from outside the chip; this is the input signal from the clock. This clock is treated as asynchronous to ipg_clk. To function properly, its frequency must be less than 1/4 of the ipg_clk frequency for GPT. This pin has hysteresis characteristics, as this is a clock input.

26.4.2 Input Capture Trigger Signals (ipp_ind_capin[1:2])

The GPT counter value can be stored into a register with an event from outside the chip. A positive or/and negative edge on these signals can trigger this capture event. These signals are treated as asynchronous to ipg_clk. Only those transitions which occur at least a single clock cycle (clock selected to run the counter) after the previous recorded transition are guaranteed to trigger a capture event.

26.4.3 Output Compare Signals (ipp_do_cmpout[1:3])

These signals show the occurrence of output compare event through a specified transition.

26.5 Memory Map and Register Definition

This section includes the module memory map and detailed descriptions of all registers.

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate and monitor the state of the GPT.

NOTE

- IP Bus write accesses to the GPT control register and GPT output compare register1 result in one cycle of wait state (ips_xfr_wait high for 1 cycle), while other valid IP bus accesses have no wait states.
- Irrespective of resp_sel signal value, a write access to the read-only registers (GPTICR1, GPTICR2, GPTCNT) generates a bus exception (ips_xfr_err signal is asserted). If resp_sel is driven low then a read or

write access to the unimplemented address space of GPT (address offset greater than 0x0028) generates a bus exception (ips_xfr_err signal is asserted). If resp_sel is driven high, then read or write access to the unimplemented address space of GPT does not create any error response.

26.5.1 Memory Map

Table 26-2 shows the GPT register memory map. For the base address of a particular module instantiation, see the system memory map.

Table 26-2. GPT Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (GPTCR)	GPT control register	R/W	0x0000_0000	26.5.2.1/26-7

26.5.2 Register Summary

Figure 26-3 shows the key to the register fields and Table 26-4 shows the register figure conventions.

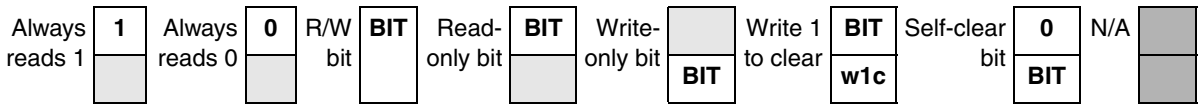

Figure 26-3. Key to Register Fields

Table 26-3. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.

Table 26-3. Register Figure Conventions

Convention	Description
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 26-4 summarizes the GPT registers.

26.5.2.1 GPT Control Register (GPTCR)

The GPTCR is used to program and configure the GPT for appropriate operation and use of its features.An IP bus write access to GPTCR results in a one-cycle wait state, while an IP bus read access has no wait states.

Figure 26-4 shows the register; Table 26-5 provides its field descriptions.

Offset 0x0000 (GPTCR) Access: User read/write

Figure 26-4. GPT Control Register

Table 26-5. Register Field Descriptions

Field	Description
31 FO3	Force output compare channel 3. The bit causes the pin action programmed for the timer output compare 3 pin (according to the bits OM3 in this register). The OF3 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect. 1 Causes pin action on timer output compare 3 pin, OF3 flag is not set
30 FO2	Force output compare channel 2. The bit causes the pin action programmed for the timer output compare 2 pin (according to the bits OM3 in this register). The OF2 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect 1 Causes pin action on timer output compare 2 pin, OF2 flag is not set
29 FO1	Force output compare channel 1. The bit causes the pin action programmed for the timer output compare 1pin (according to the bits OM1 in this register). The OF1 flag in the status register is not affected. This bit is self negating and always read as zero. 0 Writing a 0 has no effect 1 Causes pin action on timer output compare 1pin, OF1 flag is not set
28-26 OM3	Output compare channel 3 operating mode. This bit field specifies the response that a compare event generates on the output pin of output compare channel 3. The toggle, clear and set options cause a change in the output pin only on occurrence of a compare event. When OM3 is programmed as 1xx (active low pulse), the output pin is set to one, immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means clock selected by CLKSRC bits of GPT control register 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output

Table 26-5. Register Field Descriptions (Continued)

Field	Description
25-23 OM2	Output compare channel 2 operating mode. This bit field specifies the response that a compare event generates on the output pin of output compare channel 2. The toggle, clear and set options cause a change in the output pin only on occurrence of a compare event. When OM2 is programmed as 1xx (active low pulse), the output pin is set to one, immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means clock selected by CLKSRC bits of GPT Control Register. 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output
22-20 OM1	Output compare channel 1 operating mode. This bit field specifies the response that a compare event generates on the output pin of output compare channel 1. The toggle, clear, and set, options cause a change in the output pin only on occurrence of a compare event. When OM1 is programmed as 1xx (active low pulse), the output pin is set to one immediately on the next input clock, and the low pulse occurs when there is a compare event. This low pulse width is input clock wide. Here input clock means the clock selected by the CLKSRC bits of the GPT control register. 000 Output disconnected. No response on pin 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate a active low pulse of one input clock wide on output
19-18 IM2	Input capture channel 2 operating mode. This bit field determines the transition on the input pin for input capture channel 2 which triggers a capture event. 00 Capture disabled 01 Capture on rising edge only 10 Capture on falling edge only 11 Capture on both edges
17-16 IM1	Input capture channel 1 operating mode. This bit field determines the transition on the input pin for input capture channel 1 which triggers a capture event. 00 Capture disabled 01 Capture on rising edge only 10 Capture on falling edge only 11 Capture on both edges
15 SWR	Software reset. This is the software reset of the GPT module. It is a self clearing bit. This bit is set when the module is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their default reset values except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register. 0 GPT is not in reset state 1 GPT is in reset state
14-10 RESERVED	Reserved bits. These are reserved bits and writing a value does not affect the functionality of GPT. These reserved bits are always read as zero. It is recommended that all writes to these bits be 0 for forward compatibility.
9 FRR	Free-running or restart mode. This bit determines the behavior of the GPT on compare event in channel 1. In restart mode the counter resets to 0x0000_0000 and resumes counting after the occurrence of a compare event. In freerun mode, after a compare event the counter continues counting till 0xFFFF_FFFF and then rolls over to 0. 0 Restart mode 1 Freerun mode

Table 26-5. Register Field Descriptions (Continued)

Field	Description
8-6 CLKSRC	Clock source select. These bits selects which clock goes to the prescaler and subsequently be used to run the GPT counter. This bit field value should only be changed after disabling the GPT by clearing the EN bit in this register. For other programming requirements while changing clock source, see Section 26.7.1, "Change of Clock Source". 000 No clock 001 ipg_clk 010 ipg_clk_highfreq 011 ipp_ind_clkin (external clock from pad) 1xx ipg_clk_32k
5 STOPEN	GPT stop mode enable. This read/write control bit enables the operation of the GPT during stop mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 GPT is disabled in stop mode 1 GPT is enabled in stop mode
4 RESERVED	Reserved bit This is reserved bit and writing a value does not affect the functionality of GPT. Reading this bit returns the last written value.
3 WAITEN	GPT wait mode enable. This read/write control bit enables the operation of the GPT during wait mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 GPT is disabled in wait mode 1 GPT is enabled in wait mode
2 DBGEN	GPT debug mode enable. This read/write control bit enables the operation of the GPT during debug mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 GPT is disabled in debug mode 1 GPT is enabled in debug mode
1 ENMOD	GPT enable mode. When GPT is disabled (EN=0), then both main counter and prescaler counter freeze their current count values. ENMOD bit determines the value of GPT counter when EN bit is set and Counter is enabled again. If ENMOD bit is set, then both the main counter and prescaler counter value is reset to 0 on enabling GPT again (EN=1). If ENMOD bit is programmed to 0, then both the main counter & prescaler counter restart counting from their frozen values on enabling GPT again (EN=1). If GPT is programmed to be disabled in a low-power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when GPT enters low-power mode. When GPT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. Setting the SWR bit clears the counter value regardless of the value of EN or ENMOD bits. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 GPT counter retain its value when it is disabled 1 GPT counter value is reset to 0 when it is disabled
0 EN	GPT Enable. This bit is the module enable bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 GPT is disabled 1 GPT is enabled

26.5.2.2 GPT Prescaler Register (GPTPR)

The GPTPR contains bits that determine the divide value of the clock that runs the counter. Figure 26-5 shows the register; Table 26-6 provides its field descriptions.

Offset 0x0004 (GPTPR) Access: User read/write

Field	Description
31-12 RESERVED	Reserved bits. These are reserved bits and writing a value does not affect the functionality of GPT. These reserved bits are always read as zero.
11-0 PRESCALER	Prescaler bits. The clock selected by the CLKSRC field is divided by [PRESCALER + 1] and then used to run the counter. A change in the value of the PRESCALER bits result in Prescaler counter to reset & new count period to start immediately. See Figure 1-13.for timing diagram. 0x000 Divide by 1 0x001 Divide by 2 .... 0xFFF Divide by 4096

26.5.2.3 GPT Status Register (GPTSR)

The GPTSR contains bits that indicate the occurrence of rollover of the counter and any event on input capture and output compare channels. The bits are write one to clear.

Figure 26-6 shows the register; Table 26-7 provides its field descriptions.

Offset 0x0008 (GPTSR) Access: User read/write

Field	Description
31-6 RESERVED	Reserved bits. These are reserved bits and writing a value does not affect the functionality of GPT. These reserved bits are always read as zero.
5 ROV	Rollover Flag. This bit indicates that the counter has reached its maximum possible value and rolled over to 0 from which it continues counting. This bit is only set if the counter has reached 0xFFFF_FFFF in both restart and free-running modes. 0 Rollover not occurred 1 Rollover occurred
4 IF2	Input capture 2 flag. This bit indicates that a capture event has occurred on input capture channel 2. 0 Capture event not occurred 1 Capture event occurred
3 IF1	Input capture 1 flag. This bit indicates that a capture event has occurred on input capture channel 1. 0 Capture event not occurred 1 Capture event occurred
2 OF3	Output compare 3 flag. This bit indicates that a compare event has occurred on output compare channel 3. 0 Compare event not occurred 1 Compare event occurred
1 OF2	Output compare 2 flag. This bit indicates that a compare event has occurred on output compare channel 2. 0 Compare event not occurred 1 Compare event occurred
0 OF1	Output compare 1 flag. This bit indicates that a compare event has occurred on output compare channel 1. 0 Compare event not occurred 1 Compare event occurred

26.5.2.4 GPT Interrupt Register (GPTIR)

The GPTIR contains bits that control the generation of interrupt on rollover, input capture and output compare events.

Figure 26-7 shows the register; Table 26-8 provides its field descriptions.

Offset 0x000C (GPTIR) Access: User read/write

0 OF1IE	Output compare 1 interrupt enable. This bit controls the occurrence of output compare channel 1 interrupt. 0 Interrupt disabled 1 Interrupt enabled

26.5.2.5 GPT Output Compare Register 1 (GPTOCR1)

The GPTOCR1 holds the value that determines when a compare event is generated on output compare channel 1. Any write access to the compare register of channel 1 while in restart mode (FRR=0) results in the GPT counter being reset.

IP Bus Write access to GPTOCR1 results in one cycle of wait state (ips_xfr_wait high for 1 cycle), while IP Bus Read access is with 0 wait state.

Figure 26-8 shows the register; Table 26-9 provides its field descriptions.

Figure 26-13. GPT Counter Register

Table 26-14. Register Field Descriptions

Field	Description
31-0 COUNT	Counter value. These bits show the current count value in the counter register.

26.6 Functional Description

26.6.1 Operation

The EN bit of the GPT control register (GPTCR) enables the GPT's 32-bit free-running upcounter. When the EN bit is set to 1, the counter starts immediately: the counter's clock source is the output of the prescaler shown in Figure 26-1.

The STOPEN and WAITEN If GPT is programmed to be disabled in a low-power mode (stop or wait mode), then both the main counter and the prescaler counter freeze at their current count values when GPT enters the low-power mode. When GPT exits low-power mode, both main and prescaler counters start counting from their frozen values, irrespective of the ENMOD bit. GPTCNT can be read at any time by the processor. Both input capture channels use the same counter (GPTCNT).

The SWR bit in the GPTCR can be set to 1 to produce a software reset. All GPT register bits are reset except for EN, ENMOD, STOPEN, WAITEN and DBGEN bits, which are not affected by a software reset. A software reset can be invoked even when the GPT is disabled.

A hardware reset resets all the GPT registers to their respective reset values. All registers reset to 0 except for the output compare registers (GPTOCR1—GPTOCR2), which are reset to 0xFFFF_FFFF.

26.6.1.1 Clocks

The clock that feeds the prescaler can be selected from the following clock inputs.

- High-frequency reference clock (ipg_clk_highfreq)

  This clock is provided (and optionally gated) by the clock controller module (CCM). This clock should be available in low-power mode when the global functional clock (ipg_clk) is turned off. thus allowing the module to run using this clock in low-power mode. In normal mode, the CCM synchronizes this clock to the main high frequency bus clock (AHB clock) and switches to an unsynchronized version in low-power mode.

- Low-frequency reference clock (ipg_clk_32k)

  This 32 kHz clock is provided by the CCM. This clock should be available in low-power mode when the global functional clock is turned off, thus allowing the module to run using this clock in low-power mode. In normal mode, the CCM synchronizes this clock to the main high frequency bus clock (AHB clock) and switches to an unsynchronized version in low-power mode.

- Global functional clock (ipg_clk)

  This clock is typically used in normal operations. In low-power modes, if the module is programmed to be disabled (by clearing the STOPEN, or WAITEN bits), then the peripheral clock can be switched off.

- External clock (ipp_ind_clkin)

  This is the external clock from outside the chip which can be used to run the counter. This clock is treated as asynchronous to ipg_clk and synchronized to ipg_clk inside the module. Thus its frequency is limited to < 1/4 frequency of ipg_clk for proper functioning of the GPT. Also in low-power modes if ipg_clk is not available it cannot be used to run the counter.

The clock input source is determined by the clock source (CLKSRC) field in the control register. The clock input to the prescaler can also be disabled by programming the CLKSRC bits of control register to 000.

NOTE

The CLKSRC value should be changed only after disabling the GPT by clearing the EN bit in the GPTCR. For other programming requirements while changing clock source, see Section 26.7.1, “Change of Clock Source”.

The PRESCALER field is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by any value from 1–4096, and can be changed any time. A change in the value of the PRESCALER field is immediately reflected on its output clock frequency. Figure 26-14 shows the timing associated with a change in PRESCALER’s value

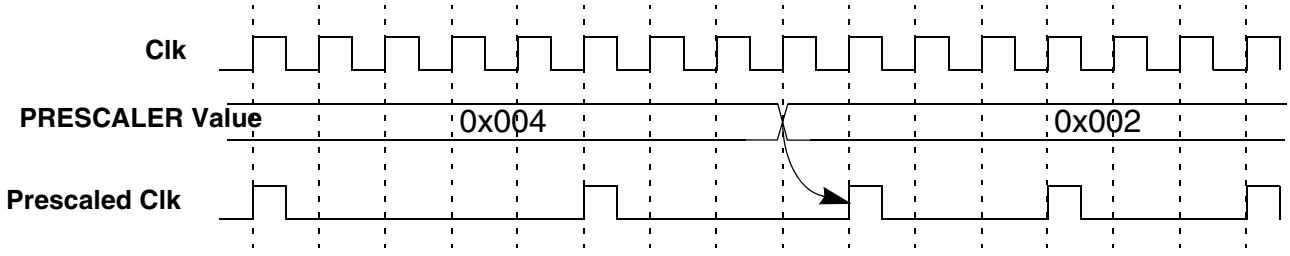

Figure 26-14. PRESCALER Value Change Timing

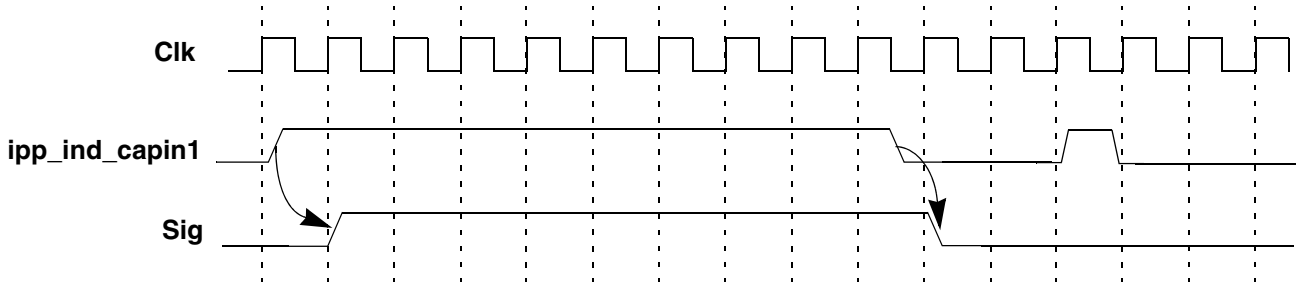
26.6.1.2 Input Capture

There are two input capture channels and each input capture channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request. When a selected edge transition occurs on an input capture pin, the contents of the GPTCNT is captured on the corresponding capture register and sets the appropriate interrupt status flag. An interrupt request can be generated when the transition is detected if its corresponding enable bit is set in the interrupt register. The capture can be programmed to occur on the input pin rising edge, falling edge, on both edges or can be disabled completely. The events are synchronized with the clock selected to run the counter. Only those transitions which occur at least a single clock cycle (clock selected to run the counter) after the previous recorded transition are guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in latching of the input transition. The input capture registers can be read at any time without affecting their values.



Clk - The clock selected from CLKSRC bit field setting
ipp_ind_capin1 - Pad signal for capture channel 1
Sig - Capture signal as sensed by the module

Figure 26-15. Input Capture Event Timing Diagram

26.6.1.3 Output Compare

The three output compare channels use the same counter (GPTCNT) as the input capture channels. When the programmed content of an output compare register matches the value in GPTCNT, an output compare status flag is set and an interrupt is generated if the corresponding bit is set in the interrupt register. Consequently, the output compare timer pin is set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (this is subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits programmed. There also exists a forced-compare feature allowing the software to generate compare event when required without the condition of the counter value being equal to the compare value. The action taken as a result of a forced compare is the same as when an output compare match occurs, except that the status flags are not set and no interrupt can be generated. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

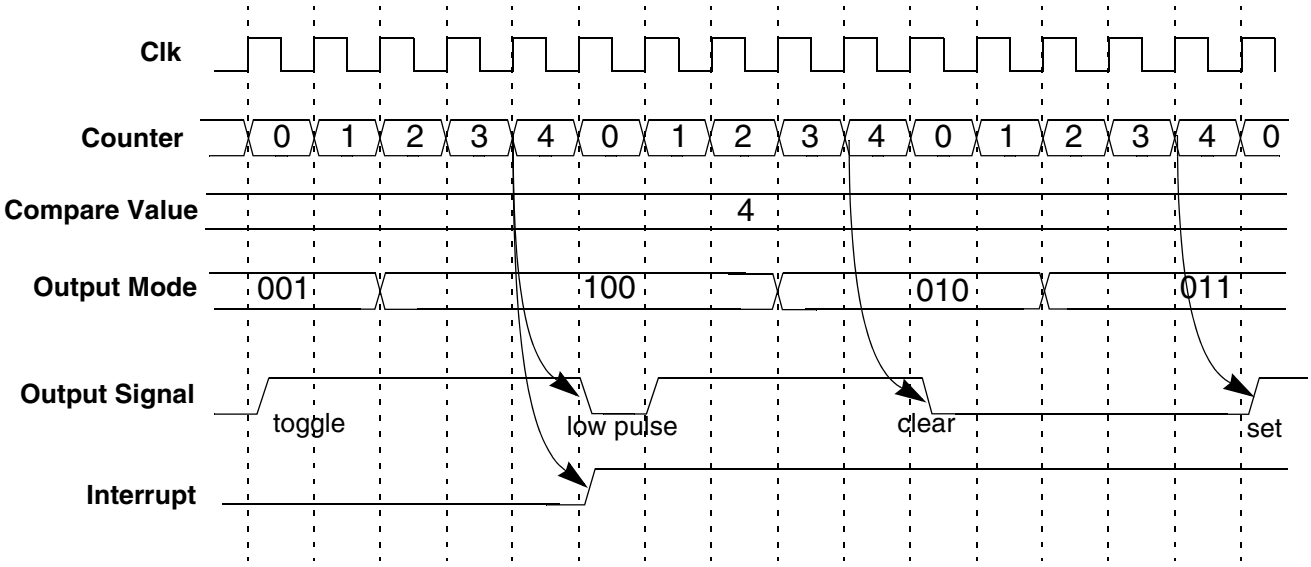


Figure 26-16. Output Compare and Interrupt Timing Diagram

26.6.1.4 Interrupts

The GPT can generate six different interrupts. All interrupts can be generated in low-power and debug modes if the selected clock for running the counter is available.

- Rollover interrupt

  This interrupt is generated when the GPT counter reaches 0xFFFF_FFFF and resets to 0x0000_0000 and continues counting. The interrupt is enabled by the ROVIE bit in GPTIR and its associated status bit is ROV bit in GPTSR.

- Input capture interrupts (1,2)

  On occurrence of a capture event, interrupts can be generated by each input capture channel. These interrupts are enabled by IF2IE and IF1IE bits in GPTIR, and their associated status bits are IF2 and IF1 in GPTSR register. The capture of the counter value due to a capture event is not affected by a pending capture interrupt. The capture register is updated with the new counter value on occurrence of capture event irrespective of whether that capture channel's interrupt has been serviced or not.

- Output compare interrupts (1,2,3)

  On occurrence of a compare event, interrupts can be generated by each output compare channel. These interrupts are enabled by the OF3IE, OF2IE and OF1IE bits in GPTIR and their associated status bits are OF3, OF2 and OF1 in GPTSR. No interrupt is generated due to a forced compare.

A cumulative interrupt line is also present which is asserted whenever any of the above interrupts are posted. This has no associated enable or status bits.

26.6.1.5 Low-Power Mode Behavior

In low-power modes (stop mode and wait mode) the counter continues to run if the clock from the selected clock source is available (except for ipp_ind_clkin, which can be used only if ipg_clk is available), and if

the control bit for that mode is set. Otherwise the main counter and the prescaler counter freeze at their current values and resume counting from their frozen values when the low-power mode is exited.

26.6.1.6 Debug Mode Behavior

In debug mode, if the DBGEN bit in GPTCR is cleared, then the GPT timer is halted. If the DBGEN bit is set, then the GPT timer continues to run in debug mode.

26.7 Initialization/ Application Information

26.7.1 Change of Clock Source

the CLKSRC field in GPTCR determines the clock source. This field value should be changed only after disabling the GPT (EN=0). Below is the software sequence to be followed when changing clock source.

1. Disable GPT by setting EN=0 in GPTCR.
2. Disable GPT interrupt register (GPTIR).
3. Program OM3,OM2,OM1 to 00 in GPTCR.
4. Change clock source CLKSRC to desired value in GPTCR.
5. Clear the GPT status register (GPTSR) by writing 1’s.
6. Enable GPT interrupt register (GPTIR).
7. Set ENMOD=1 in GPTCR, to bring GPT counter to 0x0000_0000.
8. ENABLE GPT (EN=1) in GPTCR.

Chapter 27
Graphics Processing Unit (GPU)

27.1 Overview

This block guide describes key architectural features of the graphics processing unit (GPU) as well as details of the OpenVG IP customizing and integration in the SoC.

The GPU is an embedded 2D and vector graphics accelerator targeting the OpenVG 1.1 graphics API and feature set. It accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations using a separate 2D graphics acceleration unit. Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer, which is connected to the 2D graphics acceleration unit. The core has a rich, but well-chosen set of features, with emphasis being on very high image quality and low memory bandwidth consumption.

The GPU top level block diagram is presented at Figure 27-1.

27.2 GPU Feature List

The following sections describe the functional features of the graphics processor.

27.2.1 Frame Buffer

- Frame buffer sizes supported up to 2048 x 2048
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888 frame buffer modes
- Configurable ARGB order in frame buffer: ARGB, BGRA, ABGR, RGBA
- Linear and block-based (4x4 pixels) frame buffer modes
- Fast buffer clears
- Support for OpenVG render to Image

27.2.2 2D Bitmap Graphics (Separate 2D Unit)

- BitBlt (surface-to-surface copy)
  - Format conversion from monochrome/ARGB/YUV to ARGB during BitBlt
- Block fill
- Internal 32-bit color precision
- Source bitmap format:
  - 1/4/8-bit monochrome
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888

  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
  - Packed YUV 4:2:2 formats (FOURCC codes YUY2, UYVY, YVYU), two pixels per 32 bits of data
  - 1-bit bitmap maps to foreground and background colors
  - 4-bit bitmap is optionally gamma corrected to 8-bit alpha values and can be combined with foreground color to draw anti-aliased fonts
- Destination bitmap format:
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888, B8, A8, AB88
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Supports three source bitmaps for separate mask/pattern/alpha bitmap support plus reading destination for ROP, blend and color key operations
- Supports masking source coordinates for wrapping patterns
- Supports ROP4 (ROP3 with separate ROPs for masked and unmasked pixels) logical operations
- Supports inverting mask and alpha values from source
- Supports destination rotation by 0/90/180/270 degrees
- Supports programmable blending with optional alpha un-premultiply
- Supports per pixel and constant alpha with optional modulation by source color alpha for OpenVG alpha masking
- Supports color keying by source and destination colors, with optional ignoring of alpha channel
- Supports one scissor rectangle for destination coordinates
- Dithering (ordered)
- Color component masking
- sRGB reads and writes
- Non-power of two source and destination bitmap sizes supported (stride must be a multiple of 32-bits)

27.2.3 Vector graphics

- Rasterization of convex and concave polygons with anti-aliasing
- Efficient native polygon rendering (no tessellation to triangles)
- Non-zero and odd-even fill rules
- Primitives supported:
  - Polygons
  - OpenVG path primitives (except Elliptical Arcs): Horizontal/vertical lines, generic lines, curves, smooth curves, moveto, path closing
  - Curve types supported: cubic and quadratic Bézier
  - Strokes with thickness, joints and end caps, unlimited stroke thickness
  - Special case handling of singularities for thick strokes
  - Supports paths with a maximum of 256 crossings along a horizontal or a vertical line

- Input coordinates:
  - Absolute and relative coordinate input in floating point
  - Fixed-point (byte, short, int) and floating-point coordinate input - 0.8, 0.16, 16.16 formats
  - Little- and Big-endian support separately selectable for command stream and data.
- Geometry
  - User to surface transform for vertices and stroke shape
  - Hardware curve tessellation
  - Adjustable accuracy for curve and round cap splitting
  - OpenVG/SVG join types: Miter (with miter limit), round, bevel
  - OpenVG/SVG cap types: Butt, round, square
- Pixel processing:
  - - Programmable gradient and texturing processor
  - Linear and radial gradients (with focal point)
  - Perspective texture mapping with filtering
  - Two textures supported
  - sRGB and pre-multiply support for textures
  - 16-sample anti-aliasing
  - 4x RGSS AA (Rotated Grid Super Sample)
  - Per-pixel alpha-masking
  - Maximum texture size: 1024x1024 pixels
- Vector graphics rendering system CPU load:
  - Display list generation during path creation-commands and vertices are stored to an internal format/buffer, no format conversion is performed
  - Filling or stroking a path only requires a few register writes to start the operation in hardware
  - Display lists are transferred to the vector graphics rasterizer using DMA without CPU interaction

27.3 GPU2D Block Diagram

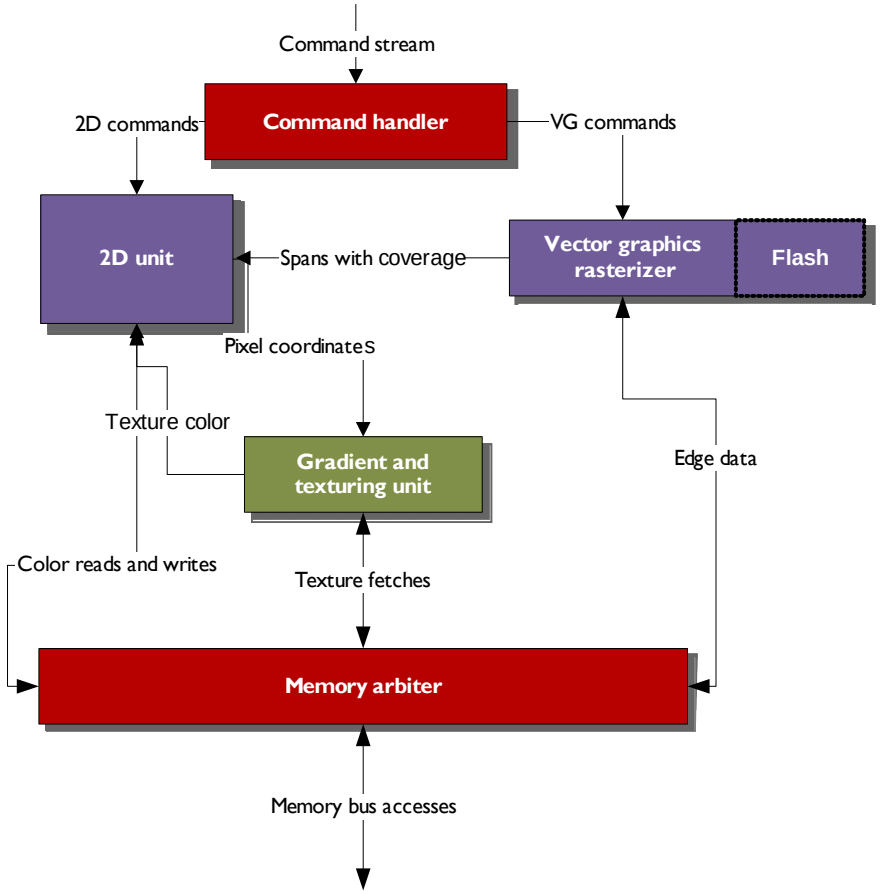

Figure 27-1. GPU Top Level Block Diagram

27.4 GPU SoC Interface

27.4.1 GPU SoC Integration Top Level Diagram

Figure 27-2 shows the method of connecting the GPU in the i.MX35.

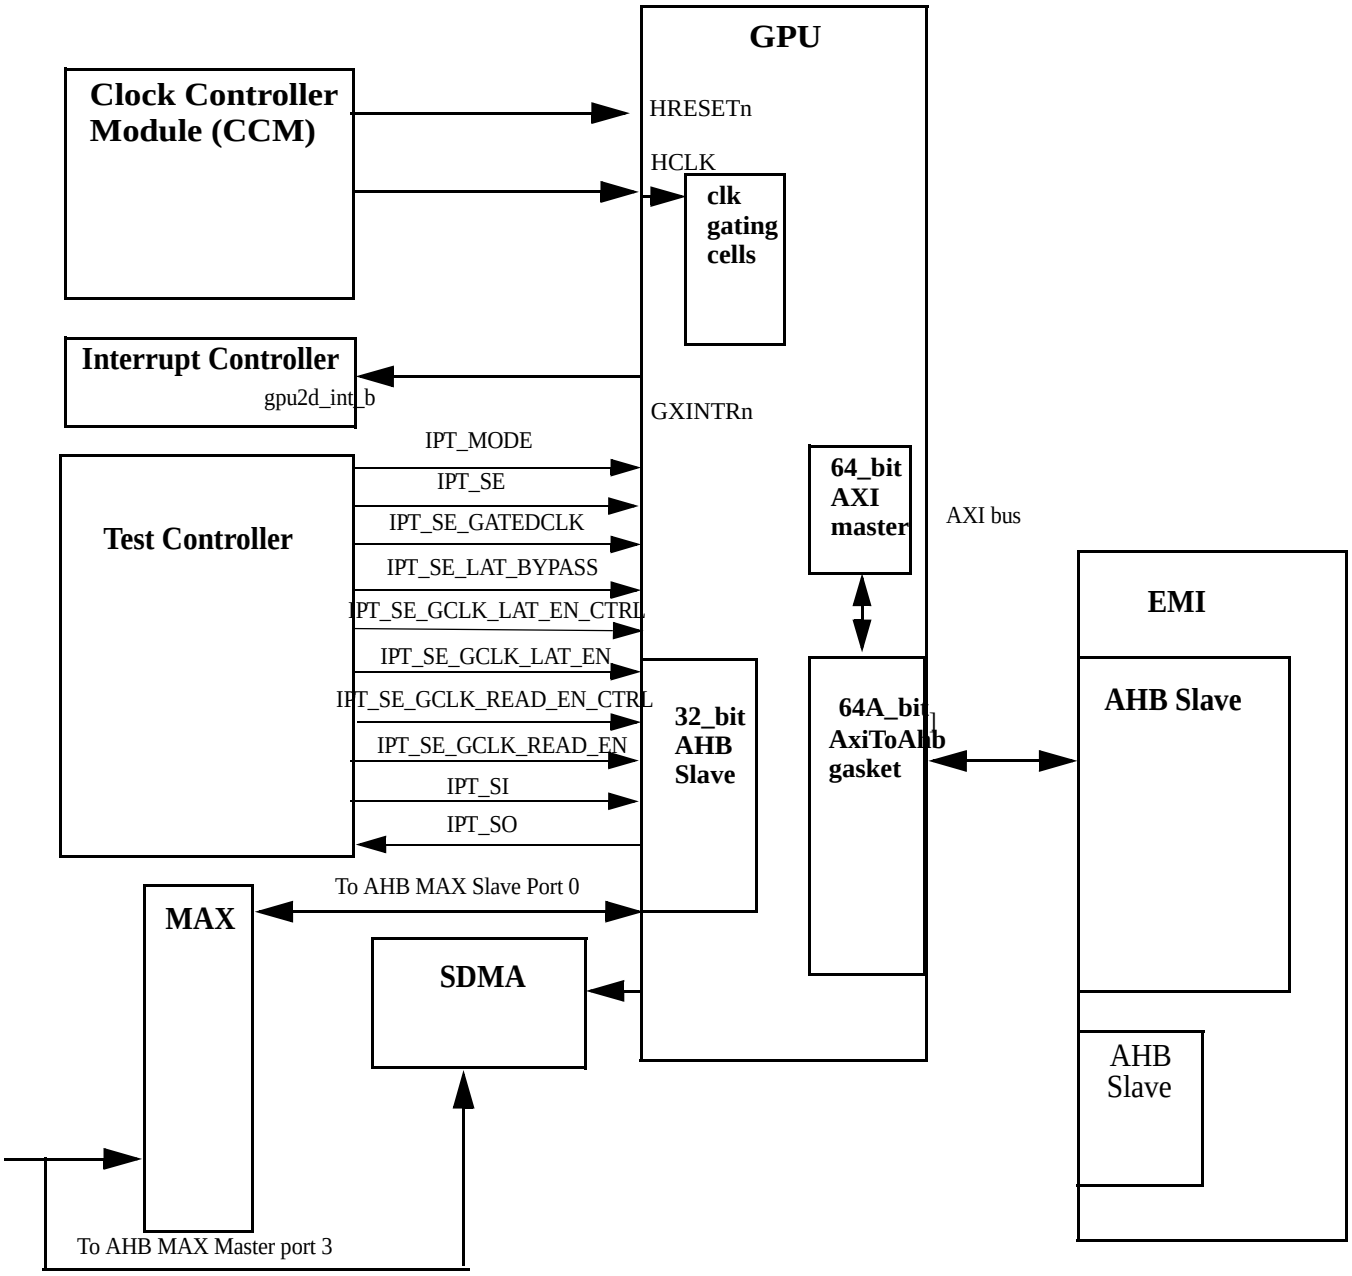

Figure 27-2. GPU System Connectivity

27.4.2 SoC Bus Connection

The GPU has the following two bus interfaces in SoC:

- 32_bit AHB slave bus.

  This port is connected to ARM, it allows access to the control registers and is the command stream input to the GPU. The AHB interface is a fully compatible ARM AMBA AHB bus interface. It has been designed to be compatible with Rev 2.0 of the AMBA specification and it implements the Retry capable Slave part of the specification

- 64_bit AHB master bus

  The external memory master bus is a standard 64_bit AMBA AHB master bus. The GPU memory master port is a 64_bit AXI bus, and there is an AxiTOAhb gasket between the GPU and the EMI. This gasket is located inside the GPU.

27.4.3 AXI to AHB Gasket

A simple parameterized gasket from ARM.

27.5 Clocking Architecture

There is one clock input to the GPU, HCLK, generated in the clock control module. It is not recommend to gate HCLK in run mode.

27.6 Modes of Operation

The GPU supports

- 2D bitmap acceleration mode
- Vector graphic acceleration mode
- Low power mode

27.7 Interrupts

The GPU generates several individual interrupts internally. Each interrupt can be enabled or disabled by changing its own enable bit. Setting the enable bit HIGH enables the corresponding interrupt. The interrupts from all sources in the GPU are combined (ORed) and output as the active LOW gpu2d_int_b interrupt.

27.8 DMA

27.9 Memory Map

The GPU memory map is described in the following sections:

- AHB slave interface
- AHB master memory interface (EMI port).

27.9.1 AHB Slave Interface

Table 27-1 shows the memory map for the AHB Slave Interface port of the GPU. This is based on the GPU occupying slave port 0 of the crossbar.

Table 27-1. GPU Memory Map

Description	Memory Address Base	Memory Address End
Registers	0x2000 0000	0x20000F00

27.9.2 AHB Master Memory Interface (EMI Port)

The GPU can access memory with or without a memory management unit (MMU):

Translation is performed using a table with 8-Kbyte entries, one for each 4-Kbyte page in a 32-Mbyte linear address space.

Chapter 28
Inter IC Module (I2C)

This chapter describes module-level operation and programming of the I^2C module. The chapter is intended for a module driver software developer. To understand how the module is integrated at the SoC level, a system software developer can refer to discussions of the module in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following reference:

1. Philips I^2C Bus Specification, Version 2.1

28.1 Overview

The Inter IC (I^2C) module provides functionality of a standard I^2C slave and master. The I^2C module is designed to be compatible with the standard Philips I^2C bus protocol.

I^2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I^2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in Figure 28-1.

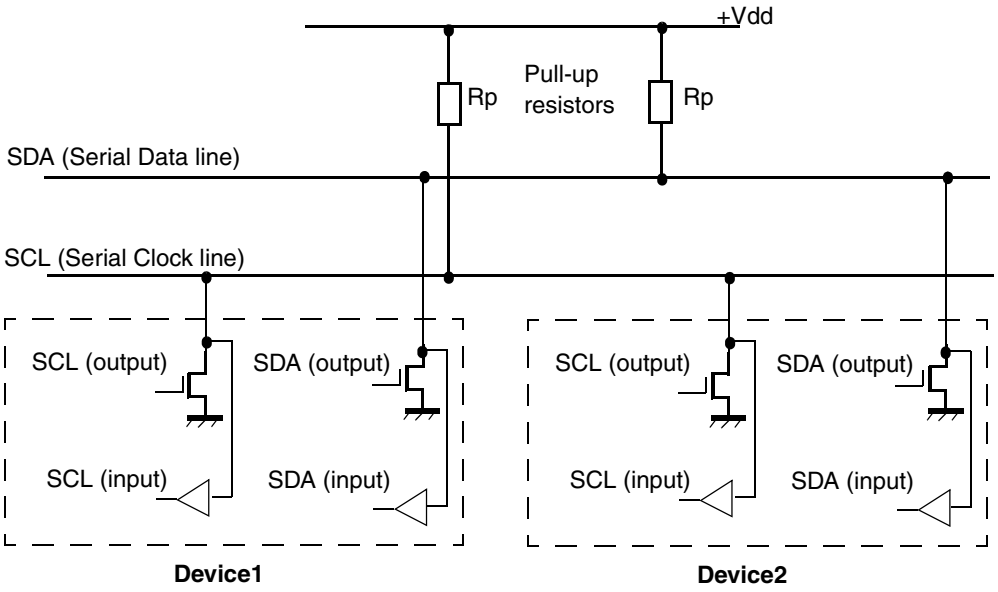

Figure 28-1. Connection of Devices to I^2C Bus

The I^2C interface operates up to 400 Kbps, but it depends on the pin loading and timing characteristics. For pin requirement details, see Philips I^2C Bus Specification, Version 2.1. The I^2C system is a true

multiple-master bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. Figure 28-2 shows the block diagram of I^{2}C module.

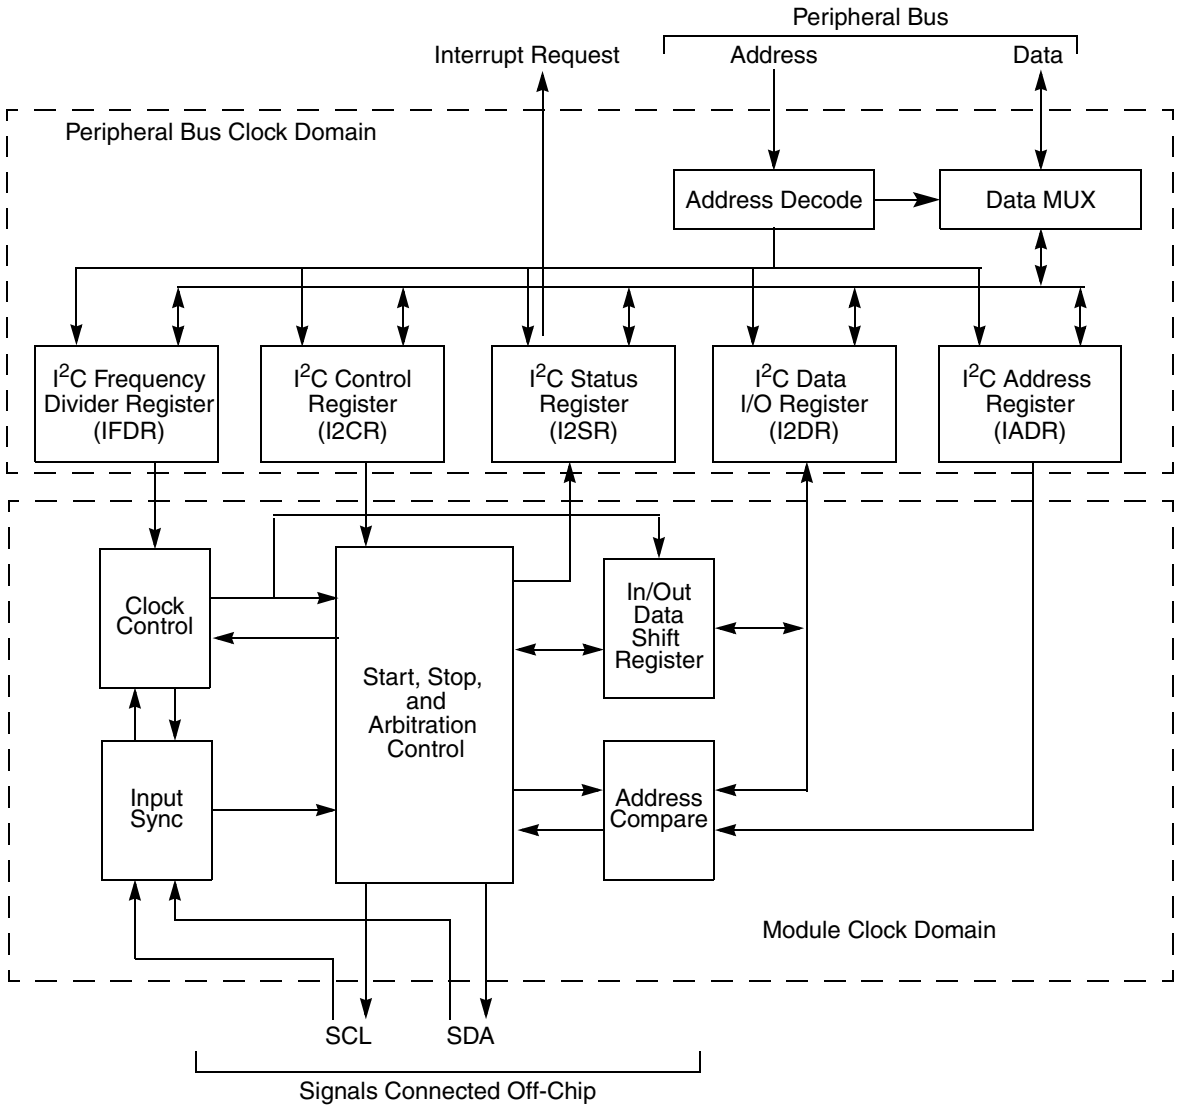

Figure 28-2. I^{2}C Block Diagram

28.1.1 Features

The I^2C module has the following key features:

- Compatibility with I^2C bus standard
- Multiple-master operation
- Software-programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated START signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

28.1.2 Modes and Operations

The I^2C module primarily operates in two different functional modes.

28.1.2.1 Standard Mode

In Standard mode, I^2C module supports the data transfer rates up to 100 Kbits/s.

28.1.2.2 Fast Mode

In Fast Mode, data transfer rates up to 400 Kbits/s can be achieved.

As per module operation, there is no special configuration required for Fast and Standard mode. It is the data transfer rate which distinguishes Standard and Fast mode.

28.2 External Signals

Table 28-1 describes all I2C signals that connect off-chip.

For I^2C compliance, all devices connected to the SCL and SDA signals must have open-drain or open-collector outputs. The logic AND function is exercised on both lines with external pull-up resistors.

NOTE

The reset state values and pull-up/down requirements provided in Table 28-1 are from the module-level perspective. To understand how the module is integrated at the SoC level, the system software developer must see discussions of the module in the appropriate SoC-level chapter(s). For example, a module signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

Table 28-1. Off-Chip Module Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down
SCL	I/O	Serial Clock	1	Active
SDA	I/O	Serial Data	1	Active

1 The reset state values and pull-up/down requirements provided in this table are from the module-level perspective. To understand how the module is integrated at the SoC level, the system software developer must see discussions of the module in the appropriate SoC-level chapter(s). For example, a module signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

28.3 Memory Map and Register Definition

The I^2C module contains five 16-bit registers. Section 28.3.3, "Register Descriptions" provides the detailed descriptions for all of the I^2C registers.

28.3.1 Memory Map

Table 28-2 is the module memory map. For the base address of a particular module instantiation, see the system memory map.

Table 28-2. Module Memory Map

Base Address Offset	Register	Access	Reset Value	Section/Page
General Registers				
0x0000 (IADR)	I^2C Address Register	R/W	0x0000	28.3.3.1/28-6
0x0004 (IFDR)	I^2C Frequency Divider Register	R/W	0x0000	28.3.3.2/28-6
0x0008 (I2CR)	I^2C Control Register	R/W	0x0000	28.3.3.3/28-7
0x000C (I2SR)	I^2C Status Register	R/W	0x0081	28.3.3.4/28-8
0x0010 (I2DR)	I^2C Data I/O Register	R/W	0x0000	28.3.3.5/28-10

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

28.3.2 Register Summary

Table 28-3 is the register summary table.

Table 28-3. Module Register Summary

Base Address Offset (Register Abbreviation)		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0000 (IADR)	R	0	0	0	0	0	0	0	0	ADR							0

28.3.3 Register Descriptions

This section provides detailed descriptions of the module's registers.

Register conventions: Figure 28-3 and Table 28-4 explain conventions used in register diagrams and tables.

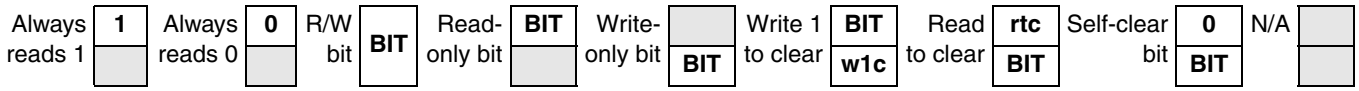

Figure 28-3. Register Field Conventions

Table 28-4. General Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
BIT	Bit or field name. Its presence in the read or write row indicates that it can correspondingly be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
rtc	Read to clear. A read-only status bit that is automatically cleared when read.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero. (Previously designated slfclr)
Reset Values	
0	Resets to 0 (zero).

Table 28-4. General Register Conventions (Continued)

Convention	Description
1	Resets to 1 (one).
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

28.3.3.1 I²C Address Register (IADR)

Figure 28-4 shows the I²C address register. Table 28-5 describes the register fields.

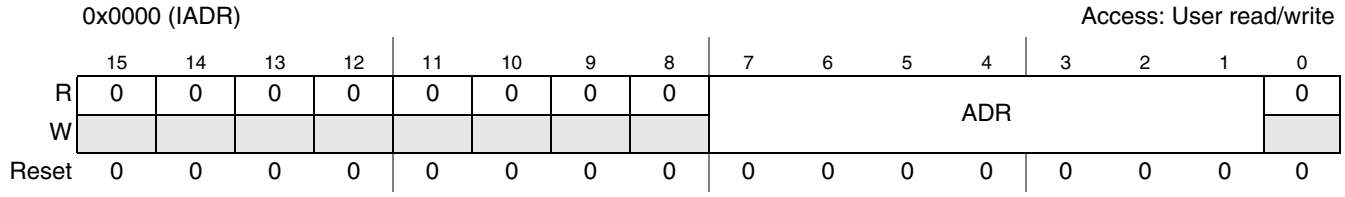

Figure 28-4. I²C Address Register

Table 28-5. I²C Address Register Field Descriptions

Field	Description
15–8	Reserved
7–1 ADR	Slave address. Contains the specific slave address to be used by the I²C module. Slave mode is the default I²C mode for an address match on the bus. **Note:** The IADR holds the address the I²C responds to when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0	Reserved

28.3.3.2 I²C Frequency Register (IFDR)

The IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by software reset. Figure 28-5 shows the I²C Frequency Register. Table 28-6 describes the register fields.

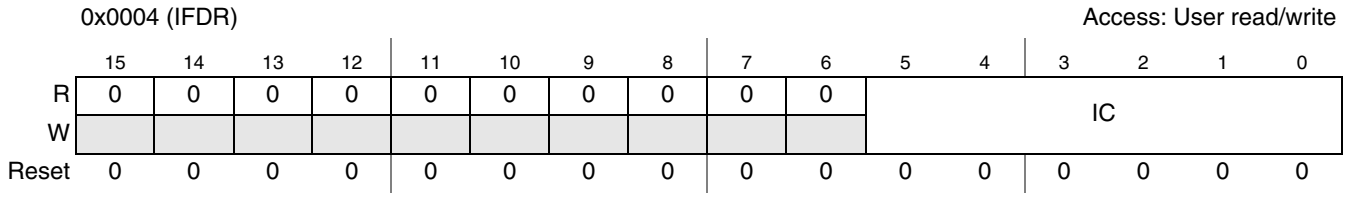

Figure 28-5. I²C Frequency Register

Table 28-6. I²C Frequency Register Field Descriptions

Field	Description
15–6	Reserved
5–0 IC	I²C clock rate. Pre scales the clock for bit-rate selection. Due to potentially slow SCL and SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency is equal to Module Clock divided by the divider shown in Table 28-7. **Note:** The IC value should not be changed during the data transfer, however, it can be changed before REPEAT START or START programming sequence in I²C module. The I²C protocol supports bit rates up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

Table 28-7. IFDR Register Field Values

IC	Divider	IC	Divider	IC	Divider	IC	Divider
0x00	30	0x10	288	0x20	22	0x30	160
0x01	32	0x11	320	0x21	24	0x31	192

0x0F	240	0x1F	3840	0x2F	128	0x3F	2048

28.3.3.3 I²C Control Register (I2CR)

The I2CR is used to enable the I²C module and the I²C interrupt. It also contains bits that govern operation as a slave or a master. Figure 28-6 shows the I²C control register. Table 28-8 describes the register fields.

0x0008 (I2CR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	IEN	IIEN	MSTA	MTX	TXAK	0	0	0
W														RSTA		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 28-6. I²C Control Register

Table 28-8. I²C Control Register Field Descriptions

Field	Description
15–8	Reserved
7 IEN	I²C enable. Also controls the software reset of the entire I²C module. Resetting the bit generates an internal reset to the module. If the module is enabled in the middle of a byte transfer, slave mode ignores the current bus transfer and starts operating when the next start condition is detected. Master mode is not aware that the bus is busy; so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I²C module to lose arbitration. After which, bus operation returns to normal. 0 The module is disabled, but registers can still be accessed. 1 The I²C module is enabled. This bit must be set before any other I2CR bits have any effect.
6 IIEN	I²C interrupt enable. 0 I²C module interrupts are disabled, but the status flag I2SR[IIF] continues to be set when an interrupt condition occurs. 1 I²C module interrupts are enabled. An I²C interrupt occurs if I2SR[IIF] is also set.
5 MSTA	Master/slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a STOP signal. **Note:** Module clock should be on for writing to the MSTA bit. 0 Slave mode. Changing MSTA from 1 to 0 generates a STOP and selects slave mode. **Note:** The MSTA bit is cleared by software to generate a STOP condition; it can also be cleared by hardware when the I²C loses the bus arbitration. 1 Master mode. Changing MSTA from 0 to 1 signals a START on the bus and selects master mode.
4 MTX	Transmit/receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I²C status register (I2SR[SRW]). 1 Transmit. In master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto SDA during acknowledge cycles for both master and slave receivers. **Note:** Writing TXAK applies only when the I²C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a repeated START condition
1–0	Reserved

28.3.3.4 I²C Status Register (I2SR)

The I2SR contains bits that indicate transaction direction and status. Figure 28-7 shows the I²C status register. Table 28-9 describes the register fields.

0x000C (I2SR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1

Figure 28-7. I²C Status Register

Table 28-9. I²C Status Register Field Descriptions

Field	Description
15–8	Reserved
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer. **Note:** If data is written during the START condition, that is, just after setting the I2CR[MSTA] and I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after START. If data is written after the START condition and falling edge of SCLK, then ICF bit is cleared as soon as data is written.
6 IAAS	I²C addressed as a slave bit. The CPU is interrupted if the interrupt enable (I2CR[IIEN]) is set. The CPU must check the slave read/write bit (SRW) and set its TX/RX mode accordingly. Writing to I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (IADR) matches the calling address.
5 IBB	I²C bus busy bit. Indicates the status of the bus. 0 Bus is idle. If a STOP signal is detected, IBB is cleared. 1 Bus is busy. When START is detected, IBB is set. **Note:** When I²C is enabled (I2CR[IEN] = 1), it continuously polls the bus data (SDAK) and clock (SCLK) signals to determine a START or STOP condition.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a “0” to it at the start of the interrupt service routine): • SDA input sampled low when the master drives high during an address or data-transmit cycle. • SDA input sampled low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of 9th SCL clock during the ACK cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. **Note:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.
3	Reserved
2 SRW	Slave read/write. When the I²C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I²C module is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave

Table 28-9. I²C Status Register Field Descriptions (Continued)

Field	Description
1 IIF	I²C interrupt. Must be cleared by the software by writing a “0” to it in the interrupt routine. **Note:** The software cannot set the bit. 0 No I²C interrupt pending. 1 An interrupt is pending. This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in slave-receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received of the SDA input for the acknowledge bit during a bus cycle. 0 An “acknowledge” signal was received after the completion of an 8-bit data transmission on the bus. 1 A “No acknowledge” signal was detected at the ninth clock.

28.3.3.5 I²C Data Register (I2DR)

In master-receive mode, reading the data register (I2DR) allows a read to occur and initiates the next byte to be received. In slave mode, the same function is available after it is addressed. Figure 28-8 shows the I²C data register. Table 28-10 describes the register fields.

0x0010 (I2DR) Access: User read/write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	DATA							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 28-8. I²C Data Register

Table 28-10. I²C Data Register Field Descriptions

Field	Description
15–8	Reserved
7–0 DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **Note:** The core-written value in I2DR cannot be read back by the core: Only data written by the I²C bus side can be read.

28.4 Functional Description

This section includes information on the following:

28.4.1 I^2C System Configuration

Out of a reset, the I^2C module defaults to slave receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I^2C module will default to the slave receiver state. For exceptions, see Section 28.5.1, “Initialization Sequence.”

NOTE

The I^2C module is designed to be compatible with the Philips I^2C bus protocol. For information on system configuration, protocol, and restrictions, see the I^2C Bus Specification, Version 2.1. The I^2C module supports Standard and Fast modes only.

28.4.2 I^2C Protocol

The I^2C communication protocol consists of six components, as follows:

- START
- Data Source/Recipient
- Data Direction
- Slave Acknowledge
- Data Acknowledge
- STOP

See Figure 28-9 for the I^2C standard communication protocol, as defined in the following sections.

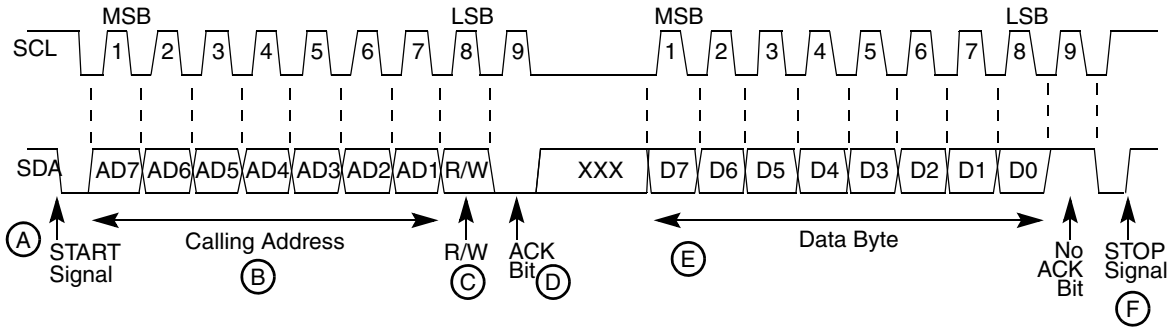

Figure 28-9. I²C Standard Communication Protocol

28.4.2.1 START Signal

When no other device is a bus master (both SCL and SDA lines are at logic high), a device can initiate communication by sending a START signal (see A in Figure 28-9). A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a data transfer (each data transfer can be several bytes long) and awakens all slaves.

28.4.2.2 Slave Address Transmission

The master sends the slave address in the first byte after the START signal (B). After the seven-bit calling address, it sends the R/W bit (C), which tells the slave data transfer direction.

Each slave must have a unique address. An I²C master must not transmit an address that is the same as its slave address; it cannot be master and slave at the same time.

The slave whose address matches that sent by the master pulls SDA low at the ninth clock (D) to return an acknowledge bit.

28.4.2.3 Data Transfer

When successful slave addressing is achieved, the data transfer can proceed (E) on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master.

Data can be changed only while SCL is low and must be held stable while SCL is high, as shown in Figure 28-9. SCL is pulsed once for each data bit, most-significant bit first. The receiving device must acknowledge each byte by pulling SDA low at the ninth clock; therefore, a data byte transfer takes nine clock pulses.

If it does not acknowledge the master, the slave receiver must leave SDA high. The master can then generate a STOP signal to abort the data transfer or generate a START signal (a repeated start, as shown in Figure 28-10) to start a new calling sequence.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means end-of-data to the slave. The slave releases SDA for the master to generate a STOP or START signal.

NOTE

Writing to the data register triggers transmit operation.

Transmit data should always be written after MTX bit is programmed. Transmit data is not latched inside until the transfer is initiated on the interface bus.

After the transmit data write in I^2C, software can either wait for a transfer-done interrupt or it can poll for ICF bit for zero, if new data has to be written during the previous data transfer. The IIF bit may not be polled if the IIEN bit is set because the I^2C will generate an interrupt when IIF is set.

28.4.2.4 STOP Signal

The master can terminate communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is at logical high (F).

NOTE

A master can generate a STOP even if the slave has made an acknowledgment; at which point, the slave must release the bus.

28.4.2.5 Repeat Start

Instead of signalling a STOP, the master can repeat the START signal, followed by a calling command (see A in Figure 28-10). A repeated START occurs when a START signal is generated without first generating a STOP signal to end the communication. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

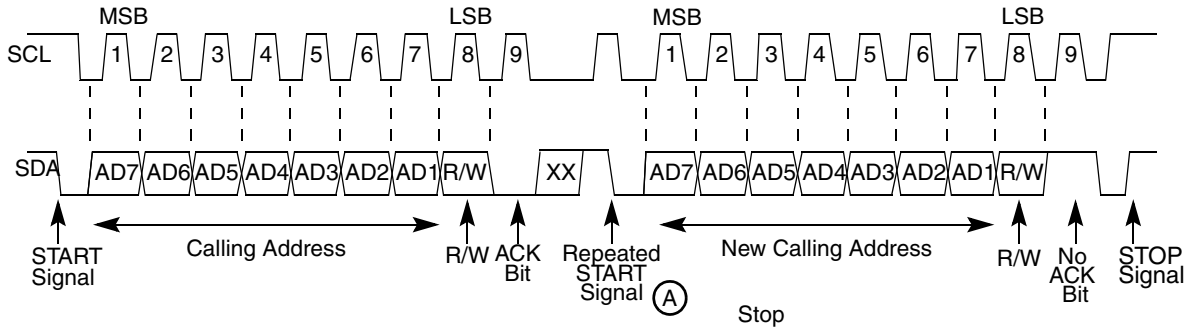

Figure 28-10. Repeated START

28.4.3 Arbitration Procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices. A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to slave-receive mode and stops driving SDA. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets the IAL bit in the I^2C Status register (I2SR) to indicate loss of arbitration.

28.4.4 Clock Synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the clock high state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low. Devices with shorter low periods enter a high wait state during this time (see Figure 28-11). When all devices involved have counted off their low period, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

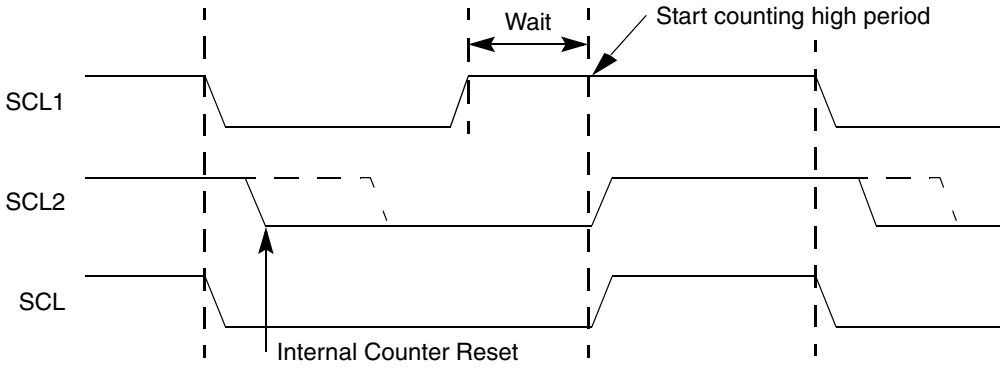

Figure 28-11. Synchronized Clock SCL

28.4.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a wait state until the slave releases SCL.

28.4.6 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

28.4.7 Peripheral Bus Accesses

I^2C is a 16-bit module. Only half-word accesses should be performed to the module.

28.4.8 Generation of Transfer Error on IP Bus

If an address is received on the Peripheral slave bus interface that is not implemented, an access error is generated.

28.4.9 Clocks

There are two input clocks for I^2C module.

- Peripheral Clock—The clock is used for peripheral bus register read/writes.
- Module Clock—This is the functional clock of the I^2C module. The serial bit clock frequency is derived from the module clock.The module clock and peripheral clocks are synchronous to each other. The minimum frequency of module clock should be 12.8 MHz for fast mode to achieve 400 Kbps operation.

28.4.10 Reset

The I^2C module can be reset in two ways.

- Global reset: A hard asynchronous reset of the whole I^2C module.
- Software reset: An internal reset for whole I^2C module, except IADR and IFDR registers, is initiated by deasserting the I2CR[IEN] bit.

28.4.11 Interrupts

There is only one interrupt from the module. The interrupt is enabled by setting the I2CR[IIEN] bit. The interrupt is generated in any one of the following conditions.

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in slave-receive mode.
- Arbitration is lost.

28.4.12 Byte Order

The module only supports the little endian mode.

28.5 Initialization

This section includes information on the following:

28.5.1 Initialization Sequence

Before the interface can transfer serial data, registers must be initialized, as follows:

1. Set the data sampling rate (IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I^2C enable bit (I2CR[IEN]) to enable the I^2C bus interface system.
4. Modify the bits in the I^2CR to select master/slave mode, transmit/receive mode, and interrupt-enable or not.

28.5.2 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the master transmitter mode. On a multiple-master bus system, the busy bus (I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the START signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a STOP and the next START condition is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy (which indicates the data register can be written) after writing the calling address to the data register (I2DR) before proceeding to load data into the data register (I2DR).

28.5.3 Post-Transfer Software Response

Sending or receiving a byte sets the data transferring bit (I2SR[ICF]), which indicates one byte communication is finished. Upon completion, the interrupt status (I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2CR[IIEN]) is set. The software must first clear the interrupt status (I2SR[IIF]) in the interrupt routine. (See the flowchart in Figure 28-13.) The data transferring bit (I2SR[ICF]) is cleared either by reading from I2DR in receive mode or by writing to this register in transmit mode.

Software can service the I^2C I/O in the main program by monitoring the interrupt status (I2SR[IIF]) if the interrupt enable is negated. In this case, the interrupt status of the data transferring bit (I2SR[ICF]) should be polled, because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in transmit mode; that is, the address is sent. If master receive mode is required, then I2CR[MTX] should be toggled and dummy read of I2DR register has to be done for triggering receive data.

During slave-mode address cycles (I2SR[IAAS] = 1), the slave read/write bit I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2CR[MTX]) should also be programmed accordingly. For slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

28.5.4 Generation of STOP

A data transfer ends when the master signals a STOP, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a STOP signal must be generated.

28.5.5 Generation of Repeated START

After the data transfer, if the master still wants the bus, it can signal another START followed by another slave address without signalling a STOP.

28.5.6 Slave Mode

In the slave interrupt service routine (see Figure 28-13), the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (I2CR[MTX]) according to the I2SR[SRW]. Writing to the I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2DR for slave transmits, or read from I2DR in slave-receive mode. A dummy read of I2DR in slave/receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch from transmitter to receiver mode. Reading the data register (I2DR) then releases SCL so that the master can generate a STOP signal.

28.5.7 Arbitration Lost

When several devices try to engage the bus at the same time, only one becomes master. Hardware immediately switches devices that lose arbitration to slave receive mode. Data output to SDA stops, but SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2SR[IAL] = 1), and the slave mode is selected (I2CR[MSTA] = 0). See the flowchart in Figure 28-13.

If a device that is not a master tries to transmit or do a START, hardware inhibits the transmission, clears MSTA without signalling a STOP, generates an interrupt to the CPU, and sets I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2SR[IAL], and the software should clear it if it is set.

For multi-master mode, when an I^2C module is enabled when the bus is busy and asserts START, the I2SR[IAL] bit gets set only for SDA=0, SCL=0/1, SDA=1, and SCL=0, but not for SDA=1 and SCA=1, which is the same as bus idle state.

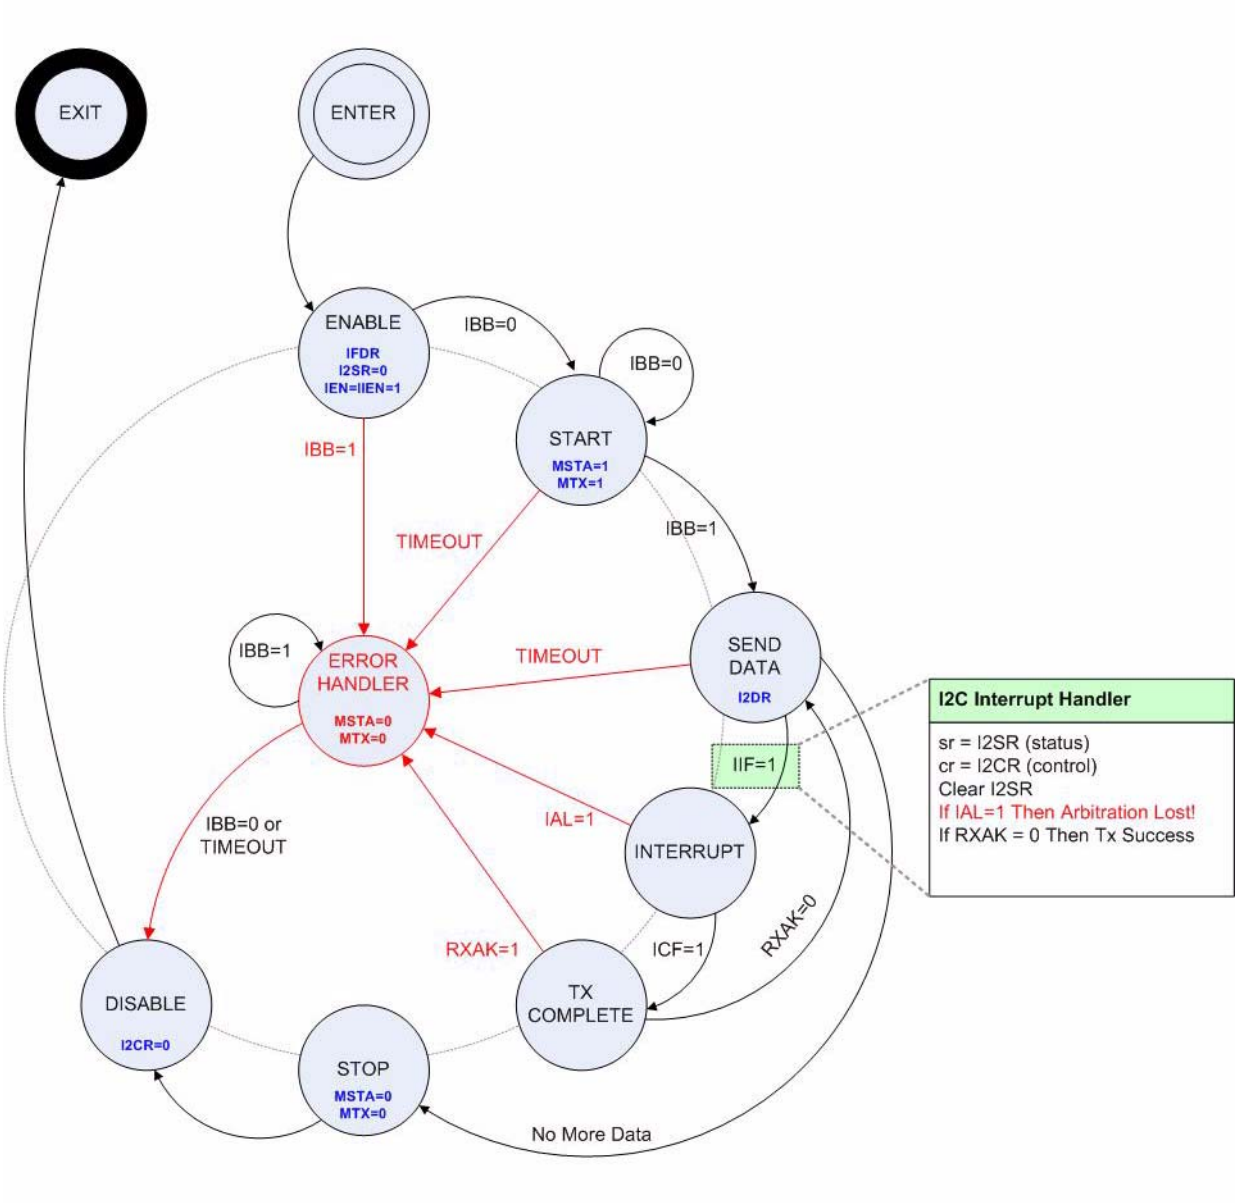

Figure 28-12. I²C Programming State Diagram

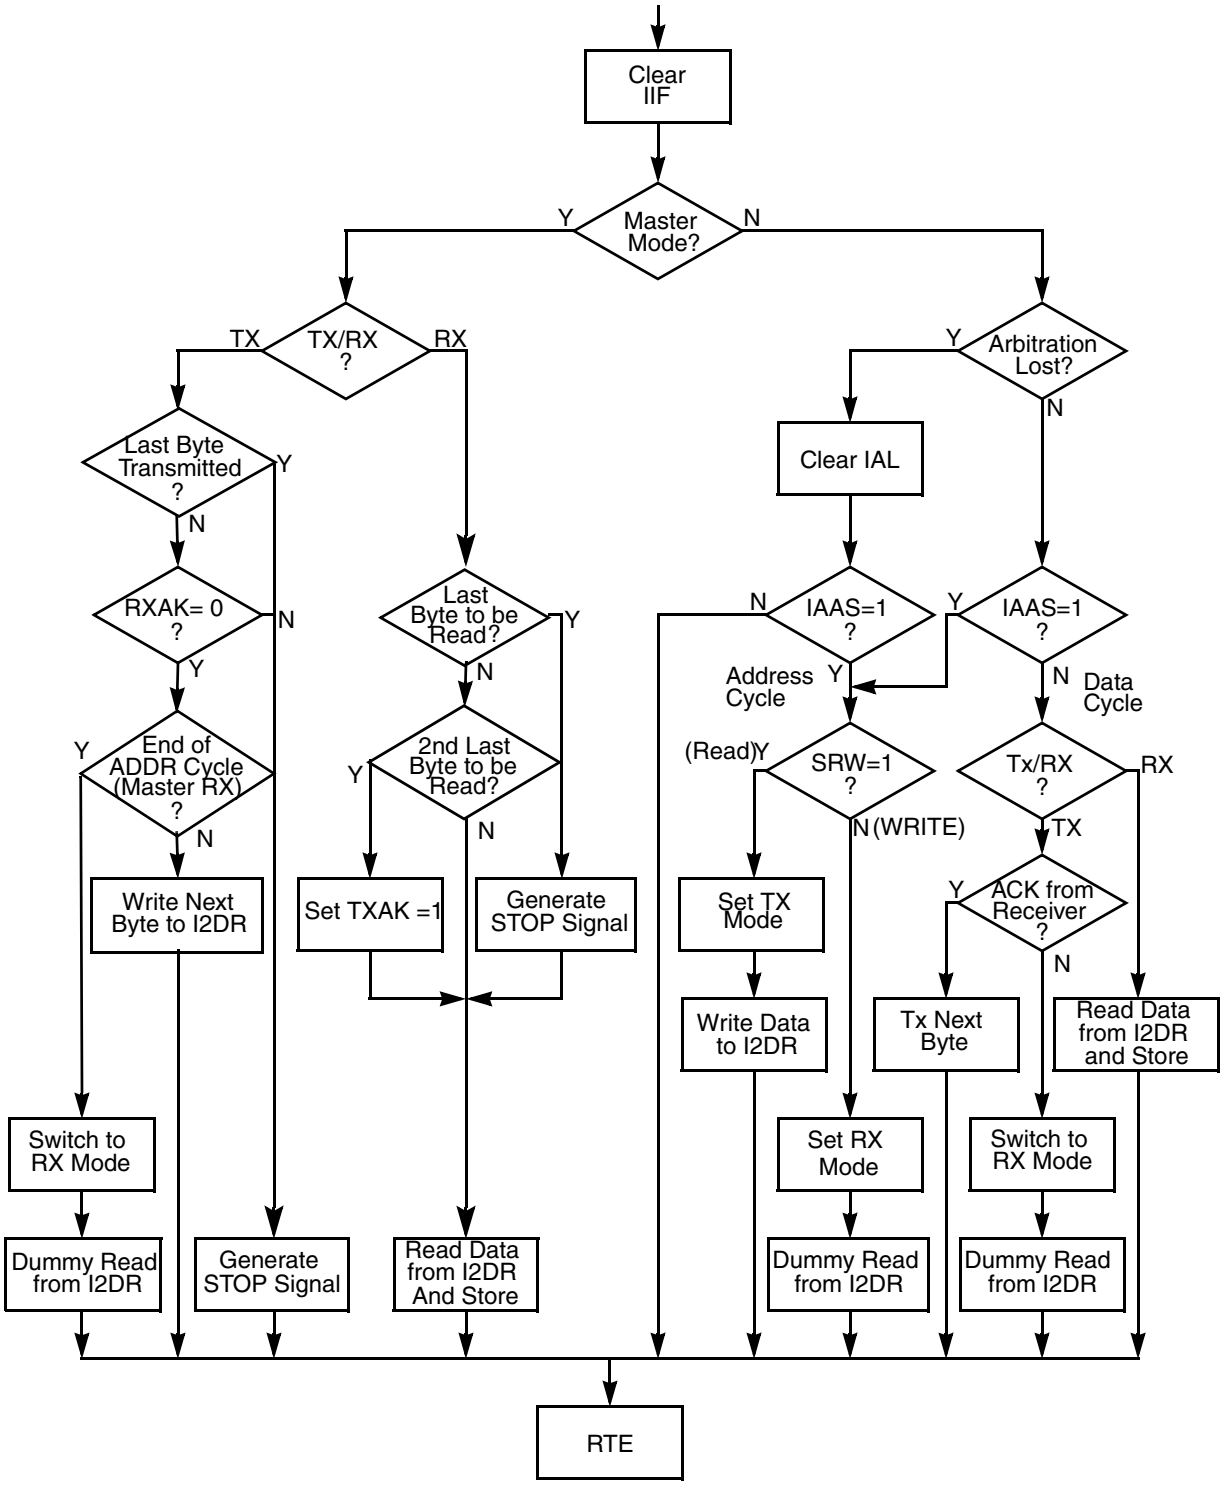

Figure 28-13. Flowchart for a Typical I²C Interrupt Routine

NOTE

For a repeated start-only, the stop generation stage will not occur in master mode. A loop will repeat itself without stopping for the next start.

For master Rx mode, I^2C is programmed as master transmit during address mode and after slave address transfer, MTX bit should be cleared and a dummy read on I2DR register should be performed so that I^2C can read the next receive data.

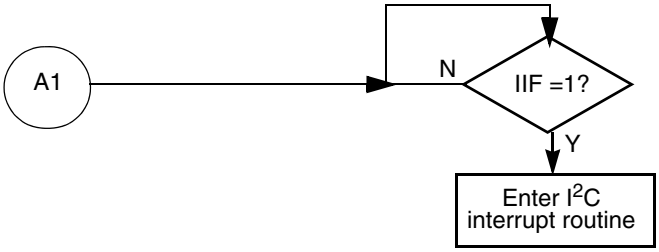

Figure 28-14. Flowchart for Typical I^2C Polling Routine

NOTE

The timeout value will depend on the bus frequency at which I^2C is operating. The Min. Timeout for polling IIF bit at I^2C Max bus frequency of 400KHz is, T_{min} = 25 μs (= 2.5*10 μs). This value can be interpolated for any bus frequency.

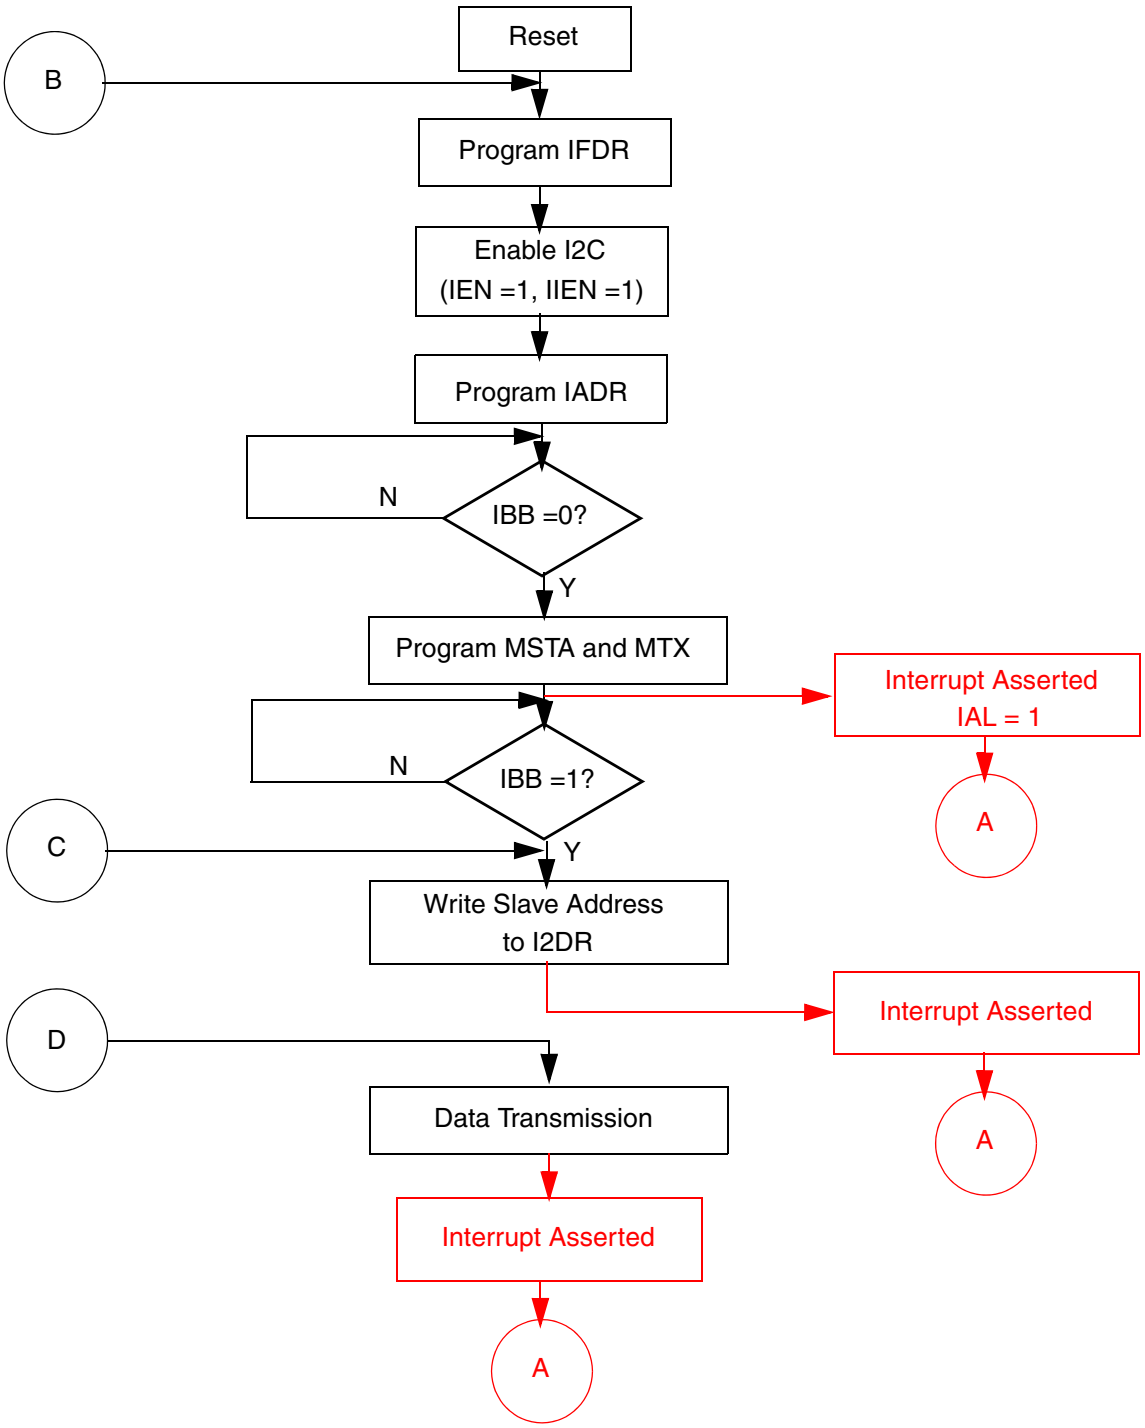

Figure 28-15. Detailed Flowchart of a Typical I^2C Master Tx Mode, Part 1

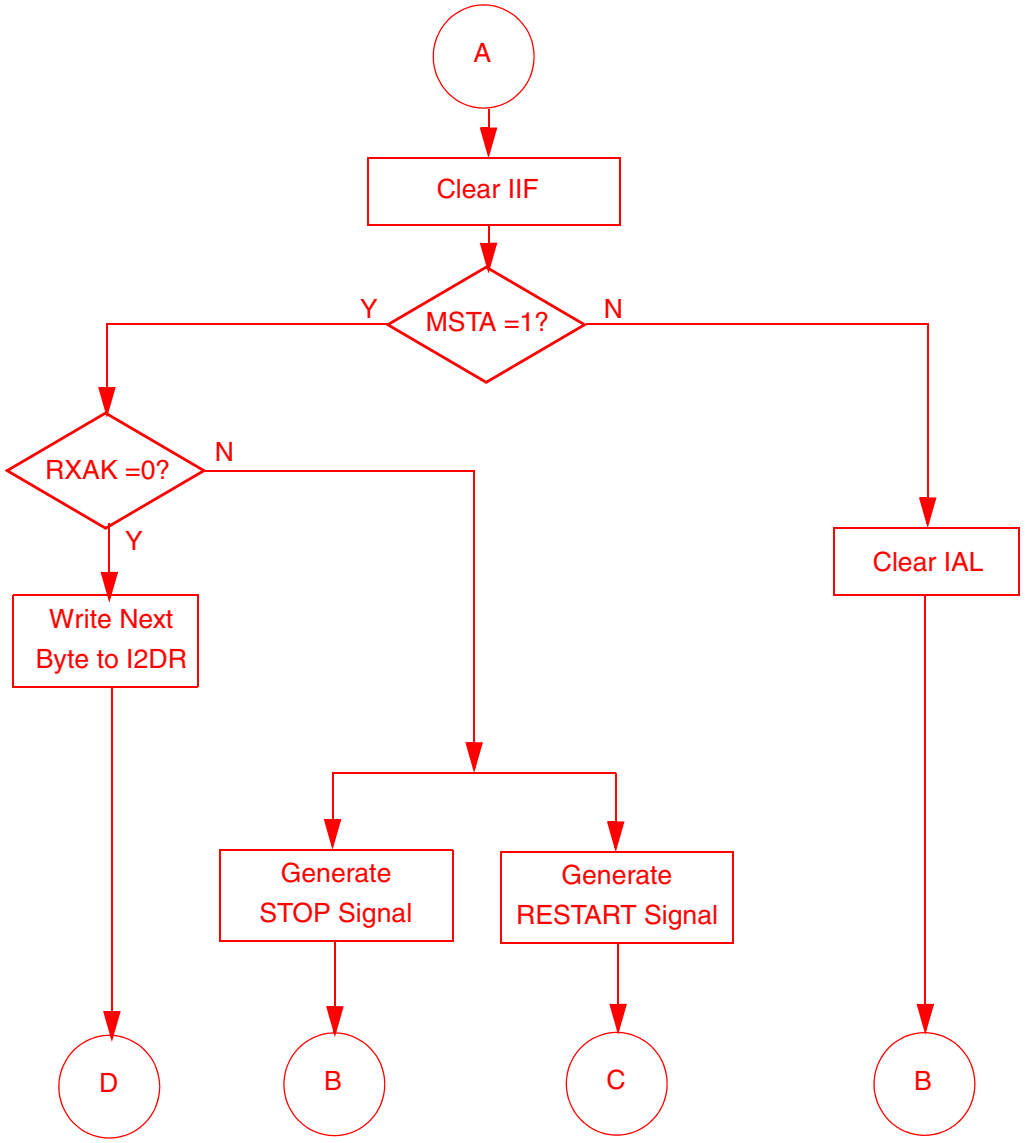

Figure 28-16. Detailed Flowchart of a Typical I^2C Master Tx Mode, Part 2

Figure 28-15 and Figure 28-16 show the master transmit mode operation with interrupt subroutine.

If an interrupt is generated while the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can then clear the IAL bit and reprogram the I^2C module.

An interrupt generated while MSTA bit is 1 is a transfer-done interrupt. Software can check the RXAK bit for data receive acknowledgement by the slave. If the RXAK bit is cleared, then software can generate STOP or RESTART by writing in I2CR register. Otherwise, the next data byte can be written to the I2DR register.

NOTE

The IBB bit is asserted by START condition on the bus, and it is negated by STOP condition on bus. Therefore, if arbitration is lost due to an unexpected STOP condition during transfer, then IBB is cleared. If arbitration is lost due to data mismatch, then it will not be cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

28.6 Software Restriction

Software should take care that there is a delay of at least two module clock cycles after it sets the I2CR[RSTA] bit before writing to the I2DR register. Maximum possible clock period of module clock is 78 ns.

Chapter 29
IC Identification Module (IIM)

The IC identification module (IIM) provides an interface for reading and in some cases programming or overriding identification and control information stored in on-chip fuse elements. The module supports laser fuses (L-Fuses) and/or electrically-programmable poly-fuses (eFuses).

The IIM also provides a set of volatile software-accessible signals which can be used for software control of hardware elements, not requiring non-volatility.

29.1 Overview

The IIM provides the primary user-visible mechanism for interfacing with on-chip fuse elements. Among the uses for the fuses are unique chip identifiers, mask revision numbers, cryptographic keys, and various control signals requiring permanent non-volatility. The IIM also provides up to 28 volatile control signals and the means to generate a second 168-bit SCC key.

The IIM consists of a master controller, a software fuse value shadow cache, and a set of registers to hold the values of signals visible outside the module. Up to eight arrays of fuses (laser fuses and/or eFuses) are associated with the IIM, but are instantiated outside it.

The IIM is accessible using an 8-bit IP bus interface. An 8-bit interface is used because it matches the natural width of the fuse arrays. All registers are 32-bit aligned, to allow the module to be instantiated on IP buses supporting only 32-bit peripherals. A subset of fuses, as well as the software-controlled volatile signals, are capable of driving top-level nets within the SoC. These signals are referred to in the following as hardware-visible signals. These signals are intended for feature enabling and disabling and similar uses within the device.

Laser fuses are only blowable during chip manufacturing (at the wafer level). The eFuses may be blown under software or JTAG control during IC final test, at the customer factory or in the field. They include a mechanism to inhibit further blowing of fuses (write-protect), to support secure computing environments. The fuse values may also be overridden by software without modifying the fuse element. Similar to the write-protect functionality, the override functionality can also be permanently disabled. Fuse banks may also be scan-inhibited on a per-bank basis to prevent reading and programming of fuses through the JTAG interface.

The design is flexible to allow a seamless transition (that is, no software changes) from laser fuses to eFuses.

The fuses are divided into banks, with specific intended uses assigned to each bank.

29.1.1 Features

- Up to eight independent fuse banks (number of fuse bank and size of the bank are parameterized)
- Maximum usable fuse bank size is 2048 bits
- Laser- and eFuse banks may be intermixed on a per-bank basis
- Support for driving secure JTAG challenge & response values to the SJC (size of each field configurable using RTL parameter; challenge default size is 64 bits, response default size is 56 bits)
- Up to 28 externally-visible software-controlled volatile signals (driving SoC-level nets for feature enabling), lockable in groups of 7
- Ability to provide up to two distinct 168-bit 3DES keys from a single set of fuses
- Ability to override fuse values in software (does not affect the fuse element); override capability can be permanently disabled on a per-bank basis
- Ability to write-protect eFuses on a per-bank basis
- Ability to scan-protect (read and program) on a per-bank basis
- Fuses may be programmed by software, directly by JTAG, or indirectly by JTAG using a processor
- Recommended signal assignments to maximize software reuse.

29.1.2 Modes of Operation

The IIM is in its functional mode (all specified functionality available) any time it is out of reset and supplied with the proper clocks.

29.2 External Signal Description

The IIM has no external signals.

29.3 Memory Map and Register Definition

Section 29.3.3, “Register Descriptions,” provides the detailed register descriptions for all of the IIM registers.

29.3.1 Memory Map

For the base address of a particular module instantiation, see the system memory map. Table 29-1 shows the memory map for the IIM registers.

Table 29-1. IIM Memory Map

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0000 (STAT)	Status register	R/W	0x– –	29.3.3.1/29-6
0x0004 (STATM)	Status IRQ Mask register	R/W	0x00	29.3.3.2/29-7
0x0008 (ERR)	Module Errors register	R/W	0x– –	29.3.3.3/29-7
0x000C (EMASK)	Error IRQ Mask register	R/W	0x– –	29.3.3.4/29-9

Table 29-1. IIM Memory Map (continued)

Base Address Offset (Register Abbreviation)	Register	Access	Reset Value	Section/Page
0x0010 (FCTL)	Fuse Control register	R/W	0x30	29.3.3.5/29-9
0x0014 (UA)	Upper Address register	R/W	0x– 0	29.3.3.6/29-10
0x0018 (LA)	Lower Address register	R/W	0x00	29.3.3.7/29-12
0x001C (SDAT)	Explicit Sense Data register	read-only	0x00	29.3.3.8/29-12
0x0020 (PREV)	Product Revision register	read-only	0x82	29.3.3.9/29-13

29.3.2 Register Summary

Figure 29-1 shows the key to the register fields, and Table 29-1 shows the register figure conventions.

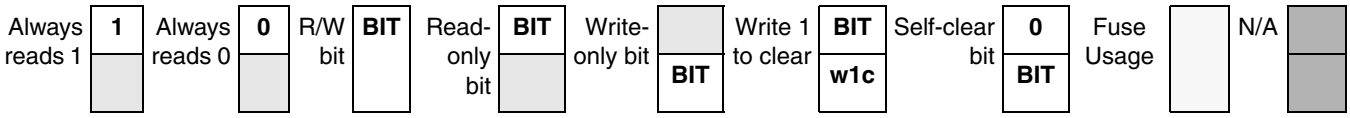

Figure 29-1. Key to Register Fields

Table 29-2. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	

Table 29-2. Register Figure Conventions (continued)

Convention	Description
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 29-2 shows the IIM register summary.

29.3.3 Register Descriptions

This section contains the detailed register descriptions for the IIM registers.

29.3.3.1 Status Register (STAT)

All module status information is read using the STAT register.

See Figure 29-3 for an illustration of the Status Register and Table 29-3 for a description of the bit fields.

Offset 0x0000 (STAT) Access: Supervisor read-only

	7	6	5	4	3	2	1	0
R	BUSY						PRGD	SNSD
W							w1c	w1c
Reset	0	0	—	—	—	—	—	0

Figure 29-3. Status Register

Table 29-3. Status Register Field Descriptions

Field	Description
7 BUSY	Indicates whether the IIM is busy with a program or sense cycle. Any attempt to access the IIM registers other than STAT while it is busy with a program or sense cycle (BUSY asserted) results in a bus error. 0 The IIM is not busy with a program or sense cycle 1 The IIM is busy with a program or sense cycle
6–2	Reserved
1 PRGD	Program Done. Indicates an eFuse program operation is done. Assertion causes an interrupt request (irq_b signal asserted) if PRGD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware upon completion of an eFuse program cycle; software must clear the bit by writing 1 to it. 0 Program operation has not finished (read); no meaning (write) 1 Program operation has finished (read); clear bit (write)
0 SNSD	Explicit Sense Cycle Done. Indicates that an explicit fuse sense cycle is done, and the data is available in SDAT. Assertion causes an interrupt request if SNSD_M is set in the Status IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 No explicit sense cycle has finished (read); no meaning (write) 1 An explicit sense cycle has finished (read); clear bit (write)

29.3.3.2 Status IRQ Mask Register (STATM)

The STATM register enables or disables IRQ generation from PRGD or SNSD events. See Figure 29-4 for an illustration of the Status IRQ Mask Register and Table 29-4 for a description of the bit fields.

Offset 0x0004 (STATM) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R							PRGD_M	SNSD_M
W								
Reset	0	0	0	0	0	0	0	0

Figure 29-4. Status IRQ Mask Register

Table 29-4. Status IRQ Mask Register Field Descriptions

Field	Description
7–2	Reserved
1 PRGD_M	Program Mask. Masks or unmasks IRQ generation due to PRGD events. 0 PRGD events do not cause an IRQ 1 PRGD events cause an IRQ
0 SNSD_M	Explicit Sense Cycle Done Mask. Masks or unmasks IRQ generation due to SNSD events. 0 SNSD events do not cause an IRQ 1 SNSD events cause an IRQ

29.3.3.3 Module Errors Register (ERR)

The ERR register displays the error status for various errors. See Figure 29-5 for an illustration of the Module Errors Register, and Table 29-5 for a description of the bit fields.

Offset 0x0008 (ERR) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R	PRGE	WPE	OPE	RPE	WLRE	SNSE	PARITYE	
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	
Reset	0	0	0	0	0	0	—	u

Figure 29-5. Module Errors Register

Table 29-5. Module Errors Register Field Descriptions

Field	Description
7 PRGE	Program Error. Indicates an eFuse program operation ended in failure. Assertion causes an interrupt request if PRGE_M is set in the Errors IRQ Mask Register. A program failure occurs when an attempt is made to program laser fuses. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 Program operation has not finished with error (read); no meaning (write) 1 Program operation has finished with an error (read); clear bit (write)
6 WPE	Write Protect Error. Indicates an eFuse program operation was attempted to a write-protected fuse bank, or a locked words, or when the value of PRG_P is not 8'hAA. Assertion causes an interrupt request if WPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-protect error (read); no meaning (write) 1 There was a write-protect error (read); clear bit (write)
5 OPE	Override Protect Error. Indicates an attempt was made to override the values in an override-protected fuse bank, or a locked words. Assertion causes an interrupt request if OPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no override-protect error (read); no meaning (write) 1 There was an override-protect error (read); clear bit (write)
4 RPE	Read Protect Error. Indicates an attempt was made to read values from a read-protected fuse bank or SCC. Assertion causes an interrupt request if RPE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no read-protect error (read); no meaning (write) 1 There was a read-protect error (read); clear bit (write)
3 WLRE	Write to Locked Register Error. Indicates an attempt was made to write to a locked SCS register. Assertion causes an interrupt request if WLRE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no write-to-locked-register error (read); no meaning (write) 1 There was a write-to-locked-register error (read); clear bit (write)
2 SNSE	Explicit Sense Cycle Error. Indicates that an explicit fuse sense was refused, because FBESP is set to 1, or more than two bits of SNS_N, SNS_1, SNS_0, PRG are asserted at the same moment. Assertion causes an interrupt request if SNSE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no explicit sense error (read); no meaning (write) 1 There was an explicit sense error (read); clear bit (write)
1 PARITYE	Cache Parity Error. Indicates that an parity error was detected in hardware fuse cache or software fuse cache. Assertion causes an interrupt request if PARITYE_M is set in the Errors IRQ Mask Register. This bit is automatically set by hardware and must be cleared by software by writing 1 to it. 0 There was no cache parity error (read); no meaning (write) 1 There was a cache parity error (read); clear bit (write)
0	Reserved

29.3.3.4 Error IRQ Mask Register (EMASK)

See Figure 29-6 for an illustration of the Error IRQ Mask Register and Table 29-6 for a description of the bit fields.

Offset 0x000C (EMASK) Access: Supervisor read/write

	7	6	5	4	3	2	1	0

Figure 29-6. Error IRQ Mask Register

Table 29-6. Error IRQ Mask Register Field Descriptions

Field	Description
7 PRGE_M	Program Error Mask. Masks or unmasks IRQ generation due to PRGE events. 0 PRGE events do not cause an IRQ 1 PRGE events cause an IRQ
6 WPE_M	Write Protect Error Mask. Masks or unmasks IRQ generation due to WPE events. 0 WPE events do not cause an IRQ 1 WPE events cause an IRQ
5 OPE_M	Override Protect Error Mask. Masks or unmasks IRQ generation due to OPE events. 0 OPE events do not cause an IRQ 1 OPE events cause an IRQ
4 RPE_M	Read Protect Error Mask. Masks or unmasks IRQ generation due to RPE events. 0 RPE events do not cause an IRQ 1 RPE events cause an IRQ
3 WLRE_M	Write to Locked Register Error Mask. Masks or unmasks IRQ generation due to WLRE events. 0 WLRE events do not cause an IRQ 1 WLRE events cause an IRQ
2 SNSE_M	Explicit Sense Cycle Error Mask. Masks or unmasks IRQ generation due to SNSE events. 0 SNSE events do not cause an IRQ 1 SNSE events cause an IRQ
1 PARITYE_M	Parity Error of Cache Mask. Masks or unmasks IRQ generation due to PARITYE events. 0 PARITYE events do not cause an IRQ 1 PARITYE events cause an IRQ
0	Reserved

29.3.3.5 Fuse Control Register (FCTL)

The FCTL register is used to program control functions. See Figure 29-7 for an illustration of the FCTL Register and Table 29-7 for a description of the bit fields.

NOTE

Only one of the four FCTL[3:0] bits (ESNS_N, ESNS_0, ESNS_1, PRG) can be set at one time. If multiple bits are set, the SNSE bit in the ERR register is asserted to indicate an error.

Offset 0x0010 (FCTL) Access: Supervisor read/write

	7	6	5	4	3	2	1	0
R	DPC	PRG_LENGTH[2:0]			0	0	0	0
W					ESNS_N	ESNS_0	ESNS_1	PRG
Reset	0	0	1	1	0	0	0	0

Figure 29-7. Fuse Control Register

Table 29-7. Fuse Control Register Field Descriptions

Field	Description
7 DPC	Delayed Program Cycle. This bit is a control bit, selecting immediate or delayed program. When this bit is cleared, program cycles start immediately upon setting of PRG bit. When this bit is asserted, program cycles is delayed until input signal delayed_pgm_start is asserted. 0 Program cycles begin immediately upon setting of the PRG bit 1 Program cycles are delayed; they do not begin until delayed_pgm_start signal is asserted
6–4 PRG_LENGTH[2:0]	Program Length. These bits define the length of program pulse as PRG_LENGTH*(period of 32k clock)
3 ESNS_N	Explicit Sense - Normal. Writing 1 to this bit initiates an unstressed (normal) explicit sense cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. 0 Return 0 for all read (read); No meaning (write) 1 Initiate an unstressed explicit sense cycle (write)
2 ESNS_0	Explicit Sense - 0-stressed. Writing 1 to this bit initiate a 0-stressed explicit sense cycle. Reads of this bit always return zero.FSM generates a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 0-stressed explicit sense cycles, the **epm_read_sense0** signal is asserted to the fuse banks (see Section 29.4.2.1, “Fuse Box Signals”). 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 0-stressed explicit sense cycle (write)
1 ESNS_1	Explicit Sense - 1-stressed. Writing 1 to this bit initiates a 1-stressed explicit sense cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when sense operation completed. During 1-stressed explicit sense cycles, the **epm_read_sense1** signal is asserted to the fuse banks (see Section 29.4.2.1, “Fuse Box Signals”). 0 Return 0 for all read (read); No meaning (write) 1 Initiate a 1-stressed explicit sense cycle (write)
0 PRG	Program. Writing 1 to this bit initiate a fuse program cycle. Read of this bit always returns zero. FSM generate a “done” signal when the operation complete. This bit is cleared automatically by hardware when program operation completed. 0 Return 0 for all read (read); No meaning (write) 1 Initiate a program cycle (write)

29.3.3.6 Upper Address Register (UA)

The UA register contains the top part of the address of the eFuse bit to be programmed or the word to be sensed in an explicit sense cycle. Note that programming is done by bit, so the program address is a full-bit address. Sensing is done on 8-bit words, so the bottom three bits of the address are ignored.

See Figure 29-8 for an illustration of the UA Register and Table 29-8 for a description of the bit fields.

Figure 29-8. Upper Address Register

Table 29-8. Upper Address Register Field Descriptions

Field	Description
7–6	Reserved
5–0 A[13–8]	The top six bits of the address of the eFuse bit to be programmed or the word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate the program/sense operation. A[13:11] select the Fuse bank. A[10:8] provide the most significant portion of the row address within the bank.

29.3.3.7 Lower Address Register (LA)

The LA register contains the bottom 8 bits of the address of the eFuse bit to be programmed or word to be sensed explicitly.

See Figure 29-9 for an illustration of the Lower Address Register and Table 29-9 for a description of the bit fields.

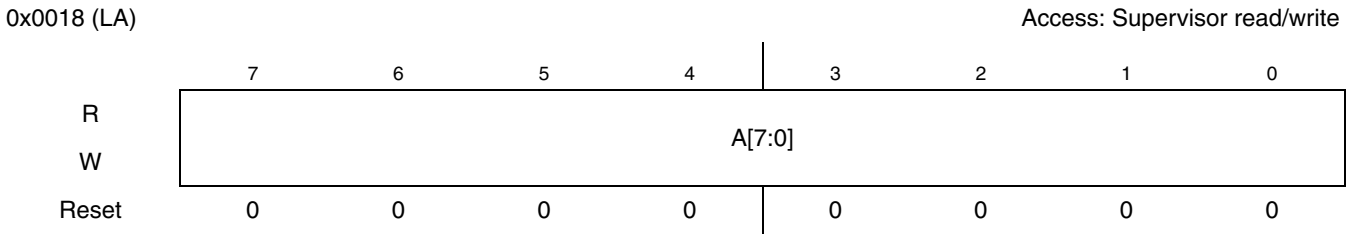

Figure 29-9. Lower Address Register

Table 29-9. Lower Address Register Field Descriptions

Field	Description
7–0 A	The bottom eight bits of the address of the eFuse bit to be programmed or word to be sensed explicitly. The address must be written prior to setting the PRG or ESNS_x bit in FCTL to initiate a program or sense operation. A[7:3] provides the least significant portion of the row address. A[2:0] select the bit position within the selected row.

29.3.3.8 Explicit Sense Data Register (SDAT)

The data sensed from the fuses in an explicit sense cycle is placed in the SDAT register at the conclusion of the sense cycle. Software can recognize the conclusion of the explicit sense cycle by the assertion of the SNSD bit in the STAT register.

See Figure 29-10 for an illustration of the SDAT Register and Table 29-10 for a description of the bit fields.

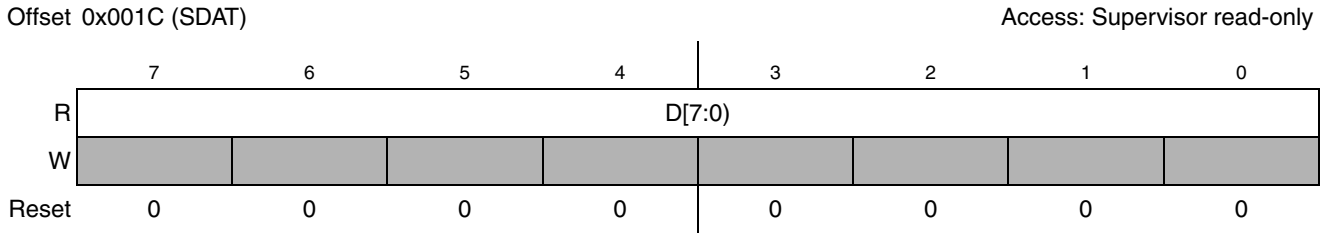

Figure 29-10. Explicit Sense Data Register

Table 29-10. Explicit Sense Data Register Field Descriptions

Field	Description
7–0 D	The data sensed from the fuses. Setting is unknown.

29.3.3.9 Product Revision Register (PREV)

The PREV register contains the product revision, and corresponds to the top eight bits of the deprecated HW_REV register.

See Figure 29-11 for an illustration of the PREV Register and Table 29-11 for a description of the bit fields.

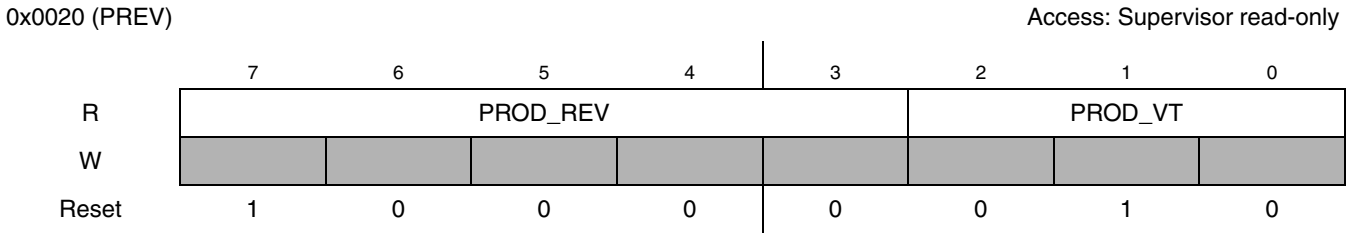

Figure 29-11. Product Revision Register

Table 29-11. Product Revision Register Field Descriptions

Field	Description
7–3 PROD_REV	Product Revision. The product revision (specific to the product or product family). Setting according to product revision.
2–0 PROD_VT	Product vendor or technology. The product vendor and/or technology (specific to the product or product family). Setting according to product vendor/technology.
Note: The values for PROD_REV and PROD_VT for the i.MX35 device are hard coded as 0x10 and 0x02, respectively (Register PREV= 0x82). Both of these values do not have significance for the user and should be ignored.	

29.3.3.10 Silicon Revision (SREV)

The SREV register contains the silicon revision (that is, mask revision), and corresponds to the bottom 8 bits of the deprecated HW_REV register.

See Figure 29-12 for an illustration of the SREV Register and Table 29-12 for a description of the bit fields.

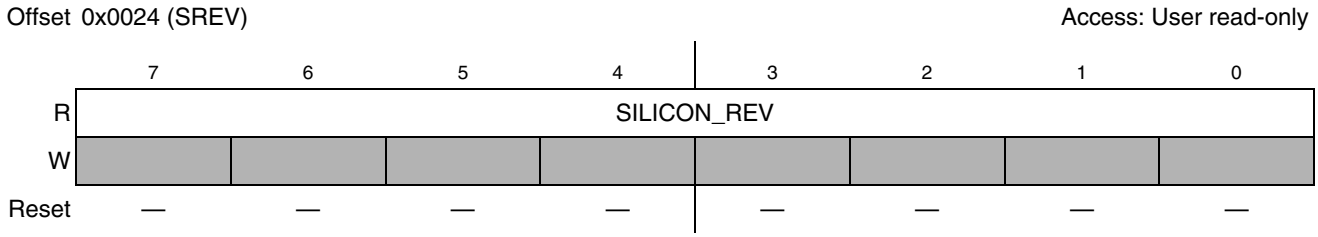

Figure 29-12. Silicon Revision Register

Table 29-12. Silicon Revision Register Field Descriptions

Field	Description
7–0 SILICON_REV	Mask Set Revision. The mask set revision used in fabrication of the part. The value changes with each change to the mask set. Setting according to mask set revision. 0×00 = TO 1.0, First silicon 0×10 = TO 2.0, Current production, "V" devices 0×11 = TO 2.1, Current production, "J" devices

29.3.3.11 Program Protection Register (PRG_P)

The PRG_P register is used to against accidental fuse programming. The fuses can be blown only when the value of this register is 0xAA. Software should only program this register to 0xAA while actively blowing fuses. After the fuse-blowing operation is complete, this register should be immediately reprogrammed to a different value.

See Figure 29-13 for an illustration of the Program Protection Register and Table 29-13 for a description of the bit fields.

7–0 PROTECTION_REG	The fuses can be blown only when the value of this register is 0xAA. Any attempt to program the fuse while the value is other than 0xAA is terminated, and the WPE error bit is set. Setting is undefined.

29.3.3.12 Software-Controllable Signals Register 0 (SCS0)

The SCS0 register is physically located in the hardware-visible signals submodule. It implements software-controlled, volatile signals which can drive SoC-level nets for feature enabling.

See Figure 29-14 for an illustration of the SCS0 register, and Table 29-14 for a description of the bit fields.

Field	Description
7 LOCK	Lock this register. This bit is used to lock the contents of this register until the next reset. The intended usage is to have trusted software program the register as desired and lock it before allowing distrusted software to run. This bit is write only, read of this bit return 0. 0 The register is not locked, it may be modified 1 The register is locked, all attempts to modify it are ignored
6 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. JTAG can be enabled by HAB_JDE bit only in Secure JTAG mode. JTAG cannot be opened in No Debug mode. The HAB musts lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by HAB_JDE bit, it can not be disabled unless the system is reset by POR. 0 JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms) 1 JTAG debugging is enabled by the HAB (though this signal may be gated off)
5–0 SCS[26:21]	These bits may be used in an implementation-defined way.

29.3.3.13 Software-Controllable Signals Registers 1–3 (SCS1–SCS3)

The SCS1–SCS3 registers are physically located in the hardware-visible signals submodule. They implement software-controlled, volatile signals that can drive SoC-level nets for feature enabling.

See Figure 29-15, Figure 29-16, and Figure 29-17 for an illustration of the Software-Controllable Signals Registers 1–3 and Table 29-15 for a description of the bit fields.

29.4 Functional Description

The IIM is an 8-bit IP Bus peripheral which implements interfaces for laser fuses and/or eFuses, as well as the hardware revision codes, cryptographic keys, and miscellaneous system-level feature enabling circuitry. Up to eight banks, each with up to 2048 fuses, are supported. Laser fuse banks and eFuse banks may be mixed.

29.4.1 Signal Groups

Listed below are the intended uses for the three fuse banks. Each fuse bank may contain up to 2048 fuses, and the unspecified fuses in each bank below may be used for implementation-specific purposes. However, access protection is specified on a per-bank basis; this may limit the uses of the unspecified fuses.

The IIM implements non-volatile “hardware-visible” control signals. These are all capable of driving SoC-level nets to allow them to permanently enable or disable features in the system.

29.4.1.1 Secure JTAG Control

Among the hardware control signals implemented in Fuse Bank 0 are the Secure JTAG control bits. These fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in Table 29-16.

Table 29-16. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	JTAG_SCC_DIS	Description
No Debug	2'b11	x	Highest security level.
Secure JTAG	2'b01	x	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	1'b1	Low Security, all JTAG features are enabled.
SCC JTAG	2'b00	1'b0	No security.

JTAG debug access may be semi-permanently enabled by blowing the JTAG Bypass Security (jtag_bp) bit. This, however, can be overridden by blowing the JTAG Security Re-enable (jtag_re) bit. Blowing the jtag_bp bit effectively changes the security level from 'Secure JTAG' to 'JTAG Enable', without actually modifying the JTAG_SMODE fuses.

NOTE

The IIM only allows the jtag_bp fuse to be blown if the JTAG debug security level is "Secure JTAG" (JTAG_SMODE = 2'b01) and ipt_response_in = 1, ipt_secur_block = 0. This indicates that the SJC has processed a valid response in its challenge/response protocol, enabling the JTAG security bypass functionality. JTAG security is re-instated to the "Secure JTAG" level by blowing the jtag_re fuse.

In addition to the three JTAG security levels, if jtag_scc is blown the JTAG debug notification passes to the Security Controller (SCC), which causes it to transition out of the secure state when debugging becomes active. If jtag_scc is left unblown, the debug active signals are masked, and do not propagate to the SCC. Normally the jtag_scc fuse is blown.

NOTE

Leaving the jtag_scc fuse unblown represents a very significant security risk, and should only be done to debug secure operation of the SCC. Once SCC debugging is complete, the jtag_scc fuse should immediately be blown.

29.4.1.2 Fuse Bank 1

Fuse Bank 1 contains the 168-bit SCC key. Two distinct keys are generated from the fuse values; the second key is derived from the first key by inverting all odd-numbered bits (bits 1, 3, 5 ... 167), as shown in Figure 29-18. According to this scheme, the Hamming code embedded within the SCC key (as described in Section 29.4.1.2.1, "SCC Key Format") and used for error-checking remains valid for the second key.

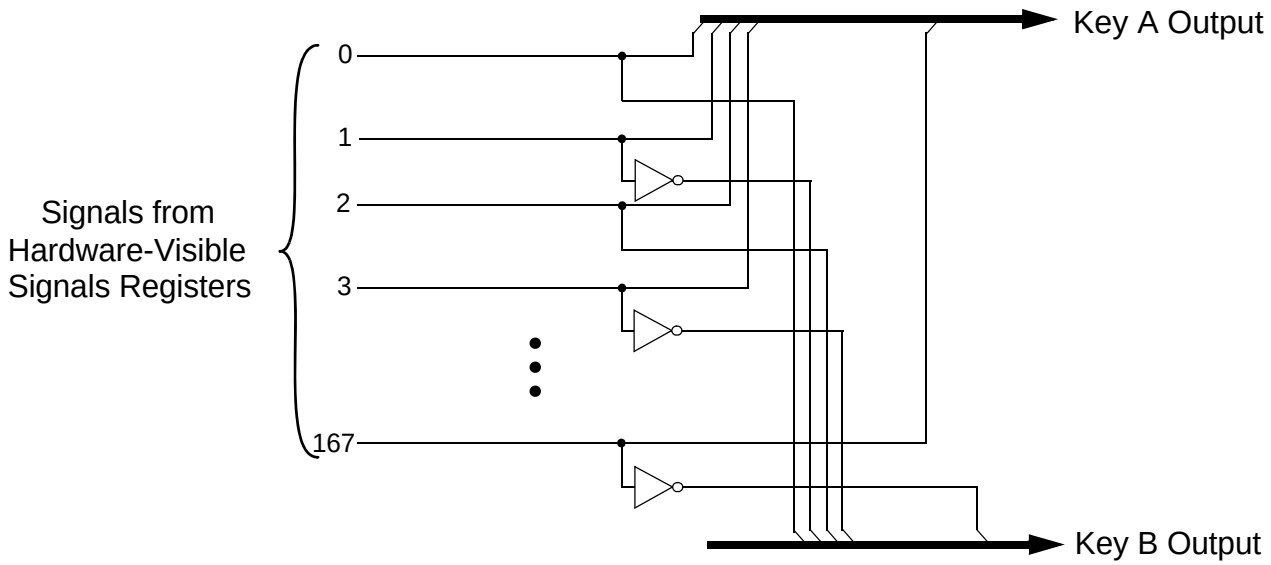

Figure 29-18. Second 3DES Key Derivation

29.4.1.2.1 SCC Key Format

The 168-bit keys derived from Fuse Bank 1are used as the secret keys for the Secure RAM controller in the SCC(s). Each key actually consists of three 56-bit keys. Each of the three 56-bit keys corresponds to a 64-bit DES key with the parity bits removed, and processed through the key permutation.

The value in Fuse Bank 1includes 159 random bits and 9 Hamming Code bits. The Hamming Code detects all 1, 2, and 3 bit errors in the codeword. It also detects most (though not all) multiple bit errors. Numbering the bits in the key from 0 to 167, the code bits are bits 0, 1, 2, 4, 8, 16, 32, 64, and 128. All of the remaining bits are data bits. Each of the code bits is the modulo 2 sum (i.e XOR or parity) of a subset of the bits in the entire word, as described below.

To determine which bits are used to form each code bit, first look at the binary representation of the bit position of each code bit (ignoring bit 0 for the time being) as shown in Table 29-17.

Table 29-17. Binary Representation of Bit Position

Code Bit Position	Binary Representation
0	0b00000000
1	0b00000001
2	0b00000010
4	0b00000100
8	0b00001000
16	0b00010000
32	0b00100000
64	0b01000000
128	0b10000000

Notice that (apart from bit position 0) the binary representation of bit position 2^n has a single 1 in its binary representation. The code bit at bit position 2^n is computed as the mod 2 sum (XOR) of all other bits *x* such that *x* has a 1 at the same place in its binary representation. For example, code bit 2 is the XOR of bits 3, 6, 7, 10, 11, 14, 15 ...166, 167; and code bit 128 is the XOR of all bits from 129 through 167 inclusive. After all of the other code bits have been calculated, code bit 0 is simply the XOR of all of the other bits, including the other code bits.

From an alternative point of view, the 1's in the binary representation of a given data bit's position indicate the code bits affected by the data bit. For example, data bit 99 (0b01100011) is XOR'ed into code bits 1, 2, 32, and 64.

29.4.1.2.2 SCC Key Checking

The SCC checks the key using the Hamming Code. If there are any errors in the key, the SCC refuses to use it. In addition, the SCC checks the key against several known weak keys, which it also refuses to use. Figure 29-19 shows a list of hexadecimal key patterns that are checked (x means don't care); no key matching any of these patterns should be programmed into Fuse Bank 1.

```

Figure 29-19. Known Weak SCC Key Patterns

29.4.1.3 Fuse Bank 2

Fuse Bank 2 contains a Unique ID (UID) consisting of fab ID, lot and wafer number, and die coordinates. The first 64 bits of this bank are usable by OS such Microsoft PocketPC, which require a unique device ID.

Together, the hardware-visible control signals (Fuse Bank 0) and the UID (Fuse Bank 2) comprise the legacy IIM signals that were previously implemented in an array of 128 laser fuses.

29.4.1.4 Software-Controllable Volatile Signals

The IIM implements up to 28 software-controllable, hardware-visible, volatile control signals. These are implemented in four 8-bit registers, each with a lock bit to inhibit modification of the associated register until the IIM is reset. These 28 signals may all drive SoC-level nets. They are always software-readable, but can only be modified by software if the Lock bit (bit 7) is not set in the register. The sequence for modifying these bits is shown in Figure 29-20.

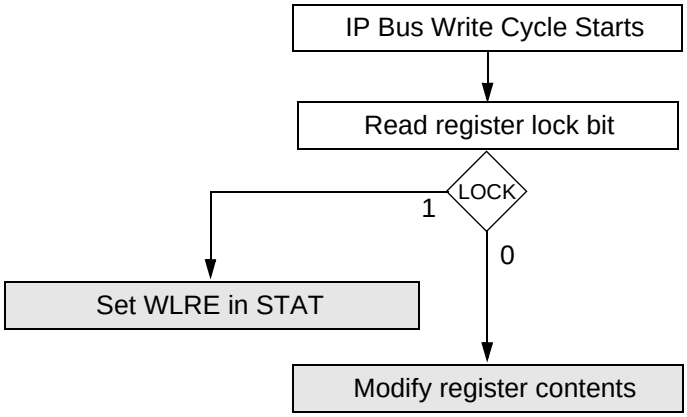

Figure 29-20. SCS Register Write Sequence

29.4.2 Fuse Box Interface

The IIM is designed to mate with up to up to eight fuse boxes, each consisting of up to 2048 laser- or eFuses. Both laser fuse and eFuse boxes share a common interface as shown in Figure 29-21.

29.4.2.1 Fuse Box Signals

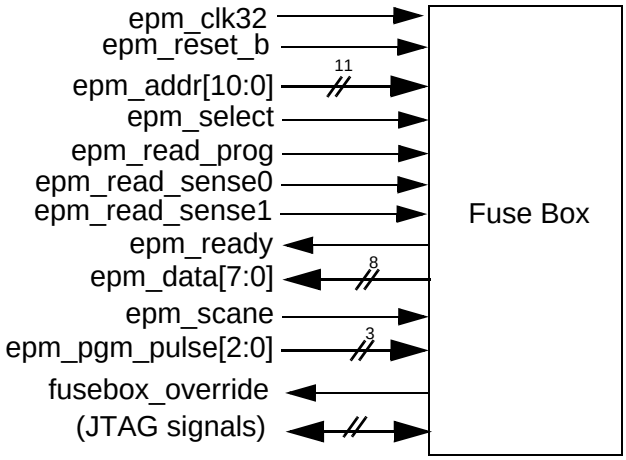

Figure 29-21. Fuse Box Interface

The signals are summarized from the fuse box's perspective in Table 29-18.

Table 29-18. Fuse Box Signal Overview

Signal Name	Signal Type	Signal Description
epm_clk32	Input	The 32.768 kHz clock used in the fuse box to time the program operation. This clock is not utilized in the IIM module.
epm_reset_b	Input	Reset signal. The reset is the early reset that negates 200us before system reset.

Table 29-18. Fuse Box Signal Overview (continued)

Signal Name	Signal Type	Signal Description
epm_addr[10:0]	Input	This bus provides the address for a read or program operation. Read operations are done on a per-word (8-bit) basis, so the word address is carried on address[10:3]. Program operations are done on a bit-basis, so the bit address is carried on address[10:0]. Address bits [2:0] carry the bit location in the byte,
epm_select	Input	This signal starts a read/program operation. The fuse box senses the rising edge of this signal to start the operation. On the rising edge, the address, operation to perform and program data are latched. This signal must remain asserted throughout the read/program operation. There is one select signal for each fuse bank.
epm_read_prog	Input	This signal selects whether the current operation is a read or program cycle. This signal is latched into the fuse box on the rising edge of epm_select.
epm_read_sense0	Input	This signal allows sensing of the 0 (unblown) state to be stressed. When asserted (high), the sense circuitry is configured to stress the sensing of the 0 (unblown) state. This can be useful in detecting marginally blown fuses.This signal is latched by the fuse box on the rising edge of epm_select.
epm_read_sense1	Input	This signal allows sensing of the 1 (blown) state to be stressed. When asserted (high), the sense circuitry is configured to stress the sensing of the 1 (blown) state. This can be useful in detecting marginally blown fuses. This can be useful in detecting marginally blown fuses.This signal is latched by the fuse box on the rising edge of epm_select.
epm_ready	Output	This signal indicates the progress of the current read/program cycle. De-asserted (low) indicates that the operation is in progress. Asserted (high) indicates that the operation is in progress. The IIM must wait for the fuse box to assert this signal before sending another command to the fuse box.
epm_data[7:0]	Output	This bus carries the read data from the fuse box during a read cycle.
epm_scane	Input	This signal indicates whether the fuse box is scannable using JTAG. De-asserting this signal (that is, tying it or driving it low) inhibits any scan access to the fuse box.
epm_pgm_length[2:0]	Input	These signals define the length of the program pulse.
fusebox_override	Output	Fuse box override signal to IIM
sjc_tdi	Input	TDI serial input from the JTAG
sjc_capture_dr	Input	Capture data control signal from JTAG
sjc_update_dr	Input	Update data control signal from JTAG
sjc_shift_dr	Input	Shift data control from JTAG
sjc_tck	Input	TCK clock input
ipt_sjc_fusebox_serial_ac_en	Input	Fuse box channel access enable signal from JTAG
fusebox_tdo	Output	TDO output from the fuse box.

29.4.2.2 Fuse Box Operations

All fuse box operations are self-timed and begin relative to the rising edge on the select line. Most interface signals are shared by all four fuse boxes. Only the fuse box selects (epm_select), read data (epm_data) and ready status (epm_ready) signals are unique to each fuse box. The 32 kHz clock is not used within the IIM.

It is passed through to the fuse box to time program operations. The clock distributed to the fuse boxes should be gated on only during fuse box operations.

29.4.2.2.1 Sense Operations

Sense operations are done on a per-word (8-bit) basis. The target word is specified by the address lines epm_addr[10:3]. The bottom three address lines (bit-select lines) are ignored in a sense operation. The timing for fuse word sense cycles is shown in Figure 29-22. This timing diagram shows one sense cycle followed by the start of a second sense, demonstrating how quickly one sense can follow another. Each sense command is registered on the rising edge of epm_select[x]. Each fuse box has its own select line and the index [x] corresponds to the selected fuse box. The address (epm_addr[10:3]) and sense command (epm_read_prog) must be stable t_{sels} before the rising edge of epm_select and must remain stable at least t_{selh} hold time beyond the rising edge. epm_ready is negated t_{nrdy} after the command is registered, indicating that the fuse box is busy. After a t_{dv} delay the data is made available on epm_data[7:0] and the epm_ready acknowledge signal is asserted t_{ready} after the initial assertion of epm_select[x]. The IIM synchronizes epm_ready and the data to the ipg_clk_s clock and drives the synchronized data onto the IP bus. This time is signified by t_{sync} in Figure 29-22 and is determined by the IIM design. Once the read data has been latched, epm_select is negated by the IIM. epm_select must remain negated a minimum cycle to cycle delay of t_{ccd} before the next cycle (sense or program) may begin. The epm_data signal remains in a steady state until replaced by data from a subsequent sense cycle. See Table 29-19 for specific timing values.

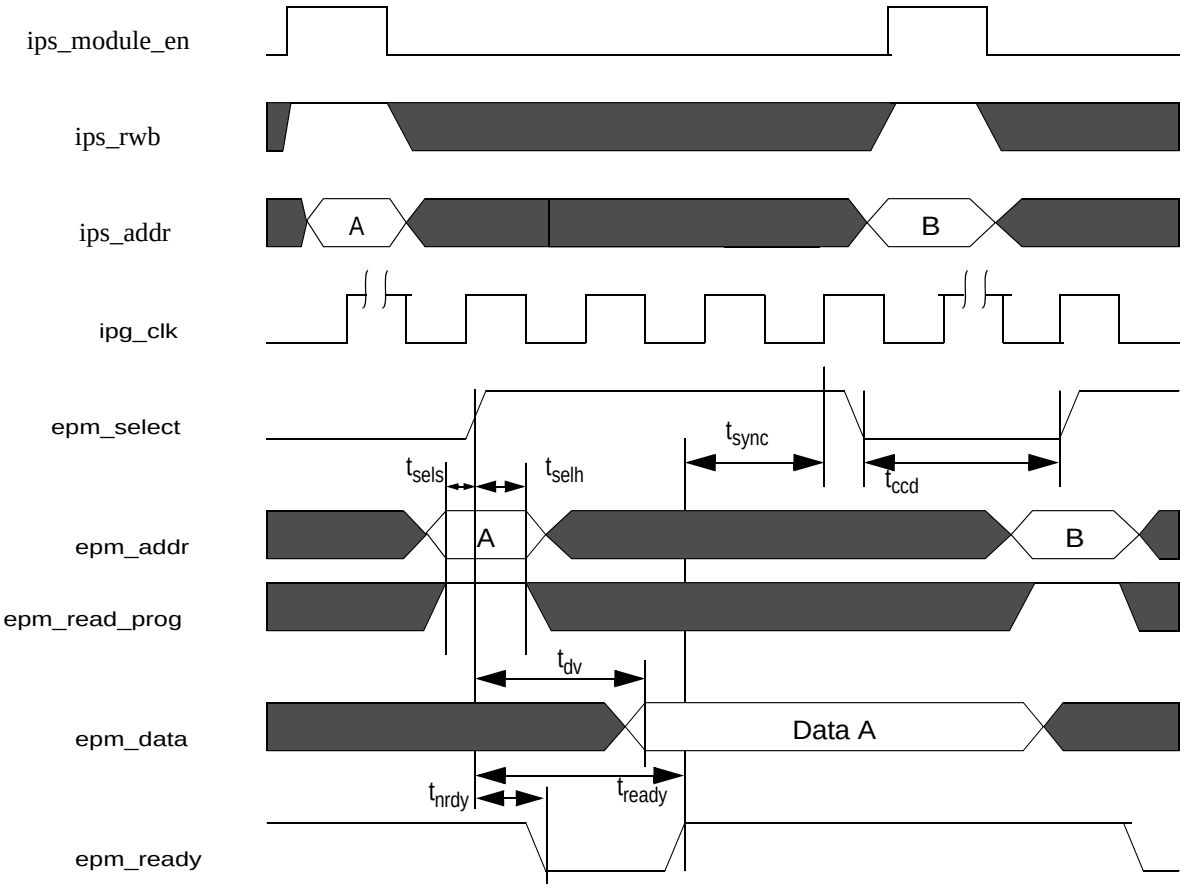

Figure 29-22. Fuse Box Sense Cycle Timing

29.4.2.2.2 Programming Operations

Fuse programming is done on a per-bit basis. The target bit is specified by the full address bus (epm_addr[10:0]). Program operations can only blow fuses (change them from logic 0 to logic 1), so there is no program data bus associated with the fuse box. The timing for a program operation is shown in Figure 29-23. As in the read cycle, the address and program command are latched on the rising edge of epm_select. Both address and data must be set t_{sels} ahead of the rising edge and remain held t_{selh} past the edge. Once the program command is registered, the fuse box negates the epm_ready signal after a delay of t_{nrdy}. On the next rising edge of the 32 kHz clock, the fuse box initiates the program operation. After the specified number of 32 kHz clocks (determined by epm_pgm_length[1:0]), the fuse box completes the programming operation and asserts the epm_ready signal. The IIM synchronizes the ready response to the ipg_clock during the period t_{sync}. After recognizing that the program operation has completed, the IIM negates the epm_select signal. See Table 29-19 for specific timing values.

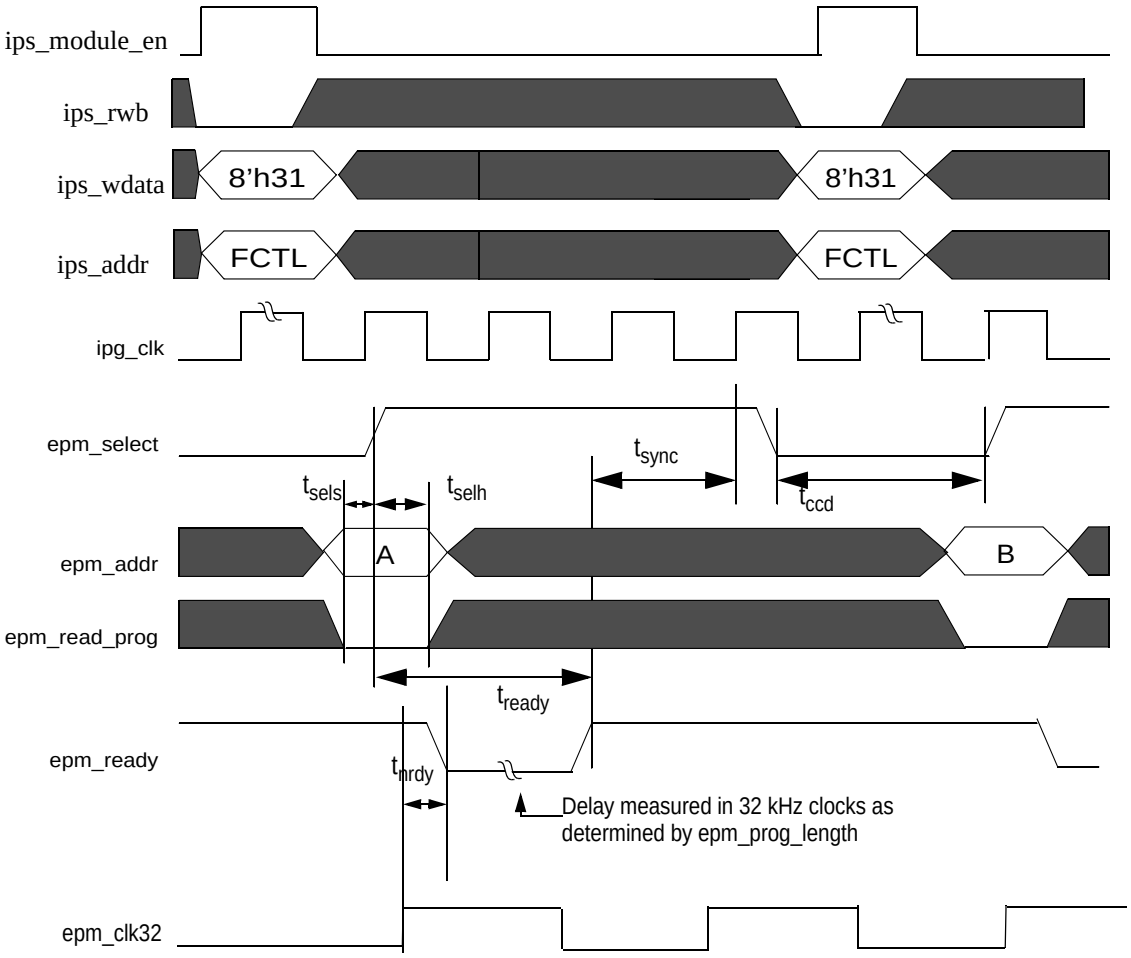
Table 29-19. Timing Values

Description	Designator	Timing Value
Setup time to select active edge	t_{sels}	2 ns
Hold time after select active edge	t_{selh}	2 ns

Table 29-19. Timing Values (continued)

Description	Designator	Timing Value
Delay from select to ready negation	t_{nrdy}	250 ps
Data valid after select active edge	t_{dv}	50 ns~100 ns
Ready signal asserted after select active edge (read only)	t_{ready}	tdv + 2 ns
Ready signal asserted after select active edge (program only)	t_{ready}	(epm_program_length) * $period_{32\ kHz}$
Data and ready IP clock synchronization delay	t_{sync}	Average 2 IP bus clocks
Minimum cycle-to-cycle delay	t_{ccd}	5 ns

A timing diagram for a fuse programming operation is shown in Figure 29-23.



The 1st rising edge after epm_select

Figure 29-23. Fuse Program Cycle Timing

NOTE

The IIM controller must determine that the target fuse bank is indeed an eFuse bank (not a laser fuse bank) before allowing the program cycle to proceed. This is determined by examining the appropriate fuse_type signal, which is fixed to b'111 for eFuse banks.

29.4.3 Fuse Value Storage

The values of fuses are read from one of three places:

- The software fuse value shadow cache
- The hardware-visible fuse value shadow cache, which drives SoC nets
- The fuse elements themselves (by sensing the fuses)

Fuse values are cached to reduce the risk of accidental programming of eFuses due to repeated sense operations, and to reduce power consumption associated with sense cycles.

29.4.3.1 Software Fuse Value Shadow Cache

Each word in the software fuse value cache RAM includes a valid bit and a parity bit, as shown in Figure 29-24. The parity bit reflects the parity of the data bits only (not including the valid bit).

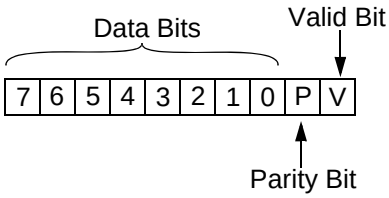


Figure 29-24. Software Cache Word Format

All bits are set to 0 when IIM comes out of reset, or when one of the fuse word bits is reprogrammed (see Figure 29-30). When a fuse word is read, the IIM first attempts to read it from the cache (except for the hardware-visible fuses; see Section 29.4.3.2, "Hardware-Visible Fuse Shadow Cache"). A sense cycle is only be run to the fuses if the parity bit disagrees with the data parity, or if the valid bit is not set. The overall cached fuse word read sequence is shown in Figure 29-28. The cache words and fuse words are one-to-one mapped.

29.4.3.2 Hardware-Visible Fuse Shadow Cache

Hardware-visible fuses include all fuses in Banks 0 and 1, as well as the Fuse Bank Access Control (FBAC) words of the other banks.The IIM must sense these fuses and write their values to the appropriate registers when it comes out of reset, and must ensure than any change to the fuses is also immediately reflected in the registers. The overall hardware-visible word read sequence is shown in Figure 29-27. Each word has a parity bit as shown in Figure 29-25.

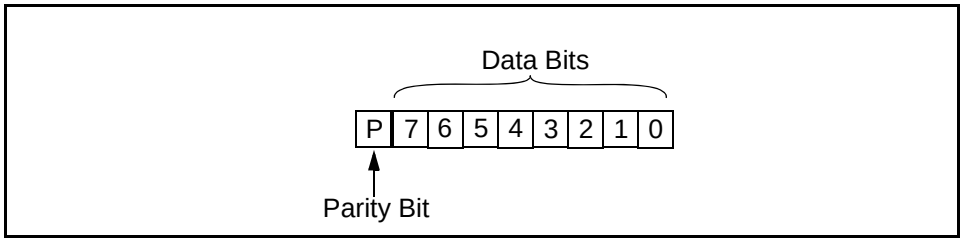

Figure 29-25. Hardware Cache Word Format

If a parity error detected is on shadow cache, the IIM sets the error bit PARITYE, and reinitializes the error byte cache by sensing the fuse values.

29.4.4 Fuse Protection

Some fuses are used as protection bits, as described below.

29.4.4.1 Fuse Bank Protection Fuses

Each fuse bank has a number of protection fuses in the corresponding Fuse Bank Access Control (FBAC) word. These protection bits have the following functions:

- FBWP — controls whether the bank can be programmed
- FBOP — controls whether the bank can be overridden
- FBRP — controls whether the bank can be read
- FBSP — controls whether the bank can be scanned
- FBESP — control whether this bank can be sensed explicitly.

29.4.4.2 Word Lock Bits

HWV0, HWV1, HWV2 all have word lock bits in bit 7. The bits control whether the containing word can be overridden or programmed.

HAB has one word lock bit HAB_LOCK in bit 7 of HAB1 (fuse bank 0). This bit controls whether HAB can be overridden or programmed

SJC_CHALL has one word lock bit SJC_CHALL_LOCK in bit 1 of FBAC0. This bit controls whether SJC_CHALL can be overridden or programmed.

SCC_KEY has one word lock bit SCC_LOCK in bit 0 of FBAC1. This bit controls whether SCC_KEY can be overridden or programmed. SCC_KEY is non-readable by default (FBRP is not blown).

SJC_RESP has one word lock bit SJC_RESP_LOCK in bit 1 of FBAC1. This bit controls whether SJC_RESP can be read, overridden or programmed.

29.4.4.3 Scan Out Protection

To prevent hackers from scanning out the secret keys, specific logic is added (shown in Figure 29-26) to reset all the flip-flops in the IIM before entering scan mode.

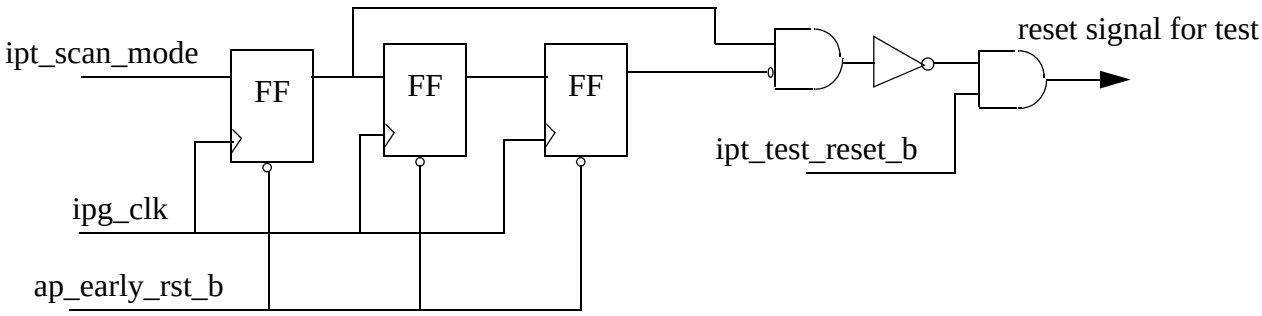

Figure 29-26. Scan Out Protection Circuit

29.4.5 Fuse Bank Operations

29.4.5.1 Read Sequence

Fuses may be read using the IP bus interface from any bank that is not read-inhibited (that is, FBAC*x*[FBRP] is unblown). The read sequence from a HW-Visible Signals word is shown in Figure 29-27.

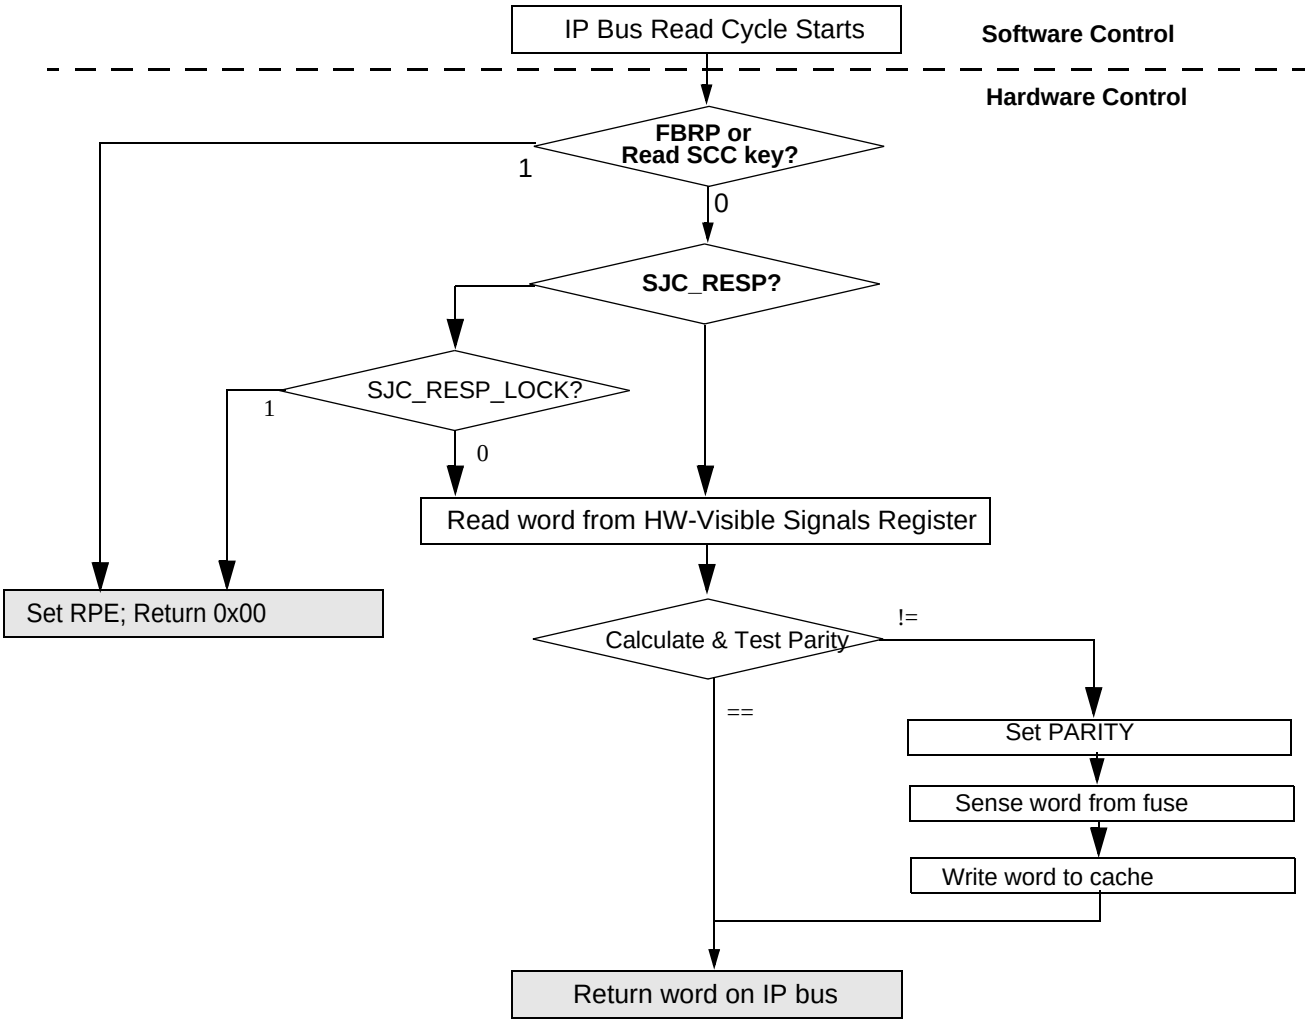

Figure 29-27. Hardware-visible Fuse Read

The read sequence to a cacheable fuse word is shown in Figure 29-28.

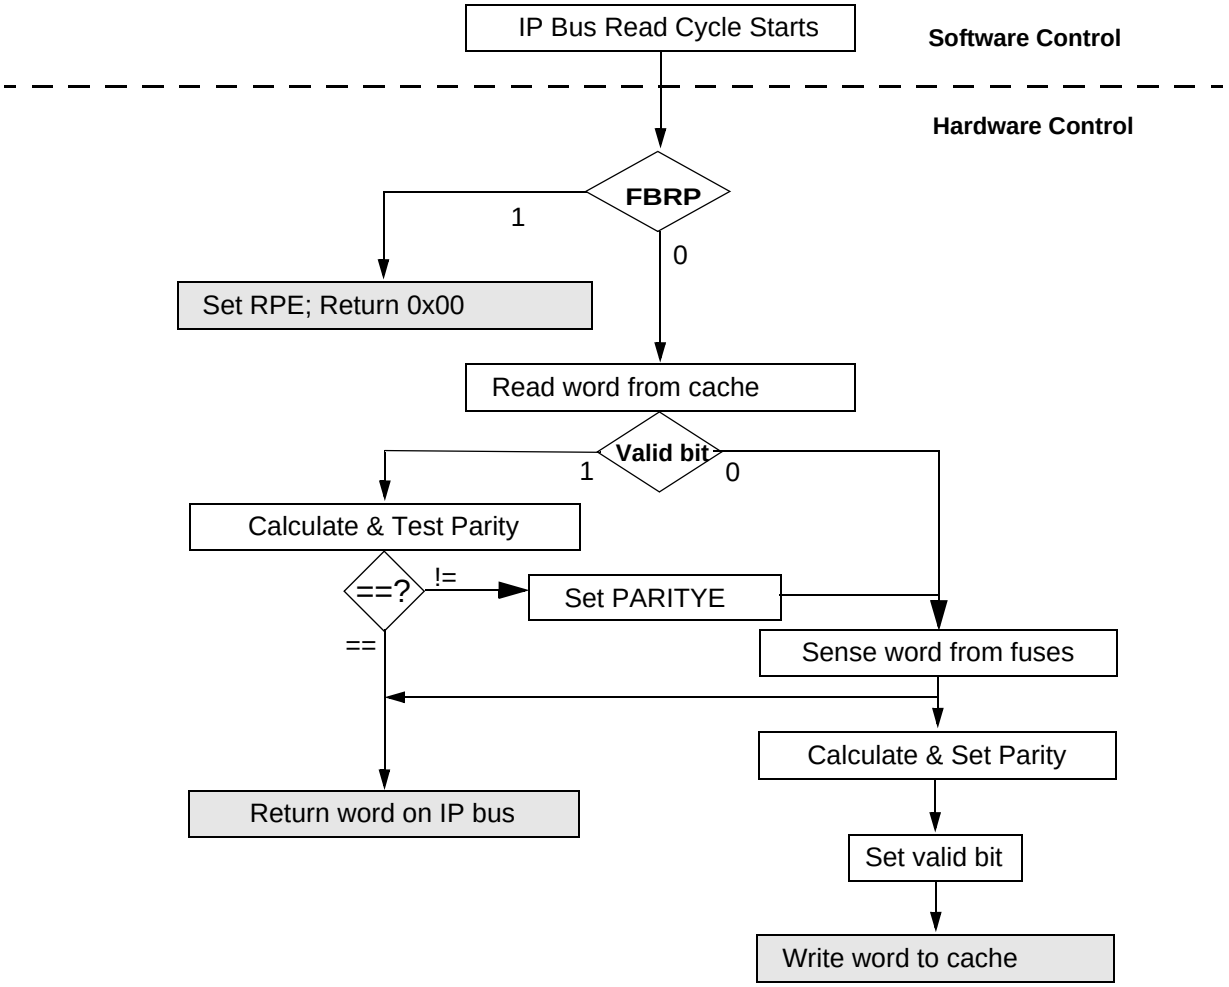

Figure 29-28. Software Fuse Read

29.4.5.2 Explicit Sense Sequence

An explicit sense sequence using the IP bus is depicted in Figure 29-29.

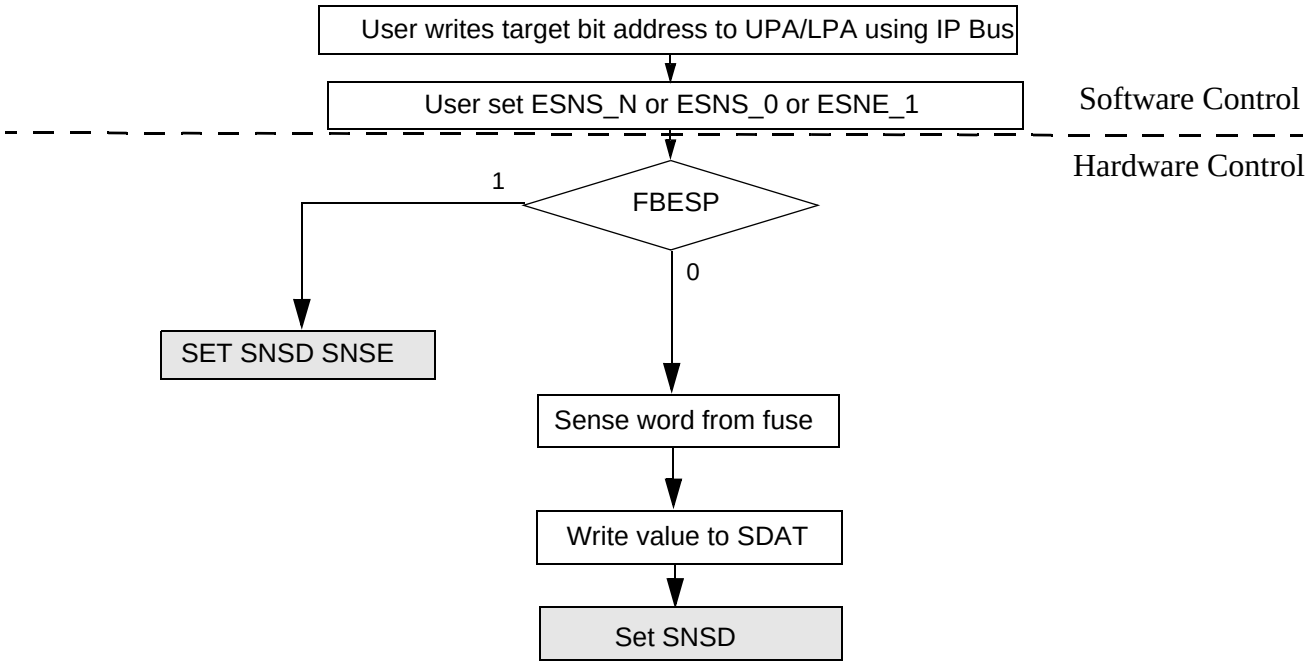

Figure 29-29. Explicit Sense Sequence

29.4.5.3 Programming Sequence

The software-controlled eFuse programming sequence using the IP bus is depicted in Figure 29-30.

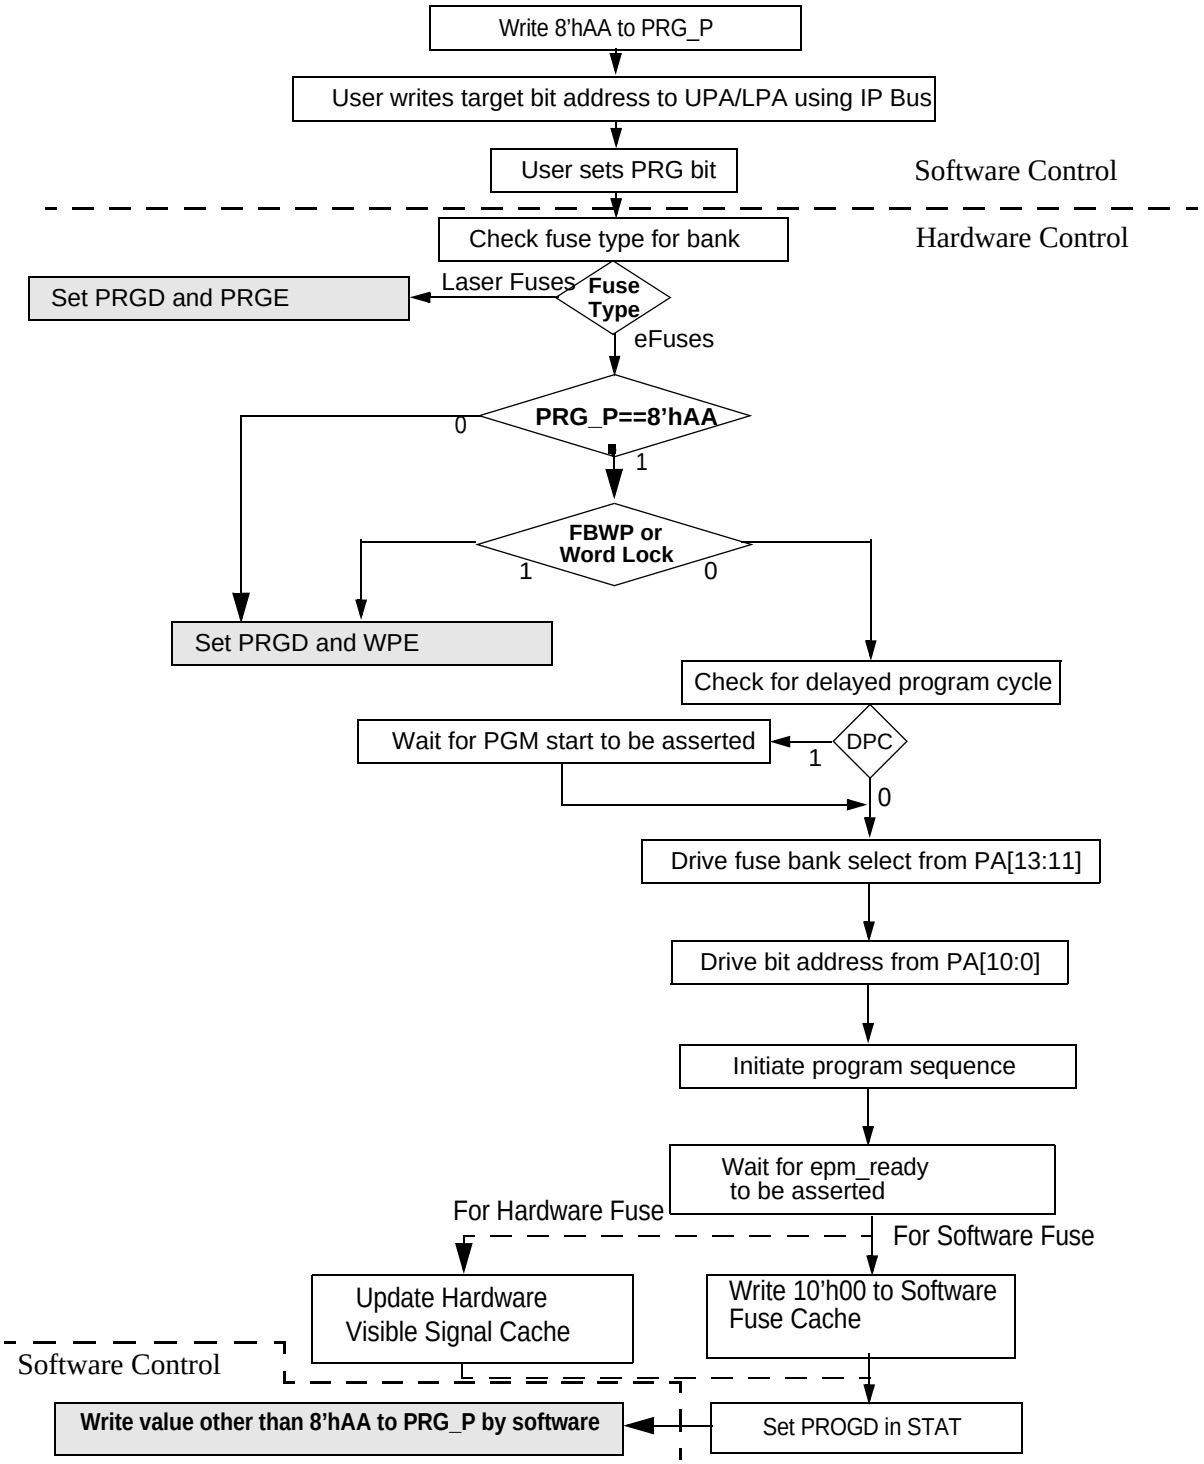

Figure 29-30. eFuse Programming Sequence

Fuses may also be programmed directly using the JTAG interface, so long as the IIM asserts the appropriate epm_scane signal. The IIM is not involved in this programming sequence aside from allowing or disallowing it using the epm_scane signal.

Note that minimum program voltage is 2.775 Volts, maximum program voltage is 3.3 Volts. This must be taken into account when designing the architecture of an IC which includes eFuses. For complete parametric specifications, see the fuse box specification.

29.4.5.4 Override Sequence

The override sequence is depicted in Figure 29-31.

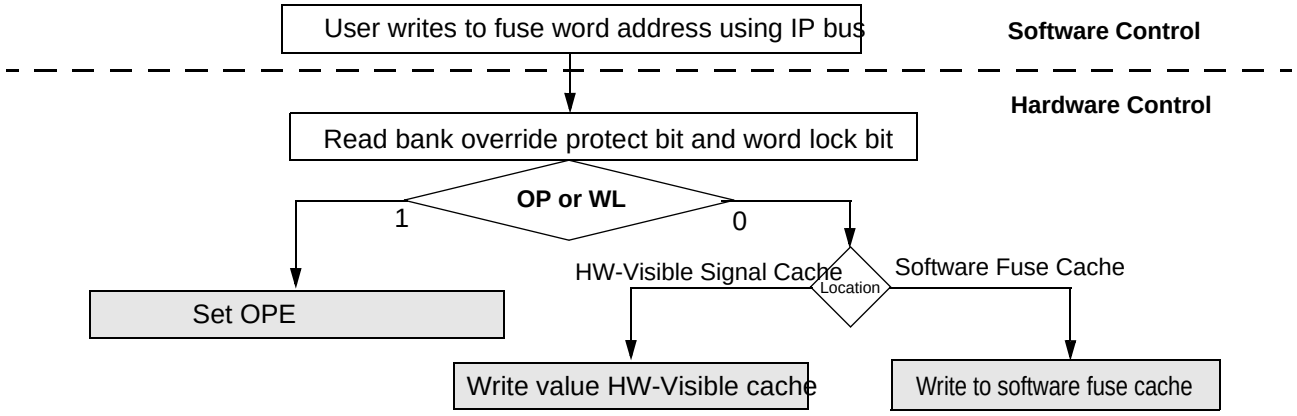

Figure 29-31. Fuse Value Override Sequence

29.5 Initialization/Application Information

29.5.1 Initialization

When the IIM comes out of reset, IIM automatically senses the hardware-visible fuses and writes their values into the appropriate registers. IIM also senses the Fuse Bank Access Control (FBAC) word from each of the fuse banks, and asserts or negates the epm_scane signal for each bank according to the corresponding FBSP bit value. Software fuses are not sensed until software makes a read request. The software cache is cleared on reset.

After the IIM comes out of reset, all the hardware-visible fuses must be read out to the hardware-visible cache within 200 µs in order to ensure that the hardware-visible fuses are loaded before the second reset at system level. IIM reads HWV2 first. iim_boot_int_ready is asserted after this read to indicate hardware-visible fuse value of BOOT_INT is valid. Then FBAC words of all banks are sensed out, the sequence of sensing of other fuses depends on the parameter definitions.

The initialization time depends on the number of hardware-visible fuses, as follows:

Initialization time = (number of hardware-visible fuse word)s x (100 ns+4 ipg_clk cycles) ***Eqn. 29-1***

After the initialization is complete the fuse_latched signal is asserted, as shown in Figure 29-32.

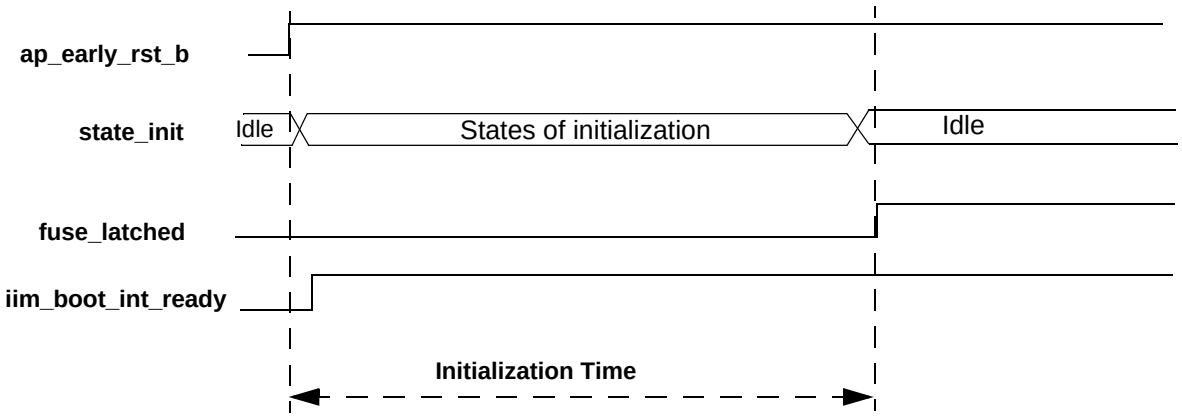

Figure 29-32. Timing Diagram of Initialization

29.5.2 Programming

After JTAG programming, reset must be applied to synchronize the fuse value to hardware-visible signal cache.

A wait period (estimated to be at least 20 µs) is required between programming and sensing operations.

Chapter 30
IPMUX

30.1 Introduction

Figure 30-1 is the IPMUX block diagram. It illustrates the IPMUX ports (inputs and outputs), the three IPMUX sub-blocks and their interconnections.

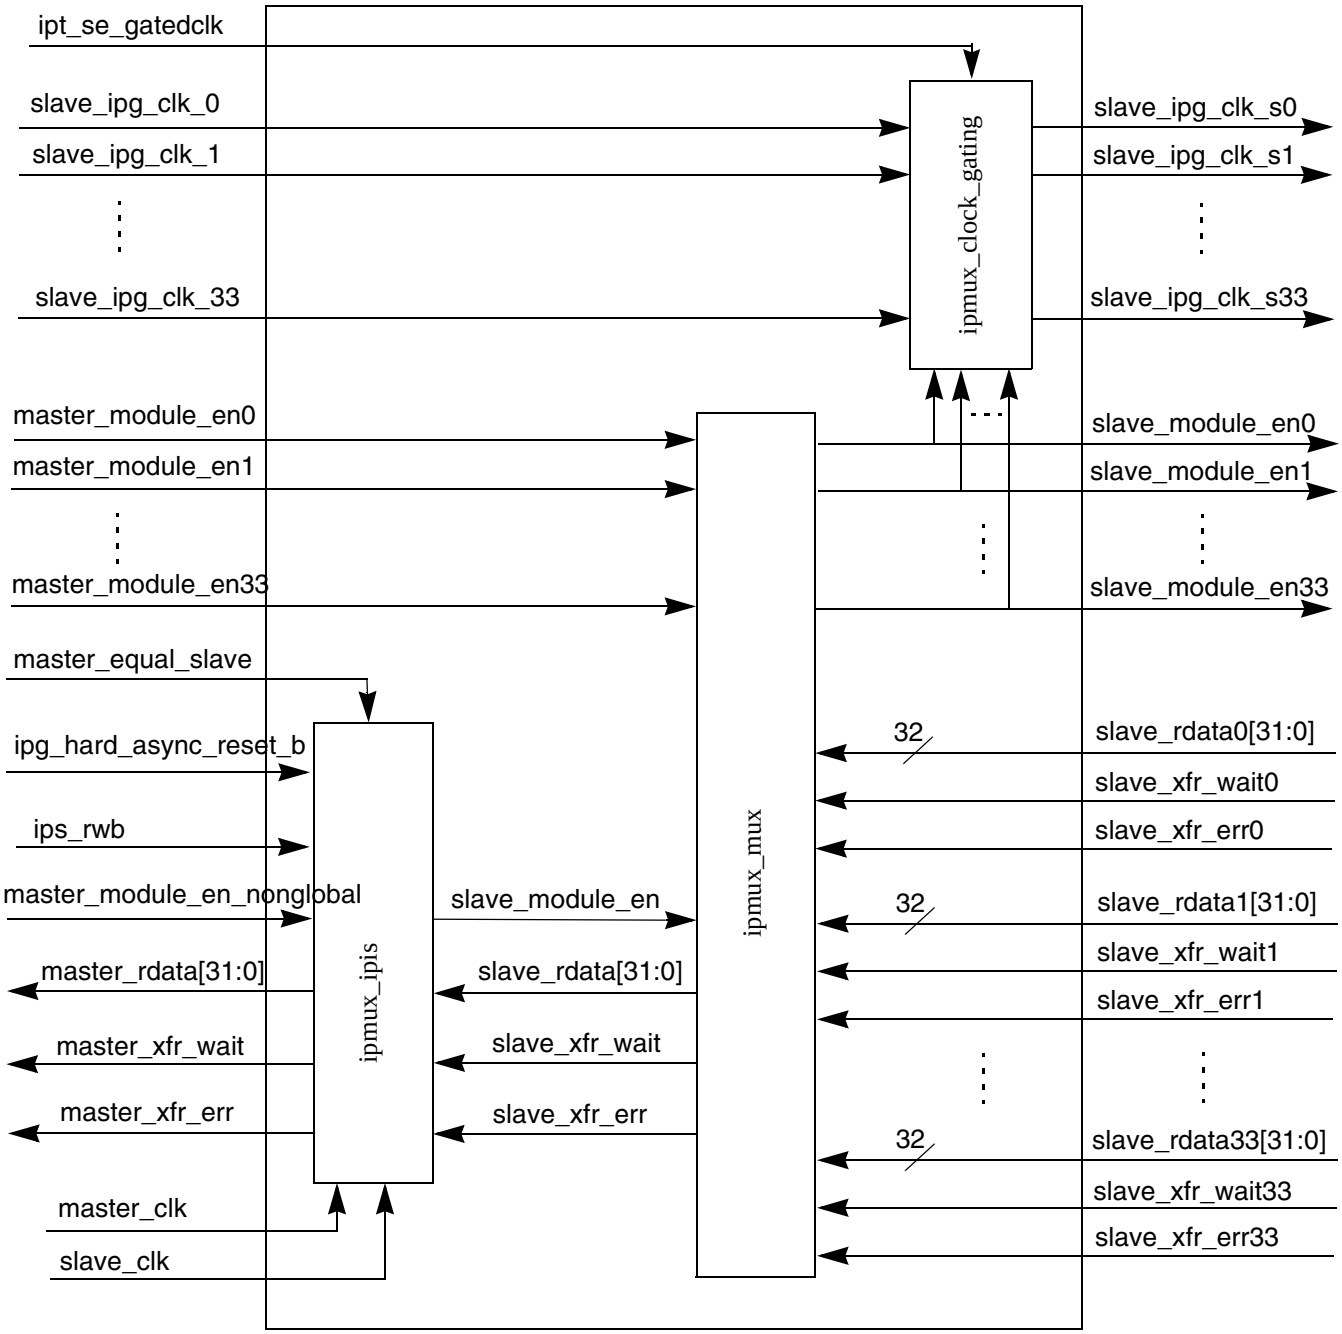

Figure 30-1. IPMUX Block Diagram

30.2 Overview

ARM/DSP platforms should be connected to most of the peripherals by the IP (also denoted IPS) bus interface. The connection between the peripherals and the ARM/DSP platform cannot be made directly, although the ARM9/ARM11/DSP platforms convert the AHB-Lite/Q-Bus bus interface to the IPS bus interface by means of the AIPI/AIPS/Q2SB modules accordingly. This is for two main reasons: the

platforms implement only one full set of IPS signals (thus muxing is required), and the platforms may run at different frequencies than the peripherals (thus synchronization is required). Hence the necessity for a block that is a bridge (gasket) between the ARM/DSP platform and the peripherals' IPS bus interface. Also, to minimize the clock toggles on the IPS bus interface, thereby reducing power, the IPMUX also implements the IPS bus gated clocks for the peripherals, which toggle only when a peripheral is actually accessed.

30.3 Features

The IPMUX includes the following features:

- Muxing of all the IP peripherals ips_rdata buses and response signals (ips_xfr_wait, ips_xfr_err) since ARM9 platform AIPI, ARM11 platform AIPS and DSP platform Q2SB can get only one set of these signals.
- Synchronizing the IPS protocol between the ARM/DSP platform (master, usually faster) and the peripherals (slaves, usually slower).
- Generating the peripherals bus clocks (IPG gated clocks active only on IPS accesses).

The IPMUX design is based on the assumption that the posedges of both Master & Slave clocks are synchronized. Practically the above assumption means that master_frequency/slave_frequency is N or 1/N where N is a positive integer: N=1, 2, 3, ...

30.4 Modes of Operation

The IPMUX has two modes of operation, dependent on the value of the master_equal_slave input:

- IPS synchronization mode (master_equal_slave negated)

  This mode should be used whenever the master clock and the slave clock are not equal and hence IPS protocol synchronization is required.

  To enter this mode the master_equal_slave input must be driven low.
- IPS synchronization bypass mode (master_equal_slave asserted)

  This mode may be used whenever the master clock and the slave clock are equal and hence IPS protocol synchronization is not required. When not using this mode in this case the block will function correctly, however, cycles may be wasted in each IPS access.

  To enter this mode the master_equal_slave input must be driven high.

30.5 External Signal Description

30.6 Overview

Table 30-1 lists all the external signals (ports) of the IPMUX along with their direction and short description. Since the IPMUX is internally connected in the SOC (none of its signals is connected to pads) a simplified table format is used.

Table 30-1. IPMUX Signals

Port Name	Direction	Function
Global Signals		
ipg_hard_async_reset_b	input	Hardware Asynch. Reset; negates synchronously
master_clk	input	The IPS Master Clock
slave_clk	input	The IPS Slave (peripheral) Clock
ipt_se_gatedclk	input	scan enable control for clock gating logic
master_equal_slave	input	Notify that master clock frequency equals slave clock frequency. If asserted synchronization logic is bypassed
master_module_en_nonglobal	input	Indication from ARM11 platform that one of the 32 ips_module_en is asserted or: indication from DSP platform that one of the 33 ips_module_en is asserted
IPS Master Signals		
master_module_en0	input	ips_module_en from IPS Master for IPS Slave #0
master_module_en1	input	ips_module_en from IPS Master for IPS Slave #1
master_module_en2	input	ips_module_en from IPS Master for IPS Slave #2
master_module_en3	input	ips_module_en from IPS Master for IPS Slave #3
master_module_en4	input	ips_module_en from IPS Master for IPS Slave #4
master_module_en5	input	ips_module_en from IPS Master for IPS Slave #5
master_module_en6	input	ips_module_en from IPS Master for IPS Slave #6
master_module_en7	input	ips_module_en from IPS Master for IPS Slave #7
master_module_en8	input	ips_module_en from IPS Master for IPS Slave #8
master_module_en9	input	ips_module_en from IPS Master for IPS Slave #9
master_module_en10	input	ips_module_en from IPS Master for IPS Slave #10
master_module_en11	input	ips_module_en from IPS Master for IPS Slave #11
master_module_en12	input	ips_module_en from IPS Master for IPS Slave #12
master_module_en13	input	ips_module_en from IPS Master for IPS Slave #13
master_module_en14	input	ips_module_en from IPS Master for IPS Slave #14
master_module_en15	input	ips_module_en from IPS Master for IPS Slave #15
master_module_en16	input	ips_module_en from IPS Master for IPS Slave #16
master_module_en17	input	ips_module_en from IPS Master for IPS Slave #17
master_module_en18	input	ips_module_en from IPS Master for IPS Slave #18
master_module_en19	input	ips_module_en from IPS Master for IPS Slave #19
master_module_en20	input	ips_module_en from IPS Master for IPS Slave #20
master_module_en21	input	ips_module_en from IPS Master for IPS Slave #21
master_module_en22	input	ips_module_en from IPS Master for IPS Slave #22
master_module_en23	input	ips_module_en from IPS Master for IPS Slave #23
master_module_en24	input	ips_module_en from IPS Master for IPS Slave #24
master_module_en25	input	ips_module_en from IPS Master for IPS Slave #25
master_module_en26	input	ips_module_en from IPS Master for IPS Slave #26
master_module_en27	input	ips_module_en from IPS Master for IPS Slave #27
master_module_en28	input	ips_module_en from IPS Master for IPS Slave #28
master_module_en29	input	ips_module_en from IPS Master for IPS Slave #29
master_module_en30	input	ips_module_en from IPS Master for IPS Slave #30
master_module_en31	input	ips_module_en from IPS Master for IPS Slave #31

Table 30-1. IPMUX Signals (Continued)

Port Name	Direction	Function
master_module_en32	input	ips_module_en from IPS Master for IPS Slave #32 dedicated slot for ips_module_en_glbl0 signal from ARM or ips_module_en[32] from DSP platform
master_module_en33	input	ips_module_en from IPS Master for IPS Slave #33 dedicated slot for ips_module_en_glbl1 signal from ARM
master_rdata[31:0]	output	ips_rdata read data bus to IPS Master
master_xfr_err	output	IPS ips_xfr_err protocol signal to IPS Master
master_xfr_wait	output	IPS ips_xfr_wait protocol signal to IPS Master
IPS Slave Signals		
slave_ipg_clk_0	input	ipg_clk clock related to IPS Slave #0
slave_ipg_clk_1	input	ipg_clk clock related to IPS Slave #1
slave_ipg_clk_2	input	ipg_clk clock related to IPS Slave #2
slave_ipg_clk_3	input	ipg_clk clock related to IPS Slave #3
slave_ipg_clk_4	input	ipg_clk clock related to IPS Slave #4
slave_ipg_clk_5	input	ipg_clk clock related to IPS Slave #5
slave_ipg_clk_6	input	ipg_clk clock related to IPS Slave #6
slave_ipg_clk_7	input	ipg_clk clock related to IPS Slave #7
slave_ipg_clk_8	input	ipg_clk clock related to IPS Slave #8
slave_ipg_clk_9	input	ipg_clk clock related to IPS Slave #9
slave_ipg_clk_10	input	ipg_clk clock related to IPS Slave #10
slave_ipg_clk_11	input	ipg_clk clock related to IPS Slave #11
slave_ipg_clk_12	input	ipg_clk clock related to IPS Slave #12
slave_ipg_clk_13	input	ipg_clk clock related to IPS Slave #13
slave_ipg_clk_14	input	ipg_clk clock related to IPS Slave #14
slave_ipg_clk_15	input	ipg_clk clock related to IPS Slave #15
slave_ipg_clk_16	input	ipg_clk clock related to IPS Slave #16
slave_ipg_clk_17	input	ipg_clk clock related to IPS Slave #17
slave_ipg_clk_18	input	ipg_clk clock related to IPS Slave #18
slave_ipg_clk_19	input	ipg_clk clock related to IPS Slave #19
slave_ipg_clk_20	input	ipg_clk clock related to IPS Slave #20
slave_ipg_clk_21	input	ipg_clk clock related to IPS Slave #21
slave_ipg_clk_22	input	ipg_clk clock related to IPS Slave #22
slave_ipg_clk_23	input	ipg_clk clock related to IPS Slave #23
slave_ipg_clk_24	input	ipg_clk clock related to IPS Slave #24
slave_ipg_clk_25	input	ipg_clk clock related to IPS Slave #25
slave_ipg_clk_26	input	ipg_clk clock related to IPS Slave #26
slave_ipg_clk_27	input	ipg_clk clock related to IPS Slave #27
slave_ipg_clk_28	input	ipg_clk clock related to IPS Slave #28
slave_ipg_clk_29	input	ipg_clk clock related to IPS Slave #29
slave_ipg_clk_30	input	ipg_clk clock related to IPS Slave #30
slave_ipg_clk_31	input	ipg_clk clock related to IPS Slave #31
slave_ipg_clk_32	input	ipg_clk clock related to IPS Slave #32
slave_ipg_clk_33	input	ipg_clk clock related to IPS Slave #33

Table 30-1. IPMUX Signals (Continued)

Port Name	Direction	Function
slave_ipg_clk_s0	output	ipg_clk_s gated clock (bus clock) to IPS Slave #0
slave_ipg_clk_s1	output	ipg_clk_s gated clock (bus clock) to IPS Slave #1
slave_ipg_clk_s2	output	ipg_clk_s gated clock (bus clock) to IPS Slave #2
slave_ipg_clk_s3	output	ipg_clk_s gated clock (bus clock) to IPS Slave #3
slave_ipg_clk_s4	output	ipg_clk_s gated clock (bus clock) to IPS Slave #4
slave_ipg_clk_s5	output	ipg_clk_s gated clock (bus clock) to IPS Slave #5
slave_ipg_clk_s6	output	ipg_clk_s gated clock (bus clock) to IPS Slave #6
slave_ipg_clk_s7	output	ipg_clk_s gated clock (bus clock) to IPS Slave #7
slave_ipg_clk_s8	output	ipg_clk_s gated clock (bus clock) to IPS Slave #8
slave_ipg_clk_s9	output	ipg_clk_s gated clock (bus clock) to IPS Slave #9
slave_ipg_clk_s10	output	ipg_clk_s gated clock (bus clock) to IPS Slave #10
slave_ipg_clk_s11	output	ipg_clk_s gated clock (bus clock) to IPS Slave #11
slave_ipg_clk_s12	output	ipg_clk_s gated clock (bus clock) to IPS Slave #12
slave_ipg_clk_s13	output	ipg_clk_s gated clock (bus clock) to IPS Slave #13
slave_ipg_clk_s14	output	ipg_clk_s gated clock (bus clock) to IPS Slave #14
slave_ipg_clk_s15	output	ipg_clk_s gated clock (bus clock) to IPS Slave #15
slave_ipg_clk_s16	output	ipg_clk_s gated clock (bus clock) to IPS Slave #16
slave_ipg_clk_s17	output	ipg_clk_s gated clock (bus clock) to IPS Slave #17
slave_ipg_clk_s18	output	ipg_clk_s gated clock (bus clock) to IPS Slave #18

slave_xfr_wait29	input	ips_xfr_wait signal from IPS Slave #29
slave_xfr_wait30	input	ips_xfr_wait signal from IPS Slave #30
slave_xfr_wait31	input	ips_xfr_wait signal from IPS Slave #31
slave_xfr_wait32	input	ips_xfr_wait signal from IPS Slave #32
slave_xfr_wait33	input	ips_xfr_wait signal from IPS Slave #33

30.7 Detailed Signal Descriptions

Following is a detailed description of the above signals.

IPS bus interface signals are detailed in SRS 3.1 section 4.

All IPS bus interface signals should meet the timing requirements listed for IPS target/initiator in the SRS 3.1 documents.

30.7.1 ipg_hard_async_reset_b

Input hardware Asynchronous reset, negates synchronously. Active low.

30.7.2 master_clk

Input IPS Master Clock. This clock is aligned with the clock which toggles the IPS Master F.F.s

30.7.3 slave_clk

Input IPS Slave (peripheral) Clock. This clock is aligned with the clock which toggles the IPS Slave F.F.s

30.7.4 ipt_se_gatedclk

Input Scan enable control for clock gating logic. Active high. Allows controllability of the clock gating in scan mode.

30.7.5 master_equal_slave

Input notify that the IPS Master clock frequency equals Slave clock frequency.

If asserted synchronization logic is bypassed to reduce clock cycles waste for synchronizing the IPS Master/Slave protocol.

When this signal is low (master_equal_slave==1’b0) the IPMUX is in: “IPS synchronization mode”, when high (master_equal_slave==1’b1) the IPMUX is in: “IPS synchronization bypass mode”

30.7.6 master_module_en_nonglobal

Input indication from ARM11 platform that one of the 32 module_en is asserted or indication from DSP platform that one of the 33 module_en is asserted. This is actually an “OR” function of ip_module_en<x> signals. Note that for ARM11 platform when the ips_module_en_glbl are active, master_module_en_nonglobal will not be active. Also note that the name of DSP platform port that should be connected to this IPMUX port is: ip_module_en_global.

30.7.7 master_module_en0, master_module_en1, ... master_module_en33

Input ips_module_en signal from IPS Master for IPS Slave #0 through IPS Slave #33 respectively.

When master_module_en<x> is asserted by the IPS Master, an access to IPS Slave (peripheral) #x is initiated.

master_module_en<x> inputs that are not used, should be tied low (0).

30.7.8 master_rdata[31:0]

Output IPS 32 bits read data bus to IPS Master.

30.7.9 master_xfr_err

Output IPS transfer error protocol signal (ips_xfr_err) to IPS Master.

When high indicates that the current access should be ignored.

30.7.10 master_xfr_wait

Output IPS transfer wait protocol signal (ips_xfr_wait) to IPS Master.

When high indicated that the Slave insert wait states: for write accesses the write data and controls signals should be kept valid by the Master, in read accesses indicates that the data is not ready yet - the Master must keep control signals valid

30.7.11 slave_ipg_clk_0, slave_ipg_clk_1, ... slave_ipg_clk_33

Input clocks related to IPS Slave #0 through IPS Slave #33 respectively.

slave_ipg_clk<x> inputs that are not used, should be tied low (0).

30.7.12 slave_ipg_clk_s0, slave_ipg_clk_s1, ... slave_ipg_clk_s33

Output gated clocks (bus clock) to IPS Slave #0 through IPS Slave #33 respectively.

This clock toggles only when the corresponding slave_module_en is asserted.

30.7.13 slave_module_en0, slave_module_en1, ... slave_module_en33

Output IPS module enable signal to IPS Slave #0 through IPS Slave #33 respectively.

When slave_module_en<x> is asserted an access to IPS Slave (peripheral) #x is activated.

30.7.14 slave_rdata0[31:0], slave_rdata1[31:0], ... slave_rdata33[31:0]

Input IPS 32 bits read data bus from IPS Slave #0 through IPS Slave #33 respectively.

slave_rdata<x> inputs that are not used should be tied low (0).

Slaves with lower number of ips_rdata bits (8/16 bits peripherals) should be connected to the LSB bits of the slave_rdata<x> bus, while other bits should be tied low (0).

30.7.15 slave_xfr_err0, slave_xfr_err1, ... slave_xfr_err33

Input IPS transfer error protocol signal (ips_xfr_err) from IPS Slave #0 through IPS Slave #33 respectively.

slave_xfr_err<x> inputs that are not used should be tied high (1)

30.7.16 slave_xfr_wait0, slave_xfr_wait1, ... slave_xfr_wait33

Input IPS transfer wait protocol signal (ips_xfr_wait) from IPS Slave #0 through IPS Slave #33 respectively.

slave_xfr_wait<x> inputs that are not used should be tied low (0)

30.8 Memory Map/Register Definition

Not Available - IPMUX doesn’t have any status/configuration registers.

30.9 Functional Description

The IPMUX is consist of 3 sub blocks which implement the 3 different features of the block:

1. ipmux_mux—Implements the muxing of all the IP peripherals ips_rdata buses and response signals (ips_xfr_wait, ips_xfr_err)
2. ipmux_ipis—Implements the synchronization of the IPS protocol between the ARM/DSP platform (master) and the peripherals (slaves)
3. ipmux_clock_gating—Implements the IPG clock gating for the peripherals (IPG bus clocks), means generating IPG gated clocks which are active only on IPS accesses

The next subsections describes each sub block in details.

30.10 ipmux_mux (IPMUX MUX)

The ipmux_mux can get as inputs 34 sets of {ips_readta[31:0], ips_xfr_wait, ips_xfr_err} signals from 34 different IPS slaves peripherals and generates as output one set of those signals. It also routes the slave_module_en input from the ipmux_ipis sub-block to the activated peripheral.

The block diagram of the ipmux_mux is illustrated in Figure 30-2..

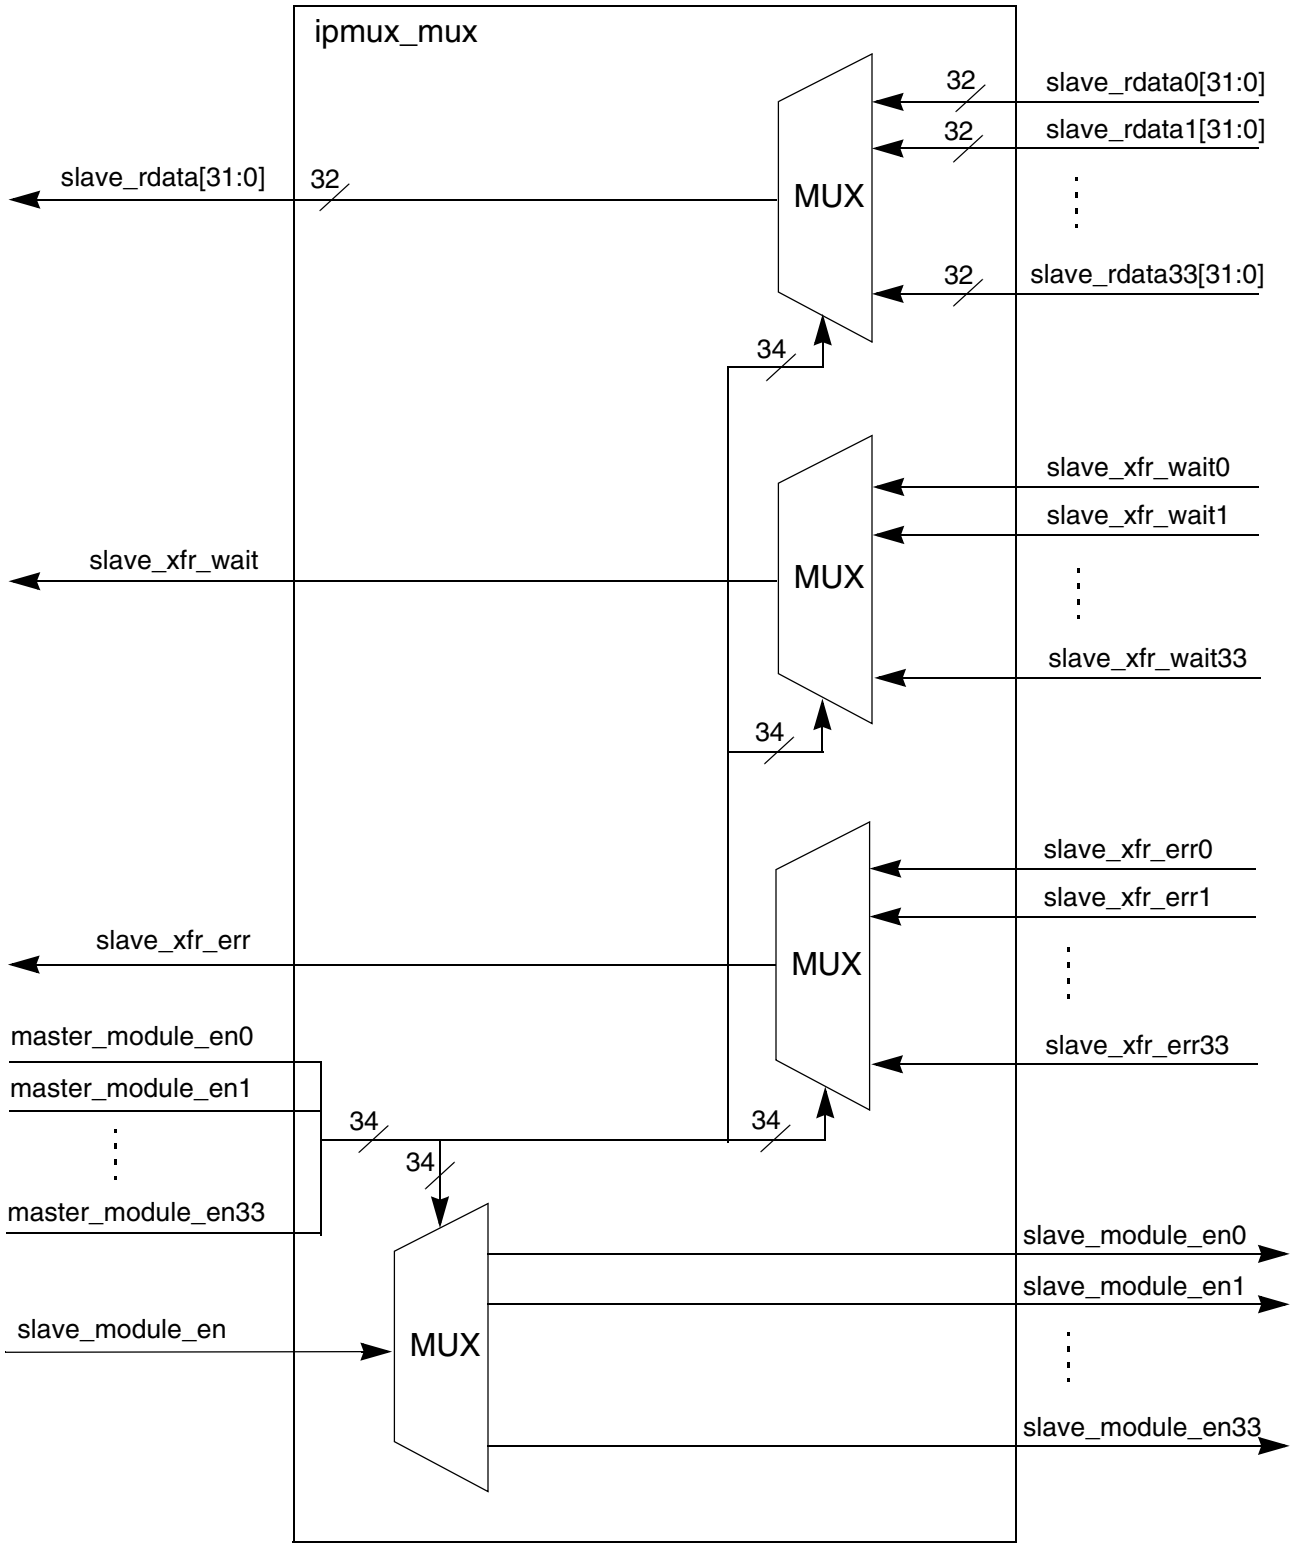

Figure 30-2. ipmux_mux Block Diagram

30.11 ipmux_ipis (IPMUX IPS Interface Synchronizer)

The ipmux_ipis is the IPMUX IP bus (also denoted IPS) interface synchronizing block which is responsible to synchronize the IPS bus protocol between IPS Master and IPS Slave which may toggle in different frequencies.

An assumption is made that both Master & Slave clocks are synchronized which practically means that master_frequency/slave_frequency is N or 1/N where N is a positive integer: N=1, 2, 3, ...

The above assumption enables not using synchronizers (double F.F.s) on signals which cross Master/Slave clock domains but using simple synchronizing state machine and logic which saves clock cycles.

The ipmux_ipis block diagram is illustrated in Figure 30-3

The main sub-block is ipmux_ipis_master_neq_slave_logic which is responsible for the IPS interface synchronizing between IPS Master and IPS Slave in case these clocks are not synchronized. Figure 30-4 and Figure 30-5 illustrates this sub-block functionality, which is controlled by a simple FSM.

The synchronization is basically done by controlling the slave_module_en signal goes to the slave and the master_xfr_wait signal which goes to the master. Sampling of slave_xfr_err and slave_rdata bus from the slave completes the synchronization task.

It can be shown that the ips_module_en signal and the ips_xfr_wait together play the major roles in the IP Interface (IPI) protocol and can be used directly to synchronize the handshake between master and slave.

Since IPS master and IPS slave may clock in different frequencies, the IPI protocol will operate at the lowest clock frequency. Three cases should be investigated:

1. Master clock and Slave clock are equal
2. Master clock is faster than Slave clock
3. Master clock is slower than Slave clock

Each one of the cases will be detailed described in section Section 30.14, “Timing Diagrams.”

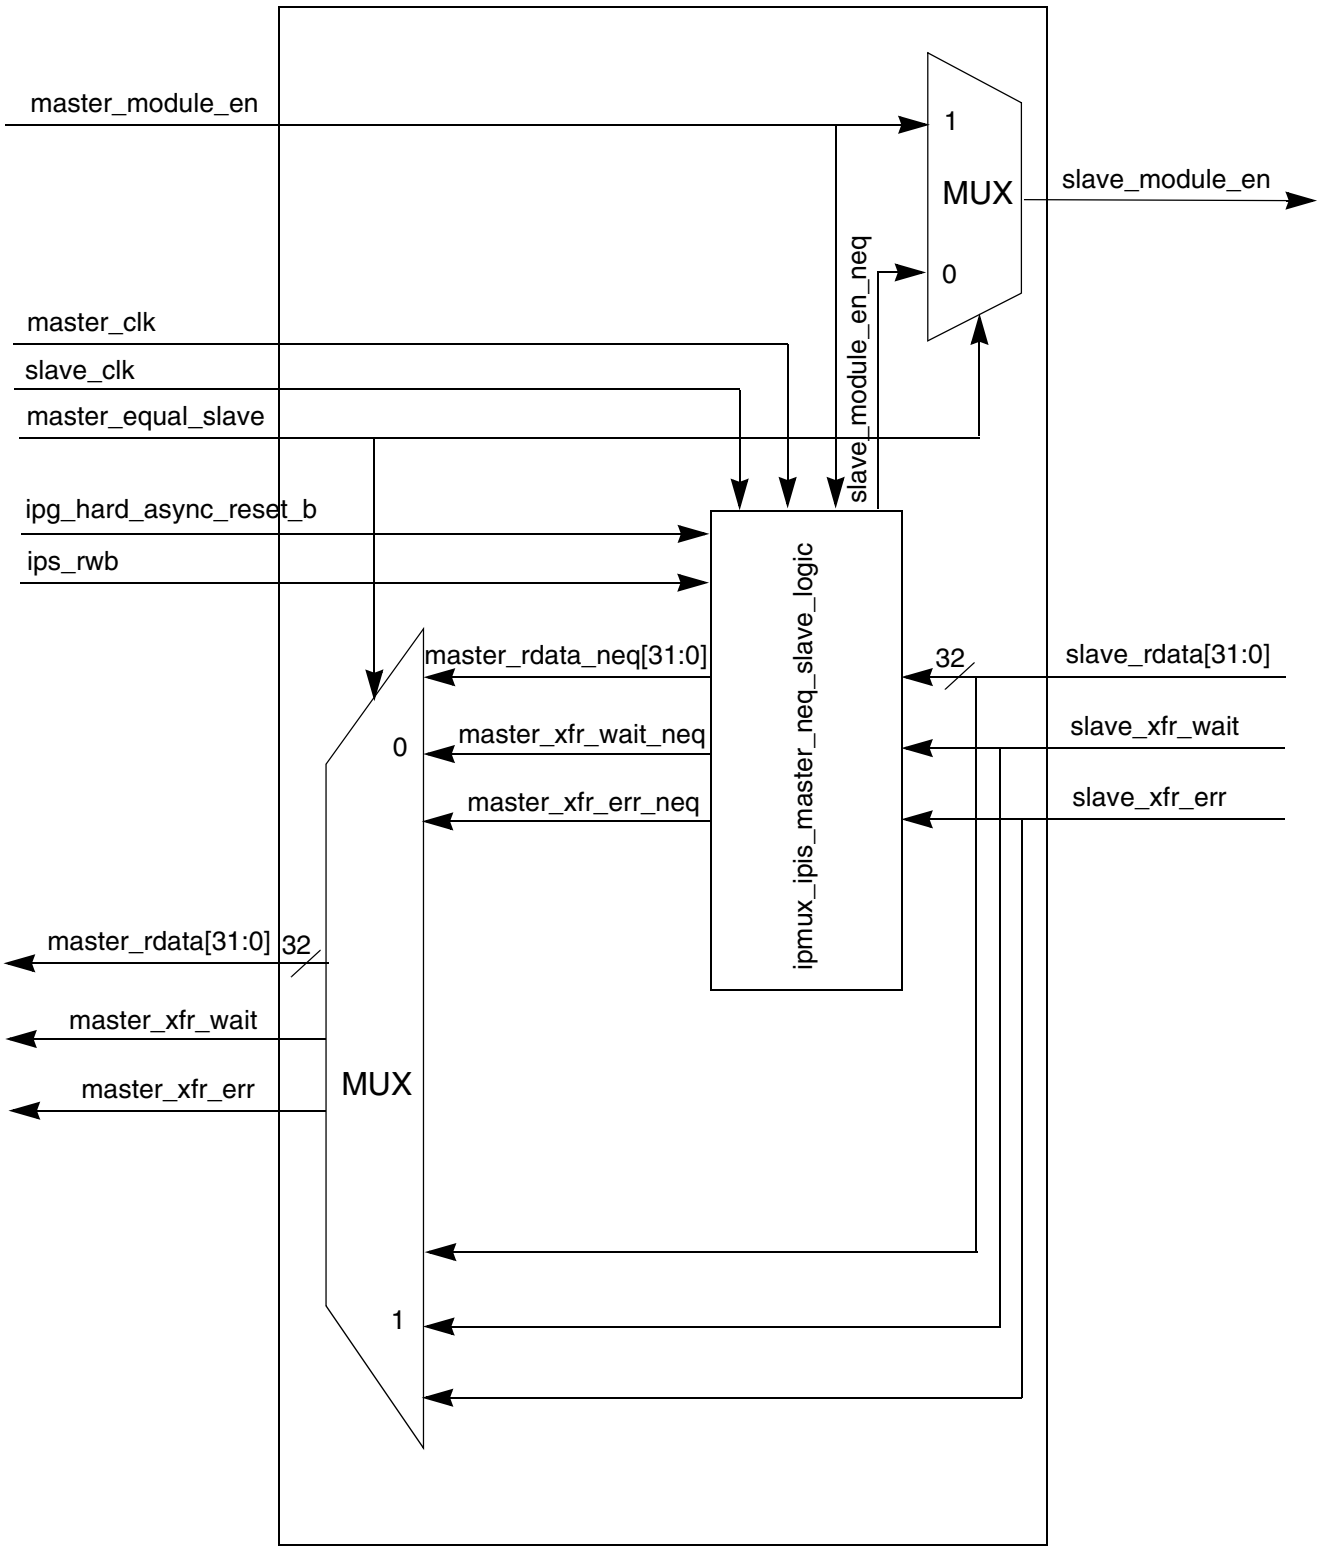

Figure 30-3. ipmux_ipis Block Diagram

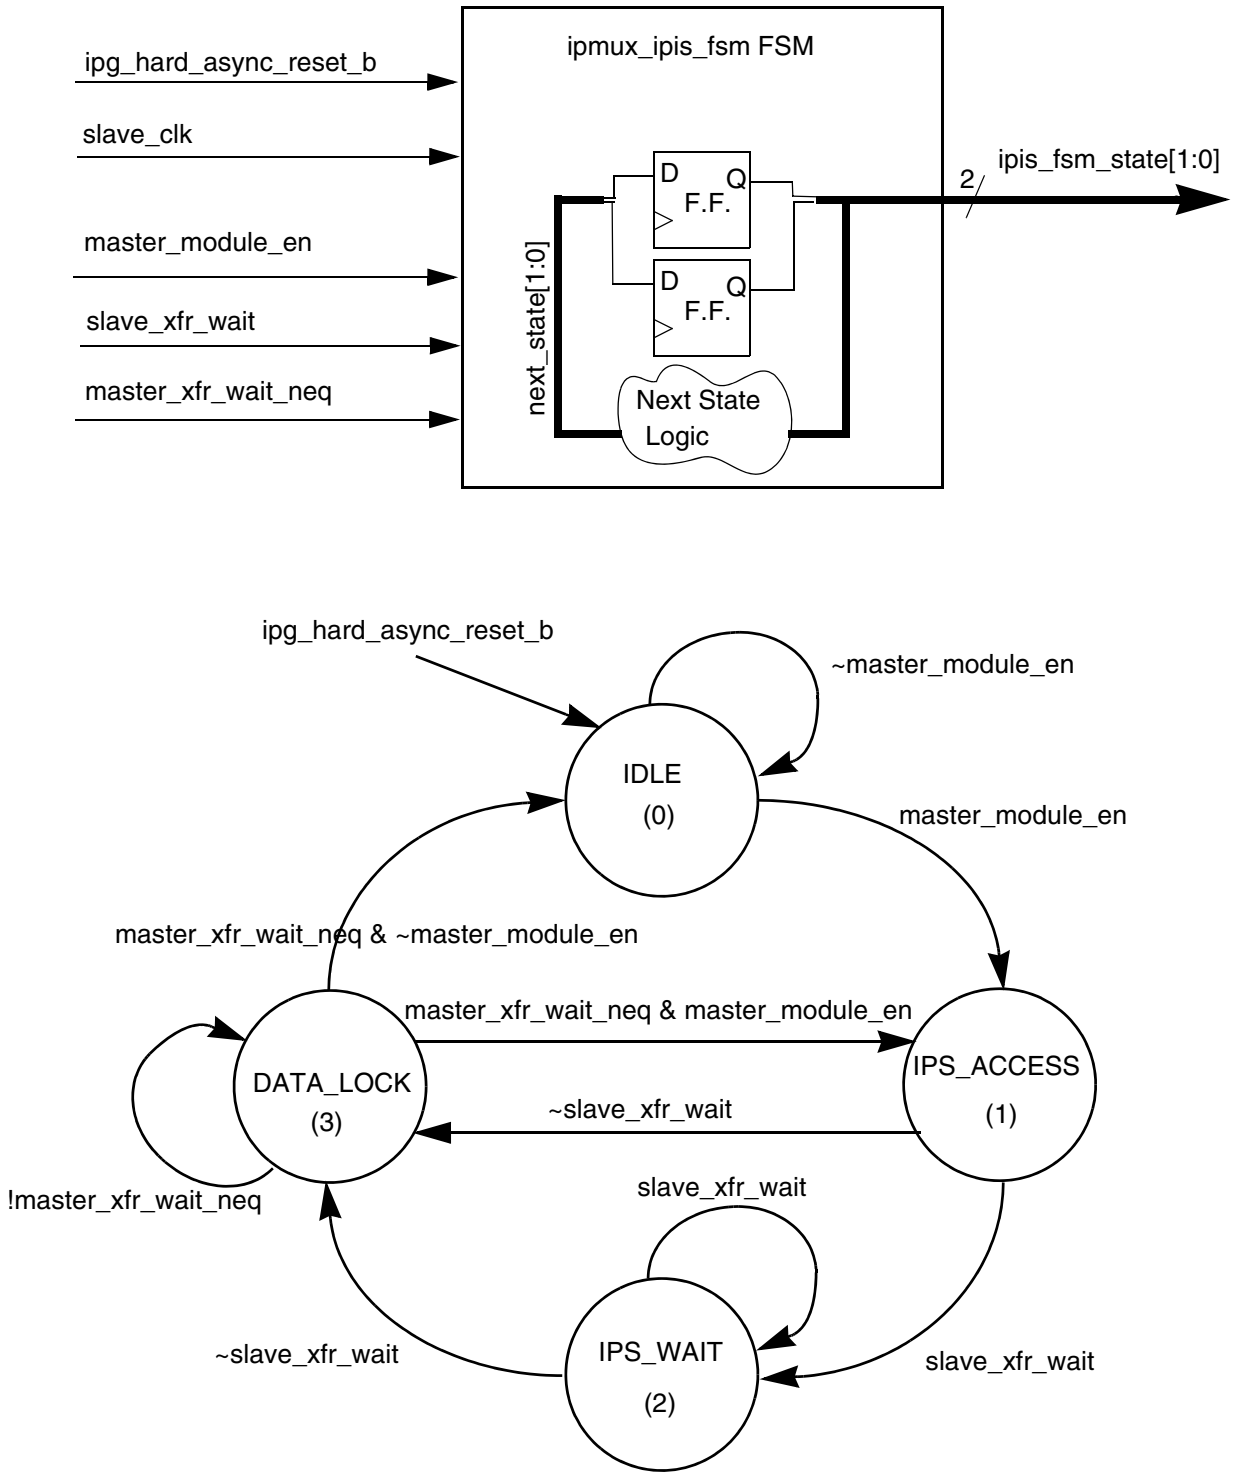

Figure 30-4. ipmux_ipis_master_neq_slave_logic block diagram part 1: ipmux_ipis_fsm

master_rdata_neq = slave_rdata sampled by slave_clk only if (ips_rwb == 1‘b1)&(master_module_en == 1‘b1)

master_xfr_err_neq = slave_xfr_err sampled by slave_clk only if (master_module_en == 1‘b1)

slave_module_en_neq = (state==IPS_ACCESS) | (state==IPS_WAIT)

master_xfr_wait_neq_not_sync = !(state==DATA_LOCK)

master_xfr_wait_neq = master_xfr_wait_neq_not_sync |
(!master_xfr_wait_neq_not_sync sampled with master_clk) <= see below figure

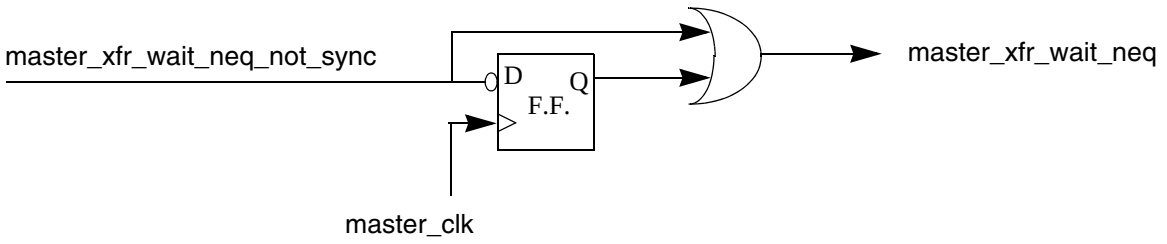

Figure 30-5. ipmux_ipis_master_neq_slave_logic block diagram part 1: Other Logic

30.12 ipmux_clock_gating (IPMUX Clock Gating)

The ipmux_clock_gating is the IPMUX clock gating sub-block which is responsible for generating the IPG gated clock, named also bus clock, for the 34 peripherals. Each gated clock will be toggling only when an IPS access is being activated for the specific peripheral. The gating which is done with the slave_module_en signal of each peripheral ensures minimum clock toggles for the proper functionality of the IPS bus interface and hence reduce power consumption.

The clock gating is done using the CMOS090LP library clock gating cells (sgclkn_seq_hivt_*). An ipt_se_gatedclk input signal to the ipmux_clock_gating sub-block will enable controllability of the clock gating during scan.

The ipmux_clock_gating block diagram is illustrated in Figure 30-6..

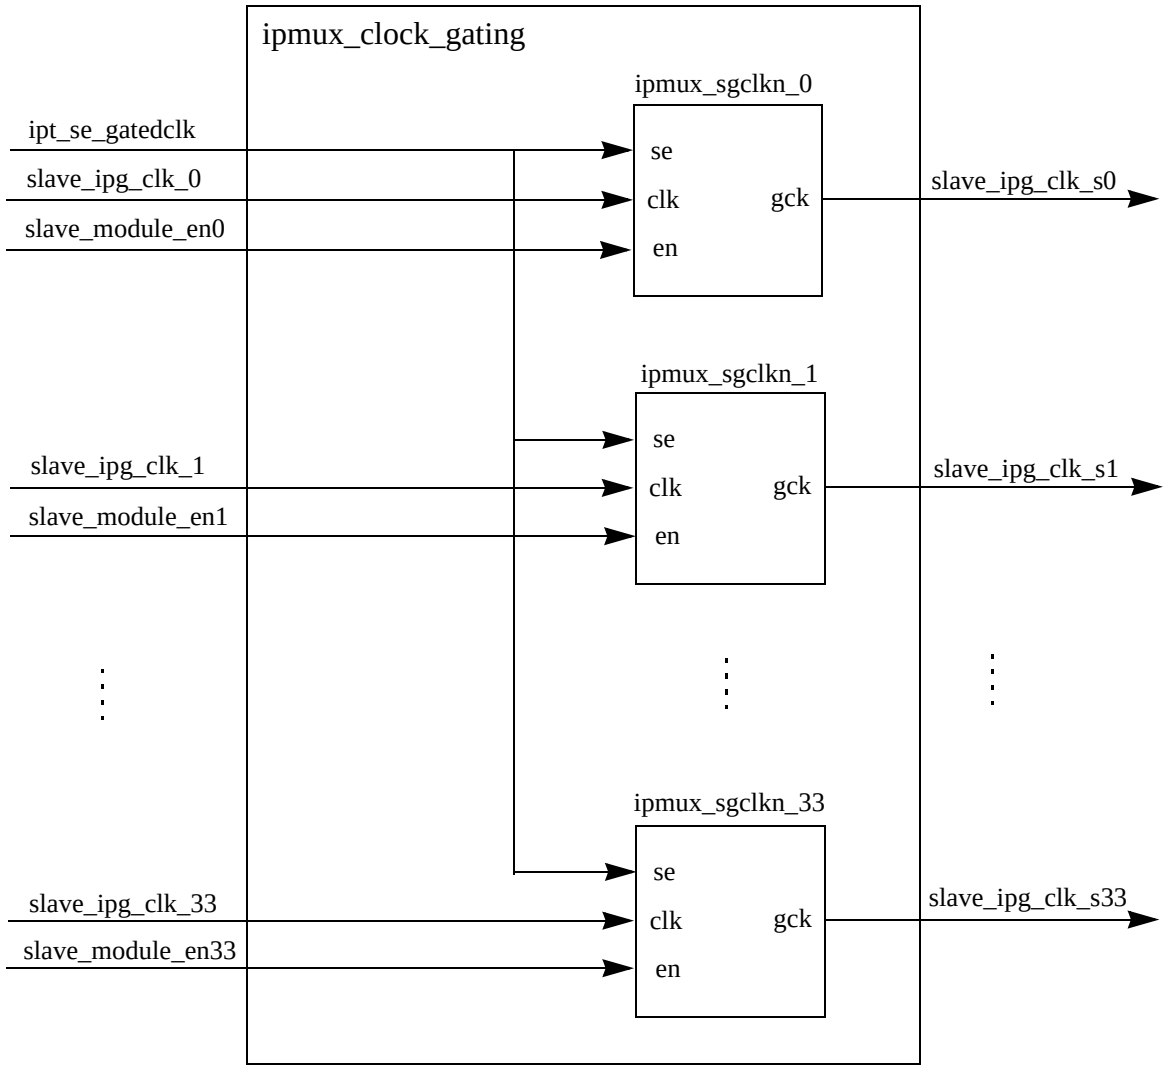

Figure 30-6. ipmux_clock_gating Block Diagram

30.13 Application Information

30.13.1 Connecting the IPMUX in the SOC

Figure 30-7. illustrates the connectivity of the IPMUX to the ARM11 platform and to the peripherals. Each IPMUX can handle up to 34 peripherals (IPS Slaves) connections, up to 32 data bits each. master_module_en33 (slot #33) should be used for module_en_glbl1 signal from ARM11 platform

master_module_en32 (slot #32) should be used for module_en_glbl0 signal from ARM11 platform or ips_module_en[32] from DSP platform

When less than 34 peripherals are connected:

- master_module_en* inputs that are not used should be tied low (0)
- slave_xfr_wait* inputs that are not used should be tied low (0)
- slave_xfr_err* inputs that are not used should be tied high (1)
- slave_rdata* inputs that are not used should be tied low (0)
- slave_ipg_clk* inputs that are not used should be tied low (0)

When less than 32 bit data peripheral is connected:

- The slave ips_rdata bus should be connected to the LSB of IPMUX slave_rdata bus
- The unused slave_rdata bits should be tied low (0)

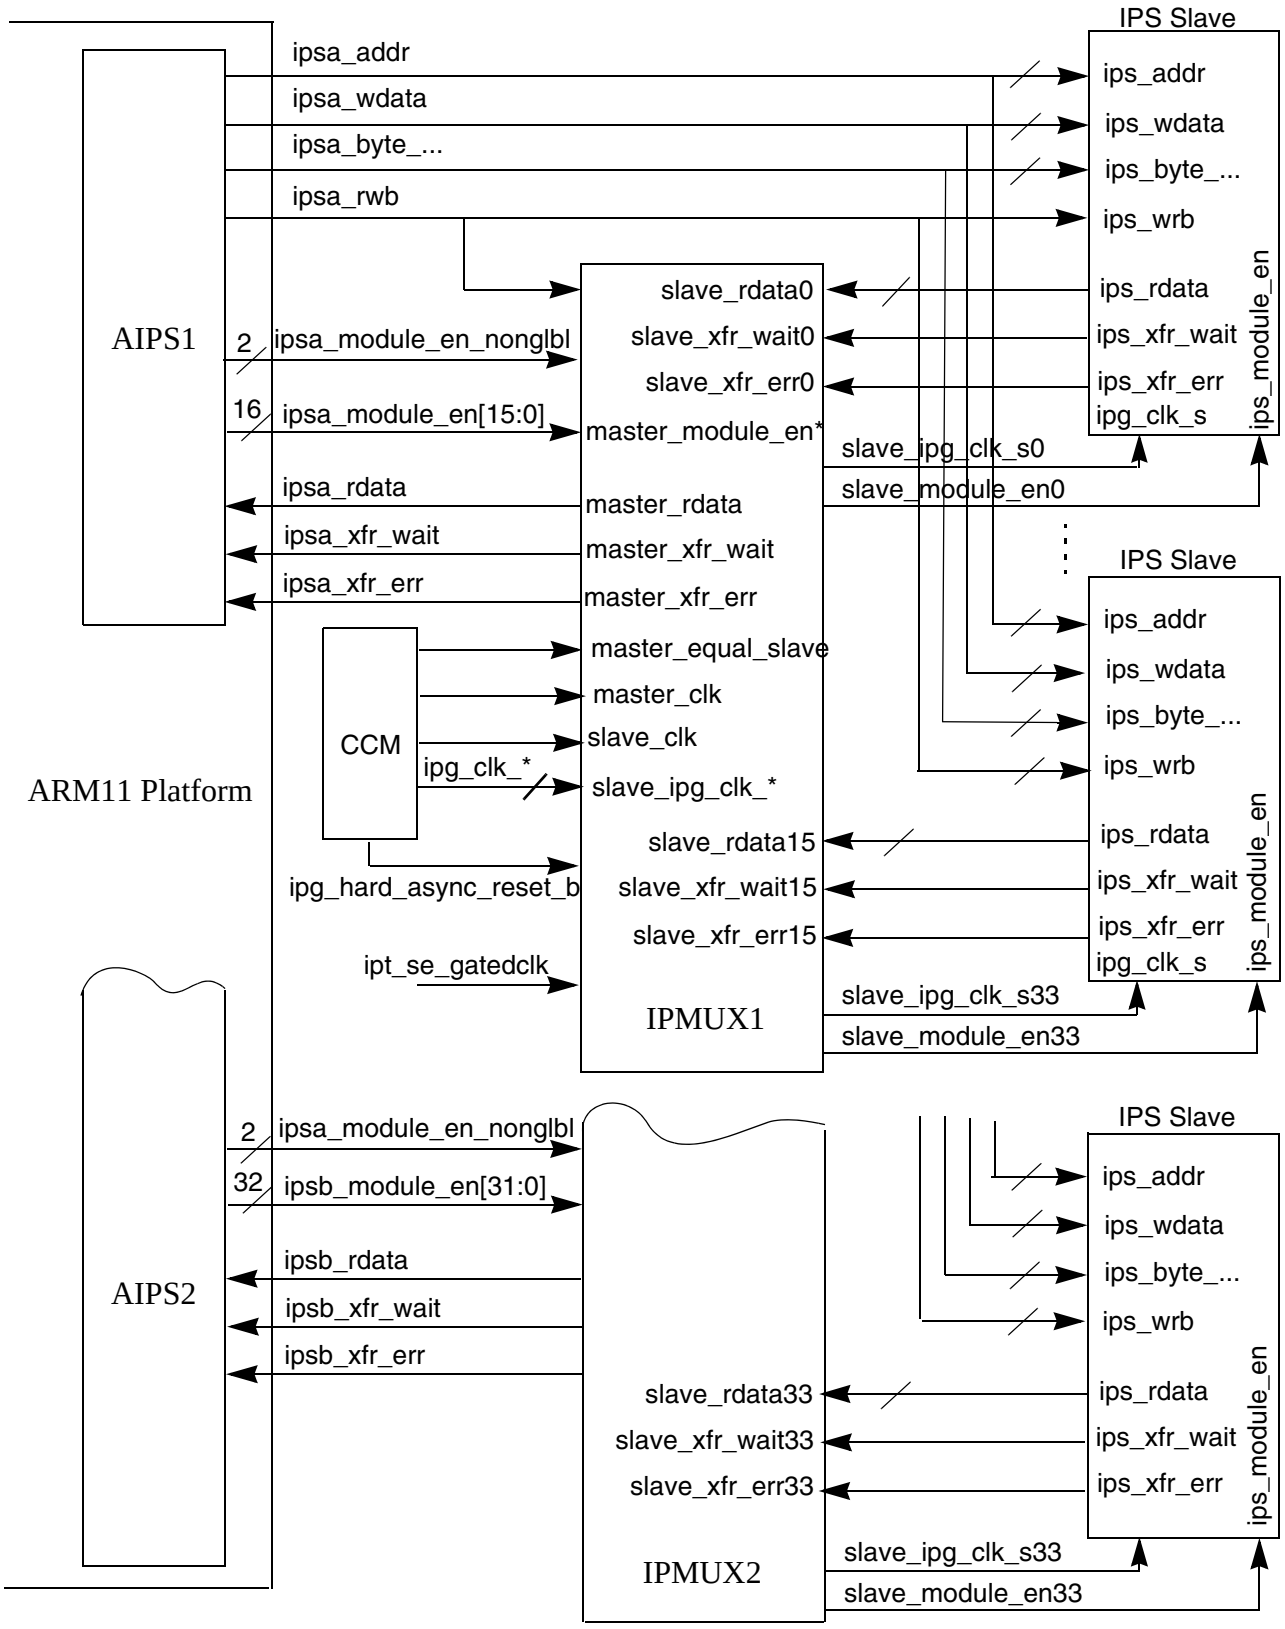

Figure 30-7. IPMUX connectivity in SOC (IPMUX2 connectivity is partially shown)

30.14 Timing Diagrams

In this section IPMUX timing diagrams will be described to expand the understanding of the IPMUX functionality. For better clarity 3 cases will be discussed separately according to the relation between the Master clock and the Slave clock:

- Master clock equal Slave clock
- Master clock is faster than Slave clock
- Master clock is slower than Slave clock

30.14.1 Master clock equal Slave clock

The case that Master clock equal Slave clock is the regular IP interface (IPI) protocol.

Access to peripheral may take only 1 cycle or may be extended by the peripheral using the ips_xfr_wait indication.

Since the ARM/DSP Platform and all peripherals should be able, by definition, to communicate by the IPI protocol in this case we need just to directly transfer all of signals without any manipulation/processing on each of the signals involved. When master clock equal slave clock the master_equal_slave input of the IPMUX may be asserted high to bypass any synchronization logic and directly connect master signals to slave signals. If master_equal_slave input will remain low the IPMUX will functional correctly, however, each IPS access will take 2 clocks longer.

The IP interface protocol is described in the SRS 3.1 IPI section, including signals detailed description, timing requirements and timing diagrams. See the IP bus interface for more details.

30.14.2 Master clock is faster than Slave clock

In case that the Master (initiator) clock is faster than the Slave (target) clock, wait states should be added in order to synchronize the Master fast clock to the Slave slow clock.

The ipmux_ipis will push the master_xfr_wait to 1, by default. This will insert the number of wait states required until the Slave will acknowledge that it is ready by slave_xfr_wait = 0.

Figure 30-8. illustrates the timing diagram for 0 wait states read access in this case.

It should be cleared here:

1. that the signals: ips_rwb, ips_addr[11:0] and ips_wdata don’t require any special treatment and may be connected directly to the peripherals, since they are generated by the Master and held valid whenever the master_module_en is enabled.
2. the master_xfr_err signal is handled like the slave_rdata[31:0] signals as it can logically be treated as bit number 33 in the slave_rdata bus (in read cycles), indicates if the data is valid or not.

Hence, write accesses and the following signals are not shown in the timing diagram: ips_addr[11:0], ips_wdata

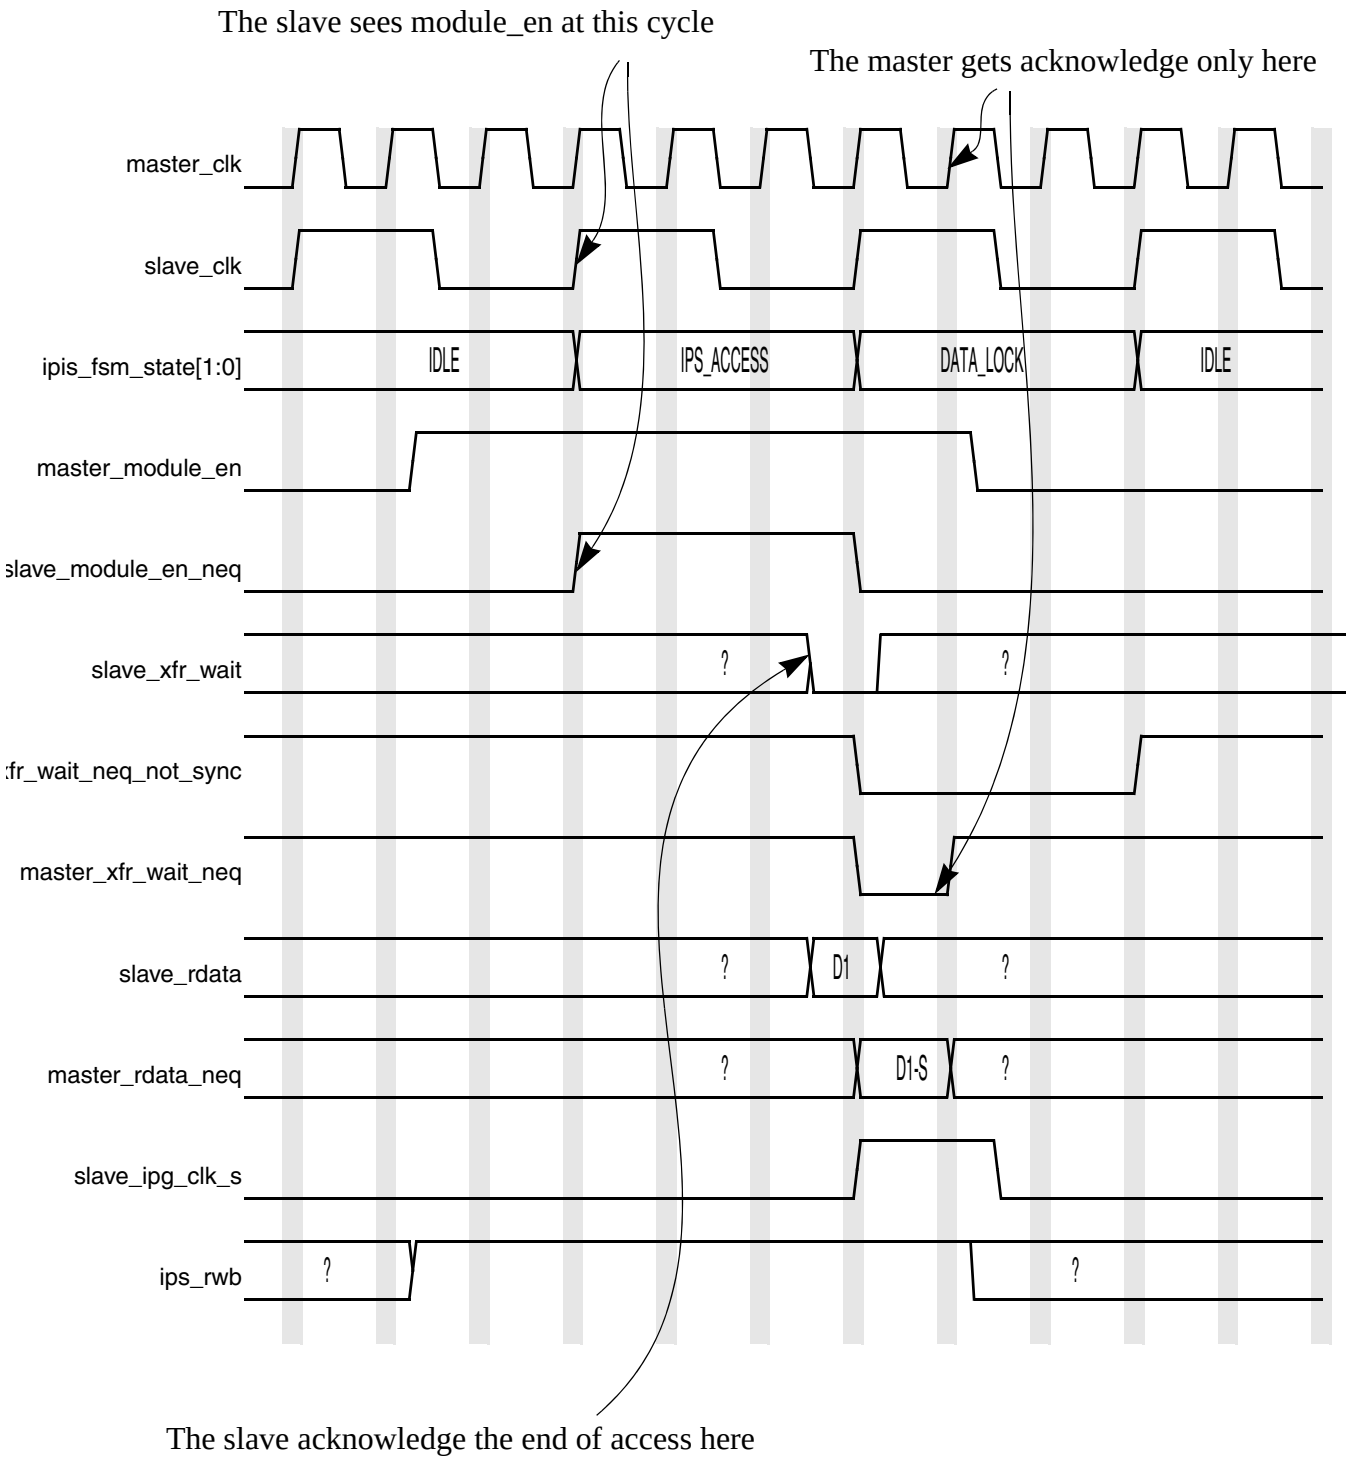

Figure 30-8. Master Clock Faster than Slave Clock—Timing Diagram (Read Access)

30.14.3 Master Clock is Slower than Slave clock

In case that the Master (initiator) clock is slower than the Slave (target) clock, the danger is that the response from the slave (xfr_wait & xfr_err) and the slave_rdata information will be lost, since not captured by the Master.

The ipmux_ipis samples the response signals, slave_xfr_wait & slave_xfr_err and the slave_rdata into F.Fs until the slow Master will be able to accept the information.

After the Master capture the information all F.Fs will be enabled again, and new access can be initialized.

Figure 30-9. illustrates the timing diagram for 2 sequential read accesses in this case.

Again, it should be cleared here:

1. that the signals: ips_rwb, ips_addr[11:0] and ips_wdata don’t require any special treatment and may be connected directly to the peripherals, since they are generated by the Master and held valid whenever the master_module_en is enabled.
2. the master_xfr_err signal is handled like the slave_rdata[31:0] signals as it can logically be treated as bit number 33 in the slave_rdata bus (in read cycles), indicates if the data is valid or not.

Hence, write accesses and the following signals are not shown in the timing diagram: ips_addr[11:0], ips_wdata

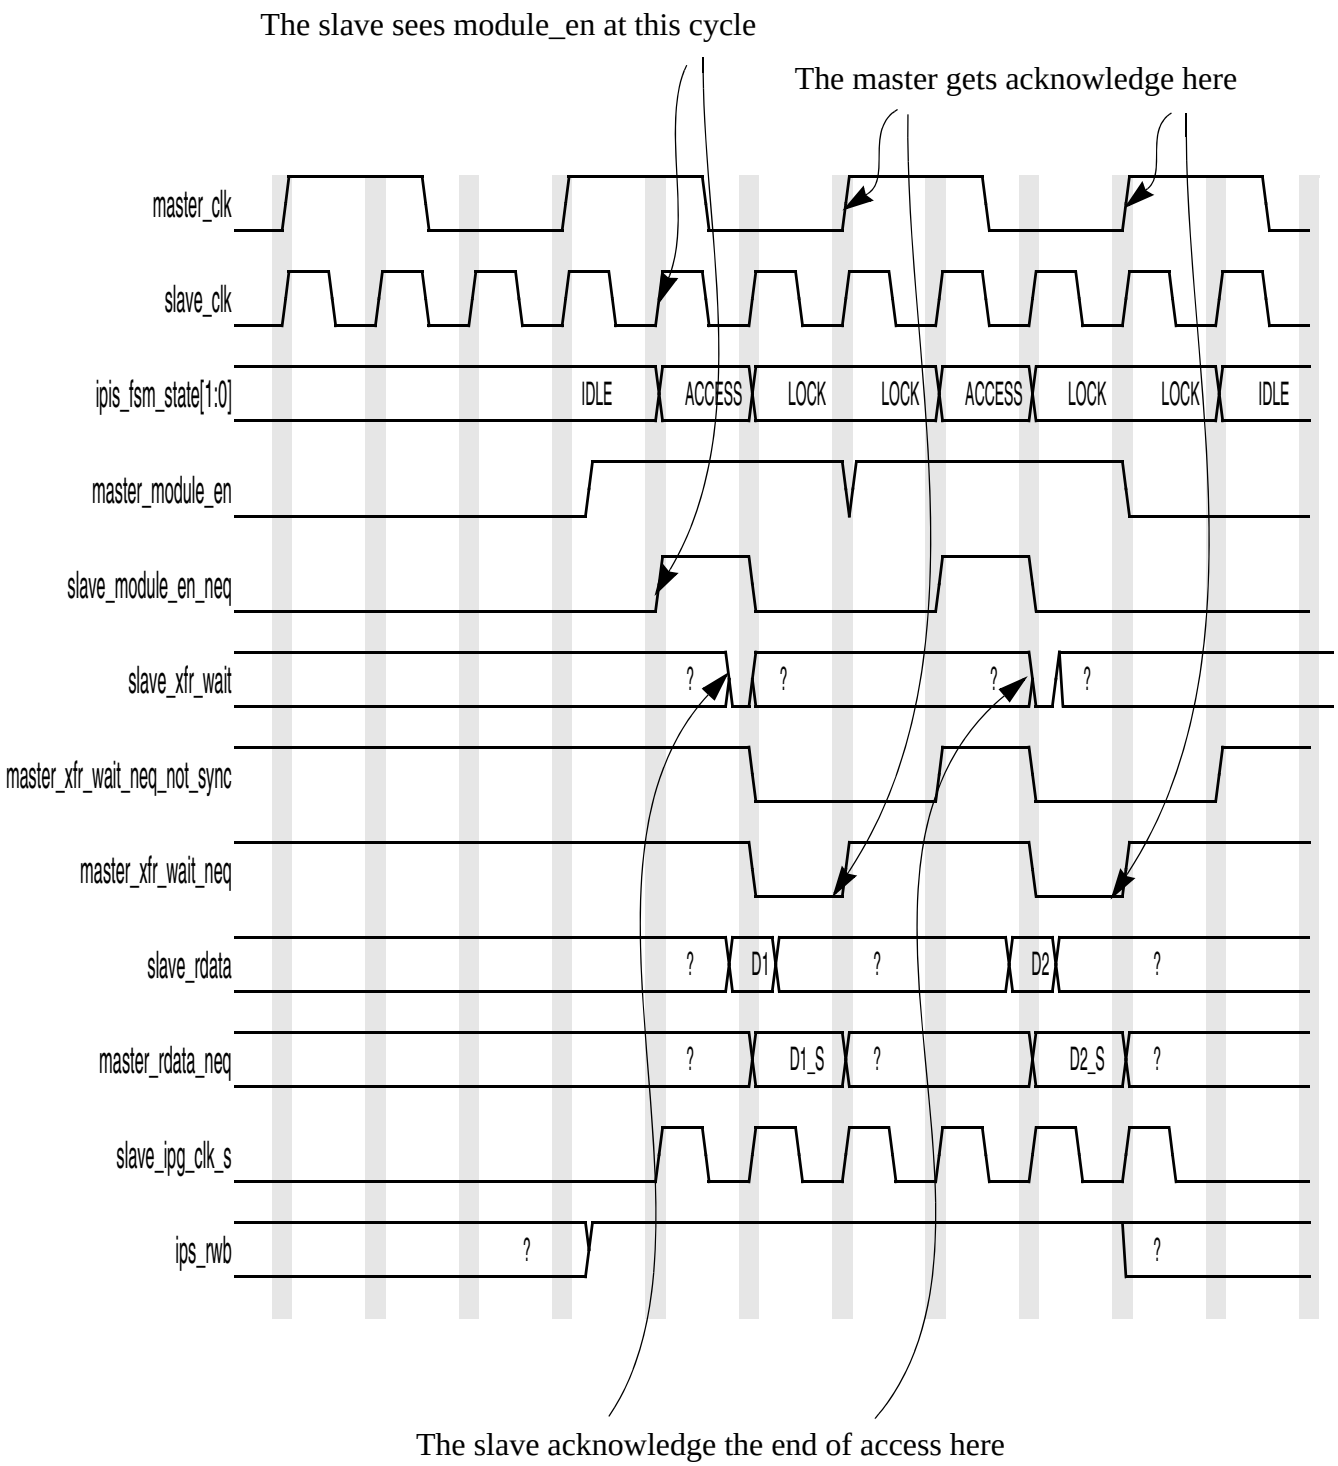

Figure 30-9. Master clock slower than Slave clock—Timing Diagram (2 read accesses)

30.15 Cycles Cost for IP Accesses

When the master clock is not equal to slave clock the IPMUX synchronization functionality cost clock cycles.

Table 30-2 describes the number of cycles added for all master clock / slave clock ratios.

Table 30-2. Cycles Cost for IP Accesses[1]

master_clk Frequency, HCLK (Period)	slave_clk Frequency (Period)	Number of Master Cycles (T multipliers) Required by AIPS		Maximum Added Master Cycles	Total Number of Master Cycles (T Multipliers) Required for Access	
		Read Access	Write Access		Read Access	Write Access
master_clk equal slave_clk (master_equal_slave == 1'b1)						
f (T)	f (T)	2	3	None (Direct Access)	2	3
master_clk equal slave_clk (master_equal_slave == 1'b0)						
f (T)	f (T)	2	3	2	4	5
master_clk faster than slave_clk						
f (T)	f/2 (2T)	2	3	$^{2}4$	6^{2}	7^{2}
f (T)	f/3 (3T)	2	3	6^{2}	8^{2}	9^{2}
f (T)	f/N (NT)	2	3	$2N^{2}$	$2N+2^{2}$	$2N+3^{2}$
master_clk slower than slave_clk						
f (T)	2F (T/2)	2	3	1	3	4
f (T)	3F (T/3)	2	3	None	2	3
f (T)	NF (T/N)	2	3	None	2	3

1 The table describes the number of cycles for each peripheral access.
It assumes 32 bit access to 32 bits peripheral or 16 bits access to 16 bits peripheral.
f is the master frequency (hclk); T is the master clock period (T=1/f)
2 This is the worst case value; it can be lower depending where the master clock "catches" the slave clock.

Chapter 31
Image Processing Unit (IPU)

The Image Processing Unit (IPU) is designed to support video and graphics processing functions and to interface to video/still image sensors and displays.

Figure 31-1 is a block diagram of the IPU.

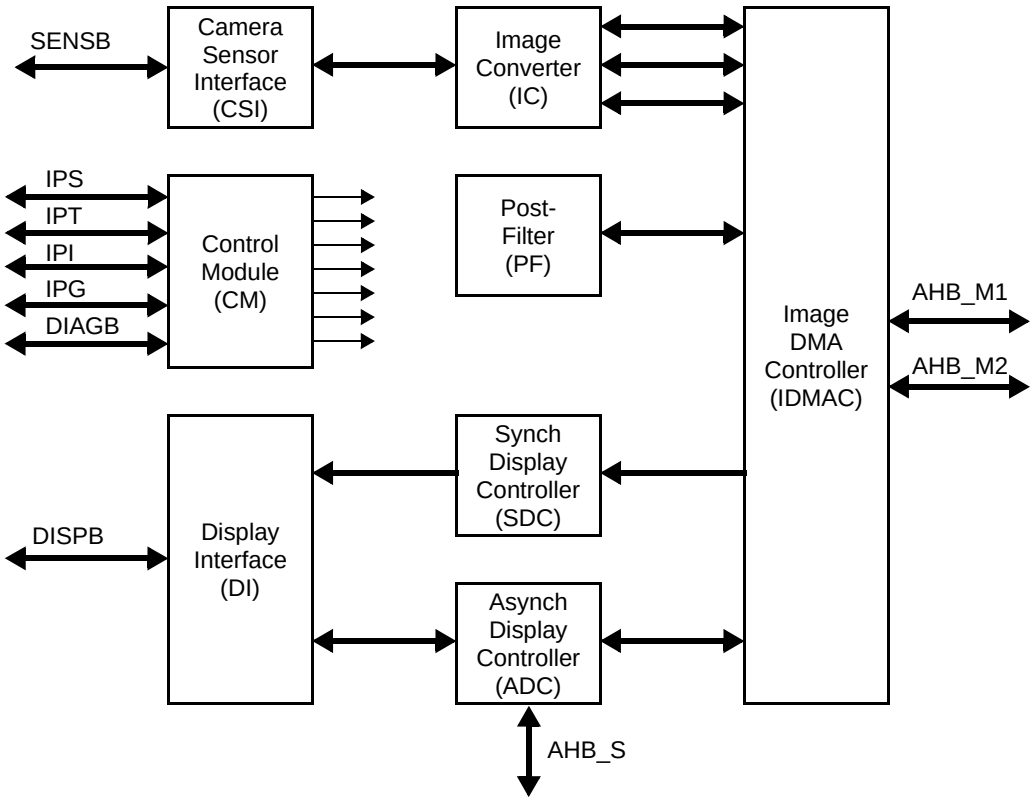

Figure 31-1. IPU Block Diagram

31.1 Overview

31.1.1 Functions Performed

The IPU performs the following main functions:

- Capturing image data from a camera sensor or from a TV decoder. The captured image can be sent to preprocessing or stored in an external system memory for additional processing by the core.

- Preprocessing of data from the sensor or from the external system memory. There are two preprocessing channels according to the data destination - an encoder or a display (viewfinder mode). Preprocessing includes the following operations:
  - Downsizing with independent integer horizontal and vertical ratios
  - Resizing with independent fractional horizontal and vertical ratios
  - Color space conversion (YUV to RGB, RGB to YUV, YUV to different YUV)
  - Combining a video plane with a graphics plane (blending on graphics on top of video plane)
  - 90-degree rotation, up/down and left/right flipping of the image.
- Postprocessing of data from the external system memory. The core can invoke a number of postprocessing channels sequentially by re-programming the IPU after finish of previous channel frame processing. Postprocessing includes the following operations:
  - downsizing with independent integer horizontal and vertical ratios
  - resizing with independent fractional horizontal and vertical ratios
  - color space conversion (YUV to RGB, RGB to YUV, YUV to different YUV)
  - combining a video plane with a graphics plane (blending on graphics on top of video plane)
  - 90 degree rotation, up/down and left/right flipping of the image.
- Post-filtering of data from the system memory with support of the MPEG-4 (both deblocking and deringing) and H.264 postfiltering algorithms.
- Displaying video and graphics on a synchronous (dumb or memory-less) display with the following options:
  - on-the-fly combination of video and graphics planes
  - generation of the hardware cursor
  - horizontal and vertical scrolling.
- Displaying video and graphics on an asynchronous (smart) display. There are two mechanisms to support smart display or graphic accelerator functionality: interleaving data and commands from a command buffer prepared by the core or automatic commands generation according to a prepared template. The data can be sent to the smart display from the system memory, internal IPU processing modules or directly from the core or the system DMA controller.
- Transferring data between IPU submodules and to/from the system memory with flexible pixel reformatting.

31.1.1.1 External Interfaces

The IPU is an autonomous module controlled by the core via the IP bus interface (IPS). Data from the sensor arrives to the IPU via the Sensor Bus (SENSB). Writing results to the external system memory and reading a previously stored data or a data received from communication channel can be performed via Master AHB Port(s). There are two possible operating modes corresponding to single and dual Master AHB Port. For dual mode, the IPU uses the ports in turn. This allows to improve data throughput in the Memory Interface by means of latency hiding. Each mode is selected by an external pin and a control bit in the peripheral bus register. If the pin sets single port mode, the control bit has no effect.

Additionally, the core can communicate directly with the IPU through the Slave AHB Port (AHB_S). The IPU output is sent to synchronous or asynchronous displays or to a TV encoder through the Display Bus (DISPB).

The IPU generates interrupts for the core via the IP bus. The IP bus provides system clock and reset signals. The IP bus is used to support scan functionality of the module. For debugging purposes, the IPU has a Diagnostic Bus (DIAGB) which allows real-time monitoring of internal signals. These signals are output via chip GPIO pins in debug mode.

Detailed description of all signals of the interface buses is found in Section 31.2.2, "Detailed Signal Descriptions." Specific connection of the buses to the core platform, the Memory Controller, the Clock Controller etc. is chip dependent. It should be described in the chip specification integration part.

31.1.1.2 Data Flows and Formats

The IPU consists of the camera sensor interface (CSI), the image converter (IC), the post-filter (PF), the synchronous display controller (SDC), the asynchronous display controller (ADC), the display interface (DI) and the image DMA controller (IDMAC).

The sensor data is fed to the CSI. The CSI output is a 64-bit word that includes two pixels (8- or 10-bits per color component) or two/eight words of generic data (16 most significant bits per 16-bit words or 8-bits per word). The IPU does not control the sensor. This function has to be performed by the core via the I^2C interface and GPIO pins connected to the sensor.

The sensor data arrives to the IC from the CSI. The CSI converts the data to one of the following formats:

- YUV 4:4:4 or RGB - 8 bits per color component,
- YUV 4:4:4 or RGB - 10 bits per color component,
- generic data (from sensor to the system memory only) - 8 or 16 bits per word.

The IC executes pre- and postprocessing tasks. There are two preprocessing and one postprocessing tasks performed by the IC in time multiplexed mode. The core programs the tasks parameters. Task context switching is transparent for the core.

The IC communicates with the IDMAC via three buses. The first bus is used for storing the sensor data in the system memory and for loading video data from the memory for pre- and postprocessing. The following data formats are supported for this bus:

- YUV 4:4:4 or RGB - 8 bits per color component,
- YUV 4:4:4 or RGB—10 bits per color component,
- generic data (from sensor to the system memory only)—8 or 16 bits per word.

The data bus width is 64 bits for write and 48 bits for read.

The second bus is intended for loading graphics data and output processing results to the system memory or the ADC. The following data formats are supported for this bus:

- YUV 4:4:4—8 bits per color component,
- RGB—8 bits per color component,
- RGBA—8 bits per color component (only for graphics).

The data bus width is 48 bits for write and 64 bits for read.

The third bus transfers image data to be rotated from the system memory to the IC and returns the rotated image to the memory. The width of each of the buses corresponds to two pixels in the following formats

- YUV 4:4:4—8 bits per color component,
- RGB—8 bits per color component,
- RGBA—8 bits per color component (only for graphics).

The bus data width is 64 bits both for read and write.

The PF implements the MPEG-4 and H.264 post-filtering algorithms. It gets the input data from the system memory and returns it to the memory via the 64-bit bus connected to the IDMAC. For MPEG-4 mode, there are two filtering steps: deblocking and deringing. For H.264, only deblocking is performed. The bus transfers simultaneously eight components of one color (Y or U or V) related to eight pixels.

The SDC is designed to support memory-less synchronous displays and synchronous interfaces of smart displays. The supported display types are TFT and TV. For TV mode, the pixels are presented in the YUV 4:2:2 format, for TFT modes—in the RGB or monochrome format. The SDC receives data from the IDMAC via a 64-bits bus. The IDMAC is responsible to convert the external memory data to one of the following bus formats:

- Two pixels in the RGB format, 8 bits per color component—for color video,
- Two pixels in the RGBA format, 8 bits per color component—for color graphics,
- Two pixels in the YUV 4:4:4 format, 8 bits per color component—for color video and a TV display,
- Eight pixels in the monochrome format, 8 bits per pixel—for monochrome video,
- Four pixels in the monochrome format, 16 bits per pixel (8 bits pixel data and 8 bits a-parameter)—for monochrome graphics,
- Sixty four control bits—for the windowing function.

The SDC combines video and graphics planes before sending data to a display. Combining is performed with α-blending. An image is combined also with a hardware cursor of programmable color and other attributes. The SDC supports the windowing function by means of display enable control. In addition to data, the SDC generates display controls with programmable timing.

The ADC controls asynchronous (smart) displays and external graphics accelerators. It supports both write and read access modes to the display memory. Write/read data can be transferred from/to the system memory or from the IC (write only) via the IDMAC. Another option is direct writing/reading by the core or the system DMA controller via the AHB_S bus. The bus connected to the IDMAC is of the 64-bits width. It can transfer data in the following formats:

- Pixel data—Two pixels in RGB format, 24 bits/pixel (located in 32-bit word each one), each pixel is aligned to the MSB bits of a 32-bit word,
- Generic data—Two data words of 24 bits/word (located in 32-bit word each one) or four data words of 16 bits/word, each data word is aligned to the LSB bits of a 32-bit word (the core software is responsible for the proper format of generic data),
- Command—Two data words of 24 bits/word (located in 32-bit word each one) or four data words of 16 bits/word, each command word is aligned to the LSB bits of a 32-bit word.

Because smart displays are represented by two interface registers—one index register and one data register, the ADC generates a sequence of commands and combines them with data for both write and read operations. There are two modes of display access: streaming commands from a memory buffer prepared by the core and automatic emulation of transparent writing/reading using access templates. The ADC is able to work with two types of displays: with full linear addressing and X/Y addressing.

The ADC includes a special mechanism to avoid image tearing. This mechanism is operating while transferring data from the system memory or directly from postprocessing and in a special case—directly from preprocessing.

The DI combines outputs of the SDC and the ADC. The DI output bus (DISPB) is shared to support simultaneously one synchronous display and up to three devices like smart display in time multiplexed mode. The DI maps the SDC and ADC outputs to the DISPB and synchronizes the SDC and the ADC. If both types of displays are used, access to the smart displays is performed during vertical blanking intervals of the memory-less display. Typically, these intervals occupy up to 15% of refresh cycle. This is the limitation for throughput of the asynchronous interface in such mode. For a dual-port smart display, the display memory can be accessed both through the synchronous and asynchronous interfaces.

The DI provides programmable display access timings both for fast and slow displays. Control signals and data polarity is also programmable. The DI performs very flexible packing and unpacking display data which allows to support different display interfaces. For example, the DI can pack the data to the RGB565 format.

The IDMAC provides data transfer of two types:

- Between internal IPU modules,
- Between IPU modules and the system memory.

The IDMAC main features are:

- General features
  - 32 full programmable DMA channels with two groups of channel priorities and random choice in a group,
  - programmable AHB burst length—from 1 to 9 words,
  - end-of-frame interrupt generation for each channel,
  - error generation for each channel,
  - Big and little-endian AHB interface mode,
- Addressing features
  - transfer of two-dimensional image frames line-by-line or by two-dimensional blocks with programmable vertical overlap,
  - interleaved and non-interleaved data addressing modes,
  - panning with data access resolution of single pixel,
  - frame rotation and flipping left/right option when transferring two-dimensional blocks,
  - frame up/down flipping option,
  - line interlacing,
  - frame scrolling,

  - frame double buffering within a DMA channel when accessing the system memory,
  - end of frame indication.
- Data conversion features
  - conversion of the data format from the system memory to the internal IPU formats (YUV 4:4:4, 8 bits/color or RGBA, 8 bits/color or RGB, 8 bits/color) including interleaving non-interleaved YUV pixels, programmable unpacking RGBA or RGB pixels, programmable look-up-table decoding color pixels from a palette. Conversion of the external formats YUV 4:2:0 and YUV 4:2:2 to the internal format YUV 4:4:4 is performed by repetition of the existing U and V color components.
  - conversion of the internal data formats to system memory formats including de-interleaving YUV pixels, programmable packing RGBA or RGB pixels. Conversion of the internal format YUV 4:4:4 to the external formats YUV 4:2:0 and YUV 4:2:2 is performed by decimation of the U and V color components.
  - transfer of a generic data without conversion.

The IDMAC accesses the AHB_M1(2) buses with bursts of 32-bit words transferred every clock cycle. Internal data transfers can be performed every second clock cycle but, because the width of the internal buses is 48 or 64 bit, throughput is the same in the case of non-packed and non-coded AHB data.

The CM performs common IPU service functions: interfacing to the peripheral IP bus interface, interrupt generation, debugging, clock and reset generation, access to internal memories. Additionally, the CM synchronizes IPU tasks triggering and transferring image frames between internal IPU modules and the system memory.

31.1.1.3 Clocking Scheme

31.1.1.3.1 General

Table 31-1 describes the IPU clocks.

Table 31-1. IPU Clocks

Name	Symbol	Source	Destination	Rate	Description
AHB clock	HCLK	Clock Controller	Master and Slave AHB IPU interfaces	up to 133 MHz	Input clock derived by integer division of high frequency core clock (~500 MHz)
Green Line IP clock	IPG_CLK	Clock Controller	IP bus IPU interface[	up to 66 MHz	Input clock derived by division of HCLK clock by 1 or 2
High speed processing clock	HSP_CLK	Clock Controller	all IPU submodules	up to 178 MHz @ 1.45 V, up to 133 MHz @ 1.1 V, equal or higher than HCLK rate	Input clock derived by integer division of high frequency core clock (~500 MHz), rising edges are aligned with HCLK and IPG_CLK rising edges

Table 31-1. IPU Clocks (Continued)

Name	Symbol	Source	Destination	Rate	Description
Sensor clock	SENSB_SENS_CLK	Clock Controller	CSI	max rate at least 73 MHz (see Section 31.4.1.5, "Sensor Interface Control")	Clock Controller should provide the required clock frequency precision (about +/-3%)
Master clock to sensor	SENSB_MCLK	CSI	Sensor	max rate at least 73 MHz (see Section 31.4.1.5, "Sensor Interface Control")	Output clock derived by repeating the SENSB_SENS_CLK clock or by integer division of the HSP_CLK clock
Pixel clock from sensor	SENSB_PIX_CLK	Sensor	CSI	max rate at least 73 MHz (see Section 31.4.1.5, "Sensor Interface Control")	Input clock used as sensor data strobe
Display interface clock	DISP0_IF_CLK, DISP1_IF_CLK, DISP2_IF_CLK, DISP3_IF_CLK	DI	displays	up to HSP_CLK rate	Output clocks used as display interface clock for driving corresponding display chip select or read/write strobe pins (for asynchronous displays 0, 1, 2) or display clock input pin (for synchronous display 3). DISP0_IF_CLK, DISP1_IF_CLK, DISP2_IF_CLK are generated internally by integer division of HSP_CLK clock, DISP3_IF_CLK is generated internally by fractional division of HSP_CLK clock.
Display pixel clock	DISP0_PIX_CLK, DISP1_PIX_CLK, DISP2_PIX_CLK,	DI	SDC, ADC	up to HSP_CLK rate	Virtual clocks generated internally by fractional division of HSP_CLK clock, used internally in SDC and ADC for tracking display refresh. Display 3 pixel clock is generated by division of DISP3_IF_CLK, the division factor is a number of cycles required for one pixel output.

Figure 31-2 shows the high level block diagram of the IPU clocking.

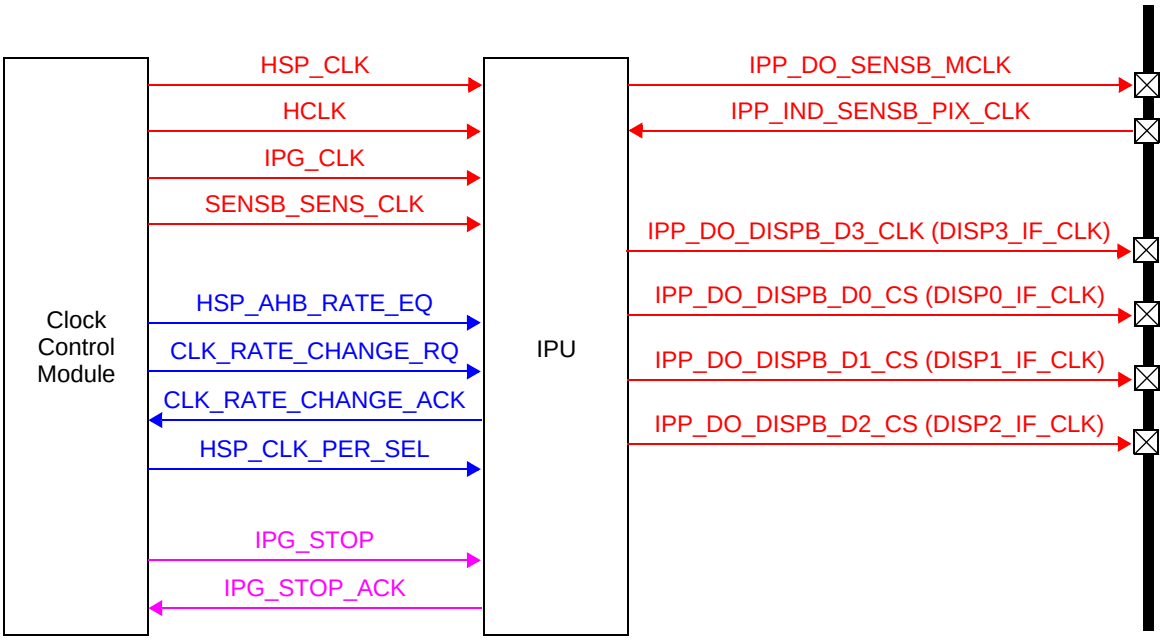

Figure 31-2. High Level Block Diagram of the IPU Clocking

31.1.1.3.2 Changing Clock Rates and Disabling Clocks

Figure 31-3 shows the relationship between the HSP_CLK, HCLK and IPG_CLK clocks.

The HSP_CLK rate can be equal or higher than the HCLK rate. The IPG_CLK rate is equal or lower than the HCLK rate. The IPU input pin HSP_AHB_RATE_EQ when high indicates equality of the HSP_CLK and HCLK rates. Transition between two HSP_AHB_RATE_EQ states (between equal and different HSP_CLK and HCLK rates and vice versa) allowed only when rising edges of all the clocks are aligned. At this time, the IDMAC and the ADC must be disabled and the core must not access the IPS and AHB_S buses.

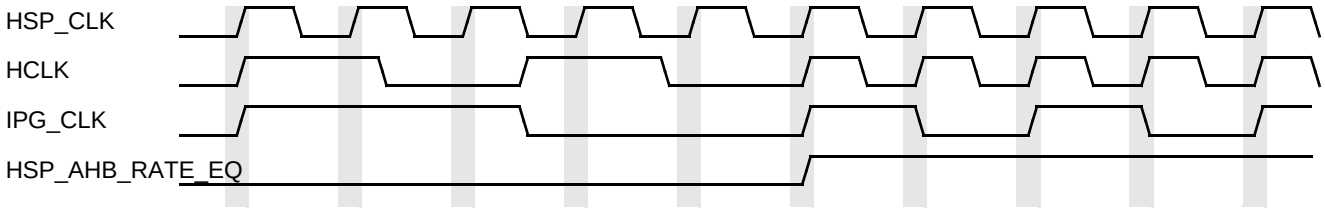

Figure 31-3. Relationship Between HSP_CLK, HCLK and IPG_CLK

The HSP_CLK and HCLK rates can be changed without stopping the IPU if the HSP_CLK rate is equal to the HCLK rate both before and after the change or the HSP_CLK rate is higher than the HCLK rate in both cases. Independently on the HSP_CLK rate change, the DISP#_IF_CLK and DISP#_PIX_CLK rates have to remain unaltered. This is achieved by means correction of the display clock rates according to the IPU input pin HSP_CLK_PER_SEL which must be toggled every time when the HSP_CLK rate is

changed. Before changing the HSP_CLK rate, the core should program the appropriate IPU register with a new value of the HSP_CLK period. The DI corrects the DISP#_IF_CLK and DISP#_PIX_CLK rates according to this data.

The operation sequence of clock rate change is as follows.

1. The core writes the new HSP_CLK period to the IPU control register.
2. The Clock Control Module asserts the CLK_RATE_CHANGE_RQ signal.
3. The IPU replays with the CLK_RATE_CHANGE_ACK pulse after it has finished current access to a display.
4. The Clock Control Module waits for alignment of positive edges of all clocks and changes clock rates simultaneously with toggling the HSP_CLK_PER_SEL signal. (See Figure 31-4.)

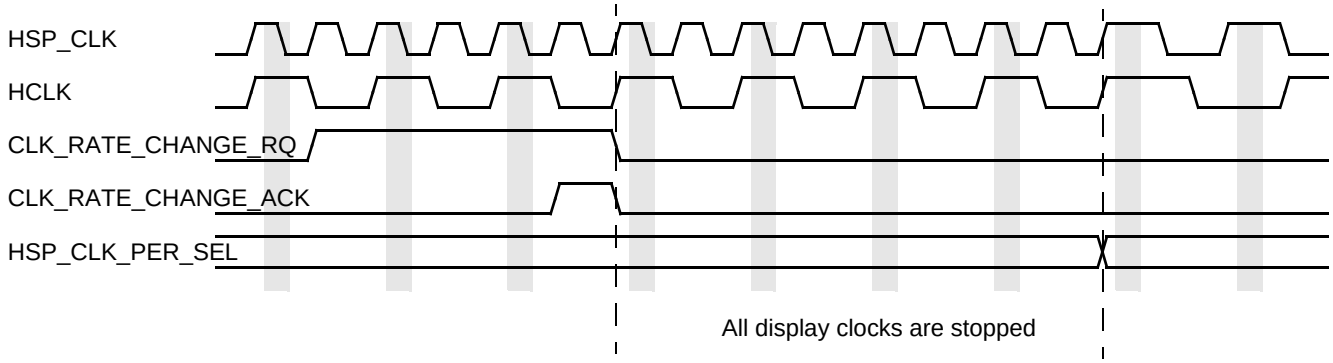

Figure 31-4. Operation Sequence of Clock Rate Change

In standby mode, all IPU clocks are gated off by the Clock Control Module. The hardware handshaking mechanism to enter standby mode is as follows (also see Figure 31-5):

1. An external standby mode controller asserts the IPG_STOP signal to the IPU.
2. The IPU stops running tasks synchronously at end of all active frames.
3. The IPU asserts the IPG_STOP_ACK signal
4. The IPU clocks are stopped by the Clock Control Module.
5. At resuming clock generation, the IPG_STOP and IPG_STOP_ACK signals are negated.

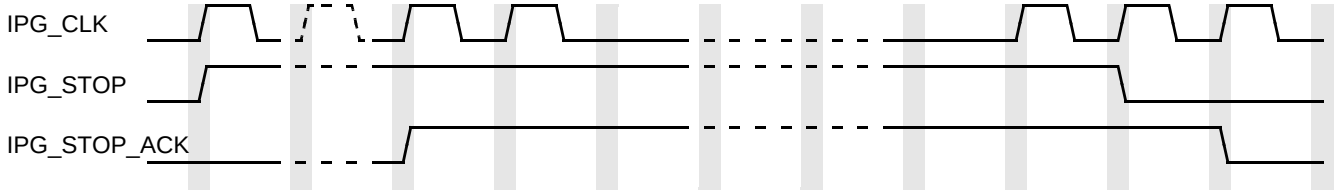

Figure 31-5. Entering and Exiting Standby Mode

31.1.1.3.3 Clocking Microarchitecture

Clocking microarchitecture in the IPU is explained in Figure 31-6.

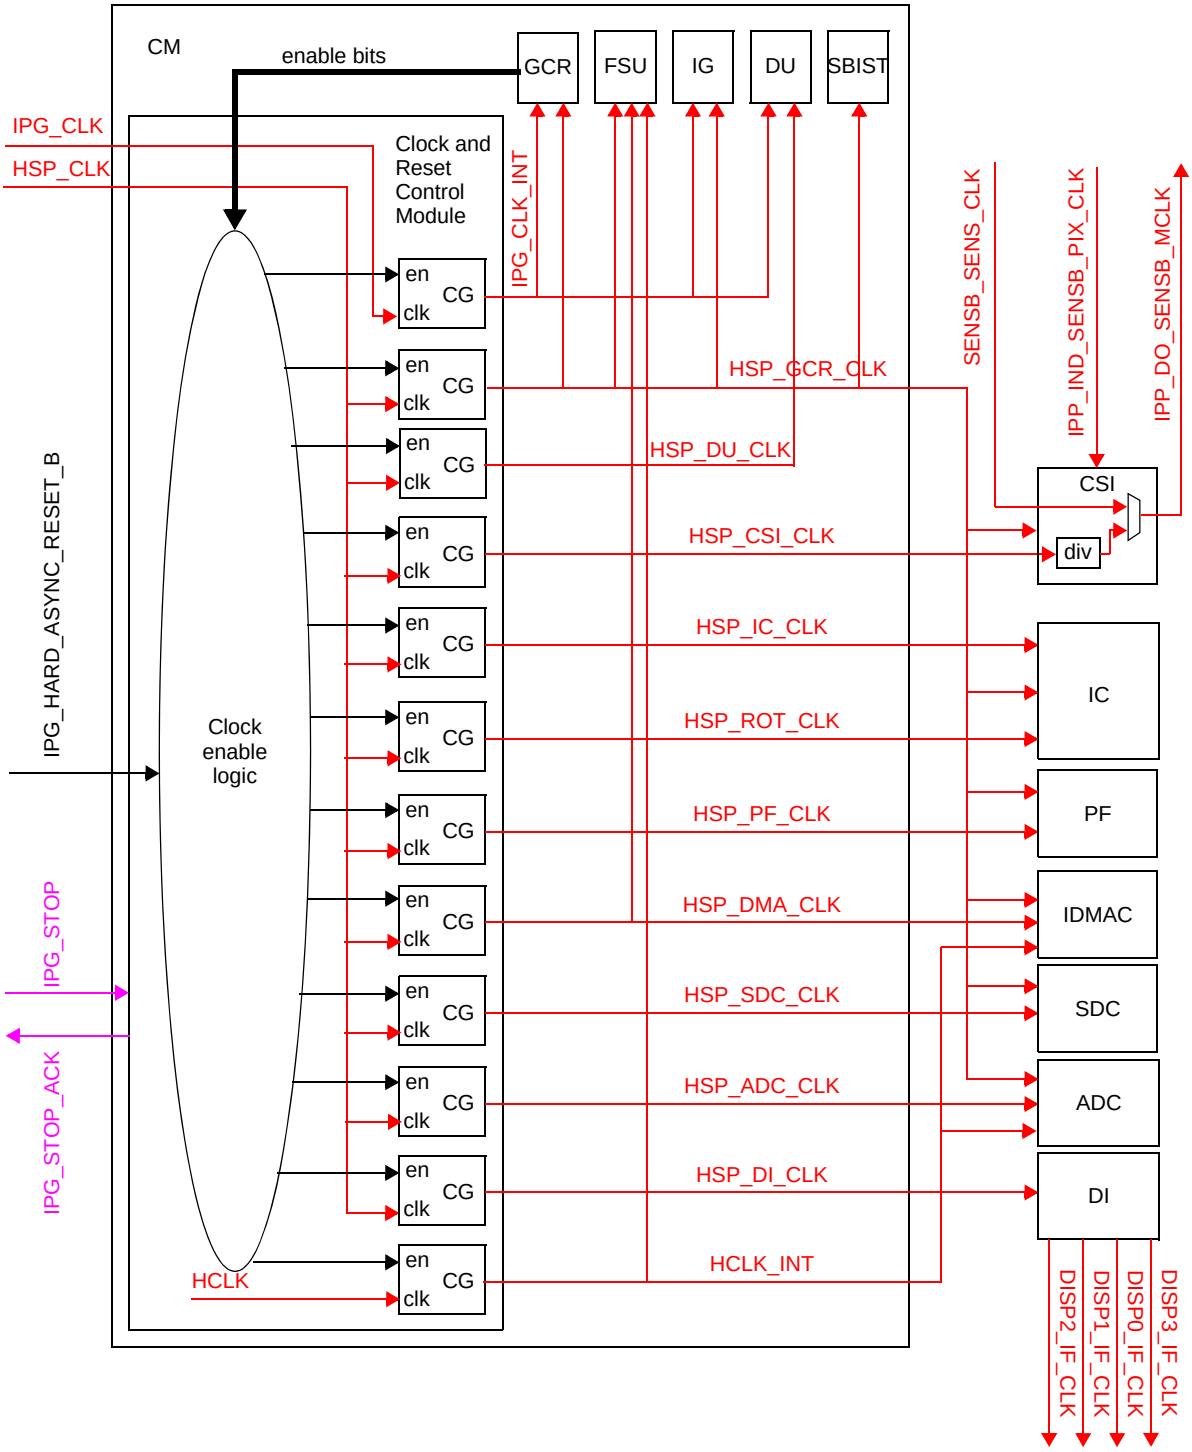

Figure 31-6. Clocking Microarchitecture in the IPU

There are two levels of clock gating. The first is done manually in the clock and reset control submodule (CRCU) which is included in the CM. The CRCU also generates reset signals for all IPU submodules. It guarantees exiting and entering reset free of contention with a submodule clock. Table 31-2 describes conditions for manual clock gating.

Table 31-2. Manual Clock Gating Conditions

Internal clock	Enabling Condition
IPG_CLK_INT	IPU is out of hard reset
HSP_GCR_CLK	IPU is out of hard reset
HSP_DU_CLK	Debug Unit in the CM is enabled
HSP_CSI_CLK	CSI is enabled
HSP_IC_CLK	IC is enabled
HSP_ROT_CLK	IC Rotation Section is enabled
HSP_PF_CLK	PF is enabled
HSP_DMA_CLK	At least one of CSI, IC, PF, ADC, SDC submodules is enabled
HSP_SDC_CLK	SDC is enabled
HSP_ADC_CLK	ADC is enabled
HSP_DI_CLK	DI is enabled
HCLK_INT	IPU is out of hard reset

Clock gating at the second level is inserted automatically by a synthesis tool.

31.1.2 IPU Features

The following tables describe the IPU features.

Table 31-3 describes general IPU features.

Table 31-3. Basic IPU Features

Feature		Implementation	Comments
Interfaces	Master AHB	Configurable one or two shared master ports for all modules	Number of ports is defined by a VIA and by a configurations bit (if the VIA enables two ports)
	Slave AHB	Dedicated slave port for display interface	
	IP bus interface	Single shared port for all modules	
	Bus modes	Bus Big or Little Endian, pixel Big or Little Endian according to configuration	
	Data burst length	1,2,..., 16 words for AHB slave, 1,2,..., 9 words for AHB master	

Table 31-3. Basic IPU Features (Continued)

Feature		Implementation	Comments
Data processing flows	From pre- or post-processing to synchronous display	Via external memory	
	From pre- or post-processing to smart display	Via external memory or closed internally	
	Graphics and video combining	For all display types, performed at frame rate, additional combining for synchronous display, performed on-the-fly	
Synchronization of processing flows	Frame transfer between processing stages and double buffering	Supported with core involvement or automatically	
	Automatic elimination of image tearing on display	Supported both for synchronous displays (data source - system memory) and for smart displays (data source - system memory or postprocessing or preprocessing)	For preprocessing the following conditions must be fulfilled: 1. Display refresh rate is two times higher than sensor refresh rate. 2. Displays VSYNC is synchronized to sensor VSYNC by the IPU 3. Image occupies the whole screen
Clocking schemes	Internal high speed clock rate	Equal or higher than the AHB clock rate (both clocks should be derived from the same high-frequency source)	
	Sensor clock	External clock, may be asynchronous to AHB clock and to internal clocks	
	Clock rate change	Supported on the fly	
	Clock stop mode	Supported	

Table 31-4 describes sensor interface features.

Table 31-4. Sensor Interface Features

Feature		Implementation	Comments
Input	Data bus width	4, 8, 10	10-bit color components packed into one 32-bit output word
		up to 16 bits (generic data)	
	Data formats	Bayer, YUV 4:2:2 interleaved, RGB interleaved	
		YUV 4:4:4 interleaved, generic data	
	Maximal input data rate	73 Mbytes/s	For YUV 4:4:4–36.5 Mpixels/s
	Maximal frame size	4096 x 4096	
Synchronization and control	Master clock signal to sensor	external clock or clock generated internally by division of IPU high-speed clock, dividers: 1,2,3,...,256	
	Synchronization input signals	PIXCLK, HSYNC, VSYNC	
	Timing	gated clock (with HSYNC) non-gated clock (without HSYNC)	
	Pseudo-CCIR656 protocol decoding	interlaced and non-interlaced	Including TV decoder support
Output	Destination	memory or/and preprocessing	
	Conversion of interlaced format to progressive scan format	supported in hardware	
	Non-contiguous system memory buffer	supported	
	Skipping frames	no skip or skip 1/5, 2/5, 3/5, 4/5 according to programmable pattern	separate skipping pattern for encoding and viewfinder channels
External flash strobe generation	Synchronization	relative to the first HSYNC of sensor frame	
	Strobe start time	from 0 to 8191 sensor row	
	Strobe duration	from 1 to 16536 sensor rows	
	Strobe polarity	programmable	

Table 31-5 describes preprocessing features.

Table 31-5. Preprocessing Features

Feature		Implementation	Comments
Input	Source	sensor or memory	
	Pixel format	YUV 4:2:2, YUV 4:4:4 interleaved, YUV 4:2:0, YUV 4:2:2, YUV 4:4:4 non-interleaved (from memory)	Row length is a multiple of 8 pixels
		RGB interleaved 24 bits/pixel (from sensor), RGB interleaved 16/24/32 bits/pixel, arbitrarily packed (from memory), RGB coded 4, 8 bits/pixel (from memory, palette look up table)	
	Maximal frame size	4096 x 4096	
Geometry conversion	Resizing options	both down- and upsizing	
	Downsizing algorithm	decimation with averaging followed by bilinear interpolation	
	Upsizing algorithm	bilinear interpolation	
	Resizing ratios	(K*N):M where K = 1, 2, 4 N = 1, 2... 16383 M = 8192	For direct capturing of sensor image upsizing ratio is limited by available MOPS
	Maximal frame size after downsizing	800x1024	
	Horizontal/vertical resizing	independent	
	Inversion	vertical and horizontal supported	
	Rotation	supported	Only via external memory
Combining with graphics	Algorithm	alpha blending with global or local (specified per pixel) alpha value or key color combining	
	Graphics format	RGBA interleaved 8/16/24/32 bits/pixel programmable arbitrarily packed, RGBA coded 4, 8 bits/pixel (palette look up table), YUVA interleaved 8 bits/pixel	
Color space conversion	YUV -> RGB	programmable coefficients	
	RGB -> YUV		
	YUV -> RGB -> YUV		For TV output
	YUV -> YUV		

Table 31-5. Preprocessing Features (Continued)

Feature		Implementation	Comments
Output	Destination	memory or/and smart (asynchronous) display	
	Pixel format	YUV 4:2:0, YUV 4:2:2, YUV 4:4:4 non-interleaved, YUV 4:2:2, YUV 4:4:4 interleaved	
		arbitrarily packed interleaved RGB, 8/16/24/32 bits/pixel	
	Page-flip double buffering	supported	

Table 31-6 describes postprocessing features.

Table 31-6. Postprocessing Features

Feature		Implementation	Comments
Input	Source	memory	
	Pixel format	YUV 4:2:0, YUV 4:2:2, YUV 4:4:4 non-interleaved, YUV 4:2:2, YUV 4:4:4 interleaved	Row length is a multiple of 8 pixels
		RGB interleaved 8/16/24/32 bits/pixel arbitrarily packed, RGB coded 4/8 bits/pixel (palette look up table)	
	Maximal frame size	4096x4096	
Geometry conversion	Resizing options	both down- and upsizing	
	Downsizing algorithm	decimation with averaging followed by bilinear interpolation	
	Upsizing algorithm	bilinear interpolation	
	Resizing ratios	(K*N):M where K = 1, 2, 4 N = 1, 2... 16383 M = 8192	
	Maximal frame size after downsizing	800x1024	
	Horizontal/vertical resizing	independent	
	Inversion	vertical and horizontal supported	
	Rotation	supported	

Table 31-6. Postprocessing Features (Continued)

Feature		Implementation	Comments
Combining with graphics	Algorithm	alpha blending with global or local (specified per pixel) alpha value or key color combining	
	Graphics format	RGBA interleaved 8/16/24/32 bits/pixel programmable arbitrarily packed, RGBA coded 4/8 bits/pixel (palette look up table), YUVA interleaved 8 bits/pixel	
Color space conversion	YUV -> RGB	programmable coefficients	
	RGB -> YUV		
	YUV -> RGB -> YUV		For TV output
	YUV -> YUV		
Output	Destination	memory or/and smart (asynchronous) display	
	Formats	YUV 4:2:0, YUV 4:2:2, YUV 4:4:4 non-interleaved or YUV 4:2:2, YUV 4:4:4 interleaved	
		programmable arbitrarily packed interleaved RGB 8/16/24/32 bits/pixel	
	Page-flip double buffering	supported	
	Processing several video streams	supported	

Table 31-7 describes post-filtering features.

Table 31-7. Post-Filtering Features

Feature		Implementation	Comments
Input	Source	memory	
	Pixel format	YUV 4:2:0 non- interleaved	
Postfiltering algorithm	MPEG-4 (and WMV)	supported	Algorithm from Motorola Labs
	H.264	supported	Pause at desired row of the Y frame is supported
	Processing several video streams	supported	
Output	Destination	memory	
	Pixel format	YUV 4:2:0 non- interleaved	

Table 31-8 describes synchronous display interface features.

Table 31-8. Synchronous Display Interface Features

Feature		Implementation	Comments
Input	Source	memory	
	Pixel format	monochrome 8 bits/pixel	
		RGBA interleaved 8/16/24/32 bits/pixel arbitrarily packed, RGB coded 4, 8 bits/pixel (palette look up table)	
		YUV 4:2:2 interleaved	For TV support
		YUV 4:2:0, YUV 4:2:2 non-interleaved	For TV support, frame width must be a multiple of 8 pixels
	Maximal frame size	1024 x 1024	
Combining image planes	Number of planes	two	
	Transparency coding	alpha blending with global or local (specified per pixel) alpha value or key color combining	
	Windowing function	supported by display enable control according to pattern from system memory	
Cursor generation	Hardware cursor	uniform color—black/white/configurable reversed color OR/XOR/AND with graphics plane, blinking/steady, size up to 31 x 31 pixels	
	Automatically animated cursor	supported, maximal cursor size 32 x 32 pixels	Via graphics plane and scrolling
Scrolling and panning	Scrolling control	automatic with programmable step of 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 20, 24, 28, 32 pixels/frame	Only for interleaved input data
	Scrolling directions	both horizontal and vertical (programmable)	
	Panning	supported	
Display access synchronization	Automatic elimination of image tearing	supported	
	Automatic skipping output of unchanged frames for dual-port smart displays	supported	

Table 31-8. Synchronous Display Interface Features (Continued)

Feature		Implementation	Comments
Display interface	Color TFT displays	12/16/18-bit I/F 4/8 bits/pixel out of a palette of 256k 12/16 bits/pixel uncoded	Data conversion is done by dropping and adding bits
		6/8/9-bit I/F 18/24 bits/pixel uncoded time-multiplexed	
	Sharp TFT display	supported	
	Contrast control	8-bit PWM	
	Programmable timing of display control signals	separate programmable read and write access periods with resolution of one high speed clock cycle, programmable strobe rise/fall time with resolution of a half of one high speed clock cycle	
	Maximal display clock rate	up to quarter of high speed processing clock rate	

Table 31-9 describes asynchronous display interface features.

Table 31-9. Asynchronous Display Interface Features

Feature		Implementation	Comments
Input for display data writing or output for display data reading	Source (writing) or destination (reading)	system memory (2 channels), preprocessing (1 channel), postprocessing (1 channel), direct core access via slave AHB bus	
	Data format	generic data 8/16/32 bits	
		pixel data in interleaved RGB format, 8/16/24/32 bits/pixel arbitrarily packed or 4, 8 bits/pixel coded (palette look up table)	
	Maximal frame size	1024 x 1024	

Table 31-9. Asynchronous Display Interface Features (Continued)

Feature		Implementation	Comments
Display access features	Writing data to display	supported using command buffer (for system memory source) or using command template (for all sources)	
	Reading data from display	supported using command template (for system memory destination or core direct access)	
	Core low level access to display registers via IP bus	supported	
	Burst transfer modes	single transfer or burst transfer with or without separate burst clock	
	Parallel transfer several windows from different sources to the same display	supported	
	Automatic display refresh	supported with programmable refresh rate and optional snooping condition	The snooping signal is received from the external memory interface
	Transfer synchronization with synchronous display	supported (transfer during blanking intervals of synchronous display)	
	Automatic elimination of image tearing	supported	For displays generated or accepted the VSYNC signal
Scrolling and panning	Scrolling	automatic with programmable step of 1, 2, 3, 4, 5, 6, 7, 8, 10, 12, 14, 16, 20, 24, 28, 32 pixels/frame in both horizontal and vertical directions	Only for interleaved input data
	Panning	supported	

Table 31-9. Asynchronous Display Interface Features (Continued)

Feature		Implementation	Comments
Display interfaces	Number of displays supported	3	Display 0—only parallel interface, displays 1 and 2—parallel or serial interfaces
	Display addressing types	X/Y addressing or full linear address	
	Parallel interface bus type	System80 (Type 1 or Type 2) or System68 (Type 1 or Type 2)	For Type 1 interface, data is sampled by chip select signal. For Type 2 interface, data is sampled by read/write/enable strobes.
	Parallel interface bus width	6/8/9/12/16/18 bits	
	Programmable packing/unpacking data and commands to display	supported with separate packing/unpacking for each display and transfer type (data or command), output in 1, 2, 3 or 4 cycles	
	Serial interface	3/4/5 lines with programmable preamble	Two types of 5-line interface—with address sampling by the serial clock or by the chip enable signal
	Programmable timing of display control signals	separate programmable read and write access periods with resolution of one high speed clock cycle, programmable strobe rise/fall time with resolution of a half of one high speed clock cycle	Separate programming per display
	Maximal display access rate	up to high speed processing clock rate	
	Access with byte enable	supported for parallel interfaces	
	Read wait states for parallel interface	0/1/2 /3 programmable wait states	

31.1.3 Modes of Operation

The IPU is a very flexible module and can be programmed for different operating modes. Examples of typical use cases are as follows:

- Table 31-10 shows IPU data flows for the case of video from system memory on a VGA asynchronous display.
- Table 31-11 shows IPU data flows for the case of video from system memory on a QVGA synchronous display.

Table 31-10. Video from System Memory on a VGA Synchronous Display

Task	Parameter		Flow	
			Postprocessing	
			Video	Graphics
Input data	Source		memory	memory
	Frame size (pixels)	h	640	640
		v	480	480

	Memory rate (Mcycles/s)	27.8		

31.1.3.1 IPU Debug Mode

The IPU has a debug mode with the following features:

- IPU can be programmed to break its data/control flow based on a core request or specified internal event
- Selected internal IPU signals can be monitored via the diagnostic bus.

The IPU debug mode operation is controlled by the debug unit (DU), and may be configured by programming the IPU break control registers (IPU_BRK_CTRL_1 and IPU_BRK_CTRL_2). Internal signals can be selected for display by programming the IP diagnostic bus control register (IP_DIAGB_CTRL).

See Section 31.4.8.4, “Debug Unit (DU)” for more details on debug unit operation.

31.2 External Signal Description

31.2.1 Overview

Table 31-12 describes IPU external signals.

Table 31-12. Signal Properties

Name	Direction	Function	Reset State	Pull-Up
Sensor Interface				
IPP_IND_SENSB_DATA[15:0]	in	Sensor data (YUV, RGB)		
IPP_IND_SENSB_PIX_CLK	in	Data latch clock from sensor		
IPP_IND_SENSB_HSYNC	in	Horizontal synchronization pulse		
IPP_IND_SENSB_VSYNC	in	Vertical synchronization pulse		
SENSB_SENS_CLK	in	Sensor clock from CCM		
IPP_DO_SENSB_MCLK	out	Master clock to sensor	0	
Display Interface				
IPP_IND_DISPB_DATA[23:0]	in	Input data from display. In byte enable mode, bits 16 and 17 are unused		
IPP_DO_DISPB_DATA[23:0]	out	Output data to display.	0	
IPP_DO_DISPB_DATA[16]		Output data to display. In byte enable mode, WRITE_H (for sys80) See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.	1	
IPP_DO_DISPB_DATA[17]		Output data to display. In byte enable mode, READ_H (for sys80) or ENABLE_H (for sys68k). See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.	1	
IPP_OBE_DISPB_DATA	out	Display data direction select for data bits [23:0]	0	
IPP_OBE_DISPB_DATA16_17	out	Display data direction select for data bits [17:16]	0	
IPP_DO_DISPB_D3_VSYNC	out	Display 3 vertical synchronization pulse (FPFRAME/VSYNC/FLM/SPS/TV)	1	
IPP_DO_DISPB_D3_HSYNC	out	Display 3 horizontal synchronization pulse (FPLINE/HSYNC/LP)	1	
IPP_DO_DISPB_D3_CLK	out	Display 3 clock (FPSHIFT/DOTCLC/LSCLC/DCLK/CLOCK)	0	
IPP_IND_DISPB_D3_DRDY	out	Display 3 data enable or Sharp display PS signal (CONTROL1/DRDY/PS/VLD/BLANK)	1	
IPP_DO_DISPB_D3_SPL	out	SPL signal for Sharp display 3	0	
IPP_DO_DISPB_D3_CLS	out	CLS signal for Sharp display 3	0	
IPP_DO_DISPB_D3_REV	out	REV signal for Sharp display 3	0	

Table 31-12. Signal Properties (Continued)

Name	Direction	Function	Reset State	Pull-Up
IPP_IND_DISPB_D0_VSYNC	in	Display 0 input vertical synchronization pulse		
IPP_DO_DISPB_D0_VSYNC	out	Display 0 output vertical synchronization pulse	1	
IPP_OBE_DISPB_D0_VSYNC	out	Display 0 vertical synchronization pulse direction select	0	
IPP_DO_DISPB_D0_CS	out	Display 1 chip select	1	
IPP_DO_DISPB_D1_CS	out	Display 2 chip select	1	
IPP_DO_DISPB_D2_CS	out	Display 3 chip select	1

31.2.2 Detailed Signal Descriptions

31.2.2.1 Sensor Interface

31.2.2.1.1 IPP_IND_SENSB_DATA[15:0]

Input data from the sensor. For sensors providing less than 16-bit output, only the most significant bits of the bus are used.

31.2.2.1.2 IPP_IND_SENSB_PIX_CLK

Input strobe for the sensor data. A selected edge of this signal indicates that new data is valid on the IPP_IND_SENSB_D[15:0] bus.

31.2.2.1.3 IPP_IND_SENSB_HSYNC

Horizontal synchronization pulse. Valid only in “Gated Clock Mode” and only when high, it validates IPP_IND_SENSB_PIX_CLK which always toggles. Not valid in “Non-Gated Clock Mode” and in “Pseudo BT.656 Video Mode”.

31.2.2.1.4 IPP_IND_SENSB_VSYNC

Vertical synchronization pulse. Valid only in “Gated Clock Mode” and in “Non-Gated Clock Mode” and indicate start of frame. Not valid in “Pseudo BT.656 Video Mode”.

31.2.2.1.5 SENSB_SENS_CLK

Input signal from the Clock Controller (sensor clock).

31.2.2.1.6 IPP_DO_SENSB_MCLK

Output clock which used as master clock signal to the sensor. When IPP_DO_SENSB_MCLK is disabled, its output state level stays low.

31.2.2.2 Display Interface

31.2.2.2.1 IPP_IND_DISPB_DATA[23:0]

Display data input bus for the parallel interface. For the 16-bit display interface with byte enable support, the bits 16 and 17 are unused. See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.

31.2.2.2.2 IPP_DO_DISPB_DATA[23:0]

Display data output bus for the parallel interface. See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.

31.2.2.2.3 IPP_OBE_DISPB_DATA

Display data bus direction select signal. When it is low data input from the display is enabled, when it is high data output is enabled.

31.2.2.2.4 IPP_OBE_DISPB_DATA16_17

Display data bus direction select signal for the data bits 16 and 17. When it is low data input from the display is enabled, when it is high data output is enabled.

31.2.2.2.5 IPP_DO_DISPB_D3_VSYNC

Vertical synchronization signal to the synchronous display (display 3). It matches the FPFRAME/ VSYNC/FLM/SPS inputs of supported displays.

31.2.2.2.6 IPP_DO_DISPB_D3_HSYNC

Horizontal synchronization signal to the synchronous display (display 3). It matches the FPLINE/ HSYNC/LP inputs of supported displays.

31.2.2.2.7 IPP_DO_DISPB_D3_CLK

Display clocking signal to the synchronous display (display 3). It matches the FPSHIFT / DOTCLC/ LSCLC / DCLK / CLOCK inputs of supported displays.

31.2.2.2.8 IPP_IND_DISPB_D3_DRDY

Display control signal to the synchronous display (display 3). It matches the CONTROL1/DRDY/VLD/ BLANK inputs of supported displays. PS control signal to the synchronous Sharp HR-TFT displays.

31.2.2.2.9 IPP_DO_DISPB_D3_SPL

Display control signal to the synchronous Sharp HR-TFT display (display 3). It matches the SPL display input.

31.2.2.2.10 IPP_DO_DISPB_D3_CLS

Display control signal to the synchronous Sharp HR-TFT display (display 3). It matches the CLS display input.

31.2.2.2.11 IPP_DO_DISPB_D3_REV

Display control signal to the synchronous Sharp HR-TFT display (display 3). It matches the REV display input.

31.2.2.2.12 IPP_IND_DISPB_D0_VSYNC

Vertical synchronization input from the asynchronous (smart) primary display (display 0).

31.2.2.2.13 IPP_DO_DISPB_D0_VSYNC

Vertical synchronization output to the asynchronous (smart) primary display (display 0).

31.2.2.2.14 IPP_OBE_DISPB_D0_VSYNC

Display vertical synchronization signal direction select for the asynchronous (smart) primary display (display 0). When it is low VSYNC input from the display is enabled, when it is high VSYNC output to the display is enabled.

31.2.2.2.15 IPP_DO_DISPB_D0_CS

Chip select signal for the for the asynchronous (smart) primary display (display 0). Corresponds to the DISP0_IF_CLK (see Table 31-1).

31.2.2.2.16 IPP_DO_DISPB_D1_CS

Chip select signal for the for the asynchronous (smart) secondary display (display 1). Corresponds to the DISP1_IF_CLK (see Table 31-1).

31.2.2.2.17 IPP_DO_DISPB_D2_CS

Chip select signal for the for the asynchronous (smart) secondary display (display 2). Corresponds to the DISP2_IF_CLK (see Table 31-1).

31.2.2.2.18 IPP_DO_DISPB_PAR_RS

DATA/COMMAND (RS) control signal for the parallel interface of the asynchronous displays 1-2.

31.2.2.2.19 IPP_DO_DISPB_SER_RS

RS control signal for the serial interface of the asynchronous displays 1-2.

31.2.2.2.20 IPP_DO_DISPB_WR

Read/enable control signal for the asynchronous displays 0-2 with parallel interfaces. It matches the WRITE signal for the System-80 interface or the READ/WRITE signal for the System-68K interface.

31.2.2.2.21 IPP_DO_DISPB_RD

Write/read control signal for the asynchronous displays 0-2. It matches the READ signal for the System-80 interface or the ENABLE signal for the System-68K interface.

31.2.2.2.22 IPP_IND_DISPB_SD_D

Data input for the serial interface of the asynchronous displays 1 and 2.

31.2.2.2.23 IPP_DO_DISPB_SD_D

Data output for the serial interface of the asynchronous displays 1 and 2.

31.2.2.2.24 IPP_OBE_DISPB_SD_D

Data direction select signal for the serial interface of the asynchronous displays 1 and 2. When it is low serial input from the display is enabled, when it is high serial output to the display is enabled.

31.2.2.2.25 IPP_DO_DISPB_SD_D_CLK

Clocking signal for the serial interface of the asynchronous displays 1 and 2.

31.2.2.2.26 IPP_IND_DISPB_D12_VSYNC

Vertical synchronization input from the asynchronous (smart) secondary displays 1 and 2.

31.2.2.2.27 IPP_DO_DISPB_D12_VSYNC

Vertical synchronization output to the asynchronous (smart) secondary displays 1 and 2.

31.2.2.2.28 IPP_OBE_DISPB_D12_VSYNC

Direction select signal for vertical synchronization input/output from/to the asynchronous (smart) secondary displays 1 and 2.

31.2.2.2.29 IPP_DO_DISPB_CONTRAST

Contrast control for the primary displays 0 and 3.

31.2.2.2.30 IPP_DO_DISPB_BCLK

Burst clock for asynchronous parallel interfaces (displays 0, 1, 2).

31.2.2.2.31 Display Interface Signals Usage

Table 31-13 summarizes the usage of the display interface signals.

Table 31-13. Display Interface Signals Usage

Signal Name	Synchronous Display (Display 3)				Asynchronous Displays (Displays 0-2)		
	Generic	Sharp HR-TFT	Synch Interface of Dual-Port Display	TV Encoder	Primary Display 0	Secondary Displays 1, 2	
					Parallel Interface		Serial Interface
IPP_DO_DISPB_DATA[23:0]	Output data				Output data See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.		
IPP_IND_DISPB_DATA[23:0]					Input data In byte enable mode, bits 16 and 17 are not used See Asynchronous Parallel Interfaces with Byte Enable Support on Page 301 for byte enable support.		
IPP_DO_DISPB_D3_VSYNC	FPFRAME / VSYNC /FLM (out)	SPS (out)	VSYNC (out)	VSYNC (out)			
IPP_DO_DISPB_D3_HSYNC	FPLINE/ HSYNC LP	LP	HSYNC	HSYNC			
IPP_DO_DISPB_D3_CLK	FPSHIFT / DOTCLC/ LSCLC	DCLK	DOTCLC	CLOCK			
IPP_DO_DISPB_D3_DRDY	DRDY	PS	VLD	BLANK			
IPP_DO_DISPB_D3_SPL		SPL					
IPP_DO_DISPB_D3_CLS		CLS					
IPP_DO_DISPB_D3_REV		REV					
IPP_IND_DISPB_D0_VSYNC IPP_DO_DISPB_D0_VSYNC					VSYNC		
IPP_DO_DISPB_D0_CS					CS1		
IPP_DO_DISPB_D1_CS						CS2	CS2
IPP_DO_DISPB_D2_CS						CS3	CS3
IPP_DO_DISPB_PAR_RS					DATA/COMMAND		
IPP_DO_DISPB_SER_RS							RS

Table 31-13. Display Interface Signals Usage (Continued)

Signal Name	Synchronous Display (Display 3)				Asynchronous Displays (Displays 0-2)	
	Generic	Sharp HR-TFT	Synch Interface of Dual-Port Display	TV Encoder	Primary Display 0	Secondary Displays 1, 2
					Parallel Interface	Serial Interface
IPP_DO_DISPB_RD					System-80: READ System-68K: ENABLE_L byte enable mode— System-80: READ_L System-68K: ENABLE_L See "Asynchronous Parallel Interfaces with Byte Enable Support," for byte enable support.	
IPP_DO_DISPB_WR					System-80: WRITE System 68K: READ/WRITE, byte enable mode— System-80: WRITE_L System-68K: READ/WRITE See "Asynchronous Parallel Interfaces with Byte Enable Support," for byte enable support.	
IPP_IND_DISPB_SD_D IPP_DO_DISPB_SD_D						D
IPP_DO_DISPB_SD_D_CLK						CLK
IPP_IND_DISPB_D12_VSYNC IPP_DO_DISPB_D12_VSYNC					VSYNC	
IPP_DO_DISPB_BCLK					CPUCLK	

Note: Burst clock for asynchronous parallel interfaces (displays 0, 1, 2)

31.3 Memory Map and Register Definition

The IPU programming model includes 112 registers. Most of them are placed physically in the GCR. Some of them will be placed at their submodules for convenience. All of the registers will be accessed by the core using the IP Bus. Section 31.3.3, "Register Descriptions," provides the detailed descriptions for all of the IPU registers.

31.3.1 Memory Map

Table 31-14 shows the IPU memory map.

Table 31-14. IPU Memory Map

Address	Register	Access	Reset Value	Section
0x53FC_0000 (IPU_CONF)	IPU Configuration Register	R/W	0x0000_0000	31.3.3.1.1/31-66
0x53FC_0004 (IPU_CHA_BUF0_RDY)	IPU Channel Buffer 0 Ready Register	R/W	0x0000_0000	31.3.3.1.2/31-68
0x53FC_0008 (IPU_CHA_BUF1_RDY)	IPU Channel Buffer 1 Ready Register	R/W	0x0000_0000	31.3.3.1.3/31-69
0x53FC_000C (IPU_CHA_DB_MODE_SEL)	IPU Channel Double Mode Select Register	R/W	0x0000_0000	31.3.3.1.4/31-70
0x53FC_0010 (IPU_CHA_CUR_BUF)	IPU Channel Current Buffer	RW	0x0000_0000	31.3.3.1.5/31-71
0x53FC_0014 (IPU_FS_PROC_FLOW)	IPU Frame Synchronization Processing Flow Register	R/W	0x0000_0000	31.3.3.1.6/31-72
0x53FC_0018 (IPU_FS_DISP_FLOW)	IPU Frame Synchronization Displaying Flow Register	R/W	0x0000_0000	31.3.3.1.7/31-75
0x53FC_001C (IPU_TASKS_STAT)	IPU Tasks Status Register	R	0x0000_0000	31.3.3.1.8/31-76

31.3.2 Register Summary

Figure 31-7 shows the key to the register fields and Table 31-15 shows the register figure conventions.

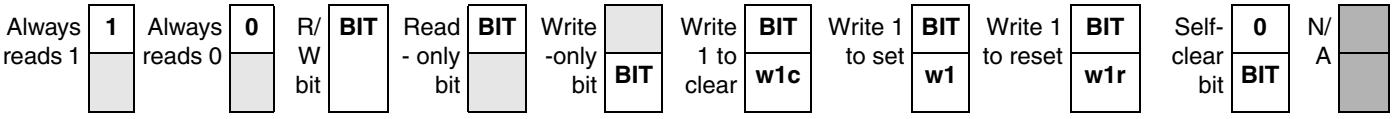

Figure 31-7. Key to Register Fields

Table 31-15. Register Figure Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 31-15. Register Figure Conventions (Continued)

Convention	Description
Register Field Types	
r	Read only. Writing this bit has no effect.
w	Write only.
rw	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
w1	Write one to set. A status bit that can be read, and is set by writing a one.
w1r	Write one to reset. A status bit that can be read, and is got a reset value by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero.
1	Resets to one.
—	Undefined at reset.
u	Unaffected by reset.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

Table 31-16 shows the IPU register summary.

31.3.3 Register Descriptions

31.3.3.1 IPU Common Registers

31.3.3.1.1 IPU Configuration Register (IPU_CONF)

This register contains general configuration parameters of IPU. It controls all units' clocks and enables.

0x53FC_0000 (IPU_CONF) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-8. IPU Configuration Register (IPU_CONF)

Table 31-17. IPU_CONF Field Descriptions

Field	Description
31–9	Reserved
8 PXL_ENDIAN	Pixel Endianness. This bit defines the pixel Endianness. 0 Little endianness 1 Big Endianness
7 DU_EN	Debug Unit enable. This bit enables the Debug Unit. 0 DU is disabled. 1 DU is enabled.
6 DI_EN	Display Interface enable. This bit enables the Display Interface. 0 DI is disabled. 1 DI is enabled.
5 ADC_EN	Asynchronous Display Controller enable. This bit enables the Asynchronous Display Controller. 0 ADC is disabled. 1 ADC is enabled.
4 SDC_EN	Synchronous Display Controller enable. This bit enables the Synchronous Display Controller. 0 SDC is disabled. 1 SDC is enabled.
3 PF_EN	Postfilter enable. This bit enables the Postfilter. 0 PF is disabled. 1 PF is enabled.
2 ROT_EN	Rotation Unit enable. This bit enables the Rotation Unit. 0 ROT is disabled. 1 ROT is enabled.

Table 31-17. IPU_CONF Field Descriptions (Continued)

Field	Description
1 IC_EN	Image Converter enable. This bit enables the Image Converter. 0 IC is disabled. 1 IC is enabled.
0 CSI_EN	Camera Sensor interface enable. This enables the CSI unit. 0 CSI is disabled. 1 CSI is enabled.

31.3.3.1.2 IPU Channels Buffer 0 Ready Register (IPU_CHA_BUF0_RDY)

The register contains buffer 0 ready control information for 32 IPU's DMA channels. Writing "1" to each field will set each bit. Writing "0" to each field simultaneously will clear all the bits.

0x53FC_0004 (IPU_CHA_BUF0_RDY) Access: User Read/Write

31.3.3.1.8 IPU Tasks Status Register (IPU_TASKS_STAT)

This register contains IPU tasks' status information.

0x53FC_001C (IPU_TASKS_STAT) Access: User Read-Only

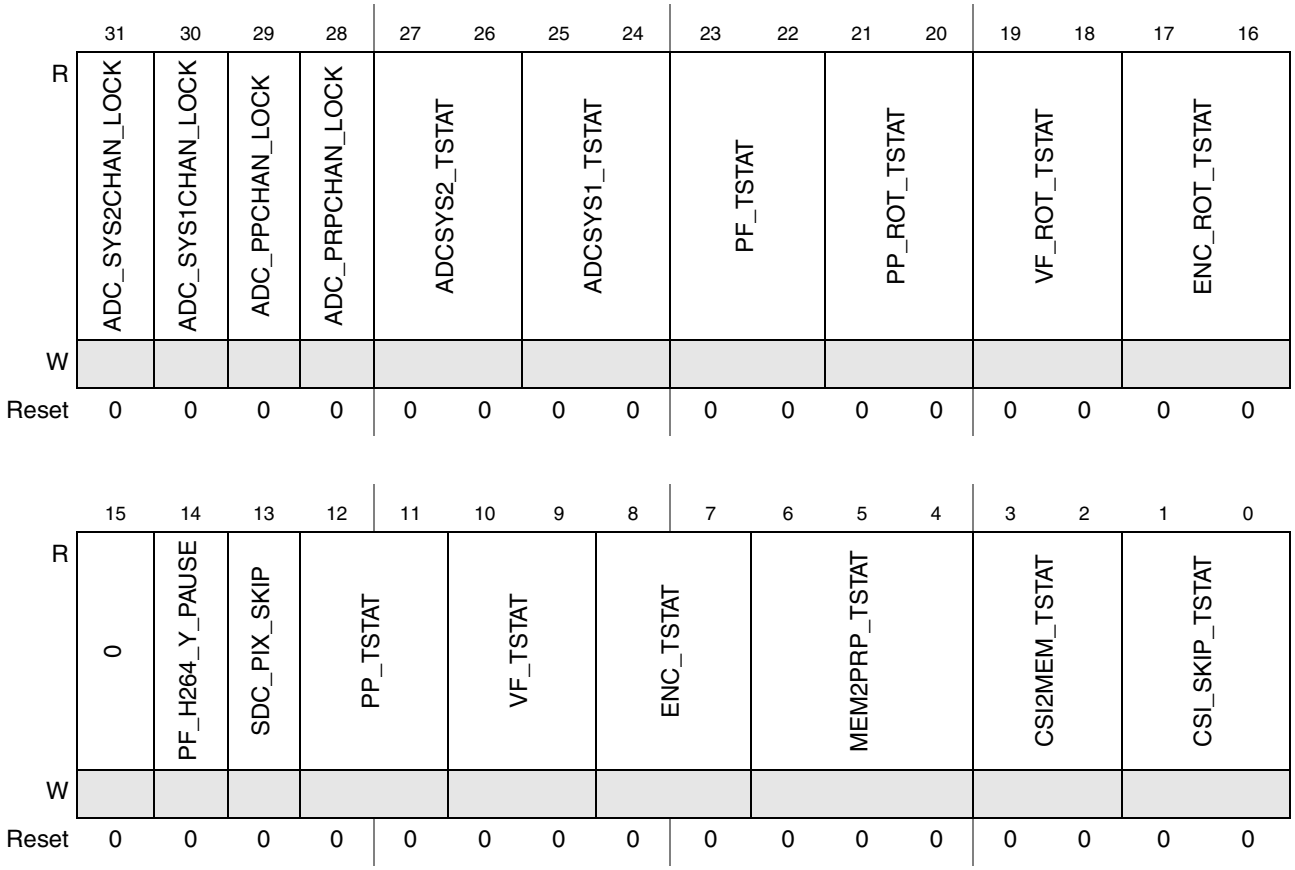

Figure 31-15. IPU Tasks Status Register (IPU_TASKS_STAT)

Table 31-24. IPU_TASKS_STAT Field Descriptions

Field	Description
31 ADC_SYS2CHAN_LOCK	ADC SYS2 Channel Locked. This bit is the Status of ADC SYS2 Channel. 0 Channel is unlocked (not busy). 1 Channel is locked (busy).
30 ADC_SYS1CHAN_LOCK	ADC SYS1 Channel Locked. This bit is the Status of ADC SYS1 Channel. 0 Channel is unlocked (not busy). 1 Channel is locked (busy).
29 ADC_PPCHAN_LOCK	ADC Post-Processing Channel Locked. This bit is the Status of ADC Post-Processing Channel. 0 Channel is unlocked (not busy). 1 Channel is locked (busy).
28 ADC_PRPCHAN_LOCK	ADC Pre-Processing Channel Locked. This bit is the Status of ADC Preprocessing Channel. 0 Channel is unlocked (not busy). 1 Channel is locked (busy).

Table 31-24. IPU_TASKS_STAT Field Descriptions (Continued)

Field	Description
27–26 ADCSYS2_TSTAT	ADC system channel 2 task status. These bits indicate ADC system channel 2 task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
25–24 ADCSYS1_TSTAT	ADC system channel 1 task status. These bits indicate ADC system channel 1 task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
23–22 PF_TSTAT	Post-flittering task status. These bits indicate post-flittering task status Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
21–20 PP_ROT_TSTAT	Rotation for post-processing task status. These bits indicate rotation for post-processing task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
19–18 VF_ROT_TSTAT	Rotation for View-Finder task status. These bits indicate Rotation for View-Finder task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
17–16 ENC_ROT_TSTAT	Rotation for encoding task status. These bits indicate rotation for encoding task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
15	Reserved
14 PF_H264_Y_PAUSE	Status bit indicates pause in the PF operation in H.264 mode.
13 SDC_PIX_SKIP	Status bit indicates skipping pixels on synchronous display after overrun error in the SDC.

Table 31-24. IPU_TASKS_STAT Field Descriptions (Continued)

Field	Description
12–11 PP_TSTAT	Post-processing task status. These bits indicate Post-processing task status. Values: 00 IDLE 01 ACTIVE 10 W4RDY 11 RSV
10–9 VF_TSTAT	Pre-processing for view-finder task status. These bits indicate this task status. Values: 00 IDLE 01 ACTIVE 10 PAUSE 11 RSV
8–7 ENC_TSTAT	Encoding directly from CSI task status. These bits indicate the direct transferring from CSI to encoding task status. Values: 00 IDLE 01 ACTIVE 10 PAUSE 11 RSV
6–4 MEM2PRP_TSTAT	Memory to PRP task status. These bits indicate the indirect transferring for Pre-processing from memory tasks status. Values: 000 IDLE 001 BOTH_ACTIVE 010 ENC_ACTIVE 011 VF_ACTIVE 100 BOTH_PAUSE 101 RSV 110 RSV 111 RSV
3–2 CSI2MEM_TSTAT	CSI directly to memory task status. These bits indicate the transferring from CSI direct to memory task status. Values: 00 IDLE 01 ACTIVE 10 PAUSE 11 RSV
1–0 CSI_SKIP_TSTAT	Next VF and ENC frames skipping status in the CSI. Values: 00 Next ENC frame and next VF frame would be skipped. 01 Next ENC frame would be skipped, and next VF frame would be valid. 10 Next VF frame would be skipped, and next ENC frame would be valid. 11 Next ENC frame and next VF frame would be valid.

31.3.3.1.9 IPU Internal Memory Access Address and Data Registers (IPU_IMA_ADDR and IPU_IMA_DATA)

The IPU_IMA_ADDR register contains an address of 32-word to be written to or read from one of internal IPU memories.

0x53FC_0020 (IPU_IMA_ADDR) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-16. IPU Internal Memory Access Address Register (IPU_IMA_ADDR)

Table 31-25. IPU_IMA_ADDR Field Descriptions

Field	Description
31–20	Reserved
19–16 MEM_NU	Memory number. This field selects the accessed memory.
15–3 ROW_NU	Row number. This field selects a row in the accessed memory. The row number begins from 0.
2–0 WORD_NU	Word number. This field selects a 32-bit word inside a row in the accessed memory. The word number begins from 0.

Table 31-26 shows the MEM_NU, ROW_NU, and WORD_NU values.

Table 31-26. MEM_NU, ROW_NU, and WORD_NU Values

MEM_NU	Memory Name	Submodule	Maximum ROW_NU	Row Width/ Maximum WORD_NU
0000	Task Parameter Memory	IC	2417	48 (1)
0001	Channel Parameter Memory	IDMAC	63	132 (4)
0010	Look-Up Table Memory	IDMAC	255	32 (0)
0011	Template Memory	ADC	383	30 (0)
0100	Asynchronous Display Buffer Memory	ADC	223	64 (1)
0101	Downsizing Output Memory	IC	2399	48 (1)
0110	Down Sizing Temporary Memory	IC	2399	36 (1)
0111	Input Buffer Memory	IC	95	64 (1)
1000	Main Processing Memory	IC	159	64 (1)
1001	Rotation Memory	IC	47	64 (1)

Table 31-26. MEM_NU, ROW_NU, and WORD_NU Values (Continued)

MEM_NU	Memory Name	Submodule	Maximum ROW_NU	Row Width/ Maximum WORD_NU
1010	Post Filter Memory	PF	271	64 (1)
1011	Synchronous Display Buffer Memory	SDC	127	64 (1)

When the core performs sequential write to or read from the IPU_IMA_DATA register, the WORD_NU and ROW_NU values increment automatically according to the selected memory size. Firstly WORD_NU sequentially increments. When it arrives end of memory row, it is cleared and ROW_NU increments by 1. After that WORD_NU increments again. So the memory is accessed via the IPU_IMA_DATA register like a FIFO. For write after read operation, the WORD_NU and ROW_NU values are not changed.

The IPU_IMA_DATA register contains a 32-bit data word written to or read from the selected memory according to the address defined in the IPU_IMA_ADDR register.

Figure 31-17. IPU Internal Memory Access Data Register (IPU_IMA_DATA)

Table 31-27. IPU_IMA_DATA Field Description

Field	Description
31–16 IMA_DATA[31:16]	Contains a 16-bit data word written to or read from the selected memory according to the address defined in the IPU_IMA_ADDR register.
15–0 IMA_DATA[15:0]	

The IPU_IMA_ADDRESS and IPU_IMA_DATA registers are used for access to IPU internal memories during normal operation and in debug mode.

The IPU has several unmapped internal memories. Four of them should be configured by the core during setup before the IPU can properly operate. The four memories are:

- TPM—Task Parameter Memory which resides at IC sub module. Must be configured before enabling processing tasks. This memory can be accessed while tasks are enabled.

- CPM—Channel Parameter Memory which resides at IDMAC sub module. Must be configured before enabling processing tasks. This memory can be accessed while tasks are enabled.
- LUTM—Look-Up Table Memory which resides at IDMAC sub module. Can be configured before enabling tasks. Must not be accessed while operation.
- TM—ADC Template Memory which reside at ADC sub module. Can be configured before enabling tasks. Must not be accessed while operation.

These memories will be mapped internally and core will have to write the targeted address to IPU_IMA_ADDR and then perform write access to IPU_IMA_DATA. The internal memory access unit which resides in the SBIST submodule of the control module, translates the address that was written by core to IPU_IMA_ADDR and the write access to IPU_IMA_DATA into an internal memory access. At the end of the access, IPU_IMA_ADDR increments for reducing IP accessed while configuring these memories sequentially.

The TPM, CPM, LUTM and TM memories can be accessed during IPU normal operation with the following restrictions:

- IC task parameters must not be changed in the TPM when the corresponding task is active.
- IDMAC channel parameters must not be changed in the CPM when the corresponding DMA channel is enabled excluding the base addresses (EBA0 and EBA1). One of these parameters can be changed during channel operation if it relates to the non-active double buffer.
- Look-up-table must not be changed in the LUTM when there is any enabled DMA channel which can use this table.
- Both read and write access to the TM is forbidden when there is any enabled ADC channel which can use templates.

All other memories can be accessed only in debug (freeze) mode. The tables in the following sections describe the four internal memory structures.

IC Task Parameter Memory

Table 31-28 presents IC task parameter memory details.

Table 31-28. IC Parameters

Address	Word	Parameter	Field	Description

[1] FR_WIDTH is the maximum frame width supported = 800 (0x320)

[2] s - sign position, x - binary digit position

IDMAC Channel Parameter Memory

The following tables show, the IDMAC channel programing bits. There are a total of 32 IDMAC channels that can be configured into 2 modes: non-interleaved and interleaved. See Table 31-29 and Table 31-30 for non-interleaved configuration, variable and constant, respectively. See Table 31-31 and Table 31-32 for interleaved configuration, variable and constant, respectively. Each channel has 2 132 configuration bit words that are located in the channel parameter memory, thus for example channel N's parameter data will be divided into two 132-bit words at address 2*N and 2*N + 1. Configuration data in 2*N addressees are divided into two parts: variable and constant data. Variable data should be initialized to zero except for the NSB bit which should initialized to one. Constant data should be configured according to the users needs. The ratio between variable bits and constant bits in 2*N address words are different for non-interleaved and interleaved configuration. In 2*N + 1 address words, all data is constant.

Table 31-29. Variable Channel Parameters for RGB/YUV Non-Interleaved Configuration

Address	Word	Parameter	Field	Description
2*N	Word0	XV	W0[9:0]	Variable coordinates for determining next block address. {X1,Y1} and {X2,Y2} coordinates will be determined according to {XV,YV} upon restart of channel. These coordinates are used for RGB and Y:U:V (Y pointer) formats.
		YV	W0[19:10]	
		XB	W0[31:20]	Variable coordinates for determining address within the block. These coordinates are used for Y:U:V (Y pointer) and RGB formats. Need 20 bits for 1D transfer support.
		YB	W0[43:32]	
		-	W0[45:44]	Reserved.
		NSB	W0[46]	This bit determines if the next value for {xb,yb} should be taken from {xb,yb} saved in channel parameter memory or from new {x1,y1}/{x2,y2}.
		LNPB	W0[52:47]	Holds the value of the last burst size incase size of row is not aligned to burst size. These bits are updated by Addressing Arithmetic Unit one channel access before the end of row access and therefore saved at the end of that channel event.

Table 31-30. Constant Channel Parameters for RGB/YUV Non-Interleaved Configuration

Address	Word	Parameter	Field	Description
2*N	Word0	UBO	W0[78:53]	Double buffer destination address offset for Y:U:V (U pointer) formats.
		VBO	W0[104:79]	Double buffer destination address offset for Y:U:V (V pointer) format.
		-	W0[107:105]	Reserved.

Table 31-30. Constant Channel Parameters for RGB/YUV Non-Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N	Word0	FW	W0[119:108]	Frame width minus 1 (in pixels). 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 4096 pixels
		FH	W0[131:120]	Frame height minus 1 (in rows). 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 4096 pixels
2*N + 1	Word1	EBA0	W1[31:0]	Double buffer page 0 destination address for RGB and Y:U:V formats. Must be aligned to 32-bit boundaries.
		EBA1	W1[63:32]	Double buffer page 1 destination address for RGB and Y:U:V formats. Must be aligned to 32-bit boundaries.
2*N + 1	Word1	BPP	W1[66:64]	Determines the size of each pixel in bits. 011 = 8 bits per color component (Only valid value) All other BPP values will cause unknown results.
2*N + 1	Word1	SL	W1[80:67]	Stride line value minus 1 for Y component buffer in bytes (number of maximum bytes in a row according to memory limitations). For U and V component buffers, the stride line value is (SL+1)/2. 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
		PFS	W1[83:81]	Selects between the following formats: Y:U:V 4.4.4, Y:U:V 4.2.2, Y:U:V 4.2.0 non-interleaved and no packing/unpacking for all 3 formats. Decoded pixels: 001 = Y:U:V Non-interleaved 4:4:4 010 = Y:U:V Non-interleaved 4:2:2 011 = Y:U:V Non-interleaved 4:2:0 All other PFS values will cause unknown results.

Table 31-30. Constant Channel Parameters for RGB/YUV Non-Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N+1	Word1	BAM	W1[86:84]	Determines mode of block arrangement on frame, for supporting all block rotation and flip constellations. BAM[0] = 0 -> No vertical flip BAM[0] = 1 -> Vertical flip BAM[1] = 0 -> No horizontal flip BAM[1] = 1 -> Horizontal flip BAM[2] = 0 -> No 90 degree rotation BAM[2] = 1 -> 90 degree rotation The BAM bits controls rotation/flipping both for the IDMAC and the IC. For the channels 10,11 and 13 all the BAM bits are valid. In this case, the IDMAC performs rotation/flipping of position of 8*8 blocks, and the IC rotation unit performs rotation/flipping of pixels inside the 8*8 blocks. The BAM[1] is also valid for the channels 0, 1, 2. The IC can perform horizontal flip for these channels. The BAM[0] is valid for all the channels (excluding the channels 24-31). This bit controls vertical flip done by the IDMAC.
		-	W1[88:87]	Reserved
2*N + 1	Word1	NPB	W1[94:89]	Burst size minus 1 (in pixels). The following are valid numbers of pixels in a memory burst access according to the BPP parameter: 000000 = 01 pixels in each burst 000001 = 02 pixels in each burst ..... 111111 = 64 pixels in each burst Range: 8bpp => 4, 8, 12, 16 pixels All other values of NPB are not valid. For channels 0 to 9 and 12, NPB must be set to 8 pixels or 16 pixels. For channels 10, 11 and 13, NPB must be set to 8 pixels. All other values for NPB for channels 0 to 13 are not valid. For channels from 18 to 23, NPB must be set to 8 or 16 pixels.
		-	W1[95]	Reserved.
		SAT	W1[97:96]	Determines what are access type (32 bit, 16 bit and 8 bit) used by the core to write/read data to/from the system memory. 00 => 08 bit 01 => 16 bit 10 => 32 bit 11 => Reserved
2*N + 1	Word1	-	W0[131:98]	Reserved.

Table 31-31. Variable Channel for Parameters for RGB/YUV Interleaved Configuration

Address	Word	Parameter	Field	Description
2*N	Word0	XV	W0[9:0]	Variable coordinates for determining next block address. {X1,Y1} and {X2,Y2} coordinates will be determined according to {XV,YV} upon restart of channel. These coordinates are used for RGB and Y:U:V (Y pointer) formats.
		YV	W0[19:10]	
		XB	W0[31:20]	Variable coordinates for determining address within the block. These coordinates are used for RGB and Y:U:V (Y pointer) formats. Need 20 bits for 1D transfer support.
		YB	W0[43:32]	
		SCE	W0[44]	Enables SX and SY to be incremented after EOF. **Note:** Users should not write to this bit.
2*N	Word0	-	W0[45]	Reserved.
		NSB	W0[46]	This bit determines if the next value for {xb,yb} should be taken from {xb,yb} saved in channel parameter memory or from new {x1,y1}/{x2,y2}.
		LNPB	W0[52:47]	Holds the value of the last burst size incase size of row is not aligned to burst size. These bits are updated by Addressing Arithmetic Unit one channel access before the end of row access and therefore saved at the end of that channel event.
		SX	W0[62:53]	Holds the temporary count for the Scroll X in between frame
		SY	W0[72:63]	Holds the temporary count for the Scroll Y in between frame
		NS	W0[82:73]	This variable holds the total number of scrolls

Table 31-32. Constant Channel Addressing Parameters for RGB/YUV Interleaved Configuration

Address	Word	Parameter	Field	Description
2*N	Word0	SM	W0[92:83]	Maximal number of scrolling steps minus 1 (in frames). 0000000000 = 0001 0000000001 = 0002 ..... 1111111111 = 1024

Table 31-32. Constant Channel Addressing Parameters for RGB/YUV Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N	Word0	SDX	W0[97:93]	Coded horizontal scrolling increment (in pixels). 00000 = 00 pixels 00001 = 01 pixel 00010 = 02 pixels ..... 11110 = 30 pixels 11111 = 32 pixels
		SDY	W0[102:98]	Coded vertical scrolling increment (in rows). 00000 = 00 rows 00001 = 01 row 00010 = 02 rows ..... 11110 = 30 rows 11111 = 32 rows
2*N	Word0	SDRX	W0[103]	Horizontal scrolling direction. 0 => Next frame will be right of current 1 => Next frame will be left of current
		SDRY	W0[104]	Vertical scrolling direction. 0 => Next frame will be down of current 1 => Next frame will be up of current
2*N	Word0	SCRQ	W0[105]	Request to start scrolling. Scrolling will start from next frame. 0 => No scrolling request 1 => Scrolling request
		-	W0[107:106]	Reserved.
2*N	Word0	FW	W0[119:108]	Frame width minus 1 (in pixels). 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 4096 pixels
		FH	W0[131:120]	Frame height minus 1 (in rows). 000000000000 = 0001 pixels 000000000001 = 0002 pixels ..... 111111111111 = 4096 pixels
2*N + 1	Word1	EBA0	W1[31:0]	Double buffer page 0 destination address for RGB and Y:U:V formats. Must be aligned to 32-bit boundaries.
		EBA1	W1[63:32]	Double buffer page 1 destination address for RGB and Y:U:V formats. Must be aligned to 32-bit boundaries.

Table 31-32. Constant Channel Addressing Parameters for RGB/YUV Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N + 1	Word1	BPP	W1[66:64]	Determines the size of each pixel in bits. BPP. Values: 000 32 Bits per pixel 001 24 Bits per pixel 010 16 Bits per pixel 011 08 Bits per pixel 100 04 Bits per pixel 101 01 Bits per pixel 110 Reserved 111 Reserved
2*N + 1	Word1	SL	W1[80:67]	Stride line in bytes minus 1 (number of maximum bytes in a row according to memory limitations). Must be a multiple of pixel size. Values: 00000000000000 = 00001 bytes 00000000000001 = 00002 bytes ..... 11111111111111 = 16384 bytes
		PFS	W1[83:81]	Selects between the following formats: R:G:B/Y:U:V interleaved with and without packing/unpacking. Decoded pixels. Values: 000 = Code 100 = R:G:B Packing/Unpacking 110 = Y:U:V Interleaved 4:2:2 111 = Generic Data All other PFS values will cause unknown results.
2*N+1	Word1	BAM	W1[86:84]	Determines mode of block arrangement on frame, for supporting all block rotation and flip constellations. The BAM bits controls rotation/flipping both for the IDMAC and the IC. For the channels 10,11 and 13 all the BAM bits are valid. In this case, the IDMAC performs rotation/flipping of position of 8*8 blocks, and the IC rotation unit performs rotation/flipping of pixels inside the 8*8 blocks. The BAM[1] is also valid for the channels 0, 1, 2. The IC can perform horizontal flip for these channels. The BAM[0] is valid for all the channels (excluding the channels 24-31). This bit controls vertical flip done by the IDMAC. BAM[0] = 0 -> No vertical flip BAM[0] = 1 -> Vertical flip BAM[1] = 0 -> No horizontal flip BAM[1] = 1 -> Horizontal flip BAM[2] = 0 -> No 90 degree rotation BAM[2] = 1 -> 90 degree rotation
		-	W1[88:87]	Reserved

Table 31-32. Constant Channel Addressing Parameters for RGB/YUV Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N + 1	Word1	NPB	W1[94:89]	Burst size minus 1 (in pixels). The following are valid numbers of pixels in a memory burst access according to the bpp parameter: 000000 = 01 pixels in each burst 000001 = 02 pixels in each burst ..... 111111 = 64 pixels in each burst Range: 32bpp => 1 -> 08 pixels 24bpp => 1 -> 10 pixels 16bpp => 1 -> 16 pixels 08bpp => 1 -> 32 pixels 04bpp => 1 -> 32 pixels 01bpp => 1 -> 64 pixels (only 64 or 32 bpp is allowed) For channels from 0 to 9 and 12, NPB must be set to 8 pixels or 16 pixels. For channels from 10, 11 and 13, NPB must be set to 8 pixels. All other values for NPB for channels 0 to 13 will cause unknown results. For channels from 18 to 23, NPB must be set to 8 or 16 pixels.
		-	W1[95]	Reserved.
		SAT	W1[97:96]	Determines what are access type (32 bit, 16 bit and 8 bit) used by the core to write/read data to/from the system memory. 00 => 08 bit 01 => 16 bit 10 => 32 bit 11 => Reserved
2*N + 1	Word1	SCC	W1[98]	Scrolling wrap-around enable. 0 => Scrolling will stop after NS reaches SM+1 1 => Scrolling will start from the beginning after NS reaches SM+1

Table 31-33. Constant Channel Formatting Parameters for YUV/RGB Interleaved Configuration

Address	Word	Parameter	Field	Description
2*N + 1	Word1	OFS0	W1[103:99]	Packing/unpacking parameter. Offset between MSB position of the color component 0 (red color) and MSB position of packed pixel. The color component 0 occupies the most significant bits of the unpacked pixel (see Figure 31-156). 00000 = No offset 00001 = u => 1 bit shift left, p => 1 bit shift right ..... 11111 = u => 31 bits left, p => 31 bits right where * u = unpacking, p = packing, sleft = shift left, sright = shift right For write specified channels, the allowed values of the OFS0 are from 00000 to 10111

Table 31-33. Constant Channel Formatting Parameters for YUV/RGB Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N + 1	Word1	OFS1	W1[108:104]	Packing/unpacking parameter. Offset between MSB position of the color component 1 (green color) and MSB position of packed pixel. The color component 1 occupies the middle left bits of the unpacked pixel (see Figure 31-156). 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking, p = packing, sleft = shift left, sright = shift right For write specified channels, the allowed values of the OFS1 are from 00000 to 10111
		OFS2	W1[113:109]	Packing/unpacking parameter. Offset between MSB position of the color component 2 (blue color) and MSB position of packed pixel. The color component 2 occupies the middle right bits of the unpacked pixel (see Figure 31-156). 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking, p = packing, sleft = shift left, sright = shift right For write specified channels, the allowed values of the OFS2 are from 00000 to 10111
		OFS3	W1[118:114]	Packing/unpacking parameter. Offset between MSB position of the color component 3 (local alpha value) and MSB position of packed pixel. The color component 3 occupies the least significant bits of the unpacked pixel (see Figure 31-156). 00000 = No offset 00001 = u => 1 bit sleft, p => 1 bit sright ..... 11111 = u => 31 bit sleft, p => 31 bit sright * u = unpacking, p = packing, sleft = shift left, sright = shift right For write specified channels, the OFS3 is ignored (the real offset is always 11000)
		WID0	W1[121:119]	Packing/unpacking parameter. Color component 0 (red color) width minus 1. The color component 0 occupies the most significant bits of the unpacked pixel (see Figure 31-156). 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits

Table 31-33. Constant Channel Formatting Parameters for YUV/RGB Interleaved Configuration (Continued)

Address	Word	Parameter	Field	Description
2*N + 1	Word1	WID1	W1[124:122]	Packing/unpacking parameter. Color component 1 (green color) width minus 1. The color component 1 occupies the middle left bits of the unpacked pixel (see Figure 31-156). 000 = 1 bits 000 = 2 bits ..... 111 = 8 bits
		WID2	W1[127:125]	Packing/unpacking parameter. Color component 2 (blue color) width minus 1. The color component 1 occupies the middle right bits of the unpacked pixel (see Figure 31-156). 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits
		WID3	W1[130:128]	Packing/unpacking parameter. Color component 3 (alpha value) width minus 1. The color component 3 occupies the least significant bits of the unpacked pixel (see Figure 31-156). 000 = 1 bits 001 = 2 bits ..... 111 = 8 bits For write specified channels, the WID3 is ignored (the real width is always 8 bits)
		DEC_SEL	W1[131]	Upon 4bpp, selects between two look-up tables 0 = addresses 0 to 15 1 = addresses 128 to 143
Interleaved configuration bit count: 257 bits				

IDMAC Look-Up Table Memory

Table 31-34. Look-Up Table Memory Structure

Address	Word	Parameter	Field	Description
0	Word0	Decoded Pixel 0 for both 8 and 4 bit coded configuration	W[31:0]	When working in coded pixel format, the data read from the memory is the decoded value of pixel according to address given. In addition, in case of 4 bit code configuration, when DEC_SEL = 0, the 4 bit decoded values are read from address 0->15 and when dec_sel=1 the 4 bit decode values are read from 128->143.
...	...	...		
15	Word15	Decoded Pixel 15 for both 8 and 4 bit coded configuration		
16	Word16	Decoded Pixel 16 for 8 bit coded configuration only		
...	...	...		
127	Word127	Decoded Pixel 127 for 8 bit coded configuration only		
128	Word 128	Decoded Pixel 0 for 4 bit and 128 for 8 bit configuration		
...	...	...		
143	Word143	Decoded Pixel 15 for 4 bit and 143 for 8 bit configuration		
...	...	...		
255	Word255	Decoded Pixel 255 for 8 bit coded configuration only		

ADC Template Memory

Table 31-35. ADC Template Memory Structure

Address	Word	Parameter	Field	Description	
0x00	Display 0 Write Template Command [29:0]	D	[23:0]	Command/data. Usually, the stream means display's command. It is relevant with WR_CMND or RD_ACK opcodes only.	
		OC	[26:24]	Opcode for stream control:	
				000	RD_DATA—Read data from the display
				001	RD_ACK—Wait for display acknowledge
				010	RD_WAIT—Wait for given number of display clock cycles
				011	WR_XADDR—Send X address or 16 lsb or full address to the display
				100	WR_YADDR—Send Y address or msb of full address to the display
				101	WR_ADDR—Send whole address to the display
				110	WR_CMND—Send command field to the display
				111	WR_DATA—Send data from the Buffer Memory to the display
		FC	[28:27]	Flow control flags:	
				00	Step-by-step
				01	Stop—Template last command, no post command. It has to be located on last command
				10	Jump—Flag for non stopping new template execute. It is used for pipeline loading of new template command after post commands of current template. It has to be located in next to last command, including post command part.
				11	Reserved
		RS	29	Register select value for display's registers

Access: User Read/Write

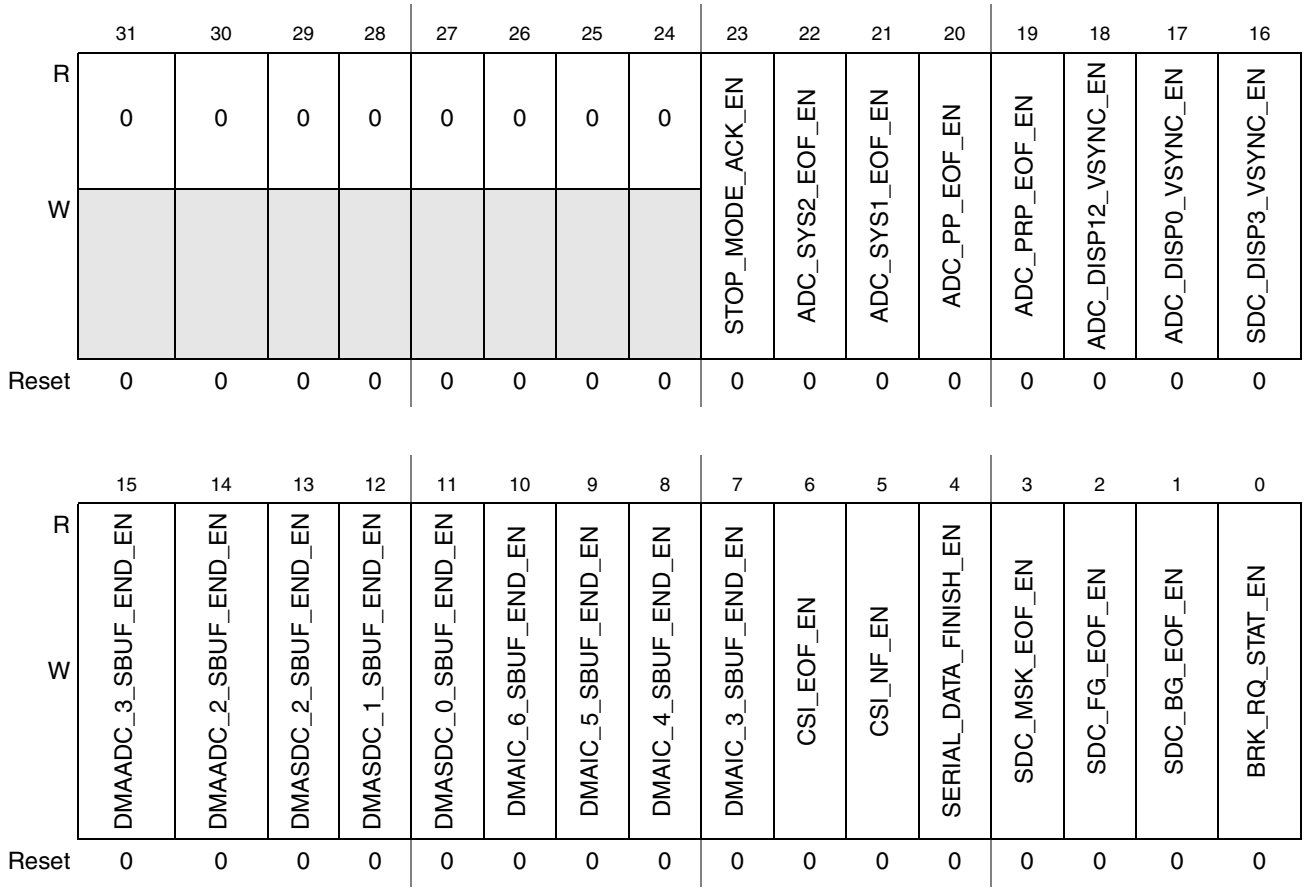

Figure 31-20. IPU Interrupt Control Register 3 (IPU_INT_CTRL_3)

Table 31-38. IPU_INT_CTRL_3 Field Descriptions

Field	Description
31–24	Reserved
23 STOP_MODE_ACK_EN	Control of stop mode interrupt. This bit enables the stop mode interrupt. The interrupt is generated when the IPU send IPG_STOP_ACK signal. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 ADC_SYS2_EOF_EN	Control of end-of-frame interrupt for the ADC system 2 channel. This bit enables end-of-frame interrupt for the ADC system 2 channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
21 ADC_SYS1_EOF_EN	Control of end-of-frame interrupt for the ADC system 1 channel. This bit enables end-of-frame interrupt for the ADC system 1 channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 31-38. IPU_INT_CTRL_3 Field Descriptions (Continued)

Field	Description
20 ADC_PP_EOF_EN	Control of end-of-frame interrupt for the ADC postprocessing channel. This bit enables end-of-frame interrupt for the ADC postprocessing channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
19 ADC_PRP_EOF_EN	Control of end-of-frame interrupt for the ADC preprocessing channel. This bit enables end-of-frame interrupt for the ADC preprocessing channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
18 ADC_DISP12_VSYNC_EN	Control of VSYNC interrupt for displays 1 and 2. This bit enables interrupt for displays 1 and 2. 0 Interrupt is disabled. 1 Interrupt is enabled.
17 ADC_DISP0_VSYNC_EN	Control of VSYNC interrupt for display 0. This bit enables interrupt for display 0. 0 Interrupt is disabled. 1 Interrupt is enabled.
16 SDC_DISP3_VSYNC_EN	Control of VSYNC interrupt for display 3. This bit enables interrupt for display 3. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 DMAADC_3_SBUF_END_EN	Control of DMAADC channel 3 scroll buffer end interrupt. This bit is the control of scroll buffer end of input system 2 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 DMAADC_2_SBUF_END_EN	Control of DMAADC channel 2 scroll buffer end interrupt. This bit is the control of scroll buffer end of input system 1 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 DMASDC_2_SBUF_END_EN	Control of DMASDC channel 2 scroll buffer end interrupt. This bit is the control of scroll buffer end of input mask SDC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 DMASDC_1_SBUF_END_EN	Control of DMASDC channel 1 scroll buffer end interrupt. This bit is the control of scroll buffer end of input background SDC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 DMASDC_0_SBUF_END_EN	Control of DMASDC channel 0 scroll buffer end interrupt. This bit is the control of scroll buffer end of input foreground SDC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 DMAIC_6_SBUF_END_EN	Control of DMAIC channel 6 scroll buffer end interrupt. This bit is the control of scroll buffer end of input graphics for PRPVF channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 31-38. IPU_INT_CTRL_3 Field Descriptions (Continued)

Field	Description
9 DMAIC_5_SBUF_END_EN	Control of DMAIC channel 5 scroll buffer end interrupt. This bit is the control of scroll buffer end of input VIDEO for PP task. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 DMAIC_4_SBUF_END_EN	Control of DMAIC channel 4 scroll buffer end interrupt. This bit is the control of scroll buffer end of input graphics for PRPPP task. 0 Interrupt is disabled. 1 Interrupt is enabled.
7 DMAIC_3_SBUF_END_EN	Control of DMAIC channel 3 scroll buffer end interrupt. This bit is the control of scroll buffer end of input graphics for PRPVF task. 0 Interrupt is disabled. 1 Interrupt is enabled.
6 CSI_EOF_EN	Enable CSI_EOF interrupt. This bit is the control of CSI_EOF interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 CSI_NF_EN	Enable CSI_NF interrupt. This bit is the control of CSI_NF interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 SERIAL_DATA_FINISH_EN	Enable the DI serial data finish interrupt. This bit is the control of DI serial data finish interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
3 SDC_MSK_EOF_EN	Enable SDC Mask EOF interrupt. This bit is the control of SDC Mask EOF interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 SDC_FG_EOF_EN	Enable SDC Foreground EOF interrupt. This bit is the control of SDC Foreground EOF interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 SDC_BG_EOF_EN	Enable SDC Background EOF interrupt. This bit is the control of SDC Background EOF interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 BRK_RQ_STAT_EN	Enable BRK_RQ interrupt. This bit is the control of BRK_RQ interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.

31.3.3.1.13 IPU Interrupt Control Register 4 (IPU_INT_CTRL_4)

This register contains part of IPU interrupts controls. All the controls of NFB4EOF_ERR Channels interrupts can be found in this register.

0x53FC_0034
(IPU_INT_CTRL_4)

Access: User Read/Write

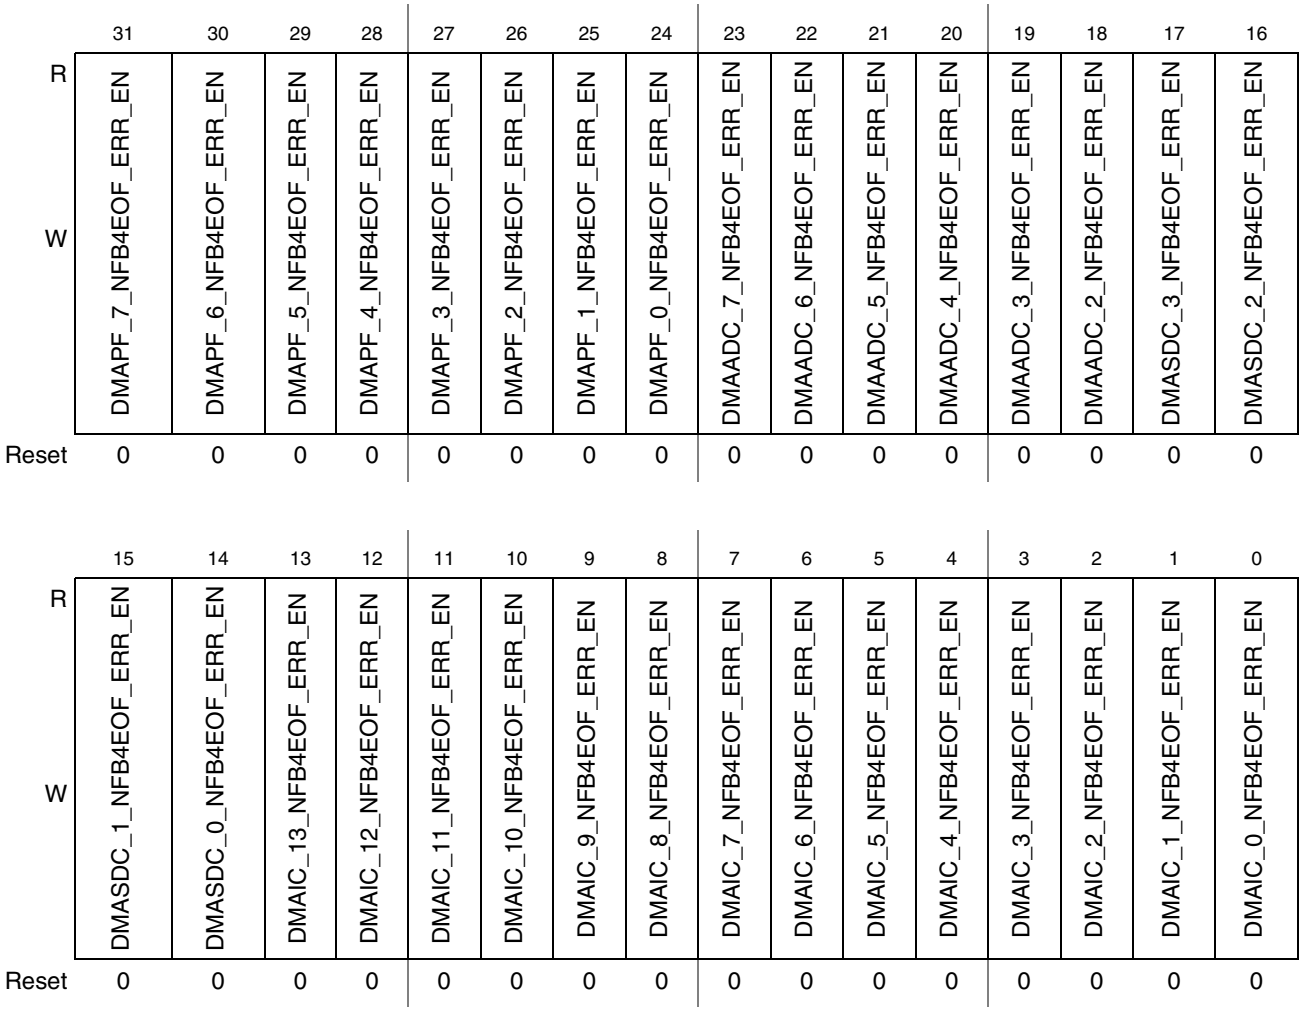

Figure 31-21. IPU Interrupt Control Register 4 (IPU_INT_CTRL_4)

Table 31-39. IPU_INT_CTRL_4 Field Descriptions

Field	Description
31–0 *_NFB4EOF_ERR_EN[1]	The control of NFB4EOF error enable. This bit is the control of new frame and ACK of channel interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.

[1] Indicates the corresponding DMA channel number noted in Figure 31-21.

31.3.3.1.14 IPU Interrupt Control Register 5 (IPU_INT_CTRL_5)

This register contains part of IPU interrupts controls.

0x53FC_0038
(IPU_INT_CTRL_5)

Access: User Read/Write

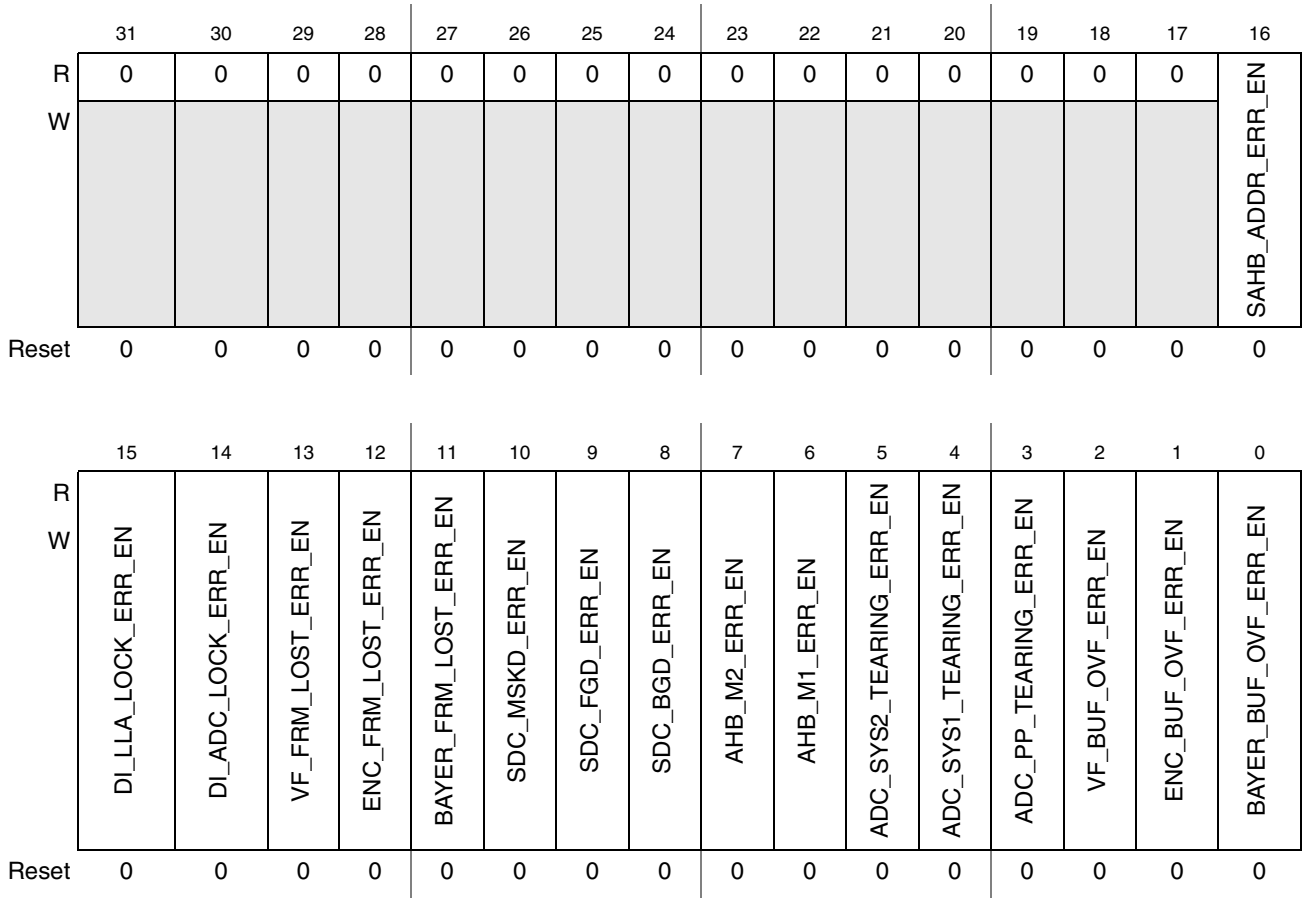

Figure 31-22. IPU Interrupt Control Register 5 (IPU_INT_CTRL_5)

Table 31-40. IPU_INT_CTRL_5 Field Descriptions

Field	Description
31–17	Reserved
16 SAHB_ADDR_ERR_EN	Enable SAHB_ADDR_ERR interrupt. This bit enables the SAHB_ADDR_ERR interrupt. The interrupt is generated if the slave AHB address most significant bits do not match the base address defined by the AHB_S_BA pins. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 DI_LLA_LOCK_ERR_EN	Enable DI_LLA_LOCK_ERR interrupt. This bit enables the DI_LLA_LOCK_ERR interrupt. The interrupt is generated if the DI has not been released by low level access when the SDC begins data transfer to a synchronous interface. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 31-40. IPU_INT_CTRL_5 Field Descriptions (Continued)

Field	Description
14 DI_ADC_LOCK_ERR_EN	Enable DI_ADC_LOCK_ERR interrupt. This bit enables the DI_ADC_LOCK_ERR interrupt. The interrupt is generated if the DI has not been released by the ADC when the SDC begins data transfer to a synchronous interface. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 VF_FRM_LOST_ERR_EN	Enable VF_FRM_LOST_ERR interrupt. This bit is the enable VF_FRM_LOST_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 ENC_FRM_LOST_ERR_EN	Enable ENC_FRM_LOST_ERR interrupt. This bit is the enable ENC_FRM_LOST_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 BAYER_FRM_LOST_ERR_EN	Enable BAYER_FRM_LOST_ERR interrupt. This bit is the enable BAYER_FRM_LOST_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 SDC_MSK_ERR_EN	Enable SDC_MSK_ERR interrupt. This bit is the control of SDC_MSK_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
9 SDC_FGD_ERR_EN	Enable SDC_FGD_ERR interrupt. This bit is the control of SDC_FGD_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 SDC_BGD_ERR_EN	Enable SDC_BGD_ERR interrupt. This bit is the control of SDC_BGD_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
7 AHB_M2_ERR_EN	Enable AHB_M2_ERR interrupt. This bit enables the AHB_M2_ERR interrupt. The interrupt is generated if master 2 AHB error appears. 0 Interrupt is disabled. 1 Interrupt is enabled.
6 AHB_M1_ERR_EN	Enable AHB_M1_ERR interrupt. This bit enables the AHB_M1_ERR interrupt. The interrupt is generated if master 1 AHB error appears. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 ADC_SYS2_TEARING_ERR_EN	Enable ADC_SYS2_TEARING_ERR interrupt. This bit enables the ADC_SYS2_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the system 2 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 ADC_SYS1_TEARING_ERR_EN	Enable ADC_SYS1_TEARING_ERR interrupt. This bit enables the ADC_SYS1_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the system 1 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 31-40. IPU_INT_CTRL_5 Field Descriptions (Continued)

Field	Description
3 ADC_PP_TEARING_ERR_EN	Enable ADC_PP_TEARING_ERR interrupt. This bit enables the ADC_PP_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the postprocessing ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
2 VF_BUF_OVF_ERR_EN	Enable VF_BUF_OVF_ERR interrupt. This bit is the control of VF_BUF_OVF_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
1 ENC_BUF_OVF_ERR_EN	Enable ENC_BUF_OVF_ERR interrupt. This bit is the control of ENC_BUF_OVF_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.
0 BAYER_BUF_OVF_ERR_EN	Enable BAYER_BUF_OVF_ERR interrupt. This bit is the control of BAYER_BUF_OVF_ERR interrupt. 0 Interrupt is disabled. 1 Interrupt is enabled.

31.3.3.1.15 IPU Interrupt Status Register 1 (IPU_INT_STAT_1)

This register contains part of IPU interrupt status. All end of frame of DMA channels can be found in this register.

0x53FC_003C
(IPU_INT_STAT_1)

Figure 31-25. IPU Interrupt Status Register 3 (IPU_INT_STAT_3)

Table 31-43. IPU_INT_STAT_3 Field Descriptions

Field	Description
31–24	Reserved
23 STOP_MODE_ACK	Control of stop mode interrupt. This bit is the status of the stop mode interrupt. The interrupt is generated when the IPU send IPG_STOP_ACK signal. 0 Interrupt is cleared. 1 Interrupt is requested.
22 ADC_SYS2_EOF	Status of end-of-frame interrupt for the ADC system 2 channel. This bit is the status of end-of-frame interrupt for the ADC system 2 channel. The interrupt is generated after the ADC has completed data transfer. 0 Interrupt is cleared. 1 Interrupt is requested.
21 ADC_SYS1_EOF	Status of end-of-frame interrupt for the ADC system 1 channel. This bit is the status of end-of-frame interrupt for the ADC system 1 channel. The interrupt is generated after the ADC has completed data transfer. 0 Interrupt is cleared. 1 Interrupt is requested.

Table 31-43. IPU_INT_STAT_3 Field Descriptions (Continued)

Field	Description
20 ADC_PP_EOF	Status of end-of-frame interrupt for the ADC postprocessing channel. This bit is the status of end-of-frame interrupt for the ADC postprocessing channel. The interrupt is generated after the ADC has completed data transfer. 0 Interrupt is cleared. 1 Interrupt is requested.
19 ADC_PRP_EOF	Status of end-of-frame interrupt for the ADC preprocessing channel. This bit is the status of end-of-frame interrupt for the ADC preprocessing channel. The interrupt is generated after the ADC has completed data transfer. 0 Interrupt is cleared. 1 Interrupt is requested.
18 ADC_DISP12_VSYNC	Status of VSYNC interrupt for displays 1 and 2. This bit is the status of interrupt for displays 1 and 2. 0 Interrupt is cleared. 1 Interrupt is requested.
17 ADC_DISP0_VSYNC	Status of VSYNC interrupt for display 0. This bit is the status of interrupt for display 0. 0 Interrupt is cleared. 1 Interrupt is requested.
16 SDC_DISP3_VSYNC	Status of VSYNC interrupt for display 3. This bit is the status of interrupt for display 3. 0 Interrupt is cleared. 1 Interrupt is requested.
15 DMAADC_3_SBUF_END	Status of DMASDC channel 3 scroll buffer end interrupt. This bit is the status of scroll buffer end of input system 2 ADC channel. 0 Interrupt is cleared. 1 Interrupt is requested.
14 DMAADC_2_SBUF_END	Status of DMAADC channel 2 scroll buffer end interrupt. This bit is the status of scroll buffer end of input system 1 ADC channel. 0 Interrupt is cleared. 1 Interrupt is requested.
13 DMASDC_2_SBUF_END	Status of DMASDC channel 2 scroll buffer end interrupt. This bit is the status of scroll buffer end of input mask SDC channel. 0 Interrupt is cleared. 1 Interrupt is requested.
12 DMASDC_1_SBUF_END	Status of DMASDC channel 1 scroll buffer end interrupt. This bit is the status of scroll buffer end of input background SDC channel. 0 Interrupt is cleared. 1 Interrupt is requested.
11 DMASDC_0_SBUF_END	Status of DMASDC channel 0 scroll buffer end interrupt. This bit is the status of scroll buffer end of input foreground SDC channel. 0 Interrupt is cleared. 1 Interrupt is requested.
10 DMAIC_6_SBUF_END	Status of DMAIC channel 6 scroll buffer end interrupt. This bit is the status of scroll buffer end of input graphics for PRPVF channel. 0 Interrupt is cleared. 1 Interrupt is requested.

Table 31-43. IPU_INT_STAT_3 Field Descriptions (Continued)

Field	Description
9 DMAIC_5_SBUF_END	Status of DMAIC channel 5 scroll buffer end interrupt. This bit is the status of scroll buffer end of input VIDEO for PP task. 0 Interrupt is cleared. 1 Interrupt is requested.
8 DMAIC_4_SBUF_END	Status of DMAIC channel 4 scroll buffer end interrupt. This bit is the status of scroll buffer end of input graphics for PRPPP task. 0 Interrupt is cleared. 1 Interrupt is requested.
7 DMAIC_3_SBUF_END	Status of DMAIC channel 3 scroll buffer end interrupt. This bit is the status of scroll buffer end of input graphics for PRPVF task. 0 Interrupt is cleared. 1 Interrupt is requested.
6 CSI_EOF	Status of CSI_EOF interrupt. This bit is the status of CSI_EOF interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
5 CSI_NF	Status of CSI_NF interrupt. This bit is the status of CSI_NF interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
4 SERIAL_DATA_FINISH	Status the DI serial data finish interrupt. This bit is the status of DI serial data finish interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
3 SDC_MSK_EOF	Status of SDC mask EOF interrupt. This bit is the status of SDC Mask EOF interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
2 SDC_FG_EOF	Status of SDC foreground EOF interrupt. This bit is the status of SDC foreground EOF interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
1 SDC_BG_EOF	Status of SDC background EOF interrupt. This bit is the status of SDC background EOF interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
0 BRK_RQ_STAT	Status of BRK_RQ interrupt. This bit is the status of BRK_RQ interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.

31.3.3.1.18 IPU Interrupt Status Register 4 (IPU_INT_STAT_4)

This register contains part of IPU interrupt status. All _NFB4EOF_ERR of DMA Channels can be found in this register.

Figure 31-27. IPU Interrupt Status Register 5 (IPU_INT_STAT_5)

Table 31-45. IPU_INT_STAT_5 Field Descriptions

Field	Description
30–17	Reserved
16 SAHB_ADDR_ERR	Status of the SAHB_ADDR_ERR interrupt. This bit indicates a status of the SAHB_ADDR_ERR interrupt. The interrupt is generated if the slave AHB address most significant bits do not match the base address defined by the AHB_S_BA pins. 0 Interrupt is cleared. 1 Interrupt is requested.
15 DI_LLA_LOCK_ERR	Status of the DI_LLA_LOCK_ERR interrupt. This bit indicates a status of the DI_LLA_LOCK_ERR interrupt. The interrupt is generated if the DI has not been released by low level access when the SDC begins data transfer to a synchronous interface. 0 Interrupt is cleared. 1 Interrupt is requested.
14 DI_ADC_LOCK_ERR	Status of DI_ADC_LOCK_ERR interrupt. This bit indicates a status of the DI_ADC_LOCK_ERR interrupt. The interrupt is generated if the DI has not been released by the ADC when the SDC begins data transfer to a synchronous interface. 0 Interrupt is cleared. 1 Interrupt is requested.

Table 31-45. IPU_INT_STAT_5 Field Descriptions (Continued)

Field	Description
13 VF_FRM_LOST_ERR	Status of VF_FRM_LOST_ERR interrupt. This bit is the Status of VF_FRM_LOST_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
12 ENC_FRM_LOST_ERR	Status of ENC_FRM_LOST_ERR interrupt. This bit is the Status of ENC_FRM_LOST_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
11 BAYER_FRM_LOST_ERR	Status of BAYER_FRM_LOST_ERR interrupt. This bit is the Status of BAYER_FRM_LOST_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
10 SDC_MSKD_ERR	Status of SDC_MSK_ERR interrupt. This bit is the Status of SDC_MSK_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
9 SDC_FGD_ERR	Status of SDC_FGD_ERR interrupt. This bit is the status of SDC_FGD_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
8 SDC_BGD_ERR	Status of SDC_BGD_ERR interrupt. This bit is the status of SDC_BGD_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
7 AHB_M2_ERR	Status of AHB_M2_ERR interrupt. This bit the status of the AHB_M2_ERR interrupt. The interrupt is generated if master 2 AHB error appears. 1 Interrupt is enabled. 0 Interrupt is disabled.
6 AHB_M1_ERR	Status of AHB_M1_ERR interrupt. This bit the status of the AHB_M1_ERR interrupt. The interrupt is generated if master 1 AHB error appears. 0 Interrupt is disabled. 1 Interrupt is enabled.
5 ADC_SYS2_TEARING_ERR	Status of ADC_SYS2_TEARING_ERR interrupt. This bit the status of the ADC_SYS2_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the system 2 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
4 ADC_SYS1_TEARING_ERR	Status of ADC_SYS1_TEARING_ERR interrupt. This bit the status of the ADC_SYS1_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the system 1 ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.
3 ADC_PP_TEARING_ERR	Status of ADC_PP_TEARING_ERR interrupt. This bit the status of the ADC_PP_TEARING_ERR interrupt. The interrupt is generated if tearing takes place for the postprocessing ADC channel. 0 Interrupt is disabled. 1 Interrupt is enabled.

Table 31-45. IPU_INT_STAT_5 Field Descriptions (Continued)

Field	Description
2 VF_BUF_OVF_ERR	Status of VF_BUF_OVF_ERR interrupt. This bit is the status of VF_BUF_OVF_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
1 ENC_BUF_OVF_ERR	Status of ENC_BUF_OVF_ERR interrupt. This bit is the status of ENC_BUF_OVF_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.
0 BAYER_BUF_OVF_ERR	Status of BAYER_BUF_OVF_ERR interrupt. This bit is the status of BAYER_BUF_OVF_ERR interrupt. 0 Interrupt is cleared. 1 Interrupt is requested.

31.3.3.1.20 IPU Break Control Register 1 (IPU_BRK_CTRL_1)

This register is the first control register of the debug unit in the control module. Figure 31-28 shows the register format, and Table 31-46 describes the register fields.

0x53FC_0050 (IPU_BRK_CTRL_1) Access: User Read/Write

Figure 31-28. IPU Break Control Register 1 (IPU_BRK_CTRL_1)

Table 31-46. IPU_BRK_CTRL_1 Field Descriptions

Field	Description
31–24 BRK_EVNT_NUM	Break event number minus 1. This field is programmed by user to break on a specific break event number.
23–21 BRK_GRP_SEL	Break group select. This field selects a group of break sources. Each group reflects signals that set status bits in the status registers. List and location of signals inside a group matches the corresponding status register. Break Sources Groups/Status Registers: Group 0/IPU_INT_STAT_1 Group 1/IPU_INT_STAT_2 Group 2/IPU_INT_STAT_3 Group 3/IPU_INT_STAT_3 Group 4/IPU_INT_STAT_3
20–16 BRK_SIG_SEL	Break signal select. This field selects which of 32 break sources in the selected group will cause a break. Values: 0 DMA stop 1 Freeze 2 Interrupt 3 RSV
15–13	Reserved
12 SDC_DBG_MASK_DIS	SDC debug mode channel mask disable. This bit disables the masking of SDC channels when a debug request arrives. 0 SDC channels are masked when debug request arrives. 1 SDC channels are not masked when debug request arrives.
11 BRK_SIG_COND_EN	Break on signal posedge enable. This bit when set enables break on signal posedge. 0 Signal posedge break is disabled. 1 Signal posedge break is enabled.
10 BRK_COL_COND_EN	Break on column number enable. This bit when set enables break on channel number. 0 Column break is disabled. 1 Column break is enabled.
9 BRK_ROW_COND_EN	Break on row number enable. This bit when set enables break on channel number. 0 Row break is disabled. 1 Row break is enabled.
8 BRK_CHA_COND_EN	Break on channel number enable. This bit when set enables break on channel number. 0 Channel break is disabled. 1 Channel break is enabled.
7–6 BRK_RQ_MODE	Break request mode. This field selects the mode of the break request. 0 DMA stop 1 Freeze 2 Interrupt 3 RSV

Table 31-46. IPU_BRK_CTRL_1 Field Descriptions (Continued)

Field	Description
5–4 DBG_ENTER_MODE	Debug entry mode. These bits defines the dependency between core and IPU debug mode entry. DBG_ENTER_MODE[1]—defines the dependency of core on IPU. DBG_ENTER_MODE[0]—defines the dependency of IPU on core. Values: 00 IPU internal break force core to enter debug. Core entering debug force IPU to enter debug. 01 IPU internal break force core to enter debug. Core entering debug DOES NOT force IPU to enter debug. 10 IPU internal break DOES NOT force core to enter debug. Core entering debug force IPU to enter debug. 11 IPU internal break DOES NOT force core to enter debug. Core entering debug DOES NOT force IPU to enter debug.
3	Reserved
2 DBG_EXIT	Exit debug mode 0 Stay in debug mode. 1 Exit debug mode.
1 FRC_DBG	Force entering debug mode. This bit forces debug mode entry by the IPU. 0 Disable unconditional debug mode entry. 1 Enable unconditional debug mode entry.
0 BRK_EN	Break enable. This bit enables the internal break. 0 Internal break is disabled. 1 Internal break is enabled.

31.3.3.1.21 IPU Break Control Register 2 (IPU_BRK_CTRL_2)

This register is the second control register of the debug unit in the control module. Figure 31-29 shows the register format, and Table 31-47 describes the register fields.

0x53FC_0054 (IPU_BRK_CTRL_2) Access: User Read/Write

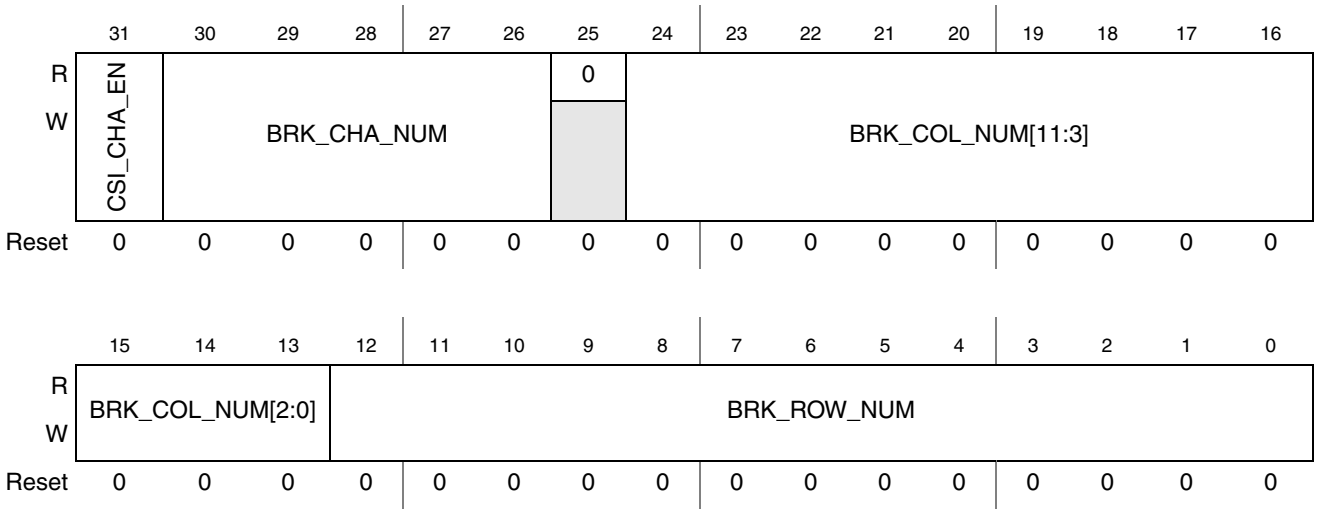

Figure 31-29. IPU Break Control Register 2 (IPU_BRK_CTRL_2)

Table 31-47. IPU_BRK_CTRL_2 Field Descriptions

Field	Description
31 CSI_CHA_EN	Enable CSI break condition. This bit enables break when CSI output frame column and row numbers matches the selected values. 0 enable CSI break condition. 1 enable CSI break condition (DMA break conditions are ignored)
30–26 BRK_CHA_NUM	DMA channel number for break condition. This field is programmed by user to break on a specific channel number. The number starts from 0.
25	Reserved
24–16 BRK_COL_NUM[11:3]	Frame column number for break condition. This field is programmed by user to break on a specific column number. The number starts from 0.
15–13 BRK_COL_NUM[2:0]	
12–0 BRK_ROW_NUM	Frame row number for break condition. This field is programmed by user to break on a specific row number. The number starts from 0.

31.3.3.1.22 IPU Break Status Register (IPU_BRK_STAT)

This register displays break status. Figure 31-30 shows the register format, and Table 31-48 describes the register fields.

0x53FC_0058 (IPU_BRK_STAT) Access: User Read-Only

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-30. IPU Break Status Register (IPU_BRK_STAT)

Table 31-48. IPU_BRK_STAT Field Descriptions

Field	Description
31–3	Reserved
2 BRK_SRC	IPU break acknowledge. This bit indicates that IPU is in break. 0 IPU is out of break mode. 1 IPU is in break mode.
1 MCU_DBGRQ	Core debug request. IPU requests the core to enter into debug mode through this bit. 0 debug request from IPU to core is negated. 1 debug request from IPU to core is asserted.
0 IPU_BREAK_ACK	Break source. This bit indicates whether break is caused by internal or external source. 0 external source 1 internal source

31.3.3.1.23 IPU Diagnostic Bus Control Register (IPU_DIAGB_CTRL)

This register controls the signal group to be displayed on the diagnostic bus. Figure 31-31 shows the register format, and Table 31-49 describes the register fields. Table 31-50 shows MON_GRP_SEL settings and the corresponding signal groups to be displayed.

Figure 31-32. CSI Sensor Configuration Register (CSI_SENS_CONF)

Table 31-51. CSI_SENS_CONF Field Descriptions

Field	Description
31–24	Reserved
23–16 DIV_RATIO	Clock division ratio minus 1. This field defines the division ratio of HSP_CLK into SENSB_MCLK: SENSB_MCLK rate = HSP_CLK rate /(DIV_RATIO+1)
15 EXT_VSYNC	External VSYNC enable. This bits select between external and internal VSYNC. 0 Internal VSYNC mode. 1 External VSYNC mode.
14–12	Reserved
11–10 DATA_WIDTH	Data width. This fields defines the number of bits per color. Values: 00 two 4-bit words per color 01 8 bits per color 10 10 bits per color 11 15 bits Bayer or generic data

Table 31-51. CSI_SENS_CONF Field Descriptions (Continued)

Field	Description
9–8 SENS_DATA_FORMAT	Data format from the sensor. This field defines the data format for the input of the CSI sensor. Values: 00 RGB or YUV444 01 Reserved 10 YUV422 (UYVY...) 11 Bayer or generic data
7 SENS_CLK_SRC	Sensor clock source. This bit defines the clock source input 0 SENSB_SENS_CLK clock. 1 HSP_CLK clock after division.
6	Reserved
5–4 SENS_PRTCL	Sensor protocol. This bit defines the sensor timing/data mode protocol. Values: 00 Gated clock mode 01 Non-gated clock mode 10 CCIR progressive mode 11 CCIR interlaced mode
3 SENS_PIX_CLK_POL	Invert pixel clock input. This bit selects the polarity of pixel clock. 0 pixel clock is directly applied to internal circuitry. 1 pixel clock is inverted before applied to internal circuitry.
2 DATA_POL	Invert data input. This bit selects the polarity of data input. 0 data lines are directly applied to internal circuitry. 1 data lines are inverted before applied to internal circuitry.
1 HSYNC_POL	Invert IPP_IND_SENSB_HSYNC input. This bit selects the polarity of IPP_IND_SENSB_HSYNC signal. 0 IPP_IND_SENSB_HSYNC is directly applied to internal circuitry. 1 IPP_IND_SENSB_HSYNC is inverted before applied to internal circuitry.
0 VSYNC_POL	Invert IPP_IND_SENSB_VSYNC input. This bit selects the polarity of IPP_IND_SENSB_VSYNC signal. 0 IPP_IND_SENSB_VSYNC is not inverted before applied to internal circuitry. 1 IPP_IND_SENSB_VSYNC is inverted before applied to internal circuitry.

31.3.3.2.2 CSI Sensor Frame Size Register (CSI_SENS_FRM_SIZE)

This register controls the sensor frame size.

0x53FC_0064 (CSI_SENS_FRM_SIZE) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-33. CSI Sensor Frame Size Register (CSI_SENS_FRM_SIZE)

Table 31-52. CSI_SENS_FRM_SIZE Field Descriptions

Field	Description
31–28	Reserved
27–16 SENS_FRM_HEIGHT	Sensor frame height minus 1. This field defines the sensor frame rows number minus 1.
15–12	Reserved
11–0 SENS_FRM_WIDTH	Sensor frame width minus 1. This field defines the sensor frame column number minus 1.

31.3.3.2.3 CSI Actual Frame Size Register (CSI_ACT_FRM_SIZE)

This register controls the actual frame size.

0x53FC_0068 (CSI_ACT_FRM_SIZE) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-34. CSI Actual Frame Size Register (CSI_ACT_FRM_SIZE)

Table 31-53. CSI_ACT_FRM_SIZE Field Descriptions

Field	Description
31–28	Reserved
27–16 ACT_FRM_HEIGHT	Actual frame height minus 1. This field defines the CSI output frame rows number minus 1.
15–12	Reserved
11–0 ACT_FRM_WIDTH	Actual frame width minus 1. This field defines the CSI output frame columns number minus 1.

31.3.3.2.4 CSI Output Frame Control Register (CSI_OUT_FRM_CTRL)

This register controls the output frame parameters.

0x53FC_006C (CSI_OUT_FRM_CTRL) Access: User Read/Write

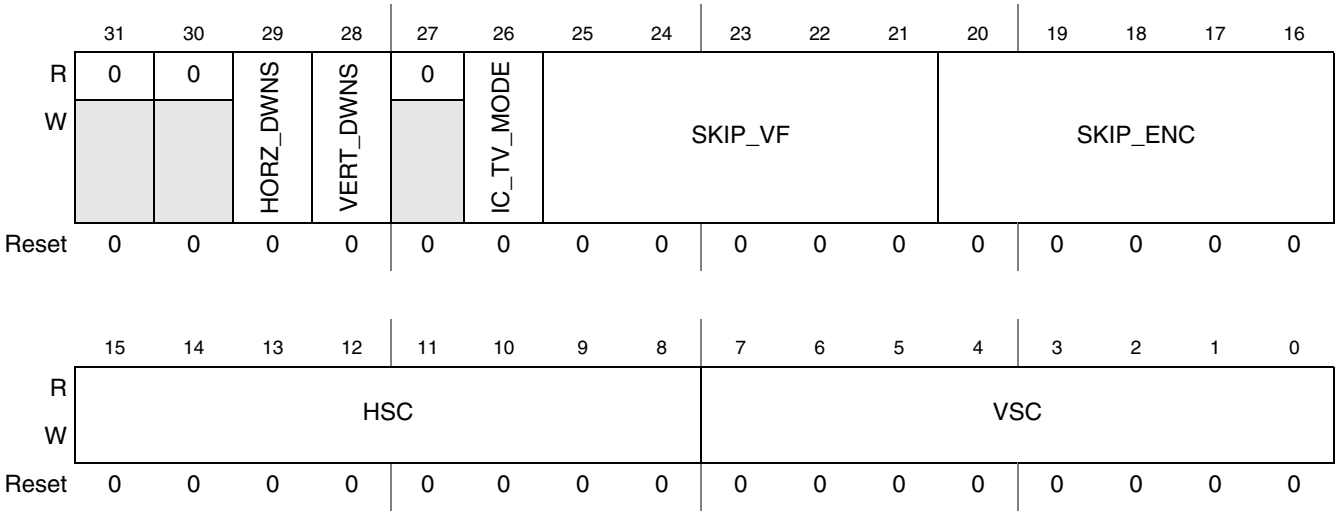

Figure 31-35. CSI Output Frame Control Register (CSI_OUT_FRM_CTRL)

Table 31-54. CSI_OUT_FRM_CTRL Field Descriptions

Field	Description
31–30	Reserved
29 HORZ_DWNS	Enable horizontal downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
28 VERT_DWNS	Enable vertical downsizing (decimation) by 2. 0 Downsizing disabled 1 Downsizing enabled
27	Reserved
26 IC_TV_MODE	Convert interlaced frame format to progressive frame format when writing to the system memory. 0 Disable format conversion 1 Enable format conversion

Table 31-54. CSI_OUT_FRM_CTRL Field Descriptions (Continued)

Field	Description
25–21 SKIP_VF	Skip viewfinder frame. This field initiated by core, is shifted each new frame and according to the bits, frames are skipped for view-finder task—each bit meaning is: 0 Frame for view-finder is valid. 1 Frame for view-finder is skipped.
20–16 SKIP_ENC	Skip encoder frame. This field initiated by core, is shifted each new frame and according to the bits, frames are skipped for encoding task—each bit meaning is: 0 Frame for encoding is valid. 1 Frame for encoding is skipped.
15–8 HSC	Horizontal skip. This field defines the number of columns to skip.
7–0 VSC	Vertical skip. This field defines the number of rows to skip.

31.3.3.2.5 CSI Test Control Register (CSI_TST_CTRL)

This register controls the sensor pattern generating in test mode.

0x53FC_0070 (CSI_TST_CTRL) Access: User Read/Write

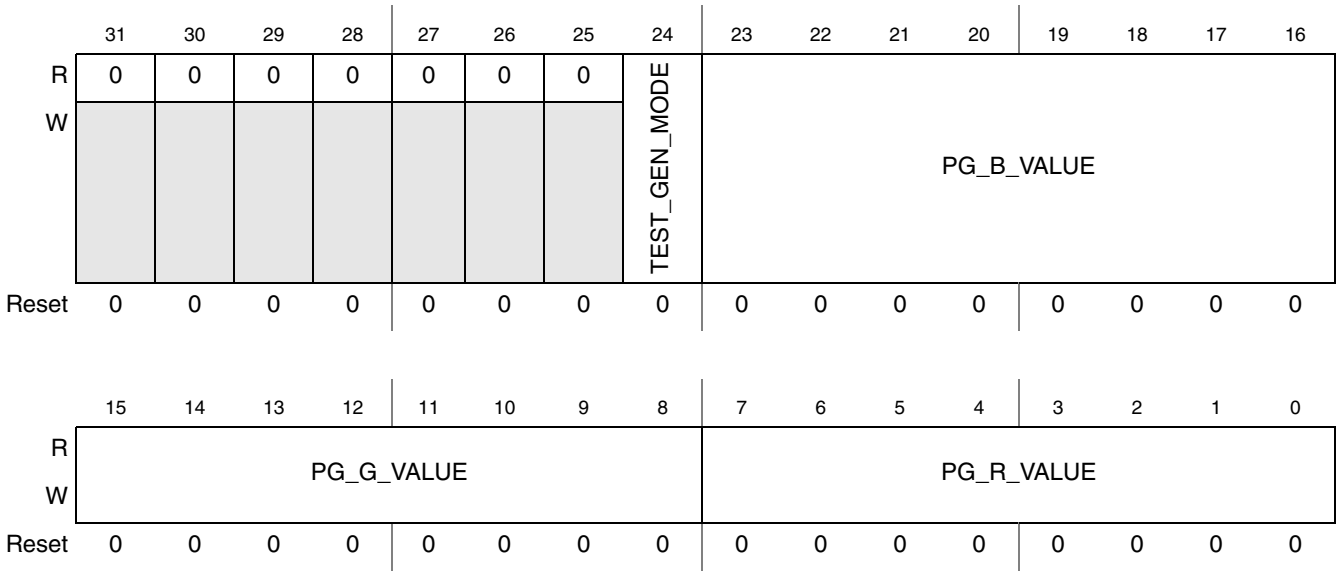

Figure 31-36. CSI Test Control Register (CSI_TST_CTRL)

Table 31-55. CSI_TST_CTRL Field Descriptions

Field	Description
31–25	Reserved
24 TEST_GEN_MODE	Test generator mode. This bit activates the signal generation. 0 Test signal generator is inactive. 1 Test signal generator is active.

Table 31-55. CSI_TST_CTRL Field Descriptions (Continued)

Field	Description
23–16 PG_B_VALUE	Pattern generator B value. This field selects the B value for the generated pattern of even pixel.
15–8 PG_G_VALUE	Pattern generator G value. This field selects the G value for the generated pattern of even pixel.
7–0 PG_R_VALUE	Pattern generator R value. This field selects the R value for the generated pattern of even pixel.

31.3.3.2.6 CSI CCIR Code Register 1 (CSI_CCIR_CODE_1)

This register controls the field 0 commands configuration.

Figure 31-37. CSI CCIR Code Register 1 (CSI_CCIR_CODE_1)

Table 31-56. CSI_CCIR_CODE_1 Field Descriptions

Field	Description
31–25	Reserved
24 CCIR_ERR_DET_EN	Enable error detection and correction for CCIR interlaced mode with protection bit. 0 Error detection and correction is disabled. 1 Error detection and correction is enabled.
31–25	Reserved
21–19 STRT_FLD0_ACTV	Start of field 0 active line command (interlaces mode). (In progressive mode, start of active line command mode).
18–16 END_FLD0_ACTV	End of field 0 active line command (interlaces mode). (In progressive mode, end of active line command mode).

Table 31-56. CSI_CCIR_CODE_1 Field Descriptions (Continued)

Field	Description
15–12	Reserved
11–9 STRT_FLD0_BLNK_2ND	Start of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
8–6 END_FLD0_BLNK_2ND	End of field 0 second blanking line command (interlaces mode). (In progressive mode this field is ignored).
5–3 STRT_FLD0_BLNK_1ST	Start of field 0 first blanking line command (interlaces mode). (In progressive mode this field indicates start of blanking line command).
2–0 END_FLD0_BLNK_1ST	End of field 0 first blanking line command (interlaces mode). (In progressive mode this field is ignored).

31.3.3.2.7 CSI CCIR Code Register 2 (CSI_CCIR_CODE_2)

This register controls the field 1 commands configuration.

0x53FC_0078 (CSI_CCIR_CODE_2) Access: User Read/Write

Table 31-58. CSI_CCIR_CODE_3 Field Descriptions

Field	Description
31–24	Reserved
23–16 CCIR_PRECOM[23:16]	CCIR pre command. This field defines the sequence which comes before the CCIR command.
15–0 CCIR_PRECOM[15:0]	CCIR pre command. This field defines the sequence which comes before the CCIR command.

31.3.3.2.9 CSI Flash Strobe Register 1 (CSI_FLASH_STROBE_1)

This register controls the flash strobe generated by the CSI.

0x53FC_0080 (CSI_FLASH_STROBE_1) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SENS_ROW_DURATION

Figure 31-40. CSI Flash Strobe Register 1 (CSI_FLASH_STROBE_1)

Table 31-59. CSI_FLASH_STROBE_1 Field Descriptions

Field	Description
31–16 SENS_ROW_DURATION	Duration of sensor row minus 1. This field specifies scan duration for one sensor row expressed in SENSB_MCLK or SENSB_PIX_CLK periods. This value is used as an unit for definition of flash strobe start time and duration.
15–1	Reserved
0 CLOCK_SEL	Select clock for sensor row duration count. This bit selects SENSB_MCLK or SENSB_PIX_CLK clock for sensor row duration count. 0 Select SENSB_MCLK clock 1 Select SENSB_PIX_CLK clock

31.3.3.2.10 CSI Flash Strobe Register 2 (CSI_FLASH_STROBE_2)

This register controls the flash strobe generated by the CSI.

0x53FC_0084 (CSI_FLASH_STROBE_2) Access: User Read/Write

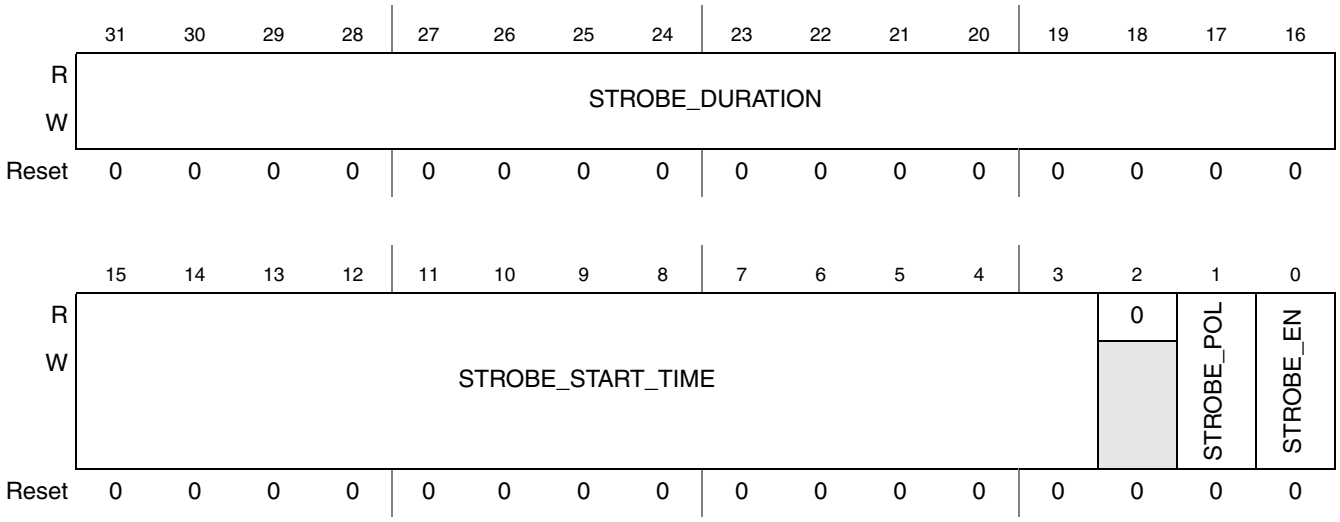

Figure 31-41. CSI Flash Strobe Register 2 (CSI_FLASH_STROBE_2)

Table 31-60. CSI_FLASH_STROBE_2 Field Descriptions

Field	Description
31–16 STROBE_DURATION	Strobe duration minus 1. This field defines flash strobe duration. The value is expressed in sensor image rows.
15–3 STROBE_START_TIME	Strobe start time minus 1. This field defines a time interval between beginning of the next sensor frame and flash strobe generation start. The value is expressed in sensor image rows. The minimal allowed value is 1.
2	Reserved
1 STROBE_POL	Strobe polarity control bit. This bit controls flash strobe polarity. 0 active low 1 active high
0 STROBE_EN	Strobe enable control/status bit. This bit enables flash strobe generation after beginning of the next sensor frame. Beginning of the sensor frame is defined as the first row start point. This bit should be set by the core. The IPU automatically clears the bit after strobe generation finish. 0 flash strobe disabled 1 flash strobe enabled

31.3.3.3 IC Registers

31.3.3.3.1 IC Configuration Register (IC_CONF)

This register contains control parameter for IC 3 tasks (pre-processing for encoding, pre-processing for view-finder and post processing).

0x53FC_0088 (IC_CONF) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-42. IC Configuration Register (IC_CONF)

Table 31-61. IC_CONF Field Descriptions

Field	Description
31 CSI_MEM_WR_EN	CSI direct memory write enable. This bit enables writing data from sensor directly to memory even when a raw sensor is not attached. 0 CSI direct writing to memory is disabled. 1 CSI direct writing to memory is enabled.
30 RWS_EN	Raw sensor enable. This bit indicate if a raw sensor is attached (bayer format). 0 Raw sensor is not attached. 1 Raw sensor is attached. This bit is used together with the CSI_MEM_WR_EN bit as follows: CSI_MEM_WR_EN=0, RWS_EN=0—data is fed from the CSI to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=0—data is fed from the CSI to the IC for processing and also for writing to the system memory; CSI_MEM_WR_EN=0, RWS_EN=1—data is fed from the CSI to the system memory (via the IC) and from the system memory to the IC for processing; CSI_MEM_WR_EN=1, RWS_EN=1—non-valid configuration.
29 IC_KEY_COLOR_EN	Key color enable. This bit enables the key color feature. 0 Key color is disabled. 1 Key color is enabled.

Table 31-61. IC_CONF Field Descriptions (Continued)

Field	Description
28 IC_GLB_LOC_A	Global alpha. This bit select the source of alpha parameter. 0 Alpha parameter is local. 1 Alpha parameter is global.
27–21	Reserved
20 PP_ROT_EN	Post-processing rotation task enable. This bit enable post-processing rotation task. 0 Rotation is disabled. 1 Rotation is enabled.
19 PP_CMB	Post-processing task combining enable. This bit enables combining. Combining can be done only when first CSC is enabled (PP_CSC1=1). Otherwise the bit has no effect. 0 Combining is disabled. 1 Combining is enabled.
18 PP_CSC2	Post-processing task color conversion RGB-->YUV enable. This bit enables YUV-->RGB. 0 RGB-->YUV is disabled. 1 RGB-->YUV is enabled.
17 PP_CSC1	Post-processing task color conversion YUV-->RGB enable. This bit enables YUV-->RGB. 0 YUV-->RGB is disabled. 1 YUV-->RGB is enabled.
16 PP_EN	Post-processing task enable. This bit enables the post-processing task. 0 Task is disabled. 1 Task is enabled.
15–13	Reserved
12 PRPVF_ROT_EN	Preprocessing rotation task for viewfinder enable. This bit enable preprocessing rotation task for viewfinder. 0 Rotation is disabled. 1 Rotation is enabled.
11 PRPVF_CMB	Preprocessing task for view-finder combining enable. This bit enables combining. Combining can be done only when first CSC is enabled (PRPVF_CSC1=1). Otherwise the bit has no effect. 0 Combining is disabled. 1 Combining is enabled.
10 PRPVF_CSC2	Pre-processing task for view-finder second color conversion enable. This bit enables second color conversion. 0 Second color conversion is disabled. 1 Second color conversion is enabled.
9 PRPVF_CSC1	Pre-processing task for view-finder first color conversion enable. This bit enables first color conversion. 0 First color conversion is disabled. 1 First color conversion is enabled.
8 PRPVF_EN	Preprocessing task for view-finder enable. This bit enables the view-finder task. 0 Task is disabled. 1 Task is enabled.

Table 31-61. IC_CONF Field Descriptions (Continued)

Field	Description
7–3	Reserved
2 PRPENC_ROT_EN	Preprocessing rotation task for encoding enable. This bit enable preprocessing rotation task for encoding. 0 Rotation is disabled. 1 Rotation is enabled.
1 PRPENC_CSC1	Preprocessing task for encoding color conversion enable. This bit enables color conversion. 0 Color conversion is disabled. 1 Color conversion is enabled.
0 PRPENC_EN	Preprocessing task for encoding enable. This bit enables the encoding task. 0 Task is disabled. 1 Task is enabled.

31.3.3.3.2 IC Preprocessing Encoder Resizing Coefficients Register (IC_PRP_ENC_RSC)

This register contains the resizing and downsizing parameters for preprocessing task for encoding.

0x53FC_008C (IC_PRP_ENC_RSC) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-50. IDMAC Channel Enable Register (IDMAC_CHA_EN)

Table 31-69. IDMAC_CHA_EN Field Descriptions

Field	Description
DMA_*n*_EN *n* = 0…31	DMA channel *n* enable. This bit selects if channel *n* is enabled 0 Channel *n* is disabled. 1 Channel *n* is enabled.

31.3.3.5.3 IDMAC Channel Priority Register (IDMAC_CHA_PRI)

This register contains the DMA channel priorities.

0x53FC_00Ac (IDMAC_CHA_PRI) Access: User Read/Write

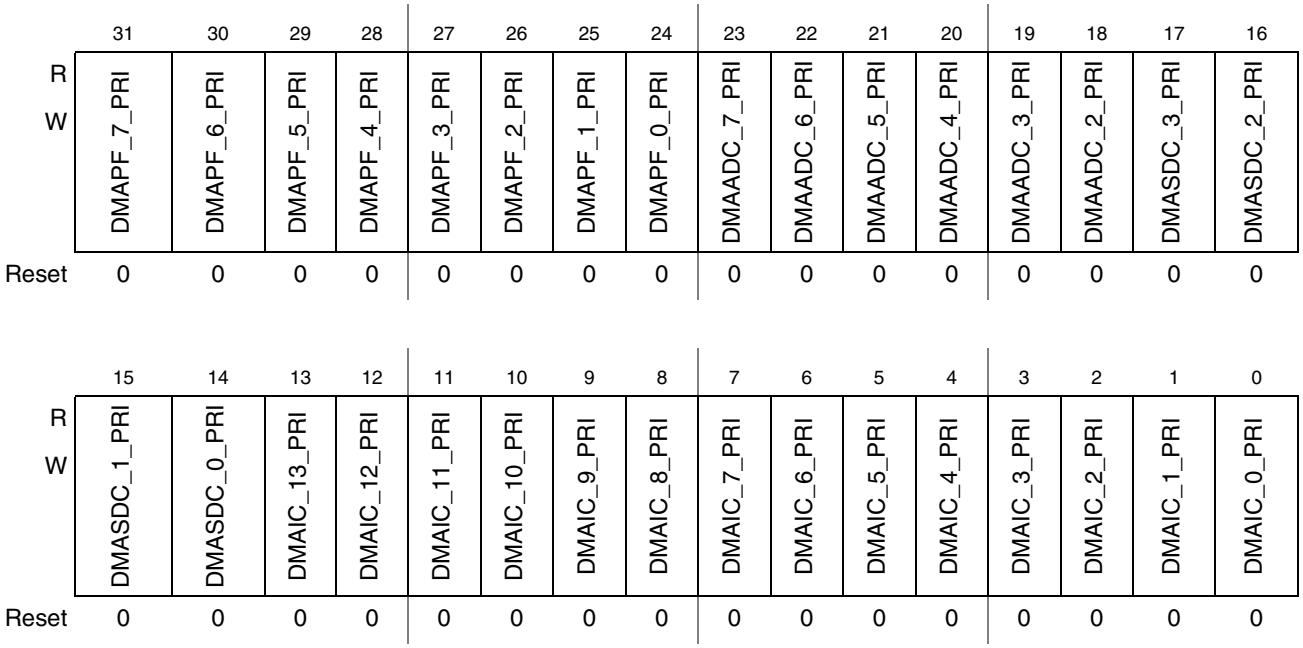

Figure 31-51. IDMAC Channel Priority Register (IDMAC_CHA_PRI)

Table 31-70. IDMAC_CHA_PRI Field Descriptions

Field	Description
DMA_*n*_PRI *n* = 0…31	DMA channel *n* priority. This field determines if channel *n* is enabled. 0 Channel *n* has low priority. 1 Channel *n* has high priority.

31.3.3.5.4 IDMAC Channel Busy Register (IDMAC_CHA_BUSY)

0x53FC_00B0 (IDMAC_CHA_BUSY) Access: User Read-Only

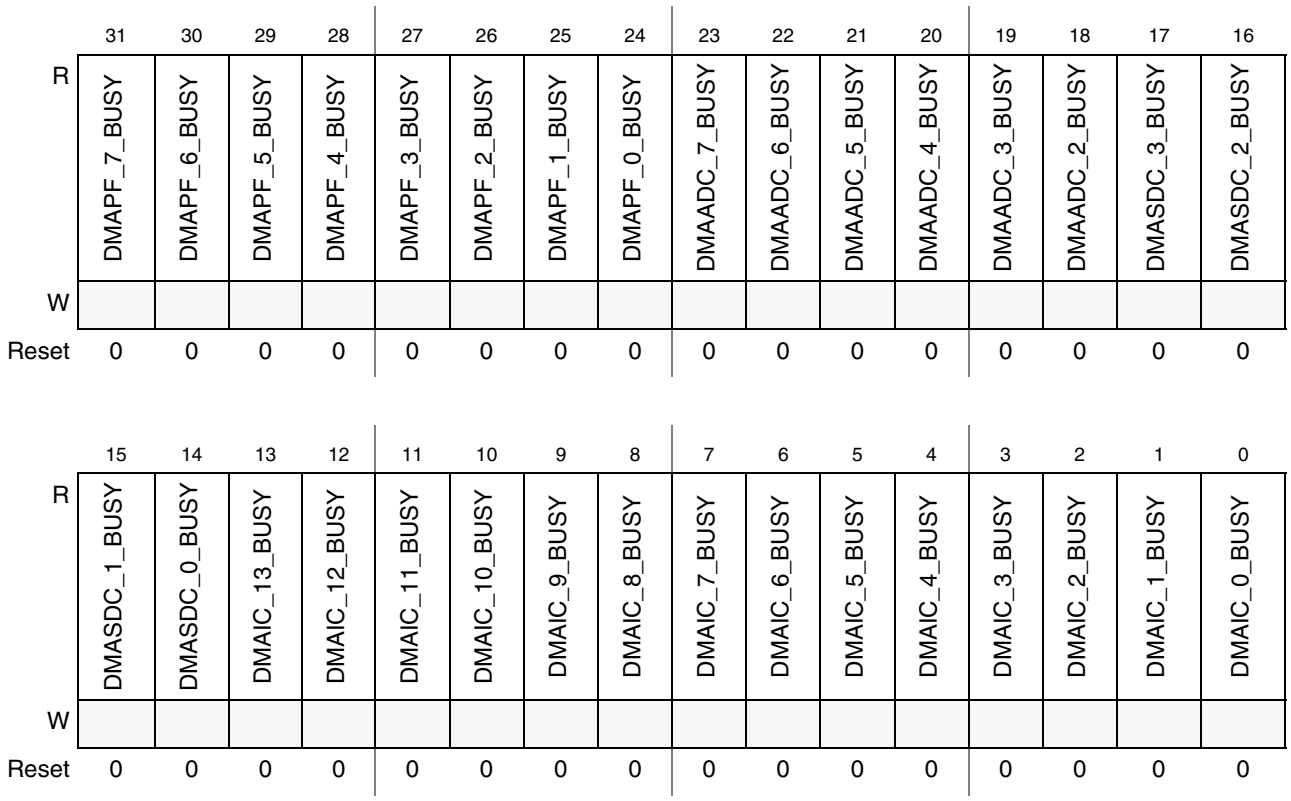

Figure 31-52. IDMAC Channel Busy Register (IDMAC_CHA_BUSY)

Table 31-71. IDMAC_CHA_BUSY Field Descriptions

Field	Description
31–0 CHA#_BUSY[1]	Channel # is ready. This bit indicates that channel is busy (in the middle of frame). 0 Channel is not busy. 1 Channel is busy.

[1] Indicates the corresponding DMA channel number noted in Figure 31-52.

31.3.3.6 SDC Registers

31.3.3.6.1 SDC Common Configuration Register (SDC_COM_CONF)

This register contains common configuration parameter for the SDC.

0x53FC_00B4 (SDC_COM_CONF) Access: User Read/Write

Figure 31-53. SDC Common Configuration Register (SDC_COM_CONF)

Table 31-72. SDC_COM_CONF Field Descriptions

Field	Description
31–19	Reserved
18–16 COC	Cursor operation control. Controls the format of the cursor and the type of arithmetic operations. 000 Transparent, cursor is disabled. 001 Full cursor. 010 Reversed cursor. 011 AND between background and cursor. 100 Reserved 101 OR between background and cursor. 110 XOR between background and cursor. 111 Reserved
15 DUAL_MODE	Dual mode enable. Enables/disables dual mode. This bit define if synch interface sends data to smart display. 0 Disable dual mode. 1 Enable dual mode.
14 SAVE_REFR_EN	Enable saving refresh mode. This bit controls saving refresh mode for synchronous interface of smart displays. If saving refresh mode is enabled, display refresh is performed only when display buffer data or displayed windows or cursor position are changed 0 Disable saving refresh. 1 Enable saving refresh.
13	Reserved

Table 31-72. SDC_COM_CONF Field Descriptions (Continued)

Field	Description
12 SHARP	Sharp panel enable. Enables/Disables signals for Sharp. 0 Disable Sharp signals. 1 Enable Sharp signals.
11–10	Reserved
9 BG_EN	Background enable. This bit enables the background channel. 0 Background channel is disabled, but control signals (HSYNC, VSYNC) are enabled. 1 Background channel is enabled.
8 MASK_EN	Mask enable. This bit enables the mask channel. 0 Mask channel is disabled. 1 Mask channel is enabled.
7 SDC_KEY_COLOR_EN	Graphic window color keying enable. Enable or disable graphic window color keying. 0 Disable color keying of graphic window 1 Enable color keying of graphic window
6 SDC_GLB_LOC_A	Graphic window alpha mode. Select the use of alpha to be global or local. 0 Local alpha. 1 Global alpha.
5 GWSEL	Graphic window select. Select graphic window to be on foreground or background. 0 Graphic window is background. 1 Graphic window is foreground.
4 FG_EN	Foreground enable. This bit enables the foreground channel. 0 Foreground channel is disabled. 1 Foreground channel is enabled.
3 FG_MCP_FORM	Foreground monochrome data format. This bit relevant only when SDC_MODE=00. It indicates if the pixels of foreground contains alpha. 0 8 bpp without alpha. 1 8 bpp and 8 bit alpha => 16 bit for pixel.
2 BG_MCP_FORM	Background monochrome data format. This bit relevant only when SDC_MODE=00. It indicates that the pixels of background contains alpha. 0 8 bpp without alpha. 1 8 bpp and 8 bit alpha => 16 bit for pixel.
1–0 SDC_MODE	SDC mode. This field selects the SDC output data format. 00 TFT monochrome 01 TFT color 10 YUV progressive 11 YUV interlaced

31.3.3.6.2 SDC Graphic Window Control Register (SDC_GRAPH_WIND_CTRL)

This register defines alpha and key color values.

0x53FC_00B8 (SDC_GRAPH_WIND_CTRL)

Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SDC_ALPHA_V								SDC_KEY_COLOR_R

Figure 31-54. SDC Graphic Window Control Register (SDC_GRAPH_WIND_CTRL)

Table 31-73. SDC_GRAPH_WIND_CTRL Field Descriptions

Field	Description
31–24 SDC_ALPHA_V	Graphic window alpha value. Defines the alpha value of graphic window used for alpha blending between graphic window and background plane. The actual value the number, that used in combining calculations. If value ≤ 0.5- 1/256 (01111111) then actual value = value. If value ≥ 0.5 (10000000), then actual value = value + 1/256. For SDC_ALPHA_V values, see Table 31-74.
23–16 SDC_KEY_COLOR_R	Graphic window color keying red component. Defines the red component of graphic window color keying. 00000000 No Red …… 11111111 Full Red
15–8 SDC_KEY_COLOR_G	Graphic window color keying green component. Defines the green component of graphic window color keying. Values: 00000000 No green …… 11111111 Full green
7–0 SDC_KEY_COLOR_B	Graphic window color keying blue component. Defines the blue component of graphic window color keying. Values: 00000000 No blue …… 11111111 Full blue

Table 31-74. SDC_ALPHA_V Values

Value	Actual Alpha Value	Meaning
00000000	00000000	Graphic window totally transparent (not displayed on LCD screen)
.....	.....	.....
01111111	01111111	.....
10000000	10000001	.....
10000001	10000010	.....
.....	.....	.....
11111110	11111111	.....
11111111	100000000	Graphic window totally opaque (overlaid on LCD screen)

31.3.3.6.3 SDC Foreground Window Position Register (SDC_FG_POS)

This register is used to determine the starting position of the foreground window relative to VSYNC.

0x53FC_00BC (SDC_FG_POS) Access: User Read/Write

Figure 31-55. SDC Foreground Window Position Register (SDC_FG_POS)

Table 31-75. SDC_FG_POS Field Descriptions

Field	Description
31–26	Reserved
25–16 FGXP	Foreground window X position. Specifies the number of pixel clock periods between the start of HSYNC and the beginning of the first data of the row. Starts from BGXP. A sum of FGXP and FW for the DMASDC_1 channel must be no greater than a sum of BGXP and FW for the DMASDC_0 channel. A sum of FGXP and FW for the DMASDC_1 channel must be less than SCREEN_WIDTH.

Table 31-75. SDC_FG_POS Field Descriptions (Continued)

Field	Description
15–10	Reserved
9–0 FGYP	Foreground window Y position. Specifies the number of lines between the start of VSYNC and the beginning of the first data. Starts from BGYP. A sum of FGYP and FH for the DMASDC_1 channel must be no greater than a sum of BGYP and FH for the DMASDC_0 channel. A sum of FGYP and FH for the DMASDC_1 channel must be less than SCREEN_HEIGHT.

31.3.3.6.4 SDC Background Window Position Register (SDC_BG_POS)

This register is used to determine the starting position of the background window relative to VSYNC.

0x53FC_00C0 (SDC_BG_POS) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31-77. SDC_CUR_POS Field Descriptions

Field	Description
31	Reserved
30–26 CXW	Cursor width minus 1. Specifies the width of the hardware cursor in pixels.
25–16 CXP	Cursor X position. Specifies the cursors horizontal starting position X expressed in pixels. Starts from BGXP. A sum of CXP and CXW must be no greater than a sum of BGXP and FW for the DMASDC_0 channel.
15	Reserved
14–10 CYH	Cursor height minus 1. Specifies the height of the hardware cursor in pixels.
9–0 CYP	Cursor Y position. Specifies the cursors vertical starting position Y expressed in rows. Starts from BGYP. A sum of CYP and CYH must be no greater than a sum of BGYP and FH for the DMASDC_0 channel.

31.3.3.6.6 SDC Cursor Blinking and PWM Contrast Control Register (SDC_CUR_BLINK_PWM_CTRL)

This register is used to control the blinking and the signal output at the IPP_DO_DISPB_CONTRAST pin, which controls the contrast of the LCD panel.

0x53FC_00C8 (SDC_CUR_BLINK_PWM_CTRL) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-58. SDC Cursor Blinking and PWM Contrast Control Register (SDC_CUR_BLINK_PWM_CTRL)

Table 31-78. SDC_CUR_POS Field Descriptions

Field	Description
31–27	Reserved
26–25 SCR	Source select. Selects the input clock source for the PWM counter. The PWM output frequency is equal to the frequency of the input clock divided by 256. Values: 00 HSYNC 01 Pixel clock 10 HSP_CLK clock 11 Reserved
24 CC_EN	Contrast control enable. Enables/disables the contrast control function. 0 Contrast control is off. 1 Contrast control is on.
23–16 PWM	Pulse width minus 1. Controls the pulse width of the built-in pulse-width modulator, which controls the contrast of the LCD screen.
15 BK_EN	Blinking enable. Determines whether the blink enable cursor will blink or remain steady. 0 Blink is disabled. 1 Blink is enabled.
14–8	Reserved
7–0 BKDIV	Blink divisor minus 1. Sets the cursor blink rate. VSYNC is used to clock the 8-bit up counter. When the counter value equals BKDIV, the cursor toggles on/off.

31.3.3.6.7 SDC Color Cursor Mapping Register (SDC_CUR_MAP)

This register defines the cursor color.

0x53FC_00CC (SDC_CUR_MAP) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 31-80. SDC_HOR_CONF Field Descriptions

Field	Description
31–26 H_SYNC_WIDTH	Horizontal synchronization pulse width minus 1. Specifies the number of pixel clock periods in active HSYNC.
25–16 SCREEN_WIDTH	Screen width minus 1. Specifies the number of pixel clock periods between the last HSYNC and the new HSYNC.
15–4	Reserved
3–0 H_SYNC_DELAY	Horizontal synchronization pulse delay. Specifies the number of pixel clock periods between VSYNC and HSYNC start points.

31.3.3.6.9 SDC Vertical Configuration Register (SDC_VER_CONF)

This register defines the vertical sync pulse timing.

0x53FC_00D4 (SDC_VER_CONF) Access: User Read/Write

25–16 PS_RISE_DELAY	PS rise delay relative to LP rising edge. This parameter defines when the PS pulse rises. 0000000000= 0 pixel clock cycles …. 1111111111= 1023 pixel clock cycles
15–10	Reserved
9–0 CLS_FALL_DELAY	CLS fall delay relative to LP rising edge. This parameter defines when CLS pulse falls. 0000000000= 0 pixel clock cycles … 1111111111= 1023 pixel clock cycles

31.3.3.7 ADC Registers

31.3.3.7.1 ADC Configuration Register (ADC_CONF)

This register contain general control bits for configuring ADC.

0x53FC_00E0 (ADC_CONF) Access: User Read/Write

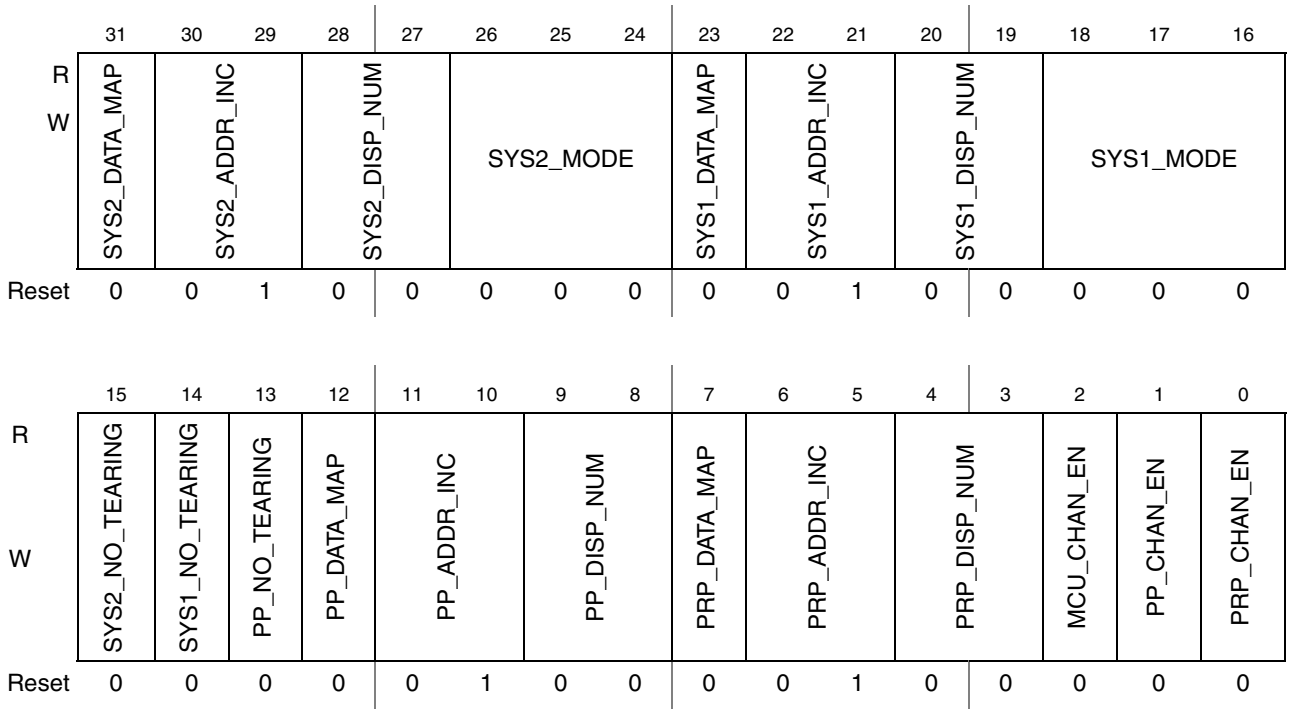

Figure 31-64. ADC Configuration Register (ADC_CONF)

Table 31-84. ADC_CONF Field Descriptions

Field	Description
31 SYS2_DATA_MAP	Select data mapping rule for the system channel 2. This field specifies data mapping rule in the DI for the system channel 2. 0 data mapping rule. 1 command mapping rule.
30–29 SYS2_ADDR_INC	Address increment for the system channel 2 (for full address display type). This field is ignored for XY address display type (increment is always 1). 00 Increment by 1—used for 8-bit access with pixel data 01 Increment by 2—used for 16-bit access with generic data (including byte enable) or pixel data 10 Reserved 11 Increment by 4—used for 32-bit access with generic data or pixel data
28–27 SYS2_DISP_NUM	Display number for system channel 2. This field contains pointer to display for system channel 2. 00 Display 0 01 Display 1 10 Display 2 11 Reserved

Table 31-84. ADC_CONF Field Descriptions (Continued)

Field	Description
26–24 SYS2_MODE	Control sequence generation mode for system channel 2. 000 Disable system channel 2 001 Write in template mode, run template if display address is not sequential 010 Read in template mode, run template if display address is not sequential 011 Write in template mode, unconditionally run template for each access 100 Read in template mode, unconditionally run template for each access 101 Write data buffer without template, RS=0 110 Write data buffer without template, RS=1 111 Write in command buffer mode (commands and data)
23 SYS1_DATA_MAP	Select data mapping rule for the system channel 1. This field specifies data mapping rule in the DI for the system channel 1. 0 data mapping rule. 1 command mapping rule.
22–21 SYS1_ADDR_INC	Address increment for the system channel 1 (for full address display type). This field is ignored for XY address display type (increment is always 1. 00 Increment by 1—used for 8-bit access with pixel data 01 Increment by 2—used for 16-bit access with generic data (including byte enable) or pixel data 10 Reserved 11 Increment by 4—used for 32-bit access with generic data or pixel data
20–19 SYS1_DISP_NUM	Display number for system channel 1. This field contains pointer to display for system channel 1. 00 Display 0 01 Display 1 10 Display 2 11 Reserved
18–16 SYS1_MODE	Control sequence generation mode for system channel 1. 000 Disable system channel 1 001 Write in template mode, run template if display address is not sequential 010 Read in template mode, run template if display address is not sequential 011 Write in template mode, unconditionally run template for each access 100 Read in template mode, unconditionally run template for each access 101 Write data buffer without template, RS=0 110 Write data buffer without template, RS=1 111 Write in command buffer mode (commands and data)
15 SYS2_NO_TEARING	The system channel 2 data will be sent to display with display line synchronization to avoid tearing. This bit can ignored for displays 1 or 2 if the DISP12_VSYNC_SEL bit in the ADC_DISP_VSYNC Register does not enable vertical synchronization for this display. 0 disable display synchronization to avoid tearing. 1 enable display line synchronization to avoid tearing.
14 SYS1_NO_TEARING	The system channel 1 data will be sent to display with display line synchronization to avoid tearing. This bit can ignored for displays 1 or 2 if the DISP12_VSYNC_SEL bit in the ADC_DISP_VSYNC Register does not enable vertical synchronization for this display. 0 disable display synchronization to avoid tearing. 1 enable display line synchronization to avoid tearing.
13 PP_NO_TEARING	The PP channel will be sent to display with display line synchronization to avoid tearing. This bit can ignored for displays 1 or 2 if the DISP12_VSYNC_SEL bit in the ADC_DISP_VSYNC Register does not enable vertical synchronization for this display. 0 disable display synchronization to avoid tearing 1 enable display line synchronization to avoid tearing

Table 31-84. ADC_CONF Field Descriptions (Continued)

Field	Description
12 PP_DATA_MAP	Select data mapping rule for the post-processing channel. This field specifies data mapping rule in the DI for the post-processing channel. 0 data mapping rule. 1 command mapping rule.
11–10 PP_ADDR_INC	Post-processing channel display address increment per display access (for full address display type). This bit is ignored for XY address display type (increment is always 1). 00 Increment by 1—used for 8-bit access with pixel data 01 Increment by 2—used for 16-bit access with pixel data 10 Reserved 11 Increment by 4—used for 32-bit access with pixel data
9–8 PP_DISP_NUM	Post-processing channel display number. This field contains pointer to display of PP channel. 00 Display 0 01 Display 1 10 Display 2 11 Reserved
7 PRP_DATA_MAP	Select data mapping rule for the pre-processing channel. This field specifies data mapping rule in the DI for the pre-processing channel. 0 data mapping rule. 1 command mapping rule.
6–5 PRP_ADDR_INC	Pre-processing channel display address increment per display access (for full address display type). This bit is ignored for XY address display type (increment is always 1). 00 Increment by 1—used for 8-bit access with pixel data 01 Increment by 2—used for 16-bit access with pixel data 10 Reserved 11 Increment by 4—used for 32-bit access with pixel data
4–3 PRP_DISP_NUM	Pre-processing channel display number. This field contains pointer to display of PRP channel. 00 Display 0 01 Display 1 10 Display 2 11 Reserved
2 MCU_CHAN_EN	Core channel enable. This bit enables core channel (direct access to display via the AHB slave interface). 0 Core channel is disabled. 1 Core channel is enabled.
1 PP_CHAN_EN	Enable post-processing channel. This bit enables post-processing channel. 0 PP channel is disabled. 1 PP channel is enabled.
0 PRP_CHAN_EN	Enable pre-processing channel. This bit enables pre-processing channel. 0 PRP Channel is disabled. 1 PRP channel is enabled.

31.3.3.7.2 ADC System Channel 1 Start Address Register (ADC_SYSCHA1_SA)

This register contains the start address of channel 1.

0x53FC_00E4 (ADC_SYSCHA1_SA) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 31-65. ADC System Channel 1 Start Address Register (ADC_SYSCHA1_SA)

Table 31-85. ADC_SYSCHA1_SA Field Descriptions

Field	Description
31–23 SYS1_START_TIME	Delay between display vertical synchronization pulse and start time point of system channel 1 window. The delay is defined in pairs of rows. It is used to eliminate tearing.
22–0 SYS1_CHAN_SA	System channel 1 start address. This field contains the start address of channel 1. • In the case of full addressing display, Start address has to be done in full addressing. • In the case of XY addressing display, X is located in the bits [log2(DISP#_SL+1)-1 : 0] and Y is located in the bits [22 : log2(DISP#_SL+1)], where display stride line DISP#_SL+1 must be a power of 2.

31.3.3.7.3 ADC System Channel 2 Start Address Register (ADC_SYSCHA2_SA)

This register contains the start address of channel 2.

0x53FC_00E8 (ADC_SYSCHA2_SA) Access: User Read/Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
21–16 DISP0_VSYNC_WIDTH	VSYNC pulse width minus 1 for display 0. This register contains number of pixels or lines according to DISP0_VSYNC_WIDTH_L definition between the posedge and negedge of VSYNC.
15–6 DISP_LN_WT	Delay between the start point of the first sensor row and the VSYNC pulse of displays 0, 1 or 2 expressed in display rows.
5	Reserved
4 DISP12_VSYNC_SEL	Selection of display 1 or 2 to be in vertical synchronization mode with the corresponding parameters from the ADC_DISP12_SS and ADC_DISP_VSYNC registers. 0 select display 1 for vertical synchronization 1 select display 2 for vertical synchronization
3–2 DISP12_VSYNC_MODE	Displays 1 or 2 vertical synchronization mode. 00 Vertical synchronization disabled 01 ADC internal VSYNC generation 10 ADC internal VSYNC generation with synchronization to sensor VSYNC 11 External VSYNC generation (by display)
1–0 DISPL0_VSYNC_MODE	Display 0 vertical synchronization mode. 00 Vertical synchronization disabled 01 ADC internal VSYNC generation 10 ADC internal VSYNC generation with synchronization to sensor VSYNC 11 External VSYNC generation (by display)

31.3.3.8 DI Registers

31.3.3.8.1 DI Display Interface Configuration Register (DI_DISP_IF_CONF)

0x53FC_0124 (DI_DISP_IF_CONF) Access: User Read/Write

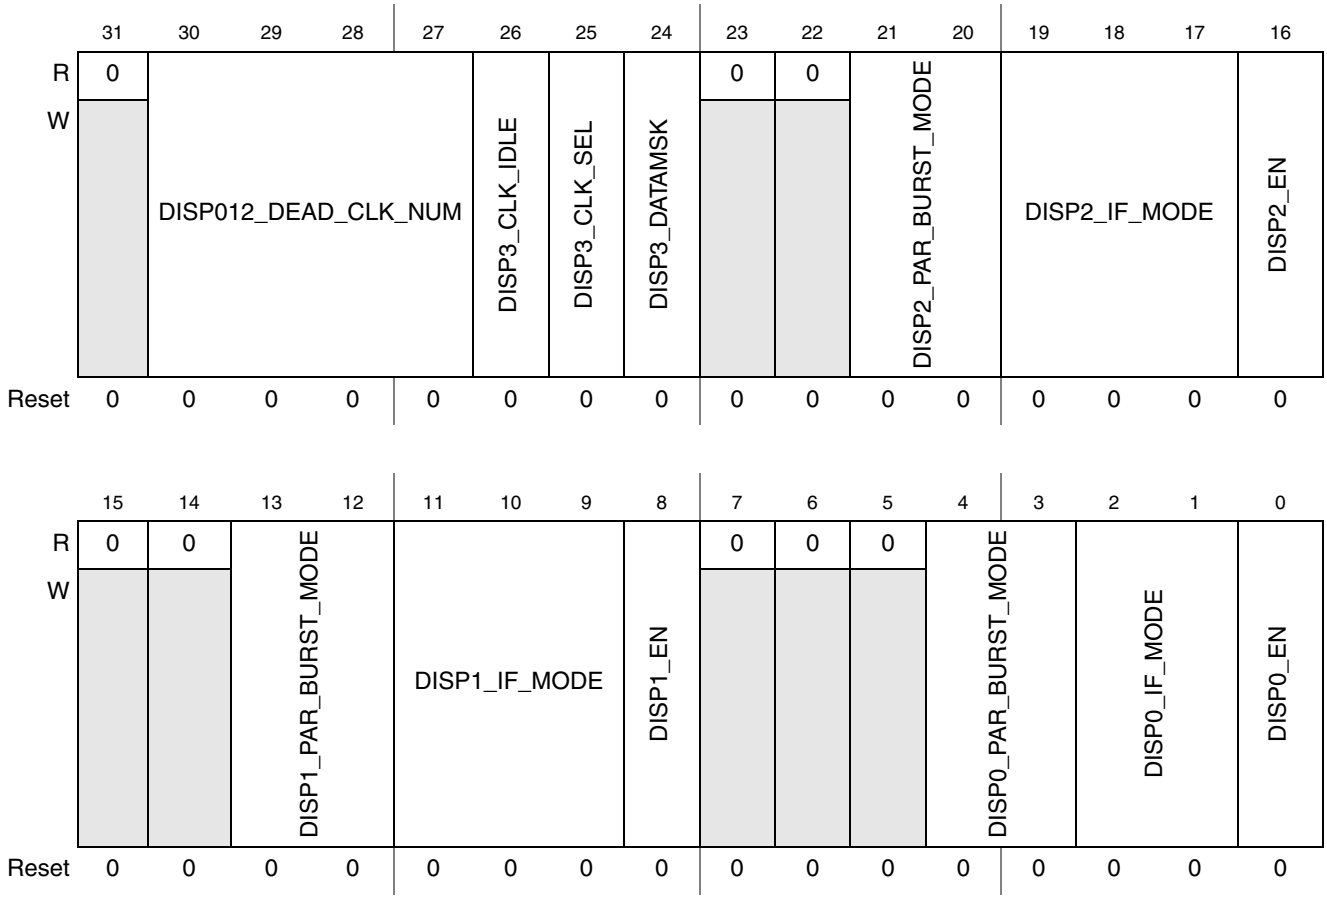

Figure 31-81. DI Display Interface Configuration Register (DI_DISP_IF_CONF)

Table 31-101. DI_DISP_IF_CONF Field Descriptions

Field	Description
31	Reserved
30–27 DISP012_DEAD_CLK_NUM	Number of dead clock cycles. Defines a number of dead cycles of the HSP_CLK clock inserted between accesses of two different displays or between two bursts transferred to/from a single display. 0000 4 dead cycles 0001 5 dead cycles .... 1111 19 dead cycles

Table 31-101. DI_DISP_IF_CONF Field Descriptions (Continued)

Field	Description
26 DISP3_CLK_IDLE	Display 3 interface clock idle enable. Enables/disables the display 3 clock when VSYNC is active. 0 Enable clock. 1 Disable clock.
25 DISP3_CLK_SEL	Select display 3 interface clock. Selects whether to enable or disable display clock when there is no data output. 0 Always enable clock even if there is no data output. 1 Disable clock when no data output.
24 DISP3_DATAMSK	Data mask for display 3. Enables/Disables the data output to zero for the Sharp TFT panel power-off sequence. 0 data is normal. 1 data always equals 0.
23–22	Reserved
21–20 DISP2_PAR_BURST_MODE	Display 2 parallel interface burst mode. Values: 00 Burst access mode with sampling by CS or R/W or ENABLE signals 01 Burst access mode with sampling by separate burst clock (BCLK) 10 Single access mode (all control signals are not active for one display interface clock after each display access) 11 Reserved
19–17 DISP2_IF_MODE	Display 2 interface mode. Values: 000 System 80 (type 1) parallel interface (sampling with CS signal) 001 System 80 (type 2) parallel interface (sampling with R/W signals) 010 System 68k (type 1) parallel interface (sampling with CS signal) 011 System 68k (type 2) parallel interface (sampling with ENABLE signal) 100 Serial 3-wire interface 101 Serial 4-wire interface 110 Serial 5-wire interface, RS is sampled with serial clock 111 Serial 5-wire interface, RS is sampled with CS signal
16 DISP2_EN	Display 2 enable. Enables/disables display 2. 0 Disable display 2. 1 Enable display 2.
15–14	Reserved
13–12 DISP1_PAR_BURST_MODE	Display 1 parallel interface burst mode. Values: 00 Burst access mode with sampling by CS or R/W or ENABLE signals 01 Burst access mode with sampling by separate burst clock (BCLK) 10 Single access mode (all control signals are not active for one display interface clock after each display access) 11 Reserved

Table 31-101. DI_DISP_IF_CONF Field Descriptions (Continued)

Field	Description
11–9 DISP1_IF_MODE	Display 1 interface mode. Values: 000 System 80 (type 1) parallel interface (sampling with CS signal) 001 System 80 (type 2) parallel interface (sampling with R/W signals) 010 System 68k (type 1) parallel interface (sampling with CS signal) 011 System 68k (type 2) parallel interface (sampling with ENABLE signal) 100 Serial 3-wire interface 101 Serial 4-wire interface 110 Serial 5-wire interface, RS is sampled with serial clock 111 Serial 5-wire interface, RS is sampled with CS signal
8 DISP1_EN	Display 1 enable. Enables/disables display 1. 0 Disable display 1. 1 Enable display 1.
7–5	Reserved
4–3 DISP0_PAR_BURST_MODE	Display 0 parallel interface burst mode. 00 Burst access mode with sampling by CS or R/W or ENABLE signals 01 Burst access mode with sampling by separate burst clock (BCLK) 10 Single access mode (all control signals are not active for one display interface clock after each display access) 11 Reserved
2–1 DISP0_IF_MODE	Display 0 interface mode 00 System 80 (type 1) parallel interface (sampling with CS signal) 01 System 80 (type 2) parallel interface (sampling with R/W signals) 10 System 68k (type 1) parallel interface (sampling with CS signal) 11 System 68k (type 2) parallel interface (sampling with ENABLE signal)
0 DISP0_EN	Display 0 enable. Enables/disables display 0. 0 Disable display 0. 1 Enable display 0.

31.3.3.8.2 DI Display Signals Polarity Register (DI_DISP_SIG_POL)

Figure 31-82. DI Display Signals Polarity Register (DI_DISP_SIG_POL)

Table 31-102. DI_DISP_SIG_POL Field Descriptions

Field	Description
31 D2_BCLK_POL	Display parallel interface burst clock polarity for display 2. Sets the polarity of the IPP_DO_DISPB_BCLK output pin when accessing display 2. 0 Straight polarity. 1 Inverse polarity.
30 D1_BCLK_POL	Display parallel interface burst clock polarity for display 1. Sets the polarity of the IPP_DO_DISPB_BCLK output pin when accessing display 1. 0 Straight polarity. 1 Inverse polarity.
29 D0_BCLK_POL	Display parallel interface burst clock polarity for display 0. Sets the polarity of the IPP_DO_DISPB_BCLK output pin when accessing display 1. 0 Straight polarity. 1 Inverse polarity.
28 D3_VSYNC_POL	Vertical synchronization signal polarity for display 3. Sets the polarity of the IPP_DO_DISPB_D3_VSYNC output pin. 0 Active low. 1 Active high.

Table 31-102. DI_DISP_SIG_POL Field Descriptions (Continued)

Field	Description
27 D3_HSYNC_POL	Horizontal synchronization signal polarity for display 3. Sets the polarity of the IPP_DO_DISPB_D3_HSYNC output pin. 0 Active low. 1 Active high.
26 D3_DRDY_SHARP_POL	Output enable polarity or Sharp signals polarity (SPL, REV, CLS, PS) for display 3. Sets the polarity of the IPP_DO_DISPB_D3_DRDY, IPP_DO_DISPB_D3_CLS, IPP_DO_DISPB_D3_REV, IPP_DO_DISPB_D3_PS output pins. The IPP_DO_DISPB_D3_DRDY pin can be used both as the output enable signal or the PS signal. Timing diagrams of Sharp signals shown in the IPU electrical specification correspond to D3_DRDY_SHARP_POL = 0. 0 Active low (for output enable signal) or straight polarity for sharp signals. 1 Active high (for output enable signal) or inverse polarity for sharp signals.
25 D3_CLK_POL	Display interface clock polarity for display 3. Sets the polarity of the IPP_DO_DISPB_D3_CLK output pin. 0 Straight polarity. 1 Inverse polarity.
24 D3_DATA_POL	Data polarity for display 3. Sets the polarity of the IPP_DO_DISPB_DATA output pin and the IPP_IND_DISPB_DATA input pin when display 3 is accessed. 0 Straight polarity. 1 Inverse polarity.
23 D2_SER_RS_POL	Address bit polarity for the display 2 serial interface. Sets the polarity of the IPP_DO_DISPB_SER_RS output pin when display 2 is accessed via serial interface. 0 Straight polarity. 1 Inverse polarity.
22 D2_SD_CLK_POL	Serial interface clock polarity for display 2. Sets the polarity of the IPP_DO_DISPB_SD_CLK output pin. 0 Straight polarity. 1 Inverse polarity.
21 D2_SD_D_POL	Serial data polarity for display 2. Sets the polarity of the IPP_DO_DISPB_SD_D output pin and the IPP_IND_DISPB_SD_D input pin when display 2 is accessed via serial interface. 0 Straight polarity. 1 Inverse polarity.
20 D2_RD_POL	Write signal polarity for display 2. Sets the polarity of the IPP_DO_DISPB_RD output pin when display 2 is accessed. 0 Active low. 1 Active high.
19 D2_WR_POL	Write signal polarity for display 2. Sets the polarity of the IPP_DO_DISPB_WR output pin (for parallel interface) or the polarity of the write control bit in the output stream (for serial interface) when display 2 is accessed. 0 Active low. 1 Active high.

Table 31-102. DI_DISP_SIG_POL Field Descriptions (Continued)

Field	Description
18 D2_PAR_RS_POL	Address bit polarity for the display 2 parallel interface. Sets the polarity of the IPP_DO_DISPB_PAR_RS output pin when display 2 is accessed. 0 Straight polarity. 1 Inverse polarity.
17 D2_CS_POL	Chip select signal polarity for display 2. Sets the polarity of the IPP_DO_DISPB_D2_CS output pin. 0 Active low. 1 Active high.
16 D2_DATA_POL	Data polarity for display 2. Sets the polarity of the IPP_DO_DISPB_DATA output pin and the IPP_IND_DISPB_DATA input pin when display 2 is accessed. 0 Straight polarity. 1 Inverse polarity.
15 D1_SER_RS_POL	Address bit polarity for the display 1 serial interface. Sets the polarity of the IPP_DO_DISPB_SER_RS output pin when display 1 is accessed via serial interface. 0 Straight polarity. 1 Inverse polarity.
14 D1_SD_CLK_POL	Serial interface clock polarity for display 1. Sets the polarity of the IPP_DO_DISPB_SD_CLK output pin. 0 Straight polarity. 1 Inverse polarity.
13 D1_SD_D_POL	Serial data polarity for display 1. Sets the polarity of the IPP_DO_DISPB_SD_D output pin and the IPP_IND_DISPB_SD_D input pin when display 1 is accessed via serial interface. 0 Straight polarity. 1 Inverse polarity.
12 D1_RD_POL	Write signal polarity for display 1. Sets the polarity of the IPP_DO_DISPB_RD output pin when display 1 is accessed. 0 Active low. 1 Active high.
11 D1_WR_POL	Write signal polarity for display 1. Sets the polarity of the IPP_DO_DISPB_WR output pin (for parallel interface) or the polarity of the write control bit in the output stream (for serial interface) when display 1 is accessed. 0 Active low. 1 Active high.
10 D1_PAR_RS_POL	Address bit polarity for the display 1 parallel interface. Sets the polarity of the IPP_DO_DISPB_PAR_RS output pin when display 1 is accessed. 0 Straight polarity. 1 Inverse polarity.
9 D1_CS_POL	Chip select signal polarity for display 1. Sets the polarity of the IPP_DO_DISPB_D1_CS output pin. 0 Active low. 1 Active high.

Table 31-102. DI_DISP_SIG_POL Field Descriptions (Continued)

Field	Description
8 D1_DATA_POL	Data polarity for display 1. Sets the polarity of the IPP_DO_DISPB_DATA output pin and the IPP_IND_DISPB_DATA input pin when display 1 is accessed. 0 Straight polarity. 1 Inverse polarity.
7	Reserved
6 D12_VSYNC_POL	Vertical synchronization signal polarity for displays 1 and 2. Sets the polarity of the IPP_DO_DISPB_D12_VSYNC output pin and the IPP_IND_DISPB_D12_VSYNC input pin. 0 Active low. 1 Active high.
5 D0_VSYNC_POL	Vertical synchronization signal polarity for display 0. Sets the polarity of the IPP_DO_DISPB_D0_VSYNC output pin and the IPP_IND_DISPB_D0_VSYNC input pin. 0 Active low. 1 Active high.
4 D0_RD_POL	Write signal polarity for display 0. Sets the polarity of the IPP_DO_DISPB_RD output pin when display 0 is accessed. 0 Active low. 1 Active high.
3 D0_WR_POL	Write signal polarity for display 0. Sets the polarity of the IPP_DO_DISPB_WR output pin when display 0 is accessed. 0 Active low. 1 Active high.
2 D0_PAR_RS_POL	Address bit polarity for the display 0 parallel interface. Sets the polarity of the IPP_DO_DISPB_PAR_RS output pin when display 0 is accessed. 0 Straight polarity. 1 Inverse polarity.
1 D0_CS_POL	Chip select signal polarity for display 0. Sets the polarity of the IPP_DO_DISPB_D0_CS output pin. 0 Active low. 1 Active high.
0 D0_DATA_POL	Data polarity for display 0. Sets the polarity of the IPP_DO_DISPB_DATA output pin and the IPP_IND_DISPB_DATA input pin when display 0 is accessed. 0 Straight polarity. 1 Inverse polarity.

31.3.3.8.3 DI Serial Display 1 Configuration Register (DI_SER_DISP1_CONF)

This register defines serial mode for display 1.

0x53FC_012C (DI_SER_DISP1_CONF) Access: User Read/Write

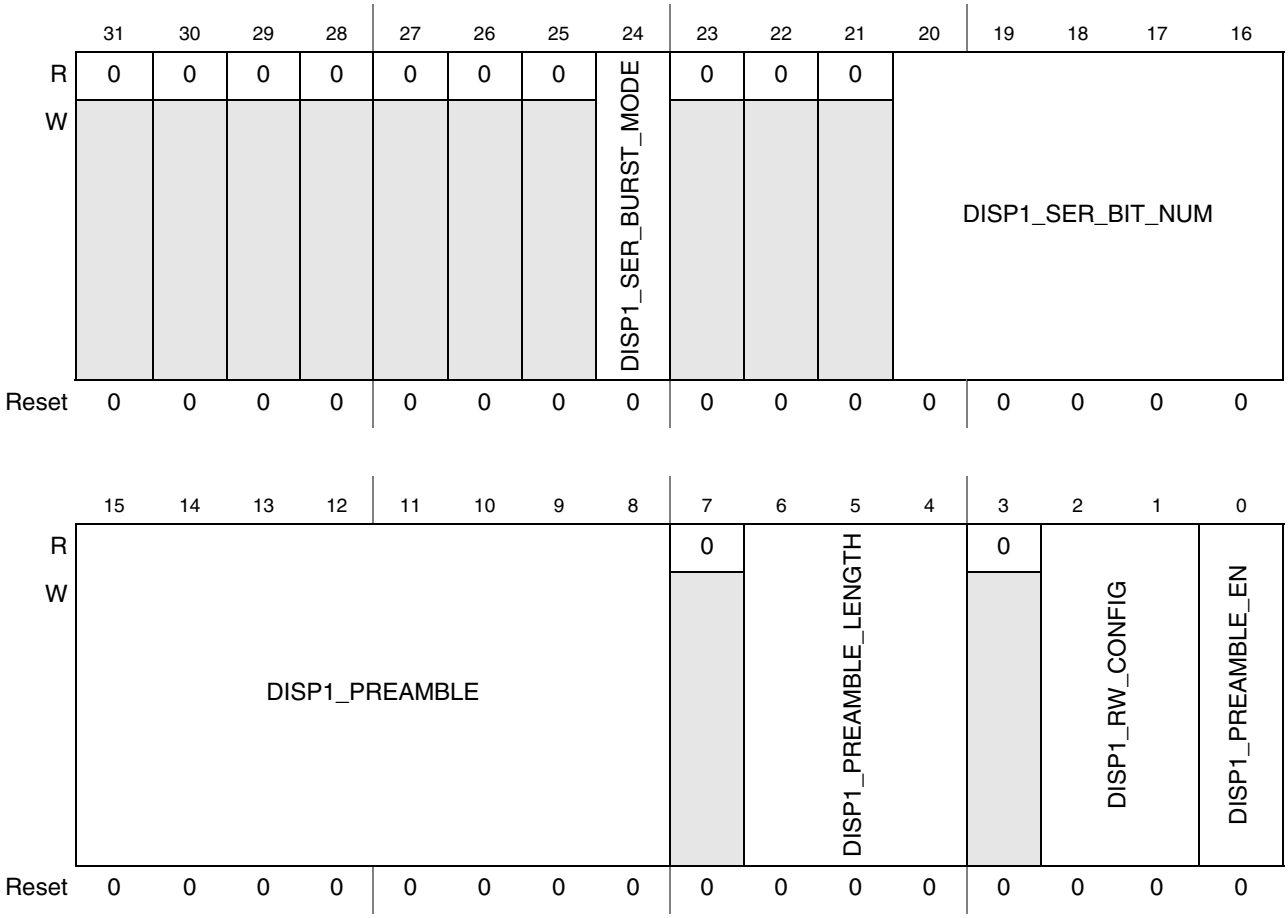

Figure 31-83. DI Serial Display 1 Configuration Register (DI_SER_DISP1_CONF)

Table 31-103. DI_SER_DISP1_CONF Field Descriptions

Field	Description
31–25	Reserved
24 DISP1_SER_BURST_MODE	Burst mode enable. Enables burst mode when the display chip select remains active during whole burst transfer. In single access mode, the display chip select is not active between display accesses. 0 single access mode. 1 burst access mode.
23–21	Reserved
20–16 DISP1_SER_BIT_NUM	Output/input data bit number minus 1. Defines number of data bits per display access. Values: 000001 bit .... 1000118 bits (max)

Table 31-103. DI_SER_DISP1_CONF Field Descriptions (Continued)

Field	Description
15–8 DISP1_PREAMBLE	Preamble contents. If DISP1_PREAMBLE_LENGTH is less than 8, only DISP1_PREAMBLE_LENGTH least significant bits of DISP1_PREAMBLE are sent.
7	Reserved
6–4 DISP1_PREAMBLE_LENGTH	Preamble length minus 1 in bits (without RS and RW bits). Values: 000 1 bit .... 101 6 bits 110 7 bits 111 8 bits (max)
3	Reserved
2–1 DISP1_RW_CONFIG	Configuration of read/write (RW) control bit to be sent via serial interface. For 5-wire serial interface (when RS is send via a separate wire), the '01' and '10' values of DISP1_RW_CONFIG have same effect. Values: 00 No RW bit in serial interface output sequence 01 RW bit is sent after preamble and before RS bit 10 RW bit is sent after preamble and after RS bit 11 reserved
0 DISP1_PREAMBLE_EN	Preamble enable. 0 disable preamble 1 enable preamble

31.3.3.8.4 DI Serial Display 2 Configuration Register (DI_SER_DISP2_CONF)

This register defines serial mode for display 2.

0x53FC_0130 (DI_SER_DISP2_CONF) Access: User Read/Write

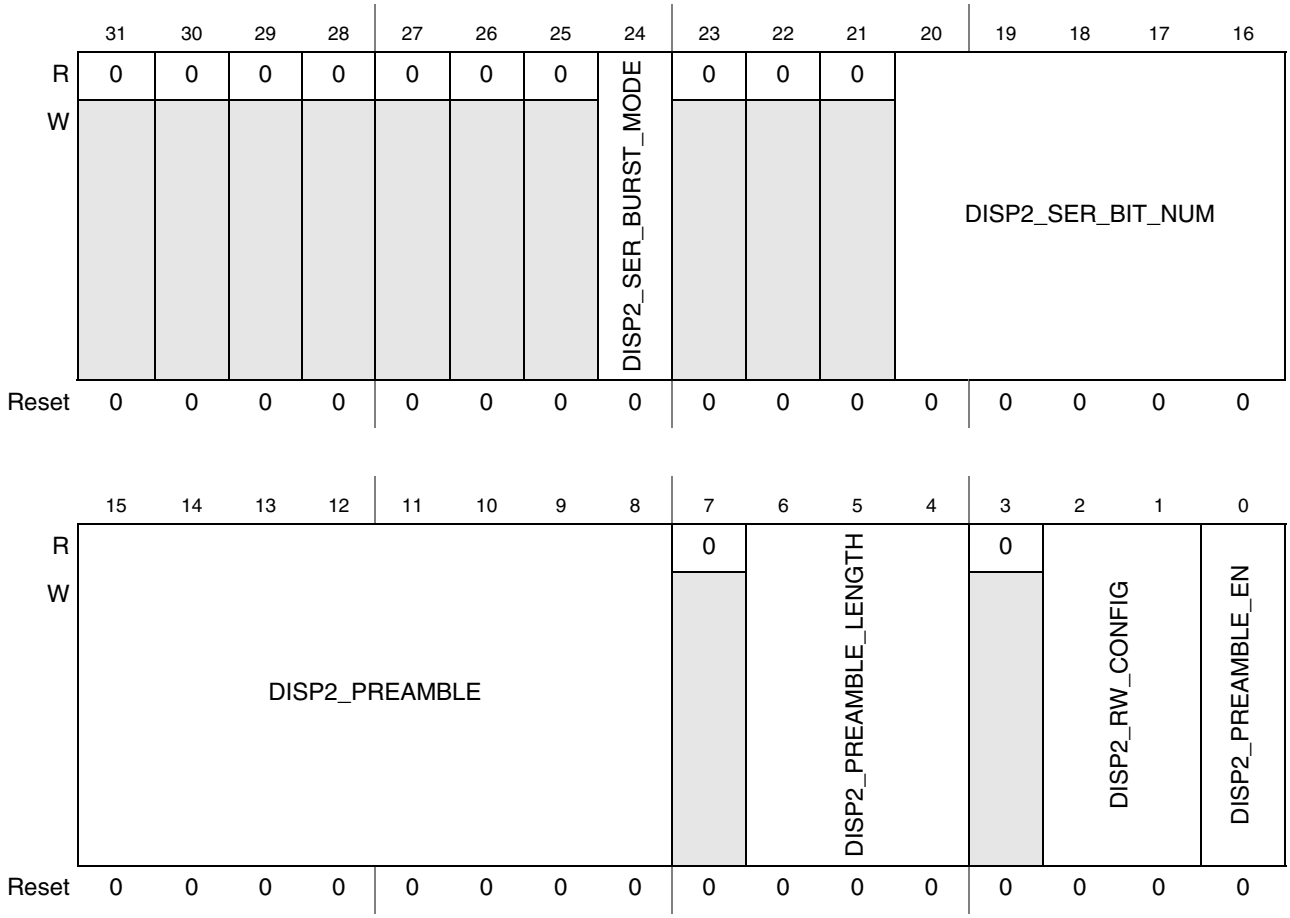

Figure 31-84. DI Serial Display 2 Configuration Register (DI_SER_DISP2_CONF)

Table 31-104. DI_SER_DISP2_CONF Field Descriptions

Field	Description
31–25	Reserved
24 DISP2_SER_BURST_MODE	Burst mode enable. Enables burst mode when the display chip select remains active during whole burst transfer. In single access mode, the display chip select is not active between display accesses. 0 single access mode. 1 burst access mode.
23–21	Reserved
20–16 DISP2_SER_BIT_NUM	Output/input data bit number minus 1. Defines number of data bits per display access. Values: 00000 1 bit .... 10001 18 bits (max)

Table 31-104. DI_SER_DISP2_CONF Field Descriptions (Continued)

Field	Description
15–8 DISP2_PREAMBLE	Preamble contents. If DISP2_PREAMBLE_LENGTH is less than 8, only DISP2_PREAMBLE_LENGTH least significant bits of DISP2_PREAMBLE are sent.
7	Reserved
6–4 DISP2_PREAMBLE_LENGTH	Preamble length minus 1 in bits (without RS and RW bits). Values: 000 1 bit .... 101 6 bits 110 7 bits 111 8 bits (max)
3	Reserved
2–1 DISP2_RW_CONFIG	Configuration of read/write (RW) control bit to be sent via serial interface. For 5-wire serial interface (when RS is send via a separate wire), the '01' and '10' values of DISP2_RW_CONFIG have same effect. Values: 00 No RW bit in serial interface output sequence 01 RW bit is sent after preamble and before RS bit 10 RW bit is sent after preamble and after RS bit 11 reserved
0 DISP2_PREAMBLE_EN	Preamble enable. 0 disable preamble 1 enable preamble

31.3.3.8.5 DI HSP_CLK Period Register (DI_HSP_CLK_PER)

This register defines HSP_CLK_PERIOD for the DI. It is used to hold the correct value of all the display clock rates display clock rates after the HSP_CLK rate has been changed on-the-fly. The core should program this value before HSP_CLK clock rate change. switch between the HSP_CLK_PERIOD_1 and HSP_CLK_PERIOD_2 values is performed on the HSP_CLK_PER_SEL signal from the Clock Controller.

0x53FC_0134 (DI_HSP_CLK_PER) Access: User Read/Write

Figure 31-85. DI HSP_CLK Period Register (DI_HSP_CLK_PER)

Table 31-105. DI_HSP_CLK_PER Field Descriptions

Field	Description
31–23	Reserved
22–16 HSP_CLK_PERIOD_2	HSP_CLK period option 2. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]).
15–7	Reserved
6–0 HSP_CLK_PERIOD_1	HSP_CLK period option 1. This parameter contains integer part (bits [6:4]) and fractional part (bits [3:0]).

31.3.3.8.6 DI Display 0 Time Configuration Register 1 (DI_DISP0_TIME_CONF_1)

This register contains the first set of timing configuration parameters for display 0.

0x53FC_0138 (DI_DISP0_TIME_CONF_1) Access: User Read/Write

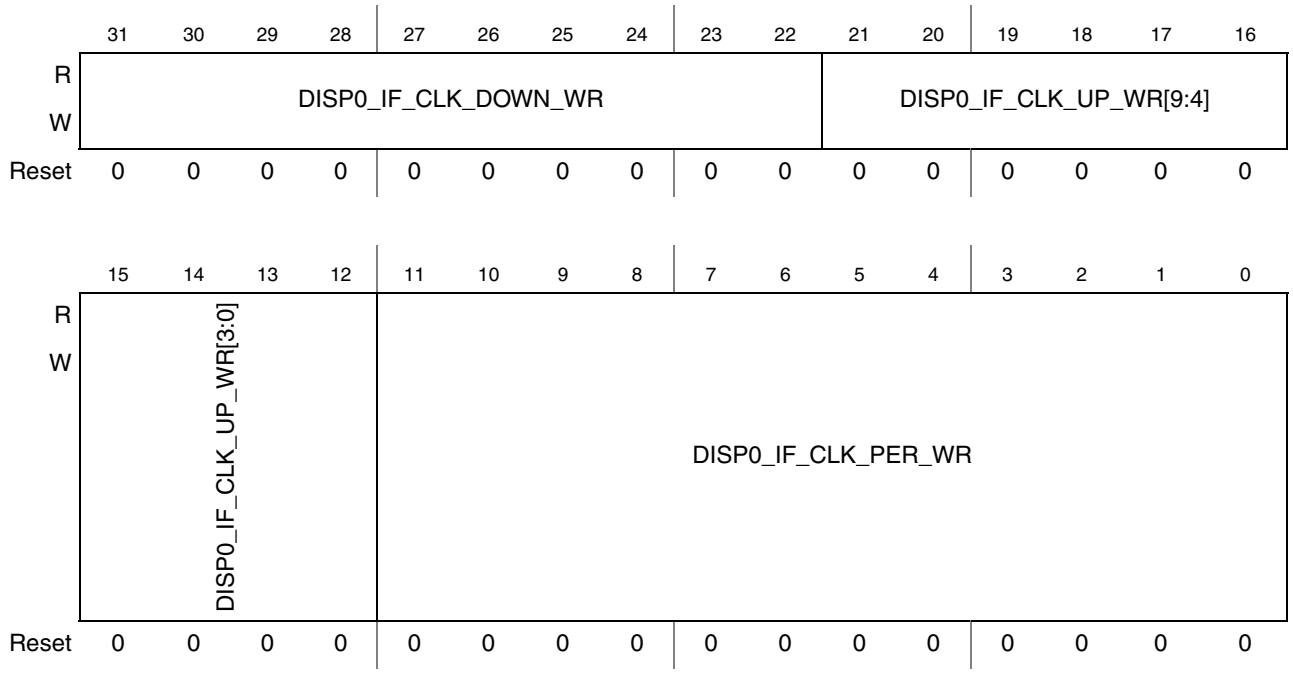

Figure 31-86. DI Display 0 Time Configuration Register 1 (DI_DISP0_TIME_CONF_1)

Table 31-106. DI_DISP0_TIME_CONF_1 Field Descriptions

Field	Description
31–22 DISP0_IF_CLK_DOWN_WR	Display 0 interface clock falling edge position for display write access. This parameter contains an integer part (bits 9:2) and a fractional part (bits 1:0). • The position value is a time interval between display write access start point and display 0 interface clock falling edge. • The actual position value is equal to CEIL[2*DISP0_IF_CLK_DOWN_WR/HSP_CLK_PERIOD_1(2)]/2 (in high speed clock (HSP_CLK) cycles). • The range of DISP0_IF_CLK_DOWN_WR should be from DISP0_IF_CLK_UP_WR+0.5*HSP_CLK_PERIOD_1(2) to DISP0_IF_CLK_PER_WR.
21–16 DISP0_IF_CLK_UP_WR[9:4]	

Table 31-106. DI_DISP0_TIME_CONF_1 Field Descriptions (Continued)

Field	Description
15–12 DISP0_IF_CLK_UP_WR[3:0]	Display 0 interface clock rising edge position for display write access. • This parameter contains an integer part (bits 9:2) and a fractional part (bits 1: 0). The position is a time interval between display write access start point and display 0 interface clock rising edge. • The actual position value is equal to CEIL[2*DISP0_IF_CLK_UP_WR/HSP_CLK_PERIOD_1(2)]/2 (in high speed clock (HSP_CLK) cycles). • The range of DISP0_IF_CLK_UP_WR should be from 0 to DISP0_IF_CLK_PER_WR-0.5*HSP_CLK_PERIOD_1(2)
11–0 DISP0_IF_CLK_PER_WR	Display 0 interface clock period for display write access. • This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). • The actual value of the interface clock period is equal to CEIL[DISP0_IF_CLK_PER_WR/HSP_CLK_PERIOD_1(2)] (in high speed clock (HSP_CLK) cycles) where CEIL(X) rounds the elements of X to the nearest integers towards infinity.

31.3.3.8.7 DI Display 0 Time Configuration Register 2 (DI_DISP0_TIME_CONF_2)

This register contains the second set of timing configuration parameters for display 0.

0x53FC_013C (DI_DISP0_TIME_CONF_2) Access: User Read/Write

Figure 31-88. DI Display 0 Time Configuration Register 3 (DI_DISP0_TIME_CONF_3)

Table 31-108. DI_DISP0_TIME_CONF_3 Field Descriptions

Field	Description
31–30	Reserved
29–28 DISP0_RD_WAIT_ST	Contains the number of wait states required to read data from the display. Values: 00 0 wait states 01 1 wait state 10 2 wait states 11 3 wait states
25–16 DISP0_READ_EN	Display 0 read point position. • The position is a time interval between display 0 read access start and data read points. This parameter contains an integer part (bits 9:2) and a fractional part (bits 1: 0). • The actual position value is equal to CEIL[DISP0_READ_EN/HSP_CLK_PERIOD_1(2) (in high speed clock (HSP_CLK) periods) where CEIL(X) rounds the elements of X to the nearest integers towards infinity. The range of DISP0_READ_EN is from 0 to DISP0_IF_CLK_PER_RD.
15–12	Reserved
11–0 DISP0_PIX_CLK_PER	Display 0 pixel clock period. • This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines fractional division ratio of the HSP_CLK clock for generation of the display 0 pixel clock. • The actual average value of the pixel clock period is equal to DISP0_PIX_CLK_PER/HSP_CLK_PERIOD_1(2) high speed clock (HSP_CLK) periods.

31.3.3.8.9 DI Display 1 Time Configuration Register 1 (DI_DISP1_TIME_CONF_1)

This register contains the first set of timing configuration parameters for display 1.

Figure 31-89. DI Display 1 Time Configuration Register 1 (DI_DISP1_TIME_CONF_1)

Table 31-109. DI_DISP1_TIME_CONF_1 Field Descriptions

Field	Description
31–22 DISP1_IF_CLK_DOWN_WR	Display 1 interface clock falling edge position for display write access. • This parameter contains an integer part (bits 9:2) and a fractional part (bits 1:0). • The position value is a time interval between display write access start point and display 1 interface clock falling edge. • The actual position value is equal to CEIL[2*DISP1_IF_CLK_DOWN_WR/HSP_CLK_PERIOD_1(2)]/2 (in high speed clock (HSP_CLK) cycles). The range of DISP1_IF_CLK_DOWN_WR should be from DISP1_IF_CLK_UP_WR+0.5*HSP_CLK_PERIOD_1(2) to DISP1_IF_CLK_PER_WR.
21–16 DISP1_IF_CLK_UP_WR[9:4]	Display 1 interface clock rising edge position for display write access. • This parameter contains an integer part (bits 9:2) and a fractional part (bits 1: 0). • The position is a time interval between display write access start point and display 1 interface clock rising edge. • The actual position value is equal to CEIL[2*DISP1_IF_CLK_UP_WR/HSP_CLK_PERIOD_1(2)]/2 (in high speed clock (HSP_CLK) cycles). The range of DISP1_IF_CLK_UP_WR should be from 0 to DISP1_IF_CLK_PER_WR-0.5*HSP_CLK_PERIOD_1(2).
15–12 DISP1_IF_CLK_UP_WR[3:0]	
11–0 DISP1_IF_CLK_PER_WR	Display 1 interface clock period for display write access. • This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). • The actual value of the interface clock period is equal to CEIL[DISP1_IF_CLK_PER_WR/HSP_CLK_PERIOD_1(2)] (in high speed clock (HSP_CLK) cycles) where CEIL(X) rounds the elements of X to the nearest integers towards infinity.

31.3.3.8.10 DI Display 1 Time Configuration Register 2 (DI_DISP1_TIME_CONF_2)

Table 31-111. DI_DISP1_TIME_CONF_3 Field Descriptions

Field	Description
31–30	Reserved
29–28 DISP1_RD_WAIT_ST	Contains the number of wait states required to read data from the display. Values: 00 0 wait states 01 1 wait state 10 2 wait states 11 3 wait states
25–16 DISP1_READ_EN	Display 1 read point position. • The position is a time interval between display 1 read access start and data read points. This parameter contains an integer part (bits 9:2) and a fractional part (bits 1: 0). • The actual position value is equal to CEIL[DISP1_READ_EN/HSP_CLK_PERIOD_1(2)] (in high speed clock (HSP_CLK) periods) where CEIL(X) rounds the elements of X to the nearest integers towards infinity. The range of DISP1_READ_EN is from 0 to DISP1_IF_CLK_PER_RD.
15–12	Reserved
11–0 DISP12_PIX_CLK_PER	Displays 1 and 2 pixel clock period. • This parameter contains an integer part (bits 11:4) and a fractional part (bits 3:0). It defines fractional division ratio of the HSP_CLK clock for generation of the displays 1 and 2 pixel clock. • The actual average value of the pixel clock period is equal to DISP12_PIX_CLK_PER/HSP_CLK_PERIOD_1(2) high speed clock (HSP_CLK) periods.

31.3.3.8.12 DI Display 2 Time Configuration Register 1 (DI_DISP2_TIME_CONF_1)

Table 31-138. DI_DISP_LLA_CONF Field Descriptions

Field	Description
31–6	Reserved
5 DRCT_BE_MODE	Set byte enable mode for core low level access of the display. This bit sets byte enable mode for core low level access of the display. This mode is valid only for parallel display interfaces. In this mode, the byte enable signals of the IP bus interface, which are active while read/write from/to the DI_DISP_LLA_DATA Register are translated to the parallel display interface together with 16-bit least significant data bits. Eight most significant data bits are ignored. 0 switch off byte enable mode 1 switch on byte enable mode
4 DRCT_MAP_DC	Display mapping select. Selects display mapping for data or command. 0 Data 1 Command
3 DRCT_LOCK	Lock bit. When the DRCT_LOCK bit is set, the DI waits for data from the core. 0 Unlock 1 Lock

Table 31-138. DI_DISP_LLA_CONF Field Descriptions (Continued)

Field	Description
2–1 DRCT_DISP_NUM	The accessed display number. These bits describe which display now active. Values: 00 Display 0 01 Display 1 10 Display 2 11 Reserved
0 DRCT_RS	Command/data address signal to display. 0 RS is 0 1 RS is 1

31.3.3.8.39 DI Display Low Level Access Data Register (DI_DISP_LLA_DATA)

This register contain the data which is to be written to display or being read from display. To read the register, the following settings are required:

1. The HSP_CLK clock must be fed to the IPU.
2. The DI_EN bit in the IPU_CONF register must be set.
3. The DRCT_DISP_NUM parameter in the DI_DISP_LLA_CONF register must be set to select a display number (default =2'b00).
4. The DISP(x)_EN bit in the DI_DISP_IF_CONF register must be set that matches the DRCT_DISP_NUM setting (the other enables are a don't care).
5. All other parameters in the DI registers corresponding to the selected display must be properly configured.

Field	Description
31–4 IPU_GP_REG	General purpose bits. Reserved for future use.
3 BE_PIN_SEL	This control bit enables 24bit interface with byte enable support
2 D2_BE_POL	This bit controls the polarity of the BE signal (be0 and be1) for display #2 0 Straight polarity. 1 Inverse polarity.
1 D1_BE_POL	This bit controls the polarity of the BE signal (be0 and be1) for display #1 0 Straight polarity. 1 Inverse polarity.
0 D0_BE_POL	This bit controls the polarity of the BE signal (be0 and be1) for display #0 0 Straight polarity. 1 Inverse polarity.

31.4 Functional Description

31.4.1 Camera Sensor Interface (CSI)

31.4.1.1 Block Diagram

The CSI Block Diagram is shown in Figure 31-121.

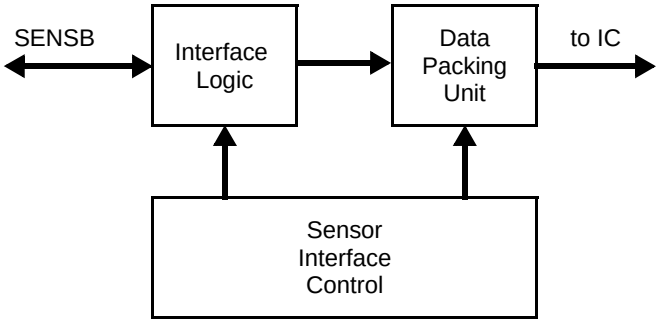

Figure 31-121. CSI Block Diagram

The CSI consists of the Interface Logic, the Data Packing Unit and the Sensor Interface Control. The CSI is controlled via the peripheral bus registers. All programming parameters for the CSI are double buffered with synchronous change at the frame start.

31.4.1.2 Sensor Image Frame Relations

Figure 31-122 illustrates the generalized relations between image frames produced by a sensor and accepted by the CSI. Generally, four frame definitions exist. The virtual frame A starts with the VSYNC signal.

The frame A includes the frame B. The HSYNC signal indicates boundaries of the frame B. The frame B includes both the active sensor frame C and blanking intervals. A size of the blanking intervals depends on sensor type and programming. The CSI selects a window (the frame D) inside the frame C by skipping rows and columns according to parameters defined in the CSI_OUT_FRM_CTRL Register. This scheme may be simpler for the specific sensor type. For example, the frames A and B or B and C can be equal.

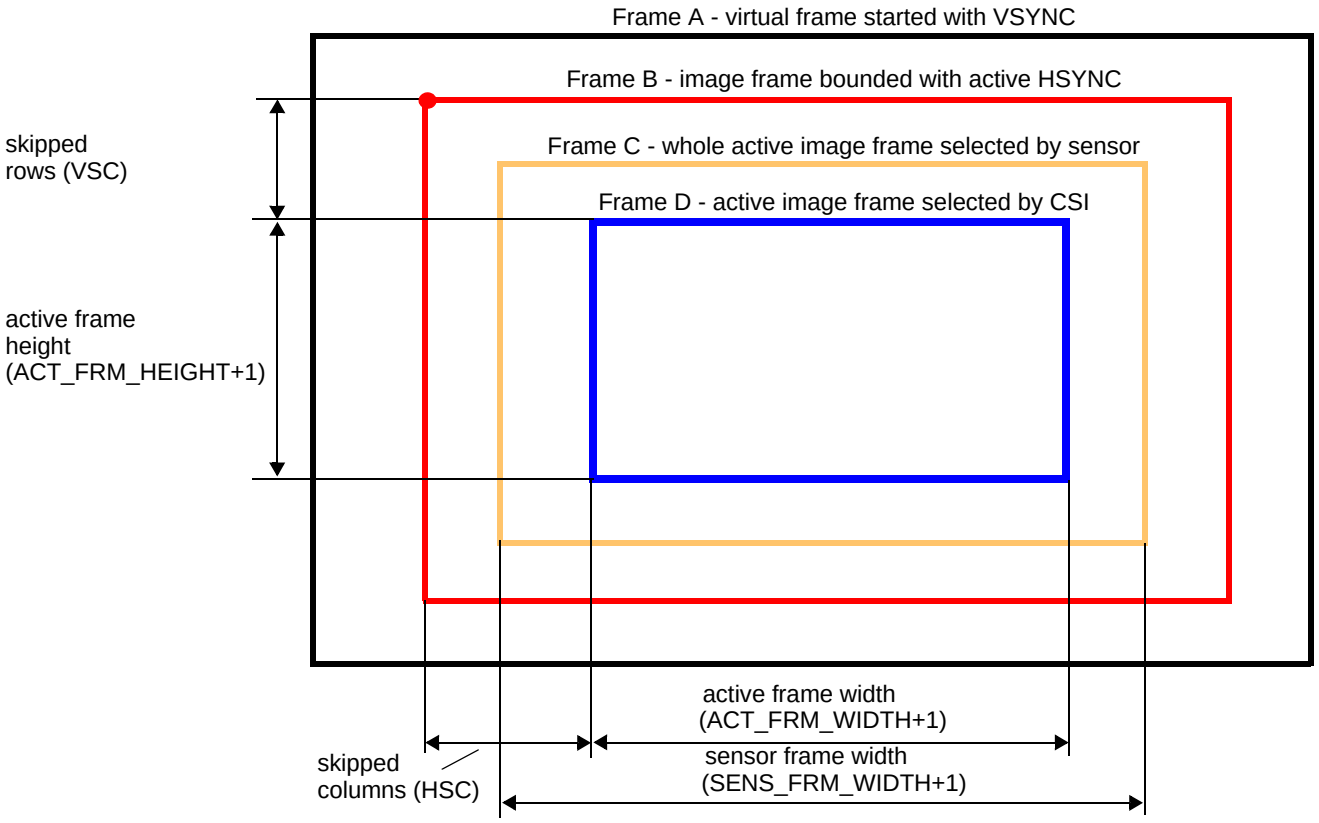

Figure 31-122. Sensor Image Frames

31.4.1.3 Interface Logic

This submodule gets a sensor data from the SENSB bus. The Interface Logic supports required sensor interface protocol according to the CSI_SENS_CONF Register. It can operate in gated clock mode or non-gated clock mode or pseudo BT.656 mode. The master clock provided for sensor can be derived by bypassing the SENSB_SENS_CLK clock or by division of the HSP_CLK clock.

A data stream from the sensor sampled at the sensor clock is split by the CSI into four streams. The sampling rate in each of the streams is a quarter of the sensor clock rate. Data of each stream are synchronized to the high-speed processing clock (HSP_CLK). The synchronized streams are merged by the CSI to a single stream with the sampling rate being equal to the sensor clock rate.

Such solution requires that the maximal sensor clock rate must be less than the HSP_CLK rate. The next bottleneck is an external system memory throughput (including a DMA throughput) which limits sensor image writing speed. This limitation depends on load of the memory by other clients (the core, the system DMA controller etc.). The maximal sensor clock limitation has been checked for the following use case:

1. Viewfinder: No writing of whole sensor image to the system memory is performed at this step.
   Use case configuration:
   — Downsizing and color conversion—by the IPU

— QVGA smart display
— 4 Mpixel smart sensor @7.5fps

Video data flow:

— Sensor to IPU: 4 Mpixel,YUV 4:2:2, 7.5 fps (skipping frames)
— IPU to system memory (downsize and color conversion), QVGA, 7.5fps
— Memory to IPU (to display): QVGA, RGB 8:8:8, 7.5 fps
— IPU to display: QVGA,7.5 fps

2. Still image capture: To move the IPU to this step, the core has to stop the viewfinder task and to enable sensor data writing to the system memory.

   Use case configuration:

   — JPEG encoding – by the core
   — Compressed video stored in SD memory,
   — 4 Mpixel smart sensor

   Video data flow:

   — Sensor to IPU:4 Mpixels,YUV 4:2:2
   — IPU transfers uncompressed image data to memory
   — Memory to core for image processing (JPEG)
   — The core transfers compressed image data to system memory
   — Compressed image is moved to SD memory for storage

Memory bus load by clients other than the IPU limits the maximal speed sensor image capture at Step 2. If there is no memory accesses by other clients during capture the maximal sensor clock rate is 90 MHz (for the exact sensor size of 2504x1748 pixels). For specific scenario when the core or other clients access the system memory during sensor image capture, the maximal sensor rate will be lower than 90 MHz. The actual value of the maximal sensor clock rate depends on the memory bus load. The software should minimize this load as much as possible when data from a large sensor is captured.

31.4.1.4 Data Packing Unit

The pixel formats on the CSI output are YUV 4:4:4, RGB (8 or 10 bits per color component) or generic data (up to 16 bits per word aligned to the most significant bit). The Data Packing Unit collects color components of two adjacent pixels or eight bytes of generic data or four 16-bit words of generic data in a single 64-bit word. The packing is controlled via the CSI_SENS_CONF Register.

31.4.1.5 Sensor Interface Control

The Sensor Interface Control synchronizes the Interface Logic and the Data Packing Unit. It includes vertical and horizontal counters for support of frame selection function as shown in Figure 31-122. The unit generates the master clock to the sensor. The master clock frequency is programmable via the CSI_SENS_CONF Register.

The unit provides also the frame skipping function according to two separate skipping patterns - one for the encoder flow and the second - for the viewfinder flow. The patterns are programmed by the core and cyclically shifted at every frame start point.

In test mode, the Sensor Interface Control generates a test pattern which replaces a real sensor data. The test pattern is a chess field with white and programmable color squares. The color is defined via the CSI_TST_CTRL Register.

31.4.1.6 Non-contiguous Memory Buffers Support

The IPU allows to write large image data from a sensor to a non-contiguous buffer in the external memory. Data transfer to the external memory is performed via the CSI, the IC and the IDMAC. In order to provide non-contiguous buffer mode, the IPU software driver should define appropriate values of frame size in the CSI_ACT_FRM_SIZE Register and the corresponding DMA Channel Parameter Memory (for the DMAIC_7 channel - see Table 31-164). Frame width values must be equal both for the CSI and the IDMAC. Frame height value for the CSI should be a multiple of the frame height for the DMAIC_7 channel. The DMAIC_7 channel must be programmed in double buffer mode via the IPU_CHA_DB_MODE_SEL Register. Writing to the non-contiguous is accomplished as follows:

1. The core defines a base address of the buffer 0 for the DMAIC_7 channel (in the Channel Parameter Memory) and enables the channel. The core configures and enables the CSI and the IC.
2. The CSI starts to send the data via the IC to the IDMAC at beginning of the next sensor frame.
3. While the IDMAC fills the buffer 0, the core defines a base address of the buffer 1 for the DMAIC_7 channel.
4. If the IDMAC has finish to fill the buffer 0 and the sensor frame is not finished yet, the CSI sends a frame signal to the IDMAC to proceed with the buffer 1. Simultaneously, the IDMAC generates the DMAIC_7_EOF interrupt (see the IPU_INT_STAT_1 Register) to the core. The steps 4, 5 are repeated.
5. If the sensor frame is finished, the CSI sends the CSI_EOF interrupt (see the IPU_INT_STAT_3 Register) to the core.

31.4.1.7 Flash Strobe Generation

The CSI can generate a strobe for the external flash. The strobe parameters are defined in the CSI_FLASH_STROBE_1 and CSI_FLASH_STROBE_2 Registers. The core sets strobe start time, duration and polarity. Both parameters are expressed in rows. The start time range is from row 0 to row 8191. The maximal strobe duration is 65536 rows. After that core enables strobe generation.

The CSI waits for the start point of the next frame. The start point corresponds to the first HSYNC of the frame (top left corner of red frame in Figure 31-122). This point is defined for all types of sensors. The CSI counts pixels and sensor rows after frame start point. The row width (CSI_SENS_FRM_SIZE) is set in the CSI_SENS_FRM_SIZE Register. The row counter output is used to generate the strobe. To produce an additional strobe, the core has to enable it again.

31.4.1.8 Interlaced Sensor Format Support

For sensors produced image data in the interlaced format, the IPU firstly has to save the data to the external memory. There are two modes of sensor data IPU operation in this case:

1. Each field of the frame is stored in a separate frame buffer of the external memory. Conversion from the interlaced format to the progressive scan format should be done by software (if needed).
2. The IPU converts the interlaced format to the progressive scan format during writing to the external memory. This mode is active if the IC_TV_MODE bit in the CSI_OUT_FRM_CTRL Register is asserted.

31.4.2 Image Converter (IC)

31.4.2.1 Block Diagram

The IC Block Diagram is shown in Figure 31-123.

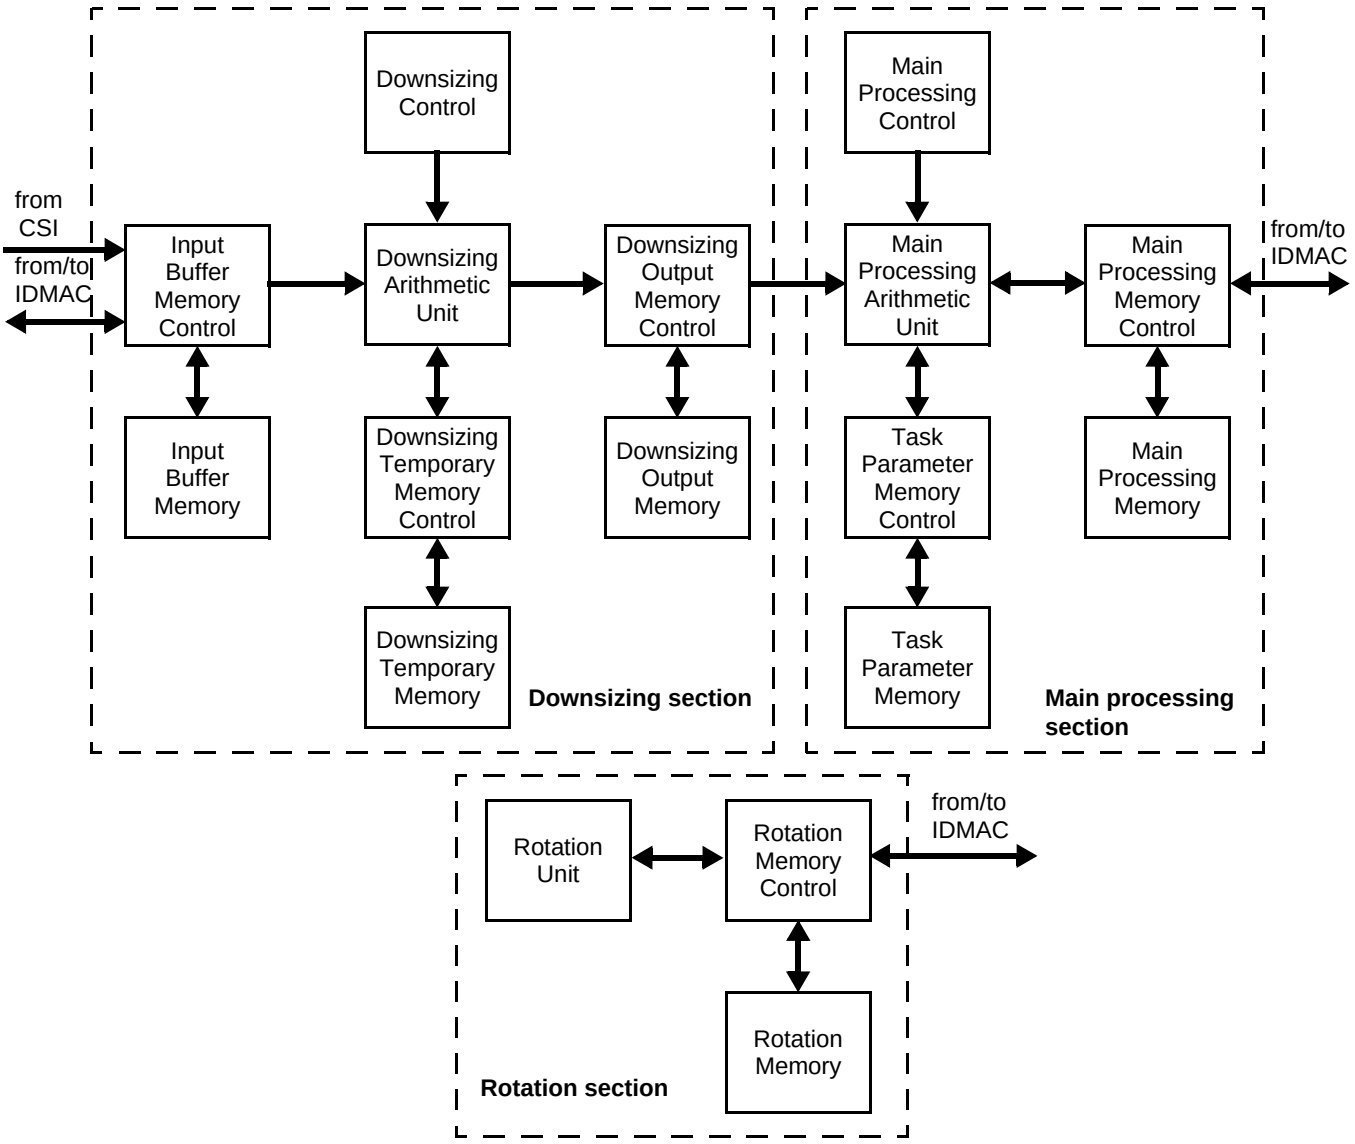

Figure 31-123. IC Block Diagram

The IC contains three processing sections: downsizing, main processing and rotation. The module is controlled via the peripheral bus registers. Some processing parameters should be written by the core to the Task Parameter Memory. Writing to the memory is performed via the CM (see Section 31.4.8, “Control Module (CM)”).

31.4.2.2 Processing tasks

Each of three processing section performs up to three processing tasks with time sharing:

1. Preprocessing task for encoding.
2. Preprocessing task for displaying image from sensor (viewfinder).
3. Postprocessing task.

The tasks are performed by single hardware. The core configures each task before enabling it. Tasks switching is transparent for the core. The time unit for task switching in the downsizing section corresponds to a processing time of one burst of eight pixels, in the main processing section - to a processing time of one image line, in the rotation section - to a processing time of one image frame.

All three tasks includes similar operations controlled by commands. Task configuring consists in definition of commands for each task as described in Table 31-141.

Table 31-141. Task Commands

Command code	Command	Processing unit	Command parameters	Description
EN	Task Enable	DSU, MPU		Task will enabled from next frame. Task 1 is preprocessing for encoding. Task 2 is preprocessing for viewfinder. Task 3 is postprocessing.
	Downsizing	DSU	Downsizing ratio (GCR)	Downsizing ratio 1:1, 2:1, 4:1
	Resizing	MPU	Resizing ratio (GCR)	Resizing ratio from 2:1 to 1:M Resizing ratio = N:M; M =2^13; N = floor(M*(SI-1)/(SO-1)); SI - input size; SO—output size
CSC1	Color space conversion 1	MPU	Color conversion coefficients and offsets (TPM)	Color conversion matrix 1
CSC2	Color space conversion 2	MPU	Color conversion coefficients and offsets (TPM)	Color conversion matrix 2 Used only for Task 2 and Task 3
GLOB_A	Global alpha	MPU		Used only for Task 2 and Task 3
CMB	Combining	MPU		Combining video with graphics. Used only for Task2 and Task3.

The core writes the commands to the IC_CONF Register. Because there is no double buffering for all the IC parameters, the core must disable a task before changing its parameters. After being disabled, the task is still allowed to complete its current frame execution. At frame finish, the IPU sends an interrupt to the core indicating that the core can change task parameters. The core enables the task again and task execution is resumed from start of the next frame.

31.4.2.3 Downsizing Section

The sensor data from the CSI is written into a FIFO located in the Input Buffer Memory. Depending on programmed processing flow, the FIFO data can be sent to the system memory via the IDMAC or straight forward to the Downsizing Unit. In the first case, the data is processed by the core and returned by the IDMAC to another FIFO located in the Input Buffer Memory.

For postprocessing, the IDMAC transfers a data from the system memory to the third FIFO. The data is read by the Downsizing Unit when the postprocessing is performed.

Each or three FIFOs has eight pages. Each page can store one burst of 4 words which corresponds to 8 pixels. The memory word width is 64 bits. Each memory word contains color components of two adjacent pixels or eight bytes of generic data (for example, Bayer). Generic data is always fed to preprocessing after transferring via the system memory and preliminary processing by the core. Access to the FIFOs is controlled by the Input Buffer Memory Control.

The Downsizing Unit performs averaging and decimation of image pixels both in horizontal and vertical directions according to the following equations:

$$HP_{R,c} = \frac{1}{DS\_R\_H} \sum_{k=0}^{DS\_R\_H-1} IP_{r+k,c}$$

$$VP_{R,C} = \frac{1}{DS\_R\_V} \sum_{l=0}^{DS\_R\_V-1} HP_{R,c+l}$$

where $IP_{r,c}$ - the input pixel, $HP_{R,c}$ - the pixel after horizontal downsizing, $VP_{R,C}$ - the pixel after vertical downsizing, DS_R_H and DS_R_V - the horizontal and vertical downsizing ratios according to the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The final calculation result is rounded to 8 bits.

Each of three downsizing tasks processes the data by bursts of 8 pixels. Normally, the current task runs until emptying the corresponding input FIFO. After finishing burst processing, the Downsizing Unit may switch between the current task and another task with higher priority, if the Input Buffer Memory has received a burst for this new task.

Averaging is performed firstly in the horizontal direction. All color components of a pixel are processed in parallel. After horizontal averaging has finished for a single output pixel, the new pixel value is added to the corresponding pixel value of a temporary row derived from previous averaging steps. This provides vertical averaging of the pixels. The temporary row is stored in the Downsizing Temporary Memory. The memory word width matches one accumulated pixel width (36 bits). There are three temporary rows stored in this memory, one per downsizing task.

After vertical averaging has been finished, the output row is written to the Downsizing Output Memory. The memory word of 48 bits includes two output pixels. For each task, the memory has a double buffer of one row. When the Downsizing Unit fills the foreground part of the double buffer, the Main Processing Unit takes pair or pixels from the background part. After the new downsized row has been ready, the foreground and background memory pointers are swapped.

31.4.2.4 Main Processing Section

The Main Processing Unit reads pairs of pixels from the Downsizing Output Memory background part. It processes the complete pixel row for the current task and after that switches to another task if the input

data for this new task is ready. For each task, the Main Processing Unit is able to perform the following sequence of operations:

1. Horizontal flipping the image (optional) performed with reading from the Downsizing Output Memory. Flipping is enabled via the BAM parameter of the corresponding DMA channels (see Table 31-32 and Table 31-33) responsible for output of the task results. The preprocessing task for encoding uses the BAM parameter from the DMAIC_0 channel, the preprocessing task for the viewfinder (from the DMAIC_1 channel), the postprocessing task (from the DMAIC_2 channel).
2. Horizontal resizing by bilinear interpolation between two adjacent pixels received from the Downsizing Output Memory according to the equation:

$$HP_{R,c} = IP_{r,c} + RS\_C\_H \cdot (IP_{r+1,c} - IP_{r,c})$$

where RS_C_H - the current horizontal resizing coefficient. The calculation result is rounded to 8 bits. The resizing coefficient is calculated as

$$RS\_C\_H = \left(\sum_{k=0}^{R-1} RS\_R\_H \right) \bmod(8196)$$

where RS_R_H - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_H parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

   The resulting row of the horizontal resizing is stored in the Task Parameter Memory.
3. Vertical resizing by bilinear interpolation between the current and previous results of horizontal resizing. Both current and previous results of horizontal resizing is stored in the Task Parameter Memory. Resizing is accomplished according to the equation:

$$VP_{R,C} = HP_{R,c} + RS\_C\_V \cdot (HP_{R,c+1} - HP_{R,c})$$

where RS_C_V - the current vertical resizing coefficient. The calculation result is rounded to 8 bits. The resizing coefficient is calculated as

$$RS\_C\_V = \left(\sum_{k=0}^{C-1} RS\_R\_V \right) \bmod(8196)$$

where RS_R_V - the horizontal resizing ratio from the IC_PRP_ENC_RSC, IC_PRP_VF_RSC and IC_PP_RSC Registers. The RS_R_V parameter is equal to a numerator N of the resizing ratio N:M with M =2^13.

At completion of vertical resizing, this row is updated—the current result of horizontal resizing replaces the previous one.

4. First color space conversion YUV to RGB or RGB to YUV with the conversion matrix CSC1. The conversion matrix coefficients are programmable. They are stored in the Task Parameter Memory. The conversion equations are:

$$Z_0 = 2^{SCALE-1} \cdot (X_0 \cdot C_{00} + X_1 \cdot C_{01} + X_2 \cdot C_{02} + A_0)$$
$$Z_1 = 2^{SCALE-1} \cdot (X_0 \cdot C_{10} + X_1 \cdot C_{11} + X_2 \cdot C_{12} + A_1)$$
$$Z_2 = 2^{SCALE-1} \cdot (X_0 \cdot C_{20} + X_1 \cdot C_{21} + X_2 \cdot C_{22} + A_2)$$

where for YUV to RGB: X_0=Y, X_1=U, X_2=V, Z_0=R, Z_1=G, Z_2=B,
for RGB to YUV: X_0=R, X_1=G, X_2=B, Z_0=Y, Z_1=U, Z_2=V.

All the parameters of the conversion matrix are written by the core to the Task Parameter Memory as shown in Table 31-28. The final calculation result is limited according to the SAT_MODE parameter and rounded to 8 bits.

5. Combining video with graphics. There are the following combining options:
   - local alpha blending,
   - global alpha blending,
   - use of key color.

   If both alpha blending and color keying are enabled, color keying has higher priority (graphic pixels of the key color are fully transparent independently on the alpha value).
   Combining mode is selected via the IC_CONF Register. The combining equation is:

$$OP = IGP \cdot \alpha + IVP \cdot (1 - \alpha)$$

where IGP - an input graphics pixel, IVP - an input video pixel, α=(A+floor(A/128))/256 - an alpha value, A - a global or local transparency parameter. The global A is written in the IC_CMBP_1 Register, the local A arrives together with the graphics pixel.

   A graphics pixel becomes transparent when color keying is enabled and a pixel color matches a key color (independently on an alpha parameter).

   The graphics data is read from a FIFO located in the Main Processing Memory. The FIFO contains eight pages of size of eight pixels. The graphics pixel format in the FIFO is RGB or RGBA or YUV 4:4:4 or YUVA. The graphics data is loaded by the IDMAC to the FIFO from the system memory.

6. Second color space conversion YUV to RGB or RGB to YUV with the conversion matrix CSC2. Typically this is color space conversion RGB to YUV. It is not performed if the first color space conversion or combining are disabled. This operation is designed for TV output. The conversion matrix coefficients are programmable with the same parameters and equation as the first color conversion.

All the operation are executed by an unified processing unit sequentially. Steps 1 and 2 cannot be interrupted by another task. All other steps can be interrupted by a task with higher priority if an input row is ready for this task. Preprocessing tasks priority is higher than postprocessing task priority.

The processing unit consists of three identical parts for each color component. All three color components are processed in parallel. Each of the processing operations can be enabled or disabled by an appropriate command according to.

The processing results are written to an output FIFO located in the Main Processing Output Memory row-by-row. The FIFO contains eight pages, each pages can include one pixel burst. The IDMAC transfers the output bursts to the system memory or to the asynchronous display. The Main Processing Memory contains three buffers for each tasks: the temporary row buffer, the graphics FIFO and the output FIFO. Each memory word (64 bits) stores two adjacent pixels in formats RGB or RGBA or YUV 4:4:4 or YUVA with 8 bits per color component.

31.4.2.5 Rotation Section

The rotation section includes the Rotation Memory which stores an input rectangular block of 8x8 pixels and an output FIFO containing four pages of 8 pixels each one. The Rotation Memory word width corresponds to two adjacent pixels - 48 bits. The input block is loaded to the memory by the IDMAC like to a FIFO.

The Rotation Unit rewrites pixels from the input block to the output FIFO with corresponding relocation of a pixel inside the block. Rotation and/or left/right flipping and/or up/down flipping are enabled separately for each of three tasks. Configuring the rotation and flipping options is performed via the BAM parameters of the corresponding DMA channels (see Table 31-32 and Table 31-33) responsible for task data input. The preprocessing task for encoding uses the BAM parameter from the DMAIC_10 channel, the preprocessing task for viewfinder - from the DMAIC_11 channel, the postprocessing task - from the DMAIC_13 channel.

Rotation and flip options are shown in Table 31-142.

Table 31-142. Rotation and Flip Options

ROT	FLR	FUD	Image
0	0	0	
0	0	1	
0	1	0	
0	1	1	

Table 31-142. Rotation and Flip Options (Continued)

ROT	FLR	FUD	Image
1	0	0	
1	0	1	
1	1	0	
1	1	1	

After finishing the rotation task, the IDMAC returns the output FIFO content to the system memory. When writing to the system memory, the IDMAC changes a location of the block relative to an input block location in order to provide proper rotation of the whole frame. Rotation tasks switching is performed after completion of rotation of the whole frame.

31.4.3 Post-Filter (PF)

31.4.3.1 Block Diagram

The PF Block Diagram is shown in Figure 31-124. The PF contains two execution units: the Mode Decision Unit and the Filter Arithmetic Unit. Both units share the Postfilter Memory. The Postfilter Flow Control synchronizes filter operations. The PF is controlled via the PF_CONF Register.

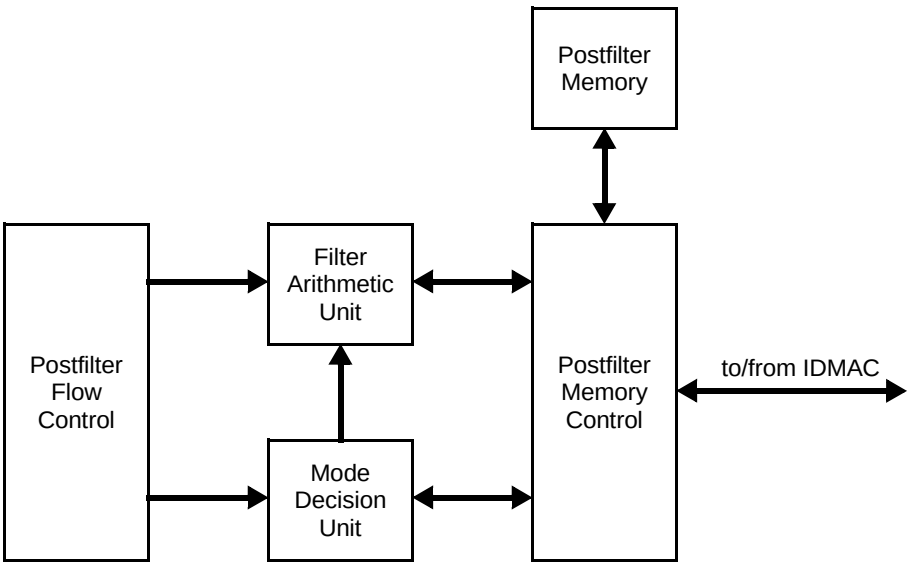

Figure 31-124. PF Block Diagram

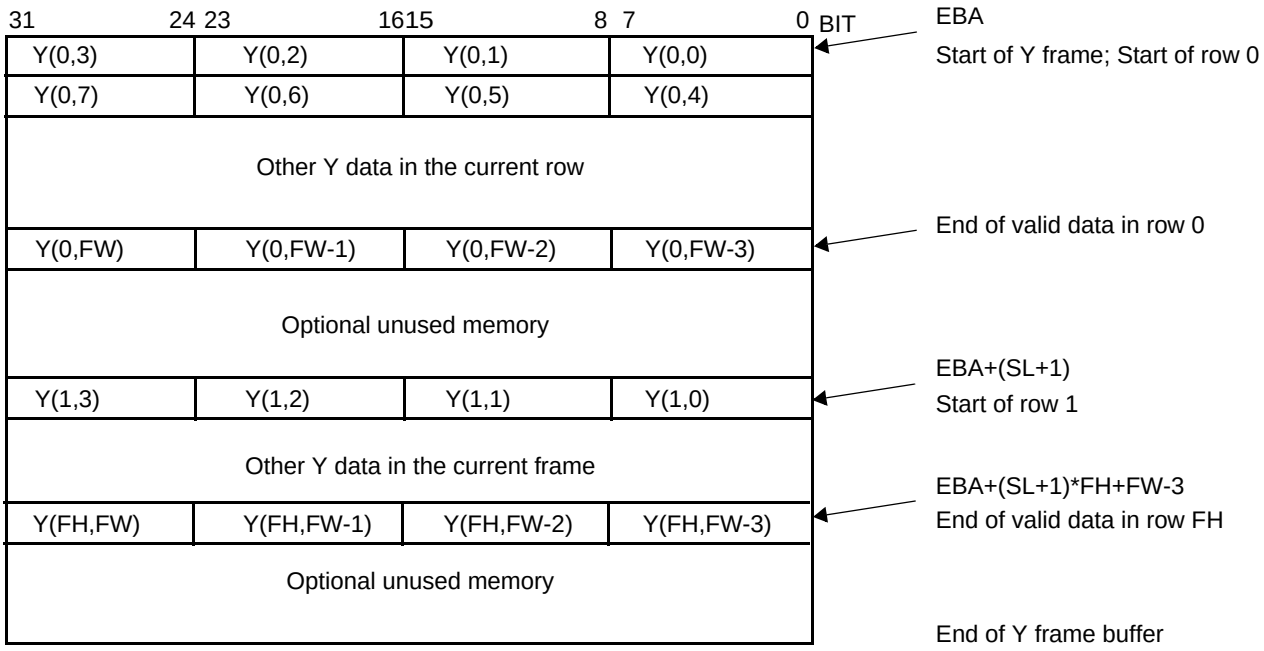
31.4.3.2 Filter Algorithms

The PF performs postfiltering for the MPEG-4 (deblocking and deringing) or H.264 (deblocking) video compression standards. The PF has two corresponding operation modes. Mode is selected in the PF_CONF Register. Only one of the modes can be used at the moment. Mode can be changed after completion of frame processing. In each mode, the PF executes a sequence of tasks.

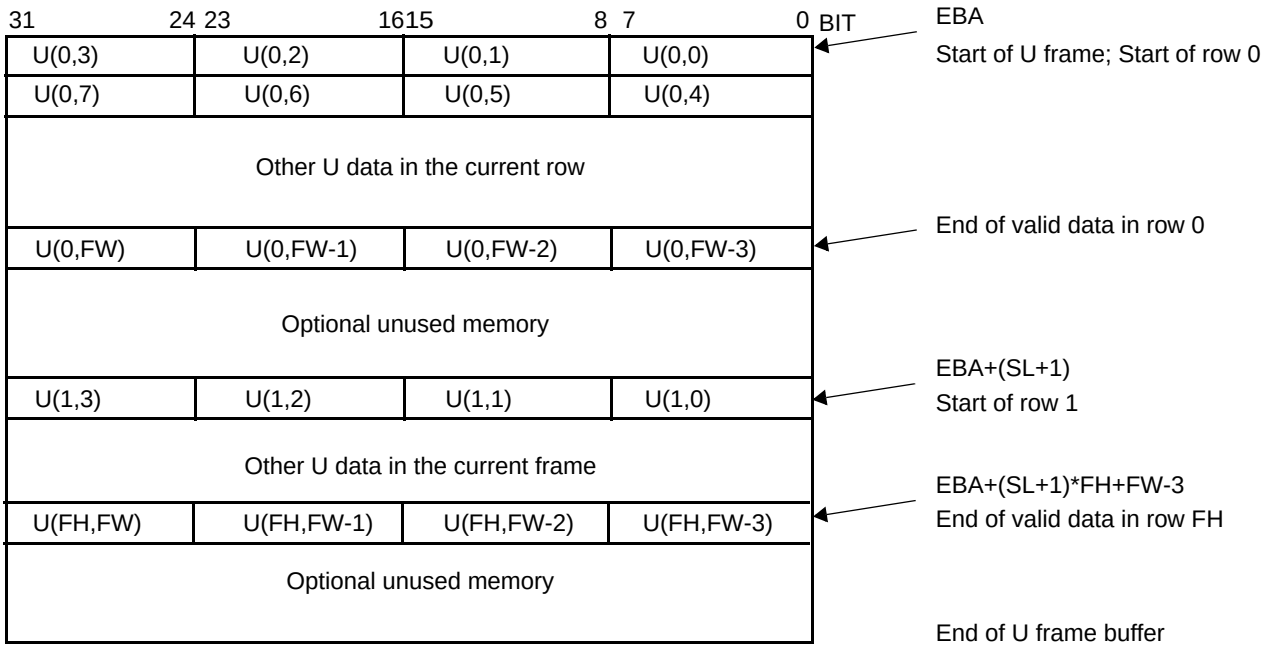
Filter input and output data has YUV 4:2:0 non-interleaved format. Every color component occupies one byte. Data allocation in the external memory is shown in Figure 31-125, Figure 31-126, and Figure 31-127.



Parameters for DMAPF_3 and DMAPF_6 channels:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width - 1
FH - Y Frame Height - 1

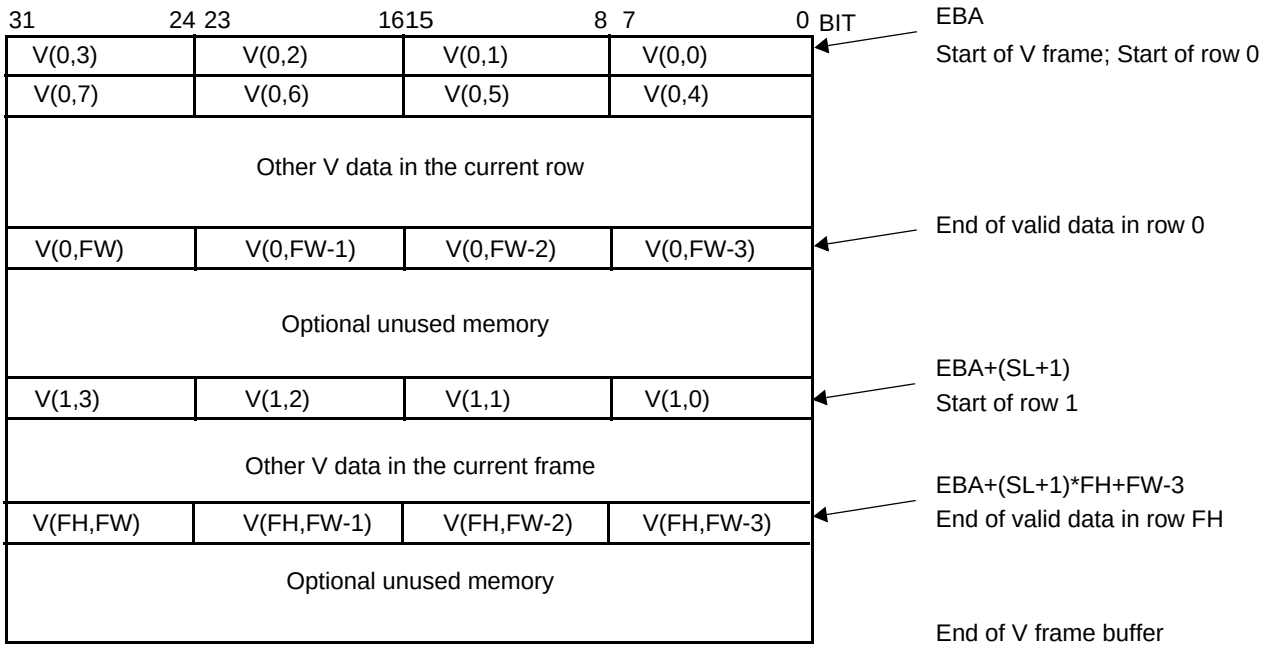
Figure 31-125. Allocation of Y Input and Output Frame Buffer in Memory (Little Endian)



Parameters for DMAPF_4 and DMAPF_7 channels:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width/2 - 1
FH - Y Frame Height/2 - 1

Figure 31-126. Allocation of U Input and Output Frame Buffer in Memory (Little Endian)



Parameters for DMAPF_5 and DMAPF_8 channels:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width/2 - 1
FH - Y Frame Height/2 - 1

Figure 31-127. Allocation of V Input and Output Frame Buffer in Memory (Little Endian)

The IDMAC transfer separately each color component to the PF without any format conversion. Seven DMA channels service the PF in MPEG-4 mode: three input data channels for each color component, three output data channels for each color component, one parameter channel for MPEG-4 or two parameter channels for H.264. Filter input and output data is transferred to and from the PF without interleaving because the PF processes separately each color component frame in the Y->U->V order.

31.4.3.2.1 MPEG-4 Mode

In MPEG-4 the operation sequence is:

1. Deblocking of a Y component macroblock.
2. Deringing of the Y component macroblock.
3. Repeating steps 1, 2 until end of frame.
4. Deblocking of a U component macroblock.
5. Repeating step 4 until end of frame.
6. Deblocking of a V component macroblock.
7. Repeating step 6 until end of frame.

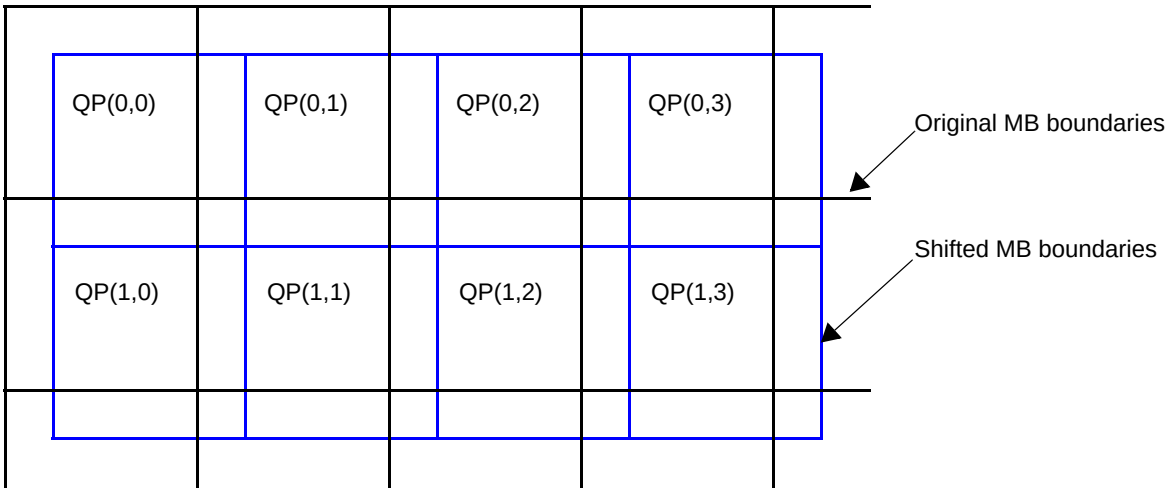
Both input, output and temporary data for the PF calculation is stored in the Postfilter Memory. The IDMAC accesses the memory to supply the input macroblock from the system memory or to put back the processed macroblock to the system memory. The Postfilter Memory word width is 64 bits. The memory stores one of Y or U or V pixel components at the moment (eight pixels per memory word). Memory mapping depends on operation mode.

For MPEG-4, there is five buffers in the Postfilter Memory: A, B, C, D and E. The buffer A is an input buffer with a maximum used size of 64x21 pixel. It consists of two pages. The buffers B and C are temporary buffers of a size of 18x16 pixels each one. The buffer D is a 32x4-pixels output buffer. The buffer E stores QP parameters.

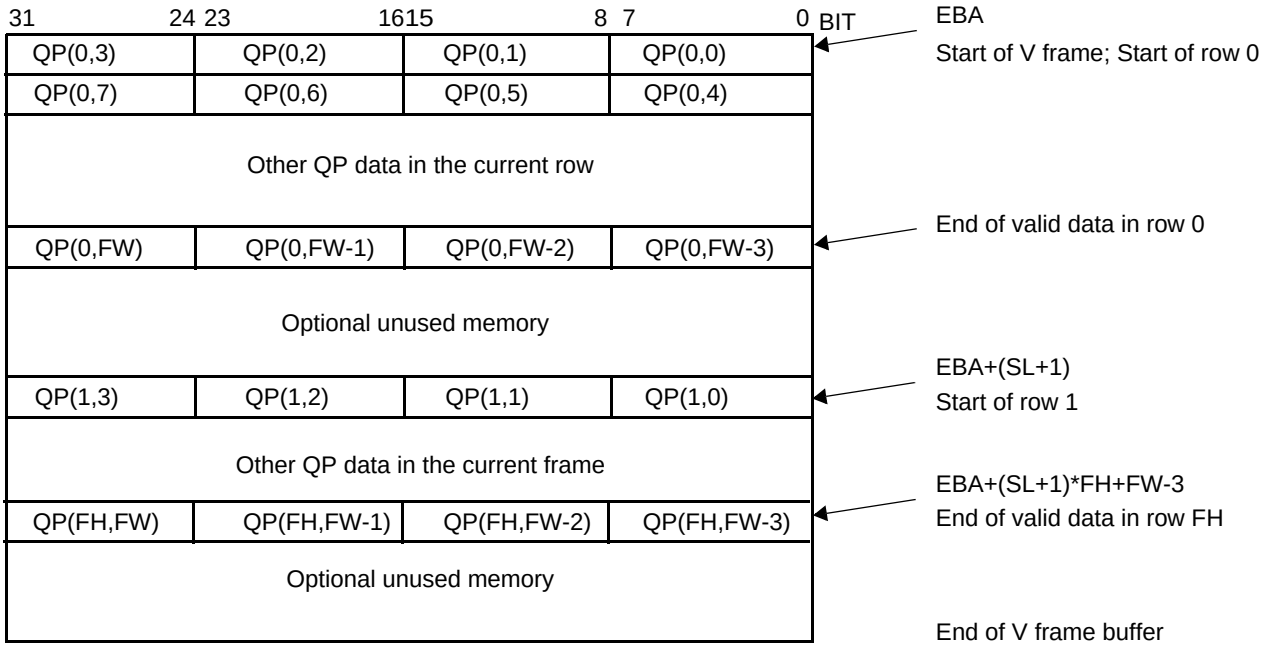
The following processing steps are performed for Y color component (Figure 31-129 and Figure 31-130):

1. Initial step before processing a page: the first page of the buffer A contains two input non-shifted macroblocks, the buffer B, C and D contents are not specified.
2. Deblocking columns of the shifted macroblock 1:
   a) the macroblock 1 is read from the buffer A in the column order for mode decision and filtering,
   b) filter results are written to the buffer B in the column order,
3. Deblocking columns of the shifted macroblock 2:
   a) the macroblock 2 is read from the buffer A in the column order for mode decision and filtering,
   b) filter results are written to the buffer C in the column order.
4. Deblocking rows of the macroblock 1:
   a) the macroblock 1 is read from the buffer A in the row order for mode decision,
   b) the macroblock 1 is read from the buffer B in the row order for filtering,
   c) filter results are written to the buffer A in the row order,
5. Deblocking columns of the shifted macroblock 3:
   a) the macroblock 3 is read from the buffer A in the column order for mode decision and filtering,
   b) filter results are written to the buffer B in the column order,
6. Deblocking rows of the macroblock 2:
   c) the macroblock 2 is read from buffer A in the row order for mode decision,
   d) the macroblock 2 is read from buffer C in the row order for filtering,
   e) filter results are written to the buffer A in the row order,
7. Deringing:
   a) the first page of the buffer A contents are read in the row order for mode decision and filtering,
   b) filter results are written to the buffer D.
   c) the buffer D contents are moved to the system memory by the IDMAC.
   d) a new data is loaded to the first page of the buffer A instead of processed rows.
8. Toggle a page pointer in buffer A and return to the step 2.

Macroblock QP parameters are calculated by the core. They should be stored in the external memory in the same order as pixel data (see Figure 31-128). Each QP parameters occupies 6 LSB bits in a byte (see Table 31-143).



sl - stride line



Parameters for DMAPF_0 channel:

EBA - External Base Address
SL - Stride Line - 1
FW - Y Frame Width/16 - 1
FH - Y Frame Height/16 - 1

Figure 31-128. QP Parameters Allocation in the System Memory

Table 31-143. QP Parameter Format

bit	7							0
contents	X	QP						

For the U and V color components, the same algorithm is used excluding deringing step. Additionally, each deblocking step described above means simultaneous processing four neighboring shifted macroblocks of the U or V component.

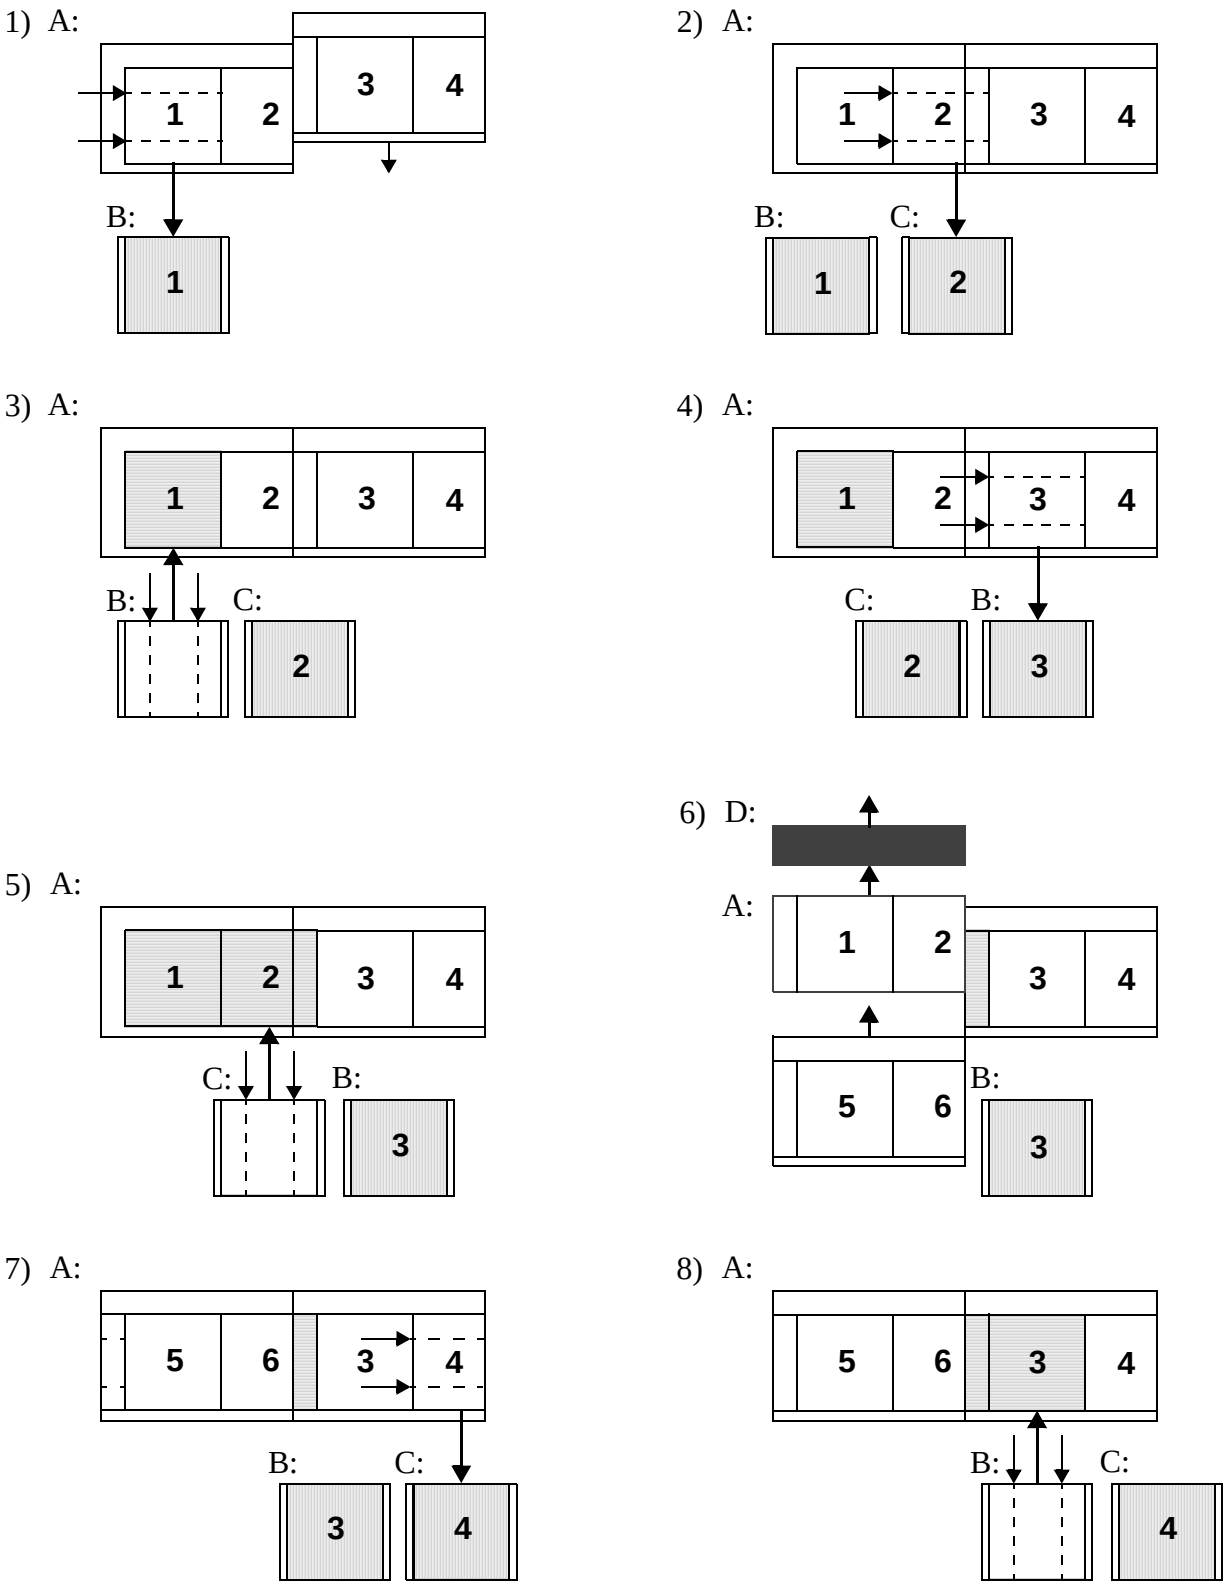


Figure 31-129. Processing Flow for Y Component in MPEG-4 Mode (Part 1)

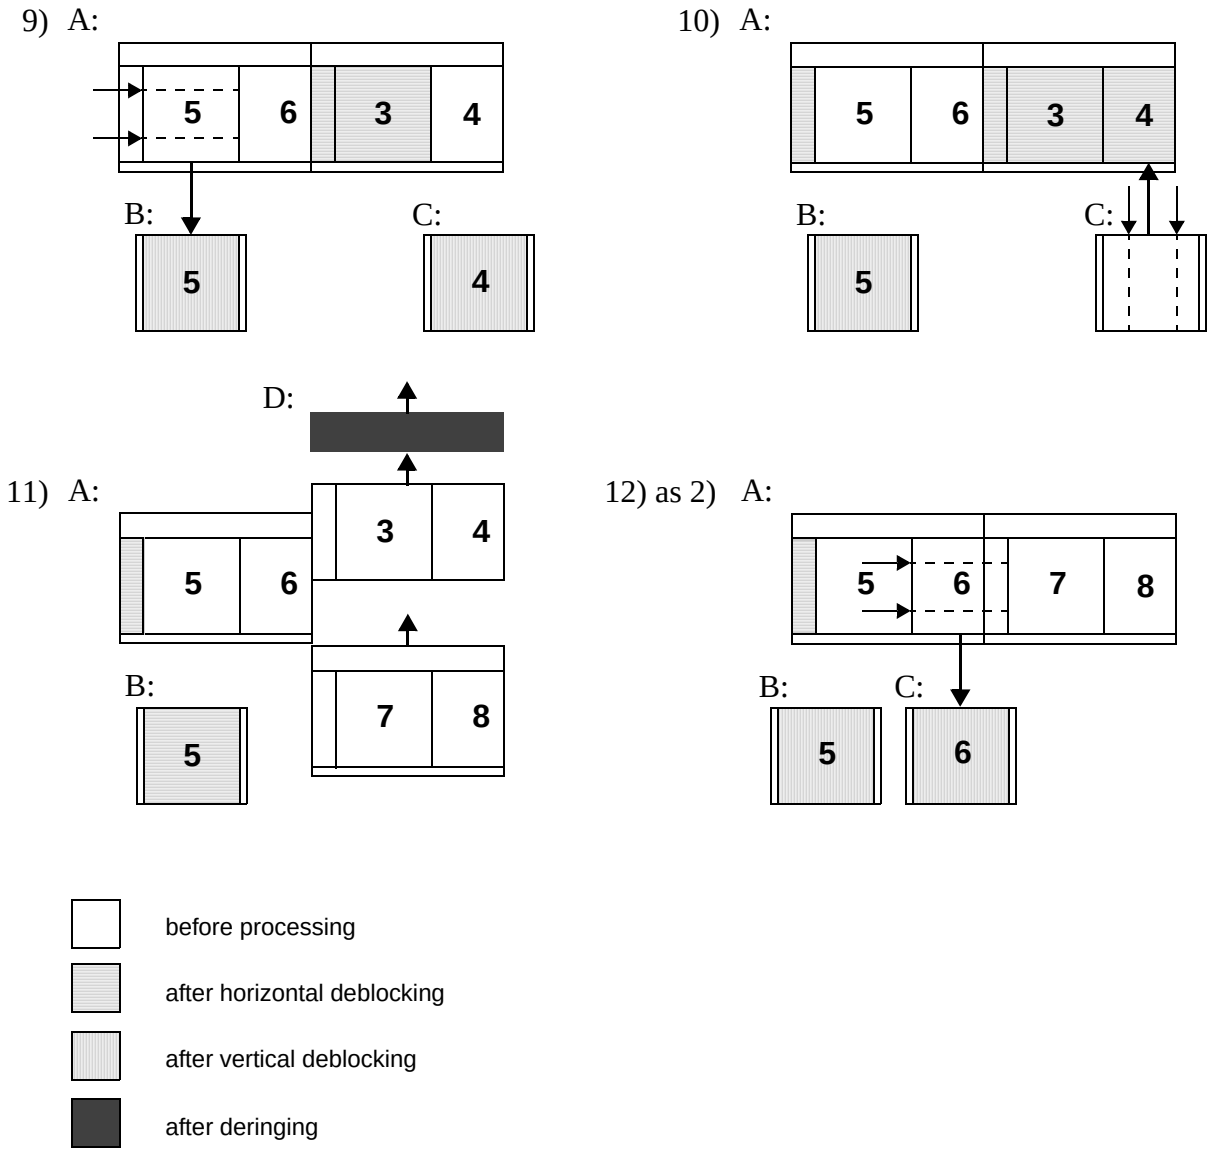

Figure 31-130. Processing Flow for Y Component in MPEG-4 Mode (Part 2)

31.4.3.2.2 H.264 Mode

For H.264 mode, the operation sequence does not include deringing task:

1. Deblocking of a Y component macroblock.
2. Repeating steps 1 until end of frame.
3. Deblocking of a U component macroblock.
4. Repeating step 3 until end of frame.
5. Deblocking of a V component macroblock.

6. Repeating step 5 until end of frame.

There is three buffers in the Postfilter Memory: A, B and C. The buffer A is an input buffer with a maximal used size of 64x20 pixel. It consists of two pages. The buffer B stores BS parameters. The buffer C stores QP parameters and filter offsets.

The following processing steps are performed (Figure 31-134 and Figure 31-135):

1. Initial step before processing a page: the first page of the buffer A contains two input non-shifted macroblocks.
2. Deblocking rows of the macroblock 1:
   a) the macroblock 1 is read from the buffer A in the row order for mode decision and filtering,
   b) filter results are written to the buffer A in the row order,
3. Deblocking columns of the macroblock 1:
   a) the macroblock 1 is read from the buffer A in the column order for mode decision and filtering,
   b) filter results are written to the buffer A in the column order.
4. Deblocking rows of the macroblock 2:
   a) the macroblock 2 is read from the buffer A in the row order for mode decision and filtering,
