*** MMC/SD/SDIO Host Controller Drivers *** <*> Secure Digital Host Controller Interface support <*> SDHCI platform and OF driver helper [*] SDHCI OF support for the NXP eSDHC controller	Enables NXP eSDHC driver support

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_MMC	y/n	n	Enable SD/MMC bus protocol
CONFIG_MMC_BLOCK	y/n	y	Enable SD/MMC block device driver support
CONFIG_MMC_BLOCK_MINORS	integer	8	Number of minors per block device
CONFIG_MMC_BLOCK_BOUNCE	y/n	y	Enable continuous physical memory for transmit
CONFIG_MMC_SDHCI	y/n	y	Enable generic sdhc interface
CONFIG_MMC_SDHCI_PLTFM	y/n	y	Enable common helper function support for sdhci platform and OF drivers
CONFIG_MMC_SDHCI_OF_ESDHC	y/n	y	Enable NXP eSDHC support

Device Tree Binding

Property	Type	Status	Description
compatible	String	Required	Should be 'fsl,esdhc'
reg	integer	Required	Register map

Default node:

```
qoriq-esdhc-0.dtsi:
sdhc: sdhc@114000 {
        compatible = "fsl,esdhc";
        reg = <0x114000 0x1000>;
        interrupts = <48 2 0 0>;
        clock-frequency = <0>;
};

For special platform (T1040 as example):
/include/ "qoriq-esdhc-0.dtsi"
        sdhc@114000 {
                compatible = "fsl,t1040-esdhc", "fsl,esdhc";
                fsl,iommu-parent = <&pamu0>;
                fsl,liodn-reg = <&guts 0x530>; /* eSDHCLIODNR */
                sdhci,auto-cmd12;
                rcpm-wakeup = <&rcpm 0x00000080>;
        };
```

```
NOTE: For different platform, the compatilbe can be different.
      And the property "sdhci, auto-cmd12" is option.
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/mmc/host/sdhci.c	Linux SDHCI driver support
drivers/mmc/host/sdhci-pltfm.c	Linux SDHCI platform devices support driver
drivers/mmc/host/sdhci-of-esdhc.c	Linux eSDHC driver

User Space Application

The following applications will be used during functional or performance testing. Please refer to the SDK UM document for the detailed build procedure.

Command Name	Description	Package Name
iozone	IOzone is a filesystem benchmark tool. The benchmark generates and measures a variety of file operations.The benchmark tests file I/O performance for the following operations: Read, write, re-read, re-write, read backwards, read strided, fread, fwrite, random read, pread ,mmap, aio_read, aio_write.	iozone

Verification in U-boot

```

Known Bugs, Limitations, or Technical Issues

1. Call trace when running `iozone` to test SD card performace on some platforms

   Workaround: increase the timeout value (in kernel configuration) and decrease the dirty_ratio in proc file system.

   a. menuconfig:

      Kernel hacking

      (xxx) Default timeout for hung task detection (in seconds)

      NOTE
      The xxx may be 400 seconds or greater

   b. Modify 'proce file system':

      ```
      echo xx > /proc/sys/vm/dirty_ratio
      echo xx > /proc/sys/vm/dirty_background_ratio
      ```

      NOTE
      The xx may be 10 or 5, which meas 10% or 5%, the default is 20%.

2. The platform whose card is required to work on a special transfer mode which is not FS or HS mode needs a special rcw. (e.g. rcw_66_15_1800MHz_emmc_ddr.rcw is for t2080qds eMMC DDR mode. Because of pin multiplexing with SPI, SPI would not work when eMMC card works on DDR mode)
3. According to SD specifications, only a power cycle could reset the SD card working on UHS-I speed mode. However, our boards couldn't provide a power cycle for SD card even with reset. This initializes SD UHS-I card to use high speed mode after board reset when the card is on UHS-I speed mode. The workaround is using power off/on instead of reset when using SD UHS-I card.

7.6 Ethernet

7.6.1 Linux Ethernet Driver for DPAA 1.x Family

7.6.1.1 Linux DPAA 1.x Ethernet Primer

Understanding the high-level concepts of the Linux driver

7.6.1.1.1 Introduction

An overview of the DPAA-Ethernet network driver, in the more generic context of Linux device drivers.

The primary concepts of the DPAA-Ethernet driver architecture are presented without going into such intricate details as device-tree configuration or code structure. The current document is neither a Linux Device Drivers tutorial, nor a replacement to the **Linux Ethernet Driver** document in the SDK, but a quick start guide which provides context for users.

The DPAA-Ethernet driver software shipped with the standard QorIQ Linux SDK is described.

7.6.1.1.2 Intended Use Cases

This chapter presents a high-level view of the standard use-cases (based on the QorIQ Linux SDK requirements) that the DPAA-Ethernet driver currently supports.

7.6.1.1.2.1 Private Net Devices

This is the primary driver and the one which currently delivers the best performance. Characteristics of this driver are:

- The private driver is a multiqueue driver - it uses 1 TX queue per CPU
- All private interfaces use a single BPID - usually dynamically allocated
- The FQIDs for the common types of queues - RX, TX, RX Error, TX Error, TX Confirm - are dynamically allocated
- The Hashing/PCD frame queues are hardcoded in the device tree. The private driver imports the PCD configuration from device tree at startup
- The above resources are allocated and visible only to the private driver

In the case of private interfaces, all network traffic takes place between the Linux kernel and the physical FMan port private to that partition.

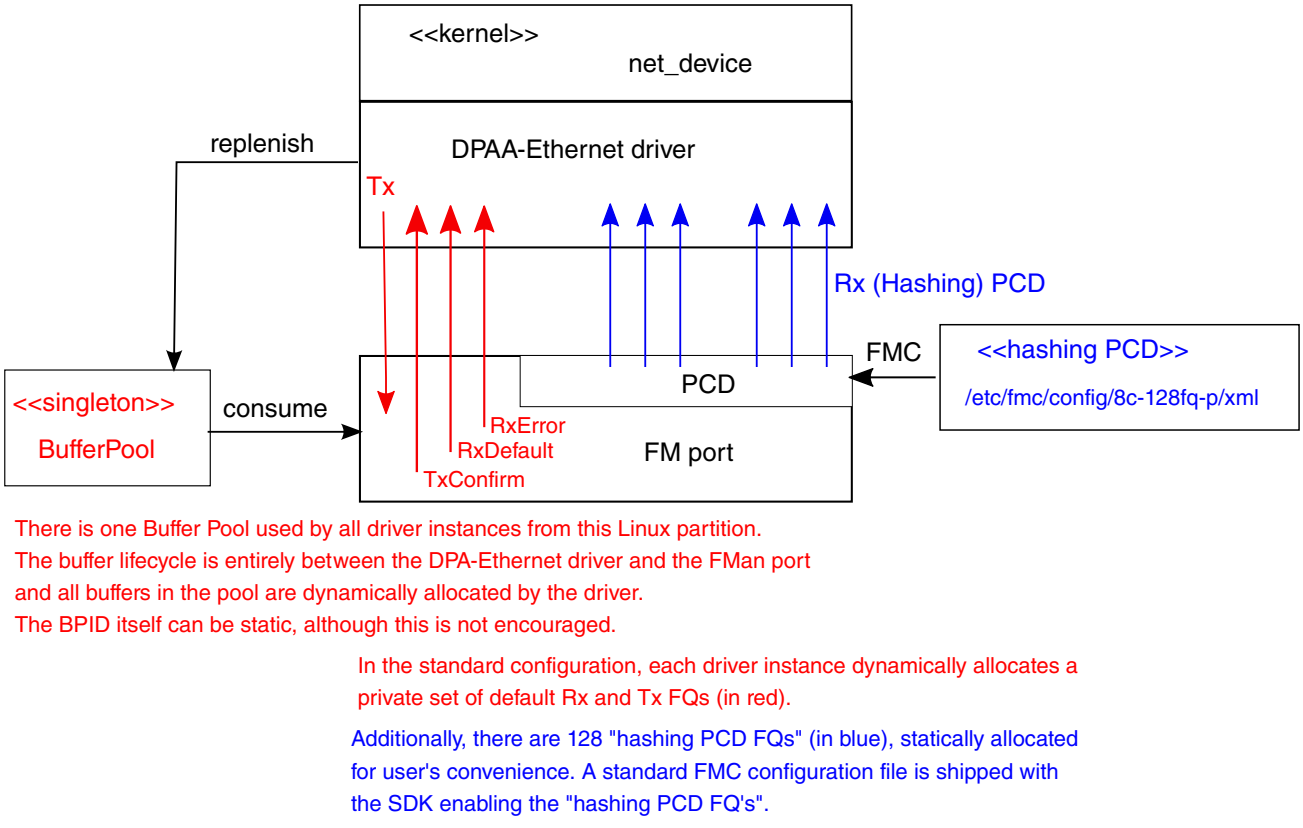

Figure 146. Network Traffic Between the Linux Kernel and the Physical FMan Port

7.6.1.1.2.2 Shared-MAC Net Devices

A shared-MAC device is one that can be used from two (or potentially more) Linux and/or USDPAA partitions. A shared-MAC encompasses one of the following partitioning scenarios:

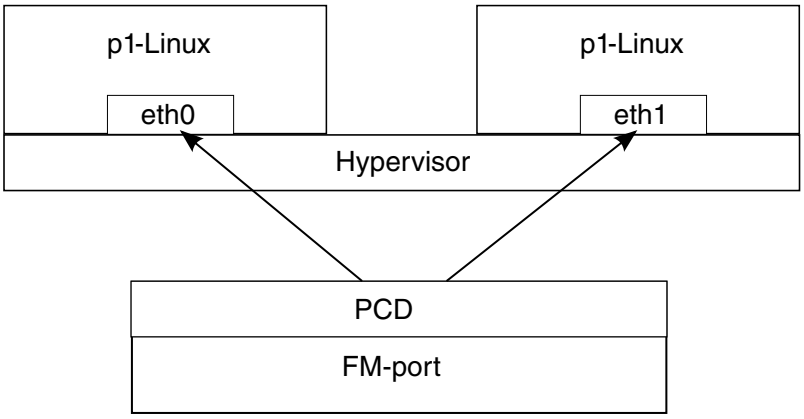

Figure 147. Two (or more) Linux separate partitions, under control of the TOPAZ hypervisor.

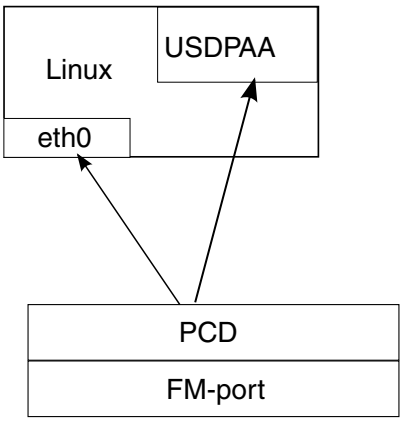

Figure 148. One Linux and one USDPAA running in the same partition

Points to emphasize

- In all cases, there is exactly one physical MAC. Linux always “owns” the MAC, which it initializes.
- A shared-MAC between two Linux interfaces (say, eth0 and eth1) from the same partition is **not supported** unless in a hypervised scenario (and has never been intended as a use-case, anyway).

Configuration and ownership of a shared-MAC is asymmetric and driven by a number of hardware and software constraints.

The following constraints and design assumptions apply to Buffer Pools in a shared-MAC device:

- FMan v2 (not supporting virtual storage profiles) picks the buffer to store the Rx frame based solely on the ingress frame size, regardless of the result of PCD.
- In shared-MAC devices used by Linux and USDPAA, to avoid the need for the USDPAA fastpath to remap the ingress buffers, the same Buffer Pool is shared between Linux and USDPAA.
- In shared-MAC devices used by two Linux partitions (no USDPAA involved), it is necessary that the Linux guests have the same true-physical to guest-physical mappings, in order for FMan-DMA to work seamlessly regardless of the destination partition. Moreover, that presumes that the buffer space seen by the two partitions is identical, which comes down to the Buffer Pools being physically shared between the two Linux partitions.

- Sharing a Buffer Pool between two or several Linux and/or USDPAA partitions requires that the BPID be statically defined (identically hard-coded) in the `.dts` configurations of all partitions.
- The convention between Linux and USDPAA is that USDPAA initializes and seeds the shared Buffer Pool. Linux dynamically remaps ingress buffers received on a shared-MAC, copies them into a buffer dynamically allocated in its own memory space, then releases the ingress buffer back into the shared Buffer Pool.
- In the case of a shared-MAC between two Linux partitions (in a hypervised scenario), only one partition will initialize and seed the shared Buffer Pool. That partition is determined by means of a special property in the `hv.dts` partition configuration. Refer to **Linux Ethernet Driver - Buffer Pools** for details.

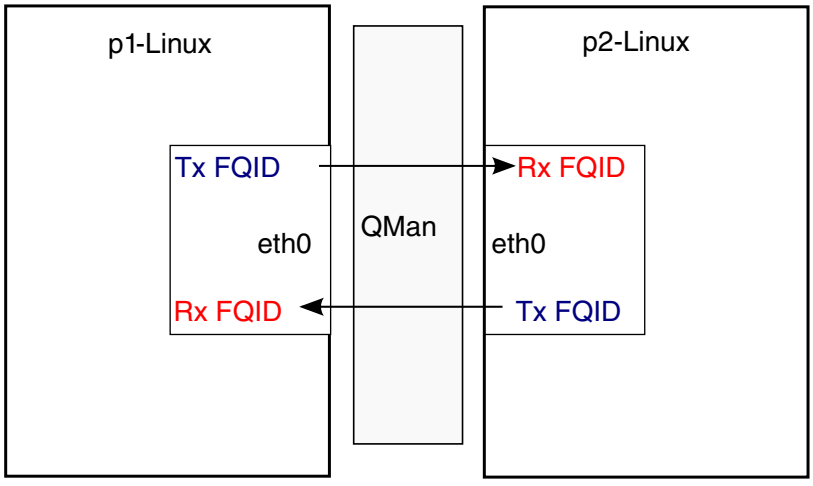
The following constraints and design assumptions apply to Frame Queues in a shared-MAC device as seen by the Linux DPAA-Ethernet (i.e. not USDPAA) driver:

- Rx traffic is driven to either partition via a PCD configuration applied on the shared physical port. This means that, for Linux partitions using a shared-MAC, at least one Rx Frame Queue has to be statically declared in the `.dts`. That may be the Rx Default Frame Queue and/or the (automatically initialized) 128 core-affine **Hashing PCD Frame Queues**.
- In the Linux-Linux shared-MAC scenario, all Tx Frame Queues must be statically specified and be the same in both partitions. The reasoning is explained in the **Linux Ethernet Driver - Virtual/Shared Controller** document. .
- In the Linux-USDPAA shared-MAC scenarios, the Linux partition will always initialize its own Tx Frame Queues, be they dynamically or statically allocated. It is up to the USDPAA application to choose its own Tx FQIDs.
- The Tx Confirm Frame Queues are always used in shared-MAC scenarios; all egress buffers are confirmed. See **Shared MAC: Tx** packet lifecycle for details.

7.6.1.1.2.3 MAC-less Net Devices

A MAC-less device, also called a Virtual Controller in the **Linux Ethernet Driver - Virtual/Shared Controller**, appears to Linux as a regular net device (Ethernet interface). It is “virtual” in the sense that it does not have a physical FMan port (be it an online or an OH port) underlying, but that is transparent to the Linux kernel and userspace applications – only the DPAA-Ethernet driver is aware of the difference.

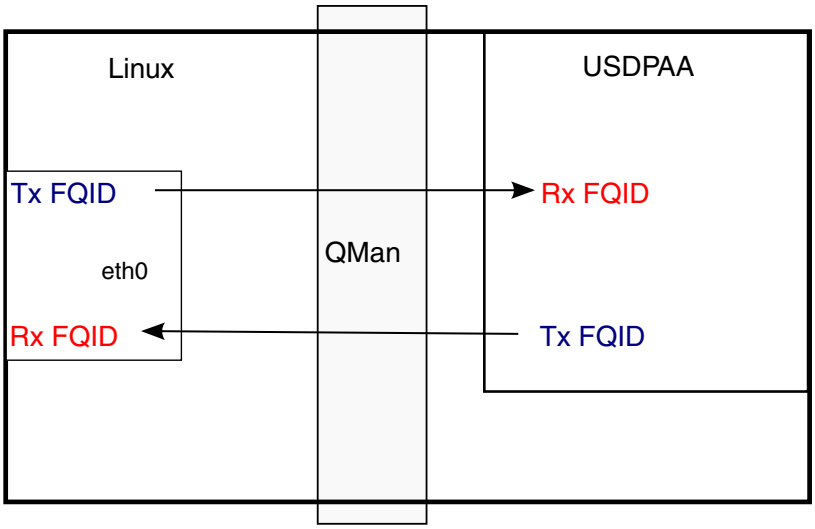
The figure below shows the typical MAC-less use-case is as a communication device between two Linux partitions:



Typical MAC-less setup between two Linux partitions
(Both under control of the hypervisor)

Figure 149. Communication device between two Linux partitions

… or between Linux and USDPAA:



MAC-less is supported between Linux and USDPAA running in the same partition.

Figure 150. Communication device between one Linux and one USDPAA in the same partition

From the DPAA resource configuration standpoint, a MAC-less net device is very similar to a **Shared MAC: Tx**. The same constraints apply to Buffer Pools and Frame Queues as in the case of a shared-MAC, with one notable difference:

- Because the Tx FQs of a MAC-less device always sink into another partition (or USDPAA) instead of a physical FMan port, there is the convention that the DPAA-Ethernet driver of a MAC-less node **only initializes its Rx FQs**. In other words, each partition initializes its own Rx FQs, because it has to bind local dequeue callbacks to them.

In a MAC-less setup, one endpoint's Tx FQIDs are the other endpoint's Rx FQIDs and vice versa.

While the previous diagrams have shown typical MAC-less use-cases, one can design more complex scenarios by interposing various processing blocks between the two MAC-less endpoints. Refer to the **Extended Use Cases** chapter for a discussion.

7.6.1.1.2.4 Choosing the Current Use Case

The following activity diagram describes the configuration selection logic in the DPAA-Ethernet driver, based on properties found in the `.dts` specification:

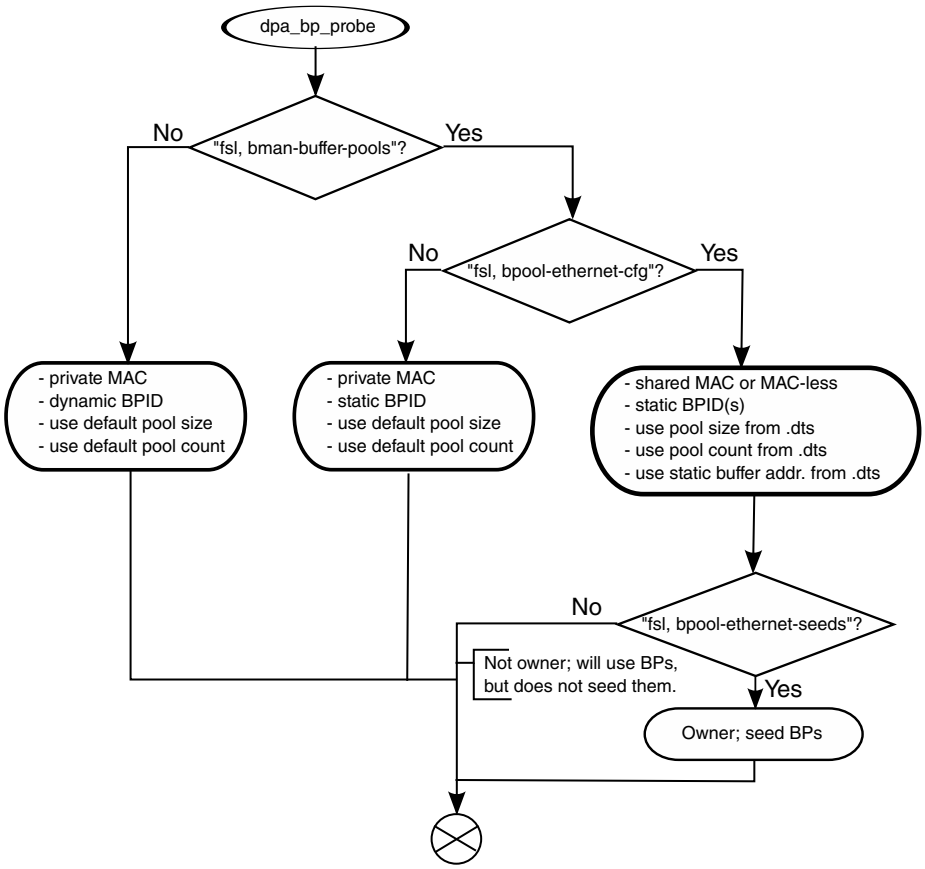


Figure 151. Configuration Selection Logic

7.6.1.1.3 The DPAA-Eth View of the World

This section presents the primary concepts behind the DPAA-Ethernet driver design.

As a Linux driver, one of DPAA-Ethernet driver's main goals is proper integration with the Linux kernel ecosystem. As a hardware device driver, the DPAA-Ethernet driver integrates functions of several DPAA IP blocks, within the scope of the defined/supported use cases.

7.6.1.1.3.1 The Linux Kernel API's

The DPAA-Ethernet drivers interface with the Linux kernel via the latter’s networking stack APIs. This is a strong requirement, mandated by the integration with the Linux kernel.

Another type of interaction with the kernel code is at boot-time, via the Open-Firmware API. That API is used to parse the PowerPC platform device tree and discover the hardware modules that need to be configured. In particular, the DPAA-Ethernet drivers use the platform device tree to discover:

- What net devices to probe and what type of hardware is underlying those devices;
- Which DPAA resources are involved: FQIDs, BPIDs, CGRIDs, FMan port IDs.

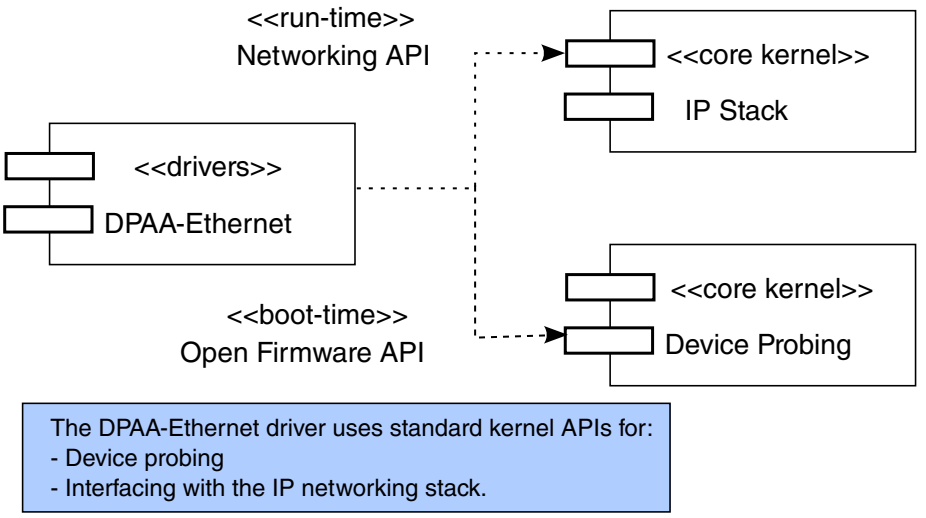

Figure 152. Platform Device Tree

Generally, we prefer drivers configurations to be dynamic and transparent to the rest of the system. Among the benefits of dynamic resource allocations, we count:

- Portability of the drivers across multiple QorIQ platforms;
- Seamless support of platform changes (e.g. via booting with different RCWs);
- Seamless support of multiple partitions under the control of a hypervisor;
- Cohabitation with other DPAA drivers (e.g. a SEC driver) in the SDK.

In certain scenarios, however, configurations are statically defined and are extracted directly from the .dts specification. This is for instance the case of shared MAC and MAC-less devices.

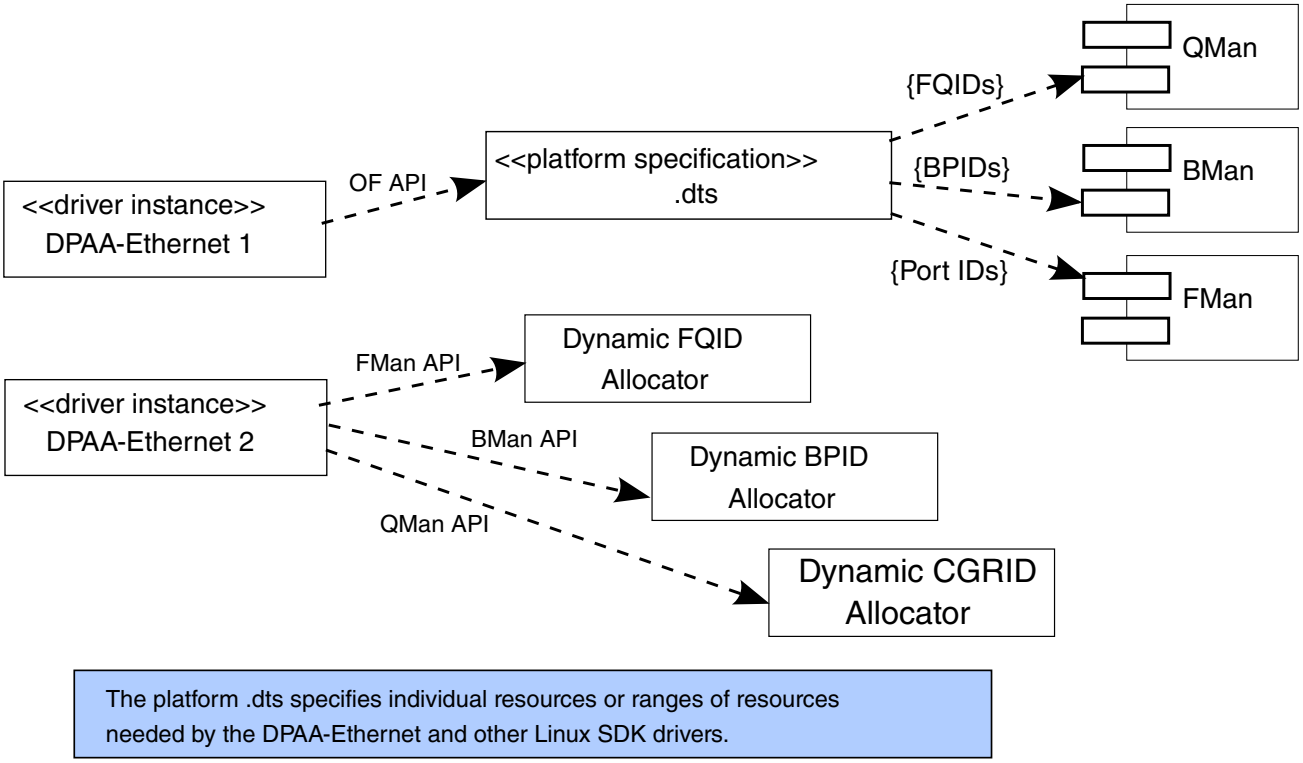

Figure 153. Shared MAC and MAC-less Devices

7.6.1.1.3.2 The Driver's Building Blocks

This chapter presents the main structures and data entities with which the DPAA-Ethernet driver operates.

The driver's building blocks are part of the interfaces of the driver with the relating components, i.e.:

- The kernel’s IP stack;
- The DPAA hardware blocks and their drivers.

The DPAA Ethernet driver is actually a series of drivers, each tailored for a specific use case:

- Private driver - maps Linux kernel network interfaces to physical ports
- Shared driver - gives simultaneous control of a physical port to the Linux kernel and user space applications
- Macless driver - although it appears to the Linux kernel as a regular net device, it does not control a physical port. It is typically used as a virtual communication device between two Linux partitions
- Proxy driver - an interface through which the Linux kernel configures a physical port, only to pass its control to user space applications
- Offline port driver - controls Offline Parsing / Host Command port (OH)

Each of the above drivers has its own code base and implements the Linux kernel API by providing its own callback functions.

7.6.1.1.3.2.1 Net Devices

A net device (`struct net_device` in C representation) is the fundamental structure of any Linux network device driver.

A net device describes a (physical or virtual) device capable of sending and receiving packets over a (virtual or physical) network. All incoming and outgoing traffic is accounted and processed on behalf of the net device it comes or goes on.

Each supported type of net device has its own kernel driver. If there are several such devices present in a system, there will be as many device driver instances.

A net device is accessible to the Linux user via the standard tools, such as ‘ifconfig’ or ‘ethtool’.

Not all net devices have real underlying hardware; tunnel endpoints, for examples, are represented by net devices but are not directly backed by hardware. Same holds for drivers such as “bonding” or “dummy”.

It is worth emphasizing, however, that **every** Linux interface is represented by a net device. This is a fundamental design aspect of all Linux networking drivers, including DPAA-Ethernet. One can describe the Linux IP stack as being a **netdev-centric** construction. Nearly all of the kernel networking APIs receive a `struct net_device` as a parameter. The `net_device` structure is the handle through which the driver and the network stack communicate.

The following diagram illustrates what has just been described:

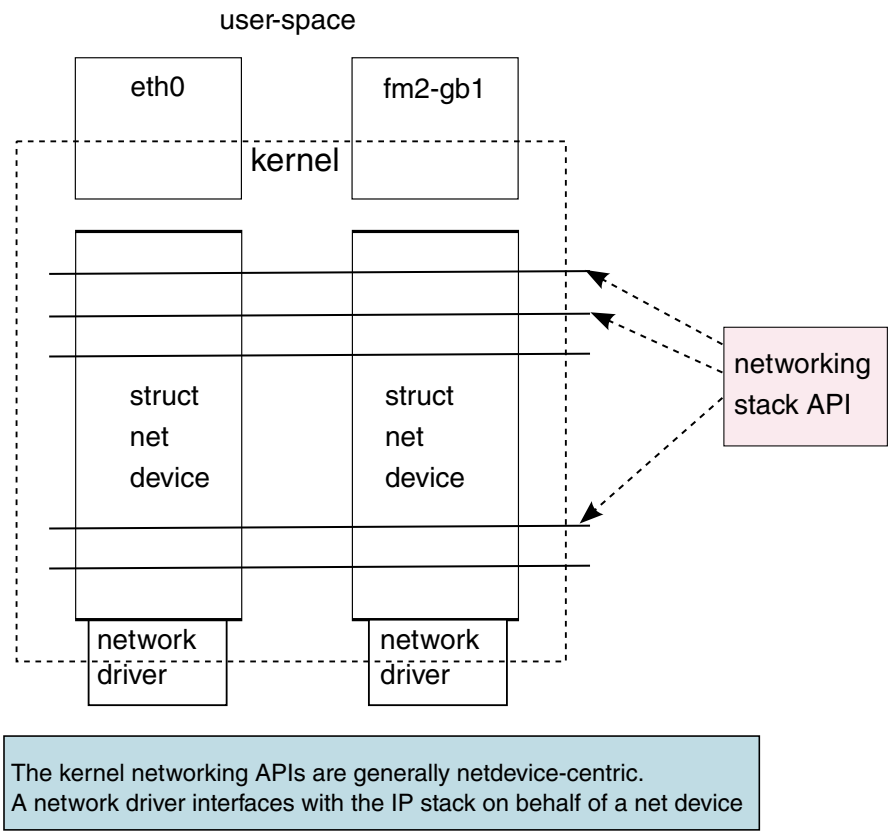

Figure 154. Every Linux Interface is Represented by a Net Device

7.6.1.1.3.2.2 Frame Queues

The Frame Queue is one of the fundamental concepts of DPAA. In the case of DPAA-Ethernet, it is the main interface between the network driver and the hardware blocks.

Ingress frames received by the DPAA-Ethernet driver on one of the Frame Queues it is servicing are sent to the IP stack on behalf of the net device structure that the driver is associated with. Conversely, outgoing frames coming from the IP stack into the driver are enqueued to one of the egress Frame Queues.

NOTE

Depending on its configuration (see usecase), the DPAA-Ethernet driver may initialize some of its Frame Queues and make assumptions over what entity initializes the others.

7.6.1.1.3.2.3 Buffer Pools

Buffer pool configuration is another fundamental part of the DPAA-Ethernet driver design.

Unlike the Frame Queue utilization – which is more flexible – the Buffer Pool utilization is conditioned by several design assumptions:

- The source and ownership of the ingress frame buffers are presumed by the DPAA-Ethernet driver. The exact allocation logic depends on the driver configuration (see usecase), but in all cases the driver makes hard assumptions on how the buffers were allocated.

  For instance, the “private MAC” driver configuration seeds the Buffer Pools at predefined checkpoints on the Rx path. There are also buffer utilization counters maintained by the driver, which influence the buffer allocation logic.

  The “shared MAC” and “MAC-less” driver configurations only work with the Buffer Pools hard-coded in the platform `.dts`.

- The layout of incoming frames is also presumed by the driver. Depending on its configuration (see usecase), the driver expects the frame layout to conform to its own allocation logic. The actual buffer layout is outside the scope of this document and should not be assumed upon by driver users.
- The existence of a static Buffer Pool configuration in the platform `.dts` determines the driver configuration. The DPAA-Ethernet driver currently assumes that, if a static Buffer Pool is configured in its device tree node (as number/size/address of buffers), then it is describing a “shared MAC” or a “MAC-less” configuration.

7.6.1.1.4 DPAA Resources Initialization

The rationale behind the “what”s, “why”s and “how”s of DPAA resource initializations made by the DPAA-Ethernet driver are presented. This description does not go into the full detail of driver configuration (please refer to the **Linux Ethernet Driver** for that level of detail).

7.6.1.1.4.1 What, Why and How Resources are Initialized

DPAA resources initialized by the various configurations of the DPAA-Ethernet driver are:

- FQs and FQIDs (where static config applies);
- BPs and BPIDs (where static config applies);
- Buffers (not quite “DPAA” resources, rather “system” resources);;
- CGRs (CGRIDs are always dynamic);
- FMan’s online ports (note: the offline ports are configured by a different driver than DPAA-Ethernet).

Frame Queues and Buffer Pools have been covered at length in the previous chapters of this document. CGRs are of lesser interest from the initialization viewpoint.

FMan’s online ports are initially probed by the FMan Driver (FMD) and later in the boot process they are configured by the DPAA-Ethernet driver instances according to the specifications in the `.dts`.

7.6.1.1.4.2 Hashing/PCD Frame Queues

Among the Frame Queues initialized by the DPAA-Ethernet driver, there is a predefined set of 128 core-affined Rx FQs, automatically initialized by the driver for user’s convenience. They are there because most performance-enhanced setups must use a PCD configuration; to that end, the standard QorIQ Linux SDK provides a “hashing PCDs” configuration that can be applied by the user via the FMC tool. Since FMC does not support dynamic FQID specification in its .xml configuration files, the “hashing PCD” Frame Queues also have static, hard-coded FQIDs.

Furthermore, apart from the core-affined Rx FQs, there is another set of 128 core-affined Rx FQs, which have a higher priority than the former. They are named throughout this documentation "Rx PCD High Priority Frame Queues". Likewise, the queues in this set are also core-affined and have static, hard-coded FQIDs.

For details about the “hashing PCD” Frame Queues and the Rx PCD High Priority Frame Queues, refer to the **Linux Ethernet Driver - Core Affined Queues**.

7.6.1.1.5 The (Simplified) Life of a Packet

This chapter presents a packet’s lifecycle in various configurations of the DPAA-Ethernet driver.

7.6.1.1.5.1 Private Net Device: Tx

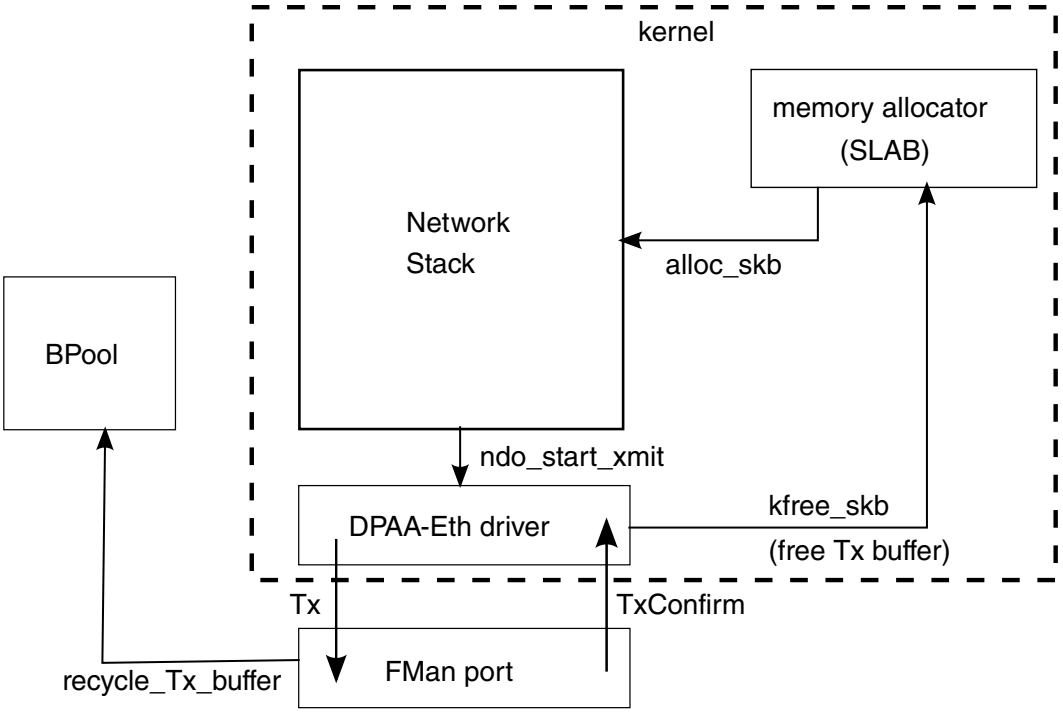

Figure 155. DPAA-Ethernet driver enqueues the packet to the FMan port

Arrows in the diagram above represent the direction of the buffer/packet flow.

A packet on the egress path is allocated by the network stack using the kernel's standard memory allocator. The DPAA-Ethernet driver enqueues the packet to the FMan port with an indication to recycle the buffer if possible. If recycling is not possible, the DPAA-Ethernet driver itself frees the buffer memory back to the kernel's allocator, when Tx delivery is confirmed by FMan.

7.6.1.1.5.2 Private Net Device: Rx

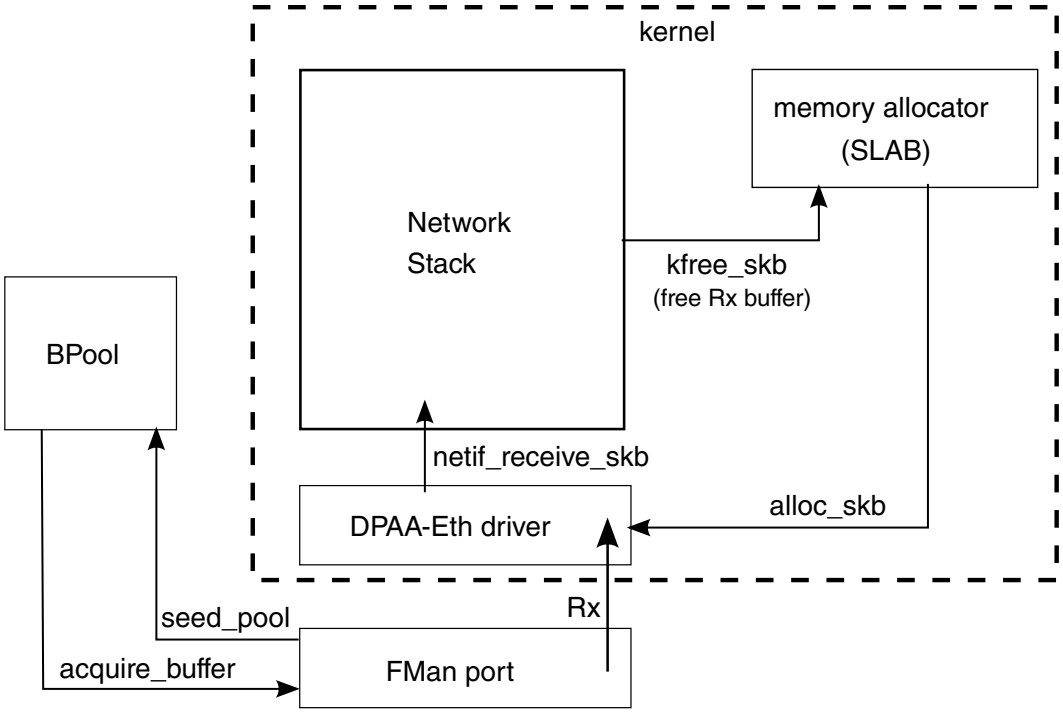

Figure 156. Buffers on the Ingress Path

Buffers on the ingress path are acquired by FMan directly from a Buffer Pool which was seeded by the DPAA-Ethernet driver. Buffer layout is important to the driver, which assumes ownership on the BP. Arrows in the diagram above represent the direction of the buffer/packet flow.

7.6.1.1.5.3 Shared MAC: Tx

The following diagram presents the lifecycle of an egress buffer/packet in the case of a shared-MAC device used by two Linux partitions (under the control of the Hypervisor, not shown in the picture):

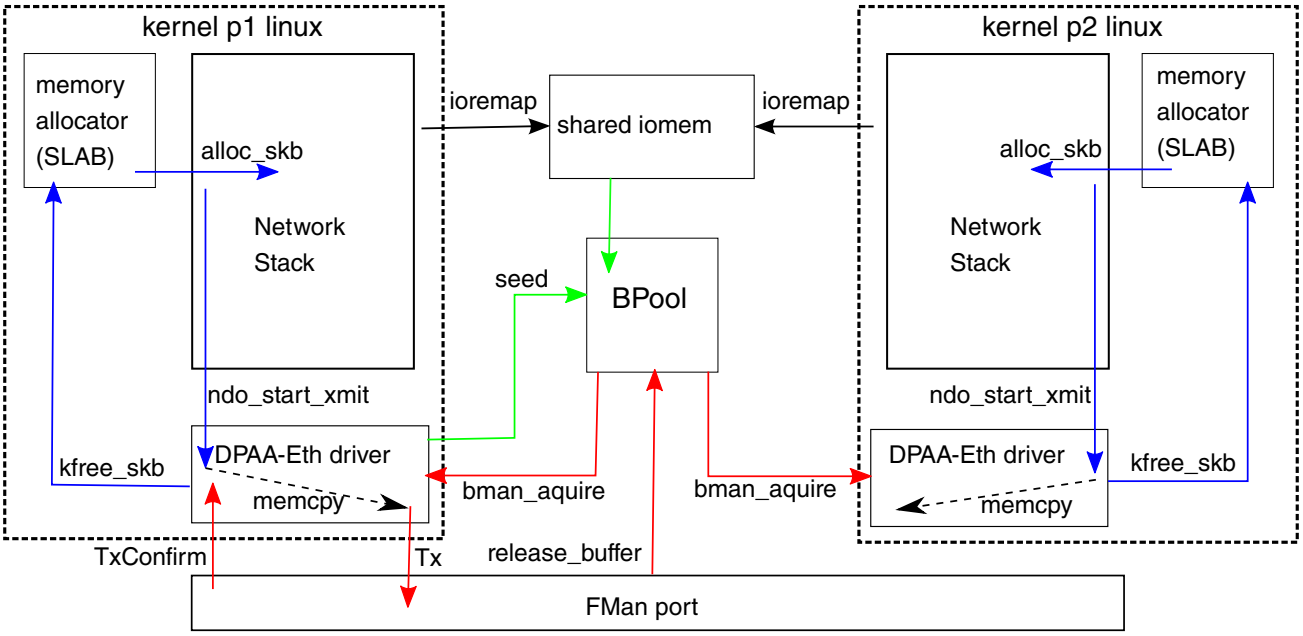

Figure 157. A Shared-MAC Device Used by Two Linux Partitions

There are essentially two buffer circuits in this scenario:

- The in-stack socket buffer lifecycle (colored in blue);
- The bpool buffer lifecycle (colored in red).

Socket buffers are dynamically allocated from the kernel memory. The DPAA-Ethernet driver memcopies them in buffers acquired from the Buffer Pool, then releases the socket buffers back into the kernel memory.

The shared Buffer Pool is seeded by one (and only one) of the Linux partitions, and is never again replenished by the software. Memory used for seeding the shared Buffer Pool is statically defined in the guest `.dts` configuration and is presented to the kernel as device memory (not as physical memory). Both DPAA-Ethernet drivers statically ioremap the entire shared Buffer Pool space (as per the static configuration in the .dts) at probe time. No run-time mapping/unmapping is effected afterwards.

After transmission, FMan confirms the frame and the Linux DPAA-Ethernet driver releases the buffers back into the Shared Buffer Pool.

Similarly to the above, the next diagram the lifecycle of an egress buffer/packet in the case of a shared-MAC device used by Linux and USDPAA:

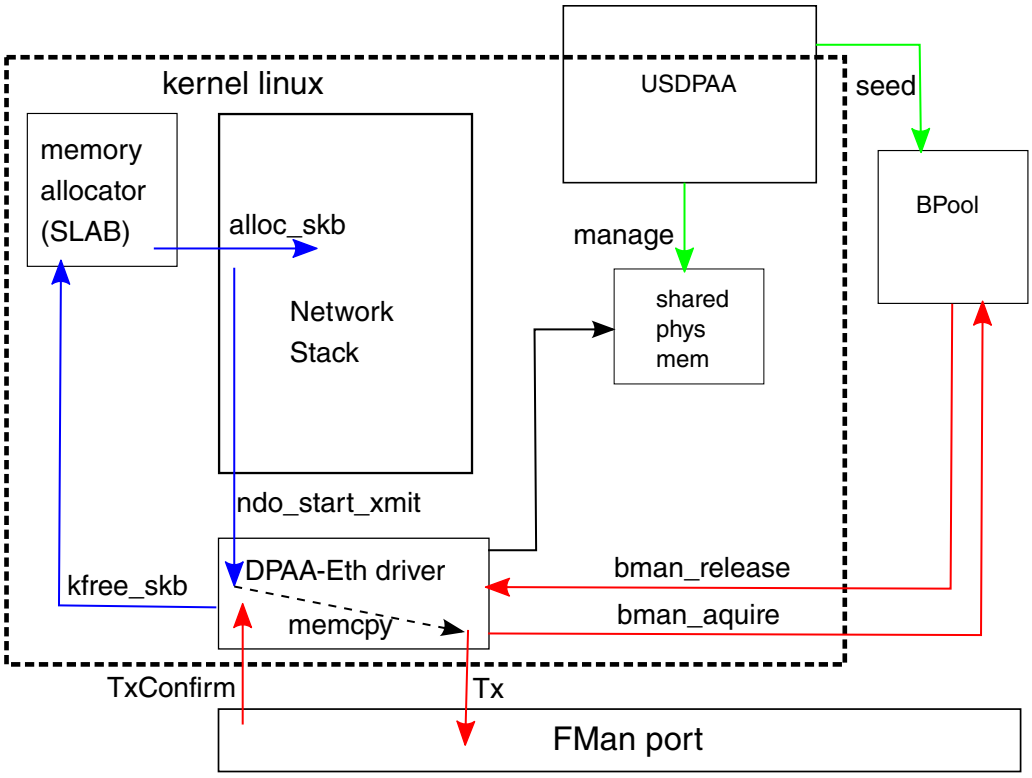

Figure 158. Shared-MAC Device Used by Linux and USDPAA

7.6.1.1.5.3.1 Shared MAC: Rx

The diagram below presents the lifecycle of a buffer/packet in the case of a shared-MAC device used by Linux and USDPAA running in the same partition.

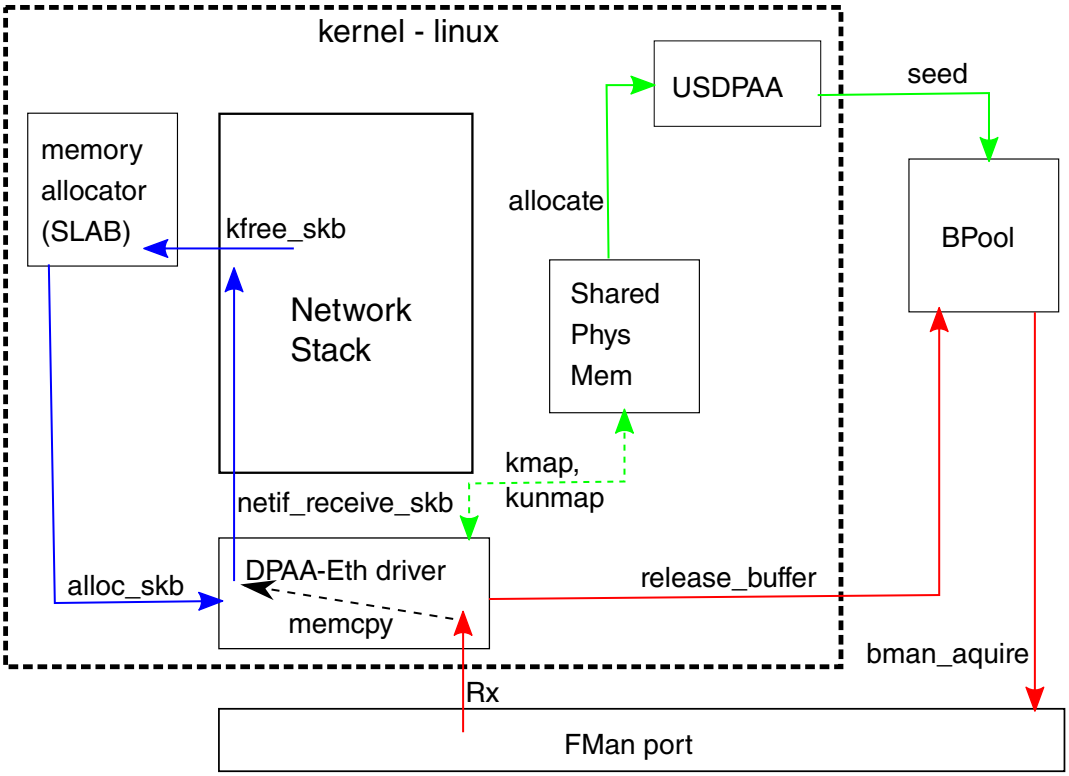

Figure 159. Shared-MAC Device Used by Linux and USDPAA

The Linux driver is the one to initialize the shared FMan port, but it is the USDPAA partition that allocates and seeds the buffers in the Shared Buffer Pool. To that end, USDPAA uses a block of physical memory reserved at boot time, such that the kernel can still map it, but not allocate from it (via either the page allocator or the object cache allocator).

Each incoming frame is dynamically mapped by the DPAA-Ethernet driver. As in the case of shared-MAC Tx, a memcopy is involved in the driver, from each incoming frame into a newly allocated socket buffer (sk_buff). The DPAA-Ethernet driver subsequently unmaps the buffer and releases it back into the shared Buffer Pool, for later reuse.

One should note the invariant that, as in all MAC-less and shared-MAC scenarios, the Shared Buffer Pool is initialized and seeded exactly once, at init-time; at run-time, the total number of in-flight buffers and buffers available in the pool is constant. One must preallocate a large enough number of buffers in the Shared Buffer Pool, such that to prevent its run-time depletion.

NOTE

A similar diagram can be obtained in the case of a shared-MAC between two different Linux partitions, with the principal change that the shared memory from which the Buffer Pool is seeded is seen as iomem (rather than physical memory), and is statically ioremapped all at once, at boot-time.

7.6.1.1.5.3.2 MAC-less Net Devices: Tx

The following diagram presents the lifecycle of a buffer/packet in the case of a MAC-less device used for communication from Linux to USDPAA:

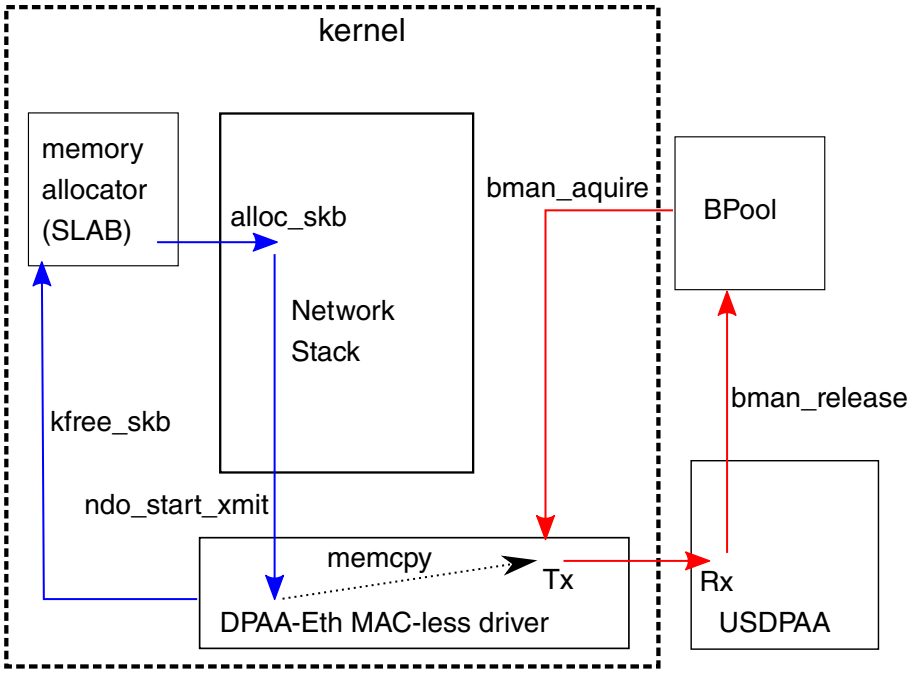

Figure 160. MAC-less Device Used for Communication from Linux to USDPAA

7.6.1.1.5.3.3 MAC-less Net Devices: Rx

The following diagram presents the lifecycle of a buffer/packet in the case of a MAC-less device used for communication from USDPAA to Linux:

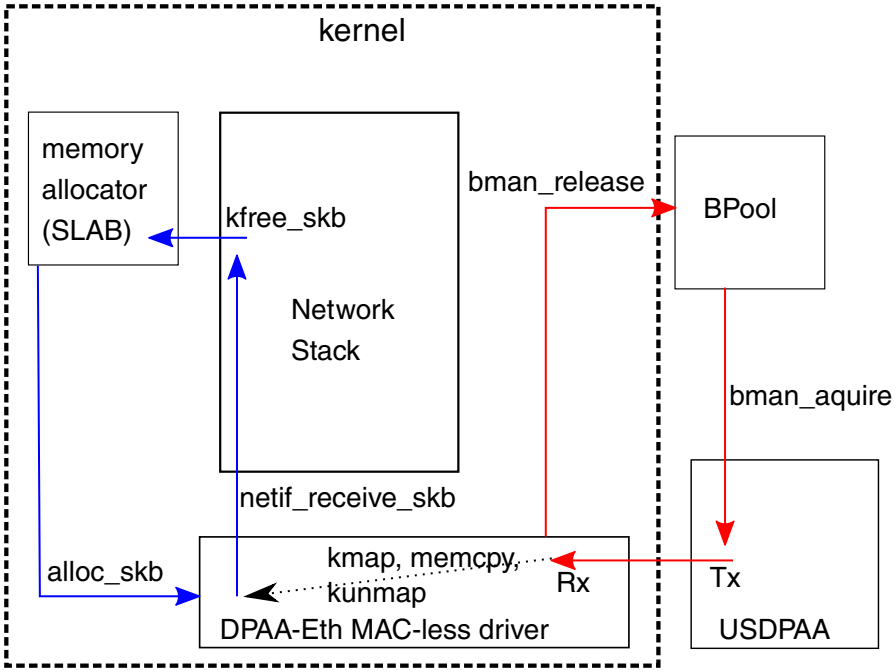

Figure 161. a MAC-less Device Used for Communication from USDPAA to Linux

7.6.1.1.6 Advanced Drivers Use Cases

This chapter is meant as an initial guideline toward building more complex use-cases, based on the predefined built-in capabilities of the DPAA-Ethernet driver that have been explained so far. (Note: Such use-cases are not currently part of the standard Linux QorIQ SDK.)

7.6.1.1.6.1 MAC-less Over OH (Linux-USDPAA

One can interpose an OH port between a Linux MAC-less net device and a USDPAA MAC-less interface, where the Linux-to-USDPAA path goes through the OH port, while the USDPAA-to-Linux path is direct:

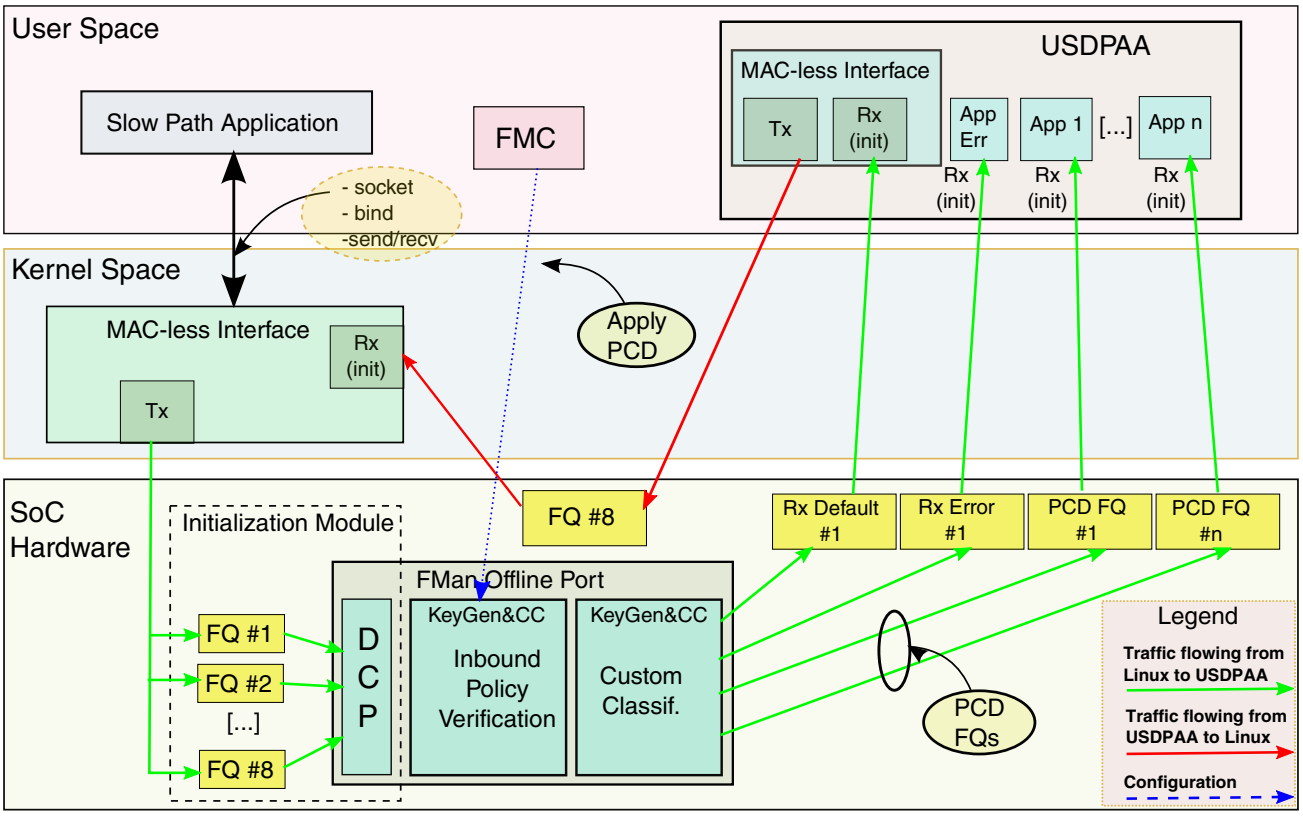

Figure 162. Linux MAC-less net device and a USDPAA MAC-less interface

In the current implementation, the DPAA Ethernet Driver initializes Linux MAC-less Rx FQs (= USDPAA's MAC-less Tx FQs).

Because there is no symmetric MAC-less endpoint to initialize the Linux endpoint's Tx FQs (as in the case of a standard MAC-less Linux-Linux setup), a separate kernel module is necessary in order to:

- Initialize the Linux MAC-less Tx FQs; and
- Add them to the DCP of the Offline Port.

The diagram shows:

Table 186. DPAA Ethernet Driver initializes FQs

#	Description	Detail
1	A MAC-less Linux interface with:	• 8 Tx FQs – initialized by the Offline Port Initialization Module and placed in the OH port's DCP; • 8 Rx FQs – initialized by the MAC-less interface and connected to the Tx FQs of the USDPAA MAC-less interface.
2	A MAC-less USDPAA interface with:	• 8 Tx FQs – initialized by the Linux MAC-less interface. (Note: USDPAA currently asserts that there are exactly 8 Tx FQs. This can be changed if a different number of frame queues are requested). • 8 Rx FQs - initialized by the MAC-less interface. Unlike in the standard Linux-Linux MAC-less scenario, these are different from the Tx FQs of the Linux MAC-less interface, because of the interposing OH port. The Offline Port's Rx Default and Rx Error FQs (and possibly the PCD FQs) use some of these FQIDs.
3	An Offline Port Initialization Module.	Responsible with initializing the 8 Tx FQs of the Linux MAC-less interface and connecting them to the DCP of the OH port.

The common idea of this design is that the entity which uses the queues for Rx is responsible with their initialization and (for software portals) specifying their dequeue callbacks. On the kernel side, this is the responsibility of the MAC-less interface (DPAA-Ethernet driver) and on USDPAA the responsibility is of the application that uses the FQs.

7.6.1.1.6.2 MAC-less Over OH (Linux-Linux)

Similarly to the previous use-case, one can use an Offline Port's interface with the QMan for interposing an OH between two MAC-less endpoints and effectively build a MAC-less-over-OH net device.

7.6.1.1.6.3 ARP Handling in Shared MAC

1. Linux-Linux: Currently (FMan-v2), ARP packets arriving on a shared-MAC interface are (in absence of relevant PCD configuration) routed to the Linux partition.
2. Linux-USDPAA: This is entirely handled by USDPAA infrastructure. Please refer to the USDPAA documentation.

7.6.1.1.6.4 Multicast Support in Shared MAC

This is not a supported feature in the FMan-v2- and FMan-v3-based DPAA-Ethernet drivers.

7.6.1.1.7 Appendix A: Infrequently Asked Questions

Table 187. Q and A

#	Question	Answer
1	How do I send a frame up the network stack?	The frame-processing network stack only exists in the context of a net device. So, “sending a frame into the stack” is an inaccurate statement: the frame must first be associated to a net device, and then the respective instance of the Ethernet driver will deliver the frame to the stack, on behalf of that net device. To achieve that, the frame must arrive via the physical device that underlies the driver (or via a MAC-less device’s ingress FQs).
2	Can I allocate a buffer and inject it as a frame into a private interface’s ingress queues?	This is probably a mistake. The DPAA-Ethernet driver makes hard assumptions on buffer ownership, allocation and layout. In addition, the driver expects FMan Parse Results to be placed in the frame preamble, at an offset which is implementation-dependent. In short, while a carefully crafted code might work, it would make for *very* brittle design, and hard to maintain, too. **NOTE** A MAC-less interface (potentially modified to interpose an OH port), however, will support this case, as long as: a) the buffer originates from the interface’s shared Buffer Pool; and b) the frame is a valid Ethernet frame.
3	But can I acquire a buffer directly from a private interface’s Buffer Pool, and inject it as such into the private interface’s Rx FQs?	While this works on a MAC-less or shared-MAC interface, it is not an intended use-case for private interfaces.
4	What format must an ingress frame have, from the standpoint of the DPAA-Ethernet driver and the Linux kernel stack?	The DPAA-Ethernet driver is expected to perform an initial validation of the ingress frame, but does not look at the Layer-2 fields directly. The current kernel networking code does make a check on the MAC addresses of the frame and the protocol (Ethertype) field. One should not make assumptions on such details of frame processing, because the kernel stack implementation is not bound by any contract.

7.6.1.1.8 Appendix B: Frequently Asked Questions

The right place to look at the driver FAQs is the **Linux Ethernet Driver** document in the SDK.

7.6.1.2 Linux DPAA 1.x Ethernet Drivers

7.6.1.2.1 Introduction

This document describes the Linux drivers which enable support for Ethernet on processors with the Datapath Acceleration Architecture (DPAA). The focus is on the theory and operation behind using Ethernet. It provides only limited discussion of the BMan, QMan, and FMan, describing instead the layer of software which allows all of these to interoperate. For the purposes of this document, all these drivers will be referred to as the DPAA Ethernet Drivers. Enablement, configuration and debugging for all DPAA Ethernet Drivers are described in this document.

Purpose

The DPAA Ethernet Driver is meant to manage the use of the Datapath hardware for communication via the Ethernet protocol. This includes facilities for:

- Allocating buffer pools and buffers
- Allocating frame queues
- Assigning frame queues and buffer pools to specified FMan ports
- Transferring packets between frame queues and the Linux stack
- Controlling Link Management features

Overview

Ethernet in the Datapath is realized by interconnecting BMan, QMan, and FMan. The primary interaction for the DPAA Ethernet Driver is between the kernel and the QMan. Ethernet frames are delivered to the driver from the frame queue via the QMan portal, and the driver delivers Ethernet frames to the outgoing frame queue via the QMan portal. For some use cases, that is the only interaction.

Usually, the frame queues are connected to a FMan port. Each FMan port has two queues which must be assigned to them: a default queue and an error queue. This assignment can be specified in the device tree, or created dynamically by the driver on initialization.

The Ethernet frames are often stored in buffers which are associated with a BMan buffer pool. The driver sets up this pool, and either seeds it with buffers, or maps the buffers which are put into the pool. Depending on the pool, the buffers may be allocated and freed by the kernel during network activity, or they may be allocated once, and return to the pool when not in use by the Datapath hardware.

DPAA Ethernet Driver types

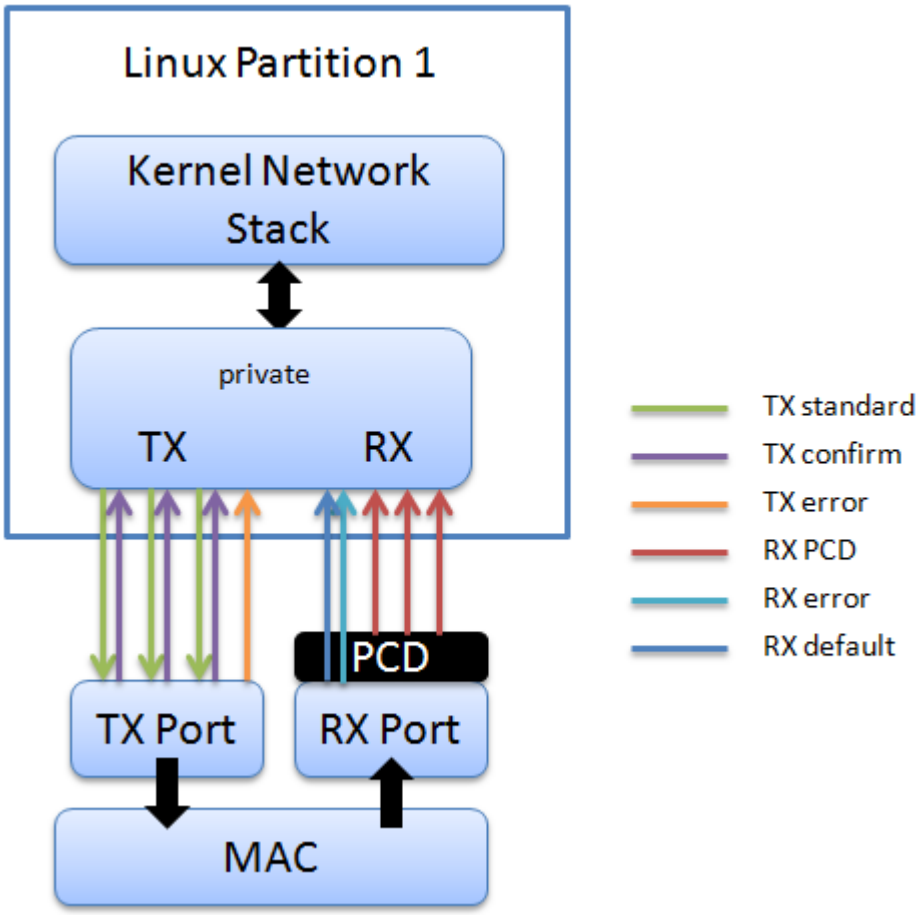
The complexity of DPAA allows a variety of possible use cases. Although speed is the key factor for performance in most use cases, customization and usability are preferred in others. Building a single Ethernet driver to cover all these tasks was, in the ever-changing world of the Linux kernel, a task that was becoming harder day-by-day. Instead we divided the single basic block into several specialized and simpler Ethernet drivers which can be combined in complex configurations:

- The Private DPAA Ethernet Driver resembles the common Linux Ethernet driver. It is highly improved for performance and uses all the features that DPAA offers;
- The Macless DPAA Ethernet Driver and the Shared DPAA Ethernet Driver flavors are used in virtualized multi-partition scenarios (with the Topaz Hypervizor) or in custom user-space traffic analyzer use cases;
- The Proxy DPAA Ethernet Driver will do the entire preliminary work in scenarios where all the control is passed to user-space, bypassing the standard Linux kernel standard.
- The Offload NIC Ethernet Driver is similar to the Macless Driver and can be used in the same scenarios. In addition, it has offloading capabilities that the Macless Driver lacks, and uses Offline Parsing/Host Command Ports.
- The MACsec Driver is used to configure the FMan MACsec hardware block that is capable of offloading the IEEE 802.1AE's protocol features.

7.6.1.2.2 Private DPAA Ethernet Driver

The Private DPAA Ethernet Driver manages the network interfaces which are fully owned by the Linux partition who runs them. Therefore, it is possible to take advantage of the DPAA facilities in order to increase the performance in both termination and forwarding scenarios.

The Private DPAA Ethernet Driver will be further referenced as the Private Driver.



7.6.1.2.2.1 Configuration

This chapter present the configuration options for the Private DPAA Ethernet Driver.

7.6.1.2.2.1.1 Device Tree Configuration

The compatible string used to define a private interface in device tree is „fsl,dpa-ethernet". The default structure for the device tree node that specifies a Private interface should be similar to the below snippet of a B4860QDS device tree node:

```
ethernet@4 {
        compatible = "fsl,b4860-dpa-ethernet", "fsl,dpa-ethernet";
        fsl,fman-mac = <&fm1mac5>;
};
```

"fsl,fman-mac" is the reference to the MAC device connected to this interface. This property is used to determine which RX and TX ports are connected to this interface.

Buffer pools

A single buffer pool is currently defined and used by all the Private interfaces. The buffer pool ID is dynamically allocated and provided by the Buffer Manager. The number and size of the buffers in the pool is decided internally by the Private driver therefore no device tree configuration is accepted.

Frame queues

The frame queues are allocated by the Private driver with IDs dynamically allocated and provided by the Queue Manager. The frame queues can also be statically defined using two additional device tree properties:

```
ethernet@0 {
        compatible = "fsl,b4860-dpa-ethernet", "fsl,dpa-ethernet";
        fsl,fman-mac = <&fm1mac5>;
        fsl,qman-frame-queues-rx = <0x100 1 0x101 1 0x180 128>;
        fsl,qman-frame-queues-tx = <0x200 1 0x201 1 0x300 8>;
};
```

Within the example above, a value of 0x100 was assigned to the RX error frame queue ID and 0x101 to the RX default frame queue ID. In addition, 128 PCD frame queues raging between 0x180-0x1ff are defined and assigned to the core-affined portals in a round-robin fashion.

There is exactly one RX error and one RX default queue hence a value of "1" for the frame count. Optionally, one can specify a value of "0" for the base to instruct the driver to dynamically allocate the frame queue IDs.

Within the example above, a value of 0x200 was assigned to the TX error queue ID and 0x201 to the TX confirmation queue ID. The third entry specifies the queues used for transmission.

If the qman-frame-queues-rx and qman-frame-queues-tx are not present in the device tree, the number of dynamically allocated TX queues is equal to the number of cores available in the partition.

7.6.1.2.2.1.2 Bootargs

Two bootarg parameters are defined for the Frame Manager driver but they also influence the behavior of the Private driver:

- fsl_fm_max_frm
- fsl_fm_rx_extra_headroom

fsl_fm_max_frm

The Frame Manager discards both Rx and Tx frames that are larger than a specific Layer2 MAXFRM value. The DPAA Ethernet driver won't allow one to set an interface's MTU too high such that it would produce Ethernet frames larger than MAXFRM. The maximum value one can use as the MTU for any interface is (MAXFRM - 22) bytes, where 22 is the size of an Eth+VLAN header (18 bytes), plus the Layer2 FCS (4 bytes).

Currently, the value of MAXFRM is set at boot-time and cannot be changed without rebooting the system.

The default MAXFRM is 1522, allowing for MTUs up to 1500. If a larger MTU is desired, one would have to reboot and reconfigure the system as described next. The maximum MAXFRM is 9600

The MAXFRM can be set in two ways:

- as a Kconfig option (CONFIG_FSL_FM_MAX_FRAME_SIZE):

```
Device Drivers
+-> Network device support
  +-> Ethernet driver support
    +-> Freescale devices
       +-> Frame Manager support
          +-> Freescale Frame Manager (datapath) support
            +-> Maximum L2 frame size
```

- as a bootarg:

- In no-HV scenarios: In the u-boot environment, add "fsl_fm_max_frm=<your_MAXFRM>" directly to the "bootargs" variable.
- In Hypervisor-based scenarios: Add or modify the "chosen" node in Hypervisor device tree having a "bootargs" property specifying "fsl_fm_max_frm=<your_MAXFRM>;".

Note that any value set directly in the kernel bootargs will override the Kconfig default. If not explicitly set in the bootargs, the Kconfig value will be used.

Symptoms of Misconfigured MAXFRM

MAXFRM directly influences the partitioning of FMan's internal MURAM among the available Ethernet ports, because it determines the value of an FMan internal parameter called "FIFO Size". Depending on the value of MAXFRM and the number of ports being probed, some of these may not be probed because there is not enough MURAM for all of them. In such cases, one will see an error message in the boot console.

fsl_fm_rx_extra_headroom

Configure this to tell the Frame Manager to reserve some extra space at the beginning of a data buffer on the receive path, before Internal Context fields are copied. This is in addition to the private data area already reserved for driver internal use. The option does not affect in any way the layout of transmitted buffers. The default value (64bytes) offers best performance for the case when forwarded frames are being encapsulated (e.g. IPSec).

The RX extra headroom can be set in two ways:

- as a Kconfig option (CONFIG_FSL_FM_RX_EXTRA_HEADROOM):

```
Device Drivers
+-> Network device support
  +-> Ethernet driver support
    +-> Freescale devices
      +-> Frame Manager support
        +-> Freescale Frame Manager (datapath) support
          +-> Add extra headroom at beginning of data buffers
```

- as a bootarg:
  - In no-HV scenarios: In the u-boot environment, add "fsl_fm_rx_extra_headroom=< your_rx_extra_headroom>" directly to the "bootargs" variable.
  - In Hypervisor-based scenarios: Add or modify the "chosen" node in Hypervisor device tree having a "bootargs" property specifying " fsl_fm_rx_extra_headroom=<your_rx_extra_headroom>;".

7.6.1.2.2.1.3 Kconfig Options

The private driver has a number of parameters which can be tuned at compile time from menuconfig. These can be found in:

```
Device Drivers
    +- Network Device Support
        +- Ethernet Driver Support
            +- Freescale Devices
                +- DPAA Ethernet
```

FSL_DPAA_ETH_JUMBO_FRAME - "Optimize for jumbo frames"

Optimizes the DPAA Ethernet driver throughput for large frames termination traffic (e.g. 4K and above).

On FMan v2 platforms this option requires modifications to the device tree, otherwise the ping will not work. Include 'qoriq-fman-0-chosen-fifo-resize.dtsi' in 'qoriq-fman-0.dtsi' and 'qoriq-fman-1-chosen-fifo-resize.dtsi' in 'qoriq-fman-1.dtsi'

```
/include/ "qoriq-fman-0-chosen-fifo-resize.dtsi"
```

Using this option in combination with small frames increases significantly the driver's memory footprint and may even deplete the system memory. Also, the skb truesize is altered and messages from the stack that warn against this are bypassed.

This option is not available on LS1043A platforms.

FSL_DPAA_1588 - "IEEE 1588-compliant timestamping"

Enables IEEE1588 support code.

FSL_DPAA_TS - "Linux compliant timestamping"

Enables Linux API compliant timestamping support.

FSL_DPAA_ETH_USE_NDO_SELECT_QUEUE - "Use driver's Tx queue selection mechanism"

The DPAA-Ethernet driver defines a ndo_select_queue() callback for optimal selection of the egress FQ. That will override the XPS support for this netdevice. If for whatever reason you want to be in control of the egress FQ-to-CPU selection and mapping, or simply don't want to use the driver's ndo_select_queue() callback, then unselect this and use the standard XPS support instead.

FSL_DPAA_ETH_MAX_BUF_COUNT - "Maximum nuber of buffers in private bpool"

Defaults to "128". The maximum number of buffers to be by default allocated in the DPAA-Ethernet private port's buffer pool. One needn't normally modify this, as it has probably been tuned for performance already. This cannot be lower than DPAA_ETH_REFILL_THRESHOLD.

FSL_DPAA_ETH_REFILL_THRESHOLD - "Private bpool refill threshold"

Defaults to "128". The maximum number of buffers to be by default allocated in the DPAA-Ethernet private port's buffer pool. One needn't normally modify this, as it has probably been tuned for performance already. This cannot be lower than DPAA_ETH_REFILL_THRESHOLD.

FSL_DPAA_CS_THRESHOLD_1G - "Egress congestion threshold on 1G ports"

The size in bytes of the egress Congestion State notification threshold on 1G ports. Ranges from 0x1000 to 0x10000000. Defaults to 0x06000000. This option can help when:

- the device stays congested for a prolonged time (risking the netdev watchdog to fire - see also the tx_timeout module param)
- preventing the Tx cores from tightly-looping (as if the congestion threshold was too low to be effective)

This might also implies some risks:

- affecting performance of protocols such as TCP, which otherwise behave well under the congestion notification mechanism
- running out of memory if the CS threshold is set too high

FSL_DPAA_CS_THRESHOLD_10G - "Egress congestion threshold on 10G ports"

The size in bytes of the egress Congestion State notification threshold on 10G ports. Ranges from 0x1000 to 0x20000000. Defaults to 0x10000000.

FSL_DPAA_INGRESS_CS_THRESHOLD - "Ingress congestion threshold on FMan ports"

The size in bytes of the ingress tail-drop threshold on FMan ports. Defaults to 0x10000000. Traffic piling up above this value will be rejected by QMan and discarded by FMan.

FSL_DPAA_ETH_DEBUGFS - "DPAA Ethernet debugfs interface"

This option compiles debugfs code for the DPAA Ethernet driver.

FSL_DPAA_ETH_DEBUG - "DPAA Ethernet Debug Support"

This option compiles debug code for the DPAA Ethernet driver.

7.6.1.2.2.1.4 ethtool Options

The private driver implements the following ethtool operations

```
-a --show-pause
    Queries the specified Ethernet device for pause parameter information.
-A --pause
    Changes the pause parameters of the specified private devices.
    rx on|off
        Specifies whether RX pause should be enabled.
    tx on|off
        Specifies whether TX pause should be enabled.
-k --show-features
    Lists the offloadable DPAA driver features. Specifies which features can be changed.
-K --features
    Changes a driver feature.
    feature on|off
        Specifies weather a certain feature should be enabled.
-s --change
    msglvl N
    msglvl type on|off ...
        Sets the driver message type flags by name or number. type names the type of message to
enable or disable; N  specifies  the new flags numerically.
-S --statistics
    Shows driver statistics and counters: interrupt counter, packet counters, error counters,
congestion state, and more.
--show-eee
    Shows the Energy-Efficient Ethernet configurations.
--set-eee
    Configures the EEE behavior.
```

7.6.1.2.2.2 Features

This chapter present the Private DPAA Ethernet Driver features.

7.6.1.2.2.2.1 Congestion Management

QMan offers 3 methods of managing congestion:

- WRED
- congestion state tail drop (CSTD)
- FQ tail drop (FQTD)

The Private driver implements CSTD both on TX and on RX. When the number of bytes residing in a TX FQ congestion group reaches a congestion threshold (high watermark), the QMan rejects any further incoming frames, until the sum of all the frames contained in the congestion groups drops under a low watermark, which is 7/8 of the high watermark. The high watermark can be configured from menuconfig. See section "Kconfig options" for more details.

7.6.1.2.2.2.1.1 Bootargs

Two bootarg parameters are defined for the Frame Manager driver but they also influence the behavior of the Private driver:

- fsl_fm_max_frm

- fsl_fm_rx_extra_headroom

fsl_fm_max_frm

The Frame Manager discards both Rx and Tx frames that are larger than a specific Layer2 MAXFRM value. The DPAA Ethernet driver won't allow one to set an interface's MTU too high such that it would produce Ethernet frames larger than MAXFRM. The maximum value one can use as the MTU for any interface is (MAXFRM - 22) bytes, where 22 is the size of an Eth+VLAN header (18 bytes), plus the Layer2 FCS (4 bytes).

Currently, the value of MAXFRM is set at boot-time and cannot be changed without rebooting the system.

The default MAXFRM is 1522, allowing for MTUs up to 1500. If a larger MTU is desired, one would have to reboot and reconfigure the system as described next. The maximum MAXFRM is 9600

The MAXFRM can be set in two ways:

- as a Kconfig option (CONFIG_FSL_FM_MAX_FRAME_SIZE):

```
Device Drivers
+-> Network device support
  +-> Ethernet driver support
    +-> Freescale devices
       +-> Frame Manager support
          +-> Freescale Frame Manager (datapath) support
            +-> Maximum L2 frame size
```

- as a bootarg:
  - In no-HV scenarios: In the u-boot environment, add "fsl_fm_max_frm=<your_MAXFRM>" directly to the "bootargs" variable.
  - In Hypervisor-based scenarios: Add or modify the "chosen" node in Hypervisor device tree having a "bootargs" property specifying "fsl_fm_max_frm=<your_MAXFRM>;".

Note that any value set directly in the kernel bootargs will override the Kconfig default. If not explicitly set in the bootargs, the Kconfig value will be used.

Symptoms of Misconfigured MAXFRM

MAXFRM directly influences the partitioning of FMan's internal MURAM among the available Ethernet ports, because it determines the value of an FMan internal parameter called "FIFO Size". Depending on the value of MAXFRM and the number of ports being probed, some of these may not be probed because there is not enough MURAM for all of them. In such cases, one will see an error message in the boot console.

fsl_fm_rx_extra_headroom

Configure this to tell the Frame Manager to reserve some extra space at the beginning of a data buffer on the receive path, before Internal Context fields are copied. This is in addition to the private data area already reserved for driver internal use. The option does not affect in any way the layout of transmitted buffers. The default value (64bytes) offers best performance for the case when forwarded frames are being encapsulated (e.g. IPSec).

The RX extra headroom can be set in two ways:

- as a Kconfig option (CONFIG_FSL_FM_RX_EXTRA_HEADROOM):

```
Device Drivers
+-> Network device support
  +-> Ethernet driver support
    +-> Freescale devices
      +-> Frame Manager support
        +-> Freescale Frame Manager (datapath) support
          +-> Add extra headroom at beginning of data buffers
```

- as a bootarg:

- In no-HV scenarios: In the u-boot environment, add "fsl_fm_rx_extra_headroom=< your_rx_extra_headroom>" directly to the "bootargs" variable.
- In Hypervisor-based scenarios: Add or modify the "chosen" node in Hypervisor device tree having a "bootargs" property specifying " fsl_fm_rx_extra_headroom=<your_rx_extra_headroom>;".

7.6.1.2.2.2.2 Scatter/Gather Support

On the Rx path, the first S/G entry is used to build the skb linear part and the other entries are used as fragments.

The Private driver can access the egress skbufs allocated in high memory (e.g. mapped directly from user-space, as is the case of the sendfile() system call). This eliminates the kernel need to copy such skbufs into newly-allocated low memory buffers, allowing zero-copy on the egress path.

7.6.1.2.2.2.3 Jumbo Frames Support

Termination traffic with large frames performs better if only linear skbs (and single buffer frames) are used. The driver has the option to allocate Rx buffers large enough to accommodate the entire frame (of max 9.6K).

This option needs to be used with caution, as the memory footprint can be a real problem when small frames are used.

The option can be enabled from the menuconfig option:

```
Device Drivers
    +-> Network Device Support
        +-> Ethernet Driver Support
            +-> Freescale Devices
                +-> DPAA Ethernet
                    +-> Optimize for jumbo frames
```

In addition to enabling this feature from menuconfig, the user is required to set the L2 maximum frame size to 9600, otherwise the configuration is not valid. This can be achieved by either setting fsl_fm_max_frm=9600 in the bootargs, or configuring CONFIG_FSL_FM_MAX_FRAME_SIZE from menuconfig. For more details see Bootargs on page 1016.

7.6.1.2.2.2.4 GRO/GSO Support

Generic Receive Offload (GRO) is tied to NAPI support and works by keeping a list of GRO flows per each NAPI instance. These flows can then "merge" incoming packets, until some termination condition is met or the current NAPI cycle ends, at which point the flows are flushed up the protocol stack. Flows merging several packets share the protocol headers and coalesce the payload (without memcopying it). This results in a CPU load decrease and/or network throughput increase. Packets which don't match any of the stored flows (in the current NAPI cycle) are sent up the stack via the normal, non-GRO path.

GRO is commonly supported in hardware as a set of "GRO assists", rather than full packet coalescing. The following features count as GRO assists:

- RX hardware checksum validation
- Receive Traffic Distribution (RTD)
- Multiple RX/TX queues
- Receive Traffic Hashing
- Header prefetching
- Header separation
- Core affinity
- Interrupt affinity

Note: With the exception of header separation, the DPAA platforms feature all other hardware assists. Most notably, they are implicitly achieved through the mechanisms that accompany PCDs.

Generic Segmentation Offload (GSO) is also a well-established feature in the Linux kernel. Normally, a TCP segment is composed in the Layer 4 of the Linux stack, based on the current MSS (Maximum Segment Size) connection setting. It has been observed, though, that delaying segmentation is a better approach in terms of CPU load, because fewer headers are processed. Linux has taken an optimization approach, called GSO, whereby the L4 segments are only composed just before they are handed over to the L2 driver.

GRO and GSO support are available by default in the Private driver and can be independently switched on and off at runtime, via *ethtool -k*.

Note: Older versions of ethtool don't support this. Ethtool version 3.0 does - and possibly others before it, too.

Generic optimizations that enhance the driver's performance in the general case also apply to the GRO/GSO-enabled driver. PCD support is therefore recommended in this regard. We have found that these optimizations yield the best results on 10Gbps traffic, and to a lesser extent (if any) on 1Gbps traffic. TCP tests, especially, can benefit from GRO by shedding CPU load and upping the network throughput. The improvements are the more visible with smaller network MTU - with MTU=1500 and below, the benefits are higher, while starting from MTU=4k they are no longer observable.

One optimization that boosts GSO performance is the zero-copy egress path. That is available thanks to the *sendfile()* system call, which may be used instead of the plain *send()* syscall, and which certain benchmark applications know about. Netperf for instance has *sendfile* support in its *TCP_SENDFILE* tests.

GRO and GSO are no panacea, one-button-fix-all kind of optimization. While under most circumstances they should be transparent (this being why GRO is by default enabled in the Linux kernel), there are scenarios and configurations where they may in fact under-perform. Traffic on 1Gbps ports sees little benefit from GRO/GSO. Also, if the Private Driver detects that PCDs are not in place, GRO is automatically by-passed.

7.6.1.2.2.2.5 Transmit Packet Steering

The Private driver exposes to the Linux networking stack a TX-multiqueue interface. This provides the stack with better control of the transmission queues and reduces the need for locking. The user may also control the mapping of egress FQs to the CPUs via a standard Linux feature called Transmit Packet Steering (XPS) and documented here: http://lwn.net/Articles/412062/

NOTE

The kernel transmission queues are different entities than the Private driver Frame Queues.

The Private driver, however, matches the two realms by mapping the DPAA FQs onto kernel's own queue structures. To that end, the Private driver provides a standard callback (net-device operation, or NDO) called ndo_select_queue(), which the stack can interrogate to find out the specific queue mapping it needs for transmitting a frame. The existence of that NDO (which is otherwise optional) overrides the kernel queue selection via XPS. This is why the Private driver provides a compile-time choice to disable the ndo_select_queue() callback, leaving it to the stack to choose a transmission queue.

To use the Private driver's builtin ndo_select_queue() callback, select the Kconfig option **FSL_DPAA_ETH_USE_NDO_SELECT_QUEUE**.

To disable the Private driver's queue selection mechanism and use XPS instead, unselect this Kconfig option. Further on, the users can configure their own txq-to-cpu mapping, as described in the LWN article above.

7.6.1.2.2.2.6 TX and RX Hardware Checksum

Introduction

The FMan block supports calculation of the L3 and/or L4 checksum for certain standard protocols.

This can be used, on the TX path, for calculating the checksum of the outgoing frame, and on the RX path, for validating the L3/L4 checksum of the incoming frame and making classification, or distribution decisions.

TX Checksum Support

On TX, the checksum computation is enabled on a per-frame basis by the Private driver. The TX checksum support for standard protocols is as follows:

Table 188. TX checksum support

Header	IPv4	IPv6	Other
IP header	yes	not available	no
TCP header	yes	yes	no
UDP header	yes	yes	no

NOTE

IP Header checksum capability also exists in SEC block (see IPSEC).

NOTE

Ethernet CRC is calculated on a per frame basis during frame transmission.

NOTE

The main precondition for TX checksum to be enabled in hardware is that IP tunneling must not be present (i.e., not GRE, not MinEnc, not IPIP). Other conditions pertain to the validity and integrity of the frame.

RX Checksum Support

This feature is disabled by default. In order to enable RX checksum computation for supported protocols, a PCD scheme must be applied to the respective RX port. In the current release, L3 and L4 are both enabled if a PCD is applied.

If enabled, L3 and L4 checksum validation is performed for TCP, UDP and IPv4.

NOTE

Controlling this feature via ethtool is not yet supported.

7.6.1.2.2.7 Pause Frames Flow Control

FMan supports IEEE 802.3x flow control. Whenever the FMan RX FIFO threshold is exceeded, FMan transmits PAUSE frames to the other peer on the link. In Linux, the transmission and reception of PAUSE frames can be enabled or disabled using ethool.

To display PAUSE frames settings in use for an interface

```
ethtool -a intf_name
```

Triggering PAUSE frames ON/OFF

PAUSE frames can be enabled/disabled on RX/TX using ethtool -A, like in the following examples

```
ethtool -A intf_name rx on
ethtool -A intf_name tx off
ethtool -A intf_name rx off tx off
```

Autonegotiation

Starting with SDK 1.6, the DPAA Private driver supports PAUSE frame autonegotiation.

When autonegotiation is enabled and the user enables/disables PAUSE frames on RX/TX, these will not automatically be triggered on/off. Instead, the local and the peer PAUSE symmetric/asymmetric capabilities will be considered. If the peer does not match the local capabilities, the following commands may have no effect:

```
ethtool -A intf_name rx on
ethtool -A intf_name rx off
ethtool -A intf_name tx on
ethtool -A intf_name tx ff
```

When autonegotiation is disabled, ethtool settings override the result of link negotiation.

PAUSE frame autonegotiation can also be enabled/disabled using ethtool -A

```
ethtool -A intf_name autoneg on
ethtool -A intf_name autoneg off
```

FMAN v3 platforms

On the following platforms: T4, B4, and T1040, 802.1Qbb Priority Flow Control is used instead of 802.3x PAUSE frames. The ethtool controls are the same, but the structure of the frames is different.

Find about DPAA Private support of PFC in the following section:

Priority Flow Control on page 1024

7.6.1.2.2.8 Priority Flow Control

Beginning with SDK 1.6, the DPAA Ethernet Driver offers experimental support for IEEE standards 802.1Qbb (Priority Flow Control) and 802.1p.

These standards aim to implement lossless Ethernet, in which the highest-priority classes of traffic benefit from maximum bandwidth and minimum delay. Up to 8 classes of service can be used, but only a minimum of 3 is required.

The terms “Class of Service (CoS)” and “priority” will be used interchangeably in this section.

802.1Qbb PFC frames are available only on platforms with FMan v3, namely T4, B4 and T1040. For the other platforms 802.3x PAUSE frames are used instead for Ethernet flow control.

Enabling PFC Support

To enable PFC support, enable the following options from menuconfig

```
Device Drivers
+ Network device support
  + Ethernet driver support
    + Freescale devices
      + Frame Manager support
        + Freescale Frame Manager (datapath) support
          + FMan PFC support (EXPERIMENTAL)
            + (3)     Number of PFC Classes of Service
            + (65535) The pause quanta for PFC CoS 0
            + (65535) The pause quanta for PFC CoS 1
```

```
            + (65535) The pause quanta for PFC CoS 2
```

The number of Classes of Service can range between 1 and 4. It defines the number of Work Queues used and the number of priorities that are set when a PFC frame is issued. 3 is the default value. Changing this value also changes the number of WQs and priorities.

The pause time can be adjusted for each CoS individually.

Enabling and disabling CoS and their pause time is unavailable at runtime. It is only possible at compile time in this release.

Selecting the Class of Service

When PFC support is enabled, the egress traffic flowing on a DPAA Private interface is distributed on the first 3 Work Queues of a TX port, namely WQ0, WQ1 and WQ2.

These function in strict priority. WQ0 has the highest priority and WQ2 the lowest priority. FMan cannot dequeue frames from WQ1 unless WQ0 is empty and from WQ2 unless WQ1 and WQ0 are empty.

The work queue a frame will be enqueued on is determined from the socket buffer priority. skb_prio is just an internal tag that the kernel applies to the frames on the egress path and is not visible to the receiver.

skb_prio	CoS
0	0
1	1
≥2	2

The default skb_prio is 0, which means all frames will be distributed to WQ0. skb_prio can be modified using a number of methods, including traffic control.

To edit a socket buffer's priority using tc, one needs to enable the following options from menuconfig.

```
Networking support
+ Networking options
  + QoS and/or fair queueing
    + Multi Band Priority Queueing (PRIO)
    + Elementary classification (BASIC)
    + Universal 32bit comparisons w/ hashing (U32)
    + Extended Matches
      + U32 key
    + Actions
      + SKB Editing
```

The following commands assign a skb_prio of 1 to traffic destined to TCP and UDP port 5000 and implicitly direct it on WQ1.

```
tc qdisc del dev fm1-mac9.0 root
tc qdisc add dev fm1-mac9.0 root handle 1: prio
tc filter add dev fm1-mac9.0 parent 1: protocol ip u32 match ip dport 5000 action skbedit
priority 1
```

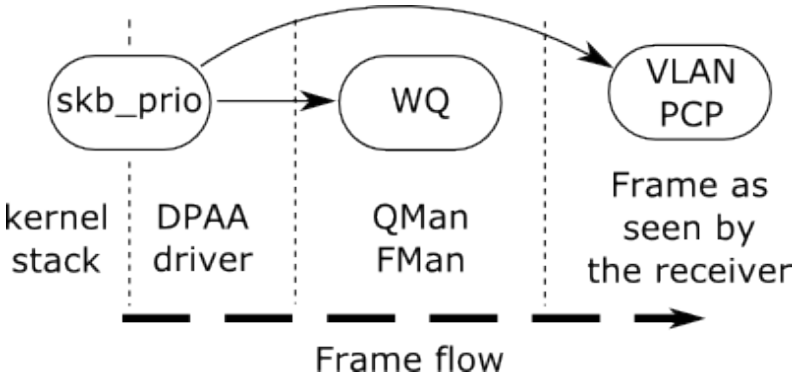
VLAN tagging

In order to be classified by the receiver according to 802.1p the egress traffic must be VLAN tagged, with the Class of Service contained in the PCP field. The PCP priority is also determined from skb_prio.

```
# create a subinterface of fm1-mac9, with VLAN ID 0
vconfig add fm1-mac9 0
# all frames tagged with skb_prio 1, will have PCP priority of 1.
vconfig set_egress_map fm1-mac9.0 1 1
```

If no mapping is specified the PCP field will be set to 0 by default.

The dependence between skb_prio, work queues and VLAN PCP priority:



Receiving PFC Frames

Unlike ordinary 802.3x PAUSE frames, PFC frames can selectively pause a certain priority/CoS.

WQ0 responds to PFC frames that have priority 0 set. Example: When a PFC frame arrives containing priority 0 and having a 100 pause time for priority 0, WQ0 i.e. all traffic from CoS 0 is ignored for dequeing for 100 bit times, and dequeing is done from WQ1 and WQ2.

Generating PFC frames

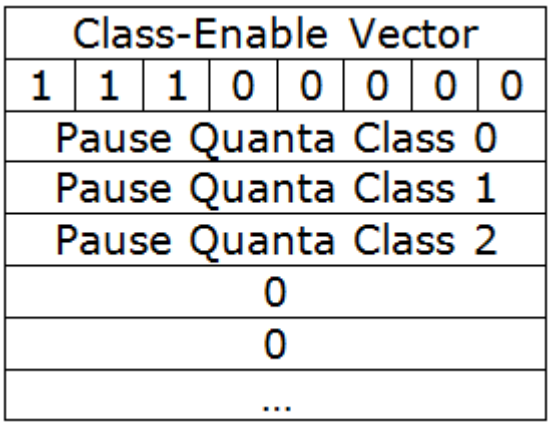
All DPAA Private interfaces share a single buffer pool which accounts for the buffers in which the frames are stored upon receiving.

When the Buffer Pool reaches the refill/depletion threshold, PFC frames are sent back to the sender in order to pause frames transmission and thus avoid frame loss.

FMan sends PFC frames that pause all Classes of Traffic defined. The only difference between the classes is the pause time.

The pause time can be configured from menuconfig. A pause time of 0 disables that Class of Service.

When the common buffer pool depletes, issued PFC frames look like this.



FMan issues either 802.1Qbb PFC or 802.3x PAUSE frames depending on the platform, but there is no difference in controlling their transmission and reception via ethtool. For more detatils, see the chapter on PAUSE frames support.

Enabling and disabling PFC using ethtool

FMan issues either 802.1Qbb PFC or 802.3x PAUSE frames depending on the platform, but there is no difference in controlling their transmission and reception via ethtool. For more detatils, see the chapter on PAUSE frames support.

Pause Frames Flow Control on page 1023

7.6.1.2.2.9 Core Affined Queues

The driver automatically creates 128 core-affined queues, intended to be used as RX PCD frame queues. These frame queues can be used in PCD configuration files to process certain types of frames on particular CPUs. In order to enhance the PCD files creation, the /etc/fmc/config/ directory from rootfs contains the default configuration and policy files for each platform.

The driver calculates the frame queue IDs based on the address of the MAC registers corresponding to the port using the following formula:

((MAC register address) & 0x1fffff) >> 6

Following are the values for various QorIQ DPAA platforms:

Table 189. FMAN v2 devices core affined queues

Interface	FQID base	P4080	P5020	P5040	P3041	P2041	T1040 (FMAN v3)
fm1-gb0	0x3800	Y	Y	Y	Y	Y	Y
fm1-gb1	0x3880	Y	Y	Y	Y	Y	Y
fm1-gb2	0x3900	Y	Y	Y	Y	Y	Y
fm1-gb3	0x3980	Y	Y	Y	Y	Y	Y
fm1-gb4	0x3a00		Y	Y	Y		Y
fm1-10g	0x3c00	Y	Y	Y			

Table continues on the next page...

Table 189. FMAN v2 devices core affined queues (continued)

Interface	FQID base	P4080	P5020	P5040	P3041	P2041	T1040 (FMAN v3)
fm2-gb0	0x7800	Y		Y			
fm2-gb1	0x7880	Y		Y			
fm2-gb2	0x7900	Y		Y			
fm2-gb3	0x7980	Y		Y			
fm2-gb4	0x7a00			Y			
fm2-10g	0x7c00	Y		Y			

Table 190. FMAN v3 devices core affined queues

Interface	FQID base	T4240	T4160	B4860	B4420	T2080
fm1-mac1	0x3800	Y	Y	Y	Y	Y
fm1-mac2	0x3880	Y	Y	Y	Y	Y
fm1-mac3	0x3900	Y	Y	Y	Y	Y
fm1-mac4	0x3980	Y	Y	Y	Y	Y
fm1-mac5	0x3a00	Y	Y	Y		
fm1-mac6	0x3a80	Y	Y	Y		
fm1-mac9	0x3c00	Y	Y	Y		Y
fm1-mac10	0x3c80	Y		Y		Y
fm2-mac1	0x7800	Y	Y			
fm2-mac2	0x7880	Y	Y			
fm2-mac3	0x7900	Y	Y			
fm2-mac4	0x7980	Y	Y			
fm2-mac5	0x7a00	Y	Y			
fm2-mac6	0x7a80	Y	Y			
fm2-mac9	0x7c00	Y	Y			
fm2-mac10	0x7c80	Y				

These queues are assigned to cores in a round-robin fashion. For instance, if there are 8 cores, 0x3800 will be serviced by core 0, 0x3801 by core 1, 0x3808 by core 0, etc. Currently, if one specifies extra RX PCD queues in the device tree, these queues will **also** be assigned in this round-robin fashion.

High Priority Core Affined Queues

Starting with SDK 2.0, a new set of RX PCD frame queues has been added, to aid in implementing complex traffic management scenarios. This set of frame queues has a higher priority than the normal RX PCD frame queues, and as such, traffic coming in on these frame queues has a higher precedence than the traffic coming on on the default RX PCD frame queues. One scenario where this is useful is the back-to-back IPsec testing scenario, where the encrypted traffic (RX) is desirable to have a higher priority than the plain text traffic.

The driver calculates the high priority frame queue IDs based on the address of the MAC registers corresponding to the port using the following formula:

65536 + ((MAC register address) & 0x1fffff) >> 6

Following are the values for various QorIQ DPAA platforms:

Table 191. FMAN v2 devices core affined queues

7.6.1.2.3 Ethernet Advanced Drivers

This current chapter describes advanced DPAA Ethernet driver configurations that can used instead of the default Private DPAA Ethernet driver.

NOTE

The DPAA Ethernet Advanced drivers are supported on the PPC platforms only.

7.6.1.2.3.1 Macless DPAA Ethernet Driver

Macless DPAA Ethernet Driver is a virtual Ethernet driver, hence not using an Ethernet controller to transmit frames. This type of DPAA Ethernet driver is a lightweight version of Private DPAA Ethernet Driver that does not have MAC device control primitives, but maintains the same structure. Macless DPAA Ethernet Driver is used with many different names, “macless”, “MAC-less” or previous SDK name, “Virtual Ethernet Driver”. This DPAA Ethernet Driver is used in simple scenarios, like communication between USDPAA and Linux or communication between two Linux partitions or more complex ones, like Offloading Architecture and Shared MAC scenarios. All these scenarios are presented in the Configuration chapter.

7.6.1.2.3.1.1 Configuration

The main configuration options are offered, like in any other embedded Linux Ethernet driver, by the device tree configuration and the common interface offered by the Linux kernel (ifconfig, ethtool, etc.). All configuration capabilities are presented in this chapter.

7.6.1.2.3.1.1.1 Device Tree Configuration

The Macless DPAA Ethernet Driver has *fsl,dpa-ethernet-macless* as compatible string in the device tree. For example, the standard structure for the device tree node that specifies a Macless interface in a B4860QDS device tree looks like:

```
ethernet@16 {
    compatible = "fsl,b4860-dpa-ethernet-macless", "fsl,dpa-ethernet-macless";
    fsl,bman-buffer-pools = <&bp10>;
    fsl,qman-frame-queues-rx = <0xfa0 0x8>;
    fsl,qman-frame-queues-tx = <0xfa8 0x8>;
    local-mac-address = [00 11 22 33 44 55];
};
```

The properties that a Macless Driver device tree node can have are:

- *fsl,bman-buffer-pools* - a list of buffer pools used by this interface. The Macless DPAA Ethernet Driver will use only static defined buffer pools because the frames are transmitted between different memory spaces. See Note 2 for more details;
- *fsl,qman-frame-queues-rx* - a list of base/count pairs of frame queues that will transmit frames to the Macless Driver. These queues are initialized as PCD queues. By default there are 8 Rx queues because there are 8 CPUs on B4860QDS boards;
- *fsl,qman-frame-queues-tx* - a list of base/count pairs of frame queues that fetch the frames from Macless Driver to the next hardware device (TX Port, O/H Port) or to another Macless Driver. These queues will only be created, but not initialized. It is the role of the next software module in the data path to initialize these queues;
- *local-mac-address* - this is a virtual L2 address used to identify the driver in the Linux kernel network stack.

Note 1: The Macless DPAA Ethernet Driver does not have a MAC device to control. Because of this the “fsl,fman-mac” property is missing from the device tree specification. This property exists for all other DPAA Ethernet Drivers.

Note 2: A static defined buffer pool should be declared as exemplified below for a B4860QDS board:

```
bp7: buffer-pool@7 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <7>;
    fsl,bpool-ethernet-cfg = < 0 256 0 192 0 0x40000000>;
    fsl,bpool-thresholds = <0x400 0xc00 0x0 0x0>;
};
```

Although the above device tree node is a representation for the BMan Driver, *fsl,bpool-ethernet-cfg* property is parsed solely by the DPAA Ethernet Driver that has a reference to this buffer pool. This property has the following meaning:

```
fsl,bpool-ethernet-cfg = <count size base_address>;
```

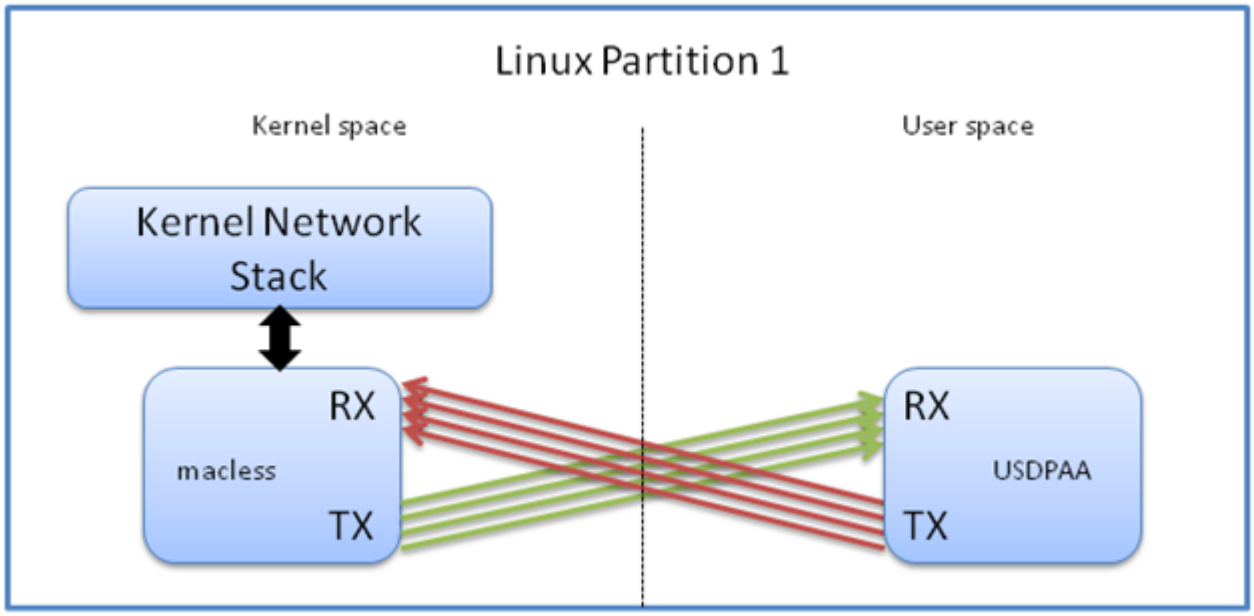
- *count* - represents the number of buffers from the buffer pool;
- *size* - buffer size;
- *base_address* - physical address of the buffer pool. Because two Linux partition have different memory spaces, this physical address will be mapped in both partitions. In scenarios where a single partition is used, this address will be invalid, particularly 0, and a dynamic mapping from user-space to kernel-space will be done.

The example above declares a buffer pool with buffer pool ID 7, and describes a pool with 256 192-byte buffers, occupying the memory region from 0x40000000 to 0x40000000 + 256*192. The reason there are two numbers per each of *count*, *size*, and *base_address* is that we support 36-bit addresses on the P4080 (and 64-bit on P5020). It should be noted that the size of those parameters should be set by the root node's *#address-cells* and *#size-cells* properties. The *fsl,bpool-ethernet-seeds* property is there to tell the driver which is using the buffer pool whether to seed the pool with the declared buffers, or not.

The above generic device tree structure can be modified, depending on the scenario that Macless Ethernet Driver is used into. These scenarios are:

Communication inside a single Linux partition between USDPAA and Linux Network Stack through a Macless DPAA Ethernet Driver.

For some applications, USDPAA needs the benefits and flexibility of Linux networking capabilities. To connect to the Linux Network Stack, it uses a Macless DPAA Ethernet Driver. This scenario is represented in the following picture:



The device tree configuration should be similar to the one below extracted from a B4860QDS device tree configuration:

```
ethernet@16 {
    compatible = "fsl,b4860-dpa-ethernet-macless", "fsl,dpa-ethernet-macless";
    fsl,bman-buffer-pools = <&bp16>;
    fsl,qman-frame-queues-rx = <0xfa0 0x8>;
    fsl,qman-frame-queues-tx = <0xfa8 0x8>;
    local-mac-address = [00 11 22 33 44 55];
};

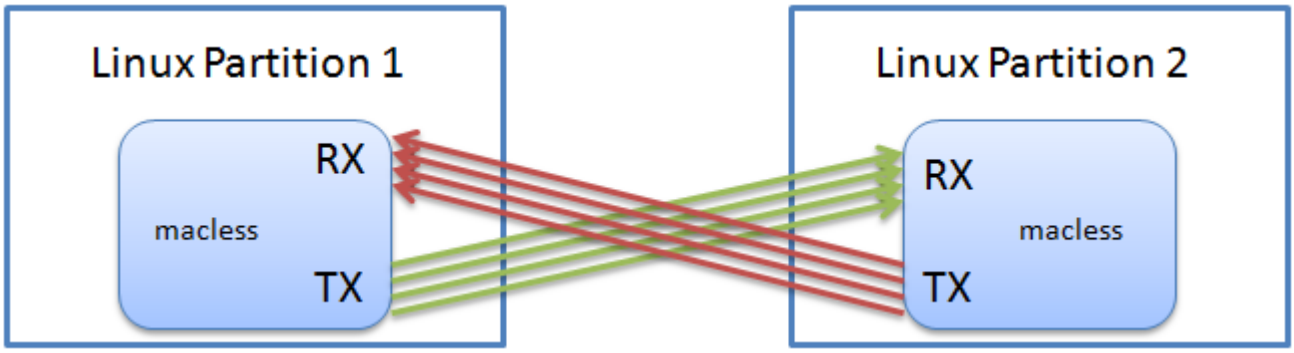
bp16: buffer-pool@16 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <0x10>;
    fsl,bpool-ethernet-cfg = <0x0 0x800 0x0 0x6c0 0x0 0x0>;
    fsl,bpool-thresholds = <0x100 0x300 0x0 0x0>;
};
```

In the above device tree snippet, there are two device tree nodes, one for the Macless DPAA Ethernet Driver and one for the static definition of the buffer pool used in the transmission. USDPAA will also parse these nodes and it will manage the buffer pool used in the communication. Additionally, because a Macless DPAA Ethernet Driver initializes only its RX frame queues, USDPAA has the additional role of initializing Macless DPAA Ethernet Driver's TX frame queues also. Another important configuration is the base address of the buffer pool. Because the communication occurs inside a single Linux partition, there is no need for the buffer pool to advertise its physical address, hence the 0 address representing an invalid physical address. The mapping of the Macless kernel memory space to USDPAA's user-space memory space is done through the kernel *kmap*/*kunmap* primitives.

Communication between two Linux partitions through a Macless DPAA Ethernet Driver

With the help of the NXP virtualization solution, called Topaz, two or more partitions can run on the same board. Every communication between partitions is supervised by Topaz. Although network communication between partitions is possible through external connections, one direct connection can be created inside the board using Macless DPAA Ethernet Driver

and hardware frame queues. To create a fast networking communication between partitions, two or more Macless DPAA Ethernet Drivers should be used as depicted below:



The TX frame queues from one partition should be the RX frame queues from the other partition. The device tree nodes in each partition are represented below.

First partition's device tree representation:

```
dpa-ethernet@10 {
    compatible = "fsl,p4080-dpa-ethernet", "fsl,dpa-ethernet-macless";
    fsl,qman-frame-queues-rx = <0x4000 8>;
    fsl,qman-frame-queues-tx = <0x4008 8>;
    local-mac-address = [02 00 c0 a8 6f fe];
    fsl,bman-buffer-pools = <&bp10>;
};
bp10: buffer-pool@10 {
    compatible = "fsl,b4080-bpool", "fsl,bpool";
    fsl,bpid = <10>;
    fsl,bpool-ethernet-cfg = <0 0x80 0 1728 0 0x80000000>;
    fsl,bpool-ethernet-seeds;
};
```

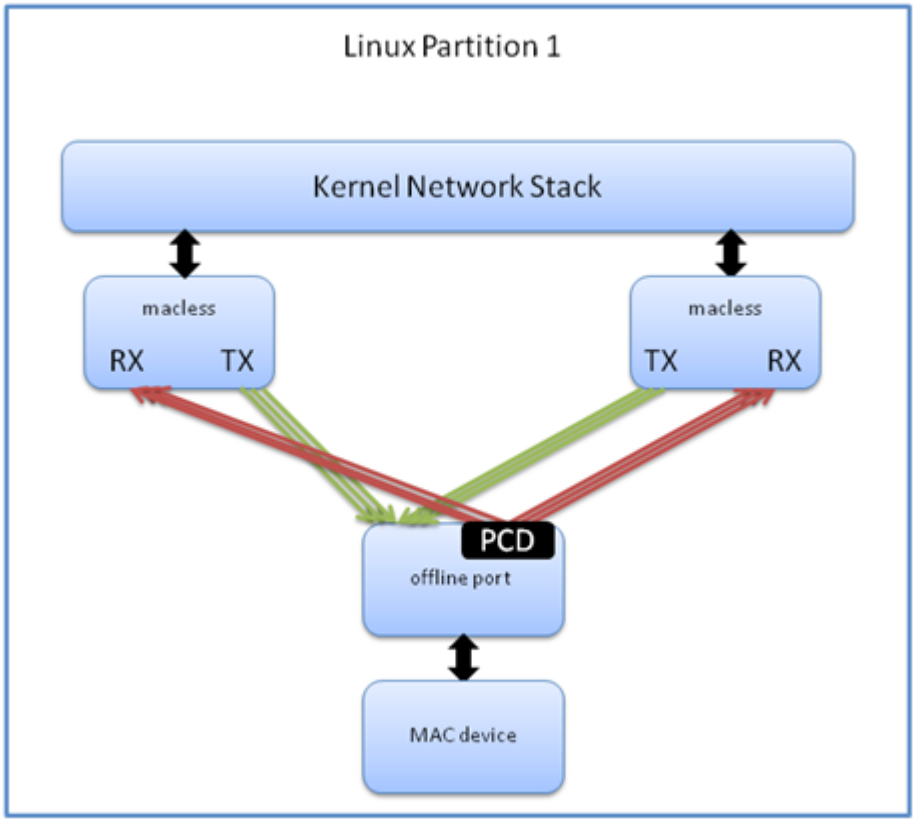
Device tree from the second partition:

```
dpa-ethernet@10 {
    compatible = "fsl,p4080-dpa-ethernet", "fsl,dpa-ethernet-macless";
    fsl,qman-frame-queues-rx = <0x4008 8>;
    fsl,qman-frame-queues-tx = <0x4000 8>;
    local-mac-address = [02 00 c0 a8 79 fe];
    fsl,bman-buffer-pools = <&bp10>;
};
bp10: buffer-pool@10 {
    compatible = "fsl,b4080-bpool", "fsl,bpool";
    fsl,bpid = <10>;
    fsl,bpool-ethernet-cfg = <0 0x80 0 1728 0 0x80000000>;
};
```

In the above configuration there are 8 TX frame queues and 8 RX frame queues used in interchangeable roles in each partition. Both interfaces share one statically defined buffer pool. The same buffer pool definition should be used in both partitions, except for the *fsl,bpool-ethernet-seeds* property. In order to easily map from one memory address space from one partition to another partition a valid physical base address must be configured. The mapping from physical address to each partition's virtual kernel address is done with *ioremap* kernel primitive. The seeding of the buffer pool will be done by the Macless DPAA Ethernet Driver from the partition that has *fsl,bpool-ethernet-seeds* in its device tree node. In the above configuration, the first partition will seed the buffer pool.

Communication inside a Linux partition using Offline Ports and Macless DPAA Ethernet Driver

DPAA has many hardware offload capabilities. One of them is the Offline Parsing/Host Command Port. This hardware portal can fetch traffic from multiple destinations (such as Macless DPAA Ethernet Drivers) and send traffic through many configurable destinations, like MAC devices. For example, this scenario can be used to offload into DPAA stack functionality, like IPSec, IP fragmentation and reassembly or TCP segmentation and reassembly.



Because the Macless DPAA Ethernet Driver does not have an Ethernet controller attached, it can be used in many hardware configuration scenarios similar to the one used in the figure above. In order to do that, special attention should be paid to Frame Queues configuration and the Buffer Pool configuration.

Communication of different Linux partitions through a single MAC device, using Macless DPAA Ethernet Driver and Shared DPAA Ethernet Driver

In this scenario, a new type of DPAA Ethernet Driver is needed. This is called Shared DPAA Ethernet Driver and its configuration is described in Shared DPAA Ethernet Driver configuration chapter. Shared DPAA Ethernet Driver together with Macless DPAA Ethernet Driver are used in a typical shared MAC scenario, described in the Shared DPAA Ethernet Driver chapter.

7.6.1.2.3.1.1.2 Configuration available through Linux interfaces

Because Macless driver does not manage a MAC device, some *ethtool* and *ifconfig* options will not be available. All Layer 3 configurations, like setting an IP address, are generally available.

7.6.1.2.3.1.2 Features

This chapter describes the features of the Macless DPAA Ethernet Driver, their configuration options, fine-tuning and known limitations.

MAC device control capability

As of SDK 1.5, the Macless DPAA Ethernet Driver is capable of controlling a MAC device on behalf of an user-space application, like USDPAA. This will add an additional control mechanism to the amount of customization available through

Macless DPAA Ethernet Driver. For example, in the scenario depicted in *Communication inside a Linux partition using Offline Ports and Macless DPAA Ethernet Driver* scenario, it is desired that one of the Macless DPAA Ethernet Drivers should control the MAC device.

Some of the MAC devices are initialized by the Proxy DPAA Ethernet Driver to be used by USDPAA. By setting the following attribute in the device tree specification of the Macless DPAA Ethernet Driver

```
proxy = <&proxy1>;
```

a reference to the MAC device initialized by the Proxy driver can be obtained in the Macless driver. This will allow basic operations regarding L2 address of the MAC device using Macless driver Linux interface. Currently, the supported operations are enablement and disablement of the MAC device and setting multicast or unicast addresses.

Scatter/Gather

The current implementation supports DPAA Scatter/Gather only on the RX path. Therefore, the Macless DPAA Ethernet Driver will know how to handle Scatter/Gather frames, but the driver does not advertise TX Scatter/Gather capability to the Linux Network Core and only linear socket buffers will be accepted on the TX path.

Hardware checksum

As previously presented in the Private DPAA Ethernet Driver's Features chapter, the FMan supports computation of the L3 and/or L4 checksum for certain protocols (mainly TCP/IP and UDP/IP). Because the same transmission procedure is used to activate hardware checksum in both Private and Macless drivers, the same limitations presented in the *Private DPAA Ethernet Driver* chapter apply to Macless driver. Currently, at frame reception, the Macless Driver is not able to fetch the checksum computed by FMan.

7.6.1.2.3.2 Shared DPAA Ethernet Driver

Shared DPAA Ethernet Driver is similar to Macless Driver, only it has a MAC device in its control. Although it has similar structures with Private DPAA Ethernet Driver, it does not have the same optimization and feature set available. This is because it can be used in pair with a Macless Driver from another Linux partition or it can be used in pair with USDPAA. Therefore, it needs portability and easiness, qualities that Private DPAA Ethernet Driver sacrifices in exchange for higher performance. Shared DPAA Ethernet Driver is also known as *shared* or *Shared Controller* in the previous SDK release. In this document Shared DPAA Ethernet Driver will be referred as *Shared Driver*. This flavor of DPAA Ethernet Driver is used in two scenarios. First, when a MAC device is shared between different partitions under a Hypervisor and second, when a MAC device is shared with a User Space DPAA application in a single Linux partition. These use cases are presented in the Configuration chapter below.

7.6.1.2.3.2.1 Configuration

The main configuration options are offered by the device tree configuration and common Linux interfaces (*ifconfig*, *ethtool*, etc.). All configuration capabilities are presented in this chapter.

7.6.1.2.3.2.1.1 Device Tree Configuration

The Shared Driver has the *fsl,dpa-ethernet-shared* string as compatible string in the device tree. Therefore, the standard structure for the device tree node that specifies a Shared interface should be similar to the below snippet of a B4860QDS device tree node:

```
ethernet@9 {
    compatible = "fsl,b4860-dpa-ethernet-shared", "fsl,dpa-ethernet-shared";
    fsl,fman-mac = <&fm1mac10>;
    fsl,bman-buffer-pools = <&bp17>;
    fsl,qman-frame-queues-rx = <0x5e 1 0x5f 1 0x2000 3>;
    fsl,qman-frame-queues-tx = <0 1 0 1 0x3000 8>;
};
```

Following are the properties of a Shared Driver's device tree node:

- *fsl,fman-mac* - this is the MAC device reference that is in Shared Driver's control;

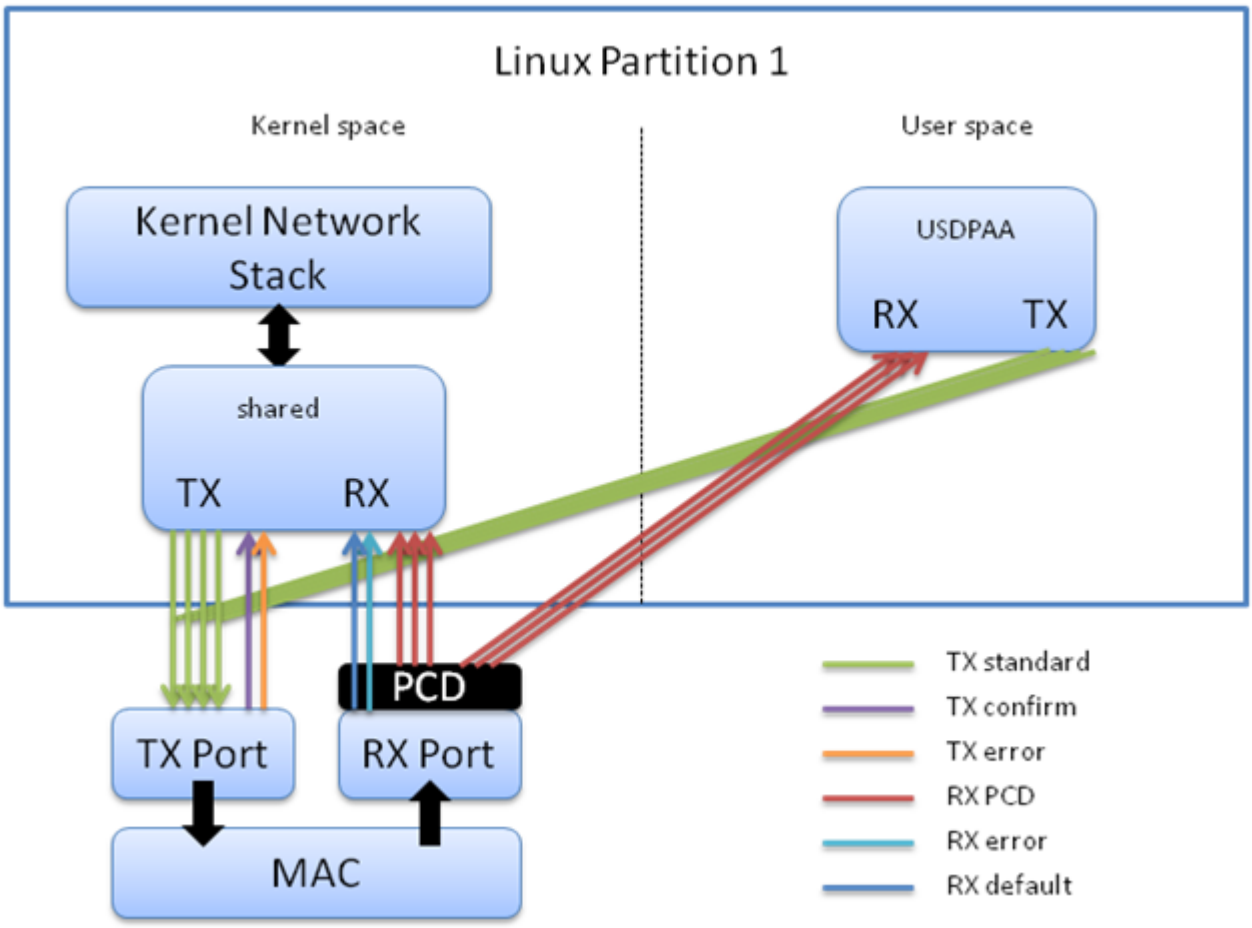
- *fsl,bman-buffer-pools* - as in Macless Driver specification this is a list of buffer pools used by this interface. Since the frames are transmitted between different memory spaces, Shared Driver will use only static defined buffer pools in both use cases;
- *fsl,qman-frame-queues-rx* - a list of base/count pairs of frame queues from which the Shared Driver dequeues frames. Because the Shared Driver has a MAC device in its control, the device tree format of the frame queues is similar to the Private Driver's device tree format. The MAC device must have at least two types of frame queues specified at initialization. These are the error frame queue which is the frame queue on which received erroneous frames will be placed and the default frame queue which is the frame queue where the frame will be placed if no other frame queue is selected for transmission. The next batch represents the PCD queues. These queues will be used by the PCD rules configured by the user. The above device tree example defines one error queue with ID 0x5e, one default queue with ID 0x5f and 3 configurable PCD queues, 0x2000, 0x2001, 0x2002;
- *fsl,qman-frame-queues-tx* - a list of base/count pairs of frame queues used by the Shared Driver send the frames to the MAC device. As in Private DPAA Ethernet Driver, these are the TX error frame queue, TX confirmation frame queue and the standard TX frame queues. In the above example, a value of 0 for TX error and TX confirmation queues enables the dynamic allocation of values for queues' IDs, letting the QMan assign available values. Besides one dynamic TX error and one dynamic TX confirmation queue, 8 standard TX queues will be created, with IDs between 0x3000 and 0x3007. It is recommended to specify up to NR_CPUs frame queues and have a direct mapping between frame queue and CPU. In the above example, B4860QDS has 8 CPUs.

Note 1: The static defined buffer pool has the same representation as defined in the Macless Driver Configuration chapter. As stated above, the Shared Driver will be used in two different scenarios. Each scenario involves entities that have different memory address spaces, but must share the buffer pools' configuration. This is the reason for not using dynamic buffer pools, like in Private DPAA Ethernet Driver.

Following are the scenarios in which Shared Driver can be used:

USDPAA and Linux stack communicating through a single MAC device, using Shared Driver inside a single Linux partition

USDPAA applications handle only a certain type of traffic, the rest of the packets being handled by Linux Network Stack. The simplest solution is to have a Shared Driver that knows about the traffic division. In order to split the traffic, PCD rules must be applied on the incoming port. This scenario is presented below.



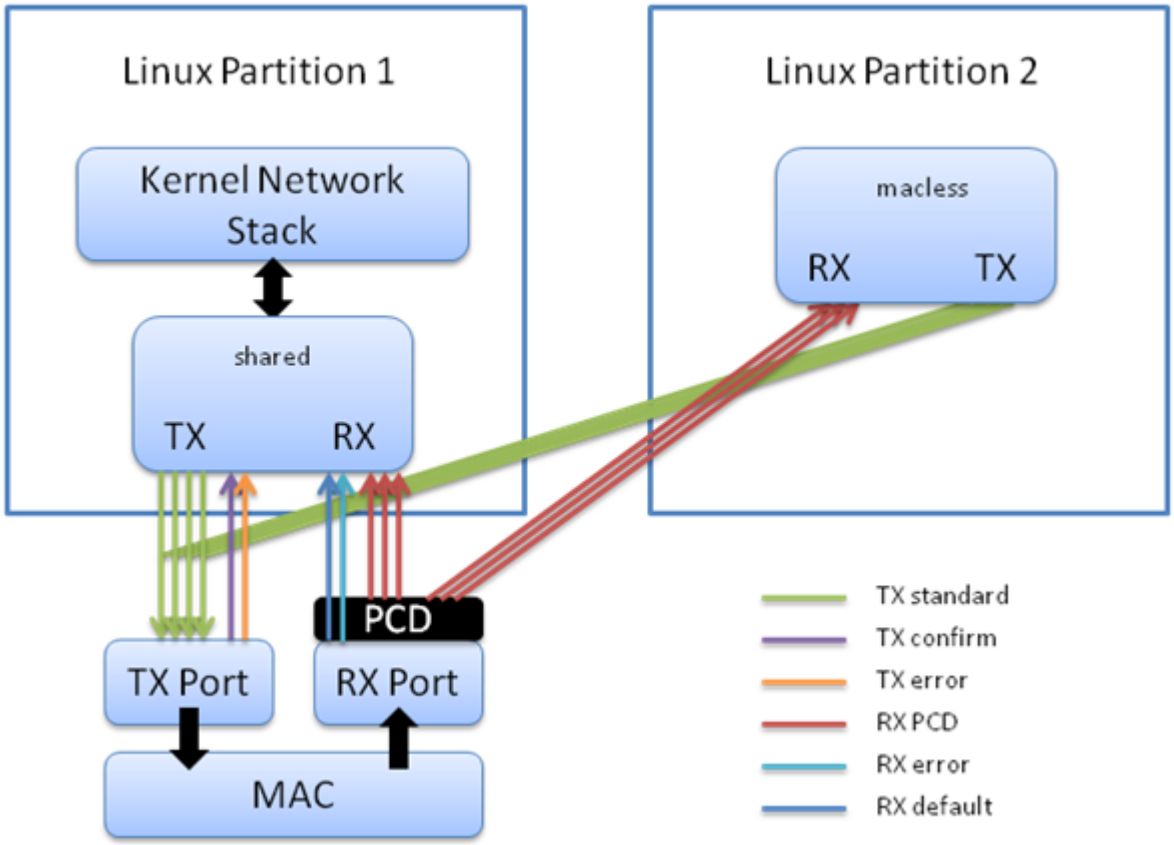
The device tree configuration should be similar to the one below extracted from a B4860QDS device tree configuration.

```
ethernet@9 {
    compatible = "fsl,b4860-dpa-ethernet-shared", "fsl,dpa-ethernet-shared";
    fsl,bman-buffer-pools = <&bp17>;
    fsl,qman-frame-queues-rx = <0x5e 1 0x5f 1 0x2000 3>;
    fsl,qman-frame-queues-tx = <0 1 0 1 0x3000 8>;
    fsl,fman-mac = <&fm1mac10>;
};
bp17: buffer-pool@17 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <17>;
    fsl,bpool-ethernet-cfg = <0 2048 0 1728 0 0>;
    fsl,bpool-thresholds = <0x100 0x300 0x0 0x0>;
};
```

In the above device tree snippet, there are two device tree nodes, one for the Shared Driver and one for the static definition of the buffer pool used for transmission. In this scenario, USDPAA allocates the buffer pool used in the communication, therefore the above device tree nodes will be parsed by USDPAA also. One important configuration is the base address of the buffer pool. Because the communication occurs inside a single Linux partition, there is no need for the buffer pool to advertise its physical address, hence the 0 address representing an invalid physical address. Because the buffers are allocated by USDPAA, these are in the virtual address space of USDPAA. The mapping of the USDPAA's user-space memory space to kernel space is done through kernel *kmap*/*kunmap* primitives.

Shared communication between two Linux partitions through a single MAC device using a Shared Driver and Macless Driver

In scenarios with multiple Linux partitions managed by a Hypervisor, it is sometimes desired to split one MAC device's traffic between partitions. To achieve this, one partition should use the Shared Driver which will manage the MAC device and the other Linux partition should use the Macless Driver as depicted below.



In scenarios with multiple Linux partitions managed by a Hypervisor, it is sometimes desired to split one MAC device's traffic between partitions. To achieve this, one partition should use the Shared Driver which will manage the MAC device and the other Linux partition should use the Macless Driver as depicted below.

First partition:

```
dpa-ethernet@4 {
    compatible = "fsl,b4860-dpa-ethernet", "fsl,dpa-ethernet-shared";
    fsl,qman-frame-queues-rx = <0x340 1 0x341 1 0x320 8>;
    fsl,qman-frame-queues-tx = <0x342 1 0x343 1 0x300 8>;
    fsl,bman-buffer-pools = <&part1_bp11>;
};
part1_bp11: buffer-pool@11 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <11>;
    fsl,bpool-ethernet-cfg = <0 0x80 0 1728 0 0x80036000>;
    fsl,bpool-ethernet-seeds;
};
```

Second partition:

```
dpa-ethernet@20 {
    compatible = "fsl,b4860-dpa-ethernet", "fsl,dpa-ethernet-macless";
    fsl,qman-frame-queues-rx = <0x350 8>;
    fsl,qman-frame-queues-tx = <0x300 8>;
    local-mac-address = [02 00 c0 a8 a1 fe];
```

```
    fsl,bman-buffer-pools = <&part2_bp11>;
};
part2_bp11: buffer-pool@11 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <11>;
    fsl,bpool-ethernet-cfg = <0 0x80 0 1728 0 0x80036000>;
};
```

In the above configuration the standard 8 TX queues from the first partition are the same as the standard 8 TX queues from the second partition. Both interfaces share one static buffer pool and the same buffer pool definition is used in both partitions. As in other multi-partition scenarios, the buffers are allocated from the physical memory, indicated by the base address parameter. In the above configuration, the base address is 0x80036000. When a frame arrives to one partition, its address should be mapped to partition's kernel address space. The mapping from physical address to each partition's virtual kernel address is done with *ioremap* kernel primitive. The seeding of the buffer pool will be done by the Shared Driver from the first partition as it has *fsl,bpool-ethernet-seeds* in its device tree node.

7.6.1.2.3.2.1.2 Configuration available through Linux interfaces

The Shared Driver has the same data structures as the Private Driver, therefore it has the same configuration capabilities available through standard Linux interfaces (*ethtool*, *ifconfig*, etc.) as the Private Driver.

7.6.1.2.3.2.2 Features

The same transmission primitives are used both by the Shared and the Macless driver. Therefore, as stated in the Macless Driver's *Features* chapter, the Shared Driver is capable of receiving Scatter/Gather frames and is able to offload checksum computation on transmission. On reception, Shared Driver is not able to fetch the checksum computed by FMan.

7.6.1.2.3.3 Proxy DPAA Ethernet Driver

USDPAA applications achieve high speeds for particular types of traffic, bypassing the processing done by the Linux Network Stack. These applications reside in user-space and need kernel-space configuration in order to initialize the necessary hardware modules used along the data path. The configuration of buffer pools and frame queues and initialization of MAC devices used by the USDPAA are delegated to the Proxy DPAA Ethernet Driver. This type of DPAA Ethernet Driver runs once at system startup and does not have a data structure at run-time like the other DPAA Ethernet Drivers. Proxy DPAA Ethernet Driver is used with many different names, *proxy* or *Initialization Manager*, as it was known in the previous SDK release. In this document, it will be referred to as *Proxy Driver*.

7.6.1.2.3.3.1 Configuration

The only configuration for this type of DPAA Ethernet Driver can be made through device tree node configuration.

7.6.1.2.3.3.1.1 Device Tree Configuration

The Proxy Driver has *fsl,dpa-ethernet-init* as compatible string in the device tree. For example, the standard structure for the device tree node that specifies a Proxy interface in a B4860QDS device tree is depicted below:

```
ethernet@8 {
    compatible = "fsl,b4860-dpa-ethernet-init", "fsl,dpa-ethernet-init";
    fsl,fman-mac = <&fm1mac10>;
    fsl,bman-buffer-pools = <&bp7 &bp8 &bp9>;
    fsl,qman-frame-queues-rx = <0x5c 0x1 0x5d 0x1>;
    fsl,qman-frame-queues-tx = <0x7c 0x1 0x7d 0x1>;
};
```

All the above properties are the same as those used by Shared Driver that has a MAC device reference:

- *fsl,fman-mac* - this is the MAC device reference that will be initialized by the Proxy Driver;

- *fsl,bman-buffer-pools* - each port needs a buffer pool to get buffers from. Since it has a MAC device reference, Proxy Driver will need a statically defined buffer pool. This buffer cannot be dynamically created because the Proxy Driver does not know the memory address space of the software entity that will use the initialized infrastructure.
- *fsl,qman-frame-queues-rx* - a list of base/count pairs of frame queues. The device tree format of this property is the same as the format used in Private and Shared Drivers. The MAC device must have at least two queues specified at initialization. These are:
  - error queue which is the queue on which received erroneous frames will be placed;
  - default queue which is the queue where the frame will be placed if none of the PCD queues is selected for transmission;
  - PCD queues are optional. These queues will be used by the PCD rules configured by the user. In the above device tree example no PCD queues are defined.
- *fsl,qman-frame-queues-tx* - a list of base/count pairs of frame queues used by the software entity to send the frames to the MAC device. As in Private or Shared Drivers, these are TX error queue, TX confirmation queue and standard TX queues. In the above example, there are no standard TX queues.

Note 1: The statically defined buffer pools have the same device tree structure as that used for other DPAA Ethernet Drivers.

The classical scenario where a Proxy Driver is used is the one in which it initializes the MAC device on behalf of USDPAA inside a single Linux partition. Another scenario is where the initialization is made on behalf of another software entity or even another Linux partition.

7.6.1.2.3.3.2 Features

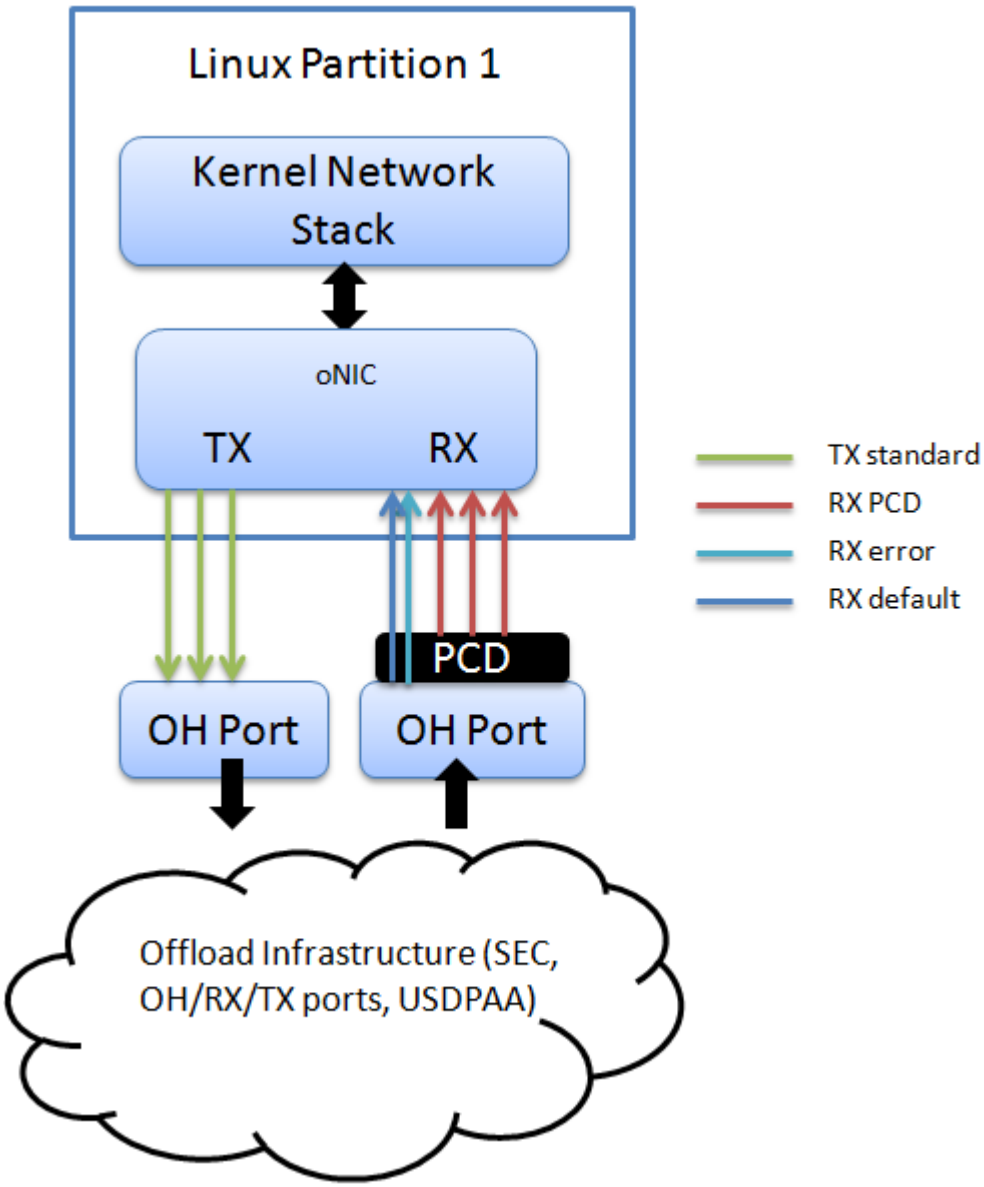
Proxy Driver is used only to initialize some of the hardware modules and does not have advanced features like other DPAA Ethernet Drivers.

7.6.1.2.3.4 Offload NIC Ethernet Driver

Offload NIC Ethernet Driver is a virtual Ethernet driver, similar to Macless. This DPAA Ethernet Driver has CSUM offload and zero-copy, features that cannot be achieved with Macless. This DPAA Ethernet Driver is used in complex scenarios, like IPSec offload or communication with USDPAA where memory space isolation between kernel space and underlying offload architecture (OH ports, SEC, USDPAA) space is needed. Some of these scenarios are presented in the Configuration chapter.

This type of DPAA Ethernet Driver needs two OH ports with VSP capabilities enabled in order to achieve zero-copy.

Offload NIC Ethernet Driver will be referred in this documentation as "oNIC".



7.6.1.2.3.4.1 Configuration

The main configuration options are offered, like in any other embedded Linux Ethernet driver, by the device tree configuration and the common interface offered by the Linux kernel (ifconfig, ethtool, etc.). All configuration capabilities are presented in this chapter.

7.6.1.2.3.4.1.1 Device tree configuration

oNIC Ethernet Driver has *fsl,dpa-ethernet-generic* as compatible string in the device tree. For example, the standard structure for the device tree node that specifies an oNIC interface in a B4860QDS device tree looks like:

```
ethernet@16 {
    compatible = "fsl,b4860-dpa-ethernet-generic", "fsl,dpa-ethernet-generic";
    fsl,qman-frame-queues-tx = <4000 8x8>;
    fsl,qman-frame-queues-rx = <4008 8x8>;
    fsl,oh-ports = <&oh1 &oh2>;
    fsl,disable_buff_dealloc;
    local-mac-address = [00 11 22 33 44 55];
};
```

The properties that the oNIC device tree node can have are:

- *fsl,qman-frame-queues-tx* - a list of base/count pairs of frame queues that forwards the frame buffers generated by oNIC to the Tx O/H port; it is recommended to have NR_CPUS Tx frame queues;
- *fsl,qman-frame-queues-rx* - a list of base/count pairs of frame queues called PCD queues that fetch the frames from the Rx O/H port to oNIC; besides these queues, oNIC uses the default and the error queue of the Rx O/H port; the PCD queues can be used in PCD schemes applied on the Rx O/H port.
- *fsl,oh-ports* – links to O/H port device tree representation. The first value is a reference to the Rx O/H port used on ingress path, the second value is a reference to the Tx O/H port used on egress path. The device tree representation for the O/H port is described below;
- *fsl,disable_buff_dealloc* - in some scenarios the TX OH port cannot enable VSP because of the OH port limitation (O/H port cannot have VSP capability and IP Fragmentation enabled in the same time), therefore another hardware module along the TX path should release the buffers generated by oNIC into the draining buffer pool. With this flag, oNIC will configure the TX OH port to NOT release the buffers into the draining buffer pool. If other hardware modules do not release the buffers into the draining pool the device will leak available memory. This is an optional attribute.
- *local-mac-address* - this is a virtual L2 address used to identify the driver in the Linux kernel network stack.

Note 1: Like Macless DPAA Ethernet Driver, oNIC does not have a MAC device to control, therefore the “fsl,fman-mac” property is missing from the device tree specification.

oNIC does not have a buffer pool specified in its device tree representation. It will use the default buffer pools specified in the O/H port device tree node. The O/H port device tree representation looks like:

```
oh2: dpa-fman0-oh@2 {
     compatible = "fsl,dpa-oh";
     fsl,bman-buffer-pools = <&bp1 &bp2 &bp3 &bp4>;
     fsl,qman-frame-queues-oh = <110 1 111 1>;
     fsl,fman-oh-port = <&fman0_oh2>;
};
```

The properties of the O/H port device tree node can have are:

- *fsl,bman-buffer-pools* - the default buffer pools managed by oNIC; up to four static buffer pools can be specified. If this O/H port has VSPs, these buffer pools will be used in the default VSP. This property is parsed by oNIC that will initialize the default buffer pools. No other entities should try to initialize these buffer pools;
- *fsl,qman-frame-queues-oh* - the default egress queues. The default queues are represented by one default frame queue and one error frame queue. This property will be parsed by oNIC that will initialize both queues and use them in case PCD frame queues are not defined;
- *fsl,fman-oh-port* - reference to FMan port device tree representation; this field is mandatory for Offline Port Driver, but it is not used by oNIC;

To activate VSP capability on a port, the user will have to configure the chosen node in the device tree. One valid entry looks like:

```
fman0_oh2-extd-args {
    cell-index = <0x1>;
    compatible = "fsl,fman-port-op-extended-args";
    vsp-window = <0x8 0x0>;
};
```

The most important property is:

- *vsp-window* - the number of VSPs that this port can have and the default VSP (starting VSP index). In the above example 8 VSPs can be added to the O/H port (with ids 0, 1, ..., 8).

The device tree node of the O/H port use statically defined buffer pools. oNIC will parse the device tree representation of the default buffer pools of the Rx O/H port and will seed them. The device tree representation of the buffer pool is:

```
bp7: buffer-pool@7 {
    compatible = "fsl,b4860-bpool", "fsl,bpool";
    fsl,bpid = <7>;
    fsl,bpool-ethernet-cfg = <0 256 0 192 0 0>;
    fsl,bpool-thresholds = <0x400 0xc00 0x0 0x0>;
};
```

oNIC parses *fsl,bpid* and *fsl,bpool-ethernet-cfg* properties to initialize its internal buffer pools structures. As in other DPAA Ethernet Drivers, *fsl,bpool-ethernet-cfg* property has the following meaning:

```
fsl,bpool-ethernet-cfg = <count size base_address>;
```

- *count* - represents the number of buffers from the buffer pool;
- *size* - buffer size;
- *base_address* - this value is ignored by oNIC.

Note 2: oNIC will seed its configured buffer pools when the Ethernet interface is raised up. Because of this the *fsl,bpool-ethernet-seeds* property is ignored.

Note 3: All the buffers are allocated in the kernel memory space, therefore the *base_address* value is ignored.

The example above declares a buffer pool with buffer pool ID 7, and describes a pool with 256 192-byte buffers, occupying the memory in the kernel space. The *base_address* with <0 0> value is ignored. It should be noted that the size of those parameters should be set by the root node's *#address-cells* and *#size-cells* properties.

7.6.1.2.3.4.1.2 Configuration available through Linux interfaces

Because oNIC does not manage a MAC device, some *ethtool* and *ifconfig* options will not be available. All Layer 3 configurations, like setting an IP address, are generally available.

7.6.1.2.3.4.2 Features

This chapter describes the features of the oNIC Ethernet Driver, their configuration options, fine-tuning and known limitations.

Hardware Checksum

The OH ports are able to validate and compute L3 and/or L4 checksums for certain protocols (mainly TCP/IP and UDP/IP). Because oNIC uses OH ports as communication points with the lower architecture, CSUM validation and computation are supported.

Zero Copy

oNIC, representing kernel space, works in memory "isolation". This capability is achieved through OH ports with VSP capability enabled, which are able to copy the frames from one memory space to another. oNIC code and the underlying offload architecture code are not aware of the existence of another memory space, therefore simplifying the communication procedures.

Scatter/Gather

The current implementation supports DPAA Scatter/Gather only on the TX path.

7.6.1.2.4 Offline Parsing Port Driver

Offline Parsing/Host Command Port, also known as *O/H Port* or simply *O/H*, is an FMan hardware module that is capable of multiplexing and de-multiplexing network traffic inside DPAA. Its behavior and programming model is similar to an “online” FMan port, supporting Parse-Classify-Distribute (PCD) function and buffer copy from one buffer pool to another. It is useful in complex DPAA scenarios, where plenty of hardware offload is desired, like IPSec or TCP fragmentation and reassembly.

Similar to most DPAA hardware modules, a Linux kernel driver for O/H Ports is needed for initialization and configuration. In this document, the Offline Parsing Port Driver will be referred to as *Offline Port Driver*.

7.6.1.2.4.1 Configuration

Like other DPAA Ethernet Drivers, the Offline Port Driver is a standard Linux platform device driver, whose configuration is available through device tree. Also, the support for Offline Port Driver is enabled through a kernel Kconfig option.

7.6.1.2.4.1.1 Kconfig Option

The Offline Port Driver is enabled in the Kbuild Linux configuration by default. It can be toggled via the following menuconfig option:

```
Device Drivers
    ---> Network device support
        ---> Ethernet driver support
            ---> Freescale devices
                ---> DPAA Ethernet
                    ---> Offline Ports support
```

7.6.1.2.4.1.2 Device Tree Configuration

The Offline Port Driver has *fsl,dpa-oh* as compatible string in the device tree. For example, the standard structure for the device tree node that specifies an Offline Port Driver in a B4860QDS device tree is depicted below:

```
dpa-fman0-oh@2 {
    compatible = "fsl,dpa-oh";
    fsl,bman-buffer-pools = <&bp10>;
    fsl,qman-frame-queues-oh = <0x6e 0x1 0x6f 0x1>;
    fsl,qman-frame-queues-tx = <0x70 0x5>;
    fsl,qman-frame-queues-ingress = <base_id1 count1 ... base_idn countn>;
    fsl,qman-frame-queues-egress = <base_id1 count1 ... base_idn countn>;
    fsl,qman-channel-ids-egress = <channel_id1 ... channel_idn>;
    fsl,fman-oh-port = <&fman0_oh2>;
};
```

This device tree node resides inside *fsl,dpaa* device tree node, near DPAA Ethernet Driver device tree node specification.

Historically the offline port driver did not initialize the frame queues that entered and exited the OH port and relied on software components (Ethernet driver, USDPAA, other kernel modules) to initialize those queues. The offline port driver added capabilities to initialize ingress queues (queues that enter the Offline Port) simplifying the work for the Ethernet driver, but maintaining the same complexity in USDPAA and/or other kernel modules. Full capability for initializing both ingress and egress queues has been added, eliminating the dependency on USDPAA and/or other kernel modules. With it, complex offload architectures that have OH ports can be largely initialized by the offline port driver.

The additional device tree attributes, qman-frame-queues-ingress, qman-frame-queues-egress and qman-channel-ids-egress are optional and do not interfere with existing code. Therefore, backward compatibility is maintained.

Following are the properties that could be used within Offline Port Driver's device tree node:

- *fsl,bman-buffer-pools* - a list of buffer pools used by this O/H Port. The O/H Port will use these statically defined buffer pools in case it will do IP Fragmentation or buffer copy from one buffer pool to another. For IP Fragmentation, one incoming frame is divided into multiple frames. In order to copy data from a buffer pool to another, VSP (Virtual Storage Profile) properties must be configured on this port and the destination buffer pool is initialized and managed by the destination software entity. Therefore, these buffer pools are not initialized or managed by the Offline Port Driver. In some scenarios, this can be done by one of DPAA Ethernet Drivers. If the O/H Port does not use IP Fragmentation or VSP capabilities, this attribute will not be used;

- *fsl,qman-frame-queues-oh* - a list of base/count pairs of frame queues through which the frames are transmitted from the O/H Port to the next hardware or software module. These queues are not initialized, but are solely used as ID references for O/H Port initialization. This is necessary because the initialization of an FMan Port (online or offline) requires a TX error and a TX default frame queues. These frame queues must be initialized by other software module. This device tree property is mandatory;
- *fsl,qman-frame-queues-tx* - deprecated
- *fsl,qman-frame-queues-ingress* - a base/count pair of frame queues to be initialized by the Offline Port Driver that will fetch the frames from the hardware or software entity to the O/H Port.
- *fsl,qman-frame-queues-egress* - a list of base/count pairs of frame queues through which the frames are transmitted from the O/H Port to the next hardware or software module. These queues are connected only to DC portals therefore the property below (qman-channel-ids-egress) is mandatory. Frame queues connected to SW portals should be created from another software entity. Also, if a frame queue uses different initialization parameters it should be created by another software entity.
- *fsl,qman-channel-ids-egress* - a list of channel ids used together with "fsl,qman-frame-queues-egress" option to configure the egress frame queues.
- *fsl,fman-oh-port* - this is the reference to the O/H Port device tree node and has the same meaning as *fsl,fman-mac* from DPAA Ethernet Driver device tree specification. This attribute is mandatory.

Note 1: It should be noted that the Offline Port Driver does not initialize frame queues specified through *fsl,qman-frame-queues-oh* attribute. When the port is probed, the O/H Port is enabled and configured with the values from the device tree, but no action is taken on the declared frame queues.

Note 2: The statically defined buffer pool should be declared in a similar way as for the DPAA Ethernet Drivers.

The O/H Ports can be used in multiple scenarios as nodes that fetch traffic from multiple sources or as intermediate nodes that multiplexes incoming traffic to multiple destinations.

7.6.1.2.4.2 Features

The Offline Port Driver is an initialization driver for the O/H Ports. This chapter presents only the Offline Port Driver initialization capabilities, not the hardware features offered by the O/H Ports.

TX queues initialization

Before SDK 1.5, no frame queue referenced by the Offline Port Driver's device tree node was initialized. It was other driver's job to initialize the frame queues used by the O/H Port. As of SDK 1.5, *fsl,qman-frame-queues-tx* and *fsl,qman-channel-id* attributes were introduced. The frame queues referenced by the above mentioned *fsl,qman-frame-queues-tx* attribute are managed by the Offline Port Driver, decreasing thus the complexity of other drivers.

7.6.1.2.5 Link Management

The FMan has two types of ethernet controllers: 1G and 10G. The two types of ethernet conform to different standards (802.3 Clause 22 and Clause 45, respectively) for link management, so there are two corresponding types of MDIO controller for those standards. Each ethernet controller has its own MDIO device, however only one of each type are pinned out on currently shipping parts (10/2011). On P4080, for example, only the MDIO on FM1's first 1G MAC is pinned out, as well as the MDIO on FM1's 10G MAC. This is true even if FM1's first 1G MAC or 10G MAC is disabled.

On the 1G MACs, the MDIO controllers serve a second purpose -- configuring the SERDES link for SGMII between the MAC and the external PHY. This is done via management commands to an on-chip "TBI" PHY. This PHY is configured to sit at the address written to the TBIPA register in the MAC, and all MDIO transactions from that MAC to that address will be intercepted by the TBI PHY. This means that the setting of this register on the first 1G MAC is very relevant to system architects, as the address must not conflict with the address of an external PHY, or that PHY will not be reachable by MDIO management commands.

7.6.1.2.5.1 Device Tree

The MDIO nodes are described in the device tree, and look like this:

```
          mdio0: mdio@e1120 {
                    #address-cells = <1>;
                    #size-cells = <0>;
                    compatible = "fsl,fman-mdio";
                    reg = <0xe1120 0xee0>;
                    interrupts = <100 1 0 0>;
                    ethernet-phy@0 {
                              reg = <0x0>;
                    };
               tbi0: tbi-phy@8 {
                        reg = <0x8>;
                        device_type = "tbi-phy";
               };
      };
```

This is one of the 1G MDIO nodes for a P4080 (Not the DS, but more on that later). It specifies that there is a PHY at address 0, and the TBI PHY will sit at address 8. Note that it is the first MAC, which is the only one whose pins are connected outside the chip. The other 7 MACs would have a similar node, but with only a TBI PHY in each. This is how one would set up PHYs under a standard MDIO bus topology; the first MAC connects to all of the PHYs (up to 31 of them), and also has its assigned internal TBI PHY.

In order to associate an ethernet controller with a PHY, one uses the phy-handle property

7.6.1.2.5.2 Bootargs

```
fsl_fm_max_frm
```

Configure this to set the L2 Maximum Frame Size. This influences the Frame Manager FIFO size resources.

```
fsl_fm_rx_extra_headroom
```

Configure this to tell the Frame Manager to reserve some extra space at the beginning of a data buffer on the receive path, before Internal Context fields are copied. This is in addition to the private data area already reserved for driver internal use. The option does not affect in any way the layout of transmitted buffers. The default value (64bytes) offers best performance for the case when forwarded frames are being encapsulated (e.g. IPSec). For plain forwarding or termination cases, a value of zero is recommended for optimum performance.

The current size of the buffers in USDPAA dts files is 1728bytes (odd_cache_line * cache_line_size) which is calculated according to the default value (64bytes) of the dpa_extra_headroom. If the dpa_extra_headroom is set to 0 then the buffer size will be 1600bytes (also multiple of odd cache line). For any extra headroom values ranging between 1 and 128bytes the buffer size is 1728bytes. For values ranging between 129bytes and 256bytes, the buffer size is 1856bytes and so on.

7.6.1.2.5.3 Muxed MDIO

The Development Systems for the QorIQ product lines do not have a standard MDIO topology. In order to support the variety of configurations that are possible under the QorIQ product line, the PHYs often reside on riser cards, many of which use the same addresses; this means that it is not possible to keep all of the PHYs on the same bus. To work around this problem, the MDIO buses have been muxed so that, at any one time, only a subset of the PHYs will be connected to the MDIO buses. In order to send an MDIO transaction to a PHY, it is therefore necessary to first modify the MUX. This is done via a set of

"virtual" MDIO interfaces. Each MUX setting is considered a separate bus, each with its own PHYs. That means that the P4080DS's MDIO node looks like this:

```
   mdio0: mdio@e1120 {
          gpios = <&gpio0 0 0
                   &gpio0 1 0>;
          tbi0: tbi-phy@8 {
                  reg = <0x8>;
                  device_type = "tbi-phy";
          };
          p4080mdio0: p4080ds-mdio0 {
                  #address-cells = <1>;
                  #size-cells = <0>;
                  compatible = "fsl,p4080ds-mdio";
                  fsl,mdio-handle = <&mdio0>;
                  fsl,muxval = <0>;
                  phyrgmii: ethernet-phy@0 {
                          reg = <0x0>;
                  };
          };
   };
```

The bus now has a subnode, "p4080ds-mdio0", which represents the bus topology when the MUX is set to 0. That bus connects to the RGMII PHY at address 0. Other buses connect to the SGMII PHYs in the 3 riser card slots. It's important to note that it is not at all required to use a muxed MDIO bus on QorIQ products; this is only a solution to the problem of trying to access PHYs which can be in multiple places. The other important thing to note is that U-Boot modifies the device tree. In the example of the P4080DS, U-Boot uses the RCW to determine which interfaces are enabled, and which PHYs those interfaces are connected to. Therefore the connections in the dts file may not be the final arrangements of the PHYs.

7.6.1.2.6 Debugging

This chapter describes the debugging capabilities of the DPAA Ethernet driver.

7.6.1.2.6.1 Ethtool support

Various counters and statistics are exported through ethtool such as the number of interrupts per core, the number of frames per core, the number of available buffers, congestion detection, etc.

Following is an example of an ethtool output:

```
root@ls1043ardb:~# ethtool -S fm1-mac1
NIC statistics:
     interrupts [CPU 0]: 1
     interrupts [CPU 1]: 1
     interrupts [CPU 2]: 2
     interrupts [CPU 3]: 2
     interrupts [TOTAL]: 6
     rx packets [CPU 0]: 0
     rx packets [CPU 1]: 0
     rx packets [CPU 2]: 0
     rx packets [CPU 3]: 0
     rx packets [TOTAL]: 0
     tx packets [CPU 0]: 0
     tx packets [CPU 1]: 0
     tx packets [CPU 2]: 6
     tx packets [CPU 3]: 0
     tx packets [TOTAL]: 6
     tx recycled [CPU 0]: 0
```

```
     tx recycled [CPU 1]: 0
     tx recycled [CPU 2]: 0
     tx recycled [CPU 3]: 0
     tx recycled [TOTAL]: 0
     tx confirm [CPU 0]: 1
     tx confirm [CPU 1]: 1
     tx confirm [CPU 2]: 2
     tx confirm [CPU 3]: 2
     tx confirm [TOTAL]: 6
     tx S/G [CPU 0]: 0
     tx S/G [CPU 1]: 0
     tx S/G [CPU 2]: 0

     qman wred: 0
     qman error cond: 0
     qman early window: 0
     qman late window: 0
     qman fq tdrop: 0
     qman fq retired: 0
     qman orp disabled: 0
     congestion time (ms): 0
     entered congestion: 0
     congested (0/1): 0
```

7.6.1.2.6.2 Read/Write of FMan Registers

Most of the FMan configuration registers are mapped into the system memory space. Efficient debugging and testing can be done by making read/write operations on the registers through specialized tools. For example, the number of pause frames received on a particular MAC device can be computed summing the base relative address of every component:

```
0xffe000000 (the address of the SoC) +
   0x400000 (FMan 1) +
```

```
    0xe8000 (MAC 5) +
      0x234 (RX pause frames) =
-------------------------------------
0xffe4e8234
```

A memory print of the 0xffe4e8234 address will display the number of pause frames received by the fifth MAC device from the first FMan on a P4080DS platform.

The entire memory map for all mapped registers of the DPAA hardware components ca be found in each platform's Reference Manual.

7.6.1.2.6.3 Sysfs support

To enable Sysfs in the Linux kernel one must set the CONFIG_SYSFS option in Kconfig. The DPAA Ethernet Driver exports a series of information in Sysfs such as the buffer pool IDs, the frame queue IDs used by the interface and the MAC registers as shown in the following examples:

```
root@p4080ds:~# cat /sys/devices/fsl,dpaa.16/ethernet.18/net/fm2-gb0/bpids
32
root@p4080ds:~# cat /sys/devices/fsl,dpaa.16/ethernet.17/net/fm1-gb1/fqids
Rx error: 262
Rx default: 263
Rx PCD: 14464 - 14591
Tx confirmation (mq): 264 - 271
Tx error: 272
Tx default confirmation: 273
Tx: 274 - 281
```

7.6.1.2.7 Adding support for DPAA Ethernet in Topaz Hypervisor

We start from the assumption that hv.dts file for the platform has already been created starting from an existing platform. The practice is to place the device tree under the following folder hierarchy: hv-cfg/"platform_name"/"RCW_name" It means that the RCW gives the number and types of ports that will be added in hv.dts. We will consider T1040RDB hv.dts as a reference throughout this guide.

Following are the steps to be followed in order to add DPAA ports (private, shared-mac and macless) in hv.dts:

1. Add bman-portal and qman-portal nodes under "part 1" node. E.g.:

```
                bman-portal@0 {
                    device = "/bman-portals/bman-portal@0";
                };

                qman-portal@0 {
                    device = "/qman-portals@ff6000000/qman-portal@0";

                    stash-mem {
                        liodn-index = <1>;
                        dma-window = <&dw_linux1>;
                        operation-mapping = <0>;
                        stash-dest = <3>;
                    };

                    stash-dqrr {
                        liodn-index = <0>;
                        dma-window = <&dw_dqrr_qportal0>;
```

```
                operation-mapping = <0>;
                stash-dest = <3>;
            };
        };
```

Make sure dma-window "dw_dqrr_qportal0" exists under "dma-windows" node:

```
        // DMA window for stash_dqrr for qman-portal0
        dw_dqrr_qportal0: window3 {
            compatible = "dma-window";
            guest-addr = <0xf 0xf6000000>;
            size = <0 0x4000>;
        };
```

All bman-portal and qman-portal nodes must be added except at least one which should be added to the second partition. For T1040RDB, bman-portal@1c000 and qman-portal@1c000 were added in the second partition. The list of available bman-portal and qman-portal nodes for T1040RDB can be retrieved from the following dtsi file included by the platform device tree: arch/powerpc/boot/dts/fsl/t1040si-post.dtsi bman-portals are located under bportals node and qman-portals under qportals node.

2. For the current RCW that is used, add the appropriate dpaa ethernet node under "part 1" parent node. For T1040RDB the following ports are added:

```
        // FMAN0 RGMII -- ethernet 3 assigned to this partition
        dpa-ethernet@3 {
            device = "/fsl,dpaa/ethernet@3";
        };

        // FMAN0 RGMII -- ethernet 4 assigned to this partition
        dpa-ethernet@4 {
            device = "/fsl,dpaa/ethernet@4";
        };
```

The full list of available ethernet ports can be retrieved from the platform device tree: arch/powerpc/boot/dts/t1040rdb.dts

3. bman, qman, fman0 and fman1 (in case there are two FMANs) nodes must be also added under "part 1" parent node. See T1040RDB example.
4. fman0 and fman1 (if applicable) must be added under "portal-devices" node. See T1040RDB example.
5. Under "node-update" node make sure you define at least two buffer pools for macless and shared-mac interfaces. While here, make sure gpma1 is defined and guest-addr reserves the inter-partition memory area. Also check that dw_linux1 and dw_linux2 both have sub-window nodes with the same memory area region matching the inter-patition area. See T1040RDB example.
6. Make sure "fsl,dpaa" node exists under "node-update" node and check or create a macless and a shared-mac interface. The compatible string for the "fsl,dpaa" node must be: compatible = "fsl,t1040-dpaa", "fsl,dpaa"; replace t1040 with the name of the platform you want to add. The compatible string for the macless interface must be: compatible = "fsl,t1040-dpa-ethernet", "fsl,dpa-ethernet-macless"; The compatible string for the macless interface must be: compatible = "fsl,t1040-dpa-ethernet", "fsl,dpa-ethernet-shared"; Make sure the macless node includes the local-mac-address identifier. See T1040RDB example.

7. Make sure "fsl,dpaa" node exists under "node-update-phandle" node. Here the buffer pools are associated with macless and shared-mac interfaces. See T1040RDB example.
8. Under "part 1" node check or add the following nodes: bman-bpids, qman-fqids@0, qman-fqids@1, qman-pools, qman-cgrids The values used by these nodes can be retrieved from arch/powerpc/boot/dts/fsl/qoriq-dpaa-res3.dtsi For T1040RDB two partitions were created therefore the resources, bpids, fqids, etc were splitted among the two partitions. In case more partitions are created the resources must be splitted accordingly. See T1040RDB example.
9. Repeat steps 3-8 for "part 2" node in case of 2 partitions scenario. The same steps must be followed in case more than 2 partitions are added. Exception for step 6: Two macless nodes must be added under "fsl,dpaa" node. The first node is the "pair" of the macless interface in the first partition and the second is the interface connected to the shared-mac port (the port shared with the first partition). See T1040RDB example.

7.6.1.2.8 MACsec

Introduction

This chapter provides information about the MACsec kernel module and user space API that can be used to configure and control the MACsec hardware block inside the Frame Manager. The Quick Start Guide lists the steps that need to be taken in order to enabled MACsec after integrating the API into the hostapd and wpa_supplicant applications. The API Reference section details the user space MACsec API and gives examples on how to use it.

Intended Audience

This chapter is intended for software developers and architects who want to develop software applications that implement the 802.1X and 802.1AE (MACsec) protocols.

7.6.1.2.8.1 MACsec User Space API Reference

The following API is implemented in the hostapd and wpa_supplicant user space applications and can be reached by including the src/drivers/dpaa_utils_macsec.h header.

MACsec API data structures

1. enable_macsec_t

Member's description:

- if_name - char* that holds the name of the interface on which MACsec is to be enabled
- if_name_length - size_t that holds the length of the if_name field, including the terminating null character
- config_unknown_sci_treatment - boolean that selects between the default value and the one in unknown_sci_treatment
- unknown_sci_treatment - enum that selects how frames received with unknown SCI are treated (default is DISCARD_BOTH - discarded on both the controlled and uncontrolled ports)
- config_invalid_tag_treatment - boolean that selects between the default value and the one in deliver_uncontrolled
- deliver_uncontrolled - boolean that selects if frames received with an invalid SecTAG or a zero PN value should be delivered on the uncontrolled port (default is FALSE)
- config_kay_frame_treatment - boolean that selects between the default value and the one in discard_uncontrolled
- discard_uncontrolled - boolean that selects if frames received with the Encryption (E) bit set and the Changed Text (C) bit clear (reserved for use by the KaY) should be discarded on the uncontrolled port (default is FALSE)
- config_untag_treatment - boolean that selects between the default value and the one in untag_treatment
- untag_treatment - enum that selects how frames received without the MAC SecTAG are treated (default is UNTAG_DELIVER_UNCTRL_DISCARD_CTRL)
- config_pn_exhaustion_threshold - boolean that selects between the default value and the one in pn_threshold
- pn_threshold - u32 that sets the TX PN exhaustion threshold (default is 0xffffffff)

- config_keys_unreadable - boolean that selects if the RX and TX keys and hash values should be unreadable (default is FALSE)
- config_sectag_without_sci - boolean that selects if the maximum frame length should not consider the SCI's size in the SecTAG (default is FALSE)
- config_exception - boolean that selects between the default values and the ones in enable_exception and exception
- enable_exception - boolean that selects if the exception mask set by the exception field should be enabled or not
- exception - enum that defines the mask of the exception that is to be enabled or disabled (default is SINGLE_BIT_ECC | MULTI_BIT_ECC - both masks are enabled)

2. enable_secy_t

Member's description:

- macsec_id - int value returned by the dpa_macsec_enable() call that identifies one MACsec instance per interface
- sci - 64bit value made from the MAC address of the interface on which MACsec has been enabled, concatenated with a Port Identifier
- config_insertion_mode - boolean that selects between the default value and the one in sci_insertion_mode
- sci_insertion_mode - enum that selects if the SCI will be included in the SecTag or not (default is SCI_INSERTION_MODE_EXPLICIT_SECTAG - the SCI is always included)
- config_protect_frames - boolean that selects between the default value and the one in protect_frames
- protect_frames - boolean that selects if the packet will be encapsulated with MACsec header (default is TRUE)
- config_replay_window - boolean that selects between the default values and the ones in replay_window and replay_protect
- replay_protect - boolean that selects if the replay protection algorithm is enabled or not (default is FALSE)
- replay_window - unsigned integer that represents the replay window dimension (default is 0)
- config_validation_mode - boolean that selects between the default value and the one in validate_frames
- validate_frames - enum that selects the behaviour of MACsec from frames validation point of view (default is VALID_FRAME_BEHAVIOR_STRICT - strictly filter out invalid frames)
- config_confidentiality - boolean that selects between the default values and the ones in confidentiality_enable and confidentiality_offset
- confidentiality_enable - boolean that selects if the packages will be encrypted or not (default is FALSE)
- confidentiality_offset - unsigned integer that represents the offset from which the data will be encrypted (default is 0)
- config_point_to_point - boolean that selects if MACsec must be configured only for point-to-point communication (default is FALSE)
- config_exception - boolean that selects between the default values and the ones in enable_exception and exception
- enable_exception - boolean that selects if the exception mask set by the exception field should be enabled or not
- exception - enum that defines the mask of the exception that is to be enabled or disabled (default is FRAME_DISCARDED)
- config_event - boolean that selects between the default values and the ones in enable_event and event
- enable_event - boolean that selects if the event mask set by the event field should be enabled or not
- event - enum that defines the mask of the event that is to be enabled or disabled (default is NEXT_PN)

MACsec API functions

1. dpa_macsec_enable

```
int dpa_macsec_enable(enable_macsec_t en_macsec)
```

Description:

- used to configure and enable MACsec on a certain interface

Parameters:

- en_macsec - MACsec data structure including the name of the interface to enable MACsec on and several configuration options

Return:

- returns the macsec_id that will be used in further calls of the API's functions
- returns a negative value in case something went wrong

2. dpa_macsec_secy_en

```
int dpa_macsec_secy_en(enable_secy_t enable_secy)
```

Description:

- used for configuring and creating SecY; also creates a corresponding TxSc (secure channel for TX)
- sets the default values for cipher suite, SCI insertion mode, protect frames, replay protection, replay window dimension, confidentiality, confidentiality offset and point-to-point connection, as IEEE802.1AE-2006 states

Parameters:

- enable_secy - SecY data structure

Return:

- returns the sc_id allocated by MACsec (a value from 15 to 0, or simply 0, if the setup is point-to-point) that uniquely identifies the SecY
- returns a negative value in case something went wrong

3. dpa_macsec_secy_create_tx_sa

```
int dpa_macsec_secy_create_tx_sa(int macsec_id, u8 an, u8 *sak, u32 sak_len)
```

Description:

- used for creating a TxSa (secure association for TX)

Parameters:

- macsec_id - MACsec interface identifier
- an - association number
- sak - secure association key (the key used for encryption)
- sak_len - length of the key (must be at most 32)

Return:

- returns 0 on success or a negative value in case something went wrong

4. dpa_macsec_secy_activate_tx_sa

```
int dpa_macsec_secy_activate_tx_sa(int macsec_id, u8 an)
```

Description:

- used for activating the secure association for TX channel

Parameters:

- macsec_id - MACsec interface identifier
- an - association number

Return:

- returns 0 on success or a negative value in case something went wrong

5. dpa_macsec_secy_create_rx_sc

```
int dpa_macsec_secy_create_rx_sc(int macsec_id, u64 sci)
```

Description:

- creates a RxSc (secure channel for RX)

Parameters:

- macsec_id - MACsec interface identifier
- sci - a 64 bit value made of the MAC address of the destination(48 bits) and a port number(16 bits)

Return:

- returns the rx_sc_id allocated by MACsec (a value from 15 to 0, or simply 0, if the setup is point-to-point) that uniquely identifies the peer to whom we are discussing MACsec
- returns a negative value in case something went wrong

6. dpa_macsec_secy_create_rx_sa

```
int dpa_macsec_secy_create_rx_sa(int macsec_id, u32 rx_sc_id, u8 an, u32 lpn, u8 *sak, u32 sak_len)
```

Description:

- creates RxSa (secure association for RX)

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number
- lpn - lowest packet number, value used in anti-replay algorithm
- sak - secure association key (the key used for decryption)
- sak_len - length of the key (must be at most 32)

Return:

- returns 0 on success or a negative value in case something went wrong

7. dpa_macsec_secy_activate_rx_sa

```
int dpa_macsec_secy_activate_rx_sa(int macsec_id, u32 rx_sc_id, u8 an)
```

Description:

- used for activating the secure association for RX channel

Parameters:

- macsec_id - MACsec interface identifier

- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number

Return:

- returns 0 on success or a negative value in case something went wrong

8. dpa_macsec_secy_disable_rx_sa

```
int dpa_macsec_secy_disable_rx_sa(int macsec_id, u32 rx_sc_id, u8 an)
```

Description:

- used for disabling the secure association for RX channel

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number

Return:

- returns 0 on success or a negative value in case something went wrong

9. dpa_macsec_secy_delete_rx_sa

```
int dpa_macsec_secy_delete_rx_sa(int macsec_id, u32 rx_sc_id, u8 an)
```

Description:

- used for deleting the secure association for RX channel

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number

Return:

- returns 0 on success or a negative value in case something went wrong

10. dpa_macsec_secy_delete_rx_sc

```
int dpa_macsec_secy_delete_rx_sc(int macsec_id, u32 rx_sc_id)
```

Description:

- used for deleting the secure channel for RX

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call

Return:

- returns 0 on success or a negative value in case something went wrong

11. dpa_macsec_secy_delete_tx_sa

```
int dpa_macsec_secy_delete_tx_sa(int macsec_id, u8 an)
```

Description:

- used for deleting the secure association for TX channel

Parameters:

- macsec_id - MACsec interface identifier
- an - association number

Return:

- returns 0 on success or a negative value in case something went wrong

12. dpa_macsec_secy_disable

```
int dpa_macsec_secy_disable(int macsec_id)
```

Description:

- used for deleting the SecY and disabling the associated TxSc

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns 0 on success or a negative value in case something went wrong

13. dpa_macsec_disable

```
int dpa_macsec_disable(int macsec_id)
```

Description:

- used for disabling MACsec

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns 0 on success or a negative value in case something went wrong

14. dpa_macsec_disable_all

```
int dpa_macsec_disable_all(int macsec_id)
```

Description:

- used as a single call for disabling all that was enabled for MACsec to work
- is the equivalent for calling dpa_macsec_secy_disable_rx_sa, dpa_macsec_secy_delete_rx_sa, dpa_macsec_secy_delete_rx_sc, dpa_macsec_secy_delete_tx_sa, dpa_macsec_secy_disable and dpa_macsec_disable one by one

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns 0 on success or a negative value in case something went wrong

15. dpa_macsec_secy_get_txsc_phys_id

```
int dpa_macsec_secy_get_txsc_phys_id(int macsec_id)
```

Description:

- obtain the ID associated with the TX SC by the Fman

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns the tx_sc_id corresponding to the SecY from Fman
- returns a negative value in case something went wrong

16. dpa_macsec_secy_modify_txsa_key

```
int dpa_macsec_secy_modify_txsa_key(int macsec_id, u8 an, u8 *sak, u32 sak_len)
```

Description:

- used to change the encryption key

Parameters:

- macsec_id - MACsec interface identifier
- an - association number
- sak - new secure association key (the key used for encryption)
- sak_len - length of the new key (must be at most 32)

Return:

- returns 0 on success or a negative value in case something went wrong

17. dpa_macsec_secy_modify_rxsa_key

```
int dpa_macsec_secy_modify_rxsa_key(int macsec_id, u32 rx_sc_id, u8 an, u8 *sak, u32 sak_len)
```

Description:

- used to change the decryption key

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number
- sak - new secure association key (the key used for decryption)
- sak_len - length of the new key (must be at most 32)

Return:

- returns 0 on success or a negative value in case something went wrong

18. dpa_macsec_secy_get_tx_sa_active_an

```
int dpa_macsec_secy_get_tx_sa_active_an(int macsec_id)
```

Description:

- used to get the active association number for this TxSc

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns the association number on success or a negative value in case something went wrong

19. dpa_macsec_secy_get_rxsc_phys_id

```
int dpa_macsec_secy_get_rxsc_phys_id(int macsec_id, u32 rx_sc_id)
```

Description:

- obtain the ID associated with the RX SC by the Fman

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call

Return:

- returns the rx_sc_id corresponding to the peer's SecY from Fman
- returns a negative value in case something went wrong

20. dpa_macsec_secy_rx_sa_update_npn

```
int dpa_macsec_secy_rx_sa_update_npn(int macsec_id, u32 rx_sc_id, u8 an, u32 pn)
```

Description:

- used to set the next packet number that MACsec should handle on RX

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number
- pn - packet number

Return:

- returns 0 on success or a negative value in case something went wrong

21. dpa_macsec_secy_rx_sa_update_lpn

```
int dpa_macsec_secy_rx_sa_update_lpn(int macsec_id, u32 rx_sc_id, u8 an, u32 pn)
```

Description:

- used to set the lowest packet number that MACsec should handle on RX

Parameters:

- macsec_id - MACsec interface identifier
- rx_sc_id - the one received from MACsec after dpa_macsec_secy_create_rx_sc call
- an - association number
- pn - packet number

Return:

- returns 0 on success or a negative value in case something went wrong

22. dpa_macsec_get_revision

```
int dpa_macsec_get_revision(int macsec_id)
```

Description:

- used to find the current revision of MACsec

Parameters:

- macsec_id - MACsec interface identifier

Return:

- returns the revision corresponding to the macsec_id
- returns a negative value in case something went wrong

23. dpa_macsec_set_exception

```
int dpa_macsec_set_exception(int macsec_id, bool enable_ex, macsec_exception ex)
```

Description:

- used to enable/disable a trigger for a certain exception

Parameters:

- macsec_id - MACsec interface identifier
- enable_ex - bool that will select if the exception given by the third argument will be enabled or not
- ex - the exception for wich a trigger will be activated/deactivated

Return:

- returns 0 on success or a negative value in case something went wrong

MACsec API usage examples

1. Basic usage

```
        enable_macsec_t en_macsec;
        enable_secy_t enable_secy;
        int i, rx_sc_id;
        u8 an = 0;
        u32 lpn = 0;
        u32 sa_key_len = 32;
        u16 port_src = 1;
        u16 port_dst = 1;
        u64 sci_src; //MAC + port - 64b
        u64 sci_dest; //MAC + port - 64b

        u8 *sa_key = malloc(sa_key_len * sizeof(u8));
        for (i = 0; i < sa_key_len; i ++)
            sa_key[i] = 0x12;

        sci_src = (mac_src << 16) | port_src;
        sci_dest = (mac_dst << 16) | port_dest;

        en_macsec.if_name = ifname;
        en_macsec.if_name_length = strlen(ifname) + 1;

        en_macsec.config_unknown_sci_treatment = FALSE;
        en_macsec.config_invalid_tag_treatment = FALSE;
```

```
en_macsec.config_kay_frame_treatment = FALSE;
en_macsec.config_untag_treatment = FALSE;
en_macsec.config_pn_exhaustion_threshold = FALSE;
en_macsec.config_keys_unreadable = FALSE;
en_macsec.config_sectag_without_sci = FALSE;
en_macsec.config_exception = FALSE;
en_macsec.enable_exception = FALSE;

macsec_id = dpa_macsec_enable(en_macsec);

enable_secy.macsec_id = macsec_id;
enable_secy.sci = sci_src;

enable_secy.config_insertion_mode = FALSE;
enable_secy.config_protect_frames = FALSE;
enable_secy.config_replay_window = FALSE;
enable_secy.config_validation_mode = FALSE;
enable_secy.config_confidentiality = FALSE;
enable_secy.config_point_to_point = FALSE;
enable_secy.config_exception = FALSE;
enable_secy.config_event = FALSE;

dpa_macsec_secy_en(enable_secy);
dpa_macsec_secy_create_tx_sa(macsec_id, an, sa_key, sa_key_len);
dpa_macsec_secy_activate_tx_sa(macsec_id, an);

rx_sc_id = dpa_macsec_secy_create_rx_sc(macsec_id, sci_dest);
dpa_macsec_secy_create_rx_sa(macsec_id, rx_sc_id, an, lpn, sa_key, sa_key_len);
dpa_macsec_secy_activate_rx_sa(macsec_id, rx_sc_id, an);

/* ... */

free(sa_key);

dpa_macsec_disable_all(macsec_id);

/* Or:
* dpa_macsec_secy_disable_rx_sa(macsec_id, rx_sc_id, an);
* dpa_macsec_secy_delete_rx_sa(macsec_id, rx_sc_id, an);
* dpa_macsec_secy_delete_rx_sc(macsec_id, rx_sc_id);
* dpa_macsec_secy_delete_tx_sa(macsec_id, an);
* dpa_macsec_secy_disable(macsec_id);
* dpa_macsec_disable(macsec_id);
*/
```

2. Enable confidentiality

Enable the confidentiality flag and set the confidentiality offset in the enable_secy_t structure.

```
enable_secy.macsec_id = macsec_id;
enable_secy.sci = sci_src;

enable_secy.config_insertion_mode = FALSE;
enable_secy.config_protect_frames = FALSE;
enable_secy.config_replay_window = FALSE;
enable_secy.config_validation_mode = FALSE;

enable_secy.config_confidentiality = TRUE;
```

```
        enable_secy.confidentiality_enable = TRUE;
        enable_secy.confidentiality_offset = 0;

        enable_secy.config_point_to_point = FALSE;
        enable_secy.config_exception = FALSE;
        enable_secy.config_event = FALSE;
```

3. Modify the TxSa and the RxSa keys

Generate a new set of keys and call the appropriate API functions.

```
        for(i = 0; i < sa_key_len; ++i) {
            txsa_key[i] = 0x23;
        }

        dpa_macsec_secy_modify_txsa_key(macsec_id, an, txsa_key, sa_key_len);

        for(i = 0; i < sa_key_len; ++i) {
            rxsa_key[i] = 0x57;
        }

        dpa_macsec_secy_modify_rxsa_key(macsec_id, rx_sc_id, an, rxsa_key, sa_key_len);
```

7.6.1.2.8.2 MACsec Quick Start Guide

After integrating the MACsec API with hostapd and wpa_supplicant, as exemplified in the MACsec User Space API Reference on page 1051 chapter, follow these steps to run the applications.

Software Installation and Build

- Compile MACsec as a module:

```
        Device Drivers
            +-> Network device support (NETDEVICES [=y])
                +-> Ethernet driver support (ETHERNET [=y])
                    +-> Freescale devices (NET_VENDOR_FREESCALE [=y])
                        +-> DPAA Ethernet (FSL_SDK_DPAA_ETH [=y])
                            +-> DPAA Macsec [=m]
```

- Increase the FMan maximum frame size to 1554 bytes. This is needed in order to accommodate the MACsec header without decreasing the MTU:

```
        Device Drivers
            +-> Network device support (NETDEVICES [=y])
                +-> Ethernet driver support (ETHERNET [=y])
                    +-> Freescale devices (NET_VENDOR_FREESCALE [=y])
                        +-> Frame Manager Support
                            +-> Freescale Frame Manager (datapath) support - SDK driver
(FSL_SDK_FMAN [=y])
                                +-> Maximum L2 frame size [=1554]
```

- Set the appropriate FMan version (needed by B-series and T-series platforms):

```
        Device Drivers
            +-> Network device support (NETDEVICES [=y])
                +-> Ethernet driver support (ETHERNET [=y])
                    +-> Freescale devices (NET_VENDOR_FREESCALE [=y])
                        +-> Frame Manager Support
                            +-> Freescale Frame Manager (datapath) support - SDK driver
(FSL_SDK_FMAN [=y])
                                +-> FMAN_V3L like T1040, T1042, T1020, T1022 [=y]
```

- Build the hostapd and wpa_supplicant

  Add the recipes to your Yocto build by adding the following lines to your `conf/local.conf` file:

```
        IMAGE_INSTALL_append = " hostapd"
        IMAGE_INSTALL_append = " wpa-supplicant"
```

  In order to integrate the MACsec API with the hostapd application, apply the `0001-Add-DPAA-MACsec-API.patch` patch from the recipe directory (`meta-freescale/recipes-connectivity/hostapd/hostapd-2.4`) on top of the hostapd version 2.4 repository. Build independently after committing the necessary changes.

Execution setup

- Generate a set of OpenSSL keys and certificates for the 802.1X authentication.
- Create a configuration file for the HostAP.

  A separate configuration file is needed for each interface on which the hostapd will run. hostapd.conf example:

```
        ctrl_interface=/var/run/hostapd
        ctrl_interface_group=0
        use_pae_group_addr=1

        # Replace the following with the appropriate interface name
        interface=fm1-gb3

        driver=wired
        logger_syslog=-1
        logger_syslog_level=2
        logger_stdout=-1
        logger_stdout_level=2
        dump_file=/tmp/hostapd.dump

        eapol_version=2
        ieee8021x=1
        eap_server=1

        # Replace the following with the path to the eap_user_file
        eap_user_file=/etc/hostapd.eap_user

        # Replace the following with your CA certificate path
        ca_cert=/etc/server.crt
        server_cert=/etc/server.crt
        private_key=/etc/server.key
```

- Create an eap_user_file for the HostAP.

  `hostapd.eap_user` example:

```
# Phase 1 users
* PEAP
# Replace the following with your desired credentials
"test" MSCHAPV2,MD5,PEAP "password" [2]
```

- Create a configuration file for the wpa_supplicant.

  `wpa_supplicant.conf` example:

```
ctrl_interface=/var/run/wpa_supplicant
ctrl_interface_group=0
ap_scan=0
fast_reauth=1
eapol_version=2

network={
    ssid=""
    key_mgmt=IEEE8021X
    scan_ssid=0
    eap=PEAP
    priority=100
    phase2="auth=MSCHAPV2"

    # Replace the following with the credentials from the HostAP's eap_user_file
    identity="test"
    password="password"

    # Replace the following with your CA certificate path
    ca_cert="/etc/server.crt"
}
```

- Boot the board according to the platform's documentation.
- Insert the `fsl-dpa-macsec` module.

  Specify in a comma separated list the interfaces on which MACsec will be enabled:

```
modprobe fsl-dpa-macsec ifs="fm1-gb3,fm1-gb4"
```

- Start the HostAP.

```
# Replace with the path to the configuration file
/usr/sbin/hostapd /etc/hostapd.conf &
```

- Start the wpa_supplicant.

```
# Replace with the path to the configuration file and the appropriate interface name
```

```
wpa_supplicant -Dwired -ifm1-gb3 -c/etc/wpa_supplicant.conf &
```

- Inspect MACsec traffic statistics with `ethtool`.

```
ethtool -S fm1-gb3
```

Limitations and known issues

- Only one SecY with one corresponding TX SC can be enabled on each interface.
- Once MACsec is enabled, all traffic passes through the SecY.
- MACsec is not compatible with ASF.
- MACsec statistics for RX path are not supported in `ethtool`.
- MACsec is not functional on ports connected to the internal L2switch on T1040 platforms. Consult your platform's specifications to determine which ports have MACsec support.

7.6.1.2.9 Changes from previous versions

- **SDK2.0**
  - *Debugging with ethtool*

    Removed the DPAA Ethernet counters from debugfs and exported them through ethtool statistics.
  - *CEETM*

    Integrated the CEETM qdisc with the DPAA Ethernet driver.
- **SDK1.8**
  - *MACsec*

    Added MACsec kernel driver and a set of User-space Linux APIs to allow developers to configure the MACsec hardware block.
  - *DPAA Ethernet as loadable modules*

    Added loadable module support for the DPAA Ethernet driver.
  - *Adding support for DPAA Ethernet in Topaz Hypervisor*

    This is a documentation section enumerating the steps to follow in order to enable DPAA Ethernet in Topaz Hypervisor.
- **SDK1.7**
  - *PCD configuration files*

    Included in the SDK package PCD configuration and policy files (.xml files) for each platform supported by the SDK. The configuration files include all the ports enabled by the RCWs associated with each platform.
- **SDK1.6**
  - *oNIC device driver - DPAA hardware offloading aware Ethernet net device*

    Added oNIC netdevice, based on OH FMAN ports in order to offer advanced DPAA offloading capabilities like: IPSec offload, zero-copy frames between USDPAA and kernel stack, OH CSUM offload.
  - *DPAA OH port driver update*

    Previous versions of the offline port driver did not initialize the frame queues that entered and exited the OH port and relied on other software components (Ethernet driver, USDPAA, or other kernel modules) to initialize those queues. This update adds full capability for initializing both ingress and egress queues, eliminating the dependency on USDPAA and/

or other kernel modules. With it, complex offload architectures that have OH ports can be largely initialized by the offline port driver.

- *Priority Flow Control (PFC) - 802.1Qbb*

  Experimental feature added on T4240/T2080 for traffic priority classes and MAC support for 802.1Qbb. PFC provides the ability to issue and respond to Pause Frames on a priority-flow basis and prevents a single flow from consuming the entire port's bandwidth. This is distinct from standard flow control which turns on or off the Ethernet port, stopping all flows.

- *Sleep/DeepSleep support and Wake on LAN (WoL) support*

  Implement the suspend/resume features that allow stopping the Ethernet port before system enters the sleep state and resuming the port to normal state when the system is waken up. Updated the Ethernet driver to work together with the Wakeup-on-LAN options of ethtool utility. More information about this can be found at Documentation/power/devices.txt in the kernel source tree.

- **SDK1.5**
  - *Single driver for termination and forwarding*

    There is only one Ethernet driver codebase now, based on the “optimized for termination” version which implements the support for S/G frames. But the driver has undergone an optimization process such that its “IP forwarding” performance is similar now to that of the removed “optimized for forwarding” driver. In addition, the “termination” performance has been improved.

    All source code related to the “forwarding” driver is removed, along with the following Kconfig options: FSL_DPAA_ETH_OPTIMIZE_FOR_IPFWD, FSL_DPAA_ETH_OPTIMIZE_FOR_TERM and CONFIG_FSL_DPAA_ETH_SG_SUPPORT. The “termination” driver support for S/G frames requires a different socket buffer layout. The **ASF** and **IEEE1588** modules has been adapted to the new buffer layout, so the existing feature set has been preserved.

  - *Buffer recycling algorithm updates*

    The most important part of the private driver performance improvement strategy consist in data buffer fragments recycling and skb structure recycling. These techniques, formerly deployed in “forwarding ” driver, has been adapted for the S/G support and the new skb layout.

  - *CPU hotplug support*

    In order to support CPU Hotplug, the DPAA Ethernet driver has been adapted to a new QMAN API and implemented a new NAPI logic which maps the portals to each available CPU. When a CPU goes offline the portal interrupts are seamlessly migrated and processed by the boot-CPU (CPU #0)..

  - *Control MAC multicast group using socket API on MAC-less netdevice.*

    The MAC-less interface is now able to configure a MAC device by using the Proxy DPAA Ethernet Driver . The proxy interface offers a simple API to MAC-less interface for enablement and disablement of the MAC device and for adding and removing mac unicast and multicast addresses. This MAC-less feature is optional and can be activated by setting "proxy" attribute in the device tree node of the MAC-less interfaces.

  - *ASF is the default SDK configuration*

    For specific use cases, ASF can provide superior performance than the upstream IP stack, bypassing the normal Ethernet driver and stack processing. Normal stack features may become unavailable in ASF configuration. But, if one needs to compile out the ASF support, the variable KERNEL_DELTA_DEFCONFIG must be set to empty.

- **SDK1.4**
  - Added pause frame control support through ethtool
  - Added netpoll support
  - Moved "QDisc bypass for performance reasons" option to ASF
  - Added Linux standard API for hardware timestamping (IEEE1588)

- Moved kernel config options for DPAA Ethernet driver from "Device Drivers -> Network device support -> Ethernet (10000 Mbit) -> NXP Data Path Frame Manager Ethernet" to "Device Drivers->Network device support->Ethernet driver support->NXP devices -> DPAA Ethernet "

- **SDK1.3**
  - The bootarg which controls the maximum frame size (previously "fsl_fman_phy_max_frm") has been renamed as "fsl_fm_max_frm" and is now available in the menuconfig via: Device Drivers --> Frame Manager support --> NXP Frame Manager (datapath) support --> Maximum L2 frame size (CONFIG_FSL_FM_MAX_FRAME_SIZE)
  - The bootarg which controls the extra headroom ("fsl_fm_rx_extra_headroom") has been moved in the Kconfig and is now available via: Device Drivers --> Frame Manager support --> NXP Frame Manager (datapath) support --> Add extra headroom at beginning of data buffers (CONFIG_FSL_FM_RX_EXTRA_HEADROOM)
  - Scatter/Gather support is activated by the driver's "Optimize for termination" compile-time choice. It is no longer explicitly accessible via the Kconfig.

7.6.1.2.9.1 Known Issues

- The MTU currently defaults to a maximum of 1522. If you want a higher MTU, it is necessary to pass fsl_fm_max_frm=N on the kernel bootargs, where "N" is the desired maximum MTU + 22.
- Scatter Gather frames and Jumbo frames are not supported on LS1043A due to the FMan A010022 errata. We recommend disabling S/G through ethtool.

```
ethtool -K <interface> tx-scatter-gather off
```

7.6.1.2.9.2 Good Questions

1. What channel are the FQs assigned to?

   A: Each interface uses by default one pool channel across all Software Portals and also the dedicated channels of each CPU. Note that any of these channels may be shared with other DPAA Eth net devices, and even with other DPAA drivers such as SEC. The *default* and *error* FQs are assigned to the pool channel. The TX queues are assigned to the (direct connect) channel linked to the TX port associated with the interface. Any other statically-defined queues will be assigned in a round-robin fashion to the core-affine portals.

2. What work queue are the FQs assigned to?

   A:

   - Tx Confirmation FQs go to WQ1
   - Rx Error and Tx Error FQs go to WQ2
   - Rx Default, Tx and PCD FQs go to WQ3

3. How do I use the core-affined queues?

   The anticipated way of using the core-affined queues is to use one of the default FMC policy files:

   ```
   /etc/fmc/config/private/common/policy_ipv4.xml
   ```

   ```
   /etc/fmc/config/private/common/policy_ipv6.xml
   ```

   Default FMC configuration files are provided for each reference board:

   ```
   /etc/fmc/config/private/<name of reference board>/<RCW directory>/<name of configuration file>
   ```

   Here are two examples showing FMC commands using the default configuration and policy files:

   ```
   (1)    fmc -c /etc/fmc/config/private/t2080rdb/RRFFXX_P_66_15/config.xml  -p /etc/fmc/config/
   private/t2080rdb/RRFFXX_P_66_15/policy_ipv4.xml -a
   ```

Note that `/etc/fmc/config/private/t2080rdb/RRFFXX_P_66_15/policy_ipv4.xml` is a soft link to `/etc/fmc/config/private/common/policy_ipv4.xml`.

```
(2)    fmc -c /etc/fmc/config/private/t4240rdb/SSFFPPH_27_55_1_9/config_20g.xml  -p /etc/fmc/config/private/common/policy_ipv4.xml  -a
```

Note that `/etc/fmc/config/private/t4240rdb/RRFFXX_P_66_15/policy_ipv4.xml` is a soft link to `/etc/fmc/config/private/common/policy_ipv4.xml`.

If you create a configuration file instead of using one of the default configuration files, be sure to use the appropriate policies found in the default policy files:

`/etc/fmc/config/private/common/policy_ipv4.xml`

`/etc/fmc/config/private/common/policy_ipv6.xml`.

7.6.1.3 Quality of Service

7.6.1.3.1 Features

DPAA platforms can offload QoS functions such as policing, shaping, scheduling and prioritization to dedicated hardware blocks.

Traffic policing is achieved on ingress through the FMan. A two rate three color marker algorithm can be configured through the fmc tool.

Traffic scheduling, shaping, and prioritization is executed on the egress path in the QMan. Multiple algorithms, such as dual rate shaping and strict prioritization, are implemented and can be configured through queuing disciplines.

7.6.1.3.2 Policing

The FMan's Policer sub block implements a two rate, three color marker (trTCM) traffic policing algorithm. The algorithm has two configurable flavors: RFC2698 and RFC4115.

The fmc tool, described in detail in Frame Manager Configuration Tool User's Guide, is used to enable the Policer and set up its parameters.

For more information regarding the FMan Policer and how it can be configured, see the FMan Policer and the Policer Section chapters.

7.6.1.3.3 Scheduling and Shaping

7.6.1.3.3.1 Description

Specific DPAA 1.x platforms offer scheduling, shaping and prioritization capabilities through CEETM (Customer Edge Egress Traffic Management). The CEETM hardware block is a member of the QMan on the NXP QorIQ T-series and B-series platforms. Its purpose is to enhance the performances of DPAA platforms by moving the egress QoS logic from software to hardware.

This chapter briefly describes the CEETM block and its capabilities. Furthermore, it presents how it can be configured through the Linux traffic control tool (`tc`) by using a custom queuing discipline.

7.6.1.3.3.1.1 The CEETM architecture

CEETM is a sub block of the QMan and is an alternative to the regular *frame queue - work queue - channel* scheduling mode. For more information regarding this workflow, or on DCPs and sub-portals, please refer to the QMan Overview chapter.

A CEETM block, pictured in Figure 163. CEETM block on page 1068, is available for each FMan and it is intended to be used by FMan sub-portals linked to Ethernet interfaces.

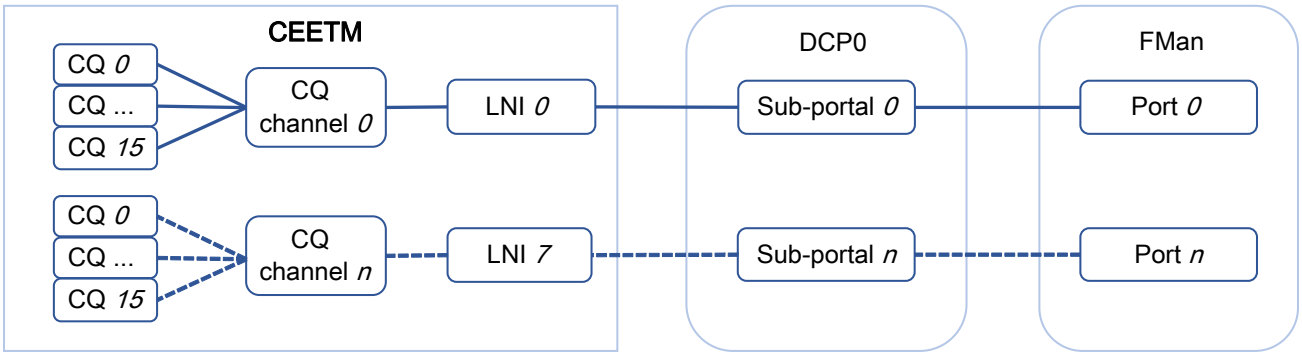

Figure 163. CEETM block

CEETM uses 8 Logical Network Interfaces (LNIs) that can be mapped to the FMan's DCP sub-portals. Depending on the platform used, there are 8 or 32 class queue channels (or CQ channels) that can be mapped to the LNIs. Multiple CQ channels can be mapped to the same LNI.

Each CQ channel contains 16 class queues. 8 CQs are independent while the other 8 can be grouped into 1 class group or 2 class groups of 4 queues each. The first group is called *group A* and the second is called *group B*.

7.6.1.3.3.1.2 Features

CEETM implements the following algorithms:

- Strict Priority scheduling
- Weighted Bandwidth Fair Scheduling (WBFS)
- dual-rate shaping with committed and excess rates (CR/ER)
- shaped and unshaped Fair Queueing scheduling (shFQ, uFQ)

These algorithms are used together in specific combinations based on the CEETM's architecture described previously and pictured in Figure 164. CEETM architecture on page 1068 .

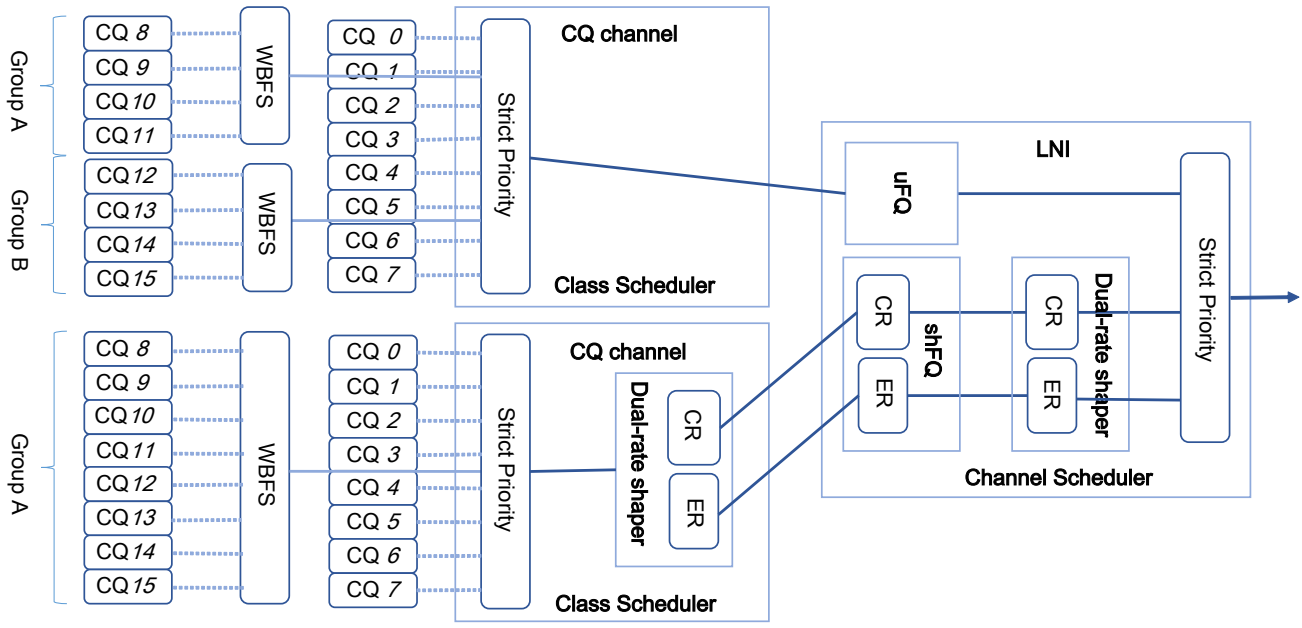

Figure 164. CEETM architecture

All the CQs connected to a CQ channel pass through a Strict Priority scheduler. The lower the CQ's ID, the higher the CQ's priority (e.g. CQ#3 has a higher priority than CQ#4, thus, as long as there are frames queued to CQ#3, CQ#4 will not be dequeued).

The priority of the CQ groups is configurable. All frames coming from the grouped CQs pass through the WBFS algorithm. Each CQ belonging to a group is assigned a weight portion of the bandwidth available to the group. The weight is a value from 1 to 248 in pseudo logarithmic steps of 1.5%. A list of available weights can be found in the platform's QorIQ DPAA Reference Manual.

The CQ channels can be shaped or unshaped. For CQs leading to a shaped channel, all frames will pass through a dual-rate shaper before entering the LNI. The independent CQs, as well as the class groups, can be configured to lead their frames through the CR shaper, the ER shaper, or both.

Each LNI aggregates frames from the CQ channels linked to it. All the unshaped frames from the unshaped CQ channels mapped to the LNI pass through the uFQ algorithm. The CR/ER frames from the shaped CQ channels pass through the shFQ algorithm and through another dual-rate shaper. Lastly, all frames pass through the LNI's Strict Priority module that schedules the unshaped frame (with high priority), the CR frames (with medium priority) and the ER frames (with low priority).

The shFQ algorithm schedules a channel for transmitting if the channel's shaper is time eligible (the shaper has a positive number of tokens in its bucket). When a channel finished its tokens, it is added to a waiting queue where it must wait for any other time eligible channels ahead of it finish transmitting.

The uFQ algorithm is similar to the shFQ. In the uFQ algorithm, all channels are time eligible. After finishing to transmit all their available data, they are added to the back of the time eligible waiting queue where their bucket is instantly refilled. The token bucket limit of the unshaped channels is configurable.

For more information regarding the CEETM's capabilities and detailed descriptions of the mentioned algorithms, take a look at your platform's QorIQ DPAA Reference Manual.

7.6.1.3.3.1.3 Integration with queuing disciplines

The CEETM block can be configured through the *ceetm* queuing discipline. A comparison between the hardware block and the traffic control's terminology is drawn in Figure 165. Comparison between CEETM and tc terminology on page 1069.

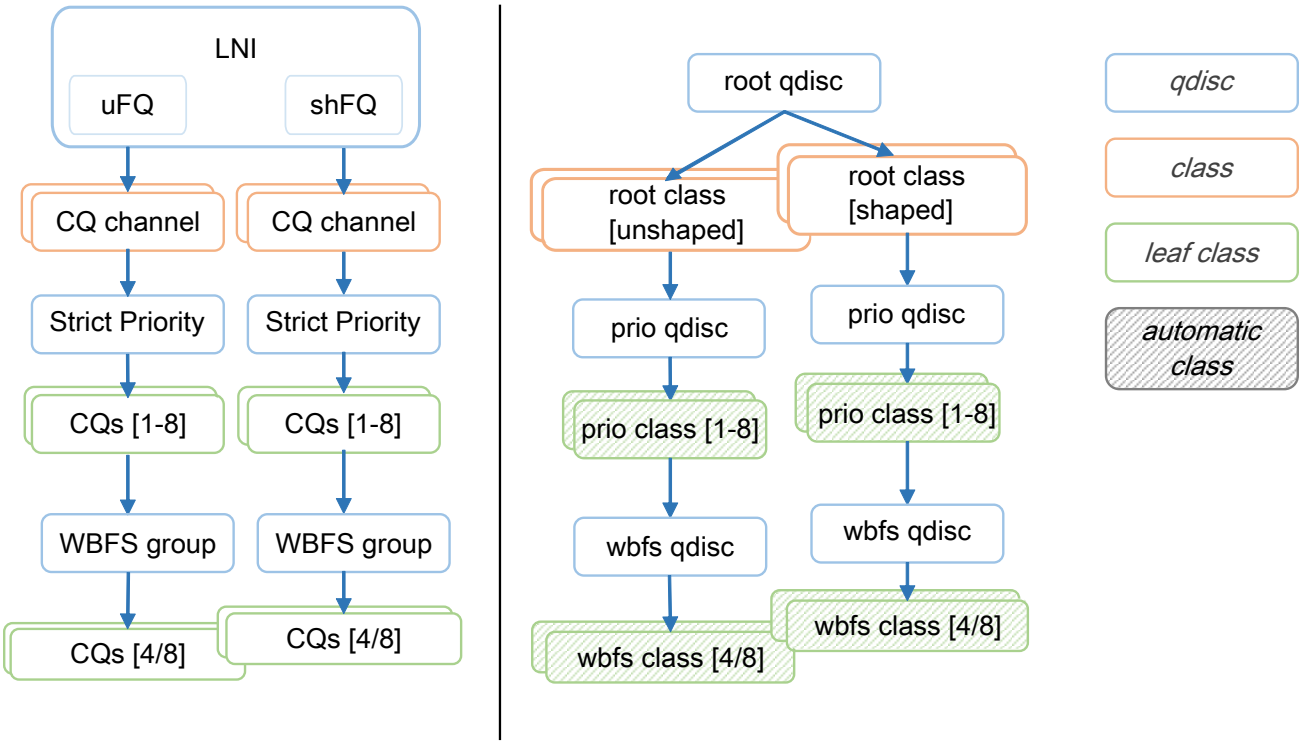

Figure 165. Comparison between CEETM and `tc` terminology

A LNI can be mapped to a FMan port by adding a *root* `ceetm` qdisc to a network interface. The LNI shaper's CR and ER are configured by setting a *rate*, and optional *ceil* and *overhead*, on the qdisc.

A CQ channel can be linked to a LNI by creating a `ceetm` *root* class mapped to the *root* qdisc. For an unshaped channel, the uFQ's token bucket limit (*tbl*) needs to be configured. For a shaped channel, the *rate*, and optional *ceil*, set the CR and ER.

Note: Shaped CQ channels can be linked to the LNI only if the LNI's shaper is enabled.

A channel's independent CQs are configured when a *prio* qdisc is linked to a *root* class. Between 1 and 8 *prio* classes are generated, each class corresponding to a CQ linked to the channel's Strict Priority scheduler. The *qcount* parameter indicates the number of child classes. If the channel is shaped, all generated classes participate by default in both CR and ER shaping. In order to disable one or the other, the CQ's corresponding *prio* class's *cr* and *er* parameters can be changed.

Note: CQs linked to a shaped CQ channel can not have both CR and ER shaping disabled.

In order to configure the CQ groups, a *wbfs* qdisc is linked to one of the *prio* classes. Either 4 or 8 *wbfs* classes are generated, depending on the number of CQs in the group indicated by the *qcount* parameter. The group is placed right after its parent in the channel's Strict Priority list (e.g. if the *wbfs* qdisc is linked to the *prio* class #2, the priority list becomes: class #1, class #2, group, class #3, class #4, etc). The CQ weights are configured through the *qweight* parameter and can be changed for each CQ individually. For groups linked to shaped CQ channels, the CR and ER shaping are enabled by the *cr* and *er* parameters.

Note: Groups linked to a shaped CQ channel can not have both CR and ER shaping disabled.

For more details on the `ceetm` qdisc's parameters and configuration, see the Usage on page 1071 chapter.

7.6.1.3.3.2 User guide

7.6.1.3.3.2.1 Supported platforms

The CEETM block is present and configurable through the `ceetm` qdisc on all T-series, B-series and LS1043A/LS1046A platforms.

7.6.1.3.3.2.2 Getting started

1. Enable the *ceetm* qdisc support in the kernel, along with any classifiers or other features that might be needed.

```
-> Device Drivers
    -> Network device support (NETDEVICES [=y])
        -> Ethernet driver support (ETHERNET [=y])
            -> Freescale devices (NET_VENDOR_FREESCALE [=y])
                -> DPAA Ethernet (FSL_SDK_DPAA_ETH [=y])
                    -> DPAA CEETM QoS (FSL_DPAA_CEETM [=y])

->  Networking support (NET [=y])
    -> Networking options
        -> QoS and/or fair queueing (NET_SCHED [=y])
            -> Universal 32bit comparisons w/ hashing (u32) (NET_CLS_U32 [=y])
```

2. Add the `ceetm` recipe to your Yocto build by adding the following line to your `conf/local.conf` file.

```
IMAGE_INSTALL_append =  "  ceetm"
```

7.6.1.3.3.2.3 Limitations

- CEETM is supported on DPAA Private Ethernet interfaces only.
- CEETM isn't supported on top of Linux bonding interfaces.

7.6.1.3.3.2.4 Usage

You can see the `ceetm` qdisc's help message by running the following command:

```
~# tc qdisc add ceetm help
Usage:
... qdisc add ... ceetm type root [rate R [ceil C] [overhead O]]
... class add ... ceetm type root (tbl T | rate R [ceil C])
... qdisc add ... ceetm type prio qcount Q
... qdisc add ... ceetm type wbfs qcount Q qweight W1 ... Wn [cr CR] [er ER]

Update configurations:
... qdisc change ... ceetm type root [rate R [ceil C] [overhead O]]
... class change ... ceetm type root (tbl T | rate R [ceil C])
... class change ... ceetm type prio [cr CR] [er ER]
... qdisc change ... ceetm type wbfs [cr CR] [er ER]
... class change ... ceetm type wbfs qweight W

Qdisc types:
root - configure a LNI linked to a FMan port
prio - configure a channel's Priority Scheduler with up to eight classes
wbfs - configure a Weighted Bandwidth Fair Scheduler with four or eight classes

Class types:
root - configure a shaped or unshaped channel
prio - configure an independent class queue

Options:
R - the CR of the LNI's or channel's dual-rate shaper (required for shaping scenarios)
C - the ER of the LNI's or channel's dual-rate shaper (optional for shaping scenarios, defaults
to 0)
O - per-packet size overhead used in rate computations (required for shaping scenarios,
recommended value is 24 i.e. 12 bytes IFG + 8 bytes Preamble + 4 bytes FCS)
T - the token bucket limit of an unshaped channel used as fair queuing weight (required for
unshaped channels)
CR/ER - boolean marking if the class group or prio class queue contributes to CR/ER shaping (1)
or not (0) (optional, at least one needs to be enabled for shaping scenarios, both default to 1
for prio class queues)
Q - the number of class queues connected to the channel (from 1 to 8) or in a class group (either
4 or 8)
W - the weights of each class in the class group measured in a log scale with values from 1 to
248 (when adding a wbfs qdisc, either four or eight, depending on the size of the class group;
when updating a wbfs class, only one)
```

Filters need to be added on each qdisc layer in order to allow packets to reach the leaf classes. Likewise, all filters need to be removed from each qdisc layer when no longer used.

7.6.1.3.3.3 Examples

7.6.1.3.3.3.1 Rate limit two streams

7.6.1.3.3.3.1.1 Setup

In the following example a platform with CEETM support (T1040RDB - Client) is connected to another board (T1024RDB - Server) through a 1G link. The described setup is pictured in Figure 166. Rate example setup on page 1072.

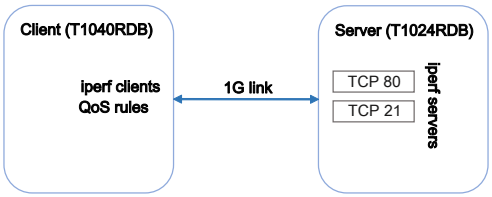

Figure 166. Rate example setup

The `iperf` clients run on the Client while the `iperf` servers run on the Server. The Server listens on 2 TCP ports (21 and 80).

```
root@t1024rdb:~# iperf -s -p 21 &
root@t1024rdb:~# iperf -s -p 80 &
```

PCDs are applied on both platforms in advance.

```
root@t1024rdb:~# fmc -c /etc/fmc/config/private/t1024rdb/RRX_PPP_95/config.xml -p /etc/fmc/config/
private/t1024rdb/RRX_PPP_95/policy_ipv4.xml -a
root@t1040rdb:~# fmc -c /etc/fmc/config/private/t1040rdb/RR_P_66/config.xml -p /etc/fmc/config/
private/t1040rdb/RR_P_66/policy_ipv4.xml -a
```

In order to keep this example minimal, ARP frames aren't filtered and classified. Thus, MAC addresses need to be exchanged and saved in advance as well.

```
root@t1040rdb:~# arp -s <server IP address> <server HW address>
root@t1024rdb:~# arp -s <client IP address> <client HW address>
```

After adding the qdiscs, the Client runs the `iperf` clients.

```
root@t1040rdb:~# iperf -c <server IP address> -p 21 &
root@t1040rdb:~# iperf -c <server IP address> -p 80 &
```

7.6.1.3.3.3.1.2 Execution

This example's corresponding qdisc and class hierarchy is pictured in Figure 167. Rate example class hierarchy on page 1072.

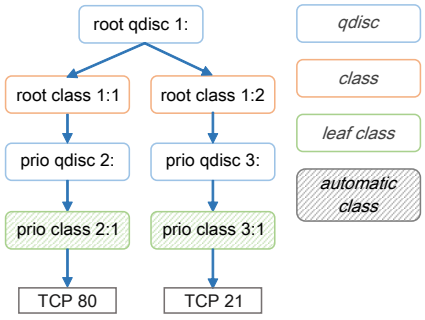

Figure 167. Rate example class hierarchy

Add a ceetm qdisc to the interface and configure the LNI's dual-rate shaper with a CR of 1Gbps.

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 root handle 1: ceetm type root rate 1000mbit overhead
24
```

Add a shaped channel to the LNI and configure its dual-rate shaper with a CR of 150mbps.

```
root@t1040rdb:~#  tc class add dev fm1-gb0 parent 1: classid 1:1 ceetm type root rate 150mbit
```

Add another shaped channel to the LNI and configure its dual-rate shaper with a CR of 850mbps.

```
root@t1040rdb:~#  tc class add dev fm1-gb0 parent 1: classid 1:2 ceetm type root rate 850mbit
```

Configure one of the first channel's priority classes (marked by default as both CR and ER eligible).

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 parent 1:1 handle 2: ceetm type prio qcount 1
```

Configure one of the second channel's priority classes (marked by default as both CR and ER eligible).

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 parent 1:2 handle 3: ceetm type prio qcount 1
```

Add filters that will classify all packets with the destination port equal to 80 and lead them through the priority class of the first channel.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 1:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 2: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 2:1
```

Add filters that will classify all packets with the destination port equal to 21 and lead them through the priority class of the second channel.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 21
0xffff flowid 1:2
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 3: prio 1 protocol ip u32 match ip dport 21
0xffff flowid 3:1
```

7.6.1.3.3.3.2 Prioritization of two streams

7.6.1.3.3.3.2.1 Setup

The same setup is used as for the rate limit example.

7.6.1.3.3.3.2.2 Execution

This example's corresponding qdisc and class hierarchy is pictured in Figure 168. Prioritization example class hierarchy on page 1073.

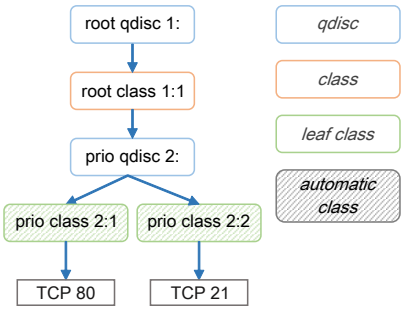

Figure 168. Prioritization example class hierarchy

Add a ceetm qdisc to the interface and configure the LNI's dual-rate shaper with a CR of 1Gbps.

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 root handle 1: ceetm type root rate 1000mbit overhead
24
```

Add a shaped channel to the LNI and configure its dual-rate shaper with a CR of 1Gbps.

```
root@t1040rdb:~#  tc class add dev fm1-gb0 parent 1: classid 1:1 ceetm type root rate 1000mbit
```

Configure two of the channel's priority classes (marked by default as both CR and ER eligible).

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 parent 1:1 handle 2: ceetm type prio qcount 2
```

Add filters that will classify all packets with the destination port equal to 80 and lead them through the highest priority class of the channel.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 1:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 2: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 2:1
```

Add filters that will classify all packets with the destination port equal to 21 and lead them through the second (lowest) priority class of the channel.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 8000
0xffff flowid 1:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 2: prio 1 protocol ip u32 match ip dport 8000
0xffff flowid 2:2
```

7.6.1.3.3.3.3 Assigning weights to two streams

7.6.1.3.3.3.3.1 Setup

The same setup is used as for the rate limit example.

7.6.1.3.3.3.3.2 Execution

This example's corresponding qdisc and class hierarchy is pictured in Figure 169. WBFS example class hierarchy on page 1074.

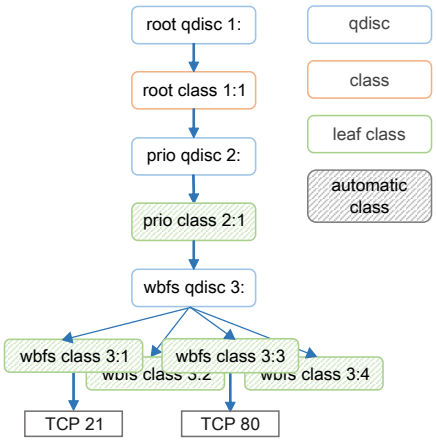

Figure 169. WBFS example class hierarchy

Add a ceetm qdisc to the interface and configure the LNI's dual-rate shaper with a CR of 1Gbps.

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 root handle 1: ceetm type root rate 1000mbit overhead
24
```

Add a shaped channel to the LNI and configure its dual-rate shaper with a CR of 1Gbps.

```
root@t1040rdb:~#  tc class add dev fm1-gb0 parent 1: classid 1:1 ceetm type root rate 1000mbit
```

Configure one of the channel's priority classes (marked by default as both CR and ER eligible).

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 parent 1:1 handle 2: ceetm type prio qcount 1
```

Configure a class group of four classes, place it after the 2:1 class in the priority list, and assign different weights to each class (10, 50, 120 and 200).

```
root@t1040rdb:~#  tc qdisc add dev fm1-gb0 parent 2:1 handle 3: ceetm type wbfs qcount 4 qweight
10 50 120 200 cr 1 er 1
```

Add filters that will classify all packets with the destination port equal to 21 and lead them through the class with the highest weight of the group.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 21
0xffff flowid 1:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 2: prio 1 protocol ip u32 match ip dport 21
0xffff flowid 2:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 3: prio 1 protocol ip u32 match ip dport 21
0xffff flowid 3:1
```

Add filters that will classify all packets with the destination port equal to 80 and lead them through another classes of the group.

```
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 1: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 1:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 2: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 2:1
root@t1040rdb:~#  tc filter add dev fm1-gb0 parent 3: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 3:3
```

7.6.1.3.3.3.4 Unshaped Fair Queuing of two streams

7.6.1.3.3.3.4.1 Setup

In the following example a platform with CEETM support (T1024RDB - Main) is connected to two other boards: a T1024RDB (Client) through a 10G link and a T1040RDB (Server) through a 1G link. The described setup is pictured in Figure 170. Unshaped Fair Queuing example setup on page 1075.

Figure 170. Unshaped Fair Queuing example setup

The `iperf` clients run on the Client while the `iperf` servers run on the Server. The Server listens on two TCP ports (80 and 81).

```
root@t1040rdb:~# iperf -s -p 80 &
root@t1040rdb:~# iperf -s -p 81 &
```

PCDs are applied on all platforms in advance.

```
root@t1024rdb:~# fmc -c /etc/fmc/config/private/t1024rdb/RRX_PPP_95/config.xml -p /etc/fmc/config/
private/t1024rdb/RRX_PPP_95/policy_ipv4.xml -a
root@t1040rdb:~# fmc -c /etc/fmc/config/private/t1040rdb/RR_P_66/config.xml -p /etc/fmc/config/
private/t1040rdb/RR_P_66/policy_ipv4.xml -a
```

In order to keep this example minimal, ARP frames aren't filtered and classified. Thus, MAC addresses need to be exchanged and saved in advance as well.

```
# Server:
root@t1040rdb:~# arp -s <main IP address> <main HW address>
# Main:
root@t1024rdb:~# arp -s <client IP address> <client HW address>
root@t1024rdb:~# arp -s <server IP address> <server HW address>
# Client:
root@t1024rdb:~# arp -s <main IP address> <main HW address>
```

IP forwarding is enabled on the Main board. Routes are added on the Server and Client boards as well.

```
# Main:
root@t1024rdb:~# echo 1 > /proc/sys/net/ipv4/ip_forward
# Client:
root@t1024rdb:~# route add -net <server network address> <server network mask> gw <main IP
address>
# Server:
root@t1040rdb:~# route add -net <client network address> <client network mask> gw <main IP
address>
```

After adding the qdiscs, the Client runs the `iperf` clients.

```
root@t1024rdb:~# iperf -c <server IP address> -p 80 &
root@t1024rdb:~# iperf -c <server IP address> -p 81 &
```

7.6.1.3.3.3.4.2 Execution

This example's corresponding qdisc and class hierarchy is pictured in Figure 171. Unshaped Fair Queuing example class hierarchy on page 1076.

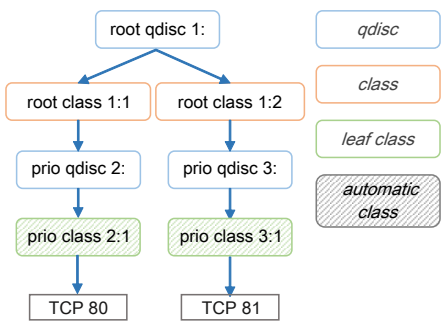

Figure 171. Unshaped Fair Queuing example class hierarchy

Add a ceetm qdisc to the interface and don't configure the LNI's dual-rate shaper.

```
root@t1024rdb:~# tc qdisc add dev fm1-mac3 root handle 1: ceetm type root
```

Add an unshaped channel to the LNI and configure its CR's token bucket limit to 1000 bytes.

```
root@t1024rdb:~# tc class add dev fm1-mac3 parent 1: classid 1:1 ceetm type root tbl 1000
```

Add another unshaped channel to the LNI and configure its CR's token bucket limit to 500 bytes.

```
root@t1024rdb:~# tc class add dev fm1-mac3 parent 1: classid 1:2 ceetm type root tbl 500
```

Configure one of the first channel's priority classes.

```
root@t1024rdb:~# tc qdisc add dev fm1-mac3 parent 1:1 handle 2: ceetm type prio qcount 1
```

Configure one of the second channel's priority classes.

```
root@t1024rdb:~# tc qdisc add dev fm1-mac3 parent 1:2 handle 3: ceetm type prio qcount 1
```

Add filters that will classify all packets with the destination port equal to 80 and lead them through the priority class of the first channel.

```
root@t1024rdb:~#  tc filter add dev fm1-mac3 parent 1: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 1:1
root@t1024rdb:~#  tc filter add dev fm1-mac3 parent 2: prio 1 protocol ip u32 match ip dport 80
0xffff flowid 2:1
```

Add filters that will classify all packets with the destination port equal to 81 and lead them through the priority class of the second channel.

```
root@t1024rdb:~#  tc filter add dev fm1-mac3 parent 1: prio 1 protocol ip u32 match ip dport 81
0xffff flowid 1:2
root@t1024rdb:~#  tc filter add dev fm1-mac3 parent 3: prio 1 protocol ip u32 match ip dport 81
0xffff flowid 3:1
```

7.6.2 Linux Ethernet for Enhanced Three Speed Ethernet Controller Family

7.6.2.1 Linux Ethernet Driver for eTSEC

7.6.2.1.1 Introduction

7.6.2.1.1.1 Overview

Gianfar is the Linux driver that enables Ethernet support for the SoCs featuring eTSEC (Enhanced Three-Speed Ethernet Controllers). Though the driver is designed to support the latest eTSEC2.0 features present on the low-power QorIQ platforms, it also maintains backward compatibility with older IPs from the same family, like eTSEC (eTSEC 1.x) and TSEC (present on the PowerQUICC III platforms) and FEC (Fast Ethernet Controller).

7.6.2.1.1.2 Purpose

The purpose of this document is to provide a user guide and configuration details for the Gianfar driver, and a high-level view of the driver's structure, as well as to describe its major functionalities with a focus on the features provided by the eTSEC2.0 IP.

7.6.2.1.1.3 Features

This section provides an overview of the major eTSEC2.0 (“virtualized” eTSEC) features:

- o MAC Layer
- *o Interrupt grouping mechanism*
- *o Virtualized register space*
- o Rx Subsystem:
  - MAC Address Filter
  - L2/L3/L4 Parser
  - Filer Engine
  - *Hash or RR Distribution*
  - *Multiple Rx Interrupt*
- o Tx Subsystem:
  - Tx Scheduler
  - L3/L4 Offload
  - *Multiple Tx Interrupt*

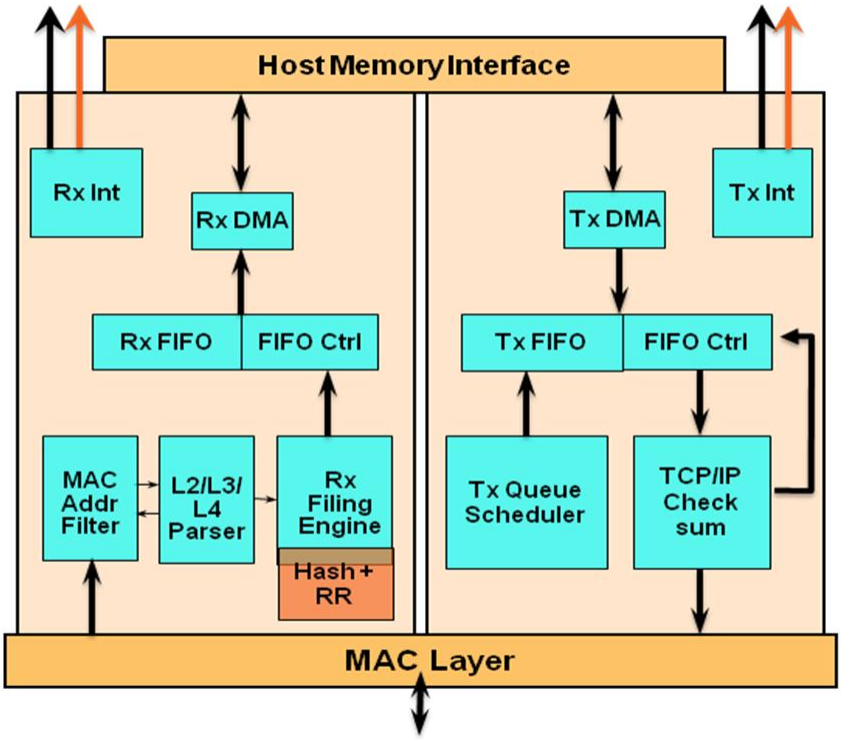

Figure 172. “Virtualized” eTSEC Block Diagram

- *o Interrupt virtualization:*
  - Each ring maps to one of two separate groups for interrupt and BD management; each group associated by software with a CPU.
  - Separate address spaces per group and for MDIO.

- Interrupt coalescing controls per ring in multi-group mode, packet-count based and timer based thresholds, for both Rx and Tx.

- *o TCP/IP Offload Engine (TOE):*
  - IP v4 and IP v6 header recognition on receive
  - IP v4 header checksum verification and generation
  - TCP and UDP checksum verification and generation
  - Per-packet configurable offload
  - Recognition of VLAN, stacked-VLAN, 802.2, PPPoE session, MPLS stacks, and ESP/AH IP-Security headers
- *o Quality of service (QoS) support:*
  - Transmission from up to eight queues: priority-based queue selection or modified weighted round-robin (MWRR) queue selection with fair bandwidth allocation
  - Reception to up to eight physical queues:

    - Table-oriented queue filing strategy based on 16 header fields or flags

    - Frame rejection support for filtering applications

    - Filing based on Ethernet, IP, and TCP/UDP properties, including VLAN fields, Ether-type, IP protocol type, IP TOS or differentiated services, IP source and destination addresses, TCP/UDP port number

7.6.2.1.1.4 Notes on high level decomposition and data flow

A system level block view, from a network device perspective, may be depicted as follows:

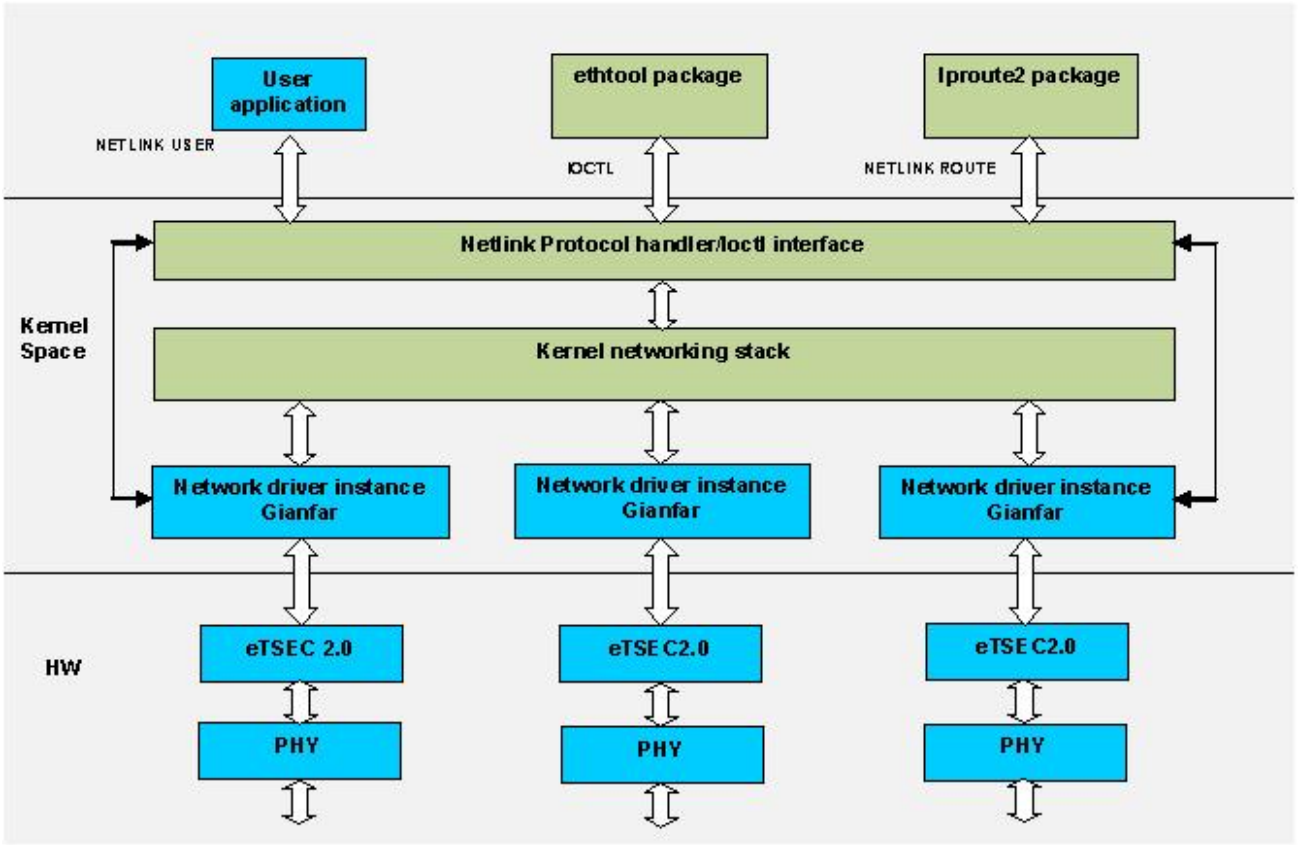

Figure 173. Gianfar High level decomposition

The eTSEC2.0 and PHY are the hardware blocks, the kernel networking stack along with the network driver are running in the Kernel space, and finally ethtool and iproute2 are examples of user space tools used for configuring the network devices.

The eTSEC2.0 includes some additional support compared with the previous versions:

- it has support for interrupt virtualization
- on the TX side, it can distribute packets to the multiple queues based on simple hashing or round robin mechanisms

The eTSEC2.0 has support for multiple RX and TX queues. On the receive side, an incoming packet will be filed to one of the queues based on the rules programmed into the filer. By default, all the packets will be filed to queue 0. On the transmit side, either a simple hash based implementation or a round robin algorithm distributes the packets to the available number of queues. User space packages like ethtool and iproute are used to configure the network device parameters. The ethtool interface is extended to provide support for filer programming.

The kernel space module for the network driver is the most important block as it communicates with both the user space and the H/W IP to control the processing of packets. The eTSEC network device driver will be referred to as Gianfar in the rest of the document.

The Gianfar driver may be divided into sub-blocks based on the number of independent threads that Linux will run in order to completely transfer a packet from ingress to egress side. The basic functionality of any Ethernet driver is to handle the reception of packets from an ingress port (might include checksum calculation, header verification, etc), as well as the transmission of packets on the egress port (might include checksum re-calculation, header manipulation, etc). There are also the device configuration and control functionalities, and device status reporting. When the Ethernet driver is actually implementing these functionalities, it needs to interact with the core (Kernel) as well as the hardware IP (the Ethernet controller).

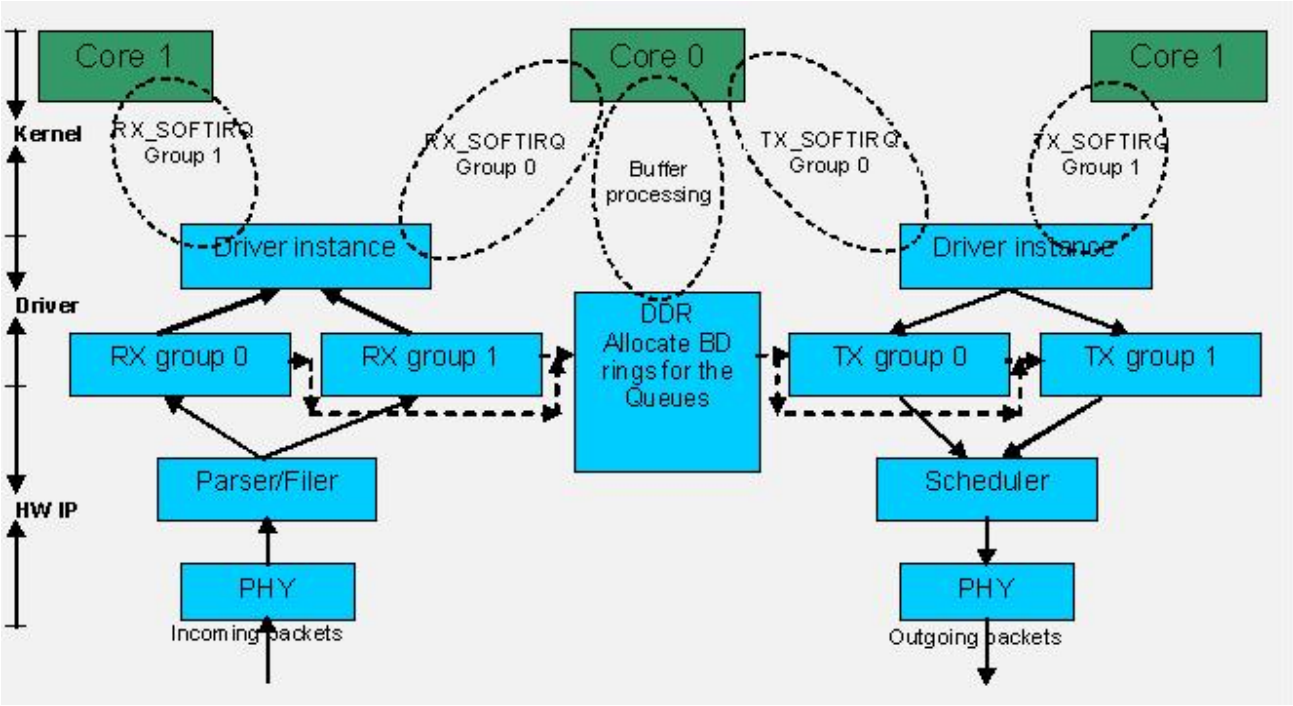

Figure 174. Gianfar Packet Flow

In the above Figure it can be noted that the receive side includes parsing/ filing before a packet is "put" into a buffer descriptor. The transmit side includes a H/W queue scheduler for transmission of packets.

As already mentioned, eTSEC2.0 has support for multiple hardware queues for Rx and Tx in hardware. These queues are basically divided into two groups; let's say all odd numbered queues correspond to one group and even numbered queues

correspond to other group. In a multi core environment (e.g. a dual core system), each group of queues can be programmed to be handled by one of the two cores, which will result in an increased performance.

For simplicity, we always assume that:

- All the even numbered queues are mapped to Group 0 and odd numbered queues are mapped to Group1.
- Group 0 interrupts can be assigned to be processed by Core 0 and Group 1 interrupts to be processed by Core 1 (except for error the interrupts, which are always destined to Core 0, which is the master core).

From the above figure, it can be noticed that there will be a receive, and a transmit thread running on each core, for processing the packets corresponding to the group assigned to that core. The receive thread processes the received packets - handles the RX buffer descriptor (BD) rings, and passes the received packets to the networking stack for further processing; the transmit thread schedules the packets passed down by the stack to be transmitted out of the device. There's also a transmission cleanup thread, triggered by the TX confirmation interrupts, to handle the TX BD rings and congestion.

Gianfar may be broadly decomposed into the following sub-blocks:

1. Initialization block
2. Receive block
3. Transmit block
4. Control block

So, the Receive and Transmit blocks handle processing of ingress and egress packets.

Before processing packets the driver needs to perform some initialization steps like:

- extracting the device tree parameters
- initialization of the multiple queues
- registering the driver with the kernel
- allocating buffer descriptors
- registering the interrupts (etc.)

All these functionalities are implemented by the Initialization block.

Each of these sub-modules implements various functionalities, as detailed in the coming section.

7.6.2.1.2 Functionality

7.6.2.1.2.1 Multi-Queue support

eTSEC features multiple physical queues or BD rings. The multi-queue support (MQ) in the driver is enabled by default for eTSEC2.0 IPs.

Hardware queue events are mapped to one of the two available CPUs via eTSEC *Interrupt Groups*. For eTSEC2.0, each Rx/Tx hardware queue or BD ring is mapped to one of the two available Interrupt Groups, and each group in turn has its Rx/Tx interrupt lines assigned to a given CPU. By default, the driver enables 1 Rx and 1 Tx queue per Interrupt Group.

eTSEC2.0 supports 2 Interrupt Groups, this is also known as the Multi-Group (MG) mode in Gianfar. Each group has its own Rx, Tx and Err interrupt lines which can be individually affined to any of the 2 CPUs, as a measure to balance the processing load. Also, each interrupt group has its own block of registers, most notably `ievent`, `imask`, `tstat`, and `rstat`, so queue events are handled at the interrupt group level. Having more than 1 Rx and 1 Tx queue assigned to a single interrupt group would thus incur a software processing overhead that would not be justifiable for the majority of use cases. This is why the driver enables by default only 1 set of Rx and Tx queues per Interrupt Group.

eTSEC1.x and other older eTSEC IPs support only one interrupt group (g0), meaning that they are working in Single Group (SG) mode.

The mapping Rx/Tx queues to interrupt groups is by default: Rx Q0 and Tx Q0 assigned to Group0 (`g0`), and Rx Q1 and Tx Q1 assigned to Group1 (`g1`).

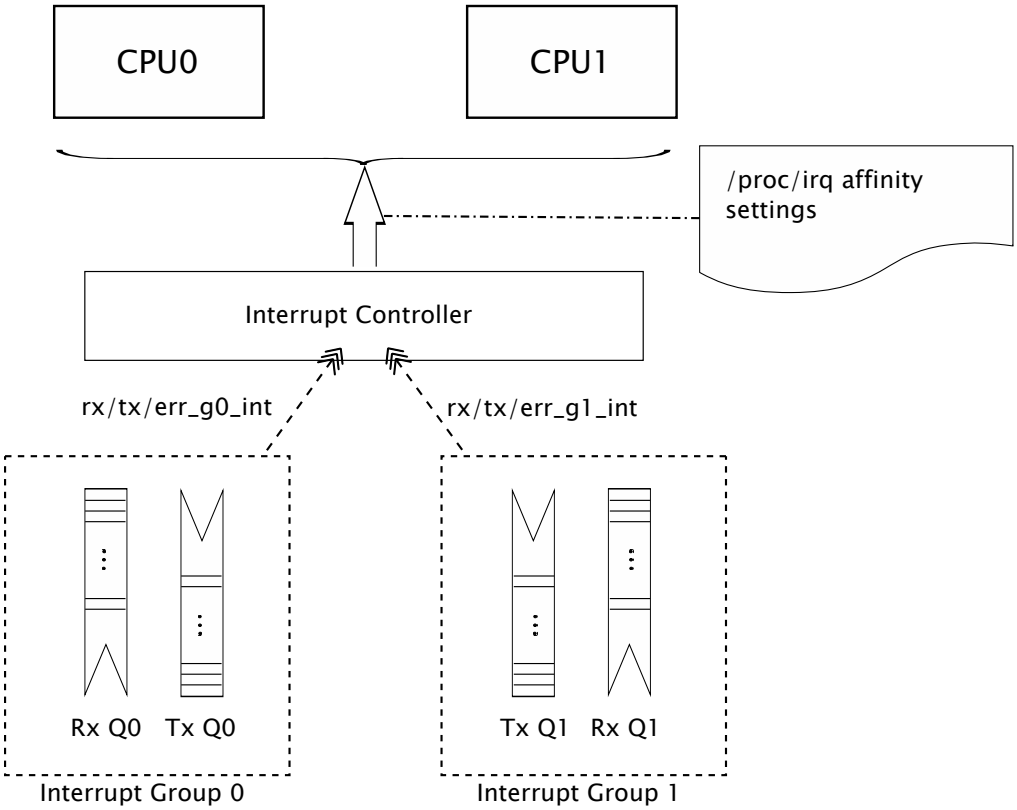

Figure 175. Multi-Queue Multi-Group

NOTE

Supporting more than one Rx/Tx queue per interrupt group has been obsoleted (see above). As a result, the following device tree properties are *obsolete*: `fsl,num-rx-queues`, `fsl,num-tx-queues`, `fsl,rx-bit-map`, and `fsl,tx-bit-map`.

7.6.2.1.2.2 Receive Side Scaling support

eTSEC supports multiple Rx and Tx descriptor queues (see multi-queue support). On reception, eTSEC can send different packets to different queues to distribute processing among CPUs. This mechanism is generally known as “Receive-side Scaling” (RSS).

In Gianfar, packets are distributed by applying "n-tuple" filters configured from `ethtool -N` (`--config-ntuple` option). These filters are converted by Gianfar to eTSEC Filer H/W rules. Based on these programmable filters, each packet is assigned to one of a small number of logical flows. Packets for each flow are steered to separate receive queues, which in turn can be processed by separate CPUs.

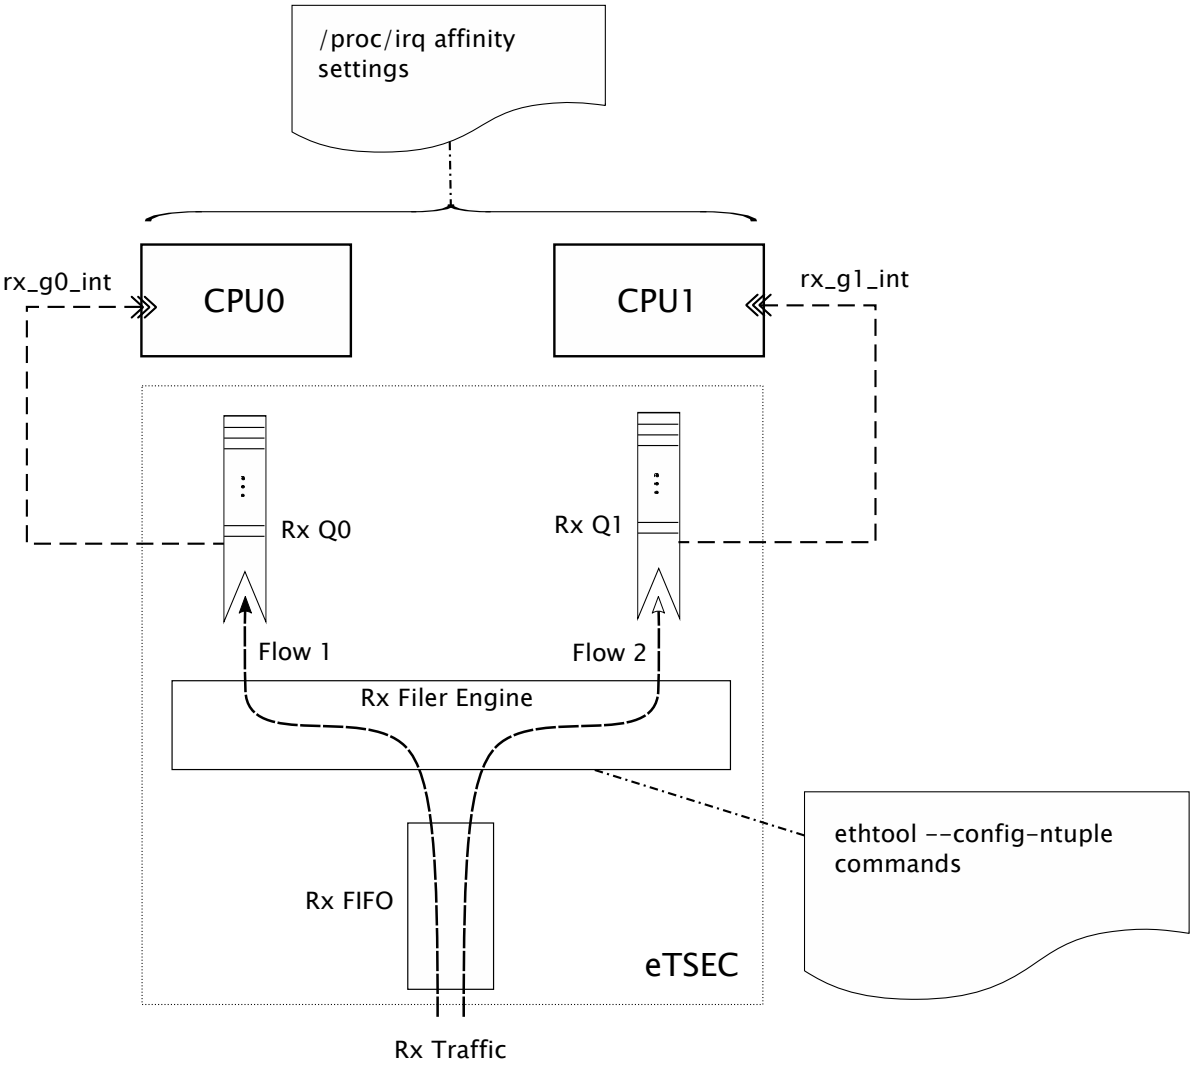

Figure 176. eTSEC RSS support

In Gianfar, Rx flows may be classified either by hashing various protocol header fields, see `ethtool -N rx-flow-hash` option, or by specifying flow type classification rules, see `ethtool -N flow-type` option. Refer to ethtool Linux man-pages for `ethtool -N` option details. A simple usage example is shown below.

```

7.6.2.1.2.3 NAPI support

Gianfar uses NAPI handling on both Rx and Tx paths, the Linux polling mechanism being triggered by frame receive interrupts and, respectively, frame transmit confirmation interrupts. The driver registers irqs for both Rx and Tx, and the NAPI (polling) handlers are provided to the Kernel.

On the receive path:

- When the receive interrupt gets triggered on a given CPU, a softirq for the polling function on Rx is scheduled.
- The RX_SOFTIRQ thread is raised by the Kernel, on the CPU on which it was triggered (and scheduled), and the Rx queues mapped to the corresponding interrupt group will be processed by the driver's polling function and the incoming packets are being passed to the networking stack.

Similarly on the transmit part:

- A frame transmit confirmation interrupt triggers the scheduling of a softirq under whose context the driver's polling routine for cleaning the Tx rings is invoked.
- The Tx polling routine is also associated with a given interrupt group and it will handle only the transmit queues that are affiliated to that interrupt group.

For packet forwarding, for instance, by mapping the per flow Rx and Tx queues to interrupt groups that are associated to the same CPU, makes it possible to maintain per CPU buffer pools used for reclaiming buffers on a per flow basis, improving cache locality at the same time.

7.6.2.1.2.4 Interrupt Coalescing

On a high speed network interface the rate of packet reception and transmission can be as high as the CPUs would be spending most of the time servicing these interrupts. With the interrupt coalescing feature, packets are collected and one single interrupt is generated for multiple packets to avoid flooding the system with interrupts from the Ethernet device.

eTSEC supports hardware coalescing of interrupts for both receive and transmit, using packet-count-based thresholds, complemented by timer-based thresholds. Gianfar provides basic support for setting the coalescing parameters via `ethtool -C`, for each device instance, by implementing the following "set coalesce" options:

Table 193. `ethtool -C` options:

rx-frames	packet count threshold for receive (Rx)
rx-usecs	time threshold in microseconds, for receive (Rx)
tx-frames	packet count threshold for transmit confirmation (Tx)
tx-usesc	time threshold in microseconds, for transmit confirmation (Tx)

7.6.2.1.2.5 Header Recognition and Csum Offload

Header recognition on receive (feature provided by eTSEC), combined with parsing functions and/or hashing of extracted property fields (in case of eTSEC2.0), is used to implement advanced TCP/IP offloading functionality and QoS provisions by programming queue filing strategies into hardware.

Gianfar provides an API to program eTSEC's filer hardware block with packet filtering rules.

On Rx, the TCP/IP Offload Engine (TOE):

- can parse frames:
  - at layer 2 of the stack only (Ethernet headers and switching headers)
  - layers 2 to 3 (including IPv4 or IPv6)
  - layers 2 to 4 (including TCP and UDP)
- provides protocol header recognition

- provides header verification (IPv4 header checksum verification)
- provides TCP/UDP payload checksum verification including verification of associated pseudo-header checksums

For large frames, offload of checksum verification saves a significant fraction of the CPU cycles that would otherwise be spent by the TCP/IP stack. IP packet fragmentation and re-assembly, and TCP stream establishment and tear-down are not performed in hardware.

On Tx side, TOE provides IPv4 and TCP/UDP header checksum generation. The eTSEC does not checksum transmitted packets with IPv6 routing headers or calculate TCP/UDP checksums from IP fragments. If a transmitted TCP segment requires checksum generation but IPv6 extension headers would prevent eTSEC from calculating the pseudoheader checksum, software can calculate just the pseudoheader checksum in advance and supply it to the eTSEC as part of per-frame TOE configuration.

On the Rx side, Gianfar lets the Kernel know that checksum verification is not required if valid IP headers or TCP/UDP headers were found and valid sums were verified, by setting the `CHECKSUM_UNNECESSARY` flag. On Tx side, the checksum is generated (offloaded) for TCP/UDP packets over IPv4 based on the pseudo-header checksum *(phcs)* provided by the Linux networking stack. Gianfar instructs the stack about its ability to provide partial checksumming, based on the *phcs* for TCP/UDP packets, by setting the `NETIF_F_IP_CSUM` device capability flag.

The Frame Control Blocks (FCBs) are 8-byte blocks of TOE control and/or status data that are passed between the driver and each eTSEC. A FCB always precedes the frame it applies to, and is present only when TOE functions are being used.

The first BD of each frame points to the initial data buffer and the FCB. Custom or received Ethernet preamble sequences also follow the FCB if preambles are visible.

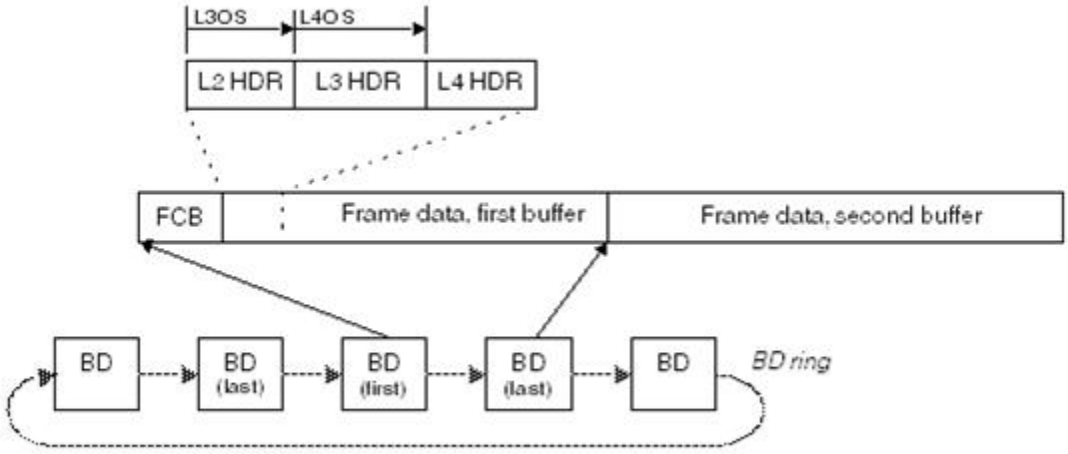

Figure 177. Location of Frame Control Blocks for TOE Parameters

For Tx, FCBs are inserted by Gianfar and TOE acceleration may be applied on a frame-by-frame basis. In the case of RxBD rings, the FCBs are inserted by eTSEC and TOE acceleration is enabled for receive for all frames in this case.

7.6.2.1.2.6 Scatter Gather Support

Scatter-Gather I/O is a method by which a single procedure call sequentially writes data from multiple buffers to a single data stream or reads data from a data stream to multiple buffers. The buffers are given in a vector of buffers. Scatter/gather refers to the process of gathering data from, or scattering data into, the given set of buffers. The I/O can be performed synchronously or asynchronously to this procedure.

On the Tx side, Gianfar supports "gathering" big packets from multiple buffers. This ability is signaled by the driver to the Linux network stack by setting the `NETIF_F_SG` device hardware feature flag. The driver takes into account the number of fragments composing the packet that is going to be transmitted, and places each fragment into consecutive BD ring buffers before issuing the command to start sending the frame.

On the Rx side, the eTSEC controller is capable of "scattering" big packets into multiple fixed size buffers having consecutive buffer descriptors (BDs). Gianfar supports this feature by implementing paged allocation, so that jumbo frames exceeding a fixed buffer size of 2048 bytes can be automatically received into multiple such buffers. Instead of pre-allocating huge memory buffers to be able to support jumbo frame reception, the paged allocation scheme implemented in Gianfar uses multiple half-page sized buffers thus reducing memory allocation pressure. The driver is also managing a local cache of memory pages, re-using free pages from the cache for future receptions, further improving Rx allocation overhead.

7.6.2.1.3 Configuration & Control

7.6.2.1.3.1 Device Tree initialization

Gianfar complies with the device tree (DTS) based open firmware support requirements, and supports multiple Ethernet device instances. The default configuration parameters that are passed via DTS for an Ethernet device instance (node) include:

1. `compatible` and `model` fields defining the driver compatibility across multiple controller H/W IP generations:

Table 194. Gianfar compatibility

Device type (IP):	`.compatible`	`.model`
eTSEC2.0 (veTSEC)	`"fsl,etsec2"`	`"eTSEC"`
eTSEC (eTSEC1.x)	`"gianfar"`	`"eTSEC"`
TSEC	`"gianfar"`	`"TSEC"`
FEC	`"gianfar"`	`"FEC"`

2. Interrupt grouping of multiple queues, for eTSEC2.0: `queue-group` subnode, including:
   - Interrupt numbers assignment for the Rx, Tx and Error lines, `interrupts` property;
   - Interrupt group register block address and size, `reg` property;
3. Power management capability properties:
   - `fsl,magic-packet`: If present, indicates that the hardware supports waking up via magic packet;
   - `fsl,wake-on-filer`: If present, indicates that the hardware supports waking up by Filer General Purpose Interrupt (FGPI) asserted on the Rx int line. This is an advanced power management capability allowing certain packet types (user) defined by filer rules to wake up the system.
4. For older DTs, number of supported TX and RX queues: `fsl,num-rx-queues` and `fsl,num-tx-queues`; *[obsolete]*
5. Various link management properties.

Typical eTSEC2.0 device tree node (LS1021a example):

```
enet0: ethernet@2d10000 {
    compatible = "fsl,etsec2";
    device_type = "network";
    #address-cells = <2>;
    #size-cells = <2>;
    interrupt-parent = <&gic>;
    model = "eTSEC";
    fsl,magic-packet;
    fsl,wake-on-filer;

    queue-group@2d10000 {
        #address-cells = <2>;
        #size-cells = <2>;
        reg = <0x0 0x2d10000 0x0 0x1000>;
```

```
        interrupts = <GIC_SPI 144 IRQ_TYPE_LEVEL_HIGH>,
            <GIC_SPI 145 IRQ_TYPE_LEVEL_HIGH>,
            <GIC_SPI 146 IRQ_TYPE_LEVEL_HIGH>;
    };

    queue-group@2d14000  {
        #address-cells = <2>;
        #size-cells = <2>;
        reg = <0x0 0x2d14000 0x0 0x1000>;
        interrupts = <GIC_SPI 147 IRQ_TYPE_LEVEL_HIGH>,
            <GIC_SPI 148 IRQ_TYPE_LEVEL_HIGH>,
            <GIC_SPI 149 IRQ_TYPE_LEVEL_HIGH>;
    };
};
```

7.6.2.1.3.2 Ethtool support

Table 195. Non-exhaustive list of the most notable *ethtool* commands implemented by Gianfar:

Commands		Description
`ethtool -C`	`rx-usecs N rx-frames N tx-usecs N tx-frames N`	Set interrupt coalescing for a given device, packet count ('frames') and time in microsecs ('usecs') thresholds, for Rx and resp. Tx.
`ethtool -G`	`rx N  tx N`	Set RxBD ring, resp. TxBD ring sizes for a given device.
`ethtool -K`	`rxvlan on|off txvlan on|off`	Turn on/off H/W VLAN tag extraction(rx) / insertion(tx).
`ethtool -S`		Show interface statistics, Linux specific counters and various eTSEC H/W counters supporting RMON MIB group 1, group 2 (ifTable counters), group 3, group 9, RMON MIB 2, and the 802.3 Ethernet MIB statistics.
`ethtool -N`	`rx-flow-hash tcp4|udp4|tcp6|udp6 v|t|s|d|f|n`	Configure Rx network flow classification options. The classified flows may be tcp/udp over ipv4/v6, and the hashing may be performed on various header fields, according to the 3rd parameter: • s,d: src/dest IP addresses; • v: VLAN id; • t: L3 PROTO field, • f,n: source and dest TCP/UDP ports.
`ethtool -N`	`flow-type ether|ip4|tcp4|udp4|sctp4`	Inserts or updates a classification rule for the specified flow type. Most IPv4 flow types are supported: raw IPv4, TCP, UDP, SCTP, as well as L2 flow specifications (ether). For a detailed description of the command sub-options refer to ethtool Linux man-pages.

NOTE

For detailed description of `ethtool` command options refer to ethtool Linux man-pages.

7.7 FlexCAN

7.7.1 FlexCAN User Manual

Description

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification. NXP's LS1021A can support 4 Flexcan IP module instances if there are 2 CAN ports brought out on DB9 male connectors on the board.

Dependencies

Hardware:

One LS1021A board, Serial cable (female-to-female) having the following connection schema, so that the DB9 CAN ports on the LS1021A board can be connected properly:

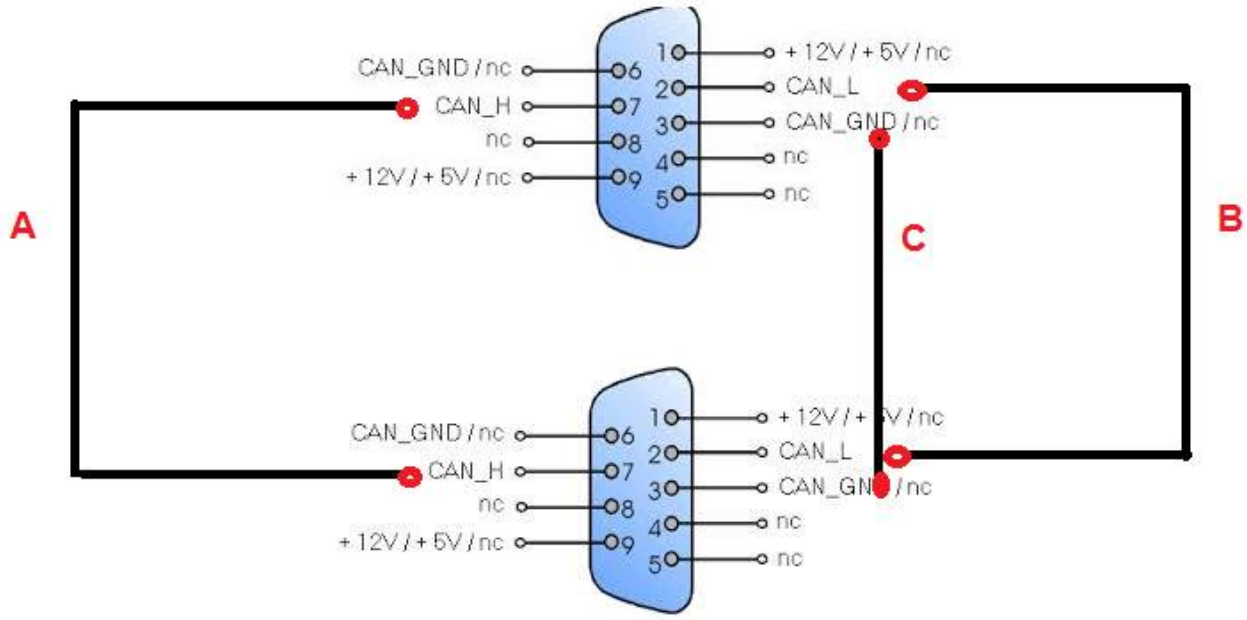

Figure 178. DB9 CAN Connections

Software:

RCW (LS1021A), U-Boot (LS1021A), Kernel (LS1021A), RFS (LS1021A Yocto RFS)

RCW Configuration

- Build the **rcw_1000_misc.bin** RCW file for FlexCAN using the following GIT tree: http://sw-stash.freescale.net/projects/SDK/repos/rcw/browse
- Flash the RCW on the LS1021A board.

U-Boot Configuration

Execute the following command at the u-boot prompt:

=> setenv hwconfig “can”

=> saveenv

Compile time options

N/A

Runtime options

Env Variable	Env Description	Option Description
hwconfig	setenv hwconfig "can"	This option is used to select CAN feature on the LS1021A board.

Kernel Configure Options

Tree View

Following is an example of how to enable FlexCAN driver support.

Kernel Configure Tree View Options	Description

[*] Networking support -->
  <*> CAN bus subsystem support -->
  -- CAN bus subsystem support
  <*> Raw CAN Protocol (raw access with CAN-ID filtering)
  < > Broadcast Manager CAN Protocol (with content filtering)
  CAN Device Drivers -->
  <*> Platform CAN drivers with Netlink support
  [*] CAN bit-timing calculation
  <*> Support for NXP FlexCAN based chips
	Enable FlexCAN driver and CAN protocol stack

NOTE

The FlexCAN driver can be statically/dynamically linked with the kernel Image.

Identifier

Option	Values	Default Value	Description
CONFIG_NET	y/n	y	Enable networking support
CONFIG_CAN	y/m/n	n	Enable CAN bus support
CONFIG_CAN_RAW	y/m/n	n	Enable CAN RAW Protocol support
CONFIG_CAN_DEV	y/m/n	n	Enable platform CAN driver support
CONFIG_CAN_CALC_BITTIMING	y/n	n	Enable baud rate setting using sysfs
CONFIG_CAN_FLEXCAN	y/m/n	n	Enable NXP FlexCAN protocol

Device Tree Binding

Below is the definition of the device tree node required by this feature

Property	Description
compatible = " fsl,ls1021a-flexcan"	Should be "fsl, ls1021a-flexcan"
reg = <0x0 0x2a70000 0x0 0x1000>	Offset and length of the register set for the device
interrupts = < GIC_SPI 127 IRQ_TYPE_LEVEL_HIGH>	IRQ line for FlexCAN controller CAN0
clocks = <&platform_clk 1>	CAN module Clock Source.
clock-names = <per>	CAN Engine Clock Source. This property selects the peripheral clock. Valid values are **ipg** and **per** **ipg**: CAN engine clock source is oscillator clock. Current release doesn't support this option. **per:** The CAN engine clock source is the peripheral clock (platform clock).

Below is an example device tree node required by FlexCAN.

```
can0@2a70000{
           compatible = "fsl, ls1021a-flexcan ";
           reg = <0x0 0x2a70000 0x0 0x1000>;
           interrupts = < GIC_SPI 127 IRQ_TYPE_LEVEL_HIGH >;
           clocks = <&platform_clk 1>;
           clock-names = <per>
};
```

Source Files

The following source file is related to Flexcan feature in u-boot.

Source File	Description
arch/arm/cpu/armv7/ls102xa/fdt.c	Providing the fix-up for clock_freq in the dts file.
board/freescale/ls1021aqds/ls1021aqds.c	Provides the support for board level FlexCAN muxing when u-boot environment variable **hwconfig** is set to can.

The following source files are related to Flexcan feature in Linux kernel.

Source File	Description
drivers/net/can/flexcan.c	Flexcan driver module

Board Connections

On the LS1021A board, mount Jumper 1 as shown in figure below to ensure that HI speed mode is working and also ensure that the 120ohm resistance b/w CAN_H and CAN_L is mounted properly on the board.

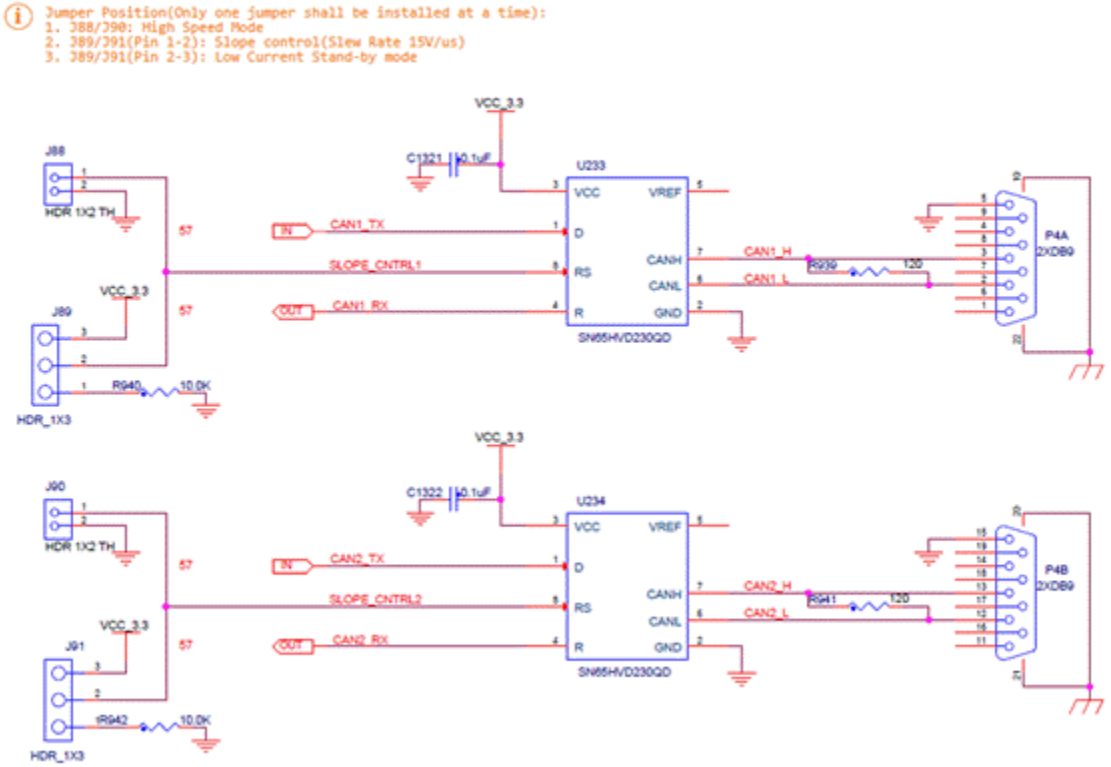

Figure 179. Board Connections

User Space Application

Please select the following package for testing Flexcan. Please refer to the LS1 Yocto WiKi page (http://wiki.freescale.net/display/layrarch/Yocto+framework+for+LS1+image+build) for the detailed build procedure.

Command Name	Description	Package Name
cansend	Userspace SocketCAN test program for sending CAN frames on a CAN interface	cansend
candump	Userspace SocketCAN test program for sniffing CAN frames received on a CAN interface	candump
ip	The iproute package contains networking utilities (ip and rtmon, for example) which are designed to use the advanced networking capabilities of the Linux kernel.	iproute(2)

Verification in U-Boot

N/A

Verification in Linux

To cross check whether FlexCAN has been configured in the kernel or not, run the following command at Linux prompt:

```
root@ls1021aqds:~# cat /proc/interrupts
           CPU0       CPU1
118:       3889          0       GIC 118  serial
120:        126          0       GIC 120  2180000.i2c
```

```
125:          0          0       GIC 125  xhci-hcd:usb1
126:       1521          0       GIC 126  mmc0
129:          0          0       GIC 129  2110000.dspi
135:          2          0       GIC 135  1710000.jr
136:          0          0       GIC 136  1720000.jr
137:          0          0       GIC 137  1730000.jr
138:          0          0       GIC 138  1740000.jr
150:       5371          0       GIC 150  Freescale ftm timer
158:          1          0       GIC 158  can0
167:          0          0       GIC 167  eDMA
189:         21          0       GIC 189  eth2_g0_tx
190:          4          0       GIC 190  eth2_g0_rx
191:          0          0       GIC 191  eth2_g0_er
201:          0          0       GIC 201  ds3232
IPI0:         0          0  CPU wakeup interrupts
IPI1:         0       5359  Timer broadcast interrupts
IPI2:      3158       3718  Rescheduling interrupts
IPI3:         0          0  Function call interrupts
IPI4:         3          3  Single function call interrupts
IPI5:         0          0  CPU stop interrupts
Err:          0
```

Test Procedure

Guide lines for testing FlexCAN on the LS1021A board.

Internal LoopBack test (SoC Level loopback)

- Enable CAN interface **can0** with root permissions on the Linux prompt

```
# ip link set can0 up type can bitrate 125000 loopback on
```

- Set candump to snif packets on can0 interface:

```
# candump can0 -n 2 &
```

- Set cansend to send a packet with standard identifier on can0 interface:

```
# cansend can0 5A1#123412341234
```

Expected behavior after internal loopback testing:

- CAN0 interface which is receiving the can frame should show, that it has read the frame ID and data correctly:

```
5A1 [6] 12 34 12 34 12 34
```

- After the successful Tx or RX from the CAN controller, the Tx and Rx Interrupt should increment for CAN0 interface.

```
   root@ls1021aqds:~# cat /proc/interrupts
           CPU0       CPU1
118:       3889          0       GIC 118  serial
120:        126          0       GIC 120  2180000.i2c
125:          0          0       GIC 125  xhci-hcd:usb1
126:       1521          0       GIC 126  mmc0
129:          0          0       GIC 129  2110000.dspi
135:          2          0       GIC 135  1710000.jr
136:          0          0       GIC 136  1720000.jr
137:          0          0       GIC 137  1730000.jr
138:          0          0       GIC 138  1740000.jr
```

```
150:       5371          0       GIC 150  Freescale ftm timer
158:          2          0       GIC 158  can0
167:          0          0       GIC 167  eDMA
189:         21          0       GIC 189  eth2_g0_tx
190:          4          0       GIC 190  eth2_g0_rx
191:          0          0       GIC 191  eth2_g0_er
201:          0          0       GIC 201  ds3232
IPI0:          0          0  CPU wakeup interrupts
IPI1:          0       5359  Timer broadcast interrupts
IPI2:       3158       3718  Rescheduling interrupts
IPI3:          0          0  Function call interrupts
IPI4:          3          3  Single function call interrupts
IPI5:          0          0  CPU stop interrupts
Err:           0
```

NOTE

The underlined number represents the interrupts on successful Tx or RX. So this number should increase on successful Tx and Rx.

External LoopBack test (Single Board).

- Attach the CAN0 and CAN1 interface on the LS1021A board with serial cable (prepared as mentioned in **Dependencies** section).
- Enable the CAN0 and CAN1 interface on the board:

```
# ip link set can0 up type can bitrate 125000
# ip link set can1 up type can bitrate 125000
```

- Set candump to snif packets on can0 interface:

```
# candump can0 -n 1 &
```

- Set cansend to send a packet with standard identifier on can1 interface:

```
# cansend can1 5A1#123412341234
```

Expected behavior after external loopback testing:

- CAN0 interface which is receiving the can frame should show, that it has read the frame ID and data correctly:

```
5A1 [6] 12 34 12 34 12 34
```

- After the successful Tx or RX from the CAN controllers, the Tx Interrupt should increase for CAN1 interface and Rx Interrupt should increment for CAN0 interface.

Benchmarking

TBD

Known Bugs, Limitations, or Technical Issues

Currently we are running Flexcan with Backwards Compatibility Configuration.

Supporting Documentation

SoC Reference Manual (for eg. LS1021A RM)

7.8 Flash Memory

7.8.1 JFFS2 on NOR Flash Device Driver User Manual

Linux SDK for QorIQ Processors

Description

Flash Controller in the SoC includes a NOR flash Machine. NOR flash machine support various type of NOR flash.

NOTE

This User Manual is also valid for Integrated Flash Controller (IFC). Please refer to the "IFC NOR Flash User Manual" to enable IFC NOR.

Module Loading

The Flash device driver supports kernel built-in and module.

U-Boot Configuration

Env Variable	Env Description	Sub Option	Option Description
bootargs	Kernel command line argument passed to kernel	setenv bootargs root=/dev/mtdblockx rootfstype=jffs2 rw console=ttyS0,115200	Uses NOR jffs2 filesystem as rootfs filesystem , and x should be the NOR jffs2 partition's mtdblock number.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_MTD	y/m/n	y	Enable Memory Technology Devices support
CONFIG_MTD_CMDLINE_PARTS	y/n	y	Enable parsing partition via kernel command line
CONFIG_MTD_BLOCK	y/m/n	y	Enables block driver for MTD device
CONFIG_MTD_OF_PARTS	y/m/n	y	Enables partition parsing of partition map from the children of the flash node
ONFIG_MTD_CFI_AMDSTD	y/m/n	y	Enables support for AMD/Fujitsu flash chips
ONFIG_MTD_PHYSMAP_OF	y/m/n	y	Enables physical memory map based on OF description
CONFIG_JFFS2_FS	y/m/n	y	Enable Journal Flash FS v2 support
CONFIG_JFFS2_FS_WRITEBUFFER	y/n	y	Enable JFFS2 write-buffering support

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
/linux/drivers/mtd	Linux MTD subsystem
/linux/drivers/mtd/chips	Linux MTD NOR device support
/linux/fs/jffs2	Linux JFFS2 FS system

In U-Boot, flash the JFFS2 FS to the NOR flash

Note: the erase block size for the NOR flash device (as example) is 128KB. Generate the JFFS2 FS accordantly.

```
=> tftp 1000000 $nor_jffs2_fs
=> erase $nor_jffs_start_address $nor_jffs_end_address /* erase address and size is decided by
your partition setting */
=> cp.b 1000000 $nor_jffs_start_address $filesize /* flash JFFS2 FS to the jffs2 partition on NOR
device */

The nor_jffs_start_address and nor_jffs_end_addresscan get from (board)_Quick_Strat_Guide or
(board)_user_manual.
```

Special MTD partition DTS

Note: The mtdblock number for JFFS2 partitions on NOR device is decided by your system configuration and your partition setting.

Use mtdparts=fe8000000.nor:1m(uboot),8m(kernel),512k(dtb),11m(jffs2),-(fs) in the bootargs for NOR partitions on B4860QDS.

Boot up the board

Note: Different boards have different partition settings. The following example is B4860QDS board's partition setting.

The mtdblock3 is NOR JFFS2 partition.

```
fe8000000.nor: Found 1 x16 devices at 0x0 in 16-bit bank. Manufacturer ID 0x000001 Chip ID
0x002801
Amd/Fujitsu Extended Query Table at 0x0040
Amd/Fujitsu Extended Query version 1.5.
number of CFI chips: 1
5 cmdlinepart partitions found on MTD device fe8000000.nor
Creating 5 MTD partitions on "fe8000000.nor":
0x000000000000-0x000000100000 : "uboot"

mtd6: 00100000 00020000 "NAND DTB Image"
mtd7: 00a00000 00020000 "NAND Linux Kernel Image"
mtd8: 1f400000 00020000 "NAND RFS Image"
mtd9: 00080000 00001000 "spife110000.0"

[root@b4860qds root]# ls /dev/mtdblock3 -l /* the block number should be the NOR jffs2
partition's mtdblock number*/
brw-r----- 1 root disk 31, 4 Mar  5 14:13 /dev/mtdblock3
[root@b4860ds root]# mount -t jffs2 /dev/mtdblock3 /mnt/
[root@b4860ds root]# ls /mnt/
bin  etc   lib      log  opt   root  sys  usr
dev  home  linuxrc  mnt  proc  sbin  tmp  var
[root@b4860qds root]# umount /mnt/
[root@b4860qds root]# ls /mnt/
cdrom  floppy  nfs  rwfs  src
[root@b4860qds root]#
```

Another way to test NOR JFFS2 support is to boot up kernel and mount JFFS2 filesystem

Note: the block number should be the NOR JFFS2 partition's mtdblock number

Under U-Boot prompt:

```
setenv bootargs root=/dev/mtdblock3 rootfstype=jffs2 rw console=ttyS0,115200
tftp 1000000 uImage
tftp c00000 dtb
bootm 1000000 - c00000
```

7.8.2 JFFS2 on NAND Flash Device Driver User Manual

Linux SDK for QorIQ Processors

Description

The Enhanced Local Bus Controller in the platform includes a special NAND flash Control Machine (FCM). FCM provides the hardware support for using small or large page NAND flash.

NOTE

This User Manual is written for Enhanced Local Bus Controller (eLBC). It is also valid for Integrated Flash Controller (IFC). Please refer to "IFC NAND Flash User Manual" for enabling IFC NAND.

Module Loading

The eLBC device driver supports kernel built-in and module.

U-Boot Configuration

Env Variable	Env Description	Sub Option	Option Description
bootargs	Kernel command line argument passed to kernel	setenv bootargs root=/dev/mtdblockx rootfstype=jffs2 rw console=ttyS0,115200	Uses NAND JFFS2 filesystem as rootfs filesystem, and x should be the NAND JFFS2 partition's mtdblock number.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
/linux/drivers/mtd	Linux MTD subsystem
/linux/drivers/mtd/nand	Linux MTD NAND device support
/linux/fs/jffs2	Linux JFFS2 FS system

In U-boot, flash the JFFS2 FS to the NAND flash

Note: the erase block size for the NAND flash device (as example) is 128KB. Generate the JFFS2 FS accordantly.

```
=> tftp 1000000 $nand_jffs2_fs
=> nand erase $nand_jffs2_start_address $nand_jffs2_size /*erase address and size is decided by
your partition setting */
=> nand write 1000000 $nand_jffs2_start_address $filesize /* flash JFFS2 FS to the jffs2-nand
partition of NAND device */
The nand_jffs2_start_address and nand_jffs2_size can get from (board)_Quick_Strat_Guide or
(board)_user_manual.
```

Special MTD partition DTS

Note: The mtdblock number for JFFS2 partitions on NAND device is decided by your system configuration and your partition setting.

Using 'mknod' command to create the corresponding mtdblock device node if it does not exist in the file system.

```
nand@2,0 {
         #address-cells = "<1>";
         #size-cells = "<1>";
         compatible = ""fsl,mpc8572-fcm-nand","fsl,elbc-fcm-nand";
         reg = <0x2 0x0 0x40000>;
         u-boot@0 {
                 reg = <0x0 0x02000000>;
                 label = "NAND - U-Boot Image";
```

```
                read-only;
        };
        jffs2@2000000 {
                reg = <0x02000000 0x10000000>;
                label = "NAND - JFFS2 Root File System";
        };
        ramdisk@12000000 {
                reg = <0x12000000 0x08000000>;
                label = "NAND - RAMDISK File System";
                read-only;
        };
        kernel@1a000000 {
                reg = <0x1a000000 0x04000000>;
                label = "NAND - Linux Kernel Image";
        };
        dtb@1e000000 {
                reg = <0x1e000000 0x01000000>;
                label = "NAND - DTB Image";
                read-only;
        };
        empty@1f000000 {
                reg = <0x1f000000 0x21000000>;
                label = "NAND - Empty";
        };
};
nand@4,0 {
        compatible = ""fsl,mpc8572-fcm-nand","fsl,elbc-fcm-nand";
        reg = <0x4 0x0 0x40000>;
};
nand@5,0 {
        compatible = ""fsl,mpc8572-fcm-nand","fsl,elbc-fcm-nand";
        reg = <0x5 0x0 0x40000>;
};
nand@6,0 {
        compatible = ""fsl,mpc8572-fcm-nand","fsl,elbc-fcm-nand";
        reg = <0x6 0x0 0x40000>;
```

Boot up the board

Note: The following example assumes that only NAND is enabled, NOR is not enabled.

Otherwise, the mtdblock number for NAND will be different, e.g. mtdblock1 will be NAND JFFS2 partition

```
....

-sh-2.05b # umount /mnt/cdrom
```

Another way to test NAND JFFS2 support is to boot up kernel and mount JFFS2 filesystem

Note: the block number should be the NAND JFFS2 partition's mtdblock number

Under U-Boot prompt:

```
setenv bootargs root=/dev/mtdblock2 rootfstype=jffs2 rw console=ttyS0,115200
tftp 1000000 uImage
tftp c00000 dtb
bootm 1000000 - c00000
```

7.8.3 Integrated Flash Controller NOR Flash User Manual

Description

NXP's Integrated Flash Controller can be used to connect various types of flashes e.g. NOR/NAND on board for boot functionality as well as data storage.

U-Boot Configuration

Compile time options

Below are major u-boot configuration options related to this feature defined in platform specific config files under include/configs/ directory.

Option Identifier	Description
CONFIG_FSL_IFC	Enable IFC support
CONFIG_FLASH_CFI_DRIVER CONFIG_SYS_FLASH_CFI CONFIG_SYS_FLASH_EMPTY_INFO	Enable CFI Driver for NOR Flash devices

Source Files

The following source files are related to this feature in u-boot.

Source File	Description
./drivers/misc/fsl_ifc.c	Set up the different chip select parameters from board header file
drivers/mtd/cfi_flash.c	CFI driver support for NOR flash devices

Kernel Configure Options

Tree View

Below are the configure options need to be set/unset while doing "make menuconfig" for kernel

Kernel Configure Tree View Options	Description

Device Drivers --->
  <*> Memory Technology Device (MTD) support --->
  [*] MTD partitioning support
  [*] Command line partition table parsing
  <*> Flash partition map based on OF description
  <*> Direct char device access to MTD devices
  -*- Common interface to block layer for MTD 'translation layers'
  <*> Caching block device access to MTD devices
  < > FTL (Flash Translation Layer) support
  RAM/ROM/Flash chip drivers --->
  <*> Detect flash chips by Common Flash Interface (CFI) probe
  <*> Support for Intel/Sharp flash chips
  <*> Support for AMD/Fujitsu/Spansion flash chips
  Mapping drivers for chip access --->
  <*> Flash device in physical memory map based on OF description
	These options enable CFI support for NOR Flash under MTD subsystem and Integrated Flash Controller support on Linux

File systems ---> [*] Miscellaneous filesystems ---> <*> Journalling Flash File System v2 (JFFS2) support	This option enables JFFS2 file system support for MTD Devices

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Special Configure needs to be enabled("Y") for LS1021 and LS1043. Please find in below table with default value as "N"

Option	Values	Default Value	Description
CONFIG_FSL_IFC	Y/N	Y	Integrated Flash Controller support
CONFIG_MTD	Y/N	Y	Memory Technology Device (MTD) support

Table continues on the next page...

Table continued from the previous page...

Option	Values	Default Value	Description
CONFIG_MTD_PARTITIONS	Y/N	Y	MTD partitioning support
CONFIG_MTD_CMDLINE_PARTS	Y/N	Y	Allow generic configuration of the MTD partition tables via the kernel command line.
CONFIG_MTD_OF_PARTS	Y/N	Y	This provides a partition parsing function which derives the partition map from the children of the flash nodes described in Documentation/powerpc/booting-without-of.txt
CONFIG_MTD_CHAR	Y/N	Y	Direct char device access to MTD devices
CONFIG_MTD_BLOCK	Y/N	Y	Caching block device access to MTD devices
CONFIG_MTD_CFI	Y/N	Y	Detect flash chips by Common Flash Interface (CFI) probe
CONFIG_MTD_GEN_PROBE	Y/N	Y	NA
CONFIG_MTD_MAP_BANK_WIDTH_1	Y/N	Y	Support 8-bit buswidth
CONFIG_MTD_MAP_BANK_WIDTH_2	Y/N	Y	Support 16-bit buswidth
CONFIG_MTD_MAP_BANK_WIDTH_4	Y/N	Y	Support 32-bit buswidth
CONFIG_MTD_PHYSMAP_OF	Y/N	Y	Flash device in physical memory map based on OF description
CONFIG_FTL	Y/N	N	FTL (Flash Translation Layer) support
CONFIG_MTD_CFI_INTELEXT	Y/N	Y	Support for Intel/Sharp flash chips
CONFIG_MTD_CFI_AMDSTD	Y/N	Y	Support for AMD/Fujitsu/Spansion flash chips
CONFIG_MTD_CFI_ADV_OPTIONS	Y/N	N	Enable only for LS1021 and LS1043
CONFIG_MTD_CFI_BE_BYTE_SWAP	Y/N	N	Enable only for LS1021 and LS1043

Device Tree Binding

Documentation/devicetree/bindings/powerpc/fsl/ifc.txt

Documentation/devicetree/bindings/memory-controllers/fsl/ifc.txt

Flash partitions are specified by platform device tree.

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/memory/fsl_ifc.c	Integrated Flash Controller driver to handle error interrupts
drivers/mtd/mtdpart.c	Simple MTD partitioning layer
drivers/mtd/mtdblock.c	Direct MTD block device access

Table continues on the next page...

Table continued from the previous page...

Source File	Description
drivers/mtd/mtdchar.c	Character-device access to raw MTD devices.
drivers/mtd/ofpart.c	Flash partitions described by the OF (or flattened) device tree
drivers/mtd/ftl.c	FTL (Flash Translation Layer) support
drivers/mtd/chips/cfi_probe.c	Common Flash Interface probe
drivers/mtd/chips/cfi_util.c	Common Flash Interface support
drivers/mtd/chips/cfi_cmdset_0001.c	Support for Intel/Sharp flash chips
drivers/mtd/chips/cfi_cmdset_0002.c	Support for AMD/Fujitsu/Spansion flash chips

Verification in U-Boot

Test the Read/Write/Erase functionality of NOR Flash

1. Boot the u-boot with above config options to get NOR Flash access enabled. Check this in boot log,

   ```
   FLASH: * MiB
   ```

   where * is the size of NOR Flash
2. Erase NOR Flash
3. Make test pattern on memory e.g. DDR
4. Write test pattern on NOR Flash
5. Read the test pattern from NOR Flash to memory e.g DDR
6. Compare the test pattern data to verify functionality.

Test Log :

Test log with initial u-boot log removed

```
--
--

FLASH: 32 MiB
L2:    256 KB enabled
--

7.8.4 Integrated Flash Controller NAND Flash User Manual

Description

NXP's Integrated Flash Controller can be used to connect various types of flashes (e.g. NOR/NAND) on board for boot functionality as well as data storage.

U-Boot Configuration

Compile time options

Below are major U-Boot configuration options related to this feature defined in platform specific config files under include/ configs/ directory.

Option Identifier	Description
CONFIG_FSL_IFC	Enable IFC support
CONFIG_NAND_FSL_IFC	Enable NAND Machine support on IFC
CONFIG_SYS_MAX_NAND_DEVICE	No of NAND Flash chips on platform
CONFIG_MTD_NAND_VERIFY_WRITE	Verify NAND flash writes
CONFIG_CMD_NAND	Enable various commands support for NAND Flash
CONFIG_SYS_NAND_BLOCK_SIZE	Block size of the NAND flash connected on Platform

Source Files

The following source files are related to this feature in u-boot.

Source File	Description
./drivers/misc/fsl_ifc.c	Set up the different chip select parameters from board header file
drivers/mtd/nand/fsl_ifc_nand.c	IFC nand flash machine driver file

Kernel Configure Options

Tree View

Below are the configure options need to be set/unset while doing "make menuconfig" for kernel

Kernel Configure Tree View Options	Description

Device Drivers --->
  <*> Memory Technology Device (MTD) support --->
  [*] MTD partitioning support
  [*] Command line partition table parsing=
  <*> Flash partition map based on OF description
  <*> Direct char device access to MTD devices
  -*- Common interface to block layer for MTD 'translation layers'
  <*> Caching block device access to MTD devices
	These options enable Integrated Flash Controller NAND support to work with MTD subsystem available on Linux.
	Also UBIFS support needs to be enabled.

Kernel Configure Tree View Options	Description
<*> NAND Device Support ---> <*> NAND support for Freescale IFC controller **Enable UBIFS filesystem in linux configuration** Device Drivers ---> <*> Memory Technology Device (MTD) support ---> UBI - Unsorted block images ---> <*> Enable UBI (4096) UBI wear-leveling threshold (1) Percentage of reserved eraseblocks for bad eraseblocks handling < > MTD devices emulation driver (gluebi) *** UBI debugging options *** [ ] UBI debugging File systems ---> [*] Miscellaneous filesystems ---> <*> UBIFS file system support [*] Extended attributes support [ ] Advanced compression options [ ] Enable debugging	

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_FSL_IFC	y/n	y	Enable Integrated Flash Controller support
CONFIG_MTD_NAND_FSL_IFC	y/n	Y	Enable Integrated Flash Controller NAND Machine support
CONFIG_MTD_PARTITIONS	y/n	Y	MTD partitioning support
CONFIG_MTD_CMDLINE_PARTS	y/n	Y	Allow generic configuration of the MTD partition tables via the kernel command line.
CONFIG_MTD_OF_PARTS	y/n	Y	This provides a partition parsing function which derives the partition map from the children of the flash nodes described in Documentation/powerpc/booting-without-of.txt
CONFIG_MTD_CHAR	y/n	Y	Direct char device access to MTD devices
CONFIG_MTD_BLOCK	y/n	Y	Caching block device access to MTD devices
CONFIG_MTD_GEN_PROBE	y/n	Y	NA
CONFIG_MTD_PHYSMAP_OF	y/n	Y	Flash device in physical memory map based on OF description

Device Tree Binding

`Documentation/devicetree/bindings/memory-controllers/fsl/ifc.txt`

Flash partitions are specified by platform device tree.

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/memory/fsl_ifc.c	Integrated Flash Controller driver to handle error interrupts
drivers/mtd/nand/fsl_ifc_nand.c	Integrated Flash Controller NAND Machine driver
include/linux/fsl_ifc.h	IFC Memory Mapped Registers

Verification in U-Boot

Test the Read/Write/Erase functionality of NAND Flash

1. Boot the u-boot with above config options to get NAND Flash driver enabled. Check this in boot log,

   ```
   NAND: * MiB

   Where * is NAND flash size
   ```

2. Erase NAND Flash
3. Make test pattern on memory e.g. DDR
4. Write test pattern on NAND Flash
5. Read the test pattern from NAND Flash to memory e.g DDR
6. Compare the test pattern data to verify functionality.

Test Log :

```
...
...

Flash: 32 MiB

L2:    256 KB enabled

NAND:  32 MiB

...
...

/* U-boot prompt */

Known Bugs, Limitations, or Technical Issues

Boards which have NAND Flash with 512byte page size, JFFS2 cannot be supported using H/W ECC support of IFC , as there is not enough remaining space in the OOB area.

To use JFFS2 use SOFT ECC.

7.9 IEEE 1588 Device Driver User Manual

7.9.1 IEEE 1588 Device Driver User Manual

Description

From IEEE-1588 perspective the components required are:

1. IEEE-1588 extensions to the gianfar driver or DPAA/DPAA2 driver.
2. A stack application for IEEE-1588 protocol.

Module Loading

IEEE 1588 device driver supports either kernel built-in or module

Kernel Configure Tree View Options

1. eTSEC - Using IXXAT stack

Kernel Configure Tree View Options	Description
Device Drivers ---> [*]Network device support ---> [*]Ethernet driver support ---> <*> Gianfar Ethernet [*] Gianfar 1588	Enable 1588 driver for IXXAT stack

2. eTSEC - Using PTPd stack

Kernel Configure Tree View Options	Description
Device Drivers ---> PTP clock support ---> <*> Freescale eTSEC as PTP clock	Enable 1588 driver for PTPd stack

3. DPAA - Using IXXAT stack

Kernel Configure Tree View Options	Description
Device Drivers ---> [*]Network device support ---> [*]Ethernet driver support ---> [*]Freescale devices ---> <*>IEEE 1588-compliant timestamping Optimization choices for the DPAA Ethernet driver ---> (X)Optimize for forwarding	Enable IEEE 1588-compliant timestamping

4. DPAA - Using PTPd stack

Kernel Configure Tree View Options	Description
Device Drivers ---> PTP clock support ---> <*> Freescale DPAA as PTP clock	Enable 1588 driver for PTPd stack

5. DPAA2 - Using PTPd stack

Kernel Configure Tree View Options	Description
Device Drivers ---> PTP clock support ---> <*> Freescale DPAA2 as PTP clock	Enable 1588 driver for PTPd stack

Compile-time Configuration Options

For eTSEC (IXXAT)

Option	Values	Default Value	Description
CONFIG_GIANFAR	y/n	y	Enable eTSEC driver support
CONFIG_FSL_GIANFAR_1588	y/n	n	Enables 1588 driver support

For eTSEC (PTPd)

Option	Values	Default Value	Description
CONFIG_GIANFAR	y/n	y	Enable eTSEC driver support
CONFIG_PTP_1588_CLOCK_GIANFAR	y/n	y	Enables 1588 driver support

For DPAA (IXXAT)

Option	Values	Default Value	Description
CONFIG_FSL_DPAA_1588	y/n	n	Enable IEEE 1588 support
CONFIG_FSL_SDK_DPAA_ETH	y/n	y	Enables DPAA driver support

For DPAA (PTPd)

Option	Values	Default Value	Description
CONFIG_PTP_1588_CLOCK_DPAA	y/n	n	Enable IEEE 1588 support
CONFIG_FSL_SDK_DPAA_ETH	y/n	y	Enables DPAA driver support

For DPAA2 (PTPd)

Option	Values	Default Value	Description
CONFIG_PTP_1588_CLOCK_DPAA2	y/n	n	Enable IEEE 1588 support
CONFIG_FSL_DPAA2_ETH	y/n	y	Enables DPAA2 driver support

Source Files

The driver source is maintained in the Linux kernel source tree.

1. eTSEC (for IXXAT)

Source File	Description
drivers/net/ethernet/freescale/gianfar.c	IEEE 1588 hooks in the Ethernet driver
drivers/net/ethernet/freescale/gianfar_1588.c	IEEE 1588 driver

2. eTSEC (for PTPd)

Source File	Description
drivers/net/ethernet/freescale/gianfar.c	IEEE 1588 hooks in the Ethernet driver
drivers/net/ethernet/freescale/gianfar_ptp.c	IEEE 1588 driver

3. DPAA (for IXXAT)

Source File	Description
drivers/net/ethernet/freescale/sdk_dpaa/dpaa_1588.c	IEEE 1588 driver support
drivers/net/ethernet/freescale/sdk_dpaa/dpaa_1588.h	IEEE 1588 driver head file
drivers/net/ethernet/freescale/sdk_dpaa/dpaa_eth.c	DPAA Ethdriver support

4. DPAA (for PTPd)

Source File	Description
drivers/net/ethernet/freescale/sdk_dpaa/dpaa_ptp.c	IEEE 1588 driver support
drivers/net/ethernet/freescale/sdk_dpaa/dpaa_eth.c	DPAA Ethdriver support

5. DPAA2 (for PTPd)

Source File	Description
drivers/staging/fsl-dpaa2/rtc/rtc.c	IEEE 1588 driver support
drivers/staging/fsl-dpaa2/ethernet/dpaa2-eth.c	DPAA Ethdriver support

Device Tree Binding

1. eTSEC (for IXXAT)

Property	Type	Status	Description
compatible	String	Required	Should be 'fsl,gianfar-ptp-timer' for IEEE 1588 driver

```
Default node:
         ptp_timer: ptimer@24e00 {
                 compatible = "fsl,gianfar-ptp-timer";
                 reg = <0x24e00 0xb0>;
                 fsl,ts-to-buffer;
                 fsl,tmr-prsc = <0x2>;
                 fsl,clock-source-select = <1>;
         };

         enet0: ethernet@24000 {
                 ......
                 ptimer-handle = <&ptp_timer>;
         };
```

2. eTSEC (for PTPd)

Property	Type	Status	Description
compatible	String	Required	Should be 'fsl,etsec-ptp' for IEEE 1588 driver

```
Default node:
         ptp_clock@b0e00 {
```

```
                compatible = "fsl,etsec-ptp";
                reg = <0xb0e00 0xb0>;
                interrupts = <68 2 0 0 69 2 0 0>;
                fsl,tclk-period = <10>;
                fsl,tmr-prsc    = <2>;
                fsl,tmr-add     = <0x80000016>;
                fsl,tmr-fiper1  = <0x3b9ac9f6>;
                fsl,tmr-fiper2  = <0x00018696>;
                fsl,max-adj     = <199999999>;
         };
```

3. DPAA

Property	Type	Status	Description
compatible	String	Required	Should be 'fsl,fman-rtc'
reg	integer	Required	Register map

```
Default node:
        fman0: fman@400000 {
                #address-cells = <1>;
                #size-cells = <1>;
                cell-index = <0>;
                compatible = "fsl,p4080-fman", "fsl,fman", "simple-bus";

                enet0: ethernet@e0000 {
                        cell-index = <0>;
                        compatible = "fsl,p4080-fman-1g-mac", "fsl,fman-1g-mac";
                        reg = <0xe0000 0x1000>;
                        fsl,port-handles = <&fman0_rx0 &fman0_tx0>;
                        tbi-handle = <&tbi0>;
                        phy-handle = <&phy0>;
                        phy-connection-type = "sgmii";
                        ptimer-handle = <&ptp_timer0>;
                };

                ...enet1/2...

                enet3: ethernet@e6000 {
                        cell-index = <3>;
                        compatible = "fsl,p4080-fman-1g-mac", "fsl,fman-1g-mac";
                        reg = <0xe6000 0x1000>;
                        fsl,port-handles = <&fman0_rx3 &fman0_tx3>;
                        tbi-handle = <&tbi3>;
                        phy-handle = <&phy3>;
                        phy-connection-type = "sgmii";
                        ptimer-handle = <&ptp_timer0>;
                };

                ptp_timer0: rtc@fe000 {
                        compatible = "fsl,fman-rtc";
                        reg = <0xfe000 0x1000>;
                };
        };

        fman1: fman@500000 {
                #address-cells = <1>;
```

```
                #size-cells = <1>;
                cell-index = <1>;
                compatible = "fsl,p4080-fman", "fsl,fman", "simple-bus";

                enet5: ethernet@e0000 {
                        cell-index = <0>;
                        compatible = "fsl,p4080-fman-1g-mac", "fsl,fman-1g-mac";
                        reg = <0xe0000 0x1000>;
                        fsl,port-handles = <&fman1_rx0 &fman1_tx0>;
                        tbi-handle = <&tbi5>;
                        phy-handle = <&phy5>;
                        phy-connection-type = "sgmii";
                        ptimer-handle = <&ptp_timer1>;
                };

                ...enet6/7...

                enet8: ethernet@e6000 {
                        cell-index = <3>;
                        compatible = "fsl,p4080-fman-1g-mac", "fsl,fman-1g-mac";
                        reg = <0xe6000 0x1000>;
                        fsl,port-handles = <&fman1_rx3 &fman1_tx3>;
                        tbi-handle = <&tbi8>;
                        phy-handle = <&phy8>;
                        phy-connection-type = "sgmii";
                        ptimer-handle = <&ptp_timer1>;
                };

                ptp_timer1: rtc@fe000 {
                        compatible = "fsl,fman-rtc";
                        reg = <0xfe000 0x1000>;
                };
        };
```

4. DPAA2

   NA.

Verification in Linux and test procedure

Connect two boards through crossover, ex, eth1 to eth1, and connect the other ethernet port on each board to switch or PC. One board runs as master, and the other as slave.

- **Using the IXXAT stack image**

  1. Enable IEEE-1588 support in the gianfar/DPAA driver, rebuild and reload it. You should get the following message during system boot:

     ```
     ...
     IEEE1588: ptp 1588 is initialized.
     ...
     ```

     - On the master side:

       ```
       # ifconfig eth1 192.168.1.100 allmulti up

       # ./ptp -i 0:eth1 -do        //run stack application
       ```

Note: On a DPAA platform, use fm1-gb1 instead of eth1

- On the slave side :

```
# ifconfig eth1 192.168.1.200 allmulti up

#./ptp -i 0:eth1 -do        //run stack application
```

Note: On a DPAA platform, use the desired interface(e.g. fm1-gb1) instead of eth1

2. You should start getting synchronization messages on the slave side.

NOTE

A detailed configuration of the IEEE-1588 stack application is described in a Quick Start Guide provided with the stack application.

- **Using the PTPd stack image**

1. Enable IEEE-1588 support in the gianfar/DPAA/DPAA2 driver, rebuild and reload it. You should get the following message during system boot:

```
...
pps pps0: new PPS source ptp0
...
```

- On the master side:

```
# ifconfig eth0 up

# ifconfig eth0 192.168.1.100

# ./ptpd -i eth0 -MV        //run stack application
```

Note: On a DPAA/DPAA2 platform, use the desired interface(e.g. fm1-gb1) instead of eth0. Also make sure the ptp device name through kernel boot log, and the stack uses default /dev/ptp0. If there is more than 1 ptp clock, please use '-o' arguement to clarify dpaa ptp clock. For example, './ptpd -i eth0 -MV -o /dev/ptp1'.

- On the slave side :

```
# ifconfig eth0 up

# ifconfig eth0 192.168.1.200

# ./ptpd -i eth0 -sV --servo:kp=0.32 --servo:ki=0.05        //run stack application
```

Note: On a DPAA/DPAA2 platform, use the desired interface(e.g. fm1-gb1) instead of eth0. Also make sure the ptp device name through kernel boot log, and the stack uses default /dev/ptp0. If there is more than 1 ptp clock, please use '-o' arguement to clarify dpaa ptp clock. For example, './ptpd -i eth0 -sV -o /dev/ptp1 --servo:kp=0.32 --servo:ki=0.05'.

2. You should start getting synchronization messages on the slave side.

Known Bugs, Limitations, or Technical Issues

- For DPAA, the PTPd stack limits to use only one ptp timer, so only the interfaces on the second FMAN (such as fm2-gb2) are available for PTPd if the platform has two FMANs.

- For eTSEC, the slave PPS signal (available on `TSEC_1588_PULSE_OUT1` pin) is not phase aligned with master PPS signal. This is a known limitation.
- For eTSEC, when running the IEEE-1588 function, the user needs to disable `CONFIG_RX_TX_BUFF_XCHG`. In the default SDK kernel image, the ASF is enabled, so `CONFIG_RX_TX_BUFF_XCHG` is enabled too. You should disable `CONFIG_RX_TX_BUFF_XCHG` and rebuild kernel for 1588 function.
- VLAN feature was disabled in the default kernel configuration. When using 1588 over VLAN in your application or solution, VLAN needs to be enabled in the Linux kernel.
- Packet loss issue could be observed on LS1021ATWR; ethernet interfaces are connected in back-to-back way. The root cause is that the PHY supports IEEE 802.11az EEE mode by default. The low speed traffic will make it go into low power mode. It affects 1588 synchronization performance greatly. Use the workaround below to disable the feature:

```
# ifconfig eth0 up
# ethtool --set-eee eth0 advertise 0
# ifconfig eth0 down
# ifconfig eth0 up
```

7.10 Low Power UART User Guide

7.10.1 Low Power UART User Guide

Description

Low Power Universal asynchronous receiver/transmitter (LPUART) is a high speed and low power uart. Refer to below table for the NXP soc can support LPUART.

SOC	Num of LPUART module
LS1021A	6
LS1043A	6

U-boot ConfigurationCompile time options

Below are major u-boot configuration options related to this feature defined in platform specific config files under include/ configs/ directory.

Option Identifier	Description
CONFIG_LPUART	Enable lpuart support
CONFIG_FSL_LPUART	Enable NXP lpuart support
CONFIG_LPUART_32B_REG	Select 32-bit lpuart register mode

Choosing predefined u-boot board configs:

Please make the defconfig include 'lpuart', like: ls1021atwr_nor_lpuart_defconfig. That's will supoort lpuart.

Runtime options

Env Variable	Env Description	Sub option	Option Description
bootargs	Kernel command line argument passed to kernel	console=ttyLP0,1152000	select LPUART0 as the system console

Kernel Configure Options

Tree View

Below are the configure options need to be set/unset while doing "make menuconfig" for kernel

Kernel Configure Tree View Options	Description
Device Drivers ---> Character devices --->\n Serial drivers --->\n <*> Freescale lpuart serial port support [*] Console on Freescale lpuart serial port	LPUART driver and enable console support

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_SERIAL_FSL_LPUART	y/m/n	n	LPUART Driver

Device Tree Binding

Below is an example device tree node required by this feature. Note that it may has differences among platforms.

```
lpuart0: serial@2950000 {
                        compatible = "fsl,vf610-lpuart";
                        reg = <0x0 0x2950000 0x0 0x1000>;
                        interrupts = <GIC_SPI 80 IRQ_TYPE_LEVEL_HIGH>;
                        clocks = <&sysclk>;
                        clock-names = "ipg";
                        fsl,lpuart32;
                        status = "okay";
```

Source Files

The following source file are related the this feature in u-boot.

Source File	Description
drivers/serial/serial_lpuart.c	The LPUART driver file

The following source file are related the this feature in Linux kernel.

Source File	Description
drivers/tty/serial/fsl_lpuart.c	The LPUART driver file

Verification in U-Boot

1. Boot up U-Boot from bank0, and update rcw and u-boot for lpuart support to bank4, first copy the rcw and U-Boot binary to the tftp directory.
2. Please refer to the platform depoly document to update the rcw and uboot.
3. After all is updated, run u-boot command to switch to alt bank, then will bring up the new U-Boot to the lpuart console.

<*> Intel (R) PRO/1000 PCI-Express Gigabit Ethernet support	
Device Drivers ---> <*> Serial ATA and Parallel ATA drivers (libata) ---> <*> Silicon Image 3124/3132 SATA support	Enable support for Silicon Image 3124/3132 Serial ATA.

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_PCI	y/n	y	Enable PCI host bridge
CONFIG_PCI_MSI	y/n	y	Message support
CONFIG_PCI_LAYERSCAPE	y/n	y	Enable PCI for Layerscape
CONFIG_E1000E	y/m/n	y	Enable Intel Pro/1000 driver
CONFIG_SATA_SIL	y/m/n	y	Silicon Image SATA support

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
arch/powerpc/sysdev/fsl_pci.c	The MPC85XX platform PCIE host bridge support source
drivers/pci/host/pcie-layerscape.c	The Layerscape platform PCIE host bridge support source
drivers/net/ethernet/intel/e1000e/	Intel Pro/1000 driver source code
drivers/ata/sata_sil.c	Silicon Image source code

SATA Card Test Procedure

```
the user can use command
fdisk, mke2fs mount to operate the ide disk.
After kernel boots up, please follow the log to operate:

[root@pX0XX /root]# fdisk -l

Disk /dev/sda: 85.8 GB, 85899345920 bytes
255 heads, 63 sectors/track, 10443 cylinders
Units = cylinders of 16065 * 512 = 8225280 bytes

Disk /dev/sda doesn't contain a valid partition table
```

```
[root@pX0XX /root]# fdisk /dev/sda
Device contains neither a valid DOS partition table, nor Sun, SGI or OSF disklabel
Building a new DOS disklabel. Changes will remain in memory only,
until you decide to write them. After that the previous content
won't be recoverable.

The number of cylinders for this disk is set to 10443.
There is nothing wrong with that, but this is larger than 1024,
and could in certain setups cause problems with:
1) software that runs at boot time (e.g., old versions of LILO)
2) booting and partitioning software from other OSs
   (e.g., DOS FDISK, OS/2 FDISK)

Command (m for help): n

Writing inode tables: done
Writing superblocks and filesystem accounting information: done

This filesystem will be automatically checked every 31 mounts or
180 days, whichever comes first.  Use tune2fs -c or -i to override.

[root@pX0XX /root]# mkdir sda1_test
[root@pX0XX /root]# mount /dev/sda1 sda1_test/
```

```
[root@pX0XX /root]# cp /bin/tar sda1_test/
[root@pX0XX /root]#
```

Ethernet Card Test Procedure

- plug Intel Pro/1000e network card into standard PCI-E slot on a board. After linux bootup, ifconfig ethx ip address and netmask, then do ping testing.

  Tips: x ethernet interface number, an example is as the following for Intel e1000 network card is eth0.

  For example:

  After kernel boot up, bring up with the pci Ethernet card

  ifconfig ethx 192.168.20.100

  ip address should not be conficted with other Ethernet port.

  In Linux window, run ping 192.168.20.101

Known Bugs, Limitations, or Technical Issues

- LSI-SAS card cannot be used on the second PCIe controller when system enables more than one PCIe controller. Use code modification below to workaround this issue:

```

7.11.3 EDAC Driver User Manual

Description

The EDAC kernel module's goal is to detect and report errors that occur within the computer system running under Linux.

Note

Currently the EDAC wasn't supported on P5040/P5020 64bit.

Module Loading

Linux EDAC Driver supports kernel built-in or module.

Kernel Configure Options

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers ---> <*> EDAC (Error Detection And Correction) reporting ---> <*> Main Memory EDAC (Error Detection And Correction) reporting <*> Freescale MPC83xx / MPC85xx	Enables EDAC support for 85xx platform

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_EDAC_MM_EDAC	y/n	y/n	Enables EDAC core support
CONFIG_EDAC_MPC85XX	y/n	y/n	Enables EDAC NXP 85xx support

Device Tree Binding

Property	Type	Status	Description
compatible	String	Required	Should be 'fsl,qoriq-memory-controller', 'fsl,p4080-pcie'
reg	integer	Required	Register map

Default node:

```
ddr1: memory-controller@8000 {
    compatible = "fsl,qoriq-memory-controller-v4.4", "fsl,qoriq-memory-controller";
    reg = <0x8000 0x1000>;
    interrupts = <16 2 1 23>;
};

/* controller at 0x200000 */
pci0 {
    compatible = "fsl,p4080-pcie";
```

```
    device_type = "pci";
    #size-cells = <2>;
    #address-cells = <3>;
    bus-range = <0x0 0xff>;
    clock-frequency = <33333333>;
    interrupts = <16 2 1 15>;
 };
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/edac/edac_core.c	Enables EDAC core support
drivers/edac/mpc85xx_edac.c	Enables EDAC NXP 85xx support

Kernel boot message:

```
 ........
 ........
EDAC MC: Ver: 2.1.0
Freescale(R) MPC85xx EDAC driver, (C) 2006 Montavista Software
EDAC MC0: Giving out device to 'MPC85xx_edac' 'mpc85xx_mc_err': DEV mpc85xx_mc_err
MPC85xx_edac acquired irq 16 for MC

PCIE ERR_CAP_R1 register: 0x00000000
PCIE ERR_CAP_R2 register: 0x00000000
PCIE ERR_CAP_R3 register: 0x00000000
 ........
 ........
 ........
p4080 login: root
Password:
```

```
[root@p4080 root]#
```

Test Procedure:

```
[root@p4080 root]#
[root@p4080 root]# cat /proc/interrupts |grep EDAC
 16:          1          0          0          0          0          0          0          0
OpenPIC Level [EDAC] MC err, [EDAC] MC err, [EDAC] PCI err, [EDAC] PCI err, [EDAC] PCI err
[root@p4080 root]#
[root@p4080 root]#
```

Now, see that whether the total number of interrupt 16 of EDAC is zero or less than twenty. If it is that, EDAC driver is OK.

7.11.4 PCIe Advanced Error Reporting User Manual

Description
How to test the PCI Express Advanced Error Reporting (AER) function.

Testing the PCIe AER error recovery code in actual environment is quite difficult because it is hard to trigger real hardware errors. So we use a software tool based error injection to fake various kinds of PCIe errors.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

`Bus options  --->`
`    [*] PCI Express support`
`    [*]   Root Port Advanced Error Reporting support`
`    <*>     PCIe AER error injector support`
	enable PCI-Express AER and AER-INJECTOR in kernel

Kernel compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_PCIEAER	y/n	y	Enable AER
CONFIG_PCIEAER_INJECT	y/n	n	Enables AER INJECT

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/pci/pcie/aer/*.c	AER driver support

- **Prepare aer-inject test tool**

```
1, Download aer-inject test utility.
```

```
2, Write a test config file
e.g. $ vi aer-cfg
     AER
     DOMAIN 0001
     BUS 1
     DEV 0
     FN 0
     COR_STATUS BAD_TLP
     HEADER_LOG 0 1 2 3

NOTE:
error type can be ["COR_STATUS", "UNCOR_STATUS"]

Corrected error can be:
["BAD_TLP", "RCVR", "BAD_DLLP", "REP_ROLL", "REP_TIMER"]

Uncorrected non-fatal error can be:
["POISON_TLP", "COMP_TIME", "COMP_ABORT", "UNX_COMP", "ECRC", "UNSUP"]

Uncorrected fatal error can be:
 ["TRAIN", "DLP", "FCP", "RX_OVER", "MALF_TLP"]
```

- **Test Steps**

```
1, insert a pcie device in PCI slot of board, ensure the pcie device has AER capability, e.g.
e1000e PCIe NIC network card.

2, In u-boot prompt, add "pcie_ports=native" in bootargs command-line.
=> setenv othbootargs pcie_ports=native

3, boot the kernel and filesystem.
=> tftp 1000000 uImage;tftp 2000000 board.dtb; tftp 3000000 rootfs.ext2.gz.uboot; bootm 1000000
3000000 2000000

4, check AER device and config
# zcat /proc/config.gz|grep -i CONFIG_PCIEAER_INJECT
CONFIG_PCIEAER_INJECT=y

# cat /proc/cmdline
root=/dev/ram rw console=ttyS0,115200 pcie_ports=native
check "pcie_ports=native" has been set.

# ls /dev/aer_inject
Check if the aer injector device is created.

# lspci
00:00.0 Class 0604: 1957:0410
01:00.0 Class 0200: 8086:10d3
e.g. here device "01:00.0" is the PCIe NIC e1000 network card in the test scenario.

5, Download aer-inject and aer-cfg from host to test-board
$ scp aer-inject aer-cfg root@test-board-ip:~

6, ensure the pcie device domain-number/bus-number/device-number/function-number in aer-cfg is
accordant to those in the output of lspci

7, Run aer-inject, corresponding error information will be reported as below and AER will recover
PCIE device according to the type of errors.
# ./aer-inject aer-cfg
```

```
example of error report as below:
pcieport 0000:00:00.0: AER: Corrected error received: id=0100
e1000e 0000:01:00.0: PCIe Bus Error: severity=Corrected, type=Data Link Layer, id=0100(Receiver
ID)
e1000e 0000:01:00.0:   device [8086:10d3] error status/mask=00000040/00002000
e1000e 0000:01:00.0:    [ 6] Bad TLP
root@p1010rdb:~#

8, The pcie device(e1000e PCIE NIC) should still work after AER error recovery.
# ping 192.168.1.1 -c 2 -s 64
PING 192.168.1.1 (192.168.1.1): 64 data bytes
72 bytes from 192.168.1.1: icmp_seq=0 ttl=64 time=0.272 ms
72 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=0.210 ms
--- 192.168.1.1 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.210/0.241/0.272/0.031 ms
```

Note:

On some legacy platforms with legacy PCI conroller(e.g. some non-DPAA platforms), hardware doesn't support Fatal error type for AER, just support Non-Fatal error.

Generally, DPAA platforms with new PCIE controller can support both Fatal error and Non-Fatal error.

7.11.5 PCI-e Remove and Rescan User Manual

Description
Describes how to remove and rescan a PCI-e device under runtime Linux system.

U-boot Configuration
Use the default configurations.

Kernel Configure Options
Use the default configurations, make sure the configure option is set while doing "make menuconfig" for kernel.

Kernel Configure Tree View Options	Description
Device Drivers ---> [*] Network device support---> [*] Ethernet (1000 Mbit) ---> [*] Intel(R) PRO/1000 PCI-Express Gigabit Ethernet support	This option enables kernel support for Intel PCI-e e1000e network card

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_E1000E	y/n	y	Intel PCI-e e1000e network card driver

Device Tree Binding

Use the default dtb file.

Verification in Linux

Make sure the PCI-e controller which you add the PCI-e e1000e network card to works as RC mode. Use the kernel, dtb and ramdisk rootfs to boot the board.

```
1. Suppose the PCI-e device under /sys/bus/pci/devices/0001\:03\:00.0 is the Intel PCI-e e1000e
network card, recognized as eth0. The
/sys/bus/pci/devices/0001\:02\:00.0 is the bus of network card. Configure an ip and ping another
host which is in the same subnet, make sure the network card works well.

    # ls /sys/bus/pci/devices/0001\:03\:00.0/net
    eth0
    # ifconfig eth0 10.193.20.100
    # ping -I eth0 10.193.20.31

2. Remove the PCI-e network card from system.
    # echo 1 > /sys/bus/pci/devices/0001\:03\:00.0/remove
    e1000e 0001:03:00.0 eth0: removed PHC

3. Check whether the PCI-e network card still exist in system. All should fail.
    # ifconfig eth0
    # ls /sys/bus/pci/devices/0001\:03\:00.0

4. Rescan it from the bus.
    # echo 1 > /sys/bus/pci/devices/0001\:02\:00.0/rescan

5. Check whether the device is rescanned and works well.
    # ls /sys/bus/pci/devices/0001\:03\:00.0
    # ifconfig eth0 10.193.20.100
    # ping -I eth0 10.193.20.31

6. All the commands of step 5 should success.
```

Known Bugs, Limitations, or Technical Issues

The support of PCI-e device remove rescan on powerpc platform is first added in NXP LInux SDK 1.4(kernel version: 3.8.4). If it fail, the PCI-e device will be rescaned, but the driver of the device will fail to loaded.

7.11.6 PCIE EP

Description

SKMM (Secure Key Management Module) is Linux user space implementation for accelerating the encryption/decryption operations on the NXP processors with SEC engine. SKMM consists of two parts of software, the host kernel driver and the application on EP side. The host driver interfaces with OpenSSL or sysfs to pass the encryption/decryption operations to EP side by abstract request and the EP application parses the abstract request to do the encryption/decryption operations, pass the results to host side. The key point here is the private key used is only kept in EP side and is invisible to host side. Also the private key(s) is stored in NOR flash using blob mechanism for protecting the key across system power cycles.

SKMM has two sub use cases:

- - SKMM with PCIe data path. (For now, only SKMM with PCIe data path is supported.)

  For SKMM with PCIe data path, the two boards are connected through the PCIe interface, the requests are sent to EP through PCIe interface.

- - SKMM with Ethernet data path.

  Requests are sent to the EP through the Ethernet port.

Platforms Supported

- P4080DS
- T4240QDS

Compiling SKMM code

Refer to SDK Documentation provided with this release for installing and using Yocto for Image compilation and building.

How to configure and build Host images for PowerPC

1. Change directory to Yocto, execute commands to configure kernel

```
> source ./poky/fsl-setup-poky -m <board-type> -j 12 -t 12

#> bitbake -c menuconfig linux-qoriq-sdk

To P4080DS and T4240QDS:
  Location:
    -> Device Drivers
      -> DMA Engine support
        ->[*] NXP Elo and Elo Plus DMA support (enable the option)
          [ ] Network: TCP receive copy offload (disable the option)
```

2. Execute Commands to build uImage with DMA enabled

```
#> bitbake linux-qoriq-sdk
```

3. Execute Command to generate RFS with kernel modules for host and SKMM application for EP

```
#> bitbake fsl-image-core
```

How to configure and build Host images for X86:

NOTE

When using X86 as Host of SKMM, need a Linux distribution to be installed to X86 PC, suggested using Ubuntu 12.04 64bit.

1. Change directory to Yocto, then extract the SKMM Host source code as following:

```
#> source  ./poky/fsl-setup-poky -m <board-type> -j 12 -t 12
#> bitbake -c patch skmmhost
```

2. The source code will be in `tmp/work/<board -type>-fsl_networking-linux/skmmhost/git-r0/git/`. Copy the source directory to your X86 Host machine for building.
3. Change the directory to the top of the SKMM Host's source code, execute the command:

```
#> make ARCH=x86_64 KERNEL_DIR=/lib/modules/$(uname -r)/build
```

4. The driver modules will be built in the current directory, named "fsl_crypto.ko" and "rsa_test.ko".

How to configure and build EP kernel:

1. Change the directory to Yocto, then execute commands to configure the kernel:

```
#> source ./poky/fsl-setup-poky -m <board-type> -j 12 -t 12
#> bitbake -c menuconfig linux-qoriq-sdk
```

   - For P4080ds: Location:

```
-> Cryptographic API
  ->[*] Hardware crypto devices
    -> < >   NXP CAAM-Multicore driver backend (disable the option)
-> Device Drivers
  -> <*> Userspace I/O drivers
    -> <*>   NXP SEC support(disable the option)
```

   - For T4240qds: Location:

```
-> Cryptographic API
  ->[*] Hardware crypto devices
    -> < >   NXP CAAM-Multicore driver backend (disable the option)
-> Device Drivers
  -> <*> Userspace I/O drivers
    -> <*>   NXP SEC support(disable the option)
  -> <*> VFIO Non-Privileged userspace driver framework(enable the option)
    -> <*>   VFIO support for Fresscale PCI Endpoint devices(enable the option)
```

2. Execute command to build the kernel image

```
#> bitbake linux-qoriq-sdk
```

3. Execute command to generate RFS with SKMM application for EP

```
#> bitbake fsl-image-core
```

Configure physical connection

EP

- For P4080ds, route the PCIe cable between slot #1 and the Host.
- For T4240qds, route the PCIe cable between slot #5 and the Host.

Host

- For P4080ds, route the PCIe cable between slot #3 and the EP
- For X86, route the PCIe cable between X86 PCIe slot with the x4 to x1 connector, and the EP
- For T4240qds, route the PCIe cable between slot #7 and the EP

How to operate EP

Store all the images for PowerPC machine on the tftp server. Configure the board IP and tftp server IP on the u-boot environment using following commands, the third step is to reserve memory for SKMM, it couldn't be ignored.

For P4080ds as EP

1.

```
#> setenv ipaddr <board ip >
```

```
#> setenv serverip <tftp server ip >
#> setenv bootargs "$bootargs usdpaa_mem=256m"
#> save
```

2. Program RCW with `R_PPPNN_0x5/rcw_ep_1500mhz.bin` to flash.
3. Execute following command at u-boot prompt to boot the board

```
#> tftp 1000000 uImage-<bsp>.bin
#> tftp 2000000 fsl-image-core-<bsp>.ext2.gz.uboot
#> tftp c00000 uImage-<bsp>.dtb
#> bootm 1000000 2000000 c00000
```

4. Once the Linux Image boots, enter username=root and password=root to logon.
5. If the SKMM application is being run for the first time, update private key into Nor flash MTD4.

```
root@p4080:flash_eraseall /dev/mtd4
root@p4080:skmm_$(host) /dev/mtd4 update-key ~/.skmm/RSA_priv3
```

NOTE

skmm_$(host) is the application for different Host. For x86 its name is "skmm_x86_64", for PowerPC its is "skmm_powerpc", please check the application used is correct to Host.

6. Run SKMM application, then EP will wait for request offloaded

```
root@p4080:skmm_$(host) /dev/mtd4
```

For T4240qds as EP

1.

```
#> setenv ipaddr <board ip >
#> setenv serverip <tftp server ip >
#> setenv bootargs "$bootargs usdpaa_mem=256m"
#> save
```

2. Program RCW with “RR_XXSSPRPH_1_28_6_12/rcw_1_28_6_12_pexep_1666MHz.bin”

```
#> tftp 1000000 uImage-<bsp>.bin
#> tftp 2000000 fsl-image-core-<bsp>.ext2.gz.uboot
#> tftp c00000 uImage-<bsp>.dtb
#> fdt addr $fdtaddr;fdt mknod /localbus/nor partition@7000000;
#> fdt set /localbus/nor/partition@7000000 reg <0x07000000 0x00100000>;
#> fdt set /localbus/nor/partition@7000000 label "blob";
#> bootm $loadaddr - $fdtaddr;
```

3. Once the Linux Image boots, enter username=root and password=root to logon.
4. If the SKMM application is being run for the first time, update private key into Nor flash MTD0

```
root@t4240:flash_eraseall /dev/mtd0
root@t4240:skmm_$(host) /dev/mtd0 update-key ~/.skmm/RSA_priv3
```

NOTE

skmm_$(host) is the application for different Host. For x86 its name is "skmm_x86_64", for PowerPC its is "skmm_powerpc", please check the application used is correct to Host.

5. Run SKMM application, then EP will wait for request offloaded

```
root@t4240:skmm_$(host) /dev/mtd0
```

How to operate Host

1. boot up PowerPC Host:
2. Configure the board IP and tftp server IP on the u-boot environment using following commands:

```
#> setenv ipaddr <board ip >
#> setenv serverip <tftp server ip >
#> save
```

3. Execute following command at u-boot prompt to boot the board

```
   #> tftp 1000000 uImage-<bsp>.bin
#> tftp 2000000 fsl-image-core-<bsp>.ext2.gz.uboot
#> tftp c00000 uImage-<bsp>.dtb
#> bootm 1000000 2000000 c00000
```

4. Once the Linux Image boots, enter username=root and password=root to logon.
5. Insmod the module to start the test process

```
Root #>:insmod /lib/modules/$(uname -r)/extra/fsl_crypto.ko dev_config_file=/etc/skmm/
skmm_crypto.cfg
```

6. boot up X86 Host
7. There is no specific setup for X86, change directory to c293_skmm_host copied from Yocto, and make sure the modules has been generated.
8. Insert the module to start the test process
   - For PowerPC Host:

```
Root #>:insmod /lib/modules/$(uname -r)/extra/fsl_crypto.ko dev_config_file=/etc/skmm/
skmm_crypto.cfg
```

   - For X86 Host:

```
root #>:insmod fsl_crypto.ko dev_config_file=crypto.cfg
```

How to test

When you complete one of RSA public key test or private key test, you have to reboot both HOST and EP, and reload the fsl_crypto.ko module above, then move on another function test step.

```
For PowerPC as Host
  RSA public key:
  Root #>:insmod /lib/modules/$(uname -r)/extra/rsa_test.ko op=rsa_pub
  RSA private key:
  Root #>:insmod /lib/modules/$(uname -r)/extra/rsa_test.ko op=rsa_priv3
```

```
For x86 as Host
  RSA_public key:
  root #>:insmod rsa_test.ko op=rsa_pub
  RSA private key:
  root #>:insmod rsa_test.ko op=rsa_priv3
```

Because PowerPC haven't supported PCIe hotplug yet, removing fsl_crypto.ko module will cause a Host kernel call trace

Funtion test result

If there was nothing “ERROR” log printed, it means test result was correct, but if the console prints the words like “!!!!! Not matching byte got [xx] original [%0x] at index [xx]”(note: xx is a number of 0 to127), it means test failed.

Performance test

```
RSA pubilc key:
Root #>:echo "RSA_PUB_OP_1K" >/sys/fsl_crypto/fsl_crypto_1/test-i/test_name
RSA private key:
Root #>:echo "RSA_PRV_OP_1K" >/sys/fsl_crypto/fsl_crypto_1/test-i/test_name
```

After console prints the start time and end time, it means the test process is finished, then please use the formula bellow to calculate the performance ops/s (The number of crypto operations in a second):

```
Ops/s = Host cpu Frequency / ((end time – start time) / 5000)
```

For example, to P4080ds, Cpu Frequency is 1.5GHz(1.5 x 109). 5000 is the number of crypto operations (it is the default setting for performance test), it has been hard code, so it couldn’t be modified.

7.12 QUICC Engine HDLC/TDM

7.12.1 QUICC Engine HDLC/TDM User Manual

Linux SDK for QorIQ Processors

Description

HDLC, standing for High-level Data Link Control, is one of the most common protocols of the Layer 2 (Data Link Layer) of the seven-layer OSI model. HDLC uses a zero insertion/deletion process (commonly known as bit stuffing) to ensure that the bit pattern of the delimiter flag does not occur in the fields between flags. The HDLC frame is synchronous and therefore relies on the physical layer for a method of clocking and of synchronizing the transmitter/receiver.

The HDLC/TDM driver is implemented by UCC and TSA(HDLC is upper layer protocol of TDM). It enables UCC1/3 to work in hdlc protocol, connected with X-TDM-DS26522 card to support T1/E1 function. It can work in normal or loopback mode both for tdm controller and phy. connect X-TDM-DS26522 card to TDM Riser slot, it can transmit data and receive data.

U-Boot Configuration

Compile time options

Below are major u-boot configuration options related to this feature defined in platform specific config files under include/ configs/ directory.

Option Identifier	Description

Choosing predefined u-boot modes:

make T1040RDB_config

before doing the actually build

Runtime options

Env Variable	Env Description	Sub option	Option Description
hwconfig	Hardware configuration for u-boot	qe-hdlc	QUICC Engine TDM enabled in DTB
bootargs	Kernel command line argument passed to kernel		

Kernel Configure Options

Tree View

T1040RDB and X-TDM-DS26522 card:

Kernel Configure Tree View Options	Description
Device Drivers ---> SOC (System On Chip) specific Drivers ---> [*] Freescale QUICC Engine (QE) Support [*] Network device support ---> [*] Wan interfaces support ---> <*> Generic HDLC layer <*> Raw HDLC support <*> Freescale QUICC Engine HDLC support <*> TDM Network Drivers ---> <*> SLIC MAXIM DS26522 CARD SUPPORT	Enable the QE TDM driver and X-TDM-DS26522 card driver.

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_QUICC_ENGINE	y/n	n	QUICC Engine enabled
CONFIG_FSL_UCC_TDM	y/n	n	QUICC Engine TDM lib
CONFIG_SLIC_MAXIM	y/m/n	n	Enable x-tdm-ds26522 card support
FSL_UCC_HDLC	y/m/n	n	QUICC Engine driver driver

Device Tree Binding

Below is the definition of the device tree node required by this feature

Property	Type	Status	Description
qe	qe	enable	QUICC Engine node
ucc	hdlc	enable	QE UCC HDLC node.
si	si	si	QE TSA node

Below is an example device tree node required by this feature. Note that it may have differences among platforms.

T1040RDB and X-TDM-DS26522 card:

```
ucc_hdlc: ucc@2000 {
                        compatible = "fsl,ucc_hdlc";
                        rx-clock-name = "clk8";
                        tx-clock-name = "clk9";
                        fsl,rx-sync-clock = "rsync_pin";
                        fsl,tx-sync-clock = "tsync_pin";
                        fsl,tx-timeslot = <0xfffffffe>;
                        fsl,rx-timeslot = <0xfffffffe>;
                        fsl,tdm-framer-type = "e1";
                        fsl,tdm-mode = "normal";
                        fsl,tdm-id = <0>;
                        fsl,siram-entry-id = <0>;
                        fsl,tdm-interface;
                };
                spi@110000 {
                        slic@3 {
                                compatible = "maxim,ds26522";
                                reg = <3>;
                                spi-max-frequency = <2000000>; /* input clock */
                        };
                };
```

Source Files

The following source file are related the this feature in Linux.

T1040RDB and X-TDM-DS26522 card:

Source File	Description
drivers/soc/fsl/qe/qe_tdm.c	QE UCC TDM lib
include/soc/fsl/qe/qe_tdm.h	QE UCC TDM lib head file.
drivers/net/tdm/slic_ds26522.c	X-TDM-DS26522 card driver.
drivers/net/wan/fsl_ucc_hdlc.*	QE HDLC driver
arch/powerpc/boot/dts/fsl/t104xrdb.dtsi	Define the device tree nodes for T1040RDB hdlc
arch/powerpc/boot/dts/fsl/t1040rdb.dts	Define the device tree nodes for T1040RDB ds26522

User Space Application

The following applications will be used during functional or performance testing. Please refer to the SDK UM document for the detailed build procedure.

Command Name	Description	Package Name

Verification in U-boot

N/A

Verification in Linux

1. After u-boot startup,set "qe-hdlc" parameter in hwconfig.
2. After bootup kernel, Kernel boot log for hdlc:

```
hdlc: HDLC support module revision 1.22
```

3. QE HDLC T1/E1 test
   a. Make X-TDM-DS26522 card connected to T1040RDB board Slot.
   b. To test tdm external ports, please plugin tdm t1/e1 loopback cable in the related port.

      The following is HDLC port mapping with X-TDM-DS26522 card:

```
HDLC Port                 X-TDM-DS26522 Port
Port A                         CH1;
Port B                         CH2;
```

   c. HDLC test using E1.

      Use the default dts to test E1 function. Test module can receive ucc_num as parameter. This number should be 1/3 related to the tdm port.

```
root@t1040rdb:~# mount /dev/mmcblk0 /mnt && cp /mnt/sethdlc ./sethdlc && ./sethdlc hdlc0
hdlc && \
 192.168.0.1 hdlc0 && \
ping 192.168.0.2> ifconfig hdlc0 192.168.0.1 up && \

7.13 Real Time Clock (off-chip)

7.13.1 RTC Driver User Manual (Linux BSP)

Linux SDK for QorIQ Processors

Description
Provides the RTC function.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers-> Real Time Clock-->[*] Set system time from RTC on startup and resume (new) (rtc0) RTC used to set the system time (new) <[*] /sys/class/rtc/rtcN (sysfs) <[*] /proc/driver/rtc (procfs for rtc0) <[*] /dev/rtcN (character devices)	Enable RTC driver

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_RTC_LIB	y/m/n	y	Enable RTC lib
CONFIG_RTC_CLASS	y/m/n	y	Enable generic RTC class support
CONFIG_RTC_HCTOSYS	y/n	y	Set the system time from RTC when startup and resume
CONFIG_RTC_HCTOSYS_DEVICE		"rtc0"	RTC used to set the system time
CONFIG_RTC_INTF_SYSFS	y/m/n	y	Enable RTC to use sysfs

Table continues on the next page...

Table continued from the previous page...

Option	Values	Default Value	Description
CONFIG_RTC_INTF_PROC	y/m/n	y	Use RTC through the proc interface
CONFIG_RTC_INTF_DEV	y/m/n	y	Enable RTC to use /dev interface

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/rtc/	Linux RTC driver

Device Tree Binding

Preferred node name: rtc

Property	Type	Status	Description
compatible	string	Required	Should be "dallas,ds3232"

Default node:

```
    i2c@3000 {
                #address-cells = <1>;
                #size-cells = <0>;
                compatible = "fsl-i2c";
                reg = <0x3000 0x100>;
                interrupts = <43 2>;
                interrupt-parent = <&mpic>;
                dfsrr;
                rtc@68 {
                        compatible = "dallas,ds3232";
                        reg = <0x68>;
                };
              };
```

Verification in Linux

Here is the rtc booting log

```
      ...
      rtc-ds3232 1-0068: rtc core: registered ds3232 as rtc0
      MC object device driver dpaa2_rtc registered
      rtc-ds3232 0-0068: setting system clock to 2000-01-01 00:00:51 UTC (946684851)
      ...

NOTE: Please refer to the related DTS file to enable the RTC driver before building.
      For example, LS2080AQDS board, should enable the below option:
      <*> Dallas/Maxim DS3232
```

Change the RTC time in Linux Kernel

```
        ~ # ls /dev/rtc -l
        lrwxrwxrwx    1 root     root            4 Jan 11 17:55 /dev/rtc -> rtc0
        ~ # date
        Sat Jan  1 00:01:38 UTC 2000
        ~ # hwclock
        Sat Jan  1 00:01:41 2000  0.000000 seconds
        ~ # date 011115502011
        Tue Jan 11 15:50:00 UTC 2011
        ~ # hwclock -w
        ~ # hwclock
        Tue Jan 11 15:50:36 2011  0.000000 seconds
        ~ # date 011115502010
        Mon Jan 11 15:50:00 UTC 2010
        ~ # hwclock -s
        ~ # date
        Tue Jan 11 15:50:49 UTC 2011
        ~ #

        NOTE: Before using the rtc driver, make sure the /dev/rtc node in your file system is
correct. Otherwise, you need to make correct node for /dev/rtc
```

7.14 SATA Controller

7.14.1 NXP Native SATA Driver User Manual

Description
The driver supports NXP native SATA controller.

Module Loading

SATA driver supports either kernel built-in or module.

Kernel Configure Tree View Options	Description
Device Drivers---> <*> Serial ATA and Parallel ATA drivers ---> --- Serial ATA and Parallel ATA drivers <*> AHCI SATA support <*> Freescale QorIQ AHCI SATA support	Enables SATA controller support on ARM-based SoCs

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_SATA_AHCI=y	y/m/n	y	Enables SATA controller
CONFIG_SATA_AHCI_QORIQ=y	y/m/n	y	Enables SATA controller

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/ata/ahci_qoriq.c	Platform AHCI SATA support

Test Procedure

```
Please follow the following steps to use USB in Simics
(1) Boot up the kernel
...
fsl-sata ffe18000.sata: Sata FSL Platform/CSB Driver init
scsi0 : sata_fsl
ata1: SATA max UDMA/133 irq 74
fsl-sata ffe19000.sata: Sata FSL Platform/CSB Driver init
scsi1 : sata_fsl
ata2: SATA max UDMA/133 irq 41
...
(2) The disk will be found by kernel.
...
ata1: Signature Update detected @ 504 msecs
ata2: No Device OR PHYRDY change,Hstatus = 0xa0000000
ata2: SATA link down (SStatus 0 SControl 300)
ata1: SATA link up 1.5 Gbps (SStatus 113 SControl 300)

Known Bugs, Limitations, or Technical Issues

- CDROM is not supported due to the silicon limitation

7.15 Serial Peripheral Interface

7.15.1 SPI Flash Over eSPI Controller User Manual

Description

Many NXP's CPU has an eSPI controller which could be connected to different devices, such as SPI flash, ABS ViocePort device, SPI Ethernet Switch etc. The SPI flash is deployed on many NXP development board, so this manual will focus on the test method using SPI flash.

This user manual will take P5020DS board as an example to describes how to select the Configuration options, how to add the DTS file and how to test the SPI flash.

Module Loading

The eSPI controller driver and the SPI flash driver can be built as module or built-in kernel.

Compile-time Configuration Options

Option	Values	Default Value	Description
SPI support --->			
CONFIG_SPI	y/n	y	SPI subsystem support
CONFIG_FSL_ESPI	y/n	y	eSPI controller driver support
Memory Technology Device (MTD) support			
CONFIG_MTD	y/n	y	MTD subsystem support
CONFIG_MTD_PARTITIONS	y/n	y	MTD partitons support
CONFIG_MTD_OF_PARTS	y/n	y	MTD OF partition support
CONFIG_MTD_CHAR	y/n	y	MTD char dev support
CONFIG_MTD_BLOCK	y/n	y	MTD block dev support
Self-contained MTD device drivers --->			
CONFIG_MTD_FSL_M25P80	y/n	y	Spansion SPI flash driver support
CONFIG_M25PXX_USE_FAST_READ	y/n	y	support FAST_READ operation

Device Tree Binding

Preferred node name: spi

Property	Type	Status	Description
Controller's compatible	string	Required	"fsl,mpc8536-espi"
interrupt	integer	Required	platform dependent
Flash's compatible	string	Required	device dependent
spi-max-frequency	integer	Required	device dependent

Default node:

```
eSPI controller DTS node for non-DPAA platform:
"arch/powerpc/boot/dts/fsl/pq3-espi-0.dtsi"
```

```
spi@7000 {
        #address-cells = <1>;
        #size-cells = <0>;
        compatible = "fsl,mpc8536-espi";
        reg = <0x7000 0x1000>;
        interrupts = <59 0x2 0 0>;
};

eSPI controller DTS node for DPAA platform:
"arch/powerpc/boot/dts/fsl/qoriq-espi-0.dtsi"
spi@110000 {
        #address-cells = <1>;
        #size-cells = <0>;
        compatible = "fsl,mpc8536-espi";
        reg = <0x110000 0x1000>;
        interrupts = <53 0x2 0 0>;
};

An example to add SPI flash DTS support on P5020DS baord:
"arch/powerpc/boot/dts/fsl/p5020si-post.dtsi"
/include/ "qoriq-espi-0.dtsi"
        spi@110000 {
                fsl,espi-num-chipselects = <4>;
        };

"arch/powerpc/boot/dts/p5020ds.dts"
/include/ "fsl/p5020si-post.dtsi"
                spi@110000 {
                        flash@0 {
                                #address-cells = <1>;
                                #size-cells = <1>;
                                compatible = "spansion,s25sl12801";
                                reg = <0>;
                                spi-max-frequency = <40000000>; /* input clock */
                                partition@u-boot {
                                        label = "u-boot";
                                        reg = <0x00000000 0x00100000>;
                                        read-only;
                                };
                                partition@kernel {
                                        label = "kernel";
                                        reg = <0x00100000 0x00500000>;
                                        read-only;
                                };
                                partition@dtb {
                                        label = "dtb";
                                        reg = <0x00600000 0x00100000>;
                                        read-only;
                                };
                                partition@fs {
                                        label = "file system";
                                        reg = <0x00700000 0x00900000>;
                                };
                        };
                };
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description

Config	Values	Default Value	Description
CONFIG_SPI_FSL_DSPI	y/n	y	Enable DSPI module
CONFIG_MTD_DATAFLASH	y/n	y	Enables MTD devices for DSPI flash

Verification in U-Boot LS1021a-qds

Verification in U-Boot:

```
=> sf probe 1:0
SF: Detected AT45DB021D with page size 256 Bytes, erase size 2 KiB, total 256 KiB
=> sf erase 0 10000
SF: 65536 bytes @ 0x0 Erased: OK
=> sf write 82000000 0 1000
SF: 4096 bytes @ 0x0 Written: OK
=> sf read 81100000 0 1000
SF: 4096 bytes @ 0x0 Read: OK
```

```
=> cm.b 81100000 82000000 1000
Total of 4096 byte(s) were the same
```

Verification in Linux:

```
The booting log

......
mtd_dataflash spi0.0: at45db021d (256 KBytes) pagesize 256 bytes (OTP)
6Freescale DSPI master initialized
......

Erase the DSPI flash

~ # mtd_debug erase /dev/mtd0 0x1100000 65536
Erased 65536 bytes from address 0x00000000 in flash

Write the DSPI flash

~ # dd  if=/bin/tempfile.debianutils of=tp bs=4096 count=1
~ # mtd_debug write /dev/mtd0 0 4096 tp
Copied 4096 bytes from tp to address 0x00000000 in flash

Read the DSPI flash

~ # mtd_debug read /dev/mtd0 0 4096 dump_file

Copied 4096 bytes from address 0x00000000 in flash to dump_file

Check Read and Write

Use compare tools(yacto has tools named diff).
~ # diff tp dump_file
~ #
If diff command has no print, the DSPI verification is passed.
```

7.15.3 QuadSPI Driver for TWR-LS1021A User Manual

7.15.3.1 QuadSPI Driver User Manual

U-Boot Configuration

Make sure your boot mode support QSPI.

Use QSPI boot mode to boot an board, please check the board user manual and boot from QSPI. (or some other boot mode decide by your board.)

Total of 4096 byte(s) were the same
```

Verification in Linux:

```
The booting log

......
fsl-quadspi 1550000.quadspi: n25q128a13 (16384 Kbytes)
fsl-quadspi 1550000.quadspi: QuadSPI SPI NOR flash driver
......

Erase the QSPI flash

~ # mtd_debug erase /dev/mtd0 0x1100000 1048576
Erased 1048576 bytes from address 0x00000000 in flash
```

```
Write the QSPI flash

~ # dd if=/bin/tempfile.debianutils of=tp bs=4096 count=1
~ # mtd_debug write /dev/mtd0 0 4096 tp
Copied 4096 bytes from tp to address 0x00000000 in flash

Read the QSPI flash

~ # mtd_debug read /dev/mtd0 0 4096 dump_file

Copied 4096 bytes from address 0x00000000 in flash to dump_file

Check Read and Write

Use compare tools(yacto has tools named diff).
~ # diff tp dump_file
~ #
If diff command has no print log, the QSPI verification is passed.
```

7.16 Time Division Multiplexing (TDM) Interface

7.16.1 TDM User Manual

Description

Time-Division Multiplexing (TDM) is a type of digital or analog multiplexing in which two or more signals or bit streams are transferred apparently simultaneously as sub-channels in one communication channel, but are physically taking turns on the channel. The time domain is divided into several recurrent timeslots of fixed length, one for each sub-channel. A sample byte or data block of sub-channel 1 is transmitted during timeslot 1, sub-channel 2 during timeslot 2, etc. One TDM frame consists of one timeslot per sub-channel. After the last sub-channel the cycle starts all over again with a new frame, starting with the second sample, byte or data block from sub-channel 1, etc.

TDM or Time Division Multiplexing is an essential component to run VoIP applications on NXP Platforms. Its function is to receive and send time division multiplexed voice samples on the physical TDM lines.

This document explains the procedure to test the TDM on FSL MPC85xx platforms.

The test procedure shows the method to run a small TDM demo application which transfers voice from one TDM channel to the other.

The overall TDM software stack and the data flow is depicted below. On the top is a generic TDM framework layer which can ideally integrate with any TDM driver beneath it.

Generally NXP platforms offer two types of TDM interfaces:

1. NXP TDM
2. QE based TDM

This manual specifically talks about NXP TDM

U-Boot Configuration

Compile time options

Please check the platform specific document to check if any specific u-boot configuration is required for TDM feature.

Also please ensure if there is any requirement from pin mux perspective to enable TDM.

Runtime options

Refer to platform specific document for any specific hwconfig or environment variables which may be required for TDM functionality.

Also the FXS ports location will be mentioned in the platform specific document.

Kernel Configure Options

Tree View

Below are the configure options need to be set/unset while doing "make menuconfig" for kernel

Kernel Configure Tree view options	Description

Device Drivers --->
  <*> TDM support --->
  --- TDM support
  [ ] TDM Core debugging messages (NEW)
  <M> TDM test Module
  TDM Device support --->
  <*> Driver for Freescale TDM controller
  Line Control Devices --->
  <*> Zarlink Slic intialization Module
	Enable TDM Framework
	Enable TDM test as Module
	Enable TDM driver
	Enable SLIC driver

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Value	Default value in BSP	Description
CONFIG_TDM	y/n/m	N	Enable / Disable TDM Framework support
CONFIG_TDM_FSL	y/n/m	N	Enable / Disable TDM driver, depends on TDM framework and CONFIG_FSL_SOC
CONFIG_SLIC_ZARLINK	y/n/m	N	Enable / Disable SLIC driver , depends on TDM driver and TDM framework, and CONFIG_FSL_ESPI
CONFIG_TDM_TEST	y/n/m	N	Enable / disable TDM test module

Device Tree Binding

Below is the definition of the device tree node required by this feature

TDM device dts entries.(as many entries as the number of TDM controllers on the platform)

Property	Type	Status	Description
compatible = "fsl,tdm1.0";	<string>		Should contain "fsl,tdm1.0"
reg = <0x16000 0x200 0x2c000 0x2000>;	<tdm-reg-offset tdm-reg-size dmac-reg-offset dmac-reg-size>		Offset and length of the register set for the NXP TDM and TDM-DMAC
interrupts = <16 8 62 8>;	<tdm-err-intr tdm-err-intr-type dmac-intr dmac-intr-type>		Defines two interrupt specifiers namely interrupt + number and interrupt type for TDM error and TDM DMAC
fsl-max-time-slots = <128>	<u32>		Maximum number of 8-bit time slots in one TDM frame that hardware supports.

SLIC device dts entries (As many entries as the number of SLICs on the platform)

Please note that the below mentioned SLIC entry is for the Legerity SLIC which is connected to the chip through SPI interface.

Property	Type	Status	Description
compatible = "zarlink,le88266";			Should be "zarlink,le88266"
reg = <1>;			Chip select number of the SPI bus SLIC is connected to
spi-max-frequency =<8000000>;			The maximum frequency the SLIC can operate at.

Below is an example device tree node required by this feature. Note that it may have differences among platforms.

```
       tdm@16000 {
               compatible = "fsl,tdm1.0";
               reg = <0x16000 0x200 0x2c000 0x2000>;
               clock-frequency = <0>;
               interrupts = <16 8 62 8>;
               phy-handle = <zarlink1>
               fsl-max-time-slots = <128>
       };

spi@7000 {
    cell-index = <0>;
    #address-cells = <1>;
    #size-cells = <0>;
    compatible = "fsl,espi";
    reg = <0x7000 0x1000>;
    interrupts = <59 0x2>;
    interrupt-parent = <&mpic>;
    mode = "cpu";
            …….
            ……..
            ……..
               legerity@0{
                       compatible = "zarlink,le88266";
                       reg = <1>;
                       spi-max-frequency = <8000000>;
               };

               legerity@1{
```

```
                        compatible = "zarlink,le88266";
                        reg = <2>;
                        spi-max-frequency = <8000000>;
                };
};
```

Source Files

The following source file are related the this feature in Linux kernel.

Source file	Purpose
include/linux/tdm.h	Header file for TDM framework
drivers/tdm/tdm-core.c	Source file for TDM framework
drivers/tdm/device/tdm_fsl.h	Header file for TDM driver
drivers/tdm/device/tdm_fsl.c	Source file for TDM driver
drivers/tdm/line_ctrl/slic_zarlink.h	Header file for SLIC driver
drivers/tdm/line_ctrl/slic_zarlink.c	Source file for SLIC driver
drivers/tdm/test/tdm_test.c	Source file for TDM test module

Verification in U-Boot

N/A

Verification in Linux

1. Attach two analog phones at the two FXS ports of the board. (Incase there are two SLIC devices there would be 4 FXS ports available).

   NOTE

   Please refer to the platform documentation for specific information on FXS ports.

2. Bring up the platform with the kernel image and dts configured as explained above.

   Look for the below mentioned messages in the kernel boot log.

   This will ensure TDM and SLIC initialization.

```
...
...

EDAC MC: Ver: 2.1.0

```

5. To test the TDM functionality Pick up both the phones. Anything spoken on one phone will be heard on the other.

Benchmarking

Voice must be clearly audible and must not break.

Known Bugs, Limitations, or Technical Issues

1. TDM functionality is not supported in 36bit Physical address mode. This is because of hardware limitation on current FSL platforms.
2. TDM_TEST is for demo purpose only and hence runs only for a small duration.

7.17 Universal Serial Bus Interfaces

7.17.1 USB 2.0 Host Driver

7.17.1.1 USB 2.0 Host Driver User Manual

Description
The driver supports USB controller in host mode

Module Loading
The USB Host driver in linux supports either kernel built-in or module driver. U-boot USB driver is always built-in

U-Boot Compile Time Configuration Options

U-Boot Configure Options	Description

`#define CONFIG_HAS_FSL_DR_USB`
 	
`#ifdef CONFIG_HAS_FSL_DR_USB`
`#define CONFIG_USB_EHCI`
 	
`#ifdef CONFIG_USB_EHCI`
`#define CONFIG_CMD_USB`
`#define CONFIG_USB_STORAGE`
`#define CONFIG_USB_EHCI_FSL`
`#define CONFIG_EHCI_HCD_INIT_AFTER_RESET`
`#define CONFIG_CMD_EXT2`
	Enables USB host Dual Role controller support. Defined inside platform config file: include/configs/<platform.h>.

`CONFIG_SYS_FSL_USB_INTERNAL_UTMI_PHY`	Enable internal UTMI Phy support. Required only for SoCs having internal UTMI PHY. Defined inside file: arch/powerpc/include/asm/config_mpc85xx.h
`CONFIG_USB_MAX_CONTROLLER_COUNT`	Tell maximum no. of USB controllers in this SoC. Defined inside file: arch/powerpc/include/asm/config_mpc85xx.h

U-Boot Source Files

The driver source is maintained in the U-boot source in following files

Source File	Description
drivers/usb/host/ehci-fsl.c	EHCI FSL USB host controller driver

Table continues on the next page...

Table continued from the previous page...

Source File	Description
common/cmd_usb.c	Common usb command file
drivers/usb/host/ehci-hcd.c	EHCI USB host controller driver

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

`Device Drivers--->`
` USB support --->`
` [*] Support for Host-side USB`
	Enables USB host controller support

`Device Drivers--->`
` USB support --->`
`<*> EHCI HCD (USB 2.0) support`
`-*- Root Hub Transaction Translators`
`[ ] Improved Transaction Translator scheduling (EXPERIMENTAL)`
`[*] Support for Freescale on-chip EHCI USB controller`
`[*] EHCI support for PPC USB controller on OF platform bus`
`<*> OHCI HCD support`
`[*] OHCI support for PPC USB controller on OF platform bus`
`[*] Support big endian HC`
`[*] Support little endian HC`
`[*] OHCI support for PCI-bus USB controllers`
	Enables EHCI Host Controller Driver and transaction translator.

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_USB	y/m/n	y	Enables USB host controller
CONFIG_USB_EHCI_HCD	y/m/n	y	Enables EHCI HCD
CONFIG_USB_EHCI_ROOT_HUB_TT	y/n	y	Enables EHCI to support USB1.1 device

Table continues on the next page...

Table continued from the previous page...

Option	Values	Default Value	Description
CONFIG_USB_OHCI_HCD	y/m/n	y	Enables OHCI HCD

Kernel Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/usb/host/ehci-fsl.c	EHCI USB host controller driver
arch/powerpc/sysdev/fsl_soc.c	Hook between OF tree and platform device
drivers/usb/host/ohci_hcd.c	OHCI USB host controller driver

Device Tree Binding

```
usb@22000 {
 #address-cells = <1>;
 #size-cells = <0>;
 compatible = "fsl-usb2-<controller-type>-v<controller version>",
              "fsl-usb2-<controller-type>";
 reg = <0x22000 0x1000>;
 interrupt-parent = <&mpic>;
 interrupts = <28 0x2>;
 phy_type = "ulpi";                          /* ulpi/utmi/utmi_dual */
 dr_mode = "host"                             /* host, peripheral */
 };
```

NOTE

controller-type: dr(dual-role), mph(multi-port-host) controller-version: 1.6, 2.2, or earlier default mode is always host

Verification in U-Boot

U-boot environment to specify usb phy and usb mode type

```
=> setenv hwconfig 'usb<controller-no>:dr_mode=<mode>,phy_type=<phy_type>;<next usb controller>'

For example:
For socs having single usb controller and ULPI phy
```

```
=> setenv hwconfig 'usb1:dr_mode=host,phy_type=ulpi'

For socs having single usb controller and UTMI phy
=> setenv hwconfig 'usb1:dr_mode=host,phy_type=utmi'

For socs having two usb controllers and ULPI phys only
=> setenv hwconfig 'usb1:dr_mode=host,phy_type=ulpi;usb2:dr_mode=host,phy_type=ulpi'
```

Then use usb start to start the usb device

```
=> usb start

(Re)start USB...

Platform support --> CPU Frequency scaling --> [*] CPU Frequency scaling <*> CPU frequency translation statistics Default CPUFreq governor (userspace) --> -*- 'userspace' governor for userspace frequency scaling CPU Frequency drivers --> [*] Support for Freescale MPC85xx CPU freq	Enable the CPU frequency driver

Verification in Linux

Sleep Capability

A system can be put into Suspend state, and can also be Resumed (woken-up) by USB. For this the following needs to be done:

1. Enable USB remote wake-up capability before putting the system into Suspend state

```
~ # echo enabled >/sys/bus/usb/devices/usb1/power/wakeup
```

2. Insert/Remove a USB flash drive into USB port after the system is put into SUSPEND state. This will bring the system out of the SUSPEND state

```
# echo standby > /sys/power/state
PM: Syncing filesystems ... done.

Deep Sleep using USB wake-up interrupt

This feature is not yet supported.

Known Bugs, Limitations, or Technical Issues

1. Across system Deep Sleep, if a device is already mounted, it may get umounted automatically. Hence, to use it again, the user needs to re-mount the device
2. USB remote wake-up during system Deep-Sleep is not yet supported
3. On some platforms where USB2 controller is muxed with some other IP, USB2 is disabled in default platform configurations inside both U-boot and Linux. For more details, please refer Platform BSP/Board User Manuals
4. Dual-Utmi Phy HW register restoration requirement for System Deep-Sleep feature: Some SoCs have a new utmi phy version called "dual-utmi" phy (for example: T1040, T1042, T1020, T1022, T2080, T2081: rev1.0 and rev1.1). This dual-phy hw registers need to be saved and restored across system Deep-Sleep. Hence, a code is added in u-boot usb driver that identifies all socs having this dual-utmi phy, and adds "dual_utmi" in phy_type property. This is used to determine if all phy registers are to be saved (during system-suspend) and restored (during system-resume). In absence of restoration of dual-phy hw registers, system restore during deep-sleep is going to fail - system hangs and goes into non-recoverable state.

7.17.2 USB Gadget Network Driver User Manual

7.17.2.1 USB 2.0 Gadget Network Driver User Manual

Description

The NXP processor has a High speed Dual-Role(DR) USB controller, which supports device mode

Module Loading

USB device controller driver can be built in kernel or compiled as a module.

Gadget drivers are recommended to be built as modules, because parameters will be passed as module parameter

Table 196. Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers ---> USB support ---> <*> Support for Host-side USB <*> EHCI HCD (USB 2.0) support -*- Root Hub Transaction Translators [ ] Use Xilinx usb host EHCI controller core [*] Support for Freescale PPC on-chip EHCI USB controller	Need to enable CONFIG_USB_FSL_MPH_DR_OF
Device Drivers ---> USB support ---> USB Gadget Support ---> < M > Support for USB Gadgets USB Peripheral Controller (Freescale Highspeed USB DR Peripheral Controller) ---> Freescale Highspeed USB DR Peripheral Controller	Enable NXP USB Device Controller support
Device Drivers ---> USB support ---> USB Gadget Support ---> < M > Support for USB Gadgets USB Gadget Drivers <M> Ethernet Gadget (with CDC Ethernet support) [*]RNDIS support (NEW) [ ]Ethernet Emulation Model (EEM) support (NEW)	Enable USB Gadget support

Table 197. Compile-time Configuration Options

Options	Values	Default	Description
CONFIG_USB_SUPPORT	y/n/m	Ym	Enable USB Support
CONFIG_USB_FSL_MPH_DR_OF	y/n/m	Y	Enable NXP EHCI USB controller
CONFIG_USB_GADGET	y/n/m	m	Enable USB Gadget modules

CONFIG_USB_ETH	y/n/m	m	Enable Ethernet Gadget
CONFIG_USB_ETH_RNDIS	y/n	y	Enable Ethernet Gadget

Source Files

The driver source is maintained in the Linux kernel source tree.

Table 198. Source Files

Source File	Description
drivers/usb/gadget/fsl_usb2_udc.c	NXP USB peripheral controller driver
drivers/usb/host/fsl-mph-dr-of.c	Hook between OF tree and platform device
drivers/usb/gadget/ether.c	Ethernet gadget driver
Drivers/usb/gadget/rndis.[ch]	Microsoft's RNDIS support

Device Tree Entry

```
usb@22000 {

 #address-cells = <1>;
 #size-cells = <0>;
 compatible = "fsl-usb2-<controller-type>-v<controller version>",
              "fsl-usb2-<controller-type>";
 reg = <0x22000 0x1000>;    /* specifies register base addr, soc dependent */
 interrupt-parent = <&mpic>;
 interrupts = <28 0x2>;     /* specifies usb interrupt line, soc dependent */
 phy_type = "ulpi";         /* phy can be ulpi(external)/utmi(internal) */
 dr_mode = "peripheral"     /* this entry specifies usb mode */
 };
```

NOTE

Controller-type: dr(dual-role), mph(multi-port-host) controller-version: 1.6, 2.2, or earlier default mode is always host. It can be either changed to peripheral inside the dts entry like above. In this case re-compilation of dts is required. DR mode can also be changed to peripheral via u-boot command line. This won't require DTS recompilation, and can work with default DTS For USB1 controller.

```
=> setenv hwconfig 'usb1:dr_mode=peripheral,phy_type=<ulpi/utmi>
```

Test Procedure

For board specific changes (required for USB Gadget mode), please refer to the board BSP User Manual.

1. Bring all USB Gadget modules (driver/usb/gadget/*.ko including fs/configfs/configfs.ko) onto the target board.
2. Load device controller driver and test ethernet gadget

   Load FSL gadget driver module **udc-core.ko** & ***fsl_usb2_udc.ko***

   ```
   bash# insmod udc-core.ko
   bash# insmod fsl_usb2_udc.ko
   ```

   Load Ethernet modules

   ```
   bash# insmod configfs.ko
   bash# insmod libcomposite.ko
   bash# insmod u_ether.ko
   bash# insmod u_rndis.ko
   bash# insmod usb_f_rndis.ko
   bash# insmod usb_f_ecm.ko
   bash# insmod usb_f_ecm_subset.ko
   bash# insmod g_ether.ko
   using random self ethernet address
   using random host ethernet address
   usb0: HOST MAC 82:14:b4:63:d1:85
   usb0: MAC 4a:b1:59:3b:b3:bd
   using random self ethernet address
   using random host ethernet address
   g_ether gadget: Ethernet Gadget, version: Memorial Day 2008
   g_ether gadget: g_ether ready

   bash# ifconfig usb0
   usb0      Link encap:Ethernet  HWaddr 5e:0c:de:2f:f9:0f
             BROADCAST MULTICAST  MTU:1500  Metric:1
             RX packets:0 errors:0 dropped:0 overruns:0 frame:0
             TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
             collisions:0 txqueuelen:1000
             RX bytes:0 (0.0 B)  TX bytes:0 (0.0 B)
   ```

3. Assign an IP to usb0

   ```
   bash# ifconfig usb0 10.232.1.11 netmask 255.255.255.0 up
   IPv6: ADDRCONF(NETDEV_UP): usb0: link is not ready

   bash# ifconfig usb0
   ```

```
usb0      usb0      Link encap:Ethernet  HWaddr 5e:0c:de:2f:f9:0f
          inet addr:10.232.1.11  Bcast:10.232.1.255  Mask:255.255.255.0
          UP BROADCAST MULTICAST  MTU:1500  Metric:1
          RX packets:0 errors:0 dropped:0 overruns:0 frame:0
          TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:0 (0.0 B)  TX bytes:0 (0.0 B)
```

4. Connect a USB cable between target board USB port and the USB port on Windows host machine.

   As soon as USB cable is plugged into a Windows XP host, the following message displays:

```
http://embedded.seattle.intel-research.net/wiki/index.php?
title=Setting_up_USBnet#Install_the_RNDIS_Driver
```

5. Download linux.inf from either of the following, and install the Windows XP RNDIS driver as mentioned in the previous step:

```
http://www.davehylands.com/linux/gumstix/usbnet/linux.inf
http://embedded.seattle.intel-research.net/wiki/files/linux.inf
```

   For Windows 7, driver will automatically install.

6. As soon as driver installed on host, the following message displays on the target:

```
bash# g_ether gadget: high-speed config #2: RNDIS
IPv6: ADDRCONF(NETDEV_CHANGE): usb0: link becomes ready
```

7. Once the RNDIS driver is installed, configured, and loaded, configure the IP address for the new network device.

   For example, assign 10.232.1.10 as IP to the RNDIS device and run ipconfig to verify the network configuration.

8. Now run ping both ways to check the connectivity between RNDIS@Windows and usb0@linux

```
D:\Profiles>ping 10.232.1.11

Pinging 10.232.1.11 with 32 bytes of data:

```

Known Bugs, Limitations, or Technical Issues

If a board/platform is having multiple USB controller, they cannot be simultaneously used in "gadget/peripheral" mode. Please do not set dr_mode as “peripheral” for both the controllers at the same time.

Supporting Documentation

Linux USB gadget framework - http://www.linux-usb.org/gadget/

Please refer to http://embedded.seattle.intel-research.net/wiki/index.php?title=Setting_up_USBnet for setting up the RNDIS on Windows XP.

Linux USBnet @ http://www.linux-usb.org/usbnet/

7.17.3 USB 3.0 Host/Peripheral Linux Driver User Manual

7.17.3.1 USB 3.0 Host/Peripheral Linux Driver User Manual

Description

The driver supports xHCI SuperSpeed (SS) Dual-Role-Device (DRD) controller

Main features of xHCI controller

- Supports operation as a standalone USB xHCI host controller
- USB dual-role operation and can be configured as host or device
- Super-speed (5 GT/s), High-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) operations
- Supports operation as a standalone single port USB
- Supports eight programmable, bidirectional USB endpoints
- OTG (On-The-Go) 2.0 compliant, which includes both device and host capability.

Modes of Operation

- Host Mode: SS/HS/FS/LS
- Device Mode: SS/HS/FS
- OTG: HS/FS/LS

NOTE

Super-speed operation is not supported when OTG is enabled

NOTE

This document explains working of **HS Host and HS Device** in Linux

Module Loading

The default kernel configuration enables support for USB_DWC3 as built-in kernel module.

Table continued from the previous page...

Kernel Configure Tree View Options	Description
Device Drivers---> <*> DesignWare USB3 DRD Core Support DWC3 Mode Selection (Dual Role mode) --->	Enable XHCI DRD Core Support

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_USB	y/m/n	y	Enables USB host controller
CONFIG_USB_XHCI_HCD	y/m/n	y	Enables XHCI HCD
CONFIG_USB_DWC3	y/m/n	y	Enables DWC3 Controller
CONFIG_USB_GADGET	y/m/n	n	Enables USB peripheral device
CONFIG_USB_ETH	y/m/n	n	Enable Ethernet style communication
CONFIG_USB_MASS_STORAGE	m/n	n	Enable USB Mass Storage disk drive
CONFIG_SOUND	y/m/n	y	Enables Sound Card Support
CONFIG_SND	y/m/n	y	Enables ALSA (Advanced Linux Sound Architecture)
CONFIG_SND_MIXER_OSS	y/m/n	y	Enables OSS Mixer API
CONFIG_SND_PCM_OSS	y/m/n	y	Enables OSS PCM (digital audio) API
CONFIG_SND_PCM_OSS_PLUGINS	y/n	y	Enables OSS PCM (digital audio) API - Include plugin system
CONFIG_SND_SUPPORT_OLD_API	y/n	y	Enables old ALSA API
CONFIG_SND_USB	y/n	n	Enables USB sound devices
CONFIG_SND_USB_AUDIO	y/m/n	n	Enables USB Audio/MIDI driver

NOTE: USB Audio configuration options default value is listed for LS1021A platform.

Source Files

The driver source is maintained in the Linux kernel source tree in below files

Table continued from the previous page...

Source File	Description
drivers/usb/host/xhci-*	xhci platform driver
drivers/usb/gadget/mass_storage.c	USB Mass Storage
drivers/usb/gadget/ether.c	Ethernet gadget driver

Device Tree Binding for Host

```
usb@3100000 {
               compatible = "snps,dwc3";
               reg = <0x0 0x3100000 0x0 0x10000>;
               interrupts = <GIC_SPI 93 IRQ_TYPE_LEVEL_HIGH>;
              dr_mode = "host;
            };
```

Device Tree Binding for Peripheral

Note: with multiple USB controller, just one can be peripheral mode at a time.

```
usb@3100000 {
               compatible = "snps,dwc3";
               reg = <0x0 0x3100000 0x0 0x10000>;
               interrupts = <GIC_SPI 93 IRQ_TYPE_LEVEL_HIGH>;
              dr_mode = "peripheral;
               maximum-speed = "super-speed";
          };
```

Host Testing

Following are serial console logs that appear during bootup if dr_mode set to host in device-tree

```
usbcore: registered new interface driver usbfs
usbcore: registered new interface driver hub
usbcore: registered new device driver usb
xhci-hcd xhci-hcd.0.auto: xHCI Host Controller
xhci-hcd xhci-hcd.0.auto: new USB bus registered, assigned bus number 1
xhci-hcd xhci-hcd.0.auto: irq 125, io mem 0x03100000
hub 1-0:1.0: USB hub found
hub 1-0:1.0: 1 port detected
xhci-hcd xhci-hcd.0.auto: xHCI Host Controller
xhci-hcd xhci-hcd.0.auto: new USB bus registered, assigned bus number 2
hub 2-0:1.0: USB hub found
hub 2-0:1.0: 1 port detected
usbcore: registered new interface driver usb-storage
```

Following are serial-console logs after connecting a USB flash drive

```
For High-Speed Device attach

root@freescale /$
root@freescale /$
root@freescale /$
root@freescale /$ fdisk /dev/sda

The number of cylinders for this disk is set to 1946.
There is nothing wrong with that, but this is larger than 1024,
and could in certain setups cause problems with:
1) software that runs at boot time (e.g., old versions of LILO)
2) booting and partitioning software from other OSs
   (e.g., DOS FDISK, OS/2 FDISK)

Command (m for help): d
Selected partition 1

Command (m for help): n
Command action
   e   extended
   p   primary partition (1-4)
p
Partition number (1-4): 1
First cylinder (1-1946, default 1): Using default value 1
Last cylinder or +size or +sizeM or +sizeK (1-1946, default 1946): Using default value 1946

Command (m for help): w
The partition table has been alter sda: sda1
ed!
```

```
Calling ioctl() to re-read partition table

Peripheral testing with Win7 as Host

NOTE

In gadget mode standard USB cables with micro plug should be used.

Below Message will appear during bootup if dr_mode set as peripheral in device-tree

```
usbcore: registered new interface driver usbfs
usbcore: registered new interface driver hub
usbcore: registered new device driver usb

usbcore: registered new interface driver usb-storage
```

Make sure "dr_mode" contains "peripheral" string

```
root@freescale /$# cat /proc/device-tree/soc/usb\@3100000/dwc3/dr_mode
peripheral root@freescale /$
```

Move all below modeules to platform

```
fs/configfs/configfs.ko
driver/usb/gadget/libcomposite.ko
driver/usb/gadget/g_mass_storage.ko
driver/usb/gadget/u_rndis.ko
driver/usb/gadget/u_ether.ko
driver/usb/gadget/usb_f_ecm.ko
driver/usb/gadget/usb_f_ecm_subset.ko
driver/usb/gadget/usb_f_rndis.ko
driver/usb/gadget/g_ether.ko
```

Mass Storage Gadget

```
To use ramdisk as a backing store use the following

root@freescale /$ mkdir /mnt/ramdrive
root@freescale /$ mount -t tmpfs tmpfs /mnt/ramdrive -o size=600M
root@freescale /$ dd if=/dev/zero of=/mnt/ramdrive/vfat-file bs=1M count=500
root@freescale /$ mke2fs -F /mnt/ramdrive/vfat-file
root@freescale /$ insmod configfs.ko
root@freescale /$ insmod libcomposite.ko
root@freescale /$ insmod usb_f_mass_storage.ko
root@freescale /$ insmod g_mass_storage.ko file=/mnt/ramdrive/vfat-file stall=n
```

We will get below messages

```
[   39.987594] g_mass_storage gadget: Mass Storage Function, version: 2009/09/11
[   39.994822] g_mass_storage gadget: Number of LUNs=1
[   39.989240]  lun0: LUN: file: /home/backing_file_20mb
[   39.994367] g_mass_storage gadget: Mass Storage Gadget, version: 2009/09/11
[   39.990902] g_mass_storage gadget: userspace failed to provide iSerialNumber
[   39.987547] g_mass_storage gadget: g_mass_storage ready
```

Attached ***USB3.0 only*** gadget cable to host and you will get below message. Now Storage is ready to use.

```
g_mass_storage gadget: super-speed config #1: Linux File-Backed Storage
```

Speaker and Microphone

1. Aplay utility can be used to list the available sound cards e.g. Here Jabra 410 USB speaker is detected as a second sound card and can be addressed as **–D hw:1,0 OR –c1**:

```
[root@freescale ~]$ aplay -l**** List of PLAYBACK Hardware Devices ****
  card 0: FSLVF610TWRBOAR [FSL-VF610-TWR-BOARD], device 0: HiFi sgtl5000-0 [ ]
  Subdevices: 1/1
  Subdevice #0: subdevice #0
  card 1: USB [Jabra SPEAK 410 USB], device 0: USB Audio [USB Audio]  Subdevices: 1/1  Subdevice
#0: subdevice #0
```

2. Sample wav file can be played using the below command:

```
[root@freescale ~]$ aplay -D hw:1,0 LYNC_fsringing.wav
Playing WAVE 'LYNC_fsringing.wav' : Signed 16 bit Little Endian, Rate 48000 Hz, Stereo
```

3. Sample wav file can be recorded using the below command:

```
[root@freescale ~]$ arecord -f S16_LE -t wav -Dhw:1,0 -r 16000 foobar.wav -d 5
Recording WAVE 'foobar.wav' : Signed 16 bit Little Endian, Rate 16000 Hz, Mono
```

NOTE: If recorded audio is not played, try to use "-D plughw:1,0" in above command.

4. Audio controls can be checked using the below command, control details and name of the controls can be checked from output of “amixer –c1” as below:

```
[root@freescale ~]$ amixer -c1 controls
numid=3,iface=MIXER,name='PCM Playback Switch'
numid=4,iface=MIXER,name='PCM Playback Volume'
numid=5,iface=MIXER,name='Headset Capture Switch'
numid=6,iface=MIXER,name='Headset Capture Volume'
numid=2,iface=PCM,name='Capture Channel Map'
numid=1,iface=PCM,name='Playback Channel Map'

[root@freescale ~]$ amixer -c1
Simple mixer control 'PCM',0  Capabilities: pvolume pvolume-joined pswitch pswitch-joined penum
  Playback channels: Mono
  Limits: Playback 0 - 11
  Mono: Playback 4 [36%] [-20.00dB] [on]

Simple mixer control 'Headset',0  Capabilities: cvolume cvolume-joined cswitch cswitch-joined
penum
  Capture channels: Mono
  Limits: Capture 0 - 7
  Mono: Capture 5 [71%] [0.00dB] [on]
```

For Example, in above output there are two controls named “PCM” and “Headset” for Speaker and microphone respectively.

Sample Audio controls Usage:

a. mute/unmute

```
[root@freescale ~]$ amixer -c1 set PCM  mute
Simple mixer control 'PCM',0
  Capabilities: pvolume pvolume-joined pswitch pswitch-joined
  Playback channels: Mono
  Limits: Playback 0 - 11
  Mono: Playback 2 [18%] [-28.00dB] [off]
[root@freescale ~]$ amixer -c1 set PCM  unmute
Simple mixer control 'PCM',0
  Capabilities: pvolume pvolume-joined pswitch pswitch-joined
  Playback channels: Mono
  Limits: Playback 0 - 11
  Mono: Playback 2 [18%] [-28.00dB] [on]
```

b. volume up/down – Below commands are trying to set volume to 11 and 2 performing volume up and down respectively.

```
root@freescale ~]$ amixer -c1 set PCM 11
Simple mixer control 'PCM',0
Capabilities: pvolume pvolume-joined pswitch pswitch-joined
Playback channels: Mono
Limits: Playback 0 - 11
Mono: Playback 11 [100%] [8.00dB] [on]
[root@freescale ~]$ amixer -c1 set PCM 2
Simple mixer control 'PCM',0
Capabilities: pvolume pvolume-joined pswitch pswitch-joined
Playback channels: Mono
Limits: Playback 0 - 11
Mono: Playback 2 [18%] [-28.00dB] [on]
```

Ethernet Gadget

```
To use Ethernet gadget use the following

root@freescale /$ insmod configfs.ko
root@freescale /$ insmod libcomposite.ko
root@freescale /$ insmod u_ether.ko
root@freescale /$ insmod u_rndis.ko
root@freescale /$ insmod usb_f_ecm.ko
root@freescale /$ insmod usb_f_ecm_subset.ko
root@freescale /$ insmod usb_f_rndis.ko
root@freescale /$ insmod g_ether.ko
```

We will get below messages

```
[   28.692611] using random self ethernet address
[   28.697156] using random host ethernet address
[   28.694271] usb0: HOST MAC 82:96:69:7e:a5:7d
[   28.698928] usb0: MAC 72:00:a5:80:2b:e8
[   28.692586] using random self ethernet address
[   28.697080] using random host ethernet address
[   28.691368] g_ether gadget: Ethernet Gadget, version: Memorial Day 2008
[   28.698028] g_ether gadget: g_ether ready
```

Make sure USB0 ethernet interface is available after this

```
root@freescale /$ ifconfig -a

```

Known Bugs, Limitations, or Technical Issues

- Some issue with Pen drives from Kingston/Transcend. This have noticed some patches floating in open-source for these issues, and also found that open-source USB community trying to fix.
- Linux allow only one peripheral at one time. Please make sure When DWC3 set as Peripheral the other should not be set in same mode.
- Erratum:A-009116 (Frame length of USB3 controller for USB2.0 and USB3.0 operation is incorrect) impacts some socs like LS1020A/LS1021A because of which some USB2.0 and USB3.0 devices may not work properly, and hence, a sw workaround is needed. This sw workaround involves programing following registers of XHCI controller as: GFLADJ[5:0] = 20H and GFLADJ[7] = 1. This is already done via u-boot and linux codebase.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers ---> [*] Watchdog Timer Support ---> [*] Disable watchdog shutdown on close [*] PowerPC Book-E Watchdog Timer	PowerPC Book-E Watchdog Timer

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_BOOKE_WDT	y/n	y	PowerPC Book-E Watchdog Timer

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/char/watchdog/booke_wdt.c	PowerPC Book-E Watchdog Timer

User Space Application

The following applications will be used during functional or performance testing. Please refer to the SDK UM document for the detailed build procedure.

Command Name	Description	Package Name
watch	watchdog is a daemon for watchdog feeding	watchdog

Verification in Linux

- Set NFS rootfs. Build a rootfs image which includes watchdog daemon.
- Set boot parameter. On the U-Boot prompt, set following parameter:

  Set nfsargs:

```
setenv bootargs wdt_period=35 root=/dev/nfs rw nfsroot=$serverip:$rootpath ip=$ipaddr:$serverip:
$gatewayip:$netmask:$hostname:$netdev:off
console=$consoledev,$baudrate $othbootargs
```

  Set nfsboot

```
run nfsargs;tftp $loadaddr $bootfile;tftp $fdtaddr $fdtfile;bootm $loadaddr - $fdtaddr
run nfsboot
```

NOTE

`wdt_period` is a watchdog timeout period. Set this parameter with the proper value depending on your board bus frequency.

`wdt_period` is inversely proportional to watchdog expiry time ie. the higher the `wdt_period`, the lower the watchdog expiry time. So if `wdt_period` is increased to high, watchdog will expiry early.

- Check watchdog feeding operation. After the system boots up, check the screen output, if you see:

```
...

PowerPC Book-E Watchdog Timer Enabled (wdt_period=35)

...
```

it means the watchdog module loaded successfully.

- Login in system. Run command `watchdog /dev/watchdog`

```
root@p1020rdb:~# watchdog /dev/watchdog
root@p1020rdb:~# ps -ae | grep watchdog
 3285 ?        00:00:00 watchdog
root@p1020rdb:~#
```

Wait a few minutes. If the system is still alive, watchdog feeding is OK.

- Check watchdog reboot operation. Run command `killall`

```
root@p1020rdb:~# killall -9 watchdog
root@p1020rdb:~#
root@p1020rdb:~# ps -ae | grep watchdog
root@p1020rdb:~#
root@p1020rdb:~# PowerPC Book-E Watchdog Exception
```

Wait for a few seconds. If the system reboots, watchdog reboot operation is OK.

Known Bugs, Limitations, or Technical Issues

On T4240RDB, if you use watchdog, disable the following menu configuration in kernel location. Otherwise these will conflict with each other:

```
|--> Device
Drivers
                |--> Hardware Monitoring support (HWMON [=n])
```

7.18.2 Watchdog Device Driver (LS1012A)

Module Loading

Watchdog device driver support kernel built-in mode.

Kernel Configure Tree View Options

Tree View

Below are the configure options which needs to be set while doing "make menuconfig" for kernel

Kernel Configure Tree view options	Description
`Processor Support ->` `[*] SPE Support`	Enables SPE so that user processes can execute SPE instructions.

Table continues on the next page...

Table continued from the previous page...

Kernel Configure Tree view options	Description
Kernel options -> [*] Math Emulation	Enables Math Emulation

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Value	Default value in BSP	Description
CONFIG_85xx	y/n	y	Dependency: MPC85xx silicon family support SPE
CONFIG_SPE	y/n	y	Enables SPE support
CONFIG_MATH_EMULATION	y/n	y	Enables Math Emulation

Device Tree Binding

N/A

Source Files

The driver source is maintained in the Linux kernel source tree.

Source file	Purpose
arch/powerpc/math-emu/math_efp.c	The emulation of SPE Floating point instructions

User Space Application

Please select the following package for testing floating point. Please refer to the SDK UM document for the detailed build procedure.

Command Name	Description	Package Name
testfloat	Testfloat is a program for testing that an implementation of floating point conforms to standards	testfloat

Verification in U-Boot

N/A

Verification in Linux

1. run command "testfloat", you can get the usage

```
[root@P2020RDB /root]# testfloat
testfloat [<option>...] <function>
    <option>:  (* is default)
```

```
-help            --Write this message and exit.

-list            --List all testable functions and exit.

-level <num>     --Testing level <num> (1 or 2).

*  -level 1

-errors <num>    --Stop each function test after <num> errors.

    *  -errors 20

    -errorstop       --Exit after first function with any error.

    -forever         --Test one function repeatedly (implies `-level 2').

    -checkNaNs       --Check for bitwise correctness of NaN results.

    -nearesteven     --Only test rounding to nearest/even.

    -tozero          --Only test rounding to zero.

    -down            --Only test rounding down.

    -up              --Only test rounding up.

    -tininessbefore  --Underflow tininess detected before rounding.

    -tininessafter   --Underflow tininess detected after rounding.

    <function>:

    int32_to_<float>                <float>_add   <float>_eq

    <float>_to_int32                <float>_sub   <float>_le

      <float>_to_int32_round_to_zero   <float>_mul   <float>_lt

      <float>_to_<float>               <float>_div   <float>_eq_signaling

      <float>_round_to_int             <float>_rem   <float>_le_quiet

      <float>_sqrt                                   <float>_lt_quiet

        -all1            --All 1-operand functions.

        -all2            --All 2-operand functions.

        -all             --All functions.

        <float>:

        float32          --Single precision.

        float64          --Double precision.
```

2. run command "testfloat -all" to perform an overall test.

Benchmarking

N/A

Known Bugs, Limitations, or Technical Issues

1. So far, TestFloat has never reported any data error. All the errors it reports concern to exception flags.
2. The exception flags errors TestFloat reports below are harmless.

   Errors that are only produced in either of these cases:

   - option "-tininessaffter" is enable or option "-tininessbefore" is disable.
   - option "-tininessbefore" is enable

   These two options decide checking underflow before or after rounding.

   The standard allows the vendor of the floating-point system to choose whether an underflow condition is detected before or after rounding.

   ```
   float32_le (float le) errors, float32_lt (float lt) errors, float64_le (double le) errors,
   float64_lt (double lt) errors
   ```

   IEEE 754 defines that Arithmetic operations upon NaNs other than SNaNs never signal INVALID.

   ```
   float32_to_int32_round_to_zero (float to int round zero), float64_to_int32_round_to_zero (double to
   int round zero)
   ```

   IEEE 754 defines that conversion from floating-point to other formats can be INVALID too, if their limits are violated, even if no NaN can be delivered.

Chapter 8
Additional Linux Use Cases

8.1 Application Specific Fastpath (ASF) User Manual

8.1.1 Description

8.1.1.1 Overview

ASF is a 'C' programmable software based fast-path in Linux Kernel, supporting data path acceleration seamlessly with Linux Kernel Networking Stack on the NXP family of processors.

ASF implementation is compiled as Kernel dynamic loadable modules that can be plugged in to Linux stack at run time. Once plugged into Linux stack, packets are snooped from the Linux network device driver (currently Ethernet) to the ASF data path module.

ASF targets the most common data applications.

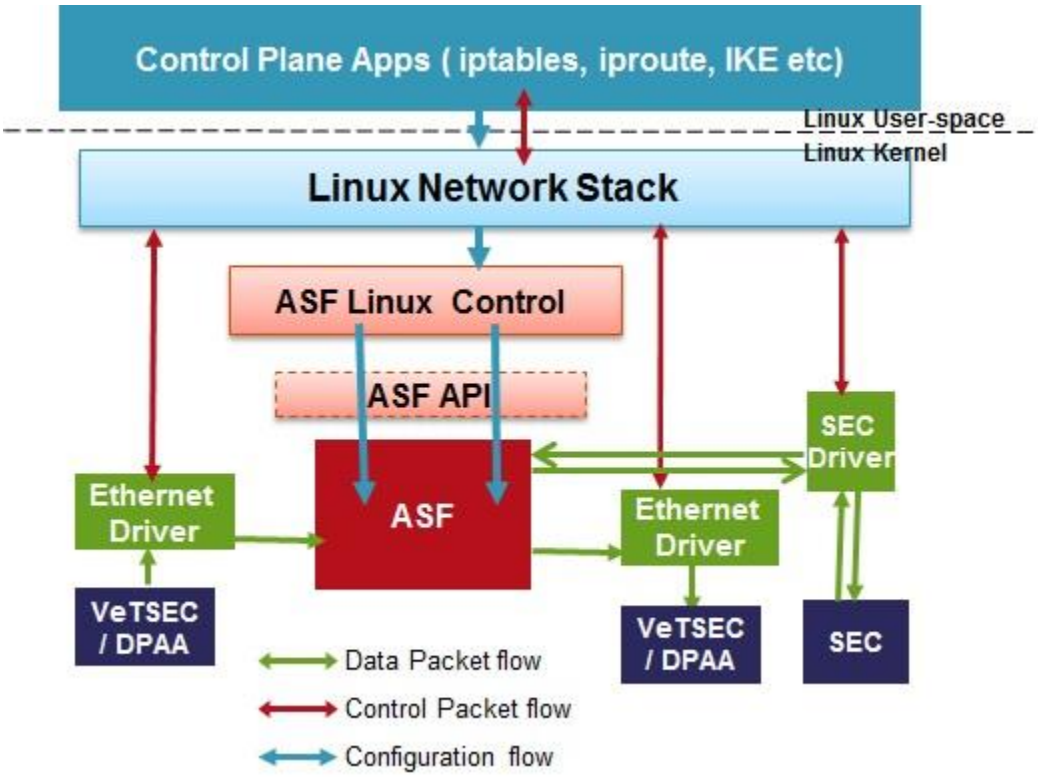

Figure 180. ASF high level view

8.1.1.2 Key Target Applications

ASF is used for accelerating throughput for

1. IPv4 Firewall and NAT/NAPT Forwarding
2. IPv6 Firewall Forwarding

3. IPv4 & IPv6 IPSec (ESP & AH) Forwarding

8.1.1.3 ASF Diagram

ASF integrates with the various network control modules of Linux to extract information for data processing. Figure below identifies how the ASF module fits in the overall system in typical network processor software architecture.

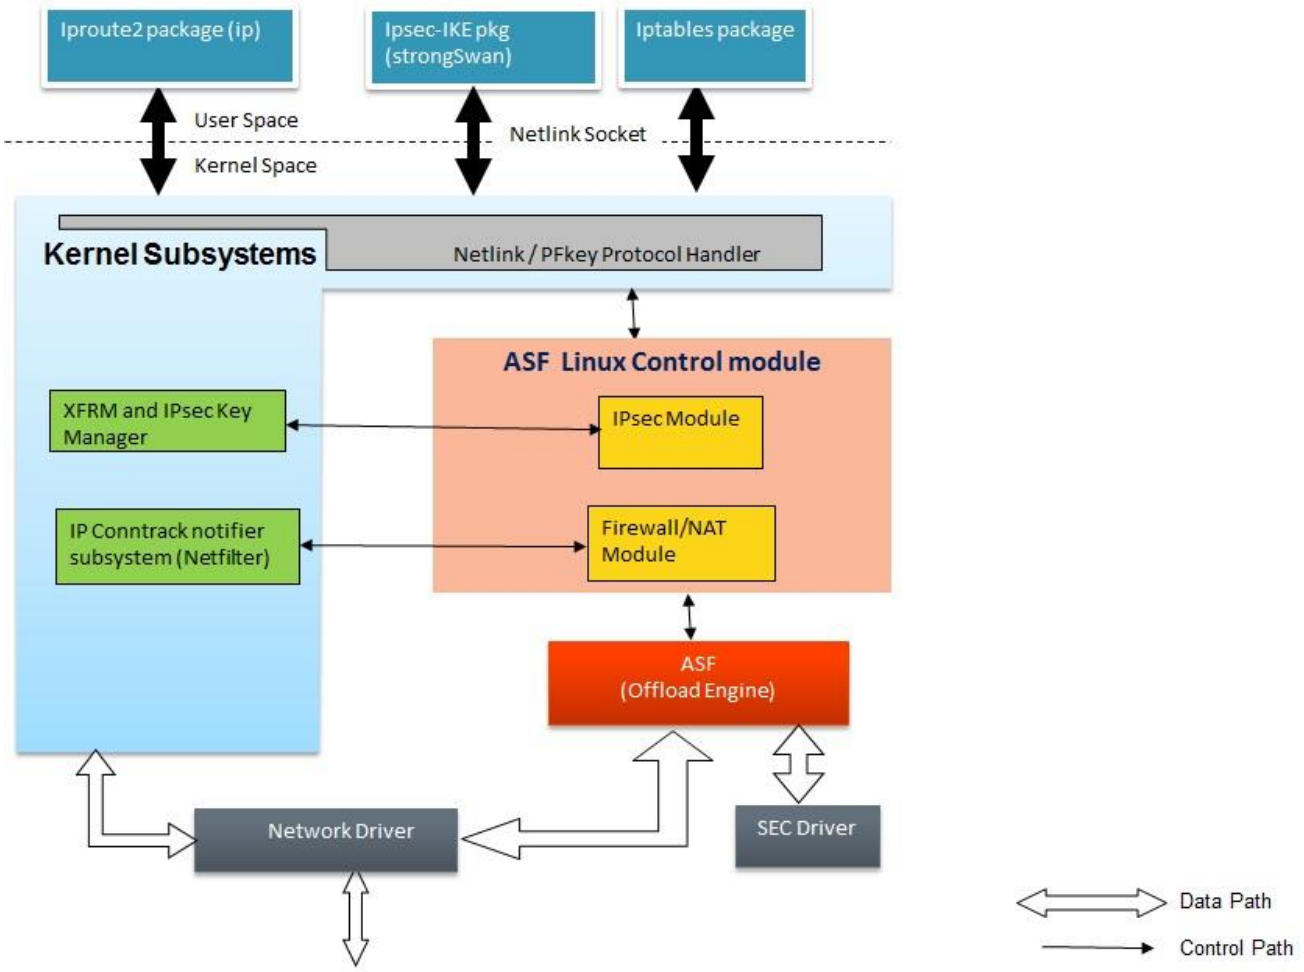

Figure 181. ASF Software Architecture

8.1.1.4 Features

As a part of delivery user will receive ASF as part of Yocto source release.

Following features are supported in this release

Table 199. Features

Feature	Detailed Description
IPv4 Firewall Forwarding	IPv4 packet forwarding for UDP and TCP packets. Firewall support only based on 5-tuple information.

Table continues on the next page...

Table 199. Features (continued)

Feature	Detailed Description
IPv6 Firewall Forwarding	IPv6 packet forwarding for UDP and TCP packets. Firewall support only based on 5-tuple information.
NAT	NAT for TCP and UDP packets
IPsec	ESP & AH in Tunnel mode
Fragmentation	Fragmentation and Re-assembly for NAT, IPsec
IKEv1 and IKEv2 Support	Dynamic key Exchange for IPsec in forwarding
VLAN	Forwarding between VLAN and non-VLAN interfaces.

8.1.1.5 Specifications

Compliance with Standards

1. RFC 791 - Internet Protocol
2. RFC2460 - Internet Protocol version 6
3. RFC 793 - Transmission Control Protocol
4. RFC 768 - UDP
5. RFC2406 - IPsec ESP
6. RFC4302 - IPsec AH
7. RFC2409 - Internet Key Exchange
8. RFC3022 - Traditional IP NAT

Limitations

1. ASF firewall/NAT support only for TCP and UDP packets.
2. Firewalling supported based on 5-tuple information i.e. Source IP, Destination IP, Source Port, Destination Port and Protocol.
3. IPsec ESP & AH supported in Tunnel mode only.
4. ASF impacts performance for data traffic not handled by ASF.
5. IEEE 1588 PTP feature will not work when “RX and TX ring buffer exchange for Routed packet” is enabled. This is valid only for non-DPAA boards.
6. To test the Jumbo frames please enable the CONFIG_FSL_DPAA_ETH_JUMBO_FRAME from kernel configuration and also increase the L2 maximum frame size to 9600 (either set CONFIG_FSL_FM_MAX_FRAME_SIZE from menuconfig or set the fsl_fm_max_frm bootarg). This option is available on DPAA based platforms.
7. ASF does not support handling of NR_FRAGS and system behavior is not known.
8. ASF is not integrated with Linux QoS/TC framework.
9. ASF only work for eTSEC or DPAA based Ethernet ports.

Platforms Supported

- T1040D4RDB

- P4080DS
- LS1021ATWR

8.1.2 Execution

8.1.2.1 Getting started

8.1.2.1.1 Installing the SDK

Refer SDK Documentation provided with this release for installing and using Yocto for image compilation and building.

8.1.2.1.2 Compiling Linux

Execute below command for a particular board

```
#> source ./poky/fsl-setup-poky -m <board-type> -j 12 -t 12
```

NOTE

Board type can be chosen for 32/64 bit architecture. Yocto can build images for both 32/64 bit architecture systems.

Supported QorIQ(powerpc) machines: p4080ds p4080ds-64b t1040d4rdb-64b t1040d4rdb ls1021atwr

```
#>bitbake -c menuconfig virtual/kernel

From “make menuconfig”
Select:
Application Specific FastPath ( Disabled by Default )
  |   Location:
  |     -> Device Drivers

Please change CONFIG_FSL_DPAA_ETH_MAX_BUF_COUNT to 512. Location of this variable is
Device Drivers -> Ethernet Driver Support -> Freescale Devices -> DPAA Ethernet ->
FSL_DPAA_ETH_MAX_BUF_COUNT
```

Execute Command to generate RFS with ASF .kos

```
#>bitbake fsl-image-core
```

ASF .ko’s will be copied to “/usr/driver/asf/min/” and “/usr/driver/asf/full/”. IPsec and FMC (for DPAA) scripts will be copied to /usr/driver/asf/scripts. In case a modified asf module is required, it can be TFTP to the board dynamically. Sections below describe how to use these dynamic loadable modules.

Boot Arguments

The following bootargs need to be configured at the U-Boot prompt.

DPAA

```
#setenv bootargs "root=/dev/ram rw rootdelay=5 console=ttyS0,115200 ramdisk_size=70000000"
```

Non-DPAA

```
#setenv bootargs "root=/dev/ram rw rootdelay=5 console=ttyS0,115200 ramdisk_size=70000000 nousb"
```

8.1.2.1.3 Booting the board

Once the build completes you will get the following directory/image files:

- **build_<bsp>_release** - project folder.
- **tmp/deploy/images/** - subdirectory with images.
- **uImage-<bsp>.bin** - kernel image that can be loaded with U-Boot
- **fsl-image-core-<bsp>.ext2.gz.u-boot** - ramdisk image that can be loaded with U-Boot.
- **u-boot-<bsp>.bin** - U-Boot binary image that can be programmed into board Flash.
- **uImage-<bsp>.dtb** - device tree binary (dtb) for kernel boot up.

The ASF related kernel modules will be placed in the /lib/modules/${KERNEL_VERSION}/asf directory in the root file system.

Once the images have been built, load the images on board:

- Store fsl-image-core-<bsp>.ext2.gz.u-boot, uImage-<bsp>.bin and uImage-<bsp>.dtb on the tftp server
- Connect board's eth0 interface to tftp server.
- Configure the board IP and tftp server IP on the u-boot environment using following commands

```
      #> setenv ipaddr <board ip >
      #> setenv serverip <tftp server ip >
      #> save
```

- Execute the following commands at u-boot prompt to boot the board with ASF specific pre-compiled images

```
For 32b images
      #> tftp 1000000 uImage-<bsp>.bin
      #> tftp 2000000 fsl-image-core-<bsp>.ext2.gz.uboot
      #> tftp c00000 uImage-<bsp>.dtb
      #> bootm 1000000 2000000 c00000

For 64b images
      #> tftp 10000000 uImage-<bsp>.bin
      #> tftp 20000000 fsl-image-core-<bsp>.ext2.gz.uboot
      #> tftp 30000000 uImage-<bsp>.dtb
      #> bootm 10000000 20000000 30000000
```

- Once the Linux Image boots, enter username=**root** and password=**root** to logon.

Next sections describes the setup and board configuration example to run ASF in the mode supported.

8.1.2.2 Firewall Forwarding

8.1.2.2.1 Firewall Forward Hardware Setup

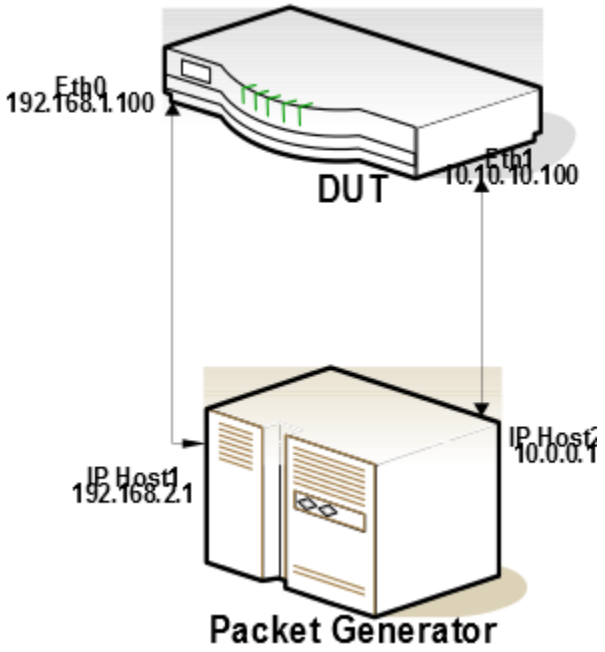

Figure 182. IPv4 Diagram

•Note : For DPAA interface name convention is different for example it will be of the kind “fm1-gb1”.

8.1.2.2.2 Software instructions

Configuration at the DUT

- Configure Ethernet address for eth0 and eth1

```
* IPv4
#>ifconfig eth0 192.168.1.100 netmask 255.255.0.0 up
#>ifconfig eth1 10.10.10.100 netmask 255.0.0.0 up

* IPv6
#> ip -6 addr add 2001::1/64 dev eth0
#> ip -6 addr add 2000::1/64 dev eth1
```

NOTE

For DPAA interface name convention is different for example it will be of the kind “fm1-gb1

- Enable routing at the DUT

```
#> echo 1 > /proc/sys/net/ipv4/ip_forward
#> echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

- Load ASF modules

```
#> insmod asf.ko
#> insmod asfctrl.ko
```

- Increase number of conntrack entries in Linux for measuring performance for 128K flows

```
#> echo 140000 > /proc/sys/net/nf_conntrack_max
```

- Change the default UDP timeout to 9000 seconds. (for performance testing)

```
#> echo 9000 > /sys/asfctrl/ffp/asfctrl_ffp_udp_tmout
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout_stream
```

Execute commands for non-DPAA platforms only

- Set the coalescing parameters

```
#> ethtool -C eth0 rx-frames 12 rx-usecs 32
#> ethtool -C eth1 rx-frames 12 rx-usecs 32
```

- Disable PTP

```
#> echo 0 > /sys/class/net/eth0/ptp_1588
#> echo 0 > /sys/class/net/eth1/ptp_1588
```

- Set the coalescing parameters for LS1021A TWR

```
#> ethtool -C eth0 rx-frames 22 rx-usecs 32
#> ethtool -C eth1 rx-frames 22 rx-usecs 32
```

- Set affinities on LS1021ATWR boards:

```
#> echo 2 > /proc/irq/182/smp_affinity ( eth1 TX interrupt )
#> echo 2 > /proc/irq/177/smp_affinity ( eth0 RX interrupt )
#> echo 1 > /proc/irq/176/smp_affinity ( eth0 TX interrupt )
#> echo 1 > /proc/irq/184/smp_affinity ( eth1 RX interrupt )
```

Execute commands for DPAA platforms only

- Execute fmc command for packet distribution

```
#> fmc –s Soft_FragParser.xml –p <policy file> –c <configuration file> –a

•Policy file for “performance” and “functionality” for DPAA boards are as below
1.“asf-fman-perf-policy.xml ” => performance policy file for P4080, T1040D4RDB boards.
2.“asf-fman-func-policy.xml” => functionality policy file for P4080, T1040D4RDB boards.

•Configuration files for “performance” and “functionality” for various DPAA boards are as below
1."asf-cfg-4080-20g.xml” => for P4080, 2X10G ports enabled
2.“asf-cfg-4080-5g.xml” => for P4080, 5X1g ports enabled
3.“asf-cfg-func-1040.xml” => for T1040D4RDB functionality testing
4.“asf-cfg-perf-1040.xml” => for T1040D4RDB performance testing

To test functionality, use only two port (ports which are functioning on the board) entries in
this file.

NOTE:
-Scripts used above are copies at /usr/lib/asf/scripts/fmc in the rootfs built with ASF enabled.
-Please make sure all the fm interfaces are up that are mentioned in the scripts. In case some
fm interface need to be put down then script shall be modified to remove that port from script.
-Once executed, fmc configuration cannot be reverted back, system need to be restarted.
```

NOTE: Disable the network interface that are not used while taking the performance numbers.

•Configuration IPv4 Flows on Traffic Generator

- Create hosts on the traffic generator Ports connected to DUTs eth1 and eth2 with IP Addresses 192.168.2.1 and 10.0.0.1 respectively.
- Create Routes at the Host

```
#> route add -net 192.169.0.0/16 gw 192.168.2.1
#> route add -net 11.0.0.0/8 gw 10.0.0.1
```

- From Host 1 connected to eth1, create flows for IP/UDP traffic with

```
* Source IP      192.169.1.1  to 192.169.X.X ( as per number of flows)
* Destination IP 11.11.1.1  to   11.11.X.X ( as per number of flows)
```

- From Host 2 connected to eth2, create flows for IP/UDP traffic with

```
* Source IP           11.11.1.1    to  11.11.X.X ( as per number of flows)
* Destination IP  192.169.1.1  to 192.169.X.X (  as per number of flows)
```

- Start the sending traffic from Packet Generator from both Host1 and Host2.
- Verify that packet send from Host1 are received at Host2 and vice-versa and take the Performance numbers.
- Configuration for IPv6 Flows on Traffic Generator

```
•Create hosts on the traffic generator ports connected to DUTs eth0 and eth1 with IP addresses
2001::1/64 and 2000::1/64 respectively.

•From Host 1 connected to eth0, create flows for IP/UDP traffic with
    * Source IP      2001::2 to 2001::x ( as per number of flows)
    * Destination IP 2000::2 to 2000::x ( as per number of flows)

•From Host 2 connected to eth1, create flows for IP/UDP traffic with
    * Source IP           2000::2    to  2000::X ( as per number of flows)
    * Destination IP    2001::2  to 2001::X (  as per number of flows)
```

- Start the sending traffic from Packet Generator from both Host1 and Host2. Verify that packet send from Host1 are received at Host2 and vice-versa and take the Performance numbers.

8.1.2.3 Nat mode

8.1.2.3.1 NAT Hardware instructions

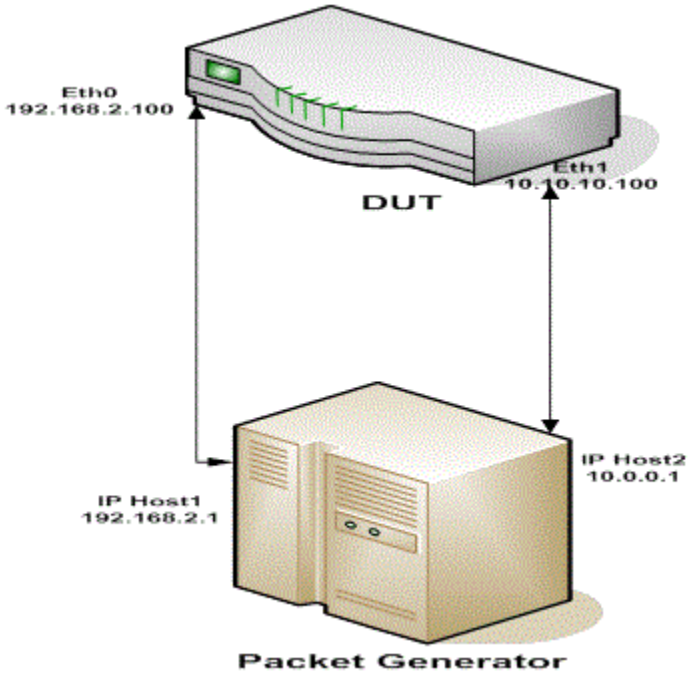

Figure 183. NAT Diagram

8.1.2.3.2 IPv4 NAT Software instructions

Configuration at the DUT

- Configure Ethernet address for eth0 and eth1

```
#> ifconfig eth0 192.168.2.100 netmask 255.255.0.0 up
#> ifconfig eth1 10.10.10.100 netmask 255.0.0.0 up
```

- Enable routing at the DUT

```
#> echo 1 > /proc/sys/net/ipv4/ip_forward
```

- Load ASF modules in IPv4 mode

```
#> insmod asf.ko
#> insmod asfctrl.ko
```

- Enable masquerading at eth1, so that NATing is done on packets going out of eth1 interface

```
#> iptables -t nat -A POSTROUTING -o eth1 -j MASQUERADE

NOTE: By default  below rule should be applied while testing NAT/Firewall
iptables -A OUTPUT -p 0x72 -j ACCEPT    /* HERE 0x72 is ASFCTRL_IPPROTO_DUMMY_TERM_L2BLOB */
```

- Increase number of conntrack entries in Linux for measuring performance for 128K flows

```
#> echo 140090 > /proc/sys/net/nf_conntrack_max
```

- Change the default UDP timeout to 9000 seconds. (*for performance testing*)

```
#> echo 9000 > /sys/asfctrl/ffp/asfctrl_ffp_udp_tmout
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout
#> echo 9000 >/proc/sys/net/netfilter/nf_conntrack_udp_timeout_stream
```

Execute commands for non-DPAA platforms only

- Set the coalescing parameters

```
#> ethtool -C eth0 rx-frames 12 rx-usecs 32
#> ethtool -C eth1 rx-frames 12 rx-usecs 32
```

- Disable PTP

```
#> echo 0 > /sys/class/net/eth0/ptp_1588
#> echo 0 > /sys/class/net/eth1/ptp_1588
```

- Set affinities on LS1021ATWR boards:

```
#> echo 2 > /proc/irq/182/smp_affinity ( eth1 TX interrupt )
#> echo 2 > /proc/irq/177/smp_affinity ( eth0 RX interrupt )
#> echo 1 > /proc/irq/176/smp_affinity ( eth0 TX interrupt )
#> echo 1 > /proc/irq/184/smp_affinity ( eth1 RX interrupt )
```

Execute commands for DPAA platforms only

- Execute fmc command for packet distribution

```
#> fmc –s Soft_FragParser.xml –p <policy file> –c <configuration file> –a

    •Policy file for “performance” and “functionality” for DPAA boards are as below
    1.“asf-fman-perf-policy.xml” => performance policy file for P4080, T1040D4RDBboards.
    2.“asf-fman-func-policy.xml” => functionality policy file for P4080, T1040D4RDB boards.

    •Configuration files for “performance” and “functionality” for various DPAA boards are as
below
    1."asf-cfg-4080-20g.xml” => for P4080, 2X10G ports enabled
    2.“asf-cfg-4080-5g.xml” => for P4080, 5X1g ports enabled
    3.“asf-cfg-func-1040.xml” => for T1040D4RDB  functionality testing
    4.“asf-cfg-perf-1040.xml” => for T1040D4RDB performance testing

 To test functionality, use only two port (ports which are functioning on the board) entries in
this file.

    NOTE:
    - Scripts used above are copies at /usr/lib/asf/scripts/fmc in the rootfs built with ASF
enabled.
    - Please make sure all the fm interfaces are up that are mentioned in the scripts. In case
some fm interface need to be put down then script shall be modified to remove that port from
script.
    - Once executed, fmc configuration cannot be reverted back, system need to be restarted.
```

- *NOTE: Disable the network interface that are not used while taking the performance numbers.*

Configuration at the Packet Generator

- Create hosts on the traffic generator Ports connected to DUT eth0 and eth1.

- From Host 1 connected to eth0, create flow for UDP traffic with

```
* Source IP as 192.168.2.1.
* Destination IP as 10.0.0.1
* Configure flows with UDP Source Port as (10000 + X) where X takes the value form 1…N and N is
the number of flows. The UDP destination Port as 10000.
```

- From Host 2 connected to eth1, create flows for IP traffic with

```
* Source IP as 10.0.0.1.
* Destination IP as 10.10.10.100
* Configure flows with UDP Source Port as 10000 and UDP destination Port as (10000 + X) where X
takes the value form 1…N and N is the number of flows.
```

•Start the sending traffic from Packet Generator from Host1 and Host2 and then Host2 to Host1.

- Verify that packet send from Host1 are received at Host2, with

```
* Source IP as 10.10.10.100.
* Destination IP as 10.0.0.1
* UDP Source Port as (10000 + X) where X takes the value form 1…N and N is the number of flows.
* UDP destination Port as 10000.
```

- Verify that packets sent from Host2 are received at Host 1, with

```
* Source IP as 10.0.0.1.
* Destination IP as 192.168.2.1.
* UDP source Port as 10000
* UDP Destination Port as (10000 + X) where X takes the value form 1…N and N is the number of
flows.
```

- Start the sending traffic from Packet Generator from Host1 and Host2 and then Host2 to Host1.
- Verify that packet send from Host1 are received at Host2, with

```
•Source IP as 10.10.10.100.
•Destination IP as 10.0.0.1
•UDP Source Port as (10000 + X) where X takes the value form 1…N and N is the number of flows.
•UDP destination Port as 10000.
```

- Verify that packets sent from Host2 are received at Host1, with

```
•Source IP as 10.0.0.1.
•Destination IP as 192.168.2.1.
•UDP source Port as 10000
•UDP Destination Port as (10000 + X) where X takes the value form 1…N and N is the number of
flows.
```

Optional Configurations at the DUT

ASF has exported following SYSFS configuration which can be used to configure the system. The SYSFS interface and their default values are shown as below.

Table 200. NAT SYSFS interface and default values

Commands	Description	Mode	Default Value
/sys/asfctrl/ffp/asfctrl_ffp_activity_divisor	The divisor value for the activity refresh interval.	Read/Write	4
/sys/asfctrl/ffp/asfctrl_ffp_tcp_state_check	Enable/Disable the TCP state check for the new flows.	Read/Write	1
/sys/asfctrl/ffp/asfctrl_ffp_tcp_tm_stmp_check	Enable/Disable the TCP timestamp check for the new flows.	Read/Write	1
/sys/asfctrl/ffp/asfctrl_ffp_tcp_tmout	TCP idle flow timeout.	Read/Write	432000
/sys/asfctrl/ffp/asfctrl_ffp_udp_tmout	UDP idle flow timeout.	Read/Write	180

Also, while loading the ASF Forwarding module we can configure the following module parameters as follows.

Table 201. Module Parameters

Module parameter	Description	Mode	Default Value
/sys/module/asf/parameters/asf_enable	Enable/Disable the ASF	Read/Write	Y (Enable)
/sys/module/asf/parameters/asf_l2blob_refresh_interval	Time period (in sec) for layer 2 header refresh for the flows	Read/Write	180
/sys/module/asf/parameters/asf_max_ifaces	Maximum no. of network interface supported by ASF.	Read	16
/sys/module/asf/parameters/asf_max_vsgs	Maximum no. of VSG interface supported by ASF	Read	2
/sys/module/asf/parameters/asf_reasm_hash_list_size	Hash list size used by reassembly functionality.	Read	256
/sys/module/asf/parameters/asf_reasm_num_cbs		Read	1024

Table continues on the next page...

Table 201. Module Parameters (continued)

Module parameter	Description	Mode	Default Value
/sys/module/asf/parameters/asf_tcp_drop_oos	TCP out of sequence drop.	Read/Write	N
/sys/module/asf/parameters/ffp_hash_buckets	Flow hash bucket size	Read	8192
/sys/module/asf/parameters/ffp_max_flows	Max no. of flows supported by ASF.	Read	131072

NOTE

All the module parameters can be used at module insert time as described below. The read only parameters can only be configured during the module install time and the read/write module parameters can be changed at runtime.

```
#> insmod asf.ko  <MODULE_PARAMETER>=<VALUE>
```

8.1.2.4 IPSec mode

8.1.2.4.1 IPSec Hardware instructions

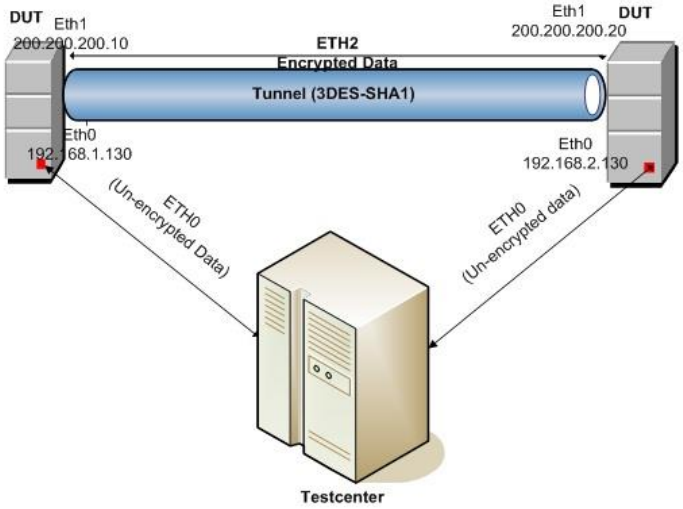

Figure 184. IPSec Diagram

8.1.2.4.2 IPSec Software instructions

IPv4 Configuration at Both the DUT Platforms

- At DUT1 run following script to verify normal IP forwarding

```
#>./setup_left
```

- At DUT2 run following script to verify normal IP forwarding

```
#>./setup_right
```

IPv6 Configuration at Both the DUT Platforms

- At DUT1 run following script to verify normal IP forwarding

```
#>./setup6_left
```

- At DUT2 run following script to verify normal IP forwarding

```
#>./setup6_right
```

After executing these scripts verify that DUT1 is able to ping Ref Board.

NOTE

For DPAA platforms, update the scripts with proper interface names like fm1-gb1.

- Bring the board up and load ASF modules

```
#> insmod asf.ko
#> insmod asfctrl.ko
#> insmod asfipsec.ko
#> insmod asfctrl_ipsec.ko
```

- Change the default UDP timeout to 9000 (for performance testing)

```
#> echo 9000 > /sys/asfctrl/ffp/asfctrl_ffp_udp_tmout
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout_stream
```

- Disable xfrm_larval_drop

```
#> echo 0 > /proc/sys/net/core/xfrm_larval_drop
```

Execute commands for non-DPAA platforms only

- Set the coalescing parameters

```
#> ethtool -C eth0 rx-frames 22 rx-usecs 32
#> ethtool -C eth1 rx-frames 22 rx-usecs 32
```

- On LS1021ATWR board configure Rx and Tx BD ring sizes

```
#> ethtool -G eth0 rx 128 tx 128
#> ethtool -G eth1 rx 128 tx 128
```

- Set affinities on LS1021ATWR boards:

```
#> echo 2 > /proc/irq/182/smp_affinity ( eth1 TX interrupt )
#> echo 2 > /proc/irq/177/smp_affinity ( eth0 RX interrupt )
#> echo 1 > /proc/irq/176/smp_affinity ( eth0 TX interrupt )
#> echo 1 > /proc/irq/184/smp_affinity ( eth1 RX interrupt )
#> echo 1 > /proc/irq/135/smp_affinity ( CAAM (sec_hw) interrupt )
#> echo 1 > /proc/irq/136/smp_affinity ( CAAM (sec_hw) interrupt )
#> echo 2 > /proc/irq/137/smp_affinity ( CAAM (sec_hw) interrupt )
#> echo 2 > /proc/irq/138/smp_affinity ( CAAM (sec_hw) interrupt )
```

Note: In the above command, the interrupt affinities for RX and Talitos interrupts are configured for the optimal performance.

- *1) For single flow scenarios : eth RX and talitos interrupt shall be affined to different cores.*
- *2) For 2 opposite flows scenario : eth RX and talitos interrupt shall be affined to same cores.*

Execute commands for DPAA platforms only

- Execute fmc command for packet distribution

```
#> fmc -s Soft_FragParser.xml -p <policy file> -c <configuration file> -a
```

```
    •Policy file for "performance" and "functionality" for DPAA boards are as below
    1."asf-fman-perf-policy.xml" => performance policy file for P4080 and T1040D4RDB boards.
    2."asf-fman-func-policy.xml" => functionality policy file for P4080 and T1040D4RDB boards.

    •Configuration files for "performance" and "functionality" for various DPAA boards are as
below
    1."asf-cfg-4080-20g.xml" => for P4080, 2X10G ports enabled
    2."asf-cxfg-4080-5g.xml" => for P4080, 5X1g ports enabled
    3."asf-cfg-func-1040.xml" => for T1040D4RDB functionality testing
    4."asf-cfg-perf-1040.xml" => for T1040D4RDB performance testing

To test functionality, use only two port (ports which are functioning on the board) entries in
this file.

    NOTE:
    - Scripts used above are copies at /usr/lib/asf/scripts/fmc in the rootfs built with ASF
enabled.
    - Please make sure all the fm interfaces are up that are mentioned in the scripts. In case
some fm interface need to be put down then script shall be modified to remove that port from
script.
    - Once executed, fmc configuration cannot be reverted back, system need to be restarted.
```

NOTE: Disable the interface that are not used while taking the performance numbers.

IPv4 Configuration

Configuring ESP IPsec using setkey:

- At DUT1 run flowing script to configure IPsec policy

```
    #>./left.conf-3des-sha1-tunnel
```

- At DUT2 run flowing script to configure IPsec policy

```
    #>./right.conf-3des-sha1-tunnel
```

- *Note : setup_left, setup_right, right.conf-3des-sha1-tunnel and left.conf-3des-sha1-tunnel are copied at /usr/lib/asf/scripts/ipsec/setkey in rootfs compiled with ASF enabled.*

Configuring AH IPsec using setkey:

- At DUT1 run flowing script to configure IPsec policy

```
#>./left.conf-ah-sha1-tunnel
```

- At DUT2 run flowing script to configure IPsec policy

```
#>./right.conf-ah-sha1-tunnel
```

- **NOTE: Dynamic re-keying is supported only in FULL mode of ASF.**

Configuring IPsec using Racoon:

In case system needs to be configured for dynamic key exchange in IPsec using Racoon then the following commands shall be used.

- At DUT1 run flowing script to configure IPsec policy

```
#>./left-ipv4-tunnel
```

- At DUT2 run flowing script to configure IPsec policy

```
#>./right-ipv4-tunnel
```

The above commands will configure the SPD database and make the system ready to start negotiating SA's for flows matching the policies. To start dynamic key exchange and SA negotiation run following commands:

- At DUT1 run flowing script to configure IPsec policy

```
#> chmod 400 psk.txt
#> racoon –f racoon.conf
```

- At DUT2 run flowing script to configure IPsec policy

```
#> chmod 400 psk.txt
#> racoon –f racoon.conf
```

left-ipv4-tunnel, right-ipv4-tunnel, psk.txt and racoon.conf are copied at /usr/lib/asf/scripts/ipsec/raccon in rootfs compiled with ASF enabled.

These commands will start the racoon which reads system configuration from the racoon.conf file present in the system and runs as a background process.

Note :- In case the debug prints needs to be enabled then while running raccoon please can specify the level of debug prints using "-dddd" option wherein the number of "d" tells the debug level. Another important option for racoon is in case it needs to be run in foreground then specify it via –F option.

Configuring IPSec using Strongswan:

In case system needs to be configured for dynamic key exchange in IPSec using Strongswan then the following commands shall be used.

- At DUT1 run following script/commands to configure IPSec policy

```
#>./strongswan_left
#> ipsec start
```

- At DUT2 run following script/commands to configure IPSec policy

```
#>./strongswan_right
#> ipsec start
#> ipsec up net-net
```

strongswan_left, strongswan_right, are copied at /usr/lib/asf/scripts/ipsec/sswan in rootfs compiled with ASF enabled.

The above commands will configure the SPD database and make the system ready to start negotiating SA's for flows matching the policies. To start dynamic key exchange and SA negotiation run following commands:

Configuration at the Packet Generator:

- Create host on the traffic generator Ports connected to DUT1 and DUT2
- For Host 1 connected to DUT1 eth0, create flows for IP traffic with

```
* Source IP 192.168.1.21
* Destination IP as 192.168.2.21
* Gateway as 192.168.1.130
```

- For Host 2 connected to eth1, create flows for IP traffic with

```
* Source IP as 192.168.2.21
* Destination IP as 192.168.1.21
* Gateway as 192.168.2.130
```

- Start the sending traffic from Packet Generator from both Host1 and Host2.
- Verify that packet send from Host1 are received at Host2 and vice- versa.
- Packet between DUT1 and DUT2 will be IPSec encrypted.
- For testing multiple flows configure Host1 and Host2 at the Packet generator to send packets with incrementing values of Source IP and Destination IP.

Ipv6 Configuration

Configuring ESP IPsec using setkey:

- At DUT1 run flowing script to configure IPsec policy

```
./left_ipv6.conf-3des-sha1-tunnel
```

- At “Reference board” run flowing script to configure IPsec policy

```
./right_ipv6.conf-3des-sha1-tunnel
```

Configuring AH IPsec using setkey:

- At DUT1 run flowing script to configure IPsec policy

```
#> ./ipv6_left.conf-ah-sha1-tunnel
```

- At “Reference board” run flowing script to configure IPsec policy

```
#> ./ipv6_right.conf-ah-sha1-tunnel
```

- *Note : setup_left, setup_right, right.conf-3des-sha1-tunnel and left.conf-3des-sha1-tunnel are copied at /usr/lib/asf/scripts/ipsec/setkey in rootfs compiled with ASF enabled.*
- Above mentioned scripts will configure p4080 board as per the configuration shown in Test bed above.
- *NOTE: After above configuration ping6 from DUT to reference board tunnel end and vice-versa. Tunnel ends should ping6 each other.*

```
•Configuration at the Packet Generator
   •Create host on the traffic generator Ports connected to DUT1 and Reference Board
   •For Port1 connected to DUT1 fm2-gb0, create flows for IP traffic with
     * Source IP 2001::1
     * Destination IP as 2002::1
     * Gateway as 2001::130
   •For  port2 connected to eth0, create flows for IP traffic with
     * Source IP as 2002::1
     * Destination IP as 2001::1
     * Gateway as 2002::130
```

- Start the sending traffic from Packet Generator from both Port1 and Port2.
- Verify that packet send from Port1 are received at Port2 and vice- versa.
- Packet between DUT1 and DUT2 will be IPSec encrypted.
- For testing multiple flows configure Port1 and Port2 at the packet generator to send packets with incrementing values of source IP and destination IP.

The tables below summarizes the supported encryption and authentication algorithm combinations for various sec versions.

Table 202. SEC4.X onwards

Mode	Encryption	Authentication
ESP	AES-CBC(256)	HMAC-SHA-1/HMAC-SHA-256
ESP	3DES_EDE-CBC(168)	HMAC-SHA-1/HAMC-SHA-256
AH		HMAC-SHA-1/HMAC-MD5

Table 203. SEC3.X

Mode	Encryption	Authentication
ESP	3DES-CBC(256)	HMAC-SHA-1/HMAC-MD5
ESP	AES-CBC(256)	HMAC-SHA-1/HMAC-MD5

ASF IPsec has exported following PROC/SYS file system configuration which can be used to configure the system. The parameters and their default values are shown as below.

Table 204. SYSFS Interface Default Values

Commands	Description	Mode	Default Value
/proc/sys/asfipsec/ulL2BlobRefreshPktCnt_g	The number of packets count after which refresh for Layer 2 header will be triggered by ASF IPsec. The value '0' indicates that refresh of Layer 2 header based on packet count is *disabled*.	Read/Write	0
/proc/sys/asfipsec/ulL2BlobRefreshTimeInSec_g	The time in seconds after which refresh for Layer 2 header will be triggered by ASF IPsec.	Read/Write	180
/proc/sys/asfipsec/ulMaxSPDContainers_g	The maximum number of Security Policies supported by ASF IPsec.	Read	256
/proc/sys/asfipsec/ulMaxSupportedIPSecSAs_g	The maximum number of Security Association's supported by ASF IPsec.	Read	256
/proc/sys/asfipsec/ulMaxTunnels_g	The maximum number of tunnels supported by ASF IPsec.	Read	256

Table continues on the next page...

Table 204. SYSFS Interface Default Values (continued)

Commands	Description	Mode	Default Value
/proc/sys/asfipsec/ulMaxVSGs_g	The maximum number of VSG's supported by ASF. *Note: Only 1 VSG is supported with Linux	Read	2*

Also, while loading the ASF IPsec Control module one can configure the following module parameters as follows.

Table 205. ASF IPsec Control Module Parameters

Module Parameter	Description	Mode	Default Value
/sys/module/asfctrl_ipsec/parameters/bRedSideFragment	Enable/Disable the Red side fragmentation(Pre IPSec fragmentation)	Read	Y (Enable)
/sys/module/asfctrl_ipsec/parameters/bAntiReplayCheck	Enable/Disable Anti Replay Check	Read	Y (Enable)

8.1.2.5 T1040D4rdb IP Fwd and IPSec Fwd

8.1.2.5.1 Hardware instructions for T1040D4RDB -8G setup

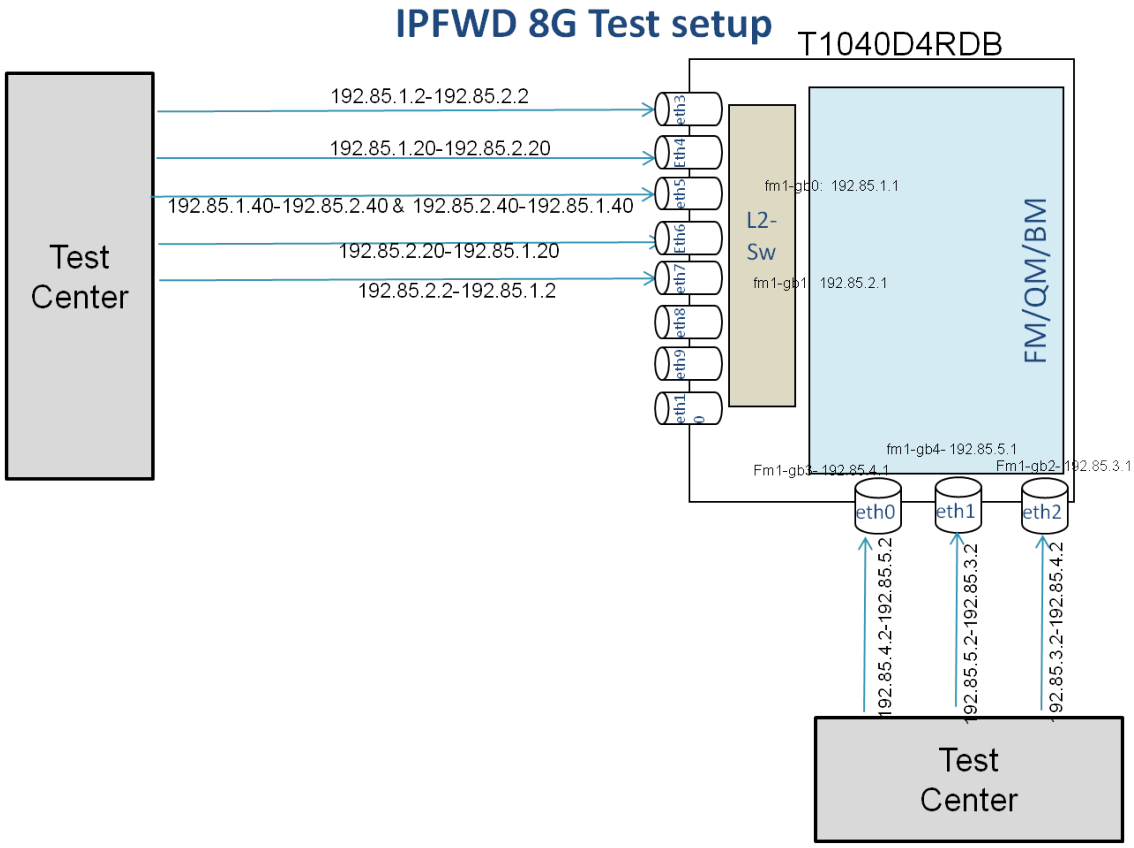

Figure 185. T1040D4RDB -IP Firewall forwarding Diagram

8.1.2.5.2 Software instructions for T1040D4RDB - 8G performance

Configuration at the DUT

- Configure Ethernet address for fm1-gb0 to fm1-gb4

```
#> ifconfig  fm1-gb0 192.85.1.1 netmask 255.255.255.0 up
#> ifconfig  fm1-gb1 192.85.2.1 netmask 255.255.255.0 up
#> ifconfig  fm1-gb2 192.85.3.1 netmask 255.255.255.0 up
#> ifconfig  fm1-gb3 192.85.4.1 netmask 255.255.255.0 up
#> ifconfig  fm1-gb4 192.85.5.1 netmask 255.255.255.0 up
```

- Enable routing at the DUT

```
#> echo 1 > /proc/sys/net/ipv4/ip_forward
```

- Load ASF modules

```
#> insmod asf.ko
#> insmod asfctrl.ko
```

- Increase number of conntrack entries in Linux for measuring performance for 128K flows

```
#> echo 140000 > /proc/sys/net/nf_conntrack_max
```

- Change the default UDP timeout to 9000 seconds. (for performance testing)

```
#> echo 9000 > /sys/asfctrl/ffp/asfctrl_ffp_udp_tmout
```

- Execute fmc command for packet distribution

```
#> fmc -s Soft_FragParser.xml -p asf-fman-perf-policy.xml -c asf-cfg-perf-1040.xml -a
```

NOTE

- Scripts used above are copies at /usr/lib/asf/scripts/fmc in the rootfs built with ASF enabled.

- Please make sure all the fm interfaces are up that are mentioned in the scripts. In case some fm interface need to be put down then script shall be modified to remove that port from script.

- Once executed, fmc configuration cannot be reverted back, system need to be restarted.

- Change the default UDP timeout to 9000 seconds. (*for performance testing*)

```
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout
#> echo 9000 >/proc/sys/net/netfilter/nf_conntrack_udp_timeout_stream
```

•Configuration of switch on T1040D4RDB board

Run the switch binary on T1040D4rdb:

```
# l2sw_bin
```

Add the source MAC address of the hosts configured in the SPIRENT streams:

```
# l2switch>mac add 00:10:94:00:00:01 2
# l2switch>mac add 00:10:94:00:00:02 3
# l2switch>mac add 00:10:94:00:00:03 4
# l2switch>mac add 00:10:94:00:00:06 4
# l2switch>mac add 00:10:94:00:00:05 5
# l2switch>mac add 00:10:94:00:00:04 6

Note: Port numbers (mentioned above) of the switch can vary based on the mapping done with the
Spirent.

Also add the MAC address of switch ports(fm1-gb0 and fm1-gb1) that board has initialized (MAC will
vary from board to board)

# l2switch>mac add 00:E0:0C:00:55:00 8
# l2switch>mac add 00:E0:0C:00:55:01 9

Switch off the polling on the board:
# l2switch>poll off
```

Configuration IPv4 Flows on Traffic Generator

- Refer to the Hardware setup
- Create hosts on the traffic generator Ports connected to DUTs interface with IP addresses 192.85.1.1, 192.85.2.1, 192.85.3.1, 192.85.4.1 and 192.85.5.1 respectively.

- From Host 1 connected to switch eth3 as in diagram(fm1-gb0), create flows for UDP traffic with

```
Source IP      192.85.1.2 (as per number of flows)
Destination IP 192.85.2.2 (as per number of flows)
```

- From Host 2 connected to switch eth4 as in diagram(fm1-gb0), create flows for UDP traffic with

```
Source IP      192.85.1.20 (as per number of flows)
Destination IP 192.85.2.20 (as per number of flows)
```

- From Host 3 connected to switch eth5 as in diagram(switch port), create flows for UDP traffic with

```
Source IP      192.85.1.40 (as per number of flows)
Destination IP 192.85.2.40 (as per number of flows)
           &
Source IP      192.85.2.40 (as per number of flows)
Destination IP 192.85.1.40 (as per number of flows)
```

- From Host 4 connected to switch eth6 in diagram(fm1-gb1), create flows for UDP traffic with

```
Source IP      192.85.2.20 (as per number of flows)
Destination IP 192.85.1.20 (as per number of flows)
```

- From Host 5 connected to switch eth7 in diagram(fm1-gb1), create flows for UDP traffic with

```
Source IP      192.85.2.2 (as per number of flows)
Destination IP 192.85.1.2 (as per number of flows)
```

- From Host 6 connected to switch eth0 (fm1-gb3), create flows for UDP traffic with

```
Source IP      192.85.4.2 (as per number of flows)
Destination IP 192.85.5.2 (as per number of flows)
```

- From Host 7 connected to switch eth1 in diagram(fm1-gb4), create flows for UDP traffic with

```
Source IP      192.85.5.2 (as per number of flows)
Destination IP 192.85.3.2 (as per number of flows)
```

- From Host 8 connected to switch eth2 in diagram(fm1-gb2), create flows for UDP traffic with

```
Source IP      192.85.3.2 (as per number of flows)
Destination IP 192.85.4.2 (as per number of flows)
```

- Start the sending traffic from Packet Generator from all the Hosts.

8.1.2.5.3 Hardware instructions for T1040D4RDB-IPSec 6G setup

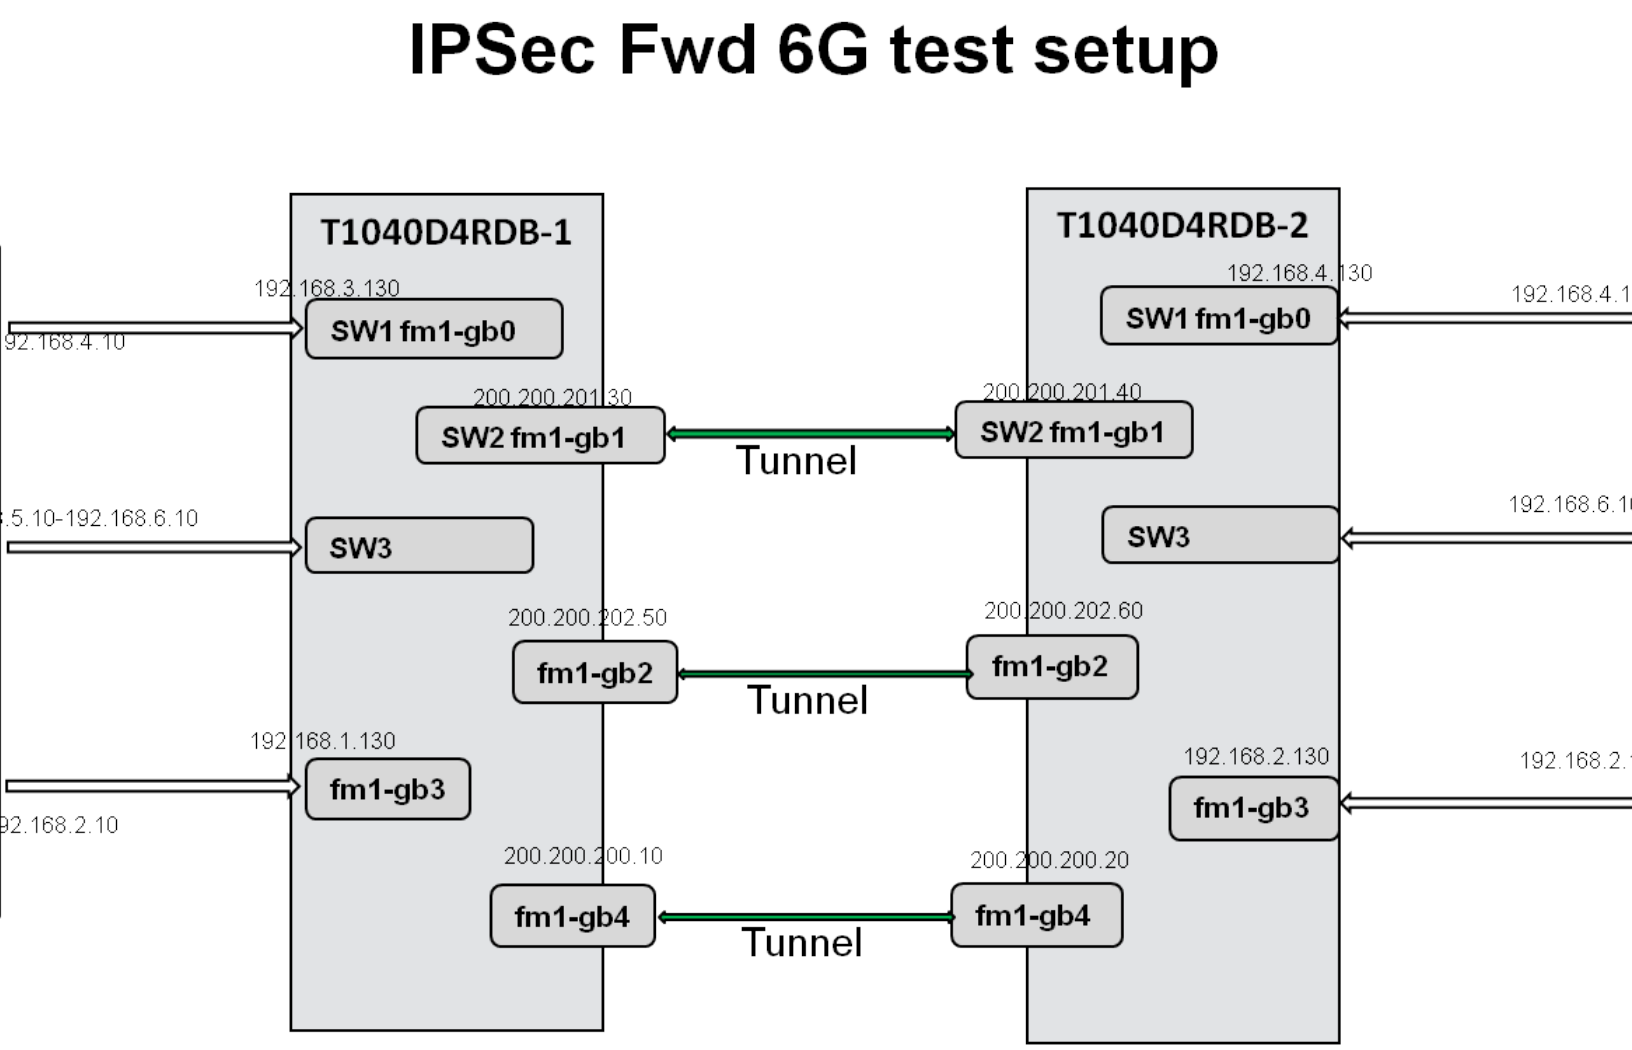

Figure 186.

8.1.2.5.4 Software instructions for T1040D4RDB IPSec - 6g

Configuration at both the DUT

- On DUT1 run flowing commands

```
# ifconfig  fm1-gb0 192.168.3.130 netmask 255.255.255.0 up
# ifconfig  fm1-gb1 200.200.201.30 netmask 255.255.255.0 up
# ifconfig  fm1-gb2 200.200.202.50 netmask 255.255.255.0 up
# ifconfig  fm1-gb3 192.168.1.130  netmask 255.255.255.0 up
```

```
  # ifconfig  fm1-gb4 200.200.200.10 netmask 255.255.255.0 up
  # ip route add 192.168.2.0/24 dev fm1-gb4
  # ip route add 192.168.4.0/24 dev fm1-gb1
  # ip route add 192.168.6.0/24 dev fm1-gb2
  # ip route add 192.168.5.0/24 dev fm1-gb0
```

- On DUT2 run flowing commands

```
# ifconfig  fm1-gb0 192.168.4.130 netmask 255.255.255.0 up
# ifconfig  fm1-gb1 200.200.201.40 netmask 255.255.255.0 up
# ifconfig  fm1-gb2 200.200.202.60 netmask 255.255.255.0 up
# ifconfig  fm1-gb3 192.168.2.130  netmask 255.255.255.0 up
# ifconfig  fm1-gb4 200.200.200.20 netmask 255.255.255.0 up
# ip route add 192.168.1.0/24 dev fm1-gb4
# ip route add 192.168.3.0/24 dev fm1-gb1
# ip route add 192.168.5.0/24 dev fm1-gb2
# ip route add 192.168.6.0/24 dev fm1-gb0
```

- **Configuration at both the DUT**

```
#> insmod asf.ko
#> insmod asfctrl.ko
#> insmod asfipsec.ko
#> insmod asfctrl_ipsec.ko
```

- Change the default UDP timeout to 9000 (for performance testing)

```
#> echo 9000 > /sys/asfctrl/ffp/asfctrl_ffp_udp_tmout

•Enable routing at the DUT
#> echo 1 > /proc/sys/net/ipv4/ip_forward
```

- Disable xfrm_larval_drop

```
#> echo 0 > /proc/sys/net/core/xfrm_larval_drop
```

- Change the default UDP timeout to 9000 seconds. (for performance testing)

```
#> echo 9000 > /proc/sys/net/netfilter/nf_conntrack_udp_timeout
#> echo 9000 >/proc/sys/net/netfilter/nf_conntrack_udp_timeout_stream
```

- Execute fmc command for packet distribution

```
#> fmc –s Soft_FragParser.xml –p asf-fman-perf-policy.xml –c asf-cfg-perf-1040.xml –a
```

NOTE

NOTE:

- Scripts used above are copies at /usr/lib/asf/scripts/fmc in the rootfs built with ASF enabled.

- Please make sure all the fm interfaces are up that are mentioned in the scripts. In case some fm interface need to be put down then script shall be modified to remove that port from script.

- Once executed, fmc configuration cannot be reverted back, system need to be restarted.

Configuring ESP IPsec using setkey:

- At T1040D4RDB-1, run flowing embedded script to configure IPsec policy

```
#> ./left_t1040D4rdb_6g_esp-sha1.txt

Create the above executable using following:

#!/usr/sbin/setkey -f
```

```
flush;

```

-

L2 switch configuration on both DUT:

- Configuration of switch on T1040D4RDB-1 board.
- Run the switch binary on T1040D4rdb

```
# l2sw_bin

Note: For Performance testing, before adding MAC address statically, start traffic for all the
streams Configured, so that both the T1040D4RDB boards creates a MAC table dynamically.
Use l2switch>mac_dump command to dump all the addresses leaned. Use the dynamically learned mac
address entries to add static mac address as below:

Add the MAC address of switch ports (fm1-gb0 and fm1-gb1) that board has initialized (MAC will
vary from board to board)

l2switch> mac add 00:e0:0c:00:8a:00 8
l2switch> mac add 00:e0:0c:00:8a:01 9

Also add the source MAC address of the hosts configured in the SPIRENT streams and for ESP
tunnel interface connected with switch ports:

l2switch> mac add 00:10:94:00:00:02 2
l2switch> mac add 00:10:94:00:00:03 3
l2switch> mac add 00:e0:0c:00:82:02 9

Switch off the polling on the board:
l2switch>poll off
```

- Configuration of switch on T1040D4RDB-2 board

- Run the switch binary on T1040D4rdb

```
# l2sw_bin

Note: For Performance testing, before adding MAC address statically, start traffic for all the
streams Configured, so that both the T1040D4RDB boards creates a MAC table dynamically.
Use l2switch>mac_dump command to dump all the addresses leaned. Use the dynamically learned mac
address entries to add static mac address as below:

Add the MAC address of switch ports (fm1-gb0 and fm1-gb1) that board has initialized (MAC will
vary from board to board)

l2switch> mac add 00:e0:0c:00:82:01 8
l2switch> mac add 00:e0:0c:00:82:02 9

Also add the source MAC address of the hosts configured in the SPIRENT streams and for ESP
tunnel interface connected with switch ports:

l2switch> mac add 00:10:95:00:00:02 2
l2switch> mac add 00:10:95:00:00:03 3
l2switch> mac add 00:e0:0c:00:8a:01 9

Switch off the polling on the board:
l2switch>poll off
```

- **NOTE**

  Port numbers (mentioned above) of the switch can vary based on the mapping done with the Spirent and other board. Use dynamic learning to identify correct ports and mac learning.

Configuration at the Packet Generator:

- Create hosts on the traffic generator Ports connected to T1040D4RDB-1 and T1040D4RDB-2
- For T1040D4RDB-1 connected to spirent, create flows for UDP traffic with

```
* Src IP 192.168.1.10, Dst IP as 192.168.2.10, GW 192.168.1.130
* Src IP 192.168.3.10, Dst IP as 192.168.4.10, GW 192.168.3.130
* Src IP 192.168.5.10, Dst IP as 192.168.6.10, GW 192.168.3.130
```

- For T1040D4RDB-2 connected to spirent, create flows for UDP traffic with

```
* Src IP 192.168.2.10, Dst IP as 192.168.1.10, GW 192.168.2.130
* Src IP 192.168.4.10, Dst IP as 192.168.3.10, GW 192.168.4.130
* Src IP 192.168.6.10, Dst IP as 192.168.5.10, GW 192.168.4.130111
```

- Start sending traffic from Packet Generator from both sides.
- Verify that packet send from DUT1 are received at DUT2 and vice- versa.
- Packet between DUT1 and DUT2 will be IPSec encrypted.

8.1.3 Troubleshooting

8.1.3.1 Viewing Statistics/Information via /proc interface

To verify that ASF is processing the packets; the proc interface which provides various options that can be used to see what is happening in the system. The proc interface gets populated based on mode in which ASF is compiled in.

In Maximum mode all the stats are visible through proc interface, in Minimal Mode various statistics are displayed as 0.

The following section shows the proc statistics

Table 206. *proc* Statistics

Commands	Description
cat /proc/asf/global_stats	Provide information for • Packets received and transmitted by the ASF. • NAT/Firewall flows allocated in ASF. • Error Counters • Number of packets sent for Linux stack for processing
cat /proc/asf/flow_stats	Displays Connection tracking entries configured in the system in the NAT mode.
cat /proc/asf/ifaces	Displays the interfaces on which ASF is enabled
cat /proc/asfipsec/global_stats	Displays IPsec statistics
cat /proc/asfipsec/global_error	Displays IPsec error statistics.
cat /proc/asfipsec/out_spd	Display Encryption IPsec Policy and SA offloaded to ASF
cat /proc/asfipsec/in_spd	Display Decryption IPsec Policy and SA offloaded to ASF

8.1.3.2 Common Usage Issues

Table 207. Common Usage Issues

Symptoms	Reason and/or Recommended actions
NAT/Firewall performance is much lower than expected.	Verify that conntrack entries are offloaded and packets are getting routed through ASF using commands cat /proc/asf/flow_stats cat /proc/asf/global_stats Make sure that ASF is loaded before starting the traffic for flows to be offloaded to ASF. Verify that no USB and MMC interrupts are coming. If interrupts come, disable the MMC and USB from Linux.
In Minimal mode Flows NAT/Firewall are offloaded but performance is still down	Dynamic ARP entries may not be offloaded at time flows were offloaded. Try with creating static ARP entries before the traffic is started for flows. If it works check why Dynamic ARP is not getting resolved at the setup.
Statistics are not updated	Verify that Image is compiled for FULL ASF mode. In Minimal mode statistics are disabled.

Table continues on the next page...

Table 207. Common Usage Issues (continued)

Symptoms	Reason and/or Recommended actions
IPsec forwarding in minimal mode is not working.	Verify that ARP for Ethernet interfaces are resolved at the DUT. Refer section 3.4
IPsec forwarding not working in minimal mode and full mode	Verify that ASF is running in NAT/Firewall mode, In IPv4 forwarding mode IPsec is not supported.
IPsec ESP/AH SHA256 is not working with Linux.	Verify that the ipsec-tools are overriding the default ICV configured by Linux. Try using strongswan for IPsec configuration.
Strongswan v5.1.1 is unable to start with "*ipsec start*" command.	Remove "auth=esp" from "/etc/ipsec.conf" file

8.2 Auto Response

8.2.1 Introduction

8.2.1.1 Purpose

This document details the usage of AR solution. AR is a Linux kernel implementation for offloading the network configuration to the ucode and processing the incoming based on the configuration.

8.2.1.2 Scope

This document is intended to help developers, test engineers and customers to use NXP AR implementation on NXP's family (QORIQ) of Network processors.

8.2.1.3 Definitions and Acronyms

AR	Auto Response
ARP	Address Resolution Protocol
ND	Neighbor Discovery
SNMP	Simple Network Management Protocol
ICMP	Internet Control Message Protocol
FMAN	Frame Manager
Ucode	FMAN Micro Code
PM	Power Management
DUT	Device Under Test

8.2.2 Product Description

8.2.2.1 Overview

AR is a Linux kernel implementation to make the device intelligent enough so that it can respond to the network packets when device is in power saving mode (Deep Sleep Mode).

AR implementation is compiled as Kernel dynamic loadable module that can be plugged in to Linux at run time. Once plugged into Linux, AR will be ready to get trigger from Power management to into deep sleep state. Once a user instructs the device to enter into deep sleep, Network configuration, for the Auto response port i.e fm1-gb3, will be offloaded to the ucode and ucode will start responding to the network packets.

8.2.2.2 Key Target Applications

AR is capable to respond the following protocols packets:

- 1)ARP
- 2)ND
- 3)ICMPv4
- 4)ICMPv6
- 5)SNMP

Also AR will be capable to wake the device for specified packets which will be configured by AR as per the user requirement.

8.2.2.3 Product Diagram

Figure below identifies how the AR module fits in the overall system in typical network processor software Architecture.

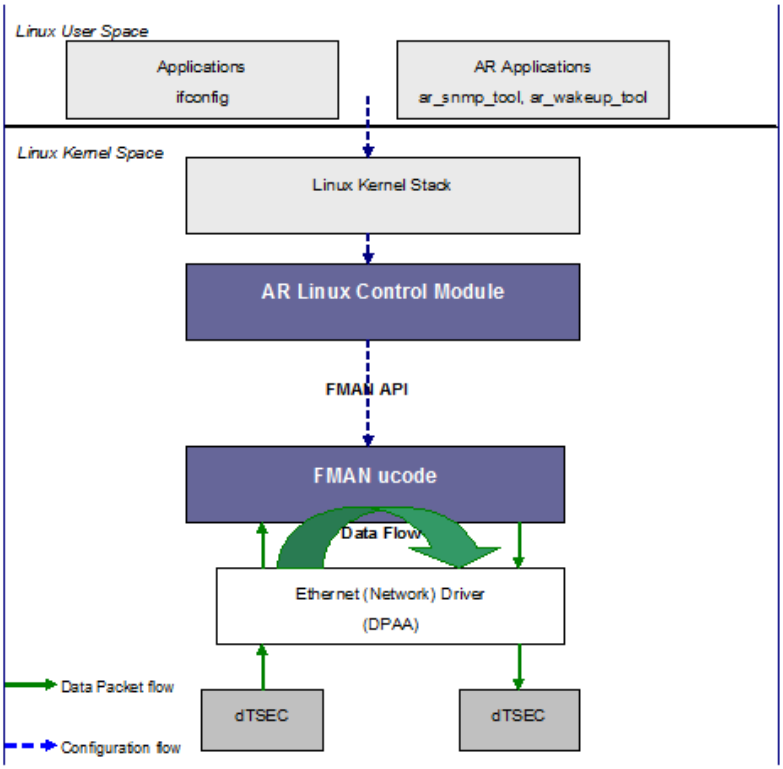

Figure 187. AR Packet Processing

8.2.2.4 Features

As a part of delivery user will receive AR as part of Yocto source release.

Following features are supported in this release for Auto response port. Following feature will be supported for both, physical and logical, interfaces.

Following features are supported in this release

Table 208. Features

Feature	Detailed Description
ARP	ARP packets will be processed by ucode as its configuration.
ND	ND packets will be processed by ucode as its configuration.
ICMPv4	ICMPv4 packets will be processed by ucode as its configuration.
ICMPv6	ICMPv6 packets will be processed by ucode as its configuration.
SNMP	SNMP packets will be processed by ucode as its configuration
WAKEup	Device will be waken-up for the configured packet rules

8.2.2.5 Specifications

Platform Supported

- T1040D4RDB
- T1042D4RDB

Limitations:

- SNMP is not functional in current release.

8.2.2.6 Environment Required

8.2.2.6.1 Hardware Configuration

Refer platform Specific Documentation for Board Configuration.

8.2.2.6.2 Software Configuration

NA

8.2.2.6.3 Software Tools

1. SNMP Client needs to be installed on some machine (Windows or Linux/Unix) for sending SNMP requests for testing.
2. SNMP Server needs to be installed on DUT to process SNMP request.

8.2.2.7 Product Directory Structure

NA

8.2.3 Product Execution

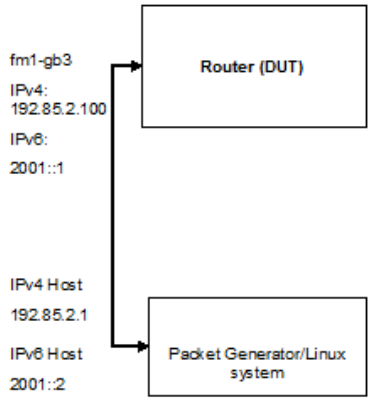
8.2.3.1 Getting started

Following are the images which are required to run Auto Response.

1. Linux Image (uImage)
2. Rootfs (Containing auto response kernel module and user space utilities)
3. Device tree blob with AR supported changes
4. Ucode which will be running in independent mode in deep sleep state

8.2.3.2 ARP/ND/ICMP Packet Processing

8.2.3.2.1 Hardware setup



8.2.3.2.2 Software instructions

Configuration at the DUT

1. Installing Auto Response module

```
insmod ar.ko ar_resport="fm1-gb3"
```

2. Configure Ethernet address for fm1-gb3

- IPv4

```
ifconfig fm1-gb3 192.85.2.100 netmask 255.255.255.0 up
```

- IPv6

```
ip -6 addr add 2001::1/64 dev fm1-gb 3
```

3. Configure Ethernet address for VLAN interface over fm1-gb3 (Optional configuration)
   - IPv4

```
vconfig add fm1-gb3 1
ifconfig fm1-gb3.1 192.85.3.100 netmask 255.255.255.0 up
```

   - IPv6

```
vconfig add fm1-gb3 1
ip -6 addr add 2002::1/64 dev fm1-gb3.1
ifconfig fm1-gb3.1 up
```

4. Configure Ethernet address for logical interface over fm1-gb3 (Optional configuration)
   - IPv4

```
ifconfig fm1-gb3:1 192.85.4.100 netmask 255.255.255.0 up
```

   - IPv6

```
ip -6 addr add 2003::1/64 dev fm1-gb3:1
ifconfig fm1-gb3:1 up
```

5. Enable/Disable conflict detection flag
   - ARP conflict detection

```
echo 1 > /sys/arctrl/arp_conflict_detect
echo 0 > /sys/arctrl/arp_conflict_detect
```

   Where:

   0 - Conflict detection is disabled.
   The host CPU will not be woken upon conflict detection and the packet will be processed by ucode as a normal frame.

   1 - Conflict detection is enabled.
   Ethernet-IPv4 ARP frames, which contain address conflict, will cause the FMan Controller to proceed to the 'Active' mode processing flow. According to the 'Active mode' configuration, this can cause a system wake-up or frame will be discarded. By default conflict detection flag is disabled.

6. Configuring rollback option during deep sleep entrance. There could be a possibility that system has some frames to be processed while getting into the deep sleep state then in this case system should not get into the deep sleep and

should roll back from suspend sequence. It needs to be configured so that system will rollback while getting into deep sleep entrance. The following is the command to configure the same:

```
echo `cat /sys/power/wakeup_count ` > /sys/power/wakeup_count && echo mem >
/sys/power/state
```

7. Getting into deep sleep state without enabling rollback option

```
  echo mem > /sys/power/state
```

Configuration of hosts on Traffic Generator

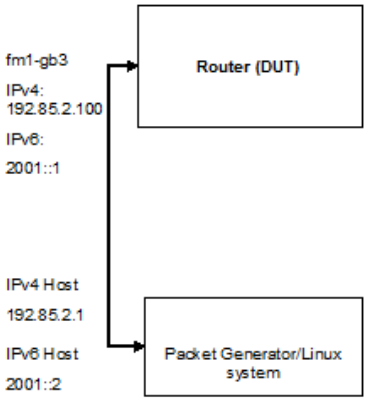
1. Create an IPv4 host on the traffic generator on port connected to DUT i.e. fm1-gb3
2. Configure the IPv4 address as on the host
3. Create an IPv6 host on the traffic generator on port connected to DUT i.e. fm1-gb3
4. Configure the IPv6 address as on the host

Run test

1. Resolve ARP Request for the configured IPv4 addresses on DUT.
2. Resolve NDP advertisement request for the configured IPv6 addresses on DUT.
3. Ping from the host to the configured IPv4/IPv6. Ping response will be successful.
4. Send any packet other than ping i.e. UDP/TCP packet. System will wake up.

8.2.3.3 Wake up processing

8.2.3.3.1 Hardware setup



8.2.3.3.2 Software instructions

Configuration at the DUT

1. Installing Auto Response module

```
insmod ar.ko ar_resport="fm1-gb3"
```

2. Configure Ethernet address for fm1-gb3
   - IPv4

```
ifconfig fm1-gb3 192.85.2.100 netmask 255.255.255.0 up
```

   - IPv6

```
ip -6 addr add 2001::1/64 dev fm1-gb3
```

3. Configure user defined wakeup rules
   a. Modify ar_wakeup_rule_cfg file to configure wakeup rules.

      The file contains rules for following filters:

      - IP protocol filters

This filter identifies the list of protocols which are to be considered to wake the system up. Protocol entry in this ar_wakeup_rule_cfg is written as a string representing the standard IP protocols. For example:

- TCP for tcp packets
- UDP for udp packets
- ICMP for IPv4 ICMP packets
- IPv6-ICMP for IPv6 ICMP packets
- IGMP for IGMP (v1/v2/v3) packets

To add more protocols, mention the protocol as per standard IP protocol keyword.

- UDP ports filters

  This filter identifies the rules on UDP port number which will be used to compare with UDP traffic for packet filtering. Rules are written in following format:

  Source port | Destination port | Source port Mask | Destination port Mask

- TCP ports filters

  This filter identifies the rules on TCP port number which will be used to compare with UDP traffic for packet filtering. Rules are written in following format:

  Source port | Destination port | Source port Mask | Destination port Mask

b. Configure action if packet hits any of the filter

```
echo (1/0) > /sys/arctrl/ip_prot_pass_on_hit
echo (1/0) > /sys/arctrl/udp_port_pass_on_hit
echo (1/0) > /sys/arctrl/tcp_port_pass_on_hit
```

where,

0 - Discard the packet in case of hit in the table. Pass the packet in case of miss.

1 - Pass the packet in case of hit in the table. Discard the packet in case of miss.

c. Configure TCP control bit flags

This flag is used to configure a bit mask for TCP packets which will cause a wakeup of the system. This must be considered with TCP port filter rules.

```
echo 003f > /sys/arctrl/tcp_flag_mask
```

If no user defined rules are configured then system will be waken-up for the following types of packets actions:

```
TCP State (SYN/FIN/RST)      Wake-up
TCP Data (Push/Ack)          Wake-up
UDP packet                   Wake-up
Default                      Wake-up
```

4. Configure wakeup rules which will be offloaded to the ucode

```
./ar_wakeup_tool ar_wakeup_rule_cfg
```

5. Configuring MPIC timer (Optional configuration)

MPIC timer is used to wake the system after the specified time interval in seconds:

```
echo (time interval in secs) > /sys/devices/system/mpic/timer_wakeup
```

To avoid time difference, always run this command with:

```
echo mem > /sys/power/state
```

6. Getting into deep sleep state

```
echo mem > /sys/power/state
```

Configuration of hosts on Traffic Generator

- Create an IPv4 host on the traffic generator on port connected to DUT i.e. fm1-gb3
  1. Configure the IPv4 address as 192.85.2.100 on the host
- Create an IPv6 host on the traffic generator on port connected to DUT i.e. fm1-gb3
  1. Configure the IPv6 address as 2001::2 on the host
- Configure a IPv4/IPv6 UDP stream with the same port numbers as given in UDP filter table
- Configure a IPv4/IPv6 TCP stream with the same port numbers as given in TCP filter table
- Configure an IP stream with the same protocol as given in IP protocol filter table

Run Test

1. Ping from the host to the configured IPv4/IPv6. Ping response will be successful.
2. Send UDP packet which can cause wakeup or will be dropped (depends on action configured).
3. Send TCP packet which can cause wakeup or will be dropped (depends on action configured).
4. Send IP protocol packet which can cause wakeup or will be dropped (depends on action configured).

8.3 Power Management

8.3.1 Power Management User Manual

Linux SDK for QorIQ Processors

Description

QorIQ Processors have features to minimize power consumption at several different levels. All processors support a sleep mode (LPM20). Some processors, such as T1040, LS1021, LS1046, also support a deep sleep mode (LPM35).

The following power management features are supported on various QorIQ processors:

- Dynamic power management
- Shutting down unused IP blocks
- Cores support low power modes (such as PW15)
- Processors enter low power state (LPM20, LPM35)
  - LPM20 mode: most part of processor clocks are shut down

- LPM35 mode: power is removed to cores, cache and IP blocks of the processor such as DIU, eLBC, PEX, eTSEC, USB, SATA, eSDHC etc.

- CPU hotplug: If cores are down at runtime, they will enter low power state.

The wake-up event sources caused quitting from low power mode are listed as below:

- Wake on LAN (WoL) using magic packet
- Wake by MPIC timer or FlexTimer
- Wake by Internal and external interrupts

For more information on a specific processor, refer to processor Reference Manual.

Kernel Configure Tree View Options

For ARM platforms

Kernel Configure Tree View Options	Description
`Power management options  -->` `  [*] Suspend to RAM and standby`	Enable sleep feature

`Device Drivers  --->`
`  SOC (System On Chip) specific Drivers  --->`
`  [*]  Layerscape Soc Drivers`
`  [*]  FTM alarm driver`
	Enable the FTM alarm (FlexTimer module) driver

`CPU Power Management  --->`
`CPU Idle  --->`
`[*] CPU idle PM support`
`[*]  Ladder governor (for periodic timer tick)`
`-*-  Menu governor (for tickless system)`
`  ARM CPU Idle Drivers  --->`
`  [*] Generic ARM/ARM64 CPU idle Driver`
	Enable the CPU Idle driver

Table continues on the next page...

Compile-time Configuration Options

Linux Framework	Hardware Feature	Platform	Kernel Config
Suspend	LPM20	LS1012, LS1021, LS1046	CONFIG_SUSPEND
	wake by Flextimer	LS1012, LS1021, LS1046	CONFIG_FTM_ALARM
CPU idle	PW15	LS1012, LS1021, LS1046	CONFIG_ARM_CPUIDLE

Device Tree Binding

Property	Type	Description
fsl,#rcpm-wakeup-cells	unsigned int	the number of cells in "rcpm-wakeup" except the pointer to "rcpm"
rcpm-wakeup	unsigned int	require if the IP block can work as a wakeup source

For processors integrated RCPM

```
rcpm: rcpm@1ee2000 {
    compatible = "fsl,ls1046a-rcpm", "fsl,qoriq-rcpm-2.1";
    reg = <0x0 0x1ee2000 0x0 0x1000>;
    fsl,#rcpm-wakeup-cells = <1>;
};

ftm0: ftm0@29d0000 {
    compatible = "fsl,ftm-alarm";
    reg = <0x0 0x29d0000 0x0 0x10000>;
    interrupts = <0 86 0x4>;
    big-endian;
    rcpm-wakeup = <&rcpm 0x0 0x20000000>;
    status = "okay";
};
```

Refer to the Linux document: Documentation/devicetree/bindings/soc/fsl/rcpm.txt

Source Files

The source files are maintained in the Linux kernel source tree.

Source File	Description
drivers/soc/fsl/layerscape/rcpm.c	the RCPM driver needed by the sleep feature
drivers/soc/fsl/layerscape/ftm_alarm.c	the FTM timer driver worked as a wakeup source
drivers/cpuidle/cpuidle-arm.c	the cpuidle driver for ARM core

Verification in Linux

- Cpuidle Driver

  The cpuidle driver can switch CPU state according to the idle policy (governor). For more information, please see "Documentation/cpuidle/sysfs.txt" in kernel source code.

```
/* Check the cpuidle driver which is currently used. */
# cat /sys/devices/system/cpu/cpuidle/current_driver

/* Check the following directory to see the detailed statistic information of each state on
each CPU. */
/sys/devices/system/cpu/cpu0/cpuidle/state0/
/sys/devices/system/cpu/cpu0/cpuidle/state1/
```

- Sleep and Wake up by FTM timer

```
/* Start a FTM timer. It will trigger an interrupt to wake up the system in 5 seconds. */
echo 5 > /sys/devices/platform/soc/29d0000.ftm0/ftm_alarm && echo mem > /sys/power/state
```

Supporting Documentation

8.3.2 CPU Frequency Switching User Manual

Linux SDK for QorIQ Processors

Abbreviations and Acronyms

DFS: Dynamic Frequency Scaling

Description

QorIQ Processors support DFS (Dynamic Frequency Switching) feature, also known as CPU Frequency Switch, which can change the frequency of cores dynamically.

For more information on a specific processor, refer to processor Reference Manual.

Kernel Configure Tree View Options	Description

CPU Power Management -->
  CPU Frequency scaling -->
  [*] CPU Frequency scaling
  <*> CPU frequency translation statistics
  Default CPUFreq governor (userspace) -->
  -*- 'userspace' governor for userspace frequency scaling
  ARM CPU frequency scaling drivers -->
  <*> CPU frequency scaling driver for Freescale QorIQ SoCs
	Enable the CPU frequency driver

Compile-time Configuration Options

Linux Framework	Hardware Feature	Platform	Kernel Config
cpufreq	DFS	ALL	CONFIG_CPU_FREQ, CONFIG_CPU_FREQ_DEFAULT_GOV_USERSPACE
cpufreq	DFS	Layerscape	CONFIG_QORIQ_CPUFREQ

User Space Application

Simply using command "cat" and "echo" can verify this feature.

Device Tree Binding

Property	Type	Status	Description
#clock-cells	unsigned int	Required	The number of cells in a clock-specifier
clocks	handle	Required	Clock source handle
compatible	String	Required	Compatible strings
reg	unsigned int	Required	register address range

Table continues on the next page...

```
clockgen: clocking@1ee1000 {
    compatible = "fsl,ls1012a-clockgen";
    reg = <0x0 0x1ee1000 0x0 0x1000>;
    #clock-cells = <2>;
    clocks = <&sysclk>;
};
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Table continued from the previous page...

Source File	Description
drivers/cpufreq/qoriq_cpufreq.c	CPU frequency scaling driver for qoriq chips

Verification in Linux

- CPU frequency mode

```
In order to test the CPU frequency scaling feature, we need to enable the CPU frequency feature
on the
menuconfig and choose the USERSPACE governor.
You can learn more about CPU frequency scaling feature by referring to the kernel documents.
They all are put under Documentation/cpu-freq/ directory.
For example: all the information about governors is put in Documentation/cpu-freq/governors.txt.

Test step:
1. list all the frequencies a core can support (take cpu 0 for example) :
 # cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_available_frequencies
1199999 599999 299999 799999 399999 199999 1066666 533333 266666

2.  check the CPU's current frequency
# cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_cur_freq
1199999

3. change the CPU's frequency we expect:
# echo 799999 > /sys/devices/system/cpu/cpu0/cpufreq/scaling_setspeed

You can check the CPU's current frequency again to confirm if the frequency transition is
```

```
successful.

Please note that if the frequency you want to change to doesn't support by current CPU, kernel
will
round up or down to one CPU supports.
```

8.3.3 Thermal Management User Manual

Description

The thermal management function is based on TMU (Thermal Monitoring Unit).

The driver sets two thresholds for management function. If the CPU temperature crosses the first one (75 C for LS2080. 85 C for other platforms), the driver will trigger CPU frequency limitation auto-scaling according to the temperature trend; If the CPU temperature crosses the second one (85 C for LS2080, 95 C for other platforms, critical for core) the driver will shut down the system.

User could also get current temperature through sysfs interface.

Specifications

Target boards:	T1040RDB, T1042RDB, T1023RDB, T1024RDB, LS1021ATWR, LS1043ARDB, LS2080ARDB.
Operating system:	Linux 3.12+

Kernel Configure Tree View Options (For PowerPC platform)

Kernel Configure Tree View Options	Description

};
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/thermal/qoriq_thermal.c	QorIQ thermal driver.

Verification in Linux

There are two parts for verification: management and monitor.

[Management:]

1. When CPU temperature cross the first threshold, CPU frequency may be reduced by changing frequency limitation, use the following command to check the current frequency:

```
~$ cat /sys/devices/system/cpu/cpu0/cpufreq/scaling_cur_freq
```

2. When CPU temperature cross the first threshold, system will shutdown.

[Monitor:]

```
You can manually read the thermal interfaces in sysfs:
~$ cat /sys/class/thermal/thermal_zone0/temp
35000
# This means the current temperature is 35 C.
```

8.3.4 System Monitor

8.3.4.1 Power Monitor User Manual

Description

There are two methods currently we can use to measure the power consumption which are called online and offline power monitoring respectively. The difference between them is that offline power monitoring support measuring power consumption during sleep or deep sleep.

The Power Monitor can be supported on P4080DS/P5020DS/P5040DS/T4240QDS board.

This User guide uses the T4240QDS board as an example.

Online Power Monitoring

The Lm-sensors tool (download from http://dl.lm-sensors.org/lm-sensors/releases) will be used to read the power/ temperature from on-boards sensors. The drivers vary from sensor to sensor. Basically they would be INA220, ZL6100 and ADT7461 etc.

The device driver support either a built-in kernel or module loading.

Kernel Configure Tree View Options

Option	Description

Please make sure to include the "sensors" command in your rootfs

Offline Power Monitoring

Inside the FPGA of some NXP QorIQ (PowerPC) reference boards is a microprocessor called the General Purpose Processor (GSMA). Running on the GSMA is the Data Collection Manager (DCM), which is used to periodically read and tally voltage, current, and temperature measurements from the on-board sensors. You can use this feature to measure power consumption while running tests, without having the host CPU perform those measurements.

This method support measuring power consumption when kernel is in sleep or deep sleep status. It gets the average power value of period from the time DCM starts to the time it ends.

Module Loading

The device driver support either kernel built-in or module.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

`Device Drivers --->`
`[*] Misc devices  --->`
`    <*>   Freescale Data Collection Manager (DCM) driver`
	Enables DCM driver

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_FSL_DCM	y/n	y	Enable DCM module

Device Tree Binding

Property	Type	Status	Description
compatible	String	Required	"fsl,t4240qds-fpga", "fsl,fpga-qixis"
reg	Integer	Required	reg = <3 0 0x300>

```
Default node:
       ifc: localbus@ffe124000 {
             board-control@3,0 {
             compatible = "fsl,t4240qds-fpga", "fsl,fpga-qixis";
             reg = <3 0 0x300>;
       };
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/misc/fsl_dcm.c	DCM driver

Test Procedure

Do the following to validate under the Kernel:

1. The bootup information is displayed:

```
......
Freescale Data Collection Module is installed.
......
```

2. Start measuring measure power

```
# echo 1 > /sys/devices/platform/fsl-dcm.0/control
```

3. Stop measuring power

```
#echo 0 > /sys/devices/platform/fsl-dcm.0/control
```

4. Display the average power consumption

```
#cat /sys/devices/platform/fsl-dcm.0/result

Name                        Average
====================        ================
CPU voltage:                1068    (mV)
CPU current:                25910   (mA)
DDR voltage:                1348    (mV)
DDR current:                740     (mA)
CPU temperature:            38      (C)
```

8.3.4.2 Thermal Monitor User Manual

Description

The Temperature Monitoring function is provided by the chip ADT7461.

This driver exports the values of Temperature to SYSFS. The user space lm-sensors tools can get and display these values.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers ---> [*] Hardware Monitoring support ---> [*] National Semiconductor LM90 and compatibles	Enable thermal monitor chip driver like ADT7461.
Device Drivers ---> <*> I2C bus multiplexing support ---> Multiplexer I2C Chip support ---> <*> Philips PCA954x I2C Mux/switches	Enable I2C PCA954x multiplexer support

Compile-time Configuration Options

Option	Values	Default Value	Description
CONFIG_HWMON	y/m/n	n	Enable Hardware Monitor
CONFIG_SENSORS_LM90	y/m/n	n	Enable ATD7461 driver
CONFIG_I2C_MUX	y/m/n	n	Enable I2C bus multiplexing support
CONFIG_I2C_MUX_PCA954x	y/m/n	n	Enable PCA954x driver

Device Tree Binding

```
    adt7461@4c {
        compatible = "adi,adt7461";
        reg = <0x4c>;
    };

    pca9547@77 {
        compatible = "philips,pca9547";
        reg = <0x77>;
    };
```

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/hwmon/hwmon.c	Linux hwmon subsystem support
drivers/hwmon/lm90.c	ADT7461 chip driver
drivers/i2c/i2c-mux.c	I2C bus multiplexing support
drivers/i2c/muxes/pca954x.c	PCA954x chip driver

Verification in Linux

There are two ways to get temperature results.

```
1. You can manually read the thermal interfaces in sysfs:
~$ ls /sys/class/hwmon/hwmon1/devices
alarms            temp1_crit        temp1_min_alarm   temp2_max_alarm
driver            temp1_crit_alarm  temp2_crit        temp2_min
hwmon             temp1_crit_hyst   temp2_crit_alarm  temp2_min_alarm
modalias          temp1_input       temp2_crit_hyst   temp2_offset
name              temp1_max         temp2_fault       uevent
power             temp1_max_alarm   temp2_input       update_interval
subsystem         temp1_min         temp2_max

~$ cat /sys/class/hwmon/hwmon1/devices/temp1_input
29000

2. You can use lm_sensors tools as follows.
~ # sensors

adt7461-i2c-1-4c
```

```
Adapter: MPC adapter
temp1:       +34.0 C  (low  =  +0.0 C, high = +85.0 C)
                      (crit = +85.0 C, hyst = +75.0 C)
temp2:       +48.5 C  (low  =  +0.0 C, high = +85.0 C)
                      (crit = +85.0 C, hyst = +75.0 C)
```

lm_sensors is integrated into Yocto file system by default. If there is no "sensors" command in your rootfs just add lmsensors-sensors package and build your own rootfs using Yocto:

```
IMAGE_INSTALL += "lmsensors-sensors"
```

8.3.4.3 Web-based System Monitor User Guide

Monitors the health of a system using a web browser in real time.

Description

Web-based System Monitor is a tool for monitoring the health of your system using a web browser in real time. The following procedures will guide you to setup the system monitor.

Kernel requirements

The raw data of this monitor system is collected from hardware monitor chips. So before you setup this monitor system you should enable the hwmon subsystem and drivers of monitor chips in the kernel. Kernel configure details are listed below.

Kernel Configure Tree View Options	Description
Device Drivers ---> [*] Hardware Monitoring support ---> [*] National Semiconductor LM90 and compatibles [*] Texas Instruments INA219 and compatibles	Enable monitor chip drivers like ADT7461(ADT7481)/INA220, etc.
Device Drivers ---> <*> I2C bus multiplexing support ---> Multiplexer I2C Chip support ---> <*> Philips PCA954x I2C Mux/switches	Enable I2C PCA954x multiplexer support

Some monitor chips may not be included in the device tree. In this case you could add the device manually. Take adt7461 on T4240QDS as an example: the monitor is attached to I2C multiplexer PCA954x channel 3 in address 0x43. T4240QDS has 4 I2C controllers so the channel index of multiplexer start from 4 (represent the channel 0). ADT7461 is connected to channel 3 which indexed as 7. Use the flowing command to add the device to kernel:

```
~$ echo adt7461 0x4c > /sys/bus/i2c/devices/i2c-7/new_device
```

Rootfs requirements

You could use the fsl-image-full rootfs in which all packages needed are included.

Or you can build your own rootfs using Yotco. Please follow the steps below.

1. Add following package group to your rootfs recipes like fsl-image-core.bb:

```
IMAGE_INSTALL += "packagegroup-fsl-monitor"
```

2. If you are using ramdisk boot please add following settings to local.conf to get enough space for monitor systems:

```
IMAGE_ROOTFS_EXTRA_SPACE = "100000"
```

NOTE

This will add 100000KB (100MB) more space to rootfs for monitor database. Each sensor needs about 10MB more space for logging raw data.

Setting up system monitor

The monitor system will be setup automatically. What you need to do is to make sure that the network on board is working. Then you can monitor the system via any web browser by visiting: http://your.ip.address/senspix/sensors.cgi. This results page will refresh itself for every 10 seconds.

If you need to re-setup the system you could enter /usr/rrd directory and run:

```
$ make clean
$ make
```

NOTE

The System Monitor only works when system time is right. So you should guarantee that.

How to configure the system monitor

The monitor results you see is based on the configuration file: "monitor.conf". It's automatically generated by scanning the hwmon subsystem. You could manually modify it too. Here is how:

1. Each line of this configuration file represents one monitor curve. It contains four fields formatted as follows:

   ```
   SENSDEV:MONITOR_TERM:DURATION:DESCRIPTION
   ```

   SENSDEV: The sensor data can be monitored from /sys/class/hwmon/ interfaces. Each sensor has a corresponding folder distinguished by hwmon# like hwmon0 or hwmon1. SENSDEV is the folder name.

   MONITOR_TERM: This is the item you want to read like temp1 or temp2 etc.

   DURATION: This is how long you want to see the results. You can set minute/hour/day here.

   DESCRIPTION: This DESCRIPTION will show up on the result picture helping you to understand the contents of the curve.

2. You could add/remove/resort the configuration file. After modifying it, you could enter the /usr/rrd directory and run:

   ```
   $ make config
   ```

3. Then the monitor results will be updated to what you configured.

Run demo

We also provide scripts to cycle the system through different PM low power states to form a out-of-box demo for PM features. Please enter /usr/pm_demo directory and simply run:

```
$ ./pm_demo.sh
```

The output of the script will state the current PM features. It helps you to understand the system monitor results better.

NOTE

The demo could be terminated by CTRL-C and will apply the default PM features back.

8.4 Real Time Application Note

8.4.1 Application Note on Real Time

Introduction

Baseband use-cases like 3G/4G have strict timelines to accomplish some particular jobs. Real Time (RT) feature available in the operating system aims at creating an environment to meet these time critical processing requirements. There are various approaches available for providing RT feature.

NXP uses Linux PREEMPT_RT patch (also known as RT patch) to meet these requirements. PREEMPT_RT patch can be pulled from kernel.org git repository

For more information regarding PREEMPT_RT refer to kernel.org wiki page

PREEMPT_RT Patch in SDK

PREEMPT_RT patch is applied in the kernel available with this SDK. By default, RT feature is disabled in all the defconfigs of this SDK, except the one mentioned in later section.

Please note that, once one enable RT feature, throughput-performance of the system might decrease (and this decrease is expected as per design of RT).

Support Status

Hardware:	Currently supported only for P4080DS, B4860qds, TWR-LS1021A, LS1012A, LS2080
Software:	Linux (with PREEMPT_RT patch), (SMP-Linux: non KVM)

Compilation Option

Default Kernel Defconfig

Kernel Configure Option

Tree view

For enabling RT in defconfig using "make menuconfig" for kernel

Kernel Configure Tree View Options	Description

`Kernel options  --->`
`  Preemption Model (Fully Preemptible Kernel (RT))  --->`
`  (X) Fully Preemptible Kernel (RT)`
	These options enable RT in Linux.

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value to enable RT	Description
CONFIG_SLAB	y/n	y	Enable SLAB Support

Table continues on the next page...

Table continued from the previous page...

Option	Values	Default Value to enable RT	Description
CONFIG_HIGHMEM	y/n	n	Disable highmem support
CONFIG_PREEMPT_RT_FULL	y/n	y	Enable Full RT support

Device Tree Binding

No RT specific changes required

Verification in Linux

To verify that PREEMPT_RT Patch is applied and RT is enabled in Linux configuration after Linux has booted, check Linux version on Linux prompt, one should see pattern “PREEMPT RT” in the version string. Eg:

```
root@bsc913x:~# uname -a

Linux bsc913x 3.8.13-rt6+ #52 PREEMPT RT Wed May 22 12:26:51 IST 2013 ppc GNU/Linux
```

Test Tool

RT-tests suit contains various test applications like cyclictest, hackbench, etc to measure latencies and induce various test loads. It come as package in yocto (can be build in rootfs) or can be downloaded from kernel.org git repository.

NOTE

PREEMPT_RT feature provides RTT (Real Time throttling) feature. For details on RTT, refer to “Documentation/scheduler/sched-rt-group.txt” in Linux source code. RTT might get triggered in case of heavy traffic leading to high latency. It can be disabled by:

```
[root@bsc913x]#echo -1 > /proc/sys/kernel/sched_rt_runtime_us
```

Supporting Documentation

https://rt.wiki.kernel.org

Known Limitations

On non-DPAA SoCs like LS1021, LS1021 with PREEMPT_RT enabled kernel, while running IPv4 forwarding benchmarking scenarios (including the IPSec forwarding benchmark) or pi-stress test-case, which are inherently CPU and traffic intensive, sometimes RCU stalls dumps were observed in dmesg. There is no negative impact on occurrence of this RCU stall dumps, the system continues to run as before.

(For IPv4, IPSEC forwarding test-cases, refer to Benchmark Reproducibility Guides in SDK documentation). Note: TCP/UPD Termination testing does not cause this issue even though CPU utilization is 100%.

Workaround: The above kind of use-case for a real-time device is unlikely. If the above kind of scenario is expected to occur in a device, the device should have some provisions to reduce the CPU load by throttling the low priority jobs.Or limit the traffic. Or use TCP/UDP terminating type traffic

8.5 C29X Card Use Cases

8.5.1 C29x SKMM User Manual

8.5.1.1 Introduction

SKMM is a software application for managing (generating, storing and retrieving) keys in a secure manner. This kind of applications is knwon in the technical literature as Secure Key Management software. The security is provided by the use of a C293 Crypto Coprocessor, which connects to the host via the PCIe bus and is optimized for public key operations.

SKMM is made up of two software components:

- skmm-ep - a userspace application running on the C293 device
- skmm-host - a driver used on the host which can be either P4080 development board or x86 machine

The SKMM supports only one of the following hardware configurations:

- P4080 host with C293 device
- x86 host with C293 device

This document details the procedure to configure, build, run and tests for the SKMM software application.

Prerequistes

Before building the images download the latest NXP SDK on a Linux machine which will be called the build machine. For the rest of the documentation the base directory for the sdk will be specified as <sdk-dir>.

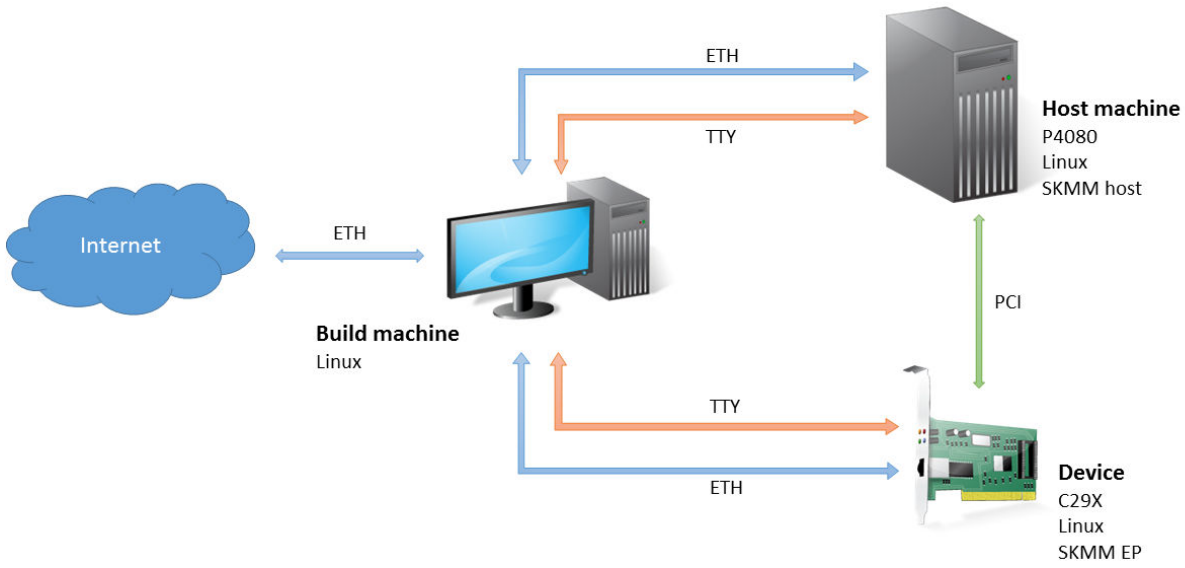
The code for both components is located in the <sdk-dir>/sources directory.

8.5.1.2 Hardware setup

This section details the hardware setup and configuration used.

SKMM Setup for PPC Based Host Systems

This section describes the basic setup used for configuring SKMM as a host-device application.



The device is a C293 board on which a user space application SKMM-EP (SKMM end-point) runs over a custom built Linux image. The device is connected via PCI to the Host, which in this setup is a P4080 machine, that contains the SKMM host module which is a kernel driver that exposes through different interfaces the cryptographic capabilities of the C293 board. Both the device and the host run a custom Linux image that is prepared on the build machine via the bitbake utility. A Linux image consists of three files: the kernel image, the device tree file and the ramdisk file. These files are transfered to the corresponding destination machine using the TFTP protocol via the ETH link and then booted from the UBoot console. The serial link (TTY) serves as a means to access the UBoot consoles from the build machines and later, after boot, the Linux console. To access the images from the destination machines the build machine should have a TFTP server installed and the build files should be accessible from the TFTP shared folder. Additionally the build machine should be able to access the internet in order to retrieve third party software that is bundled in with the Linux image created.

SKMM Setup for X86 Hosts

When using an Intel x86 machine as a host the usual setup is the one in the image above. Here the host is also used as the build machine. For this setup the host Linux image is the one provided by the chosen distro and the SKMM host driver is built against the distos kernel header files. Currently we support only Ubuntu 12.04 and CentOS 3.10.0-229.7.2 64 bits.

C293 card switch settings

This section provides the details applicable to the NXP C293 PCIe development platform. These switch settings may not be valid for other version of cards.

For SKMM mode booting from NOR flash, the switches are set as the following:

```
SW4: 01011000
SW5: 11110000
SW6: 00001111
SW7: 10000111
SW8: 00000001
```

1 = OFF, 0 = ON.

Here is the corresponding frequency of different blocks:

```
CPU: 800 MHz
CCB: 400 MHz
DDR: 400 MHz (800MT/s)
IFC: 100 MHz
```

Device Detection

For x86 you can validate the presence of the C293 PCIe Card by running "sudo lspci -vvv" command. Please note that you must run the command as root to have a usefull degree of verbosity. Otherwise not enough information may be presented to the console. The following is an example output:

```
$sudo lspci -vvv
04:00.0 Power PC: Freescale Semiconductor Inc Device 0800 (rev 10) (prog-if 01)

```

8.5.1.3 Build Procedure

The build process is done via the bitbake tool. For C293 and P4080 SKMM software components (skmm-ep for C293 and skmm-host driver for P4080) are included in the images. For x86 building and running is done on the same machine and has some particularities that will be provided in the corresponding chapter.

C293 - Firmware (building and deployment)

Building C293 images cand be done in the following sequence of steps:

- **Generate build directories**

  This step is only required if the build directory has not been previously generated.

```
$ cd <sdk-devel>
$ source fsl-setup-env -m c293pcie -j 4 -t 4 -l
```

- **Clear configuration**

This step is only required if P4080 images are generated using the same sdk directory and a P4080 image has been previously built.

```
$ bitbake -c cleansstate virtual/kernel
```

- **Configure the kernel**

```
$ bitbake -c menuconfig virtual/kernel
```

Disable hardware crypto devices, MMC/SD/SDIO card support and enable userspace I/O driver:

```
Cryptographic API  ---
    [ ]   Hardware crypto devices  ----

Device Drivers  --->
    < > MMC/SD/SDIO card support ----
    <*> Userspace I/O drivers  --->
        <*> Freescale SEC support
```

- **Build image**

```
$ bitbake fsl-image-core
```

- **Copy binaries**

The resulting binaries will be copied to the tftp server directory called <tftpboot-dir>

```
$ cd tmp/deploy/images/c293pcie/
$ cp uImage-c293pcie.bin <tftpboot-dir>
$ cp uImage-c293pcie.dtb <tftpboot-dir>
$ cp fsl-image-core-c293pcie.ext2.gz.u-boot <tftpboot-dir>
$ cp u-boot-c293pcie.bin <tftpboot-dir>
```

P4080 - Linux Kernel SKMM Host Driver (build and deployment)

Build P4080 images with the following sequence of steps:

- **Generate build directories**

This step is only required if the build directory has not been previously generated.

```
$ cd <sdk-devel>
$ source fsl-setup-env -m p4080ds -j 4 -t 4 -l
```

- **Clear configuration**

This step is only required if C293 images are generated using the same sdk directory and a C293 image has been previously build.

```
$ bitbake -c cleansstate virtual/kernel
```

- **Build image**

```
$ bitbake fsl-image-core
```

- **Copy binaries**

The resulting binaries will be copied to the tftp server directory called <tftpboot-dir>

```
$ cd tmp/deploy/images/p4080ds
$ cp uImage-p4080ds.bin <tftpboot-dir>
$ cp uImage-p4080ds.dtb <tftpboot-dir>
$ cp fsl-image-core-p4080ds.ext2.gz.u-boot <tftpboot-dir>
$ cp u-boot-P4080DS.bin <tftpboot-dir>
$ cp rcw/R_PPPNN_0x5/rcw_rc_1500mhz.bin <tftpboot-dir>
```

x86 - Linux Kernel SKMM Host Driver (build and deployment)

It is assumed that the build machine is also the target for the purpose of testing. Cross-building for x86 machines is out of the scope of this manual. Driver compilation has been verified for CentOS 3.10.0-229.7.2 64bit and Ubuntu 12.04. Please use the same version to avoid dependency related errors.

NOTE

If the SDK directory doesn't contain the skmm-host director (which is the case when downloading the ISO image from the NXP site) you can get it from the following freescale repository:

```
$ git clone git://git.freescale.com/ppc/sdk/skmm-host.git -b sdk-
v2.0.x
```

Follow the following sequence of steps to generate the skmm-host and cryptodev kernel modules and OpenSSL userspace application:

- **Apply patches**

  Paching is required before building and runnign skmm-host driver. The patches are located at <sdk-dir>/sources/skmm-host/crypto-patches. These patches were created on kernel version 3.11.0-15 and if their application fails, apply them manually.

```
$ cd /lib/modules/$(uname -r)/build/include/linux/
$ patch -p0 < <sdk-dir>/sources/skmm-host/crypto-patches/crypto-add-pkc-support.patch
$ cd /lib/modules/$(uname -r)/build/include/crypto/
$ patch -p0 < <sdk-dir>/sources/skmm-host/crypto-patches/algapi-add-pkc-support.patch
```

- **Build driver**

```
$ cd <sdk-dir>/sources/skmm-host
```

- **Configure driver**

  Edit Makefile:

```
EXTRA_PKC = 'y'
```

- **Build driver**

```
$ make ARCH=x86
```

Building OpenSSL

Building OpenSSL is only needed for functional tests and not required for performance tests.

For PPC hosts (P4080) both cryptodev and OpenSSL are built during kernel build through the bitbake recipe. After booting the kernel the user can simply insert the cryptodev.ko module and run the OpenSSL commands as both resources are available at boot time.

For x86 hosts additional steps must be followed.

- **Build cryptodev**

```
$ cd <sdk-dir>/sources/cryptodev
$ make
$ sudo make modules_install
$ sudo install -D crypto/cryptodev.h /usr/include/crypto/cryptodev.h
```

- **Build OpenSSL**

```
$ cd <sdk-dir>/sources/openssl
$ make clean
$ ./config --prefix=/usr/local --openssldir=/usr/local/openssl shared -DHAVE_CRYPTODEV
$ make
$ sudo make install
$ sudo ldconfig
```

8.5.1.4 Run SKMM

For SKMM to work properly the following startup order must be followed:

- boot C293 device
- run SKMM-EP
- boot host
- insert SKMM driver

Boot C293 device - Boot Kernel Image and Run SKMM EP Application

- **Boot C293 Kernel Image**

  Booting cand be done in one of two ways:

  1. **Flash boot**

```
setenv bootargs "root=/dev/ram rw ramdisk_size=800000 console=ttyS0,115200 cache-
sram=0xfffa00000,0x40000 $otherbootargs"
setenv linuxfile <tftpboot-dir>/uImage-c293pcie.bin
setenv fdtfile <tftpboot-dir>/uImage-c293pcie.dtb
setenv ramdiskfile <tftpboot-dir>/fsl-image-core-c293pcie.ext2.gz.u-boot

setenv loadaddr 1000000

setenv linuxaddr ec000000
setenv fdtaddr ecf00000
setenv ramdiskaddr ed000000

protect off all
tftp $loadaddr $linuxfile && erase $linuxaddr +$filesize && cp.b $loadaddr $linuxaddr $filesize
tftp $loadaddr $fdtfile && erase $fdtaddr +$filesize && cp.b $loadaddr $fdtaddr $filesize
tftp $loadaddr $ramdiskfile && erase $ramdiskaddr +$filesize && cp.b $loadaddr $ramdiskaddr
$filesize
protect on all

setenv bootcmd 'bootm $linuxaddr $ramdiskaddr $fdtaddr'
saveenv

boot
```

2. **TFTP boot**

```
setenv bootargs "root=/dev/ram rw ramdisk_size=800000 console=ttyS0,115200 cache-
sram=0xfffa00000,0x40000 $otherbootargs"
setenv linuxfile <tftpboot-dir>/uImage-c293pcie.bin
setenv fdtfile <tftpboot-dir>/uImage-c293pcie.dtb
setenv ramdiskfile <tftpboot-dir>/fsl-image-core-c293pcie.ext2.gz.u-boot

setenv linuxaddr 1000000
setenv fdtaddr c00000
setenv ramdiskaddr 2000000

setenv bootcmd 'tftp $linuxaddr $linuxfile && tftp $fdtaddr $fdtfile && tftp $ramdiskaddr
$ramdiskfile && bootm $linuxaddr $ramdiskaddr $fdtaddr'
saveenv

boot
```

Run SKMM-EP Application

After booting the board using the SDK image, login as root (no password) and run SKMM application:

```
$ flash_erase /dev/mtd3 0 0
$ skmm fffa00000
```

At this point the skmm application will wait for host driver handshake.

You can specify the l2sram address by giving one argument to skmm application to avoid the platform SRAM LAW setting conflict with other LAWs, for example: skmm fffa00000. The size of l2sram is 1M Bytes. You can use command reginfo checking LAWs setting in u-boot prompt. If you do not give any argument or give more than one argument, it will use the default address 0xfffa00000.

Deploy SKMM-Host Kernel Driver on Host Machine

- **Boot Host Kernel Image**

```
setenv bootargs "root=/dev/ram rw ramdisk_size=800000 console=ttyS0,115200 $otherbootargs"
setenv linuxfile <tftpboot-dir>/uImage-p4080ds.bin
setenv fdtfile <tftpboot-dir>/uImage-p4080ds.dtb
setenv ramdiskfile <tftpboot-dir>/fsl-image-core-p4080ds.ext2.gz.u-boot

setenv linuxaddr 1000000
setenv fdtaddr c00000
setenv ramdiskaddr 2000000

setenv bootcmd 'tftp $linuxaddr $linuxfile && tftp $fdtaddr $fdtfile && tftp $ramdiskaddr
$ramdiskfile && bootm $linuxaddr $ramdiskaddr $fdtaddr'
saveenv

boot
```

Login with user "root" and no password.

Insert SKMM Driver

When inserting the SKMM driver a configuration file called "crypto.cfg" can be provided that is located at <sdk-dir>/sources/skmm-host. It has a pseudo-xml structure and can configure the firmware path and the ring pairs. Each ring contains the following details:

depth	Ring size.
affinity	Sec engine affinity.
priority	Relative priority of rings.
order	Whether the ring processing is ordered or not.

Users can create a maximum of 6 rings. If the ring configuration needs to be changed, the driver must be unloaded and reloaded for the new configuration to take effect. The command ring is disabled when HIGH_PERF_MODE flag is set in Makefile.

After configuration step insert the skmm and cryptodev driver:

```
insmod /lib/modules/$(uname -r)/extra/fsl_skmm_crypto_offload_drv.ko dev_config_file=/etc/skmm/
skmm_crypto.cfg
```

After all the operations have been completed, the following prints can be seen in kernel logs

```
$ dmesg |tail
[FSL-CRYPTO-OFFLOAD-DRV] DevId:1 DEVICE IS UP
cryptodev: driver 2.0 loaded.
```

Driver is up now, and it can be used to send crypto operations.

Deploy SKMM-Host Kernel Driver on x86 Host Machine

For x86 machines the kernel has already been booted. The only thing left to do is to just insert the SKMM-Host kernel driver. Go to the skmm-host directory, where it has been built, and run the following commands:

```
$ cd <sdk-dir>/sources/skmm-host
$ insmod fsl_skmm_crypto_offload_drv.ko dev_config_file=./crypto.cfg
```

Known Issues

- the skmm driver will not work if hyperthreading is disabled on the host kernel (for example by means of using boot argument smt-enabled=off)

8.5.1.5 Function Test

OpenSSL

Standard openSSL does not support SKMM offload in cryptodev engine. A version of OpenSSL tweaked for SKMM has been included and maintained in the build for demonstration purposes.

Before performing these tests first you have to build cryptodev and openSSL. Please refer to chapter "Build Procedure", sub-chapter "Building OpenSSL". After this step you are required to insert the cryptodev module. For PPC systems the cryptodev modules comes bundled with the kernel images so inserting the kernel is done via modprobe:

```
$ modprobe cryptodev.ko
```

For x86 systems you have go to the cryptodev directory, where it has been built, and to manually insert the module:

```
$cd <sdk-dir>/sources/cryptodev.ko
$sudo insmod cryptodev.ko
```

Supported tests

SKMM supports RSA 1k 2k 4k and DSA 1k 2k 4k crypto operations. Only the sequence of commands presented bellow has been tested.

Run the following commands on the host side for function test:

```
# echo "1234567890" > a
```

RSA 1k:

```
# openssl genrsa -out rsa.key_1024 1024 -engine cryptodev
# openssl rsa -in rsa.key_1024 -pubout -out rsa.pub_1024
# openssl rsautl -encrypt -in a -pubin -inkey rsa.pub_1024 -out e_a -engine cryptodev
# openssl rsautl -decrypt -in e_a -inkey rsa.key_1024 -out aa -engine cryptodev
# diff a aa
```

RSA 2k:

```
# openssl genrsa -out rsa.key_2048 2048 -engine cryptodev
# openssl rsa -in rsa.key_2048 -pubout -out rsa.pub_2048
# openssl rsautl -encrypt -in a -pubin -inkey rsa.pub_2048 -out e_a -engine cryptodev
# openssl rsautl -decrypt -in e_a -inkey rsa.key_2048 -out aa -engine cryptodev
# diff a aa
```

RSA 4k:

```
# openssl genrsa -out rsa.key_4096 4096 -engine cryptodev
# openssl rsa -in rsa.key_4096 -pubout -out rsa.pub_4096
# openssl rsautl -encrypt -in a -pubin -inkey rsa.pub_4096 -out e_a -engine cryptodev
# openssl rsautl -decrypt -in e_a -inkey rsa.key_4096 -out aa -engine cryptodev
# diff a aa
```

DSA 1k:

```
# openssl dsaparam -out dsa.param_1024 1024
# openssl gendsa -out dsa.key_1024 -engine cryptodev dsa.param_1024
# openssl pkey -in dsa.key_1024 -pubout -out dsa.pub_1024
# openssl pkeyutl -sign -in a -inkey dsa.key_1024 -out s_a -engine cryptodev
# openssl pkeyutl -verify -in a -sigfile s_a -pubin -inkey dsa.pub_1024 -engine cryptodev
```

DSA 2k:

```
# openssl dsaparam -out dsa.param_2048 2048
# openssl gendsa -out dsa.key_2048 -engine cryptodev dsa.param_2048
# openssl pkey -in dsa.key_2048 -pubout -out dsa.pub_2048
# openssl pkeyutl -sign -in a -inkey dsa.key_2048 -out s_a -engine cryptodev
# openssl pkeyutl -verify -in a -sigfile s_a -pubin -inkey dsa.pub_2048 -engine cryptodev
```

DSA 4k:

```
# openssl dsaparam -out dsa.param_4096 4096
# openssl gendsa -out dsa.key_4096 -engine cryptodev dsa.param_4096
# openssl pkey -in dsa.key_4096 -pubout -out dsa.pub_4096
# openssl pkeyutl -sign -in a -inkey dsa.key_4096 -out s_a -engine cryptodev
# openssl pkeyutl -verify -in a -sigfile s_a -pubin -inkey dsa.pub_4096 -engine cryptodev
```

8.5.1.6 Performance Test

Introduction

SKMM supports kernel space performance test.

Before any performance test the private keys in the blob mtd bloc 3 on c293pcie board must be removed:

```
c293# flash_erase /dev/mtd3 0 0
```

SKMM test script "c29x_skmm_perf_profile.sh" is used to do performance test in kernel space. The test script can be found at:

```
skmm-host/perf
```

The test script may be run either by invoking the test script from its original directory or by copying it to a directory visible by the operating system:

```
sudo cp skmm-host/perf/c29x_skmm_perf_profile.sh /usr/bin
```

In the examples below we will asume the ladder strategy.

Supported Tests

SKMM supports RSA 1K, 2K, 4K both public and private operations and DSA 1K, 2K, 4K sign and verify operations. Please note that DSA signature test must be run before DSA verification test. This is how the test are run:

- RSA public key 1K, 2K, 4K:

```
HOST# sh c29x_skmm_perf_profile.sh RSA_PUB_OP_1K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh RSA_PUB_OP_2K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh RSA_PUB_OP_4K -m 0xe0 -t 2 -s 3
```

- RSA private key 1K, 2K, 4k:

```
HOST# sh c29x_skmm_perf_profile.sh RSA_PRV_OP_1K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh RSA_PRV_OP_2K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh RSA_PRV_OP_4K -m 0xe0 -t 2 -s 3
```

- DSA signature 1K, 2K, 4K:

```
HOST# sh c29x_skmm_perf_profile.sh DSA_SIGN_TEST_1K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh DSA_SIGN_TEST_2K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh DSA_SIGN_TEST_4K -m 0xe0 -t 2 -s 3
```

- DSA verify 1K, 2K, 4K:

```
HOST# sh c29x_skmm_perf_profile.sh DSA_VERIFY_TEST_1K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh DSA_VERIFY_TEST_2K -m 0xe0 -t 2 -s 3
HOST# sh c29x_skmm_perf_profile.sh DSA_VERIFY_TEST_4K -m 0xe0 -t 2 -s 3
```

Usage

The "c29x_skmm_perf_profile.sh" accepts the following configuration parameters:

Argument	Value	Description
-m	cpu mask	Test threads will be created on the CPUs masked by the value in above option.
-t	thread per cpu	Number of threads per cpu.
-s	Test duration in seconds.	The length of the test specified in seconds
-r	Test enqueue-dequeue count.	The length of the test specified in the actual number of enqueued-dequeued tests

Table continues on the next page...

Notes:

- The test can be stopped at any time by pressing CTRL+C
- If both configuration parameters '-s' and '-r' are given the 's' has precedence.
- For a full list of configuration parameters run:

```
$ c29x_skmm_perf_profile.sh --help
```

- On success the test script outputs something akin to:

```
******** Result ***********
Test Name:
Host CPU Frequency:
# job finished successfully:
Per job in us:
Total jobs in 1 sec:
```

8.5.2 PK Calculator User Guide

8.5.2.1 Hardware setup

C293PCIe Switch Settings

This section provides details applicable to the NXP C293 PCIe development platform. These switch settings may not be valid for other version of cards. For PKC mode, the switches are set as following:

```
SW4: 01011000
SW5: 11110000
SW6: 00001111
SW7: 00000111
SW8: 00000001

1:OFF 0:ON
```

In particular, the following switches affect the behaviour of the board. See "C29x PCIe Card Quick Start Guide" for different configurations.

```
SW7[1]   - ON (0) - hold-off boot
SW7[2-4] - ON ON ON  (000) for PCIe-x4 5GHz or
           ON ON OFF (001) for PCIe-x4 2.5GHz
```

Device Detection

Run "sudo lspci" or "sudo lspci –vvv" to check the presence of the C293 card. Depending on the actual lspci binary beeing used (busybox or true lspci), you can find more details about the installed board:

```
01:00.0 Power PC: NXP Semiconductors Inc Device 0800 (rev 10) (prog-if 01)
        Control: I/O+ Mem+ BusMaster+ SpecCycle- MemWINV- VGASnoop- ParErr- Stepping- SERR-

8.5.2.2 Build Procedure

PKC host driver Build Configuration

These are the build time parameters that can be changed in the Makefile.

Variable name	Default Value	Description
DEBUG_PRINT	N	Defines the print level. If set to 'y', debug level prints will be enabled.
INFO_PRINT	N	Defines the print level. If set to 'y', info level prints will be enabled.
DEBUG_DESC	N	Enable/disable descriptors debug-print
ENHANCE_KERNEL_TEST	N	Enhance PKC kernel test performance by disabling kernel test schedule

Prerequisites

- NXP SDK
- For x86 targets, two kernel patches must be applied before building the PKC driver. These are header patches provided with the PKC driver sources. For powerpc or arm , no kernel patching is necessary.

Build Driver for PowerPC or ARM

The binaries for pkc-host, cryptodev and openssl packages are delivered with fsl-image-core. No additional steps are necessary.

Build Driver for x86

This section details the manual build procedure for x86 targets. It is assumed that the build machine is also the target for the purpose of testing. Cross-building for x86 machines is out of the scope of this manual. After installing the SDK, sources of pkc-host, cryptodev and openssl will be available in:

```
<sdk_dir>/sources/
```

Before building the pkc-host module, as root, apply PKC patches to kernel headers. Kernel rebuild is not necessary after patching:

```
# cd /lib/modules/$(uname -r)/build/include/linux/
# patch -p0 < path_to/pkc-host/crypto-patches/crypto-add-pkc-support.patch
# cd /lib/modules/$(uname -r)/build/include/crypto/
# patch -p0 < path_to/pkc-host/crypto-patches/algapi-add-pkc-support.patch
```

Build pkc-host driver

```
$ cd path_to/pkc-host
$ make
$ sudo make modules_install
$ sudo install -D images/pkc-firmware.bin /etc/crypto/pkc-firmware.bin
$ sudo install perf/c29x_driver_perf_profile.sh /usr/bin/c29x_driver_perf_profile.sh
```

Build cryptodev and openssl for user-space testing:

```
$ cd path_to/cryptodev-module
$ make
$ sudo make modules_install
$ sudo install -D crypto/cryptodev.h /usr/include/crypto/cryptodev.h
```

```
$ cd path_to/openssl
$ make clean
$ ./config --prefix=/usr/local --openssldir=/usr/local/openssl shared -DHAVE_CRYPTODEV
```

```
$ make
$ sudo make install
```

```
To refresh the linker cache with newly added openssl library:
$ sudo ldconfig
```

8.5.2.3 Driver Configuration

This list shows the parameters can be provided to the driver:

Parameter	Default value	Description
napi_poll_count	1	Specifies how many times the worker threads should be polling for new jobs after the stream of jobs stopped. Workers stay on a stream until it dries and then either return or poll for new jobs as specified by this parameter

Examples:

```
modprobe fsl_crypto_offload_drv.ko
```

```
modprobe fsl_crypto_offload_drv.ko napi_poll_count=2
```

8.5.2.4 Performance Test

The PKC driver is delivered together with a kernel performance test. This test allows a quick check of the driver functionality and raw performance. For user-space testing, NXP SDK has PKC enabled versions of openssl and cryptodev. The upstream versions of openssl and cryptodev do not have PKC offloading support and can't be used for PKC driver testing.

Kernel test

The test consist of a user shell script and a driver block that communicates with this script. This user-space shell script sends commands to the kernel driver though /sysfs. The script must be run as root and the driver must be loaded before running the script. Without any parameters, the script will print a help screen:

```
$ c29x_driver_perf_profile.sh
or
$ c29x_driver_perf_profile.sh --help
```

Usage:

```
$ sudo c29x_driver_perf_profile.sh <test_name> [option]...
```

Option	Value	Description
-m	cpu mask	Test threads will be created on the CPUs identified by the mask
-t	threads per cpu	Number of threads per cpu (defaults to one)
-s	seconds	Test execution time
-r	job count.	The test will execute the specified number of jobs

NOTE

Tests can be stopped at any time with CTRL-C. If both -s and -r are specified, then -s is selected by the test script. If the driver was built with ENHANCE_KERNEL_TEST=y the load on the CPU will increase and the test script may miss CTRL-C signals. In this case, always run the script with -s option to stop it after a certain time.

NOTE

The test script accepts options only in the order given by the help screen. Options in arbitrary order are not supported.

Example:

```
$ sudo modprobe fsl_crypto_offload_drv.ko

$ sudo c29x_driver_perf_profile.sh RSA_PUB_OP_2K
$ sudo c29x_driver_perf_profile.sh RSA_PUB_OP_1K -m 0xf -t 1 -s 10
$ sudo c29x_driver_perf_profile.sh RSA_PUB_OP_1K -m 0xf -t 1 -r 100000
```

See the following list for available tests:

```
1. RSA_PUB_OP_1K
2. RSA_PUB_OP_2K
3. RSA_PUB_OP_4K
4. RSA_PRV_OP_1K

Openssl

For user-space tests with openssl, both pkc and cryptodev drivers must be loaded. Only RSA and DSA tests are supported with OpenSSL

```
$ sudo modprobe fsl_crypto_offload_drv.ko
$ sudo modprobe cryptodev.ko

$ openssl speed -multi 10 -elapsed rsa -engine cryptodev
```

8.6 PCIe DMA Test User Manual

8.6.1 Introduction to PCI DMA Test

Introduction

When NXP PCIE controller working in EP mode, it can be connected to a host such as x86 computer or PowerPC board, and works as a PCI device. The PCI DMA test application is for the scenario and is used to test PCI memory write performance. It contains two parts. One is PCI DMA EP application running on EP side, the other is PCI DMA host driver module running on host side.

Test Environment

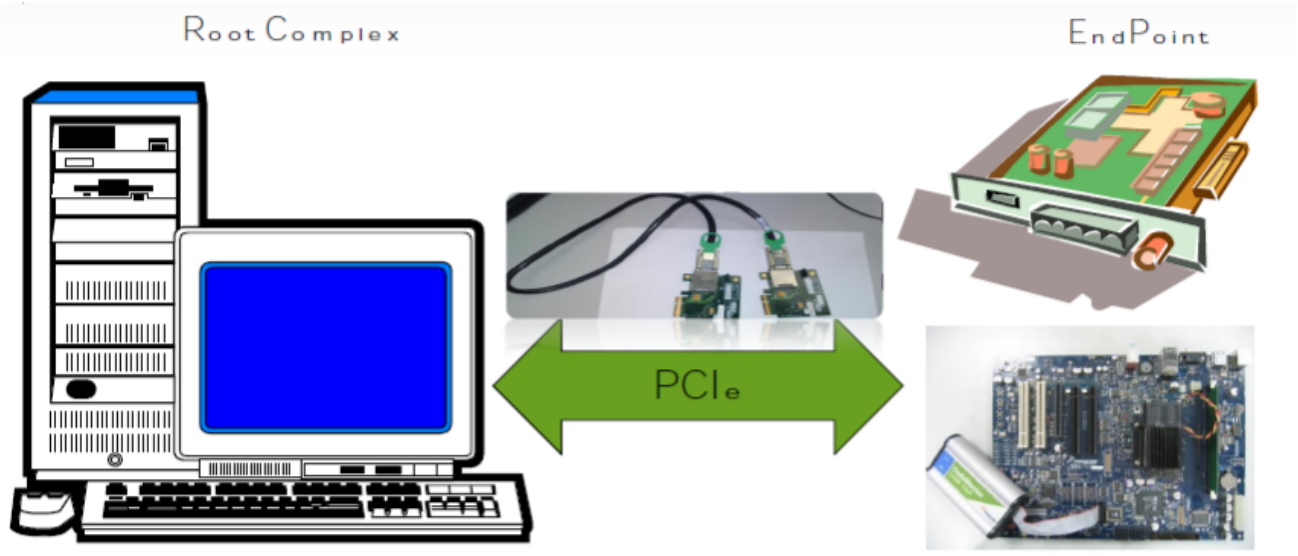

Figure 188. Test environment

As the above figure shown, we can directly insert the PCI card into host or use PCI card and cable to connect host and EP board.

Host side supports x86 and PowerPC boards.

EP side supports P5020DS, T4240QDS.

Data processing

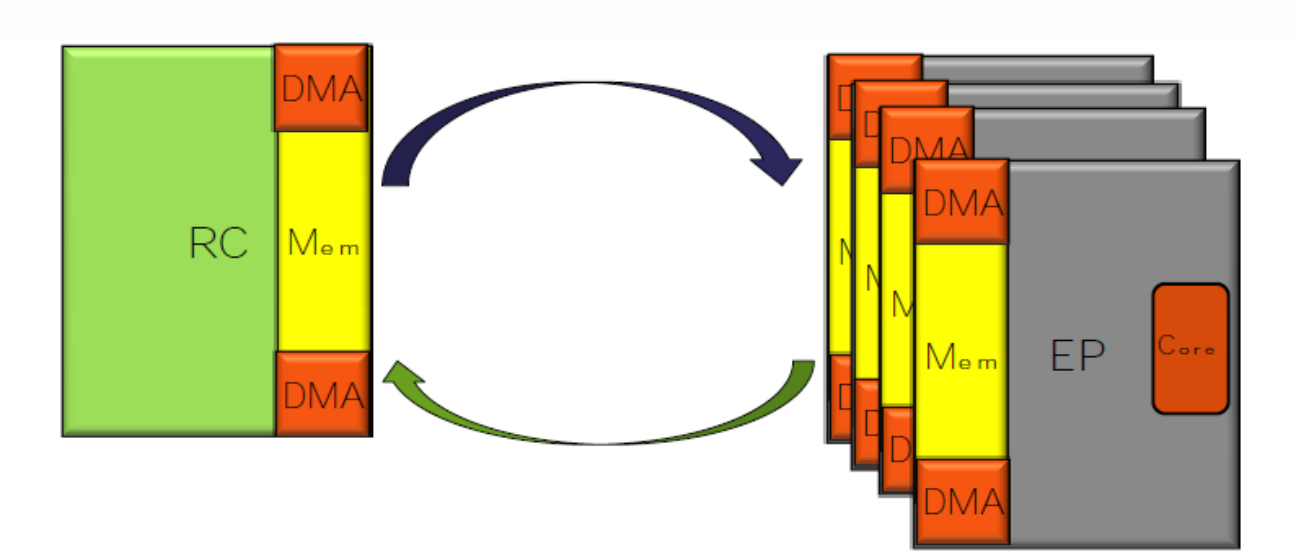

Figure 189. Data processing

As the above figure shown, EP may include multiple functions, each function is looked as a PCI device. EP application will initialize all the functions, allocate memory to store the data from host, and can write data to host. In host side, the driver module also allocates memory to store the data from EP, and can write data to the specified EP.

8.6.2 PCI DMA EP Application

Introduction

PCI DMA EP application is a user space application running on EP side. It initializes all the PCI functions of the specified PCI controller. For T4240QDS, the first PCI controller contains two physical functions and each physical function supports 64 virtual functions. Each function is looked as a PCI DMA device indexed by PF index and VF index, and is created three or four inbound windows.

1. Inbound window 0 is associated with BAR0 mapped to CCSR. Only enabled for Physical function.
2. Inbound window 1 is associated with BAR1, which is used for MSIX.
3. Inbound window 2 is associated with BAR2, which is used to store configuration information including RC command, EP status and test result.
4. Inbound window 3 is associated with BAR4, which is used to receive data from host.

The application can create a test thread on a specified PCI DMA device. Test thread will wait for host command and start performance test.

EP Kernel Image

PCI DMA EP application depends on DMA UIO driver and PCI EP VFIO driver. please make sure the two drivers are selected when compiling the EP kernel image.

```
 -> Device Drivers
     ->VFIO Non-Privileged userspace driver framework
         <*>   VFIO support for NXP PCI Endpoint devices

     -> Userspace I/O drivers
<*>   NXP DMA support
```

Compile EP Application

1. Use yacto to compile EP application.

   The detailed information can refer to SDK documents.

```
#> bitbake fsl-image-core
```

2. Directly Compile EP application

   a. Get the code and move them to sdk folder.

```
git clone git://git.am.freescale.net/gitolite/sdk/skmm-ep.git
git checkout remotes/origin/pciedma_multi_chan_perf -b pciedma_multi_chan_perf
```

   b. Configure the compile environment

```
lmh@lmh:~/work/sdk-devel-gerrit/skmm-ep$ source standalone-env -m t4240qds
```

   c. Compile code

```
lmh@lmh:~/work/sdk-devel-gerrit/skmm-ep$ make
 [CC] common.c          (lib:skmm_common)
 [AR] libskmm_common.a
 [CC] skmm_pci.c        (lib:skmm_pci)
 [AR] libskmm_pci.a
 [CC] skmm_sec.c        (lib:skmm_sec)
 [AR] libskmm_sec.a
 [CC] skmm_ddr.c        (lib:skmm_mem)

 [CC] ecdh.c            (bin:skmm)
```

```
  [LD] skmm
  [CC] pciep_dma.c      (bin:pciep_dma)
  [LD] pciep_dma
```

Run EP Application

The EP application is named pciep_dma and locates skmm-ep/bin folder. We can directly run this application on EP side, for example:

```
root@p5020ds:~# ./pciep_dma  0
Initialized pci0-pf0
pcidma>
```

The following commands are provided to perfom the PCI DMA performance test.

1. help: list the available command

   ```
   pcidma> help
   Available commands:
   list
   rm
   add
   dump
   info
   help
   ```

2. add : create a test thread on the specified PF/VF waiting the RC command to start the performance test .

   The command format:

   ```
   add [pf idx] [vf idx]
   ```

   For example:

   ```
   pcidma> add 0 0
   pcidma> Starting a pci0-pf0's test thread on cpu1
   ```

3. rm : remove the test thread

   The command format:

   ```
   rm [pf idx] [vf idx]
   ```

   For example:

   ```
   pcidma> rm 0 0
   Leaving pci0-pf0's test thread on cpu1
   ```

4. list : list all the running test thread

   The command format:

   ```
   list
   ```

   For example:

   ```
   pcidma> list
   pci0-pf0's test thread is runing on cpu0
   ```

5. info : display the inbound/outbound/Registers/configuration windows information.

   The command format:

```
 info [PF index][VF index]
```

   For example:

```
  pcidma> info 0 0
PCI EP device pci0-pf0 info:
 type: PF

Outbound windows:
Win0: cpu_addr:0x0 pci_addr:0x0 size:0x1000000000 attr:0x80044023  vfio_off:0x10000000000
Win1: cpu_addr:0xc00000000 pci_addr:0x100f1400000 size:0x400000 attr:0x80044015  vfio_off:

Win2: cpu_addr:0xff8000000 pci_addr:0x0 size:0x10000 attr:0x8008800f  vfio_off:0x12000000000
Win3: cpu_addr:0x0 pci_addr:0x0 size:0x0 attr:0x0  vfio_off:0x13000000000
Win4: cpu_addr:0x0 pci_addr:0x0 size:0x1000000000 attr:0x44023  vfio_off:0x14000000000

Inbound windows:
Win0: cpu_addr:0xffe000000 pci_addr:0xe0000000 size:0x1000000  attr:0x80e44017  vfio_off:0x0
Win1: cpu_addr:0xe0000000 pci_addr:0xe1000000 size:0x2000  attr:0xa0f5500c  vfio_off:
0x1000000000
Win2: cpu_addr:0xe0002000 pci_addr:0xe1002000 size:0x1000  attr:0xa0f5500b  vfio_off:
0x2000000000
Win3: cpu_addr:0xe0400000 pci_addr:0xe1400000 size:0x400000  attr:0xa0f55015  vfio_off:
0x3000000000

Registers window:
cpu_addr:0xffe200000 size:0x1000 vfio_off:0x40000000000

 PCI configurations window:
cpu_addr:0x0 size:0x0 vfio_off:0x50000000000
pcidma>
```

6. dump : dump the Hexadecimal values of the registers, EP configuration local buffer and remote buffer on the function

   The command format:

```
dump [pf idx] [vf idx] [reg config msix local_buffer remote_buffer] [length]
```

   For example:

```
pcidma> dump 0 0 local_buffer
dump local_buffer:
00000000: 0xa5a5a5a5 0xa5a5a5a5 0xa5a5a5a5 0xa5a5a5a5

0000000c: 0x00000000 0x00000000 0x00000000 0x00000000
pcidma>  dump 0 0 config
dump config:
00000000: 0x00000000 0x00000000 0x00000000 0x00000000
00000004: 0x00000000 0x00000000 0x00000000 0x00000000
```

```
00000008: 0x00000000 0x00000000 0x00000000 0x00000000
0000000c: 0x00000000 0x00000000 0x00000000 0x00000000
```

8.6.3 PCI DMA Host Driver Module

Introduction

PCI DMA host driver module is a PCI driver module running in the host side and is used to measure PCI memory write performance. It supports multiple PCI functions and SR-IOV, it an create a thread on the specified function to measure performance using host DMA or memcpy. It also can control EP device to start EP DMA and calculate the performance. The driver also provides some sysfs interface to change test settings such as packet length loop times and write direction (RC to EP or EP to RC).

Host Kernel Image

PCI DMA Host driver module depends on DMA driver and PCI IOV. Please make sure the two drivers are selected when compiling the host kernel image.

```
    -> Device Drivers
        -> DMA Engine support
           [*] Freescale Elo and Elo Plus DMA support (enable the option)
           [ ] Network: TCP receive copy offload (disable the option)

    ->Bus options                                                              [*]
PCI IOV support
```

Compile Host Module

1. Use yacto to compile EP application.

   The detailed information can refer to SDK documents.

   ```
   #> bitbake fsl-image-core
   ```

2. Directly Compile host module

   a. Get the code and move them to sdk folder.

   ```
   git clone git://git.am.freescale.net/gitolite/sdk/skmm-host.git
   git checkout remotes/origin/pciedma_multi_chan_perf -b pciedma_multi_chan_perf
   ```

   b. Compile code

   For x86:

   ```
   lmh@lmh:~/work/sdk-devel-gerrit/skmm-host$ make ARCH=x86
   make -C /lib/modules/3.8.0-31-generic/build SUBDIRS=`pwd` modules
   make[1]: Entering directory `/usr/src/linux-headers-3.8.0-31-generic'
     LD [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/"pci_dma_test".o
     Building modules, stage 2.
     MODPOST 1 modules
     LD [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test.ko
   make[1]: Leaving directory `/usr/src/linux-headers-3.8.0-31-generic'
   cc  -Wall perf/mini_calc/mini_calc.c -o mini_calc
   lmh@lmh:~/work/sdk-devel-gerrit/skmm-host$
   ```

For PowerPC:

```
lmh@lmh:~/work/sdk-devel-gerrit/skmm-host$ make KERNEL_DIR=<path_to_your_linux_kernel>
CROSS_COMPILE=<name_of_your_toolchain> ARCH=powerpc
make -C /home/lmh/work/linux SUBDIRS=`pwd` modules
make[1]: Entering directory `/home/work/linux'
  CC [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test/pci_dma_dev.o
  CC [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test/pci_dma_sys.o
  CC [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test/pci_dma_test.o
  LD [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/"pci_dma_test".o
  Building modules, stage 2.
  MODPOST 1 modules
WARNING: ".dma_find_channel" [/home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test.ko]
undefined!
  CC      /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test.mod.o
  LD [M]  /home/lmh/work/sdk-devel-gerrit/skmm-host/pci_dma_test.ko
make[1]: Leaving directory `/home/work/linux'
cc  -Wall perf/mini_calc/mini_calc.c -o mini_calc
lmh@lmh:~/work/sdk-devel-gerrit/skmm-host$
```

Run Host Module

The host module is named pci_dma_test.ko. We can directly insert the module. For example:

```
root@t4240qds:~# insmod pci_dma_test.ko
FSL PCI DMA Test Driver.
root@t4240qds:~#
```

We can use 'num_vfs' to make the driver enable virtual function. If we set ‘num_vfs=4’, the module will create 4 virtual functions for PF0 and PF1 respectively. For example:

```
root@t4240qds:~# insmod pci_dma_test.ko num_vfs=4
FSL PCI DMA Test Driver.
root@t4240qds:~#
```

The driver module provides the following sysfs interface to configure test settings. We can use cat and echo to change the related value.

such as packet length loop times and write direction(RC to EP or EP to RC)

1. bars_info: show the device bar information

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat bars_info
PCI DMA BAR0:
cpu_addr:0x0000000c00000000 size:0x0000000001000000
PCI DMA BAR1:
cpu_addr:0x0000000c01000000 size:0x0000000000002000
PCI DMA BAR2:
cpu_addr:0x0000000c01002000 size:0x0000000000001000
PCI DMA BAR3:
cpu_addr:0x0000000000000000 size:0x0000000000000000
PCI DMA BAR4:
cpu_addr:0x0000000c01400000 size:0x0000000000400000
```

2. config_info : display PCI EP configuration information

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat config_info
status:0x00000001 commond:0x00000000
```

```
rx config: addr:0x100f1000000, size:0x400, loop:0x3e8
root@t4240qds:/sys/class/pcidma/pcidma0#
```

3. test_dma_enable : enable/disable DMA

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_dma_enable
test dma status: enable
root@t4240qds:/sys/class/pcidma/pcidma0# echo 0 > test_dma_enable
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_dma_enable
test dma status: disable
root@t4240qds:/sys/class/pcidma/pcidma0#
```

4. test_loop : test loop times

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_loop
test loop: 500
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1000 > test_loop
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_loop
test loop: 1000
```

5. test_lens: test packet length

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_lens
test length: 64B 256B 1024B 4096B 1048576B 2097152B
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1024 > test_lens
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_lens
test length: 1024B
```

6. test_rc2ep: test direction RC writes to EP.

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_rc2ep
test rc2ep: true
root@t4240qds:/sys/class/pcidma/pcidma0# echo 0 > test_rc2ep
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_rc2ep
test rc2ep: false
root@t4240qds:/sys/class/pcidma/pcidma0#
```

7. test_ep2rc: test direction EP writes to RC

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_ep2rc
test ep2rc: false
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_ep2rc
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_ep2rc
test ep2rc: true
```

8. test_start: start to test, when finished the results will be printed.

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_start
test starting
```

```
root@t4240qds:/sys/class/pcidma/pcidma0#
test info:
test0 packet length:1024B loop:1000times
EP->RC throughput:2570Mbps
```

9. test_info: display the current test results.

   For example:

```
root@t4240qds:/sys/class/pcidma/pcidma0# cat test_info
test info:
test0 packet length:1024B loop:1000times
EP->RC throughput:2570Mbps
root@t4240qds:/sys/class/pcidma/pcidma0#
```

8.6.4 Test Procedure

Start EP Application

1. Configure PCI controller in EP mode via changing RCW
2. Start EP board and login using EP kernel image
3. Run PCI DMA EP application to initialize EP device.

```
root@p5020ds:~# ./pciep_dma  0
Initialized pci0-pf0
pcidma>
```

4. Start test thread on the specified PCI functions.

```
pcidma> add 0 0
pcidma> Starting a pci0-pf0's test thread on cpu1
```

Start Host driver module

1. Start host computer or board and login
2. Run PCI DMA host module.

```
root@t4240qds:~# insmod pci_dma_test.ko
FSL PCI DMA Test Driver.
FSL-PCIDMA-Driver 0001:01:00.0: BAR:0  addr:0xc20000000 len:0x16777216
FSL-PCIDMA-Driver 0001:01:00.0: BAR:1  addr:0xc21000000 len:0x8192
FSL-PCIDMA-Driver 0001:01:00.0: BAR:2  addr:0xc21002000 len:0x4096
FSL-PCIDMA-Driver 0001:01:00.0: BAR:3  addr:0x0 len:0x0
FSL-PCIDMA-Driver 0001:01:00.0: BAR:4  addr:0xc21400000 len:0x4194304
```

Test performance

1. Test RC to EP DMA performance

```
root@t4240qds:/sys/class# cd pcidma/pcidma0/
root@t4240qds:/sys/class/pcidma/pcidma0# ls
bars_info  config_infodevicesubsystem  test_dma_enable  test_ep2rctest_info  test_lens
test_loop  test_rc2ep  test_start  uevent
```

```
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_start
test starting
root@t4240qds:/sys/class/pcidma/pcidma0#
test info:
test0 packet length:64B loop:500times
RC->EP throughput:49Mbps
test1 packet length:256B loop:500times
RC->EP throughput:164Mbps
test2 packet length:1024B loop:500times
RC->EP throughput:658Mbps
test3 packet length:4096B loop:500times
RC->EP throughput:1594Mbps
test4 packet length:1048576B loop:500times
RC->EP throughput:11216Mbps
test5 packet length:2097152B loop:500times
RC->EP throughput:11337Mbps
```

2. Test RC to EP memcpy performance

```
root@t4240qds:/sys/class/pcidma/pcidma0# echo 0 > test_dma_enable
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_start
test starting
root@t4240qds:/sys/class/pcidma/pcidma0#
test info:
test0 packet length:64B loop:500times
RC->EP throughput:767Mbps
test1 packet length:256B loop:500times
RC->EP throughput:720Mbps
test2 packet length:1024B loop:500times
RC->EP throughput:767Mbps
test3 packet length:4096B loop:500times
RC->EP throughput:763Mbps
test4 packet length:1048576B loop:500times
RC->EP throughput:762Mbps
test5 packet length:2097152B loop:500times
RC->EP throughput:372Mbps
```

3. Test EP to RC DMA performance

```
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_ep2rc
root@t4240qds:/sys/class/pcidma/pcidma0# echo 0 > test_rc2ep
root@t4240qds:/sys/class/pcidma/pcidma0# echo 1 > test_start
test starting
root@t4240qds:/sys/class/pcidma/pcidma0#
test info:
test0 packet length:64B loop:500times
EP->RC throughput:353Mbps
test1 packet length:256B loop:500times
EP->RC throughput:1270Mbps
test2 packet length:1024B loop:500times
EP->RC throughput:3893Mbps
test3 packet length:4096B loop:500times
EP->RC throughput:7710Mbps
test4 packet length:1048576B loop:500times
EP->RC throughput:12148Mbps
test5 packet length:2097152B loop:500times
EP->RC throughput:12162Mbps
```

Note: PCI DMA host module does not support KVM.

8.7 ARMv8 AArch32 User Manual

8.7.1 ARMv8 AArch32 User Manual

Linux SDK for QorIQ Processors

Some of QorIQ Processors are compatible with ARMv8 architecture, such as LayerScape platforms. The LayerScape platforms include LS1043A, LS1046A and so on.

The ARM architecture v8, ARMv8 supports two Execution states,

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, which is compatible with previous versions of the ARM architecture.

LayerScape platforms can support AArch32 Execution state.

U-Boot and Kernel configurations and builds

For AArch32 support, the specific U-Boot and Kernel images are used.

To set up a cross compile environment and perform builds using Yocto Project, xxx-32b is used as the <machine>.

$ . ./fsl-setup-env -m <machine>

For example:

```
$ . ./fsl-setup-env -m ls1043ardb-32b
```

The corresponding images built by Yocto can be found in the following directory:

```
<sdk-install-dir>/build_<machine>/tmp/deploy/images/<machine>/
For example:
<sdk-install-dir>/build_ls1043ardb-32b/tmp/deploy/images/ls1043ardb-32b
```

Deploy and Boot Process

Deploy and boot process are the same with AArch64 platform, please refer to each board's reference manual.

Chapter 9
Linux User Space

9.1 QorIQ OpenDataPlane (ODP) User Manual

9.1.1 Introduction

This document provides information about ODP Sample Applications built on ODP API v1.11 implementation. User can experience the main functionalities of OpenDataPlane (ODP) with these applications and can also learn how to use the ODP API from source code of these applications.

The document explores the following target applications:

- ODP generator sample application
- ODP pktio sample application
- ODP ipsec transport and tunnel sample applications
- ODP packet classify sample application
- ODP timer sample application
- ODP traffic manager sample application
- ODP LPM IP Forwarding sample application
- ODP OpenFastPath Applications (FPM & FPM_BURSTMODE)

More information about ODP introduction, architecture and user guide are available on Linaro web site:

OpenDataPlane API Reference Manual for linux-generic

OpenDataPlane (ODP) User Guide

OpenDataPlane (ODP) Implementers Guide

9.1.1.1 Intended audience

This document is intended for software developers and architects who want to develop ODP applications on QorIQ based platforms. The document assumes that users are familiar with Linux-based software development, and also with the ODP concepts and APIs.

9.1.1.2 Definitions and acronyms

SDK	Software Development Kit
RDB	Reference Design Board
DUT	Device Under Test
FMan	Frame Manager
PBL	Pre Boot Loader

Table continues on the next page...

Table continued from the previous page...

RCW	Reset Configuration Word
UDP	User Datagram Protocol
SIP DIP	Source Internet Protocol and Destination Internal Protocol

9.1.1.3 Supported platforms

Current release is supported on the following QorIQ processing platforms:

- LS2088A

9.1.1.4 Unsupported ODP API's

Following ODP API's are not supported in this release

```
odp_packet_add_data
odp_packet_rem_data
odp_packet_extend_head
odp_packet_trunc_head
odp_packet_extend_tail
odp_packet_trunc_tail
odp_packet_copy_from_pkt
odp_packet_concat
odp_packet_split
odp_packet_copy_part
odp_packet_align
odp_packet_move_data
odp_packet_copy_data
odp_packet_has_ts
odp_packet_has_ts_clr
odp_packet_ts_set
odp_packet_ts
odp_cos_drop_set
odp_cls_cos_pool_set
odp_pktio_skip_set
odp_cls_cos_pool
odp_cos_drop
```

9.1.1.5 ODP Limitations and Known Issues

The following are the limitations and known issues for this release.

Limitations

- Route option with subnet is not supported in odp_ipsec and odp_ipsec_offload application.
- CRYPTO – DPAA hardware is an asynchronous hardware. Hence only asynchronous mode is supported for crypto operations.
- CRYPTO – Only ESP sessions are supported (crypto algorithm supported : 3DES, AES, authentication algorithm : SHA1, MD5, SHA256)
- CRYPTO – New buffer/Out of place crypto mode is not supported.

- CRYPTO – Sessions with requirement of authentication before cipher are not supported.
- Per CoS pool is not supported.
- Refer to the Unsupported ODP API's on page 1282 chapter for a list of the API's that are not supported in this release.

Known Issues

- **ODP-879** - FPM: application cleanup causes segmentation fault and can't be restarted.
- **ODP-894** - FPM burst mode is not working with single Tx Queue.
- **ODP-867** - Ordered queues are supported with only 500 buffers configured for all interfaces.
- **ODP-819** - Adding new SA cause the existing traffic to halt for some time.
- **ODP-837** - Ordered queues are not supported if there are more than one Tx queue per DPNI.
- **ODP-882** - Shaper with rate above 1Gbps is not supported.
- **ODP-416** - Freed buffer pool memory can't be reclaimed.
- **ODP-806** - IPsec offload application fails to re-run in ordered mode.
- **ODP-694** - Software queues can't be re-attached to schedular.

9.1.2 Product Description

9.1.2.1 Product diagram

The figure below identifies how ODP application runs in a typical network processor software architecture.

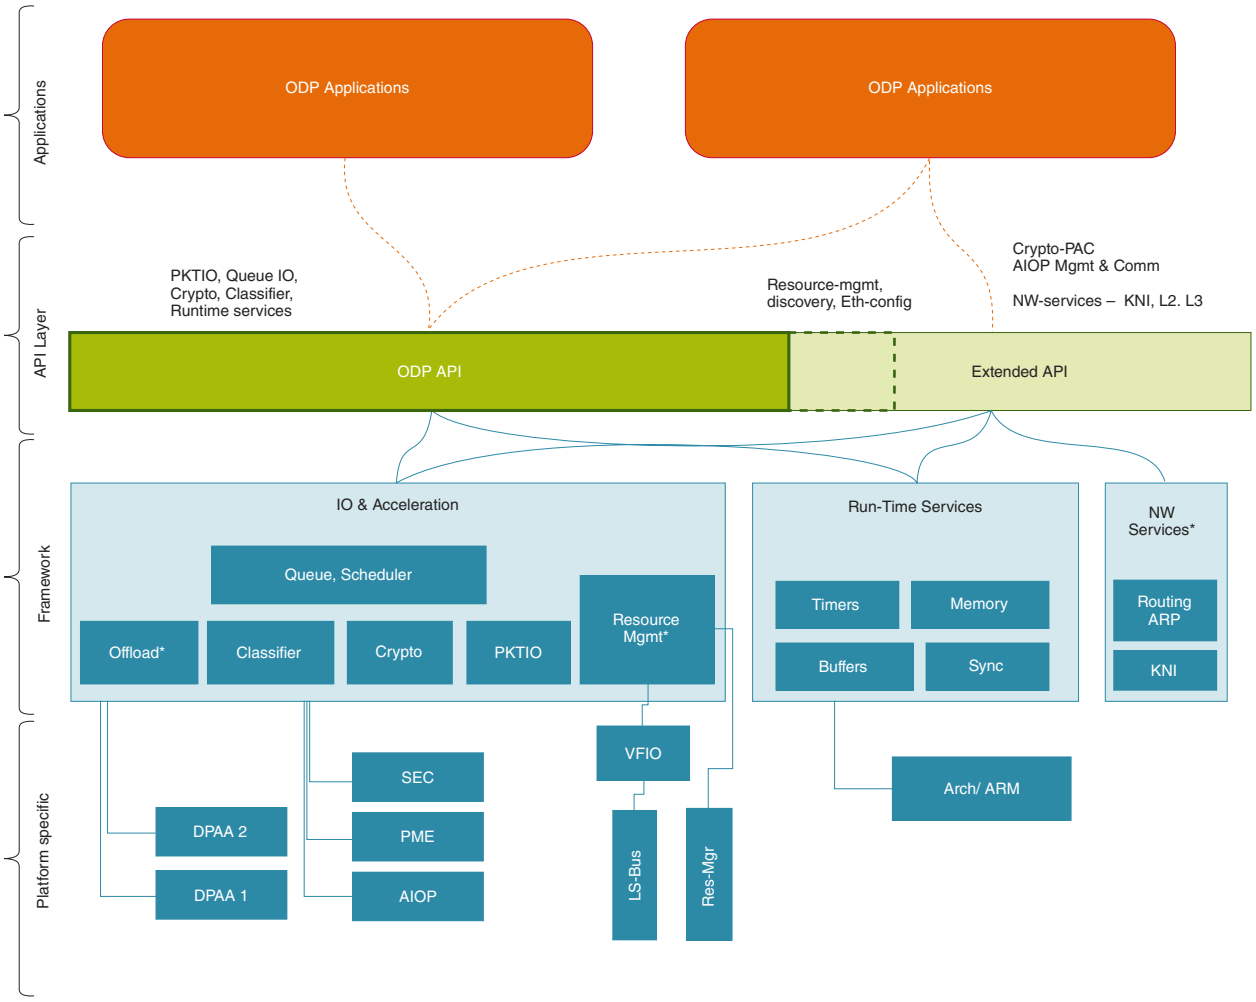

Figure 190. ODP on QorIQ

9.1.3 Build ODP Through Yocto

9.1.3.1 How to Install and Build SDK

For detailed information on ISO installation, see “Essential Build Instructions” under “Getting Started” within the QorIQ SDK documentation.

9.1.3.2 Building ODP applications only

ODP applications can also be compiled alone using Yocto once you have ran "*bitbake fsl-image-kernelitb*". The steps are as follows:

1. cd build_<board-name>/
2. source SOURCE_THIS
3. Clean ODP: bitbake -f -c cleansstate odp
4. Make ODP: bitbake -f -c compile odp

NOTE

The above step will only compile the odp applications. For adding them to rootfs and creating a Kernelitb, use the command given below.

5. bitbake fsl-image-kernelitb

9.1.4 Using ODP Applications

Execute the below commands to allocate resources for ODP applications.

9.1.4.1 LS2088ARDB/LS2085ARDB Board Preparation and Bring-up

Board Bring-up

The LS2088A documentation contains Software Deployment Guides for all the LS2088ARDB reference board. Refer to the LS2088ARDB Software Deployment Guide for instructions on how to deploy U-Boot, Linux kernel and Management Complex and root file system to the board.

Interface Naming Conventions

Throughout the ODP User Manual, ODP application commands are listed. These commands use intf-1, intf-2, …, intf-x as generic interface names. Use dpni.<x> in placeof intf-<x> when running ODP commands on LS2088ARDB/LS2085ARDB.

Example command listed in user manual:

```
$ ./odp_pktio -c 2 -m 2 -i <intf-1>,<intf-2>
```

The table below provides the mapping between the generic interface names and the names to be used in the ODP commands for LS2088ARDB/LS2085ARDB:.

Generic Interface Names	LS2088ARDB/LS2085ARDB Ports	LS2088ARDB/LS2085ARDB Interface Names
intf-1	eth4	dpmac.1(dpni.x*)
intf-2	eth5	dpmac.2(dpni.x*)
intf-3	eth6	dpmac.3(dpni.x*)
intf-4	eth7	dpmac.4(dpni.x*)
intf-5	eth0	dpmac.5(dpni.x*)
intf-6	eth1	dpmac.6(dpni.x*)
intf-7	eth2	dpmac.7(dpni.x*)
intf-8	eth3	dpmac.8(dpni.x*)

NOTE

Mapping between dpmac to dpni is auto-generated by the resource allocation "`dynamic_dpl.sh`" script. See the steps below for details.

Resource Allocation Commands

Execute the following commands to allocate the resources required to run the ODP applications.

```
$ cd /usr/odp/scripts
$ source ./dynamic_dpl.sh dpmac.1 dpmac.2  (Reference command)
```

NOTE

In order to use multiple interfaces, user can run the following command:

```
source ./dynamic_dpl.sh dpmac.1 dpmac.2 …… dpmac.8
```

The output log of the reference command is shown below:

```
###################### Container  dprc.2  is created ####################

Container dprc.2 have following resources :=>

 * 4 DPBP
 * 5 DPCON
 * 1 DPSECI
 * 3 DPNI
 * 10 DPIO
 * 10 DPCI

######################### Configured Interfaces #########################

Interface Name        Endpoint              Mac Address
==============        ========              ==================
dpni.1                dpmac.1               00:00:00:00:0:1
dpni.2                dpmac.2               00:00:00:00:0:2
dpni.3                dpni.3                00:00:00:11:11:11
```

NOTE

`dynamic_dpl.sh` script allocates default number of resources like buffer pools (DPBP), I/O thread context (DPIO), S/W queues (DPCI) etc. as shown in output above.

To increase the number of resources required by an application the environment variables below shall be exported to overwrite the default configuration before executing `dynamic_dpl.sh` script.

```
DPIO_COUNT : Defines the number of I/O contexts that are available to the application. Current
implementation allocates one DPIO for each timer thread spawned internally; in addition to
allocating a DPIO for a worker thread. Example - If an application initiates 8 worker threads
which
internally may spawn 8 timer threads; DPIO count for that case shall be at least 16. If
application
is not spawning timer threads then the DPIO count would be equal to the number of worker threads.

Usage : export DPIO_COUNT=<n>
    eg. "export DPIO_COUNT=10"

DPBP_COUNT : Defines number of buffer pools that can be allocated in an application.

Usage : export DPBP_COUNT=<n>
    e.g "export DPBP_COUNT=4"
```

```
DPCI_COUNT : Defines the number of queues that can be created in an application.

Usage : export DPCI_COUNT=<n>
    e.g "export DPCI_COUNT=10"

DPCONC_COUNT : Defines number of scheduler groups that can be created in an application. 3 DPIO's
are created by default for all applications to create Control, Worker and 'All' scheduler group.

Usage : export DPCONC_COUNT=<n>
    eg. "export DPCONC_COUNT=6"
```

Configuration for ODP OpenFastPath applications(fpm & fpm_burstmode)

```
DPCI_COUNT : Defines the number of queues that can be created in an application.
        Set the DPCI_COUNT=128 for OpenFastPath applications, using below command:

Usage : export DPCI_COUNT =<n>
e.g "export DPCI_COUNT =128"
```

Execute the command below to specify the memory requirement for ODP application:

```
export APPL_MEM_SIZE=32
```

The command above reservers 32MB of memory for the ODP application.

Note: If the command above is not executed, then first ODP application will consume all memory and no other ODP application can be run.

9.1.4.2 odp_pktio application

9.1.4.2.1 Overview

The odp_pktio application is a sample packet input/output application which receives packets from external traffic source and reflects back the packets after swapping the IP addresses and MAC addresses.

The application will be configured using its available command line options:

```
       Usage: %s OPTIONS
             E.g. %s -i eth1,eth2,eth3 -m 0

           OpenDataPlane example application.

           Mandatory OPTIONS:
             -i, --interface Eth interfaces (comma-separated, no spaces)

           Optional OPTIONS
             -c, --count <number> CPU count.
             -m, --mode      0: Receive and send directly (no queues)
                             1: Receive and send via queues.
                             2: Receive via scheduler, send via queues.
             -h, --help           Display help and exit.
            environment variables: ODP_PKTIO_DISABLE_SOCKET_MMAP
                                   ODP_PKTIO_DISABLE_SOCKET_MMSG
                                   ODP_PKTIO_DISABLE_SOCKET_BASIC
            can be used to advanced pkt I/O selection for linux-generic
```

9.1.4.2.2 Test setup

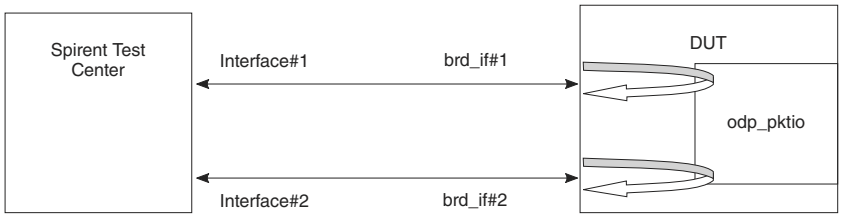

Figure 191. Test setup (odp-pktio)

9.1.4.2.3 Running odp_pktio on DUT

Execute below commands on DUT to run odp_pktio:

```
$ ./odp_pktio -c 2 -m 2 -i <intf-1>,<intf-2>
```

NOTE

Interfaces intf-1 can be dpni.<index>. See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 for interface details.

For additional details on options, see the command line options mentioned above.

9.1.4.2.4 Test description

The application will receive traffic from the traffic generator – and this will be seen in the application console, on one interface or on multiple interfaces where the application is running. Once a packet is received, its destination Ethernet addresses will be swapped (and so the IP addresses) and the packet will be sent back on the port it came from, to the packet originator.

As a reference, packet scheduler mode is chosen.

A number of 100000 packets will be sent on one port, from the Spirent test center/traffic generator.

Packet format

Eth source	Eth destination	Ip source	Ip destination	Proto
Any	Any	Any	Any	Ipv4/UDP

The application will send back 100000 packets to the Spirent test center, each packet having its Ethernet and IP addresses swapped.

9.1.4.3 odp_generator application

9.1.4.3.1 Overview

The odp_generator application is a sample application which demonstrate termination use cases. It supports the following functionalities:

1. Receive packets from external traffic source.
2. Transmit self generated UDP packets to external network.
3. Initiate a self generated PING request and expects corresponding response from the external network source.

The application will be configured using its available command line options:

```
Usage: %s OPTIONS
             E.g. %s -I eth1 -r

           OpenDataPlane example application.

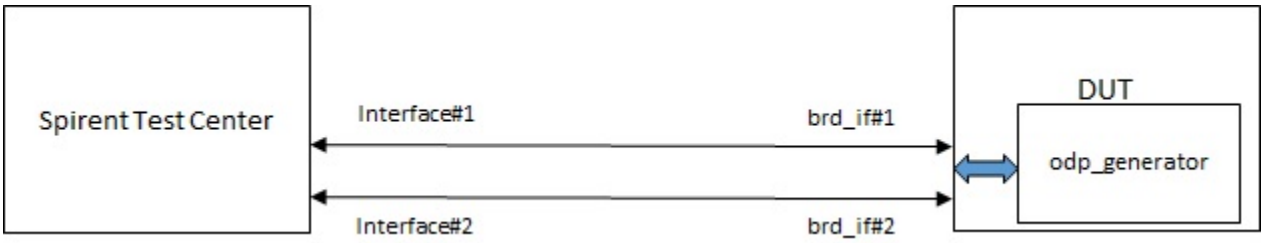
             Work mode:
               1.send udp packets
               2.receive udp packets
               3.works like ping

           Mandatory OPTIONS:
             -I, --interface Eth interfaces (comma-separated, no spaces)
             -a, --srcmac src mac address
             -b, --dstmac dst mac address
             -c, --srcip src ip address
             -d, --dstip dst ip address
             -s, --packetsize payload length of the packets
             -m, --mode work mode: send udp(u), receive(r), send icmp(p)
             -n, --count the number of packets to be send
             -t, --timeout only for ping mode, wait ICMP reply timeout seconds
             -i, --interval wait interval ms between sending each packet
                           default is 1000ms. 0 for flood mode

           Optional OPTIONS
             -h, --help       Display help and exit.
            environment variables: ODP_PKTIO_DISABLE_SOCKET_MMAP
                                   ODP_PKTIO_DISABLE_SOCKET_MMSG
                                   ODP_PKTIO_DISABLE_SOCKET_BASIC
            can be used to advanced pkt I/O selection for linux-generic
```

9.1.4.3.2 Test setup

Figure 192. Test setup (odp_generator)



9.1.4.3.3 Running odp_generator on DUT

Execute below commands on DUT to run odp generator application:

Receive mode:

```
$ ./odp_generator -I <intf-1> -m r -w 1
```

UDP mode:

```
$ ./odp_generator -I <intf-1>--srcmac 00:00:00:00:00:0X --dstmac
00:00:10:00:94:02 --srcip 192.85.2.2 --dstip 192.85.1.2 --packetsize 64 -m u
```

Ping mode:

```
$ ./odp_generator -I <intf-1> --srcmac 00:00:00:00:00:0X --dstmac
00:10:94:00:00:02 --srcip 192.85.2.2 --dstip 192.85.1.2 --packetsize 64   -m
p
```

NOTE

Interfaces intf-1 can be dpni.<index> . See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 for interface details.

For additional details on options, see the command line options mentioned above.

9.1.4.4 ODP ipsec application (odp_ipsec, odp_ipsec_offload)

9.1.4.4.1 Overview

The “odp_ipsec” application functions as a simple L3 IPv4 router with support for IPsec 3DES cipher in both transmit and receive directions. Note that both IPsec "transport" and “tunnel” modes are supported. These applications authenticate and encrypts/decrypts traffic from external source and forwards the encrypted/decrypted packets.

The applications will be configured using its available command line options:

```
Usage: %s OPTIONS
             E.g. %s -i eth1,eth2,eth3 -m 0

           OpenDataPlane example application.

           Mandatory OPTIONS:
            -i, --interface Eth interfaces (comma-separated, no spaces)
            -m, --mode   0: SYNC
                         1: ASYNC_IN_PLACE
                         2: ASYNC_NEW_BUFFER
                    Default: 0: SYNC api mode

           Routing / IPSec OPTIONS:
            -r, --route SubNet:Intf:NextHopMAC
            -p, --policy SrcSubNet:DstSubNet:(in|out):(ah|esp|both)
            -e, --esp SrcIP:DstIP:(3des|aes|null):SPI:Key192
            -a, --ah SrcIP:DstIP:(md5|sha1|null):SPI:Key128

             Where: NextHopMAC is raw hex/dot notation, i.e. 03.BA.44.9A.CE.02
                    IP is decimal/dot notation, i.e. 192.168.1.1
                    SubNet is decimal/dot/slash notation, i.e 192.168.0.0/16
                    SPI is raw hex, 32 bits
                    KeyXXX is raw hex, XXX bits long

             Examples:
                -r 192.168.222.0/24:p8p1:08.00.27.F5.8B.DB
                -p 192.168.111.0/24:192.168.222.0/24:out:esp
                -e 192.168.111.2:192.168.222.2:3des:
201:656c8523255ccc23a66c1917aa0cf30991fce83532a4b224
                -a 192.168.111.2:192.168.222.2:sha1:201:2122232425262728292a2b2c2d2e2f3031323334
```

In addition, the odp_ipsec_offload application demonstrates IPSec ESP protocol offload advantages over standard algorithm-oriented ipsec API.

The applications will be configured using its available command line options:

```
Usage: %s OPTIONS
             E.g. %s -i eth1,eth2,eth3

           OpenDataPlane example application.

           Mandatory OPTIONS:
            -i, --interface Eth interfaces (comma-separated, no spaces)

           Routing / IPSec OPTIONS:
            -r, --route SubNet:Intf:NextHopMAC
            -p, --policy SrcSubNet:DstSubNet:(in|out):(ah|esp|both)
            -e, --esp SrcIP:DstIP:(3des|aes|null):SPI:Key192
            -a, --ah SrcIP:DstIP:(md5|sha1|null):SPI:Key128

             Where: NextHopMAC is raw hex/dot notation, i.e. 03.BA.44.9A.CE.02
                    IP is decimal/dot notation, i.e. 192.168.1.1
                    SubNet is decimal/dot/slash notation, i.e 192.168.0.0/16
                    SPI is raw hex, 32 bits
                    KeyXXX is raw hex, XXX bits long
       Modes Options:
       -q,   specify the queue type
               0: ODP_SCHED_SYNC_PARALLEL
               1: ODP_SCHED_SYNC_ATOMIC (default)
               2: ODP_SCHED_SYNC_ORDERED

             Examples:
                -r 192.168.222.0/24:p8p1:08.00.27.F5.8B.DB
                -p 192.168.111.0/24:192.168.222.0/24:out:esp
                -e 192.168.111.2:192.168.222.2:3des:
201:656c8523255ccc23a66c1917aa0cf30991fce83532a4b224
                -a 192.168.111.2:192.168.222.2:sha1:201:21222324252627282a2b2c2d2e2f3031323334
```

9.1.4.4.2 Test setup

This test uses the hardware setup described in below figures:

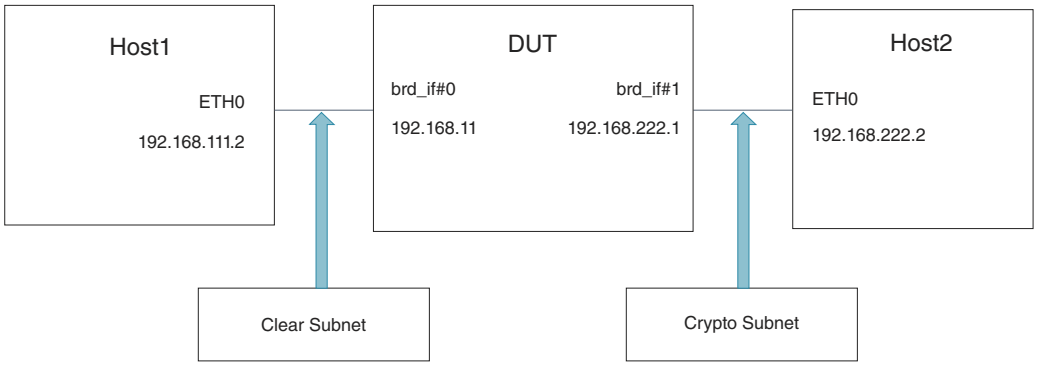


Figure 193. Transport mode setup

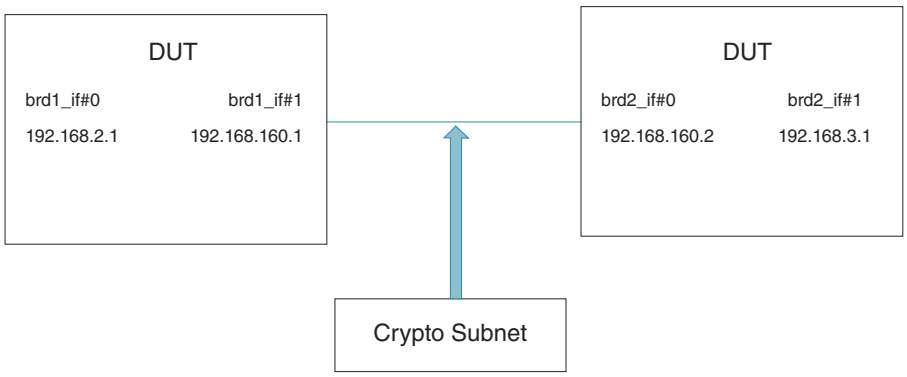

Figure 194. Tunnel mode setup

9.1.4.4.3 Running ODP ipsec applications on DUT

Transport mode (odp_ipsec)

Execute below commands on DUT for odp_ipsec application in transport mode.

```
$ ./odp_ipsec -i brd_if#0, brd_if#1 -c <Num of cores> -m 1 -
r 192.168.111.2/32: brd_if#0:00.11.00.00.00.01 -r 192.168.222.2/32: brd_if#1:00.22.00.00.00.02 -p
192.168.111.0/24:192.168.222.0/24:out:esp -e
192.168.111.2:192.168.222.2:3des:201:656c8523255ccc23a66c1917aa0cf30991fce83532a4b224
-p 192.168.222.0/24:192.168.111.0/24:in:esp -e

```

Execute below commands on Host1:

- ifconfig eth0 192.168.111.2 up
- ifconfig eth0 hw ether 00:11:00:00:00:01
- ip route add 192.168.222.0/24 via 192.168.111.1
- arp -s 192.168.111.1 00:00:00:00:00:01

Execute below commands on Host2 for odp_ipsec application in transport mode

- ifconfig eth0 192.168.222.2 up
- ifconfig eth0 hw ether 00:22:00:00:00:02
- ip route add 192.168.111.0/24 via 192.168.222.1
- arp -s 192.168.222.1 00:00:00:00:00:02

Host2 has the following setkey configuration file applied. Use reference setkey script as below:

```
#!/usr/sbin/setkey -f
# Flush the SAD and SPD
flush;
spdflush;

add 192.168.111.2 192.168.222.2 esp 0x201 -E 3des-cbc
0x656c8523255ccc23a66c1917aa0cf30991fce83532a4b224;

add 192.168.222.2 192.168.111.2 esp 0x301 -E 3des-cbc
0xc966199f24d095f3990a320d749056401e82b26570320292;
```

```
        spdadd 192.168.111.2 192.168.222.2 any -P in ipsec
                  esp/transport//require;

        spdadd 192.168.222.2 192.168.111.2 any -P out ipsec
                  esp/transport//require;
```

Tunnel mode (odp_ipsec_offload and odp_ipsec)

Execute the below commands for tunnel mode in odp_ipsec_offload application

```
On Left board(DUT):

$ ./odp_ipsec_offload -i brd1_if#0,brd1_if#1 -r 192.168.2.2/32:brd1_if#0:02.00.c0.a8.3c.01 -r

192.168.3.2:192.168.2.2:3des:2:656c8523255ccc23a66c1917aa0cf30991fce83532a4b224 -a
192.168.3.2:192.168.2.2:md5:2:a731649644c5dee92cbd9c2e7e188ee6 -t
192.168.3.2:192.168.2.2:192.168.160.2:192.168.160.1 -c 1 -m 1
```

For LS208xARDB:

```
brd1_if#0 dpni.<DPNI_INDEX_1>
brd2_if#0 dpni.<DPNI_INDEX 2>
brd2_if#1 dpni.<DPNI_INDEX_1>
brd1_if#1 dpni.<DPNI_INDEX_2>
```

For additional details on options, see the command line options mentioned above.

9.1.4.5 odp_classifier application

9.1.4.5.1 Overview

odp_classifier is a sample application to demonstrate classification among the queues based on configured packet matching rules along with the rules for non-matching(default queue) as well as error'ed packets. The current implementation demonstrates classification based on following parameters:

1. IP Source address
2. IP QoS
3. VLAN Priority

The following are functional behavior of the application:

- Application configures multiple packet matching rules specifying the queue as a target place.
- Traffic, matching with the configured rules, will be distributed among the target queues.
- Remaining traffic will be forwarded to default queue.

Application is supported for two modes as given below:

- **Drop mode**: All the received frames are dropped at application.
- **Reply mode:** Received frame are reflected back onto the same interface after swapping its Ethernet SMAC & DMAC and SIP & DIP addresses.

The application will be configured using its available command line options:

```
Usage: %s OPTIONS

           Mandatory OPTIONS:
             -i, --interface Eth interfaces (comma-separated, no spaces)
   -p, --policy <odp_pmr_term_e>:<value>:<mask bits>:<queue name>
odp_pmr_term_e: Type of packet matching rule
value: Value of rule to be matched
mask bits: Masking bits for matching rules
queue name: Target Queue where packet is to be received
   -l, --l2_policy <VLAN Priority Value>:<queue name>
VLAN Priority Value: L2 VLAN priority value
:Queue Name: Target Queue where packet is to be received
   -q, --l3_policy <L3 QoS Value>:<queue name>
L3 QoS Value: L3 QoS or IP TOS (One byte) value
Queue Name: Target Queue where packet is to be received
           Optional OPTIONS
  -c, --count <number> CPU count.
```

```
  -m, --mode Mode of application
0: Packet Drop mode. Received packets will be dropped
1: Packet Reply mode. Received packets will be sent back
Default: Packet Drop mode.
   -t, --timeout Time to run the classifier
1: Time for which the classifier will be run in seconds
0: Runs in infinite loop
Default: Runs in infinite loop.
   -a, --l3_policy_precedence Flag to flip precedence between L2 and L3 Policy.
1: L3 policy rule will take precedence over L2 Policy rules
0: L2 policy rule will take precedence over L3 policy rules
Default: 0
             -h, --help       Display help and exit
```

9.1.4.5.2 Test setup

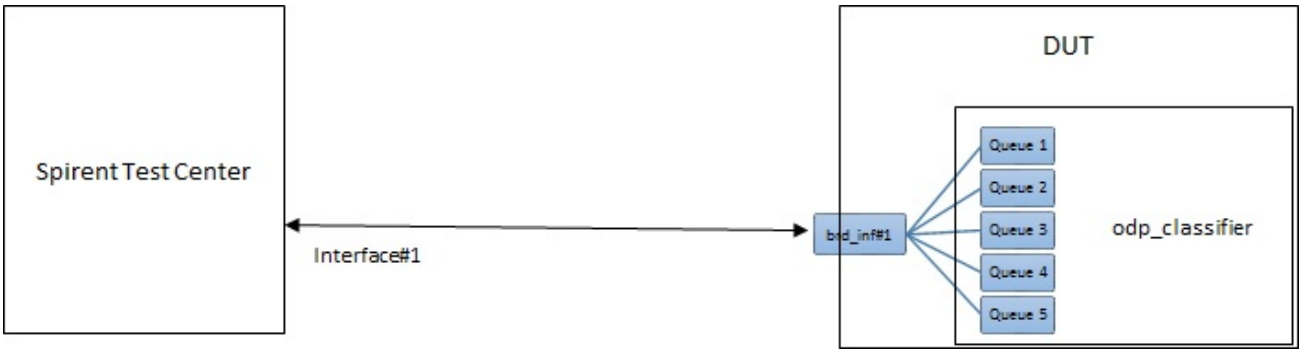

Figure 195. Test setup (odp_classifier)

9.1.4.5.3 Running odp_classifier on DUT

Execute below commands on DUT to odp classifier application:

```
Reply mode:
$./odp_classifier –i <intf-1> -p ODP_PMR_SIP_ADDR:192.85.1.1:FFFFFFFF:queue1 -l 1:queue2 -q
40:queue3 -m 1
Drop Mode:
$./odp_classifier –i <intf-1> -p ODP_PMR_SIP_ADDR:192.85.1.1:FFFFFFFF:queue1 -l 1:queue2 -q
40:queue3 -m 0
```

NOTE

Interface intf-1 can be dpni.<index> or fm<X>-mac<Y>. See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 for interface details as per board in use.

NOTE

For LS2085ARDB/LS2088ARDB, DPBP objects are required to be increaesed to 16 for configuring multiple rules for classifciation. Refer section LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 to increase object count in resource container.

For additional details on options, see the command line options mentioned above.

9.1.4.6 odp_timer application

9.1.4.6.1 Overview

odp_timer is a sample application that will enqueue an event after a certain time period, when the timer expires and dequeues that event and validates it.

The application will create number of threads, given by –c option and allocate a timer for each thread. Each timer will be added by the application with ticks given by –p option.

Feasibility of ticks will be checked by min and max values given by options –m and –x.

When timer expires, a timeout buffer will be enqueued into a queue that will be received by application using odp_schedule() API. After that, buffer will be validated and timer will reset if more timeouts remain given by –t option.

The application will be configured using its available command line options:

```
Usage: %s OPTIONS
  -c, --count <number>    CPU count);
  -r, --resolution <us>   timeout resolution in usec
  -m, --min <us>          minimum timeout in usec
  -x, --max <us>          maximum timeout in usec
  -p, --period <us>       timeout period in usec
  -t, --timeouts <count>  timeout repeat count
  -h, --help                    this help
```

9.1.4.6.2 Test setup

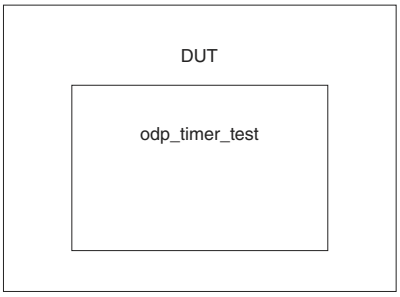

Figure 196. Test setup (odp_timer)

9.1.4.6.3 Running odp_timer on DUT

Execute below commands on DUT to run the odp timer application

```
$./odp_timer_test -c 2 -t 2
```

For additional details on options, see the command line options mentioned above.

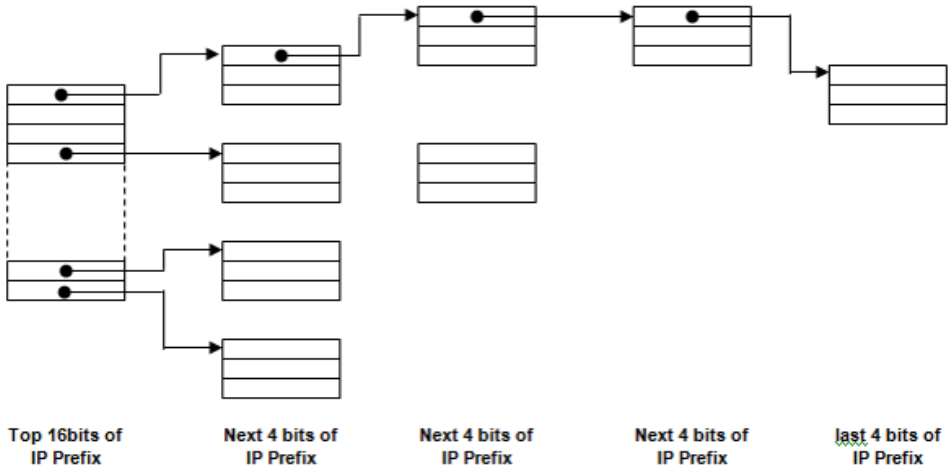
9.1.4.7 odp_lpmfwd application

9.1.4.7.1 Overview

odp_lpmfwd application demonstrates the IPv4 packets forwarding based upon Longest Prefix Match methodology. The LPM based IPv4 forwarding application is a multi-threaded application that routes IPv4 packets from one Ethernet interface to another. The packets that reach the LPM application can be forwarded to destination IP address using LPM route algorithm. The LPM routing algorithm uses the prefix for destination IP address to do the route look up.

Longest Prefix Match Algorithm:

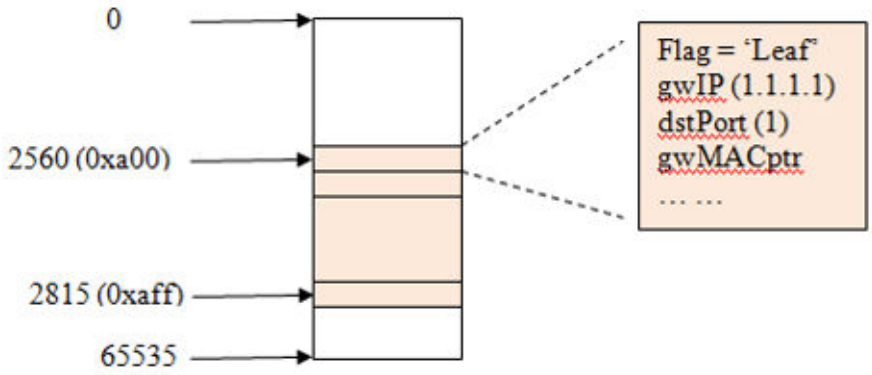
Instead of using traditional Radix-Trie algorithm, here we choose to use one simpler LPM algorithm. It uses 5 level tables: First level table – 65536 entries array, indexed by the top 16 bits of IP address. Second level table – 32 entries array, indexed by bit12~15 of IP address. Third level table – 32 entries array, indexed by bit8~11 of IP address. Fourth level table – 32 entries array, indexed by bit4~7 of IP address. Fifth level table – 32 entries array, indexed by bit0~3 of IP address. The 2nd level to 5th level tables are only created when its first level table entry has valid value. See below figure:



At init time, only the first level (i.e. top16 bits) array is created which contains 65536 null entries. While adding route entries to the FIB table, the 2nd level to 5th level arrays will be created accordingly. This is a typical ASIC design algorithm of LPM which is fast and simple to search while costs far more memory. The worst case is to index and compare 5 times when searching an IP address, but it's still fast enough.

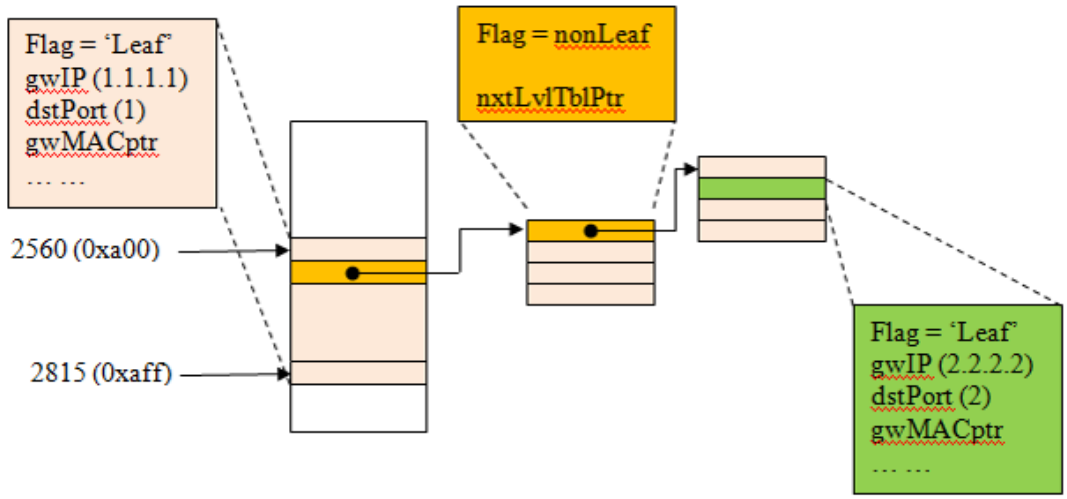
Examples:

1) Add one Class A route 10.0.0.0/8 to the route table. (Gateway is 1.1.1.1, destination port is 1) The first 16bit of 10.0.0.0 (0x0a000000) is 0x0a00 (2560). And the mask is 8 bit which is smaller than the 1st level bit-length (16b), so below entries (from 0x0a00 to 0x0aff) will be created in the FIB table:



From entry No.2560 to No.2815 (total 255 entries) are filled with same content (flag, gwIP, dstPort, ptr …). Now if a packet with DIP of 10.1.1.1 comes in, its first 16 bit value is 0x0a01 (2561). So, the No.2561 entry of the 1st level table will be checked. If it's a 'leaf' node (now it is), then the best-match is found. And the packet will be forwarded to the 'dstPort' after replacing the SMAC and DMAC. And, any DIP of 10.x.x.x will all be forwarded to port 1 with gwIP 1.1.1.1 based on above table.

2) Now, a new route 10.1.1.0/24 is added to the FIB table. The table will be like this:



The new route will overwrite the No.2561 (0x0a01) entry with 'flag' of 'nonLeaf' and a pointer to 'next-level-table'. Now a 16-entry-block memory will be allocated as the 'next-level-table' because the 2nd level is 4bit indexed. And the base address of this new block will be set to the 'nxtLvlTblPtr' of No.2561. Because the next 4 bit of the new route is 0 (bit16 to bit19 of 0x0a010100), so the 1st entry in the 2nd level table is used as another 'nonLeaf' entry. While all the other entries in the 2nd level table should be filled with the same value of its 'parent' route (10.0.0.0/8). The netmask is 24bit which is larger than 16+4, so the 3rd level table should also be allocated (16 entries). And the next 4bit of the new route is 1 (bit20 to bit23 of 0x0a010100), so the 2nd entry will be used for the new route. And because the netmask (24bit) is no-larger-than 16+4+4, so this entry will be the 'Leaf' entry of this new route (see above figure in green). And the according values (gwIP, dstPort, etc.) will be filled in that entry. Now a frame with DIP of 10.1.1.100 comes. There will have 3 lookups to get the final result:

- Index with first 16bit of DIP, whose value is 0x0a01. 'Non-leaf' means to continue the next-level lookup.
- Index with the next 4bit of DIP, whose value is 0. Then 'Non-leaf' again.
- Index with the next 4bit of DIP, whose value is 1. Then the 'leaf' node is found and the lookup reaches an end.

Now a frame with DIP of 10.1.192.10 comes. You can see it will find the 'leaf' node in the 2nd level table and get the route of net-address 10.0.0.0/8. And a frame with DIP of 10.1.10.10 will find its 'leaf' node in the 3rd level table and also get the route of net-address 10.0.0.0/8 as we expected. The multi-branch trie algorithm provides a very fast way of route-lookup but a relatively complicated way of route-add/deletion.

Application Usage:

There are two binaries for LPM based IPv4 packets forwarding:

odp_lpmfwd : Main binary which will do forwarding.

odp_lpmfwd_config : Helper binary to configure the routes, interfaces and ARPs.

Both binaries will communicate via Linux message queues.

odp_lpmfwd usage:

./odp_lpmfwd -h

```
OpenDataPlane LPM forwarding application.

Usage: odp_lpmfwd OPTIONS
  E.g. odp_lpmfwd -i eth1,eth2 -m 0 -c 1
 In the above example,
 eth1 and eth2 are the interfaces from which pkts will be forwarded
```

```
 depends upon the routes

Mandatory OPTIONS:
  -i, --interface eth interfaces (comma-separated, no spaces)

Optional OPTIONS
  -m, --mode      0: Burst send & receive packets (no queues)
                  1: Send & receive packets through ODP Schedular.
                        Default: Packet burst mode.
  -c, --count <number> CPU count.
  -h, --help           Display help and exit.
```

odp_lpmfwd_config usage:

./odp_lpmfwd_config --help

```
Usage:
        odp_lpmfwd_config[OPTIONS…]
    -B, --routeadd=TYPE        adding a route
    -E, --showintf=TYPE        show interfaces
       -F, --intfconf=TYPE        change intf config
    -G, --arpadd=TYPE          adding a arp entry
    -P, --PID=TYPE             pid to hook with (Mandatory param)
        -?, --help                Give this help list
        --usage                   Give a short usage message
        -V, --version             Print program version
```

Help for show all enabled interfaces:

./odp_lpmfwd_config –P <pid of odp_lpmfwd> -E –help

```
Usage: -E [OPTION...]
        -a, --a=ALL      All interfaces
          -?, --help        Give this help list
          --usage           Give a short usage message
          -V, --version     Print program version

Example:
                ./odp_lpmfwd_config -P 2234 -E -a true
```

Help for assign IP addresses to interfaces:

./odp_lpmfwd_config –P <pid of odp_lpmfwd> -F –help

```
Usage: -F [OPTION...]
 -a, --a=IPADDR             IP Address
-i, --i=IFNUM               If Number
-?, --help                  Give this help list
--usage                 Give a short usage message
-V, --version               Print program version

Example:       ./odp_lpmfwd_config -P 2234 -F -a
        192.168.222.1 -i 1Where i is the index of the interface.

e.g.: For following command:
./odp_lpmfwd –i intf-2,intf-1
In odp_lpmfwd_config to assign the IP addresses “i” should be 1 for intf-2 and 2 for intf-1
```

Help for ARP entry addition:

./odp_lpmfwd_config –P <pid of odp_lpmfwd> -G –help

```
Usage: -G [OPTION...]
-m, --m=MACADDR      MAC Address
-r, --r=Replace      Replace Exiting Entry - true/ false {Default:false}
-s, --s=IPADDR       IP Address
-?, --help           Give this help list
--usage                 Give a short usage message
-V, --version               Print program version

Example:       ./odp_lpmfwd_config -P 2234 -G -s 192.168.111.2 -m 00:00:00:00:00:11 -r true
```

Help for route entry addition:

./odp_lpmfwd_config –P <pid of odp_lpmfwd> -B –help

```
Usage: -B [OPTION...]

  -c, --c=FIBCNT             Number of FIB entries
  -d, --d=DESTIP             Destination IP
  -g, --g=GWIP               Gateway IP
  -n, --n=NETMASK            netmask length to be used by LPM
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version

Example:
    ./odp_lpmfwd_config -P 2234 -B -d 192.168.111.0 -g 192.168.222.2 -n 24 -c 256

Mandatory or optional arguments to long options are also mandatory or optional
for any corresponding short options.
```

9.1.4.7.2 Running odp_lpmfwd on DUT

Execute below commands on DUT to run odp_lpmfwd:

```
$ ./odp_lpmfwd –i <intf-1>,<intf-2> &
```

NOTE

Interfaces intf-1 and intf-2 can be `fm<X>-mac<Y>`. See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 for interface details as per board in use.

To configure the interfaces, routes and ARPs, run the following commands:

```
$ ./odp_lpmfwd_config -P $1 -E -a true
$./odp_lpmfwd_config -P $1 -F -a 192.168.222.1 -i 1
$./odp_lpmfwd_config -P $1 -F -a 192.168.111.1 -i 2
$./odp_lpmfwd_config -P $1 -G -s 192.168.222.2 -m 00:00:00:00:00:10 -r true
$./odp_lpmfwd_config -P $1 -G -s 192.168.111.2 -m 00:00:00:00:00:11 -r true
$./odp_lpmfwd_config -P $1 -B -d 192.168.111.0 -g 192.168.222.2 -n 24 -c 256
$./odp_lpmfwd_config -P $1 -B -d 192.168.222.0 -g 192.168.111.2 -n 24 -c 256
```

Where $1 is PID of the process odp_lpmfwd.

9.1.4.7.3 Test description

When a packet is received on one of the input interfaces, it will be routed and forwarded according to the LPM algorithm. The packet will be changed - destination Ethernet address will be updated according to received command line options, the TTL

(Hop Limit) will be decremented and the checksum will be recalculated. Finally the packet will be transmitted on the outgoing interface.

Packet format

Stream 1 on interface#1: IPv4 stream, DIP 192.168.222.4

Stream 2 on interface#2: IPv4 stream, DIP 192.168.111.4

9.1.4.8 odp_tm application

9.1.4.8.1 Overview

odp_tm application demonstrate general Traffic management mechanism on egress side that accepts packets from input queues and applies scheduling and/or bandwidth controls to decide which input packet should be chosen as the next output packet and when this output packet can be sent to external network.

odp_tm supports upto 8 tm_queues (0 to 7) on egress side. Number of tm_queues are configurable (discussed in later sections). Once a packet is received then tm_queue selection is done based on below criteria:

If packet contains a VLAN header then VLAN priority signifies the output tm_queue i.e. VLAN prio 0 to tm_queue0, VLAN prio 1 to tm_queue1 and so on. If configured tm_queues are lesser than VLAN prio value then non-matching VLAN priority packet will always be enqueued to last tm_queue. If packet does not contains any VLAN header then packet will always be enqueued to last tm_queue. PRIO=0 having the highest priority and PRIO=7 having the lowest priority.

Supported scheduling algorithm:

- Strict Priority Scheduling upto 8 priority tm_queues.
- Weighted Fair Queue Scheduling. If weights on each are same then weighted round robin scheduling will be in effect.

Along with Scheduling, single rate bandwidth shaper can also applied on outgoing traffic.

Output interface will be selected based on the configured route using option "-d" (--Destination SubNet:Intf:NextHopMAC)

```
Usage: odp_tm OPTIONS
 E.g. odp_tm -i eth1,eth2,eth3 -m 0
OpenDataPlane example application.
Mandatory OPTIONS:
    -i, --interface Eth interfaces(comma-separated, no spaces)
Optional OPTIONS
     -c, --count <number> CPU count.
     -d, --Destination SubNet:Intf:NextHopMACSubNet: IPaddress with mask bits
              i.e. aa:bb:cc:dd/maskbitsIntf: Interface name i.e. dpni-0NextHopMAC: Destination Mac
Address for next hop.
              Bytes are dot(.) separated i.e. 00.00.00.00.08.01
     -m, --mode 0: Scheduling profile as Strict Priority
                1: Scheduling profile as Weighted scheduling.
                Default Scheduling profile as Strict Priority
    -s, --shaping <boolean> Flag to enable/disable shaping.
                0: To disable
                1: To enable.
                Default shaper is disabled
     -r, --rate <number> Shaping rate in Mbps. Valid only if shaping enabled Values must be in range
(1, 10000)
     -b, --burst-size <number> maximum burst size in KB.Valid only if shaping enabled Values must
be in range (1, 64)
     -n, --num-prio <number> Number of priority queues configured on egress side.
                            Only valid if scheduling profile is strict prio Default all supported
priority queues will be configured.
```

```
     -w, --weight <queue_name>:<weight> Weight value corresponding to each queue.
                        multiple queues configuration will be comma-separated and no spaces. Values
must be in range (1, 255).
               E.g. odp_tm -w queue1:10,queue2:20 -h, --help Display help and exit.
```

NOTE

Input configuration used in command will be applied on all the network interfaces that are being used in the command.

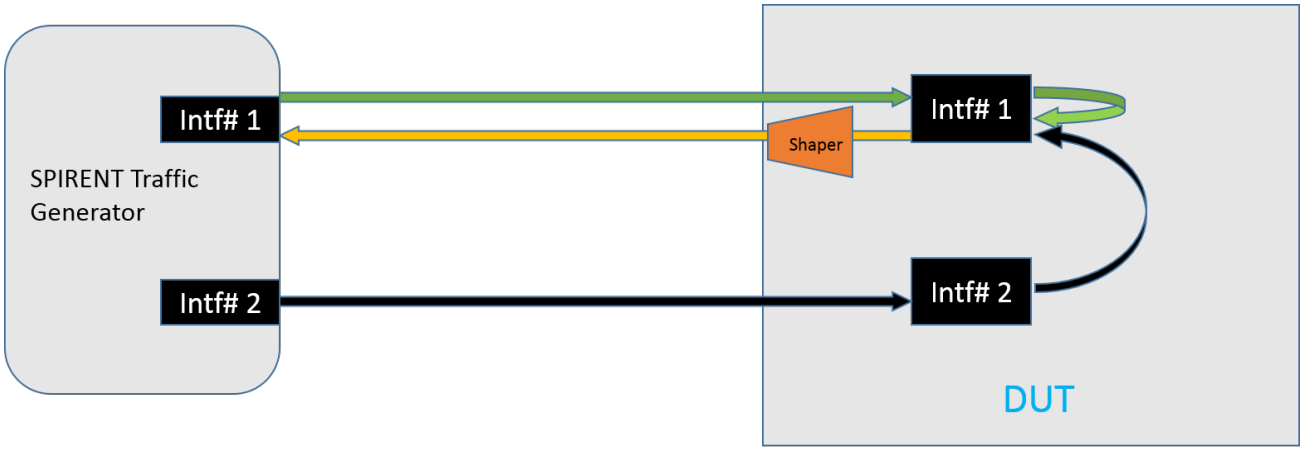
9.1.4.8.2 Running odp_tm on DUT

Execute below commands on DUT to run odp_tm application:

```
./odp_tm -i <intf-1>,<intf-2> -c 8 -d 192.168.111.0/24:dpni.2:00.00.00.00.08.02 -d
192.168.222.0/24:dpni.1:00.00.00.00.08.01 -s 1 -r 500 -b 32
```

Note: The following environment variables needs to be set " export MAX_TCS=8" "export OPR_ENABLE=0" "export FS_ENTRIES=1" before running dynamic_dpl.sh script. Interfaces intf-1 can be dpni.<index>. See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up on page 1285 for interface details.

9.1.4.8.3 Test Setup



9.1.4.8.4 Test Description

Validation of scheduling without shaper:

Configure traffic stream on both the interfaces, having VLAN priority 0 to 7 and destination IP address targeting to a common output interface. Inject traffic to both the input interfaces.

- In case of strict priority scheduling, highest priority traffic (VLAN prio 0) should be received on output interface if input traffic rate is greater than output rate(10Gbps) otherwise mixed traffic will be received.
- In case of weighted priority scheduling, mixed traffic will be received depending upon the queue weights on output interface with 10Gbps output rate. If configured weights are equal, then mixed traffic will be in equal percentage.

Validation of scheduling with shaper:

Configure traffic stream on both the interfaces, having VLAN priority 0 to 7 and destination IP address targeting to a common output interface. Inject traffic to both the input interfaces.

- In case of strict priority scheduling, highest priority traffic (VLAN prio 0) should be received on output interface if input traffic rate is greater than output rate(Configured shaping rate) otherwise mixed traffic will be received.

- In case of weighted priority scheduling, mixed traffic will be received depending upon the queue weights on output interface with configured shaping rate. If configured weights are equal, then mixed traffic will be in equal percentage.

9.1.4.9 OpenFastPath applications

9.1.4.9.1 Overview

OpenFastPath is an open source implementation of a high performance TCP/IP stack that provides features that network application developers need to cope with today's fast-paced network. To enable this packet processing OFP uses OpenDataPlane.

Following application have been integrated in the ODP for the use on Layerscape architecture:

1.FPM (Forwarding Plane Manager)

```
./fpm -h
Usage: fpm OPTIONS
 E.g. fpm -i eth1,eth2,eth3
ODPFastpath application.

Mandatory OPTIONS: -i, --interface Eth interfaces (comma-separated, no spaces)

Optional OPTIONS
 -c, --count <number> Core count.
 -p, --performance Performance Statistics
 -h, --help Display help and exit.
```

2. FPM_BURSTMODE (Forwarding Plane Manager in burstmode)

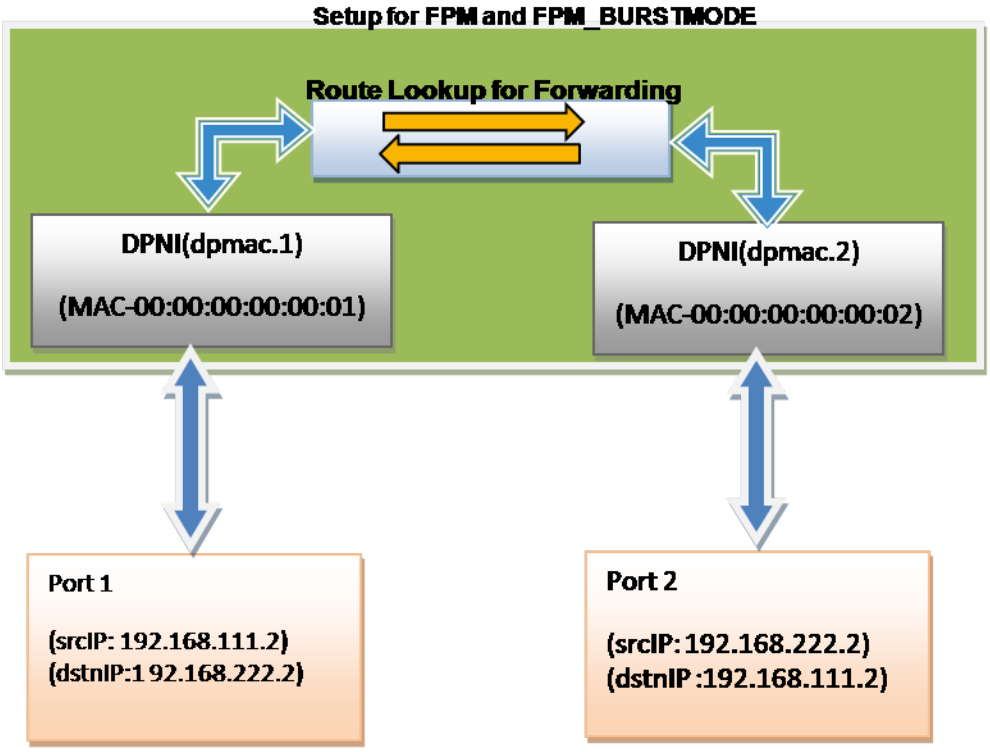
```
./fpm_burstmode -h
Usage: fpm_burstmode OPTIONS
 E.g. fpm_burstmode -i eth1,eth2,eth3
ODPFastpath application.

Mandatory OPTIONS: -i, --interface Eth interfaces (comma-separated, no spaces)

Optional OPTIONS -c, --count <number> Core count.
-h, --help Display help and exit.
```

.

9.1.4.9.2 Test Setup OpenFastPath (fpm & fpm_burstmode)



9.1.4.9.3 Running fpm and fpm_burstmode applications

Execute below commands on DUT to run "fpm" and "fpm_burstmode" applications on the LS1088ardb boards:

```
$ cd /usr/ofp/bin
<Execute the application>
$ ./fpm -i <intf-1>,<intf-2> -c 8 (For running fpm application)
or
$ ./fpm_burstmode -i <intf-1>,<intf-2> -c 8  (For running fpm_burstmode application)

<Assign IP Address to the TAP devices created for each interface used>
$ ifconfig fp0 192.168.111.1/24 up
$ ifconfig fp1 192.168.222.1/24 up
$ echo 1 > /proc/sys/net/ipv4/ip_forward
```

NOTE

DPCI_COUNT must be increased to 128 to run these applications. This can be done by setting the environment variable using "export DPCI_COUNT=128" command before running the dynamic_dpl.sh. Additionally for fpm_burstmode following environment variables needs to be set " export MAX_TCS=8" "export OPR_ENABLE=0" "export FS_ENTRIES=1 ". Interfaces intf-1 can be dpni.<index>. See LS2088ARDB/LS2085ARDB Board Preparation and Bring-up for interface details.

9.1.4.9.4 Test description-ODP OpenFastPath (fpm & fpm_burstmode)

When a packet is received on one of the input interfaces, it will be routed and forwarded according to the forwarding algorithm. The packet will be changed - destination Ethernet address will be updated according to received command line options, the TTL (Hop Limit) will be decremented and the checksum will be recalculated. Finally the packet will be transmitted on the outgoing interface.

Packet format

Stream 1 on interface#1: IPv4 stream, SIP 192.168.111.2 DIP 192.168.222.2

Stream 2 on interface#2: IPv4 stream, SIP 192.168.222.2 DIP 192.168.111.2

Note: User can create desired routes for different Source and Destination IPs using following commands on the board:

```
$ route add -net <subnet/subnet mask> gw <gw address>
for example, Route for destination Subnet 11.11.11.0 to go out through the DPMAC.2(Refer Setup
diagram) should look like:
 route add -net 11.11.11.0/24 gw 192.168.222.2
```

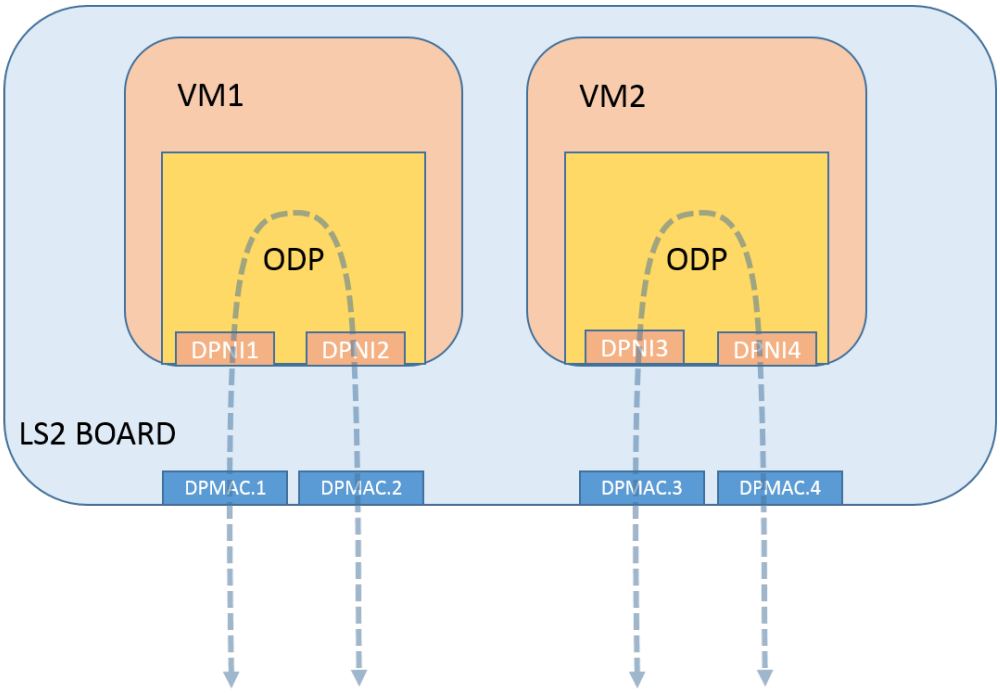
9.1.5 ODP over Virtual Machine (LS2080A)

On LS2080A, ODP is supported over Virtual Machine (VM) with DPAA2 Ethernet Interfaces directly assigned to the Virtual Machine.

The following ODP applications are supported:

- odp_pktio
- odp_l3fwd

ODP_on_VM Setup:



9.1.5.1 Building Images for Virtual Machine

Refer Build ODP Through Yocto on page 1284 section for installing SDK ISO for ODP.

Execute the commands below to build images for ODP on VM in <INSTALL_PATH_FOR_ISO>/QorIQ-SDK-V2.0-20160527-yocto:

1. `. ./fsl-setup-env -m ls2080ardb`

2. `echo 'ROOTFS_IMAGE = "fsl-image-virt"' >> conf/local.conf`
3. bitbake -c cleansstate odp
4. bitbake -c patch odp
5. Uncomment the below line in file *"<INSTALL_PATH_FOR_ISO>/build_ls2080ardb/tmp/work/ls2080ardb-fsl-linux/odp/git-r0/git/platform/linux-dpaa2/Makefile.inc*"
   a. *# DPAA2_CFLAGS += -DODP_USE_PHYS_IOVA*
6. `bitbake fsl-image-kernelitb`

After compiling successfully, the images will be generated at `'<INSTALL_PATH_FOR_ISO>/build_ls2080ardb/tmp/deploy/images/ls2080ardb/'`.

The following images are used for LS2080ARDB and Virtual Machine Bring-up:

- *u-boot-ls2080ardb.bin*
- *PBL_0x2a_0x41_1867_533_1867.bin (rcw)*
- *mc_9.0.5_ls2080a_20160414.itb*
- *dpc-0x2a41.dtb*
- *dpl-odp.0x2A_0x41.dtb*
- *kernel-fsl-ls2080a-rdb.itb*
- *Image*
- *fsl-image-virt-ls2080ardb.ext2.gz.u-boot*

9.1.5.2 Running Virtual Machine

The virtual machine runs inside the host Linux system and it is launched by an application called QEMU. In order to run a virtual machine instance we have to do some preparation steps:

1. Download the Guest Kernel and rootfs Image from Image server.

2. Mount Huge TLBFS on host so that QEMU can use huge pages.

3. Bind Guest's DPRC to the VFIO driver on host.

Please note that console logs for the Guest Linux do not appear on the host Linux console (i.e UART). The guest logs are exposed through telnet, and they can be accessed by doing telnet on the host boards IP Address (IP_ADDR_BRD) and GUEST_CONSOLE_TELNET_PORT. Each Virtual machine that is run on a single host is allocated a different GUEST_CONSOLE_TELNET_PORT, and this port number is specified by user running Virtual machine through QEMU command line.

Steps for running Virtual machine

1. Log-in into to the host Linux.
2. Assign IP_ADDR_BRD to network interface connected to Image server and to the machine from which guest console is accessed.

```
# ifconfig eth0 <IP_ADDR_BRD>
```

3. Mount Huge TLB FS

   Execute the commands below to initialize the resources required by VM to be run:

```
# echo "hugetlbfs /hugetlbfs hugetlbfs defaults,mode=0777 0 0" >> /etc/fstab
```

```
# mkdir /hugetlbfs
# mount /hugetlbfs
```

4. Create DPRC Containers for VM

   a. Create container for VM kernel

   ```
   # ./vm_dpl_setup.sh vm_dpl_setup_parent.conf
   ```

   b. Create container for VM user space

   ```
   # ./vm_dpl_setup.sh vm_dpl_setup_child.conf <DPMAC1> <DPMAC2>
   ```

   Please note that DPMAC1 and DPMAC2 have to be replaced with the DPMACs which have to be given to DPDK running in VM.

   The configuration files for DPL setup i.e. vm_dpl_setup_child.conf and vm_dpl_setup_parent.conf provide the sample configuration for single VM running on 8 cores. For other configurations, the environment variables in configuration file have to be modified accordingly.

   In case of running two virtual machines, step a) and step b) have to be run twice. Each run will create the container for one virtual machine. In the second run the PARENT_DPRC env variable in vm_setup_child.conf has to be updated with the DPRC created in second run of step a).

5. Check the new IOMMU groups created for child dprc container of Guest VM root container. dprc.1 is the system DPRC root container which always belongs to Host Linux. In this example dprc.2 is the child of dprc.1 and this is going to be the root container of VM.

```
# ls sys/devices/platform/80c000000.fsl-mc/dprc.1/dprc.2/
    dpbp.1     dpcon.1   dpio.1   dpmcp.23   dpmcp.27   dprc.3   power
    dpbp.2     dpcon.2   dpio.2   dpmcp.24   dpmcp.28   driver   rescan
    dpbp.3     dpcon.3   dpio.3   dpmcp.25   dpmcp.29   driver_override  subsystem
    dpbp.4     dpcon.4   dpio.4   dpmcp.26   dpni.1     iommu_group  uevent

 DPRC.3 is the only child container of DPRC.2, Check the iommu-group of dprc.3
# readlink /sys/devices/platform/80c000000.fsl-mc/dprc.1/dprc.2/dprc.3/iommu_group

Output
../../../../../../kernel/iommu_groups/7 IOMMU group “6” and “7” should be available in /dev/
vfio/

# ls /dev/vfio/
6 7  vfio
```

NOTE

:- dprc.2 and dprc.3 are resource container that contain pre-allocated resources like ethernet interfaces to be used by virtual machines.

   The child’s IOMMU group has to be given to VM while launching. In above example child’s IOMMU group 7 has to be given to VM during launch. Child’s IOMMU group is referred as CHILD_IOMMU_GROUP in further steps.

6. Go to a directory that has space to copy files. Copy Guest linux kernel and Guest root file system to the directory:

```
#  cd /tmp/
#  scp <USER>@<IP_ADDR_IMAGE_SERVER>:<TFTP_BASE_DIR>/Image   .
#  scp <USER>@<IP_ADDR_IMAGE_SERVER>:<TFTP_BASE_DIR>/ fsl-image-core-ls2085ardb.ext2.gz .
```

7. Launch the Virtual Machine

```
 #   qemu-system-aarch64 -m 4096 -nographic -mem-path /hugetlbfs -cpu host-machine type=virt -
kernel ./Image -enable-kvm -initrd ./fsl-image-ls2085ardb.ext2.gz
        -append 'root=/dev/ram0 rw console=ttyAMA0,115200 rootwait earlyprintk
ramdisk_size=1000000' -serial tcp::4446,server,telnet
        -device vfio-fsl-mc,host=dprc.2 -device vfio-smmu,x-group=<CHILD_IOMMU_GROUP> -smp 8  -S
```

NOTE

- Please note that GUEST_CONSOLE_TELNET_PORT is given as 4446 in above example, if you are running two virtual machines you can give 4446, 4447 to the two virtual machines respectively/
- Value of CHILD_IOMMU_GROUP is 7 in the example that is taken in this document.

The following logs appear on Host UART console upon launching the Virtual Machine

```
QEMU 2.4.0 monitor - type 'help' for more information
(qemu) QEMU waiting for connection on: disconnected:telnet::4446,server
qemu-system-aarch64: -device vfio-fsl-mc,host=dprc.2: Failed to create KVM VFIO device: No such
device
qemu-system-aarch64: -device vfio-fsl-mc,host=dprc.2: Failed to create KVM VFIO device: No such
device
Only One Root DPRC can exists
```

Please note that QEMU logs come completely only when you log-in to the guest machine using telnet as specified in section "Accessing virtual machine console".Also note that The log saying "Failed to create KVM VFIO device: No such device" is currently a known issue, it can be ignored all functionality works even with this log.The –S option mentioned in the qemu command stops the Virtual Machine bootup after initial setup. The QEMU threads needs to be affined to cores sequentially (this is needed because of few H/W limitations). Run 'info cpus' command on QEMU CLI interface to see the QEMU threads.

Console To access the console for launched VM, telnet to the Host Linux ip address with telnet port as specified in the QEMU command while launching the VM

```
$ telnet <IP_ADDR_BRD> 4446
Trying 192.168.1.102...
Connected to 192.168.1.102.
Escape character is '^]'.
```

Console print on UART where VM was launched After connecting to the VM through telnet, qemu command prompt will appear:

```
(qemu) QEMU waiting for connection on: disconnected:telnet::4446,server
qemu-system-aarch64: -device vfio-fsl-mc,host=dprc.2: Failed to create KVM VFIO device: No such
device
qemu-system-aarch64: -device vfio-fsl-mc,host=dprc.2: Failed to create KVM VFIO device: No such
device
Only One Root DPRC can exists
[Press Enter to drop to Qemu shell]
(qemu)
```

Affine VM core threads to Physical CPU

The Virtual Machine core threads needs to be affined to physical cores sequentially to avoid VM core migrating on physical cores.

Run ‘`info cpus command on QEMU CLI interface to get the VM threads ids`

```
 cid="dWNBT">(qemu) info cpus
* CPU #0: thread_id=<tid1>
  CPU #1: (halted) thread_id=<tid2>
  CPU #2: (halted) thread_id=<tid3>
  CPU #3: (halted) thread_id=<tid4>
  CPU #4: (halted) thread_id=<tid5>
  CPU #5: (halted) thread_id=<tid6>
  CPU #6: (halted) thread_id=<tid7>
  CPU #7: (halted) thread_id=<tid8>
```

Open a new SSH session to the host Linux to affine VM threads to physical cores ---------- Affine core for VM on physical cores 0,1,2,3,4,5,6,7 ----------

```
~# taskset -p 0x1 <tid1>
~# taskset -p 0x2 <tid2>
~# taskset -p 0x4 <tid3>
~# taskset -p 0x8 <tid4>
~# taskset -p 0x10 <tid5>
~# taskset -p 0x20 <tid6>
~# taskset -p 0x40 <tid7>
~# taskset -p 0x80 <tid8>
```

*******Continue launching and booting the Virtual Machine********

On the console where qemu was launched, run

```
(qemu) c
```

Once the VM is launched, prompt will come on telnet console

```

ls2080ardb login:
```

8. Launching two Virtual machines

   In case of two virtual machines, please take care of following:

   - Memory assigned to each virtual machine should not exceed the total number of huge pages assigned on system. In above example (step 8) giving 2048 Mega bytes to each virtual machine works fine.

- Console telnet port of both virtual machine must be different, for example 4446 could be console of VM1 and 4447 could be console for VM2.

Following are the example launch commands for two VMs:

VM1:

```
qemu-system-aarch64 -m 2048 -nographic -mem-path /hugetlbfs -cpu host -machine type=virt -
kernel ./Image -enable-kvm -initrd ./fsl-image-ls2085ardb.ext2.gz -append 'root=/dev/ram0 rw
console=ttyAMA0,115200 rootwait earlyprintk ramdisk_size=1000000' -serial tcp::
4446,server,telnet -device vfio-fsl-mc,host=dprc.2 -device vfio-smmu,x-
group=<CHILD_IOMMU_GROUP> -smp 8 –S
```

VM2:

```
qemu-system-aarch64 -m 2048 -nographic -mem-path /hugetlbfs -cpu host -machine type=virt -
kernel ./Image -enable-kvm -initrd ./fsl-image-ls2085ardb.ext2.gz -append 'root=/dev/ram0 rw
console=ttyAMA0,115200 rootwait earlyprintk ramdisk_size=1000000' -serial tcp::
4447,server,telnet -device vfio-fsl-mc,host=dprc.2 -device vfio-smmu,x-
group=<CHILD_IOMMU_GROUP> -smp 8 -S
```

ConsoleTo access the console for launched VM, telnet to the Host Linux ip address with telnet port as specified in the QEMU command while launching the VM machine.

9.1.5.3 Running ODP Application in VM

Resources Allocated to VM

Physical interfaces are assigned to VM through the resource container (dprc.x) assigned to the VM while executing the QEMU command

Data**P**ath**L**ayout (dpl) file used to boot up the system contains two resource containers dprc.2 and dprc.4. Below table lists the interfaces allocated to these two resource containers and below mentioned interface names shall be used while executing the ODP applications.

Host - dprc.2 **(dprc.3 – vm dprc)**			**Host dprc.4** **(dprc.5 – vm dprc)**		
Physical Port	*Port Name to be used in ODP*	*Mac Address*	*Physical Port*	*Port Name to be used in ODP*	*Mac Address*
eth4	dpni-1	02:00:c0:a8:47:01	eth6	dpni-3	02:00:c0:a8:47:03
eth5	dpni-2	02:00:c0:a8:47:02	eth7	dpni-4	02:00:c0:a8:47:04

Execute the commands below on the Virtual Machine before running the ODP application:

```
# echo 512 > /proc/sys/vm/nr_hugepages
# cd /usr/odp/scripts/
# export DPRC=<dprc.x>
# ./bind_dprc.sh <dprc.x>
# export HOST_START_CPU=0
```

NOTE

For <*dprc.x*> use:

- *'dprc.3' for VM launched with dprc.2*
- *'dprc.5' for VM launched with dprc.4*

For *HOST_START_CPU :*

- *First phyical core which is assigned to VM. Default value is 0*

See Using ODP Applications for instructions on how to run ODP Applications.

9.1.6 Troubleshooting

- Please ensure to use correct bootargs:

```
bootargs console=ttyS1,115200 root=/dev/ram0 earlycon=uart8250,mmio,0x21c0600,115200
ramdisk_size=0x2000000 default_hugepagesz=2m hugepagesz=2m hugepages=256
```

- In case application is not able to run please ensure dpni.<index> is used correctly in the command line.

In case packets are not flowing:

- Ensure that traffic generator to board connectivity is proper.
- Ensure that the stream is configured properly having the destination MAC address of that interface where the stream is destined.
- Ensure that there should be no space when interface are specified in application command.

If multiple instances of ODP applications need to be run:

Make sure to set APPL_MEM_SIZE environment variable before running the application to specify the memory to be used by application. The size is specified in MegaBytes e.g in case application plans to use 32MB of memory, then following command can do reservation:

```
export APPL_MEM_SIZE=32
```

9.1.7 Using Debug Tool to Get Hardware Statistics for DPAA2 Platforms

Using DEBUG TOOL to get hardware stats for DPAA2 platforms:

plat_debug_tool is used to display stats of hardware blocks like QBMAN, Crypto, etc.

How to use plat_debug_tool

NOTE

The plat_debug_tool is only applicable to DPAA2 platforms.

1. Enabling Debug Server in ODP applications

By default debug server is disabled in ODP applications. To enable debug server, execute following commands

```
$ export PLAT_DEBUG_THREAD=1
$ export PLAT_DEBUG_PORT=<x>
```

- *<x> : UDP port number on which debug server will listen upon.*
- *Valid range: 1024 to 65535.*

- *Default port is 10000.*

2. Running plat_debug_tool client

Before running plat_debug_tool, execute following command:

```
$ export PLAT_DEBUG_PORT=<x>
```

- *<x> : UDP port number on which client will bind to.*
- *Default port is 10000.*

NOTE

UDP port number should be same as given for server.

For running plat_debug_tool, execute following command.

```
$ ./plat_debug_tool -d dpni.1 -o 0 -c 0 -i 192.168.10.10 (Reference Command)
```

- Usage: ./plat_debug_tool OPTIONS
  - Mandatory OPTIONS:
    - -d, --device Device name like dpni.1, dpbp.1

      NOTE

      Execute restool command to identify the HW devices used by ODP application

      Supported devices:
      - dpni.x - for hardware interfaces
      - dpbp.x - for buffer pools
      - dpseci.x - for ipsec

      NOTE

      option not required for object ID 20 (will be ignored if given)

    - -o, --obj_id all: Display all the stats for a given device.

      Stats for dpni.x
      - 0: Dpni Stats
      - 1: Dpni Attributes
      - 2: Dpni Link State
      - 3: Dpni Max Frame Length
      - 4: Dpni MTU
      - 5: L3 chksum hardware offload (enable/disable)
      - 6: L4 chksum hardware offload (enable/disable)
      - 7: Dpni Primary Mac Addr
      - 8: Congestion Group Id for FQs
      - 9: Scheduling Priority for FQs
      - 10: Tail Drop Threashold for FQs
      - 11: FQ Context
      - 12: FQ State

Stats for dpbp.x

- 13: Qbman frame count
- 14: Qbman byte count
- 15: Qbman has free buffers or not
- 16: Qbman buffer pool is depleted or not
- 17: Number of free buffers in qbman

Stats for dpsec.x

- 18: DPseci Attributes
- 19: DPseci counters
- 20: Per SA stats (only for odp_ipsec and odp_ipsec_proto apps)

NOTE

To use per SA stats option, It is required to enable the ipsec-debugs at compile time. Following are the steps to enable the ipsec-debugs in yocto:

1. Go to the following path:
   a. cd sources/meta-fsl-dataplane/recipes-extended/odp
2. Add a following line in the file "odp_git.bb"
   a. For board ls2080ardb:
      i. EXTRA_OECONF_append_ls2080ardb += "--enable-ipsec-debug=yes"
   b. For board ls2088ardb:
      i. EXTRA_OECONF_append_ls2088ardb += "--enable-ipsec-debug=yes"
3. Go back to the build directory and run the following commands to recompile the ODP:
   a. bitbake -f -c clean odp
   b. bitbake -f -c compile odp

- -c, --command
  - 0: get
  - 1: reset
- -i, --dest_ip
  - IP address of debug server
  - Default: local host (127.0.0.1)
- -h, --help
  - Display help and exit.

9.2 DPDK User Manual

9.2.1 Introduction

Scope

This document contains instructions for installing and configuring the user space based Data Plane Development Kit (DPDK) software. It is designed to get customers up and running quickly. The document describes how to compile and run a DPDK application in a Linux application (linuxapp) environment, without going deeply into detail.

Intended audience

This document is intended for software developers and architects who want to use or develop DPDK API complaint user space applications on QorIQ based platforms. The document assumes that users are familiar with Linux-based software development, and also with the DPDK concepts and APIs.

9.2.1.1 Supported Platforms

- LS1043ARDB
- LS1046ARDB
- LS2088ARDB

9.2.1.2 Definitions and Acronyms

Definition and acronyms

Acronym/Term	Description
DPDK	Data Plane Development Kit
RCW	Reset and control word
Host	The term ‘Host’ is used for Linux running on Layerscape board directly
Guest/VM	The term ‘Guest’ is used for Linux running inside the virtual machine(s) that are in turn running over Host Linux operating system.VM and Guest have been used interchangeably in this guide
IP_ADDR_BRD	This term is used for IP address of LS1 and LS2 RDB boards
IP_ADDR_IMAGE_SERVER	This term is used for IP address of the machine on which all the software images are kept
TFTP_BASE_DIR	Base directory of TFTP server where all the images are kept
GUEST_CONSOLE_TELNET_PORT	Telnet port for accessing guest console
DPAA2	Data Path Acceleration Architecture Gen 2. Steps/text marked with this marker are applicable for DPAA2 platforms
DPAA	Steps/Test marked with this marker are applicable for DPAA platforms

9.2.1.3 References

Document	Link	Version	Description
LS1043ARDB	LS1043A-RDB: QorIQ LS1043A Reference Design Board		
LS1046ARDB	LS1046A-RDB: QorIQ LS1046A Reference Design Board		
LS2088ARDB	LS2088A-RDB: QorIQ LS2088A Reference Design Board		
L2fwd	L2fwd usage	NA	L2fwd usage and setup
L2fwd-Crypto	L2fwd-crypto	NA	L2fwd-crypto usage and setup
L3fwd	L3fwd usage	NA	L3fwd usage and setup
Ipsec-secgw	Ipsec-secgw usage	NA	Ipsec-secgw usage and setup

9.2.2 DPDK Overview

The main goal of the DPDK is to provide a simple, complete framework for fast packet processing in data plane applications. Users may use the code to understand some of the techniques employed, to build upon for prototyping or to add their own protocol stacks.

The framework creates a set of libraries for specific environments through the creation of an Environment Abstraction Layer (EAL), which may be specific to a mode of the specific platform. These environments are created through the use of make files and configuration files. Once the EAL library is created, the user may link with the library to create their own applications. Other libraries, outside of EAL, including the Hash, Longest Prefix Match (LPM) and rings libraries are also provided. Sample applications are provided to help show the user how to use various features of the DPDK.

The DPDK implements a run to completion model for packet processing, where all resources must be allocated prior to calling Data Plane applications, running as execution units on logical processing cores. The model at present does not support a scheduler and all devices are accessed by polling. The primary reason for polling is the performance overhead imposed by interrupt processing. On the flip side, it causes the the core to be 100% utilized always even on low traffic scenario.

In addition to the run-to-completion model, a pipeline model may also be used by passing packets or messages between cores via the rings. This allows work to be performed in stages and may allow more efficient use of code on cores.

More information on general working of DPDK can be found at: http://dpdk.readthedocs.io/en/v16.07/prog_guide/index.html

9.2.2.1 DPDK DPAA Platform Support

The NXP Data Path Acceleration Architecture comprises a set of hardware components which are integrated via a hardware queue manager and use a common hardware buffer manager. Software accesses the DPAA via hardware components called "*Software Portals or DPIO*". These directly provide queue and buffer manager operations such as enqueues, dequeues, buffer allocations, and buffer releases and indirectly provide access to all of the other DPAA hardware components via the queue manager.

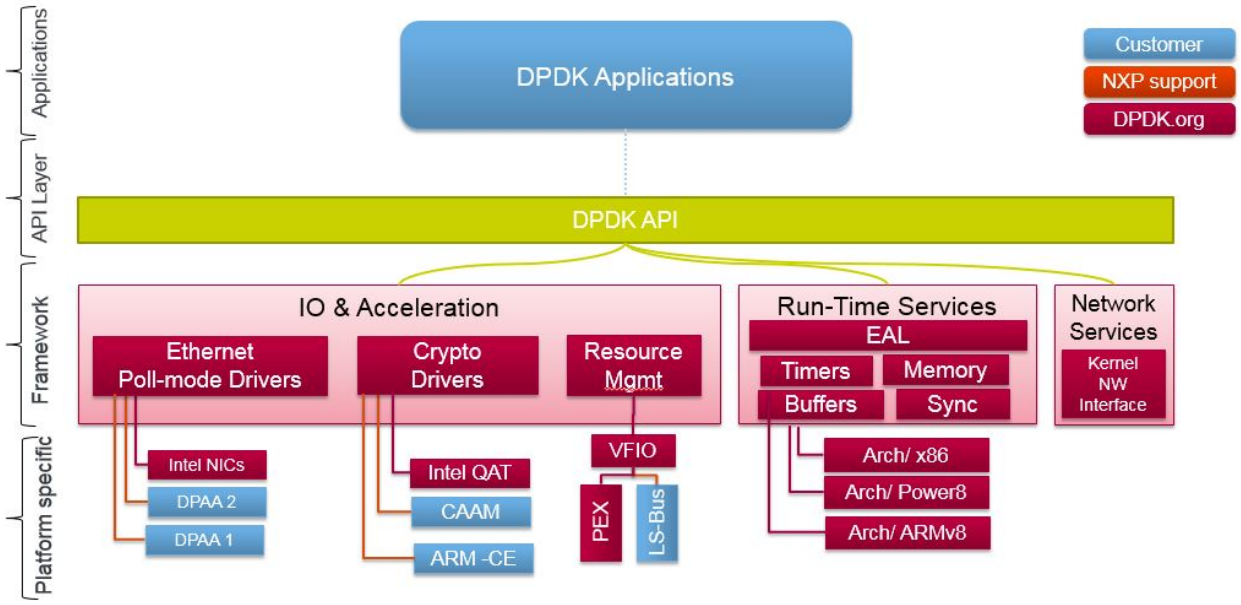

Figure 197. DPDK Architecture with NXP DPAA Components

NXP DPAA architecture based *PMD (Poll Mode Drivers)* has been added to DPDK infrastructure to support seamless working on NXP platform. With the addition of these drivers, DPDK framework on NXP platforms permits Linux user space applications to be build using standard DPDK APIs in a portable fashion. The drivers directly access the DPAA queue and buffer manager software portals in a high performance manner and the internal details remains hidden from higher level DPDK framework. The *PMD*s has also been added for security co-processor as `dpaa2_caam`.

Some of these changes to support NXP DPAA architecture in DPDK are not yet part of Open Source DPDK Repository. Efforts are underway to publish the complete *PMD* code in the upstream repository.

Multithread environment

DPDK was originally designed for Intel architectures, however efforts are underway to make it multiple architecture friendly. Still, there are some restrictions, which should be taken care, when used on NXP platforms.

1. Multiple pthreads

   DPDK usually pins one pthread per core to avoid the overhead of task switching. This allows for significant performance gains, but lacks flexibility and is not always efficient. DPDK is comprised of several libraries. Some of the functions in these libraries can be safely called from multiple threads simultaneously, while others cannot. This section allows the developer to take these issues into account when building their own application.

   The run-time environment of the DPDK is typically a single thread per logical core. Typically, it is best to avoid sharing data structures between threads and/or processes where possible. Where this is not possible, the execution blocks must access the data in a thread-safe manner. Mechanisms such as atomics or locking can be used to allow execution blocks to operate serially. However, this can have an effect on the performance of the application.

2. Fast-path APIs

   Applications operating in the data plane are performance sensitive but certain functions within those libraries may not be safe to call from multiple threads simultaneously.

   The Hash, LPM, Mempool libraries and RX/TX in the PMD are examples of such multithread unsafe functions. The RX/TX of the *PMD* are the most critical aspects of a DPDK application and it is recommended that no locking be used with these paths as it will impact performance. Note, however, that these functions can safely be used from multiple threads when each thread is performing I/O on a different NIC queue. If multiple threads are to use the same hardware queue on the same NIC port, then locking or some other form of mutual exclusion is necessary. In the NXP implementation, each thread has to use a software portal (DPIO) instance to access the underlying DPAA hardware. Thus, it is recommended that only one thread per logical core should be created for RX/TX and other I/O access to DPAA hardware.

Since this guide contains support for both DPAA2 and DPAA platforms, the following markers are used throughout the guide:

- DPAA2 – This marker marks the steps/text applicable only for DPAA2 platforms. e.g. LS2088
- DPAA – This marker marks the steps/text applicable only for DPAA platforms. e.g. LS1043

All other steps which don't have any marker are applicable for both platforms.

9.2.3 Build DPDK

For detailed information on ISO installation, see "Essential Build Instructions" under "Getting Started" within the QorIQ SDK documentation.

9.2.3.1 Standalone compilation of DPDK framework and example binaries

A limited set of DPDK binaries are already part of the Root filesystem used for booting up the LSXXXXA RDB. Steps mentioned in below sections are for illustrating standalone DPDK framework and application compilation.

DPDK Sources can be obtained as per the Release Note. Following steps assume that DPDK sources are available from notified location.

Compilation Steps

1. Common commands to be run for both DPAA2 and DPAA platforms:

```
# export KERNEL_PATH=<kernel path>
# export CROSS_COMPILE=<toolchain path>
```

2. DPAA2 and DPAA specific commands

   a. DPAA2

```
#source standalone-dpaa2
(Change the standalone script as per your environment)
# make T=arm64-dpaa2-linuxapp-gcc install
```

   b. DPAA

```
#source standalone-dpaa
(Change the standalone script as per your environment)
# make T=arm64-dpaa-linuxapp-gcc install
```

NOTE

Depending on the platform for which build is targeted (DPAA2 or DPAA) either 2.a or 2.b is required, both steps should not be used in same compilation iteration.

3. DPDK sample application compilation (same steps for both DPAA and DPAA2 platforms)

   For compiling the example applications, following steps can be used: (only steps for l2fwd and l3fwd applications are shown below, but similar steps would be application for other applications available as part of DPDK framework):

```
# make -C examples/l3fwd
# make -C examples/l2fwd
# testpmd and test applications get compiled along with DPDK framework
```

Location of binaries

```
examples/l2fwd/build/l2fwd
examples/l3fwd/build/l3fwd
arm64-dpaa2-linuxapp-gcc/build/app/test-pmd/testpmd
```

The ARMCE driver compilation is enabled by default, and it needs openssl libraries for compilation. Follow the steps to compile DPDK with ARMCE:

The code base of openSSL can be downloaded from OpenSSL Git. Use tag “OpenSSL_1_0_2h” for checkout the code and build openSSL using the following commands:

```
# ./configure linux-aarch64 --prefix=<OpenSSL library path> shared
# make
# make install# export OPENSSL_PATH=<OpenSSL library path>
```

Modify `config/defconfig_arm64-dpaa2-linuxapp-gc`c to `enable/disable`ARMCE:

```
CONFIG_RTE_LIBRTE_PMD_ARMCE=n
```

Recompile DPDK after any change in the config files.

If you are not using standard rootfs, you may need the openssl libraries (libcrypto.so.1.0.0 and libssl.so.1.0.0) to be copied at location `/lib` and `/usr/lib` respectively on the board.

After compilation of DPDK (with ARMCE), compile the l2fwd-crypto and test application as shown below.

L2fwd-crypto

```
# make -C examples/l2fwd-crypto
```

L2fwd-crypto binary is built in `examples/l2fwd-crypto/build/`

ipsec-secgw

```
# make -C examples/ipsec-secgw
```

Ipsec-secgw binary is built in `examples/ipsec-secgw/build/`

Test

```
# make -C app/test
```

test binary is built in `app/test/build/app/`

9.2.3.2 Yocto based Build

DPDK applications can also be compiled alone using Yocto once you have ran "*bitbake fsl-image-kernelitb*". The steps are as follows:

1. cd build_<board-name>/
2. source SOURCE_THIS
3. Clean DPDK: bitbake -f -c cleansstate dpdk
4. Make DPDK: bitbake -f -c compile dpdk

   Note: the step above will only compile the dpdk library and applications. To add them to rootfs and to create a Kernelitb, use the command given below.
5. bitbake fsl-image-kernelitb

Note: For dpdk virtual kernel .itb generation use below command before starting “bitbake fsl-image-kernelitb”

echo 'ROOTFS_IMAGE = "fsl-image-virt"' >> conf/local.conf

9.2.3.3 Pktgen

Compiling Pktgen

Get pktgen-dpdk sources:

Pktgen source has to be cloned from upstream repository and following steps have to be followed to build pktgen:

```
# git clone git://dpdk.org/apps/pktgen-dpdk => do the make install in DPDK.
# make sure the CROSS_COMPILE path is set.
# export RTE_SDK=<DPDK Source DIR>
```

For DPAA2 platforms set `RTE_TARGET=arm64-dpaa-linuxapp-gcc`:

```
# export RTE_TARGET=arm64-dpaa2-linuxapp-gcc
```

For DPAA platforms set `RTE_TARGET=arm64-dpaa-linuxapp-gcc`:

```
# export RTE_TARGET=arm64-dpaa-linuxapp-gcc
```

To build:

```
# make
```

Copy "`Pktgen.lua`" and "`pktgen`" (available at: `app/app/arm64-dpaa2-linuxapp-gcc/pktgen`) to the board.

NOTE

Pktgen is not yet integrated with Yocto based build, so it has to be built standalone as described in this section.

9.2.4 Software Images and Overview

The list of images below are used to run DPDK and related applications on the target platform.

NOTE

The tables given in the following subsections contain:

*MACRO/name is used for the image (“*_IMG”) - this name is used in this document wherever the image should be referenced.

*Non-specific platform suffix is given as ‘X’ - exact name of image for a platform is defined in platform subsection for each platform in

The images which are common for all platforms i.e images without any “X” suffix are mentioned in this chapter only with their correct names applicable for all platforms, thus they are not mentioned in

9.2.4.1 Platform Images

Images common for both DPAA and DPAA2 platform:

S/No	File/Image Name	Macro/Name used for this image within the guide	Description
1	u-boot-<X>.bin	PLAT_UBOOT_IMG	u-boot binary
2	rcw_1600.bin or PBL_0x2a_0x41_1867_533_1867.bin	PLAT_RCW_IMG	RCW Binary
3	kernel-fsl-<X>.itb	PLAT_KRNL_IMG	ITB binary containing Linux kernel binary and Root file system.

Images applicable only to DPAA platforms:

S/No	File/Image Name	Macro/Name used for this image within the guide	Description
1	fsl_fman_ucode_<X>.bin	DPAA_FMAN_UCODE_IMG	FMAN Binary
2	ppa.itb	DPAA_PPA_IMG	PPA Binary

Images applicable only to DPAA2 platforms:

S/No	File/Image Name	MACRO/NAME used for image within the guide	Description
1	mc_<version>_<X>.itb	DPAA2_MC_IMG	Management complex binary
2	dpc-0x2a41.dtb	DPAA2_DPC_IMG	DPC Image
3	dpl-eth.0x2A_0x41.dtb	DPAA2_DPL_IMG	DPL Image

9.2.4.2 Virtual machine (VM or guest) images

S/No	File/Image name [with absolute path in target platform rootfs]	MACRO/NAME used for image throughout the guide	Description
1	/boot/Image	VM_KRNL_IMG	Virtual machine's Kernel Image
2	/boot/fsl-image-core-<X>.ext2.gz	VM_ROOTFS_IMG	Virtual machine's Root file system image

9.2.4.3 DPDK and application images

S/No	File/Image name [absolute path in target platform rootfs]	Description

Table continues on the next page...

Table continued from the previous page...

1	`/usr/bin/dpdk-example/l2fwd`
	`/usr/bin/dpdk-example/l3fwd`
	`/usr/bin/dpdk-example/l2fwd-crypto`
	`/usr/bin/dpdk-example/testpmd`
		DPDK Example applications

2	`/usr/bin/dpdk-example/extras/usdpaa_config_ls<PLAT>.xml`
	`/usr/bin/dpdk-example/extras/usdpaa_policy_hash_ipv4_1queue.xml`
	`/usr/bin/dpdk-example/extras/usdpaa_policy_hash_ipv4_2queue.xml`
	`/usr/bin/dpdk-example/extras/usdpaa_policy_hash_ipv4_4queue.xml`
		DPAA
		FMC Configurations and Policy files. These are applicable only for DPAA platforms. Plat is platform name for DPAA platform for example ls1043 or ls1046

3	`/usr/bin/dpdk-example/extras/dynamic_dpl.sh`	DPAA2 Dynamic DPL container creation script. This is applicable only for DPAA2 platforms
4	`/usr/sbin/dpdk_nic_bind`	DPDK NIC binding utility. This is only applicable for executing DPDK applications in VM.
5	`/usr/bin/ovs-dpdk/ovsdb-tool`	OVS database tool image
6	`/usr/bin/ovs-dpdk/ovsdb-server`	OVS data base server
7	`/usr/bin/ovs-dpdk/ovs-vsctl`	OVS switch control tool
8	`/usr/bin/ovs-dpdk/ovs-vswitchd`	OVS switch daemon
9	`/usr/bin/ovs-dpdk/ovs-ofctl`	OVS flow control tool

NOTE

DPAA1

For DPAA1, OVS images (`/usr/bin/ovs-dpdk`) are only included in the kernel itb with virtualization support i.e. the kernel itb is created by changing rootfs using the following command:

```
$ echo 'ROOTFS_IMAGE = "fsl-image-virt"'>>conf/local.conf
```

9.2.5 Supported Platforms and Platform-specific Details

NOTE

DPDK in this SDK release supports DPAA platforms (LS1043A and LS1046A), and DPAA2 platform LS2088A.

9.2.5.1 LS1043A Reference Design Board (RDB)

LS1043A is a DPAA-based platform. Follow all the optional steps marked for DPAA platforms in this document. For more information on LS1043ARDB, see www.nxp.com/LS1043ARDB

Hardware specifications

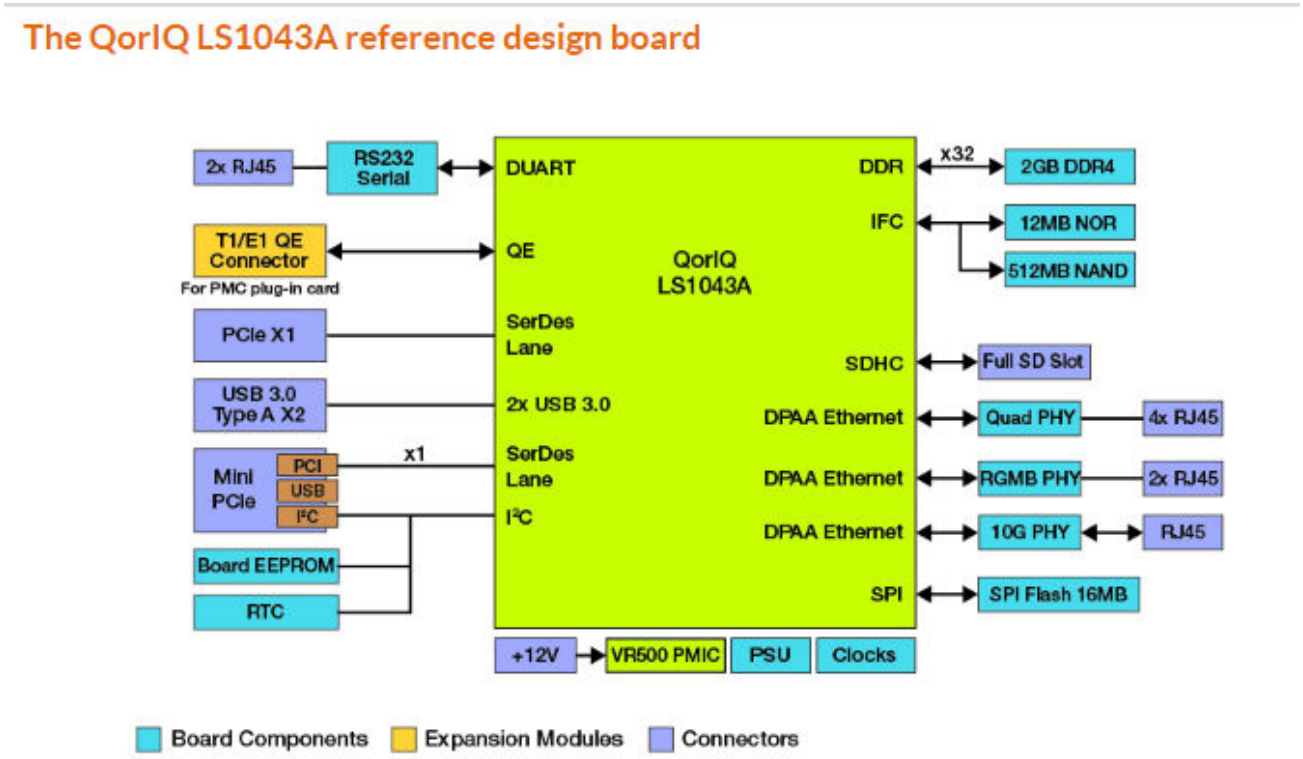

Figure 198. QorIQ LS1043A Reference Design

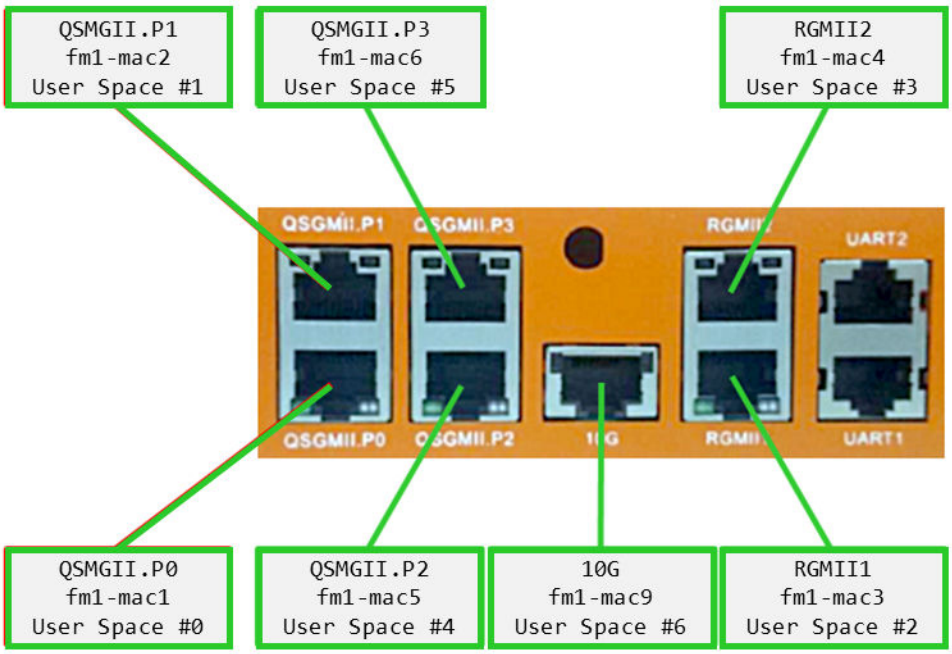

Figure 199. LS1043A Port Layout

Software image names

S/No	File name for this platform	MACRO/name used for image throughout this guide	Description
1	`u-boot-ls1043ardb.bin`	PLAT_UBOOT_IMG	U-Boot Image
2	`rcw_1600.bin`	PLAT_RCW_IMG	RCW Image
3	`kernel-fsl-ls1043a-rdb-usdpaa.itb`	PLAT_KRNL_IMG	Host kernel Image
4	`fsl_fman_ucode_ls1043_r1.1_106_4_18.bin`	DPAA_FMAN_UCODE_IMG	FMAN microcode image
5	`fsl-image-core-ls1043ardb.ext2.gz`	VM_ROOTFS_IMG	Virtual machine's Root FS image.

9.2.5.2 LS1046A Reference Design Board (RDB)

LS1046A is a DPAA-based platform. Follow all the optional steps marked for DPAA platforms in this guide. For more information on QorIQ LS1046A, see www.nxp.com/LS1046ARDB.

Hardware specifications

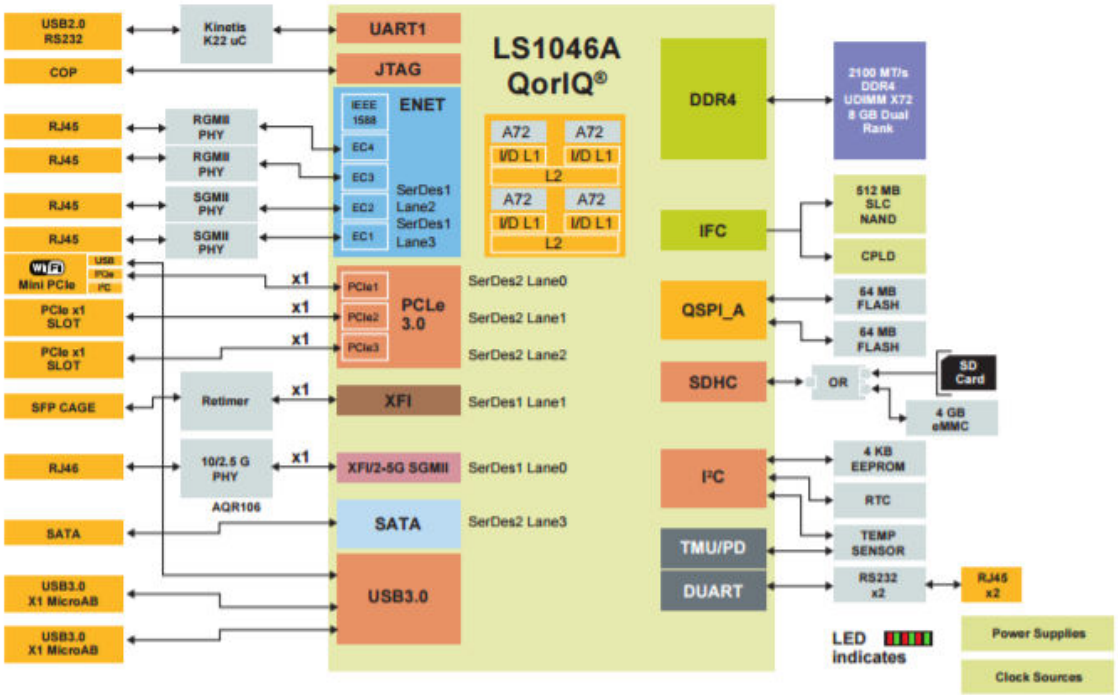

Figure 200. QorIQ LS1046A Reference Design

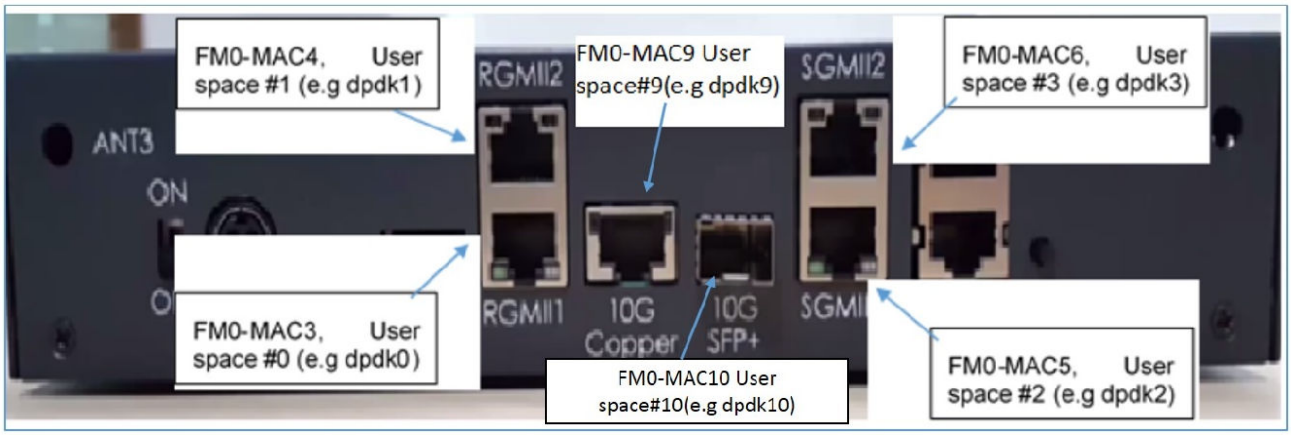

Figure 201. LS1046A Port Layout

Software image names

S/No	File name for this platform	MACRO/name used throughout this section	Description
1	`u-boot-qspi.bin`	PLAT_UBOOT_IMG	U-Boot Image
2	`rcw_1600_qspiboot.bin` or `rcw_1800_qspiboot.bin`	PLAT_RCW_IMG	RCW Image
3	`kernel-fsl-ls1046a-rdb-usdpaa.itb`	PLAT_KRNL_IMG	Host kernel Image
4	`fsl_fman_ucode_ls1046_r1.0_106_4_18.bin`	DPAA_FMAN_UCODE_IMG	FMAN microcode Image
5	`fsl-image-core-ls1046ardb.ext2.gz`	VM_ROOTFS_IMG	Virtual machine's Root FS image.

9.2.5.3 LS2088A Reference Design Board (RDB)

Hardware specifications

LS2088A Reference Design Board

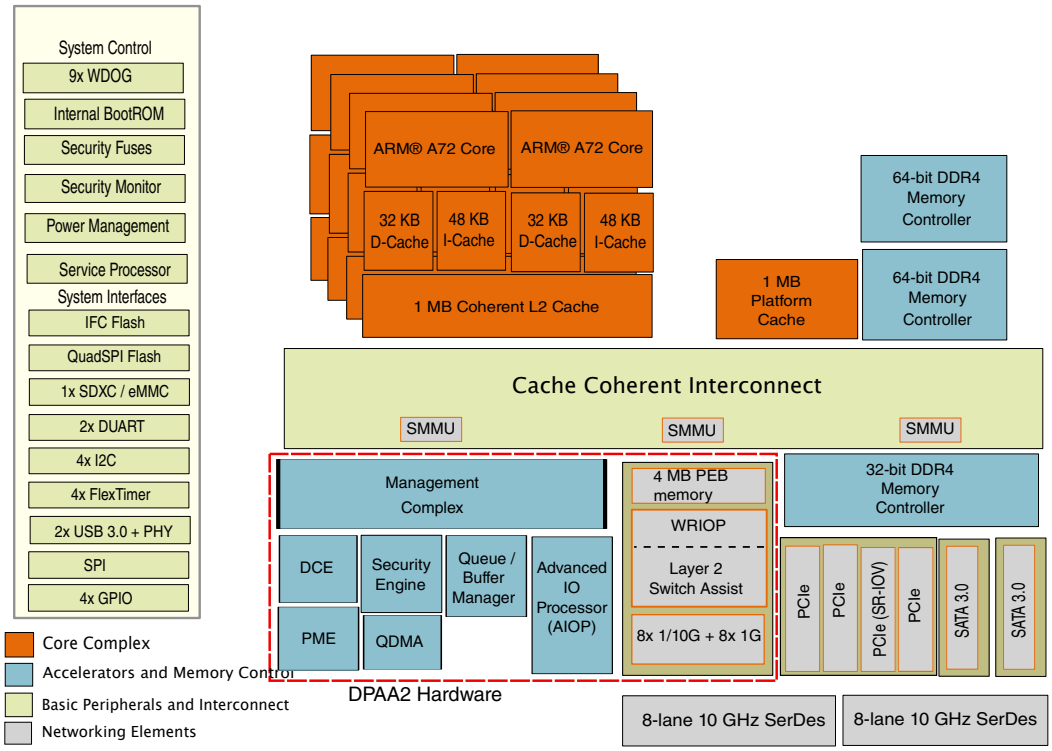

Figure 202. QorIQ LS2088A Architecture

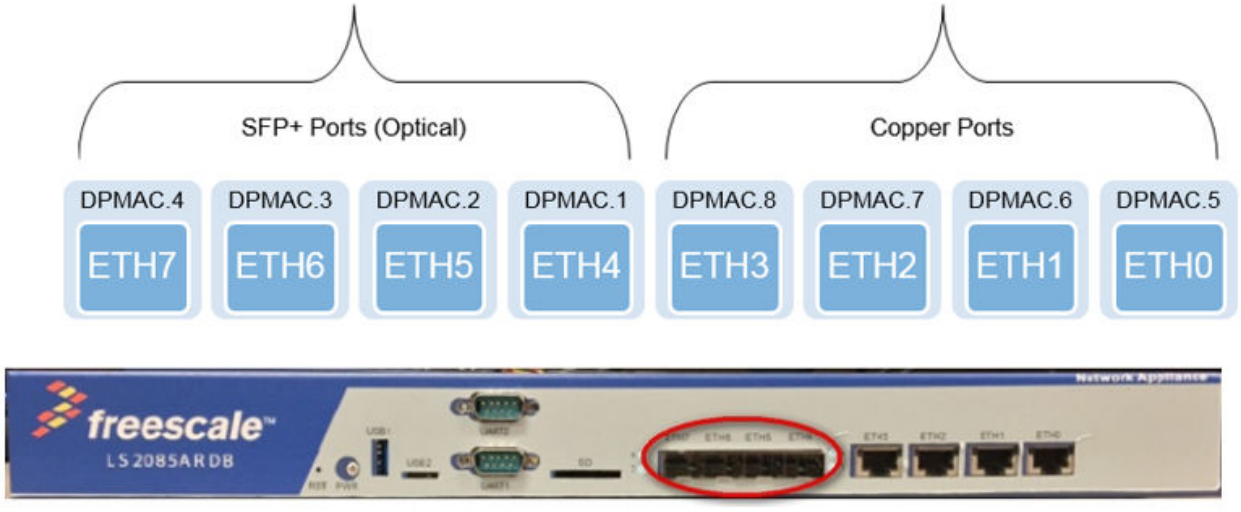

Figure 203. LS208xARDB Connector Locations (Panel)

Software specifications

The LS2088ARDB and DPDK binary images are built using the Yocto Project build process. The root filesystem includes a minimal set of DPDK example and helper scripts. Refer the Yocto build process guide provided as part of the release to obtain the following images:

Table 209. List of LS2088ARDB Images from Yocto Project build process

S/No	File/Image Name	Description
1	u-boot-ls2088ardb.bin	u-boot binary
2	PBL_0x2a_0x41_1800_700_1866_1600.bin or PBL_0x2a_0x41_2000_800_2133_1600.bin(for rev. F boards only)	RCW Binary
3	mc_10.1.2_ls2088a.itb	MC Binary 10.1.x
4	dpc.0x2A_0x41.dtb	DPC Image
5	dpl-eth.0x2A_0x41.dtb	DPL Image
6	kernel-fsl-ls2088a-rdb.itb	ITB binary containing Linux kernel binary and Root file system.

9.2.6 Executing DPDK Applications on Host

This section describes how to execute DPDK and related applications in both Host and VM environments.

NOTE

IP_ADDR_BRD, IP_ADDR_IMAGE_SERVER, and TFTP_BASE_DIR are not U-Boot or Linux environment variables. They are used in this document to represent:

1. **IP_ADDR_BRD**: IP address of target board in test setup.
2. **IP_ADDR_IMAGE_SERVER**: IP address of the machine where all the software images are kept. These images are transferred to the board using either tftp or scp.
3. **TFTP_BASE_DIR**: TFTP base directory of TFTP server running on the machine where images are kept.

9.2.6.1 Flashing and booting up the target board

Follow the SDK documentation instructions to flash following images for the target board:

Common Images:

- U-boot
- RCW

DPAA specific images:

- FMAN micro code
- PPA image

DPAA2 specific images:

- Management complex Image
- DPC Image
- DPL Image

Ensure correct settings for IP_ADDR_BRD and IP_ADDR_IMAGE_SERVER, so that the board and server machine are reachable/ping-able.

9.2.6.2 DPDK examples and DPDK-based applications

This section describes the procedures once the target platform is booted up and logged into the Linux shell. This section is applicable to both DPAA and DPAA2 platforms and is organized as follows:

- *Generic Setup – DPAA* and *Generic Setup – DPAA2* contain common steps to be executed before executing any of DPDK example or DPDK-based applications. Only one of the sections must be followed depending on whether you are using a DPAA- or DPAA2-based platform.
- Application specific sections contain steps on how to execute the DPDK example and related applications.

9.2.6.2.1 Test Setup

Figure 204. Test Setup

9.2.6.2.2 Generic Setup - DPAA

This section contains steps which are common for all applications; these steps must be followed before executing any DPDK or related application on a DPAA-based platform.

DPAA-based platforms have DPAA hardware acceleration. The queues are hardware accelerated queues. They need to be configured in the DPAA-FMAN prior to being used. This can be done by choosing the appropriate policy configuration file. One can select either 1, 2 or 4 queue-based policy files. e.g. running a l3fwd application configuration may be 1 queue per port or 2 queues per port, so choose appropriate policy configuration file.

Any of the policy files below can be used while running the FMAN configure i.e. FMC script:

- `usdpaa_policy_hash_ipv4_1queue.xml`
- `usdpaa_policy_hash_ipv4_2queue.xml`
- `usdpaa_policy_hash_ipv4_4queue.xml`

All the DPDK binaries are part of the rootfs and can be found at:

```
# /usr/bin/dpdk-example
```

All the supporting DPDK XML files can be found at:

```
# /usr/bin/dpdk-example/extra
```

NOTE

Based on the policy files used, make sure that the DPDK applications runtime parameters are configured appropriately.

- *Configure the number of queues for distribution*

```
# export DPAA_NUM_RX_QUEUES=<Number of queues>
```

For example, if FMC policy file `usdpaa_policy_hash_ipv4_1queue.xml` is being used, set:

```
# export DPAA_NUM_RX_QUEUES=1
```

- *Configure FMAN (DPAA Ethernet block)*

  Run the FMC script as follows:

```
# fmc -c /usr/bin/dpdk-example/extras/usdpaa_config_ls1043.xml -p /usr/bin/dpdk-example/extras/
usdpaa_policy_hash_ipv4_1queue.xml -a
```

- *Setup huge pages*

  Using `mount | grep hugetlbfs` check to see if hugepages is already mounted. If the mount point does not exist, the command will not print any output.

```
# mkdir /mnt/hugepages
# mount -t hugetlbfs none /mnt/hugepages
```

9.2.6.2.3 Generic Setup - DPAA2

This section contains steps which are common for all applications; these steps must be followed before executing any DPDK or related application on a DPAA2-based platform.

These steps must be performed before running any of the DPDK application on host (including nxp-vhost application for running VM):

- Configure the DPAA2 resources with restool and define the resource container i.e. add the DPRC for application

```
# /usr/bin/dpdk-example/extras/dynamic_dpl.sh <DPMAC1_IDX> <DPMAC2_IDX>
# export DPRC=dprc.<DPRC_INDEX>
```

For example

```
/usr/bin/dpdk-example/extras/dynamic_dpl.sh  dpmac.1 dpmac.2

###################### Container  dprc.2  is created ####################

Container dprc.2 have following resources :=>

 * 16 DPBP
 * 5 DPCON
 * 4 DPSECI
 * 3 DPNI
 * 10 DPIO
 * 10 DPCI

######################### Configured Interfaces #########################

Interface Name        Endpoint              Mac Address
==============        ========              ==================
dpni.1                dpmac.3               00:00:00:00:0:3
dpni.2                dpmac.2               00:00:00:00:0:2
```

Once the steps above are performed, the environment will be set with appropriate container variable (DPRC) for DPDK Application execution. The script above also includes mounting of hugepages.

```
# export DPRC=dprc.2
```

9.2.6.2.4 DPDK example applications

L2fwd

For more information on L2fwd application, refer to L2 Forwarding Sample Application (in Real and Virtualized Environments).

```
# /usr/bin/dpdk-example/l2fwd -c 0x2 -n 1 -- -p 0x1 -q 1
```

L3fwd

For more information on L3fwd application, refer to L3 Forwarding Sample Application.

```
# /usr/bin/dpdk-example/l3fwd -c 0x6 -n 1 -- -p 0x3 --config="(0,0,1),(1,0,2)"
```

4 core - 2 Port, 2 queue per port

```
./l3fwd -c 0xF -n 4 -- -p 0x3 -P --
      config="(0,0,0),(0,1,1),(1,0,2),(1,1,3)"
```

4 core - 2 Port with dest mac

```
./l3fwd -c 0xF -n 4 -- -p 0x3 -P --config="(0,0,0),(0,1,1),(1,0,2),(1,1,3)" --eth-
dest=0,11:11:11:11:11:11 --eth-dest=1,00:00:00:11:11:11
```

8 core - 2 Port with 4 queue per port

```
./l3fwd -c 0xFF -n 1 -- -p 0x3 --config="(0,0,0),(0,1,1),(0,2,2),(0,3,3),(1,0,4),(1,1,5),(1,2,6),
(1,3,7)"
```

L2fwd-Crypto - ARMCE

For more information on L2fwd-crypto application, refer to L2 Forwarding with Crypto Sample Application.

L2fwd-crypto Application favors physical devices with respect to virtual devices. So in order to run ARMCE, blacklist the physical devices by adding following command line parameters before ' -- ' in the commands shown below.

DPAA

```
-b 0002:10:10.0 -b 0002:10:11.0 -b 0002:10:12.0 -b 0002:10:13.0
```

DPAA2

```
-b 0000:00:00.3 -b 0000:00:01.3 -b 0000:00:02.3 -b 0000:00:03.3
```

- Cipher_only
  - 1 core:

    ```
    # ./l2fwd-crypto --vdev "cryptodev_armce_pmd"  -c 0x2 -n 1 -- -p 0x1 -q 1 -s --chain CIPHER_ONLY
    --cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key 01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:
    0e:0f:10
    ```

  - 2 core:

    ```
    # ./l2fwd-crypto --vdev "cryptodev_armce_pmd0" --vdev "cryptodev_armce_pmd1" -c 0x6 -n 1 -- -p
    0x3 -q 1  --chain CIPHER_ONLY  --cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key
    01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:0f:10
    ```

- 4 core:

```
# /usr/bin/dpdk-example/l2fwd-crypto --vdev "cryptodev_armce_pmd0" --vdev
"cryptodev_armce_pmd1" --vdev "cryptodev_armce_pmd2" --vdev "cryptodev_armce_pmd3" -c 0xf -n 1
-- -p 0xf -q 1  --chain CIPHER_ONLY  --cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key
01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:0f:10
```

- Cipher_hash
  - 1 core:

```
# /usr/bin/dpdk-example/l2fwd-crypto --vdev "cryptodev_armce_pmd" -c 0x2 -n 1 -- -p 0x1 -q 1 --
chain CIPHER_HASH  --cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key
01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:0f:10 --auth_algo SHA1_HMAC --auth_op GENERATE
```

NOTE

For multi core and multi port, add vdev and modify portmask (-p) and coremask (-c) options as described in cipher only use case.

- Hash_cipher
  - 1 core:

```
# /usr/bin/dpdk-example/l2fwd-crypto --vdev "cryptodev_armce_pmd" -c 0x2 -n 1 -- -p 0x1 -q 1 -s
--chain HASH_CIPHER --auth_algo SHA1_HMAC --auth_op GENERATE --cipher_algo AES_CBC --cipher_op
ENCRYPT --cipher_key 01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:0f:10
```

NOTE

For multi core and multi port, add vdev and modify portmask (-p) and coremask (-c) options as described in cipher only use case.

- Hash_only
  - 1 core:

```
# /usr/bin/dpdk-example/l2fwd-crypto --vdev "cryptodev_armce_pmd" -c 0x2 -n 1 -- -p 0x1 -q 1 --
chain HASH_ONLY --auth_algo SHA1_HMAC --auth_op GENERATE
```

NOTE

For multi core and multi-port, add vdev and modify portmask (-p) and coremask (-c) options as described in cipher only use case.

L2fwd-Crypto – DPAA-SEC HW or DPAA2-SEC-HW

- Cipher only

```
# /usr/bin/dpdk-example/l2fwd-crypto -c 0x2 -n 1 -- -p 0x1 -q 1  --chain CIPHER_ONLY  --
cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key 01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:
0f:10
```

- Cipher - hash

```
# /usr/bin/dpdk-example/l2fwd-crypto -c 0x2 -n 1 -- -p 0x1 -q 1 --chain CIPHER_HASH  --
cipher_algo AES_CBC --cipher_op ENCRYPT --cipher_key 01:02:03:04:05:06:07:08:09:0a:0b:0c:0d:0e:
0f:10 --auth_algo SHA1_HMAC --auth_op GENERATE
```

- Hash only

```
# /usr/bin/dpdk-example/l2fwd-crypto -c 0x2 -n 1 -- -p 0x1 -q 1 --chain HASH_ONLY --auth_algo
SHA1_HMAC --auth_op GENERATE
```

NOTE

For multi core and multi-port, modify portmask (-p) and coremask (-c) options as described in ARMCE cipher only use case.

Ipsec-secgw - DPAA-SEC-HW or DPAA2-SEC-HW

For IPsec application, two boards need to be configured as endpoint 0 (ep0) and endpoint 1 (ep1). Port 0 and port 1 of ep0 should be connected to port 0 and port 1 of ep1 respectively. Port 2 and port 3 of ep0 should be connected to packet generator tool (eg. Spirent) with destination IP addresses as 192.168.105.XXX and 192.168.106.XXX respectively. Port 2 and port 3 of ep1 should be connected to packet generator tool (eg. Spirent) with destination IP addresses as 192.168.115.XXX and 192.168.116.XXX respectively. For more information, refer to IPsec Security Gateway Sample Application .

Endpoint 0 configuration

```
./ipsec-secgw -c 0xf  -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep0
```

Endpoint 1 configuration

```
./ipsec-secgw -c 0xf  -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep1
```

ARM-CE based Ipsec-secgw

For IPsec application, two boards need to be configured as endpoint 0 (ep0) and endpoint 1 (ep1). Port 0 and port 1 of ep0 should be connected to port 0 and port 1 of ep1 respectively. Port 2 and port 3 of ep0 should be connected to packet generator tool (eg. Spirent) with destination IP addresses as 192.168.105.XXX and 192.168.106.XXX respectively. Port 2 and port 3 of ep1 should be connected to packet generator tool (eg. Spirent) with destination IP addresses as 192.168.115.XXX and 192.168.116.XXX respectively. For more information, refer to IPsec Security Gateway Sample Application.

DPAA

Endpoint 0 configuration

```
./ipsec-secgw -c 0xf --vdev "cryptodev_armce_pmd0" --vdev "cryptodev_armce_pmd1" --vdev
"cryptodev_armce_pmd2" --vdev "cryptodev_armce_pmd3" -b 0002:10:10.0 -b 0002:10:11.0 -b
0002:10:12.0 -b 0002:10:13.0 -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep0
```

Endpoint 1 configuration

```
./ipsec-secgw -c 0xf --vdev "cryptodev_armce_pmd0" --vdev "cryptodev_armce_pmd1" --vdev
"cryptodev_armce_pmd2" --vdev "cryptodev_armce_pmd3" -b 0002:10:10.0 -b 0002:10:11.0 -b
0002:10:12.0 -b 0002:10:13.0 -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep1
```

DPAA2

Endpoint 0 configuration

```
./ipsec-secgw -c 0xf --vdev "cryptodev_armce_pmd0" --vdev "cryptodev_armce_pmd1" --vdev
"cryptodev_armce_pmd2" --vdev "cryptodev_armce_pmd3" -b 0000:00:00.3 -b 0000:00:01.3 -b
0000:00:02.3 -b 0000:00:03.3 -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep0
```

Endpoint 1 configuration

```
./ipsec-secgw -c 0xf --vdev "cryptodev_armce_pmd0" --vdev "cryptodev_armce_pmd1" --vdev
"cryptodev_armce_pmd2" --vdev "cryptodev_armce_pmd3" -b 0000:00:00.3 -b 0000:00:01.3 -b
0000:00:02.3 -b 0000:00:03.3 -- -p 0xf -P -u 0x3 --config="(0,0,0),(1,0,1),(2,0,2),(3,0,3)" --ep1
```

Pktgen

#3 port - 1 core each

```
# ./pktgen -l 0-3 -n 3 --proc-type auto --file-prefix pg --log-level 8 -- -T -P -m "[1].0, [2].1,
[3].2"
```

#2 port - 2 core each

```
# ./pktgen -l 0-3 -n 3 --proc-type auto --file-prefix pg --log-level 8 -- -T -P -m "[0:1].0, [2:3].
1"
```

#To start traffic on specific port:

```
start 0
stop 0
```

#To start on all ports

```
str
stp
```

OVS

Run OVS switch with two DPDK ports (physical ports) added to ovs switch and hard coded flows programed as:

- Incoming traffic Port 1 -> output to port 2
- Incoming traffic Port2 -> output to port 1

Mount huge pages for OVS:

```
#mkdir -p /dev/hugepages
#mount -t hugetlbfs -o pagesize=1G none /dev/hugepages
#mkdir -p /usr/local/etc/openvswitch
#mkdir -p /usr/local/var/run/openvswitch
#rm /usr/local/etc/openvswitch/conf.db
#export SOCK_MEM=1024
```

Setup and execute ovs-vswitchd, and configure flows.

Create and configure OVS data base:

```
#cd /usr/bin/ovs-dpdk/
#./ovsdb-tool create /usr/local/etc/openvswitch/conf.db ./vswitch.ovsschema
#./ovsdb-server --remote=punix:/usr/local/var/run/openvswitch/db.sock --
remote=db:Open_vSwitch,Open_vSwitch,manager_options --pidfile=/tmp/ovsdb-server.pid --detach --log-
file=/var/log/openvswitch/ovs-vswitchd.log
```

Initialize OVS switch configuration:

```
#./ovs-vsctl --no-wait set Open_vSwitch . other_config:dpdk-init=true
#./ovs-vsctl  --no-wait set Open_vSwitch . other_config:pmd-cpu-mask=6
#./ovs-vsctl --no-wait set Open_vSwitch . other_config:dpdk-socket-mem="$SOCK_MEM"
```

Launch ovs vswitchd daemon:

```
#export DB_SOCK=/usr/local/var/run/openvswitch/db.sock
#./ovs-vswitchd unix:$DB_SOCK --pidfile --detach -c 0x6
```

NOTE

—detach option makes the daemon run in background. If this option is given same shell can be used to run further commands, otherwise ssh to the target board and run further commands.

Add bridge interface and DPDK ports to vswitch:

```
#./ovs-vsctl add-br br0 -- set bridge br0 datapath_type=netdev
#./ovs-vsctl add-port br0 dpdk0 -- set Interface dpdk0 type=dpdk
#./ovs-vsctl add-port br0 dpdk1 -- set Interface dpdk1 type=dpdk
```

Configure Flows to set data path across the ports:

```
#./ovs-ofctl del-flows br0
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=1,actions=output:2
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=2,actions=output:1
```

The flows above configure a hard coded bi-directional data path between port 1 and port 2.

9.2.7 OVS-DPDK and DPDK in VM with VIRTIO Interfaces

DPDK example and DPDK-based applications can also run inside the virtual machine. This section describes steps to run these applications inside the virtual machine on both DPAA and DPAA2 platforms.

The virtual machine runs inside the host Linux system and is launched by an application called QEMU.

Note that console logs for the guest Linux do not appear on the host Linux console (i.e UART). The guest logs are exposed through telnet, and they can be accessed by doing telnet on the host board's IP Address (IP_ADDR_BRD) and GUEST_CONSOLE_TELNET_PORT. Each Virtual machine that is run on a single host is allocated a different GUEST_CONSOLE_TELNET_PORT, and this port number is specified by user running virtual machine through the QEMU command line.

This chapter is organized as follows:

- *Generic steps – DPAA & DPAA2 platforms* describes generic or common steps to be executed on DPAA and DPAA2 platforms in order to run virtual machine.
- *OVS-switch as VHOST USER backend* describes OVS switch execution. OVS acts as backend for VHOST user devices. If DPDK applications are run in VM using VIRTIO and VHOST USER then this section has to be followed.
- *Launch virtual machine and access console* describes launching QEMU and accessing virtual machines.
- *Running DPDK applications in VM* describes Running of DPDK and DPDK based applications in virtual machine.

9.2.7.1 Generic steps - DPAA & DPAA2 platforms

Mount huge tlbfs so that QEMU can use huge pages. Also give IP address to board so that virtual machine console can be accessed using telnet.

```
#echo hugetlbfs /hugetlbfs hugetlbfs defaults,mode=0777 0 0 >> /etc/fstab
#mkdir /hugetlbfs
```

```
#mount /hugetlbfs
#ifconfig eth<x> <IP_ADDR_BRD>
```

Follow steps given in *Generic Setup – DPAA* or *Generic Setup – DPAA2* to setup DPDK for your platform. Note that only one of these sections must be followed depending on whether you are usin a DPAA or DPAA2-based platform.

9.2.7.2 OVS-switch as VHOST USER backend

OVS is used as backend for VHOST USER ports. The physical ports on the target platform and the vhost user ports (virtio devices) are added to ovs-vswitch and hard-coded flows are created to establish traffic switching between physical ports and vhost devices as follows:

Incoming traffic Physical port1 -> output to vhost-user port 1

Incoming traffic on vhost-user port1 -> output on physical port 1

Incoming traffic on physical port 2 -> output on vhost-user port 2

Incoming traffic on vhost-user port 2 -> output on physical port 2

The following steps must be followed to setup OVS as vhost switching backend:

Mount huge pages and create OVS directories:

```
#mkdir -p /dev/hugepages
#mount -t hugetlbfs -o pagesize=1G none /dev/hugepages
#mkdir -p /usr/local/etc/openvswitch
#mkdir -p /usr/local/var/run/openvswitch
#rm /usr/local/etc/openvswitch/conf.db
```

Export socket memory:

```
#export SOCK_MEM=1024
```

NOTE

For LS208X platforms use SOCK_MEM=1024, for LS104X platforms use SOCK_MEM=200

Initialize OVS DB:

```
#mkdir -p /usr/local/etc/openvswitch
#mkdir -p /usr/local/var/run/openvswitch
#./ovsdb-tool create /usr/local/etc/openvswitch/conf.db ./vswitch.ovsschema
```

Start the OVS Server:

```
#./ovsdb-server --remote=punix:/usr/local/var/run/openvswitch/db.sock --
remote=db:Open_vSwitch,Open_vSwitch,manager_options --pidfile=/tmp/ovsdb-server.pid --detach --log-
file=/var/log/openvswitch/ovs-vswitchd.log
```

Initialize OVS:

```
#./ovs-vsctl --no-wait set Open_vSwitch . other_config:dpdk-init=true
#./ovs-vsctl  --no-wait set Open_vSwitch . other_config:dpdk-lcore-mask=3
#./ovs-vsctl  --no-wait set Open_vSwitch . other_config:pmd-cpu-mask=3
#./ovs-vsctl --no-wait set Open_vSwitch . other_config:dpdk-socket-mem="$SOCK_MEM"
```

Start the vSwitch daemon:

```
#export DB_SOCK=/usr/local/var/run/openvswitch/db.sock
#./ovs-vswitchd unix:$DB_SOCK --pidfile --detach -c 0x3
```

Initialize the vSwitch bridge and define DPDK ports:

```
#./ovs-vsctl add-br br0 -- set bridge br0 datapath_type=netdev
#./ovs-vsctl add-port br0 dpdk0 -- set Interface dpdk0 type=dpdk
#./ovs-vsctl add-port br0 dpdk1 -- set Interface dpdk1 type=dpdk

#./ovs-vsctl add-port br0 vhost-user1 -- set Interface vhost-user1 type=dpdkvhostuser
#./ovs-vsctl add-port br0 vhost-user2 -- set Interface vhost-user2 type=dpdkvhostuser
```

Clear flows and add new flows for switching packets arriving on port 1 to port 2 and reverse. In case a different combination of ports and switching is required, modify accordingly:

```
#./ovs-ofctl del-flows br0
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=1,actions=output:3
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=3,actions=output:1
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=2,actions=output:4
#./ovs-ofctl add-flow br0 -O OpenFlow13 table=0,in_port=4,actions=output:2
```

NOTE

OVS Switch must be run before launching the virtual machine using QEMU, otherwise the virtual machine launch will fail.

9.2.7.3 Launch virtual machine

```
#export ROOTFS_IMG=[VM_ROOTFS_IMG]
#export VM_MEM=650M
# export CORES=2
# export NUM_QUEUES=1
# export VHOST1_PATH=/usr/local/var/run/openvswitch/vhost-user1
# export VHOST2_PATH=/usr/local/var/run/openvswitch/vhost-user2
#qemu-system-aarch64 -nographic -object memory-backend-file,id=mem,size=$VM_MEM,mem-path=/
hugetlbfs,share=on -cpu host -machine type=virt -kernel /boot/Image -enable-kvm -initrd $ROOTFS_IMG
-smp 2 -serial tcp::4446,server,telnet -append 'root=/dev/ram0 rw console=ttyAMA0,115200 rootwait
earlyprintk ramdisk_size=1000000' -m $VM_MEM -numa node,memdev=mem -chardev socket,id=char1,path=
$VHOST1_PATH -netdev type=vhost-user,id=hostnet1,chardev=char1 -device virtio-net-pci,disable-
modern=false,addr=0x3,netdev=hostnet1,id=net1 -chardev socket,id=char2,path=$VHOST2_PATH -netdev
type=vhost-user,id=hostnet2,chardev=char2 -device virtio-net-pci,disable-
modern=false,addr=0x4,netdev=hostnet2,id=net2 -smp $CORES -S
```

NOTE

* `GUEST_CONSOLE_TELNET_PORT` is given as 4446 in the example above. You need to telnet to `IP_ADDR_BRD` and `GUEST_CONSOLE_TELNET_PORT` to access guest terminal

* `VM_ROOTFS_IMG` has to be replaced with correct rootfs image name from *Supported platforms and platform specific details*.

* For LS104xA platforms, set `VM_MEM` to 650M. For L208xA platforms, set `VM_MEM` to 2048M.

* Set ROOTFS_IMG name as "fsl-image-core-lsxxxxardb.ext2.gz" as per LS1 and LS2 platform.

The following logs appear on Host UART console:

```
# /usr/bin/qemu-system-aarch64 -nographic -object memory-backend-file,id=mem,size=800M,mem-path=/
hugetlbfs,share=on -cpu host -machine type=virt -kernel /boot/Image -enable-kvm -initrd $
{ROOTFS_IMG} -smp 4 -serial tcp::4446,server,telnet -append 'root=/dev/ram0 rw
console=ttyAMA0,115200 rootwait earlyprintk ramdisk_size=1000000' -m 800M -numa node,memdev=mem -
chardev socket,id=char1,path=/home/root/sock1 -netdev type=vhost-user,id=hostnet1,chardev=char1 -
device virtio-net-pci,disable-modern=false,addr=0x3,netdev=hostnet1,id=net1 -chardev
socket,id=char2,path=/home/root/sock2 -netdev type=vhost-user,id=hostnet2,chardev=char2 -device
virtio-net-pci,disable-modern=false,addr=0x4,netdev=hostnet2,id=net2 -
qemu-system-aarch64: -netdev type=vhost-user,id=hostnet1,chardev=char1: chardev "char1" went up
qemu-system-aarch64: -netdev type=vhost-user,id=hostnet2,chardev=char2: chardev "char2" went up
QEMU 2.6.0 monitor - type 'help' for more information
(qemu) QEMU waiting for connection on: disconnected:telnet::4446,server
VHOST_DATA: (0) Failed to add device MAC address to VMDQ
(qemu)
```

NOTE

QEMU logs come completely only when you log-in to the guest machine using telnet as specified in section *Accessing virtual machine console*.

The `-S` option mentioned in the qemu command stops the Virtual Machine bootup after initial setup. Run the `info cpus` command on QEMU CLI interface to see the QEMU threads.

```
(qemu) info cpus
* CPU #0: thread_id=2559
  CPU #1: (halted) thread_id=2560
```

SSH on the board (telenet to `IP address IP_ADDR_BRD`) from other console and affine the threads to the cores using the `taskset` command:

```
taskset -p 0x4 <tid1>
taskset -p 0x8 <tid1>
```

NOTE

It is better to affine the VCPUs to the cores on which OVS threads are not running. For better performance VCPU threads should be given one physical CPU each if possible.

Run the `c` command from the QEMU CLI to continue the VM boot-up:

```
(qemu) c
```

9.2.7.4 Accessing virtual machine console

Telnet to the `IP_ADDR_BRD` at port `GUEST_CONSOLE_PORT` from any machine, which can reach `IP_ADDR_BRD` over network:

```
$ telnet 192.168.3.155 4446
Trying 192.168.3.155...
Connected to 192.168.3.155.
Escape character is '^]'.

9.2.7.5 Launching two virtual machines

This section is optional. It is only required if two virtual machines need to be launched for a use case.

In case of two virtual machines, please take care of following:

- Memory assigned to each virtual machine should not exceed the total number of huge pages assigned on system. In above example (step 8) giving 2048 Mega bytes to each virtual machine works fine.
- Console telnet port of both virtual machine must be different, for example 4446 could be console of VM1 and 4447 could be console for VM2.

Following are the example launch commands for two VMs:

VM1:

```
# qemu-system-aarch64 -nographic -object memory-backend-file,id=mem,size=$VM_MEM,mem-path=/
hugetlbfs,share=on -cpu host -machine type=virt -kernel /boot/Image -enable-kvm -initrd /boot/$
{ROOTFS_IMG}  -serial tcp::4446,server,telnet -append 'root=/dev/ram0 rw console=ttyAMA0,115200
rootwait earlyprintk ramdisk_size=1000000' -m $VM_MEM -numa node,memdev=mem -chardev
socket,id=char1,path=$VHOST1_PATH -netdev type=vhost-user,id=hostnet1,chardev=char1 -device virtio-
net-pci,disable-modern=false,addr=0x3,netdev=hostnet1,id=net1 -chardev socket,id=char2,path=
$VHOST2_PATH -netdev type=vhost-user,id=hostnet2,chardev=char2 -device virtio-net-pci,disable-
modern=false,addr=0x4,netdev=hostnet2,id=net2 -smp $CORES -S
```

VM2:

```
# qemu-system-aarch64 -nographic -object memory-backend-file,id=mem,size=$VM_MEM,mem-path=/
hugetlbfs,share=on -cpu host -machine type=virt -kernel /boot//Image -enable-kvm -initrd /boot/$
{ROOTFS_IMG}  -serial tcp::4447,server,telnet -append 'root=/dev/ram0 rw console=ttyAMA0,115200
rootwait earlyprintk ramdisk_size=1000000' -m $VM_MEM -numa node,memdev=mem -chardev
socket,id=char1,path=$VHOST1_PATH -netdev type=vhost-user,id=hostnet1,chardev=char1 -device virtio-
net-pci,disable-modern=false,addr=0x3,netdev=hostnet1,id=net1 -chardev socket,id=char2,path=
$VHOST2_PATH -netdev type=vhost-user,id=hostnet2,chardev=char2 -device virtio-net-pci,disable-
modern=false,addr=0x4,netdev=hostnet2,id=net2 -smp $CORES -S
```

9.2.7.6 Running DPDK applications in VM

All the DPDK applications mentioned in this section have been tested in following configuration:

- Two Physical network interfaces.
- Two virtio-net devices in the virtual machine.

Following figure illustrates the test setup:

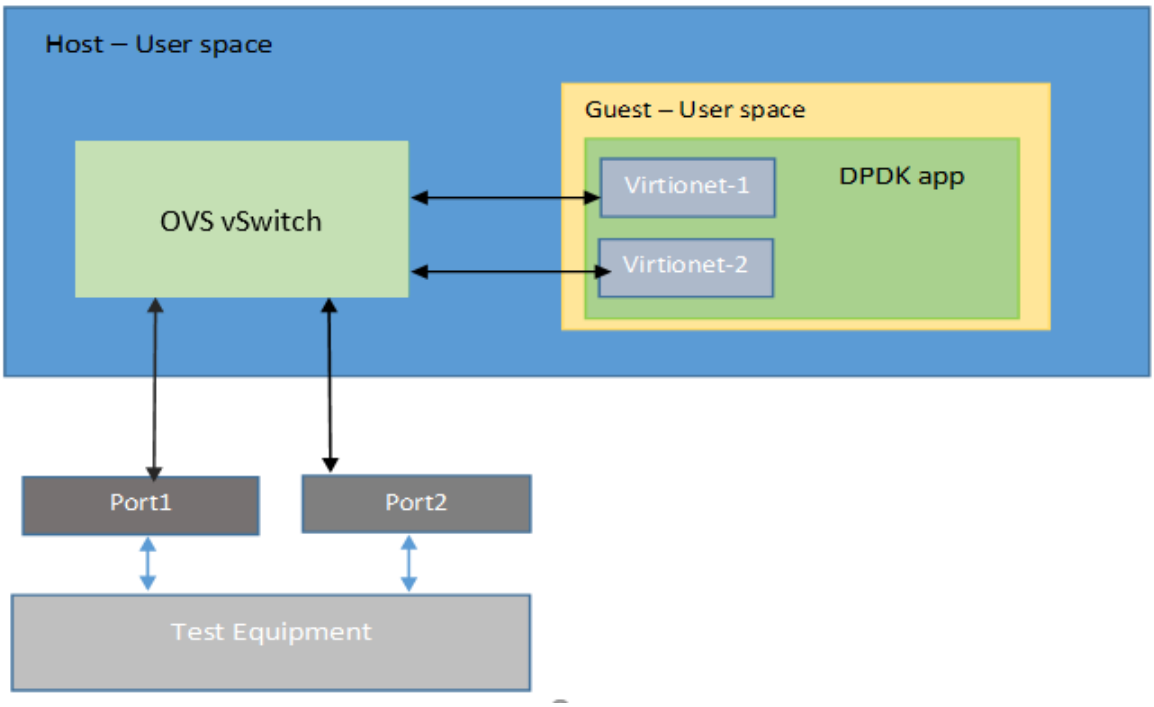

Figure 205. DPDK virtionet test setup

Generic Setup (for all the applications)

All the DPDK binaries and other supporting XML files are part of the rootfs and can be found at:

```
#/usr/bin/dpdk-example/
```

Setup huge pages

```
# mkdir /mnt/hugepages
# mount -t hugetlbfs none /mnt/hugepages
# echo 512 > /proc/sys/vm/nr_hugepages
```

Bind the virtio-net devices

```
# /usr/share/tools/dpdk_nic_bind.py --status
# /usr/share/tools/dpdk_nic_bind.py -b uio_pci_generic 0000:00:03.0
# /usr/share/tools/dpdk_nic_bind.py -b uio_pci_generic 0000:00:04.0
```

L2fwd

```
# /usr/bin/dpdk-example/l2fwd -c 0xf -n 1 -- -p 0x3 -q 1
```

L3fwd

```
# /usr/bin/dpdk-example/l3fwd -c 0x1 -n 1 -- -p 0x1 --config="(0,0,0)" --parse-ptype
```

Testpmd

For TX only:

```
#/usr/bin/dpdk-example/testpmd -c 1 -n 1 -- -i --nb-cores=1 --nb-ports=1 --total-num-mbufs=1025 --
forward-mode=txonly --disable-hw-vlan --port-topology=chained
```

For RX only:

```
# /usr/bin/dpdk-example/testpmd -c 1 -n 1 -- -i --nb-cores=1 --nb-ports=1 --total-num-mbufs=1025 --
forward-mode=rxonly --disable-hw-vlan --port-topology=chained
```

9.2.7.7 Multi Queue VIRTIO support

To scale the performance vs number of VM cores, the VIRTIO devices need to be configured with multiple queues. This section explains the steps required for setup and usage of multi queue virtio devices.

Adding multiple queues to physical devices and host-user devices is control by parameters in sections *Generic Setup – DPAA2* and *OVS-switch as VHOST USER backend*. These parameter additions/values are given in sections *Multi queue parameters in Common steps for DPAA2* and *Additional steps for OVS setup*.

QEMU commands for multiqueue vhost devices are different and are shown later in the section.

Multi queue parameters in Common steps for DPAA2

For using multiple queues on physical devices on DPAA2, `MAX_TCS` and `MAX_DIST_PER_TC` has to be set to 8 in generic steps for DPAA2 as given in *Generic Setup – DPAA2*

```
# export DPRC=dprc.2
# export MAX_TCS=8
# export MAX_DIST_PER_TC=8,8,8,8,8,8,8,8
# /usr/bin/dpdk-example/extras/dynamic_dpl.sh <DPMAC 1> <DPMAC 2>
```

Multi queue parameters in Common steps for DPAA1

For using multiple queues on physical devices on DPAA1, DPAA_NUM_RX_QUEUES has to be set to '2' or '4' in generic steps for DPAA1 as given in *Generic Setup – DPAA. Also, fmc should be run accordingly. Considering 2 queue scenario:*

```
# export DPAA_NUM_RX_QUEUES=2
# fmc -c /usr/bin/dpdk-example/extras/usdpaa_config_ls1043.xml -p /usr/bin/dpdk-example/extras/
usdpaa_policy_hash_ipv4_2queue.xml -a
```

Additional steps for OVS setup

Set number of queues for all the devices while configuring devices. Underlined steps configure the number of queues for all the devices (physical and vhost) added to OVS. All other steps (not underline) remain the same as given in section *OVS-switch as VHOST USER backend* (all other steps remains same as given in the section)

Run following commands after adding DPDKx and vhost-user ports to the bridge:

```
./ovs-vsctl set Interface dpdk0 options:n_rxq=2
./ovs-vsctl set Interface dpdk1 options:n_rxq=2
./ovs-vsctl set Interface dpdk0 options:n_txq=2
./ovs-vsctl set Interface dpdk1 options:n_txq=2
./ovs-vsctl set Interface vhost-user1 options:n_rxq=2
./ovs-vsctl set Interface vhost-user2 options:n_rxq=2
./ovs-vsctl set Interface vhost-user1 options:n_txq=2
./ovs-vsctl set Interface vhost-user2 options:n_txq=2
```

Launch VM with multi queue VHOST devices

Underlined text is the addition to the QEMU command and parameters given in section Launch virtual machine

```
export VM_MEM=2048M (For DPAA1 use VM_MEM=650M)
export CORES=2
export NUM_QUEUES=2
ROOTFS_IMG=<VM_ROOTFS_IMG>
SERIAL_PORT=4446
export VHOST1_PATH=/usr/local/var/run/openvswitch/vhost-user1
export VHOST2_PATH=/usr/local/var/run/openvswitch/vhost-user2
qemu-system-aarch64 -nographic -object memory-backend-file,id=mem,size=$VM_MEM,mem-path=/
hugetlbfs,share=on -cpu host -machine type=virt -kernel /boot/Image -enable-kvm -initrd
$ROOTFS_IMG  -serial tcp::$SERIAL_PORT,server,telnet -append 'root=/dev/ram0 rw
console=ttyAMA0,115200 rootwait earlyprintk ramdisk_size=1000000' -m $VM_MEM -numa node,memdev=mem
-chardev socket,id=char1,path=$VHOST1_PATH -netdev type=vhost-
user,id=hostnet1,chardev=char1,vhostforce,queues=$NUM_QUEUES -device virtio-net-pci,disable-
modern=false,addr=0x3,netdev=hostnet1,mq=on,id=net1,vectors=6 -chardev socket,id=char2,path=
$VHOST2_PATH -netdev type=vhost-user,id=hostnet2,chardev=char2,vhostforce,queues=$NUM_QUEUES -
device virtio-net-pci,disable-modern=false,addr=0x4,netdev=hostnet2,mq=on,id=net2,vectors=6 -smp
$CORES
```

DPDK applications in VM

Connect to VM terminal as explained in *Accessing Virtual Machine Console*. Once logged-in as Guest, DPDK applications using multiple queues can be run in VM.

NOTE

DPDK application in VM must use the same number of queues as used in VM setup in section *Launch VM with multiqueue VHOST devices* (`NUM_QUEUES`). If the number of queues is not same then virtio device will fail to start and it will not work in VM.

Common steps

```
mkdir /mnt/hugepages
mount -t hugetlbfs none /mnt/hugepages
echo 512 > /proc/sys/vm/nr_hugepages
/usr/share/tools/dpdk_nic_bind.py -b uio_pci_generic 0000:00:03.0
/usr/share/tools/dpdk_nic_bind.py -b uio_pci_generic 0000:00:04.0
```

L3fwd

```
/usr/bin/dpdk-example/l3fwd -c 0x3 -n 1 -- -p 0x3 --config="(0,0,0),(0,1,1), (1,0,0), (1, 1, 1)" --
parse-ptype
```

Testpmd

```
/usr/bin/dpdk-example/testpmd -c 3 -n 1 -- -i --nb-cores=1 --nb-ports=1 --total-num-mbufs=1025 --
forward-mode=txonly --disable-hw-vlan --rxq=2 --txq=2 --port-topology=chained
```

9.2.8 Known Limitations and Future Work

1. DPAA: Ports assigned to user space cannot be assigned dynamically to kernel space or vice-versa.
2. DPAA: The FMAN configuration script cannot be re-run without system restart. i.e. number of queues configured cannot be changed.
3. DPAA: Ipsec-secgw: Traffic halts with error messages when running medium to large size packets on all 4 ports.

4. DPAA: DPDK-204 Performance of DPAA1 application degrades on assigning some ports to linux.
5. DPAA2: Performance drop is observed in case of Host and VM because of use of Physical addressing in default code. To switch to virtual addressing, use CONFIG_RTE_LIBRTE_DPAA2_USE_PHYS_IOVA=n option while compiling the source code.
6. DPAA and DPAA2: Some of the DPDK Ethernet ops are not yet implemented or are empty e.g Multicast fitlering.
7. DPAA and DPAA2: The hardware internally uses the hardware access portals for each thread doing packet I/O, which limits the number of I/O threads thereby impacting the performance. The number of available portals is different for DPAA and DPAA2.

9.2.9 Troubleshooting

Following are some common steps and suggestions outlined for best performance from DPDK Applications:

1. To obtain best performance, please ensure that the boot-up time command line arguments are similar to below:

```
console=ttyS1,115200 root=/dev/ram0 earlycon=uart8250,mmio,0x21c0600 ramdisk_size=2000000
default_hugepagesz=1024m hugepagesz=1024m hugepages=8 isolcpus=1-7
```

   `isolcpus` in the above ensures that only Linux Kernel schedules its threads on Core 0 only. Core 1-7 would be used for DPDK application threads.

   Hugepage count defined by `hugepages` should also be modified to maximum possible so as to allow DPDK applications to have larger buffers.

2. If RX or TX is not happening, verify the following points:
   a. Ensure that no error has been reported by DPDK application at startup. Generally the output is descriptive enough for cause of problem.
   b. Ensure that correct `dpni.X` has been used in the `dynamic_dpl.sh` script while creating the `dprc` containers. A common pitfall is to use an incorrect `dpni` as against the physical port being used for IO.
   c. Ensure that traffic generator to board connectivity is proper. You may run testpmd in tx_only mode to validate if the packets are going out on specific interfaces.
   d. Ensure that the traffic generator Stream settings are correct and enough streams are being generated for proper distribution between DPDK application cores.
   e. Ensure that the MAC address of stream generated by traffic generator matches that of the `dpni` port, or the interface is in promiscous mode.
3. If the performance is not as expected:
   a. Ensure that the stream configuration of the traffic generator is approrpriate and that it can generate multiple streams. In case the streams have all same IP destination and/or source, the distribution of traffic across multiple cores wouldn't happen.
   b. Using standard process tools in Linux, for example `ps`, `top`, verify that all the DPDK application threads have been started (as per application configuration on command line) and busy looping.

9.3 IPC

9.3.1 IPC Specification

9.3.1.1 Introduction

Scope

The scope of the IPC (inter-processor communication) software module is to provide a framework for communication between two heterogeneous systems. These systems can be connected through either of Shared Memory or other interconnect mechanism like Queue Manager.

Examples of heterogeneous systems:

- 8156-P2020 SoC on a combo card
- DSP-PA in 9131 SoC running an LTE solution
- DSP1-PA and DSP2-PA in 9132 SoC running LTE and WCDMA together
- DSP-PA on B4860

A Heterogeneous system is a logical entity which defines an application use case.

IPC, in this document refers to communication between s/w running on PA core and DSP core across heterogeneous systems. For intra PA and intra DSP (Homogeneous) communication existing OS supported communication mechanisms should be used.

The scope of IPC is limited to providing a communication framework which may not conform to any existing standard like MCAPI. SoC which would be supported by the IPC framework are B4860 and B4420.

Audience

- System architects
- Linux and SmartDSP OS developers, and
- LTE L1 L2 protocol developers

9.3.1.2 General Description

This section describes the general factors that affect the product and its requirements. It provides background for specifications that will be defined in detail in the section Specifications below.

Product Perspective

In a typical use case of communication between two heterogeneous systems, a communication framework layer is required for exchanging data between the two. The heterogeneous systems may have different operating systems and processor architecture. A block diagram of such an organization is:

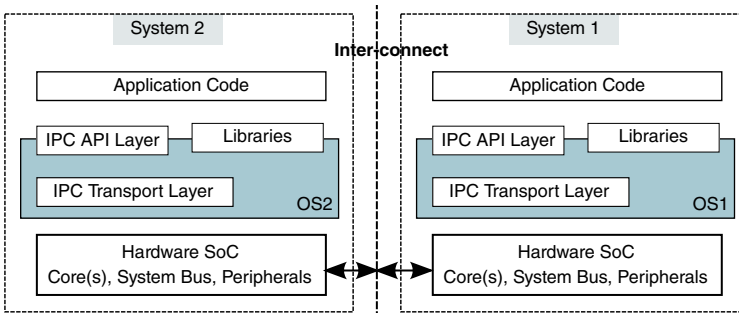

Figure 206. Communication Framework

In the above diagram, two systems are connected using an interconnect. The systems have their OS, own cores, system bus and other set of peripherals. The applications which require transferring data to/from other system take the services of IPC layer, which consists of 2 parts API layer and transport layer.

The API layer provides an interface for applications, while the transport layer manages interconnect. When moving from one interconnects to another, this is the only layer that requires change.

Use Cases

- LTE L1-L2 communication
- Shared Devices Initialization
- L1 and L2 framework synchronization as required for a fully synchronized system startup procedure
- Multi RAT (LTE and WCDMA or 2 instances of LTE or WCDMA)
- L1 –L1 communication depends upon the Application

9.3.1.3 Definitions

Table 210. Definitions and Terminology

Term	Definition	Notes
Producer	A ‘producer’ is defined as a processing entity which creates a message to be sent over to ‘consumer’ using the communication framework.	They are also referred as ‘endpoints’
Consumer	A ‘consumer’ is a processing entity which consumes the message.	A consumer polls for reception of a message.
Message	Message’ is defined as a sequence of bytes. No limitation is set on the endianness/ data format.	A message is sent by producer to a consumer on a specified channel.

Table continues on the next page...

Table 210. Definitions and Terminology (continued)

Term	Definition	Notes
Channel	1. Acts as a logical medium of communication between producer and consumer. 2. Is unidirectional. a. If a producer interacts with two consumers a separate channel is required for each consumer. b. If a consumer interacts with two producers, separate channel is required for each producer-consumer pair. 3. The channel storage is modelled as a circular queue (BD ring). The transport layer may allocate the memory for storage, or the producer/consumer allocates the memory for the message. 4. Has a depth which is fixed at the time of initialization. 5. A channel has 2 indices a producer index and consumer index. This is used to maintain lock free access to the BD ring. 6. A channel's notifications can be VIRQ on DSP side whereas it is only polling mode at PA side. 7. There are essentially 2 types of channels: a. Pointer Channel • Producer-Consumer exchange pointers rather than actual messages. b. Message Channel • Actual Message is exchanged.	see the figure below.
Channel-ID	A 32bit static value which is predefined and used as a way to identify the consumer and its channels.	
Notification	The method of notifying the consumer that a message has been added in the BD ring. The consumer provides the details of how the notification has to be generated.	This information is filled in the channel structure at the time of initialization
IPC Instance	An object of ipc data structure. An ipc object contains set of channel structures.	Each ipc instance object would point to its own set of channel structures.

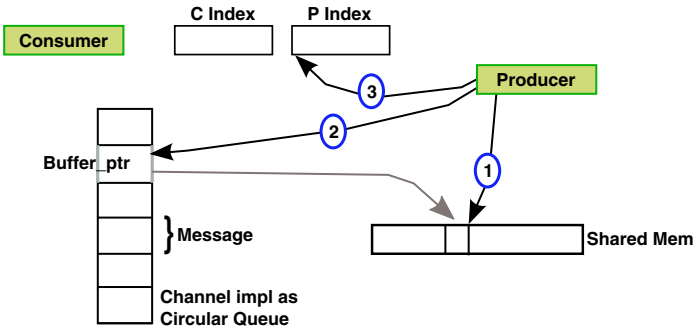

Figure 207. Consumer/Producer Dynamic Model

9.3.1.4 IPC Architecture

IPC Framework Details

Table 211. IPC Detail Described

Detail	Description
A	The IPC framework provides the basic building blocks for the communication between the producer and the consumer. While there are different types of channels from the applications view, internally all are derived from the pointer channel.
B	IPC framework does not limit the number of channels. The default values is 64, any value less than or equal to 0 will be set to 64.
C	IPC framework can have instances and applications can communicate with each other based on an instance ID. This would help in providing isolation between LTE and WCDMA L2 stacks using IPC. For example: • LTE L1 (DSP) and LTE L2 (PA) would communicate on ipc instance 1 • WCDMA L1 (DSP) and WCDMA L2 (PA) would communicate on ipc instance 2

IPC Layer Initialization

As the actual data needs to be in shared memory, IPC requires the calling application to provide the physical to virtual address conversion callback (p2vcb). The p2v function should be passed as an argument to the init function

```
IPC Initialization APIs
-----------------------

Old API
-------
fsl_ipc_t fsl_ipc_init(ipc_p2v_t p2vcb,
                       mem_range_t sh_ctrl_area,
                       mem_range_t dsp_ccsr,
                       mem_range_t pa_ccsr,
                       char uiodevbuf[]);

NOTE: This API is now deprecated. It now internally calls following API "fsl_ipc_init_rat" with a
new argument rat_id.

New API
-------
```

```
fsl_ipc_t fsl_ipc_init_rat(uint32_t rat_id,
                           ipc_p2v_t p2vcb,
                           mem_range_t sh_ctrl_area,
                           mem_range_t dsp_ccsr,
                           mem_range_t pa_ccsr,
                           char uiodevbuf[]);

Whereas:
       rat_id - is the multi-rat instance it can be 0/1
       uiodevbuf[] - is the uio interface corresponding to the DMA channels
```

The above API internally binds to the specific ipc_t object created in the shared control area. Any subsequent ipc calls will try to get information from that ipc_t object.

IPC Channel Initialization

(d) There are separate producer and consumer API's for opening a channel, unless the consumer has opened the channel producer should not start the communication.

The APIs are

```
Linux Producer API
------------------
int fsl_ipc_open_prod_ch(uint32_t channel_id,
                         fsl_ipc_t ipc);

Linux Consumer API
------------------
int fsl_ipc_configure_channel(uint32_t channel_id,
                              uint32_t depth,
                              ipc_ch_type_t channel_type,
                              unsigned long msg_ring_paddr,
                              uint32_t msg_size,
                              ipc_cbfunc_t cbfunc,
                              fsl_ipc_t ipc)

*For more details on API refer Appendix
```

Generic IPC Layer

Pointer Ring

The generic IPC layer provides a method of transferring a pointer value on a channel. Along with the pointer the length of the message it points is also stored in the bd ring.

```
Linux User Producer API
-----------------------
int fsl_ipc_send_ptr(uint32_t channel_id,
                     unsigned long buffer_ptr,
                     uint32_t len,
                     fsl_ipc_t ipc)

Linux User Consumer API
-----------------------
int fsl_ipc_recv_ptr(uint32_t channel_id,
                     unsigned long *addr,
                     uint32_t *len,
```

```
                     fsl_ipc_t ipc);

int fsl_ipc_recv_ptr_hold(uint32_t channel_id,
                          unsigned long *addr,
                          uint32_t *len,
                          fsl_ipc_t ipc);

Note: the "hold" API does not increment the consumer index. Calling fsl_ipc_set_consumed_status on
the channelid increments the consumer index
```

Message Ring

In cases where a requirement of sending small or medium messages of size <1024 bytes, IPC layer provides another ring called a message ring.

Applications which does not want to incur the overhead of DMA and if the message size is small to be copied by core , the IPC layer message api can be used. IPC layer will copy the application buffer into the message ring.

NOTE

The consumer allocates the message buffers for the message ring using the (`unsigned long msg_ring_paddr, uint32_t msg_size`) in the fsl_ipc_configure_channel API.

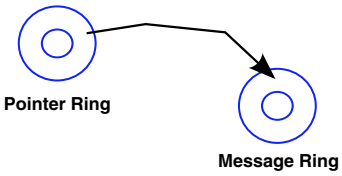

Figure 208. Message Ring Model

```
Linux User API
--------------
fsl_ipc_send_msg(uint32_t channel_id,
                 void *src_buf_addr,
                 uint32_t len,
                 fsl_ipc_t ipc);
```

IPC: L2 I/F Layer

The IPC layer provides a method for L2 stack to send the data PDU's using DMA. This is in addition to the Generic API layer and is provided specific for L2 layer.

This layer has API's which are tightly coupled with the L2 downlink flow.

For example an API Is provided to send a tx.request with a set of Transfer blocks to the L1 stack. The individual TB's are further scattered in the memory so it is the task of this api to linearize the TB's. This linearization can be achieved using DMA engine rather than using core.

Table 212. Memory Allocation for the Buffers

Detail	Description
1	L1 as a consumer creates a MSG_CH and provide memory to store TxRequest messages.

Table continues on the next page...

Table 212. Memory Allocation for the Buffers (continued)

Detail	Description
2	L2 allocates memory for linearized TB's and provides to IPC using `fsl_ipc_configure_tq_req`.
3	IPC will use the linearized TB's as DMA destination to linearize the scatter gather buffers.

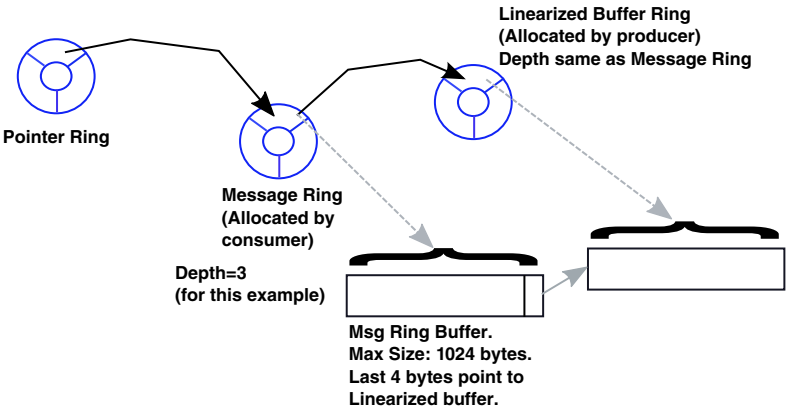

Figure 209. Message Ring Producer/Consumer Behavior

IPC does the following

- Finds the next position (ping/pong/pang) where the message has to be copied
- Does a memcpy to copy the TxRequest fapi message in Message Ring based on the position
- Creates a DMA descriptor based on Scatter gather list
- Add entries in DMA descriptor to increment the producer index and generate a interrupt to DSP

Using a DMA chain ensures that all the operations are done in a serial fasion.

The API polls for DMA completion so as to notify the producer that the buffers can be freed.

Note: DMA Controller requires the DMA descriptor list be stored in DDR, as the IPC does not allocate memory, it requests the producer to allocate depth + 2 number of buffer in the fsl_ipc_configure_txreq api.

IPC Initialization Sequence

Table 213. Sequential Flow

Term	Definition
1	Linux IPC driver, running on PA reads the boot arguments to find: 1. IPC instance. 2. Numbers of channels in the system. 3. Maximum size of the pointer ring.
2	For each IPC instance `ipc_t` data structure is allocated, which has its own set of channel structures in shared control area.
3	The channel data structures and the pointer rings are allocated in the shared control area.

Table continues on the next page...

Table 213. Sequential Flow (continued)

Term	Definition
4	The consumer application using IPC should set the depth of the channel and if the channel is a MSG channel, set the message size using `fsl_ipc_configure_channel` (on Linux).
5	The consumer application using IPC should set the channel parameter pertaining to indication triggering.
6	For Tx request channel, the producer (PA) has to call the api `fsl_ipc_configure_txreq` to allocate the memory to hold the linearized TBs
7	The Tx Request IPC api `fsl_ipc_send_tx_req` triggers the DMA channel to send the TB's and Tx Request (Linux only).
8	The `fsl_ipc_get_last_tx_req_status` should be called by the producer application to get the status of the last tx request send API (Linux only).
9	IPC layer provides `fsl_ipc_chk_recv_status` api to get the status of all the consumer channels which are not empty. This returns a bitmask where each bit represents a channel number which when set denotes that the channel is not empty (i.e has something to consume). This API is only for polling based consumption

IPC Layer memory requirement

1. Linux

   The IPC layer never allocates any memory, the application invoking IPC should pre-allocate memory and attach to the channel.

   For example:

   - - For MSG_CH, the consumer application when calling fsl_ipc_configure_channel, should set the msg_ring memory equal to the msg_size*depth and aligned to the msg_size
   - - For TXREQ_CH, the producer application should call fsl_ipc_configure_txreq to provide buffers where linearization should be done by DMA.

2. SmartDSP OS

   The IPC layer will allocate OS internal structures for optimizing the access to the IPC control area. Buffers, used by message channels, are to be pre-allocated by the application and the memory manager (os_mem_part_t*) handle will be passed during opening the channel.

9.3.1.5 IPC Layer Components

Linux

The IPC layer is implemented as a library and is dynamically linked with a user space application. The IPC framework has the following components

IPC Lib - The IPC lib is dynamically linked with the application requiring the IPC functionality.

usmmgr (User Space Memory Manager) - Not directly a part of IPC but provides DMAable buffers to user space application. The usmmgr internally uses Linux hugetlbfs framework. Applications need to grab all the required memory during their initialization time and should not request memory from this memory manager during their run time.

Dsp boot loader Application - This apllication does the following

- Load the dsp data in dsp DRR and enable the dsp core/cores

- Allocates the channel control structures at the last 1MB of hugepage

- Allocates the channel pointer bd rings from hugepage

User Space DMA Driver

- Provides an interface for the application to reserve the DMA channels. This will make the fsl DMA driver API not allow the usage of channels reserved by IPC. The IPC layer does not poll on DMA completion rather provides an api for the caller to return the status of last dma activity for the particular instance.

- User space DMA driver requires one dedicated h/w DMA channel per ipc instance for simultaneously sending tx.request packets.

- User space DMA requires an UIO interface to bind it with its dma channels. UIO interface is part of user I/O driver in kernel, so it has to be enabled before running IPC in the Linux Kernel.

9.3.1.6 Functional Specification

IPC Lib Operation

The IPC lib provides shared libraries for the user space application. The library maps the shared control structure in user space. After which the api directly updates the channel structure.

Shared Control Area and IPC channels

For B4 platforms - Some portion of Shared Memory Area is reserved to holds the IPC data structure and the channel structures which are referenced by both Linux and SmartDSP OS. Also the pointer Bd rings are allocated from this area. Refer to the appendix for details

Since Shared Control Area is not mapped as cacheable at PA side by Linux kernel therefore IPC metadata is moved to Shared Memory Area which is mapped as cachable.

9.3.1.7 Linux IPC API

9.3.2 IPC User Guide

9.3.2.1 IPC User Guide

Heterogeneous IPC Module

IPC module is provided as user space library (libipc.so) and loadable kernel modules. Apart from providing APIs for L2-L1 communication, a hugepage based user space shared memory manager is also provided as a user space library (libmem.so). In order to use IPC services, user space application needs to be linked with these libraries

Directory Structure

```
ipc/include  - Include directory for IPC public and private header
               files
ipc/lib      - Source code of IPC, user space ipc helper memory
               manager, user space dma driver
fsl_shm      - Source code of user space Shared Memory Manager
dsp_boot     - Source code of DSP boot loader
test         - Reference Test application which uses IPC channels
Kernel       - It contains the IPC kernel code. Compilation will
               generate three kernel loadable modules namely,
               hetmgr.ko, shm.ko and l1d.ko
```

Compilation Procedure

```
Following needs to be modified in kernel image before booting Linux:
Enable the DMA UIO user driver in kernel so to access DMA channel from user space and disable
kernel dma engine.
        Disable the Kernel dma engine.
        [ ] DMA Engine support  --->

        Enable Userspace's I/O driver
        Device Drivers  --->
               <*> Userspace I/O drivers  --->
                    <*> Freescale DMA support

I. Kernel loadable modules:
   1. cd ipc/kernel
   2. Set KERNEL_DIR as the path of Linux source code
   3. Set CROSS_COMPILE as the <path of toolchain>/.../powerpc-linux-gnu- (toolchain should be 64
bit toolchain)
```

```
   4. run make B4860=1
        This will generate the hetmgr.ko, shm.ko and l1d.ko.
        Install the ".ko" with the following command after the Linux is booted.
        Run step 5 only if you want to build kernel modules for multirat applications
   5. run make clean; make B4860=1 CONFIG_MULTI_RAT=1

II. User space code:
   1. cd ipc
   2. Set CROSS_COMPILE as the <path of toolchain>/.../powerpc-linux-gnu- (toolchain should be 32
bit toolchain)
   3. make B4860=1
   4. Following user space libraries and binaries get generated:
      1. under ipc directory
         - libipc.so,
         - libmem.so,
         - ipc_test,
         - ipc_test67
         - l1d_app

      2. under dsp_boot directory
         - libdspboot.so
         - dsp_bt
```

Required u-boot bootargs

```
Please append the following in bootargs:
  - default_hugepagesz=256m
  - hugepagesz=256m
  - hugepages=1

Set DDR size visible to Linux.
  - setenv bootm_size=0x100000000 (This make 0-4 GB for linux and rest for SDOS 4-6 GB)
OR
Set DDR size visible to Linux.
  - setenv bootm_size=0x70000000 (any value less than 2 GB is good enough)
```

Update DDR size to 6GB on uboot

```
This is required for only when L1d and IPC is suppose to work with New Memory Map (4GB-2GB)
DDRC1:
 tftp the SPD binary onto the board
   - tftp 0x1000000 <path/of/bin>spd_1866_dual_rank_4GB_DDRC1.bin
 Update SPD binary with help of i2c
   - mw.b ffdf0055 0x8
   - i2c write 0x1000000 0x51 0 0x80
DDRC2:
 tftp the SPD binary onto the board

 Update SPD binary with help of i2c
   - mw.b 0xffdf0055 0x8
   - i2c write 0x2000000 0x53 0 0x80
```

Test Application (Single RAT only Solutions)

```
1. insmod /usr/driver/IPC/single_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
```

```
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/single_rat/shm.ko

3. insmod /usr/driver/IPC/single_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin

             Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
             whereas,
              <hw_sem> : 1 to 7 for use hardware semaphore
                       : 0 No hardware semaphore used
              <core_id> : 0 to 5 dsp core number
              <image_name> : dsp image name
                          -c option should be followed by -i option
              <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Test applications (ipc_test, ipc_test67) can be started once the DSP/SDOS image
   is loaded successfully with the help of dsp loader(dsp_bt).

   Test runs with the help of 6 IPC channels, where for each pair of channels PowerPC is producer
   and DSP is consumer. For each of the channel pairs a seperate thread is
   started by the test application.

   The channel pairs are
        2-3     Channel 2 is a MSG Channel where DSP is consumer
                Channel 3 is a PTR Channel where PowerPC is consumer.

                Linux sends a message on Channel 2, DSP returns back the pointer of the
                message on channel 3.

                On Channel 2, DSP receives VIRQ
```

```
                On Channel 3, Linux polls for recv pointer.

        4-5     Channel 4 is a PTR channel where Linux is a consumer.
                Channel 5 is a MSG channel where DSP is a consumer.

                Linux receives a ptr on channel 4, copies the length number of characters
                from the pointer into a local buffer and sends the buffer on to channel 5.

                On Channel 4, Linux Polls
                On Channel 5, DSP Polls

        6-7     Channel 6 is a TX Request Channel where Linux is producer.
                Channel 7 is a PTR channel were linux is consumer.

                Linux sends a dummy TX request fapi message a set of buffer using DMA.
                DSP returns to linux a pointer which points to a memory location
                containing first 16 bytes of fapi message and the first buffer.

   Format
   ------
   For channel 2-3,4-5
   $./ipc_test
   Usage: ./ipc_test -r <rat_id> -i <nr_msg>
   whereas,
   <rat_id> : 0 for SingleRAT
            : 1 for MultiRAT
   <nr_msg> : Number of Messages to be exchanged on an IPC channel
   OR
   $ ./ipc_test -r 0 -i 20

   For Channel 6-7
   $./ipc_test67
   Usage: ./ipc_test67 -r <rat_id> -i <nr_msg>
   whereas,
   <rat_id> : 0 for SingleRAT
            : 1 for MultiRAT
   <nr_msg> : Number of Messages to be exchanged on an IPC channel
   OR
   $ ./ipc_test67 -r 0 -i 20

NOTE: ipc_test67 requires a user input,which is the uio interface corresponding
      to the DMA channel.

     for Eg:
        Enter uio_interface you want to use
        like:
        /dev/uio0

        /dev/uio0

NOTE: If -i option is not provided the test run till eternity.
      If -r option is not provided, it take rat_id as 0.
```

Test Application (Multi RAT)

```
0. Since SDOS cannot be reloaded, reboot the system to load multi rat kernel modules.

1. insmod /usr/driver/IPC/multi_rat/hetmgr.ko
     Following modules params can be passed to override their default
```

```
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/multi_rat/shm.ko

3. insmod /usr/driver/IPC/multi_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS Multi-RAT image

    Format
    ------
    $ ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin -c 1 -i c1.bin

             Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
             whereas,
              <hw_sem> : 1 to 7 for use hardware semaphore
                       : 0 No hardware semaphore used
              <core_id> : 0 to 5 dsp core number
              <image_name> : dsp image name
                          -c option should be followed by -i option
              <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges from 0-5.

7. Test applications (ipc_test, ipc_test67) can be started once the DSP multi rat images
   are loaded successfully with the help of dsp loader(dsp_bt),present in rootfs under /ipc.

   ipc_test and ipc_test67 are upgraded for testing multirat support from PA side.
   rat id should be added after the executable name

   Format
   ------
   $./ipc_test
   Usage: ./ipc_test -r <rat_id> -i <nr_msg>
   whereas,
   <rat_id> : 0 for SingleRAT
            : 1 for MultiRAT
```

```
   <nr_msg> : Number of Messages to be exchanged on an IPC channel
   OR
   $ ./ipc_test -r 1 -i 20

   For Channel 6-7
   $./ipc_test67
   Usage: ./ipc_test67 -r <rat_id> -i <nr_msg>
   whereas,
   <rat_id> : 0 for SingleRAT
            : 1 for MultiRAT
   <nr_msg> : Number of Messages to be exchanged on an IPC channel
   OR
   $ ./ipc_test67 -r 1 -i 20

NOTE: ipc_test67 requires a user input,which is the uio interface corresponding
      to the DMA channel.

     for Eg:
        Enter uio_interface you want to use
        like:
        /dev/uio0

        /dev/uio1

NOTE: If -i option is not provided the test run till eternity.
      If -r option is not provided, it take rat_id as 0.
```

l1d Test Application (Single Core only Solutions)

```
1. insmod /usr/driver/IPC/single_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/single_rat/shm.ko

3. insmod /usr/driver/IPC/single_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
```

```
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin

             Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
             whereas,
              <hw_sem> : 1 to 7 for use hardware semaphore
                       : 0 No hardware semaphore used
              <core_id> : 0 to 5 dsp core number
              <image_name> : dsp image name
                         -c option should be followed by -i option
              <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Test application (l1d_app) can be started once the DSP/SDOS image
   is loaded successfully with the help of dsp loader(dsp_bt).

   Test sends an ioctl call to the kernel, inside the kernel it waits on a waitqueue,
   the ioctl returns only if an interrupt is generated by the dsp core towards the PA core via
MPIC interface.
   This interrupt sets the WSRSR register, value set in this register is returned to the proccss
invoking the ioctl
   and this register is cleared.

   Format
   ------
   L1 defense without IPC is use
   $ ./l1d_app 0 0
   Usage:
     ./l1d_app <single core/multi core> <ipc in use>
   Where as,
      0: single core
      1: multi core
      0: IPC not used
      1: IPC used

   OR
   Usage:
     ./l1d_app
   Where as,
     "./l1d_app" means <single core> <ipc not used>
     Same as "./l1d_app 0 0"

NOTE: This test requires user inputs,which are mentioned below:

     for Eg:
        Enter your choice
          0 means not in use for all Parameters
          Only Values mentioned below are valid, rest all values are invalid

        WARM_RESET_MODE <1 or 2 or 3> Enter value as <0x1, 0x2, 0x4>
        MAPLE_RESET_MODE <0x0,0x2,0x4,0x8,0x6,0xA,0xC,0xE>
        Debug_print <0x0,0x1>
        HW_SEM_NUM <0x0,0x1,0x2,0x3,0x4,0x5,0x6,0x7>
        Number of Shared images <0x0,0x1,0x2,0x3,0x4>

        4 0 1 1 0
```

```
        Is it B4420 ? <0x0, 0x1>
        0

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.
      L1d feature can also be used in others MODE-1 and MODE-2
      Shared images are valid for MODE-3 only.
```

l1d Test Application (Multi RAT)

```
0. Since SDOS cannot be reloaded, reboot the system to load multi rat kernel modules.

1. insmod /usr/driver/IPC/multi_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/multi_rat/shm.ko

3. insmod /usr/driver/IPC/multi_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 1 -i c1.bin -c 0 -i c0.bin -c 2 -i c2.bin -c 3 -i c3.bin -c 4 -i c4.bin -c
5 -i c5.bin -s sh0.bin

             Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
             whereas,
              <hw_sem> : 1 to 7 for use hardware semaphore
                       : 0 No hardware semaphore used
              <core_id> : 0 to 5 dsp core number
              <image_name> : dsp image name
                         -c option should be followed by -i option
              <shared_image> : Shared Image name
```

```
NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Test application (l1d_app) can be started once the DSP/SDOS image
   is loaded successfully with the help of dsp loader(dsp_bt).

   Test sends an ioctl call to the kernel, inside the kernel it waits on a waitqueue,
   the ioctl returns only if an interrupt is generated by the dsp core towards the PA core via
MPIC interface.
   This interrupt sets the WSRSR register, value set in this register is returned to the proccss
invoking the ioctl
   and this register is cleared.

   Format
   ------
   L1 defense without IPC is use
   $ ./l1d_app 1 0
   Usage:
     ./l1d_app <single core/multi core> <ipc in use>
   Where as,
      0: single core
      1: multi core
      0: IPC not used
      1: IPC used

   OR
   Usage:
     ./l1d_app
   Where as,
     "./l1d_app" means <single core> <ipc not used>
     Same as "./l1d_app 0 0"

NOTE: This test requires user inputs,which are mentioned below:

     for Eg:
        Enter your choice
          0 means not in use for all Parameters
          Only Values mentioned below are valid, rest all values are invalid

        WARM_RESET_MODE <1 or 2 or 3> Enter value as <0x1, 0x2, 0x4>
        MAPLE_RESET_MODE <0x0,0x2,0x4,0x8,0x6,0xA,0xC,0xE>
        Debug_print <0x0,0x1>
        HW_SEM_NUM <0x0,0x1,0x2,0x3,0x4,0x5,0x6,0x7>
        Number of Shared images <0x0,0x1,0x2,0x3,0x4>

        4 0 1 1 1

        Is it B4420 ? <0x0, 0x1>
        0

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.

      L1d feature can also be used in others MODE-1 and MODE-2.

      Shared images are valid for MODE-3 only.
```

l1d Test Application with IPC used (Single Core only Solutions)

```
1. insmod /usr/driver/IPC/single_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/single_rat/shm.ko

3. insmod /usr/driver/IPC/single_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin

              Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
              whereas,
               <hw_sem> : 1 to 7 for use hardware semaphore
                        : 0 No hardware semaphore used
               <core_id> : 0 to 5 dsp core number
               <image_name> : dsp image name
                           -c option should be followed by -i option
               <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Run IPC tests:
         $ ./ipc_test -r 0 -i 10
         $ ./ipc_test -r 0 -i 10
         $ ./ipc_test67 -r 0 -i 10
         $ ./ipc_test67 -r 0 -i 10
         $ ./ipc_test -r 0 -i 100
```

```
NOTE: When total numbers message exchanged is 100 on any channel,
       DSP generated a watchdog interrupt, after this failures can be seen on IPC channels.

8. Recover DSP core with the help of test application (l1d_app).

     Test sends an ioctl call to the kernel, inside the kernel it waits on a waitqueue,
     the ioctl returns only if an interrupt is generated by the dsp core towards the PA core via
MPIC interface.
     This interrupt sets the WSRSR register, value set in this register is returned to the
proccss invoking the ioctl
     and this register is cleared.

   Format
   ------
   L1 defense with IPC is use
   $ ./l1d_app 0 1
   Usage:
     ./l1d_app <single core/multi core> <ipc in use>
   Where as,
      0: single core
      1: multi core
      0: IPC not used
      1: IPC used

   OR
   Usage:
     ./l1d_app
   Where as,
     "./l1d_app" means <single core> <ipc not used>
     Same as "./l1d_app 0 0"

NOTE: This test requires user inputs,which are mentioned below:

     for Eg:
        Enter your choice
          0 means not in use for all Parameters
          Only Values mentioned below are valid, rest all values are invalid

        WARM_RESET_MODE <1 or 2 or 3> Enter value as <0x1, 0x2, 0x4>
        MAPLE_RESET_MODE <0x0,0x2,0x4,0x8,0x6,0xA,0xC,0xE>
        Debug_print <0x0,0x1>
        HW_SEM_NUM <0x0,0x1,0x2,0x3,0x4,0x5,0x6,0x7>
        Number of Shared images <0x0,0x1,0x2,0x3,0x4>

        4 0 1 1 0

        Is it B4420 ? <0x0, 0x1>
        0

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.

9. Kill the l1d_app when you see Warm reset success (ctrl+c)
         == DSP Booted up ==
         Still at BEGIN_WARM_RESET_OS_INIT or BEGIN_WARM_RESET_APP_INIT sleep 2 sec
         Warm reset success on core_id = 0x1
         sleep 5 sec
```

```
10. Rerun IPC tests to see that dsp core is recovered.
```

l1d Test Application with IPC used (Multi RAT)

```
0. Since SDOS cannot be reloaded, reboot the system to load multi rat kernel modules.

1. insmod /usr/driver/IPC/multi_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/multi_rat/shm.ko

3. insmod /usr/driver/IPC/multi_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin

              Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
              whereas,
               <hw_sem> : 1 to 7 for use hardware semaphore
                        : 0 No hardware semaphore used
               <core_id> : 0 to 5 dsp core number
               <image_name> : dsp image name
                          -c option should be followed by -i option
               <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Run IPC tests:
         $ ./ipc_test -r 0 -i 10
         $ ./ipc_test -r 1 -i 10
         $ ./ipc_test67 -r 0 -i 10
```

```
         $ ./ipc_test67 -r 1 -i 10
         $ ./ipc_test -r 0 -i 100

NOTE: When total numbers message exchanged is 100 on any channel,
       DSP generated a watchdog interrupt, after this failures can be seen on IPC channels.

8. Recover DSP cores with the help of test application (l1d_app).

     Test sends an ioctl call to the kernel, inside the kernel it waits on a waitqueue,
     the ioctl returns only if an interrupt is generated by the dsp core towards the PA core via
MPIC interface.
     This interrupt sets the WSRSR register, value set in this register is returned to the
proccss invoking the ioctl
     and this register is cleared.

   Format
   ------
   L1 defense with IPC is use
   $ ./l1d_app 1 1
   Usage:
     ./l1d_app <single core/multi core> <ipc in use>
   Where as,
      0: single core
      1: multi core
      0: IPC not used
      1: IPC used

   OR
   Usage:
     ./l1d_app
   Where as,
     "./l1d_app" means <single core> <ipc not used>
     Same as "./l1d_app 0 0"

NOTE: This test requires user inputs,which are mentioned below:

     for Eg:
        Enter your choice
          0 means not in use for all Parameters
          Only Values mentioned below are valid, rest all values are invalid

        WARM_RESET_MODE <1 or 2 or 3> Enter value as <0x1, 0x2, 0x4>
        MAPLE_RESET_MODE <0x0,0x2,0x4,0x8,0x6,0xA,0xC,0xE>
        Debug_print <0x0,0x1>
        HW_SEM_NUM <0x0,0x1,0x2,0x3,0x4,0x5,0x6,0x7>
        Number of Shared images <0x0,0x1,0x2,0x3,0x4>

        4 0 1 1 0

        Is it B4420 ? <0x0, 0x1>
        0

        NR_DSP_CORE <0x2,0x6>
        2

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.

9. Kill the l1d_app when you see Warm reset success (ctrl+c)
         == DSP Booted up ==
```

```
          Still at BEGIN_WARM_RESET_OS_INIT or BEGIN_WARM_RESET_APP_INIT sleep 2 sec
          Warm reset success on core_id = 0x1
          sleep 5 sec

10. Rerun IPC tests to see that dsp cores are recovered.
```

Hardware Watchpoint (For Multi RAT and Single RAT)

```
A hardware watchpoint register's primary task is to raise an exception, when the monitored
location is accessed.

After the reboot process is completed, initial Watchpoint that was configured in the DSP/Star
core's DTU gets deleted.

1. insmod /usr/driver/IPC/multi_rat/hetmgr.ko
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/multi_rat/shm.ko

3. insmod /usr/driver/IPC/multi_rat/l1d.ko

4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
    $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin

              Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image">
              whereas,
               <hw_sem> : 1 to 7 for use hardware semaphore
                        : 0 No hardware semaphore used
               <core_id> : 0 to 5 dsp core number
               <image_name> : dsp image name
                          -c option should be followed by -i option
               <shared_image> : Shared Image name
```

```
NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Run l1d_app test

8. Add Watchpoint(wpt) in the l1d_app test

NOTE: This test requires user inputs,which are exemplified below:

   Format
   ------
   configure watchpoint ? (0/1)
   1
   Core ID (0-5), Begin_address (32-bit), End address (32-bit), type(w/r/b)

   0 0xfff00000 0xffffffff b
   Add More watchpoint ? (0/1)
   1
   Core ID (0-5), Begin_address (32-bit), End address (32-bit), type(w/r/b)

   1 0xfff003bc 0xfff003c0 b
   Add More watchpoint ? (0/1)
   0

NOTE:
    w stands for write access
    r stands for read access
    b stands for both, read and write

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.
```

L1d and IPC with New Memory Map (For Multi RAT and Single RAT)

```
A New Memory map is created to provide Linux/PA with 4GB of DDR and SC with 2GB of DDR.
  - SDOS can now run in 4GB to 6GB Address space.
  - Prevents Star core from going into debug state.
  - MMU configuration is configured at run time.
  - DDRC target ID can now be configured with dsp_bt.

1. insmod /usr/driver/IPC/multi_rat/hetmgr.ko shared_ctrl_addr=0x17ff00000
dsp_private_addr=0x100000000
     Following modules params can be passed to override their default
     values:
       - dsp_shared_size  (default value 0x1000000)
       - dsp_private_addr (default value 0x80000000)
       - dsp_private_size (default value 0x7FF00000)
       - shared_ctrl_addr (default value 0xFFF00000)
       - shared_ctrl_size (default value 0x100000)
       - max_num_ipc_channels (default value 64)
       - max_channel_depth    (default value 16)

NOTE: Other Module params are optional, required only when default setting needs to be altered.

2. insmod /usr/driver/IPC/multi_rat/shm.ko

3. insmod /usr/driver/IPC/multi_rat/l1d.ko
```

```
4. Create device nodes with major number flashed while loading kernel modules
     cat /proc/devices will show the major numbers as well

     mknod /dev/fsl_shm c <major number> 0
     mknod /dev/het_mgr c <major number> 0
     mknod /dev/fsl_l1d c <major number> 0

5. Populate shmmax value in proc file system
     echo 0x10000000 > /proc/sys/kernel/shmmax

6. Command to load SDOS image

    Format
    ------
   $./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image"> -d <"DDR Controller ID">

    $ ./dsp_bt -h 1 -c 0 -i c0.bin -d 0x10

            Usage: ./dsp_bt -h <hw_sem> -c <core_id> -i <"image_name"> -s <"shared_image"> -d <"DDR
Controller ID">
             whereas,
              <hw_sem> : 1 to 7 for use hardware semaphore
                       : 0 No hardware semaphore used
              <core_id> : 0 to 5 dsp core number
              <image_name> : dsp image name
                         -c option should be followed by -i option
              <DDR Controller ID> : 0x10, 0x11, is an optional parameter
              <shared_image> : Shared Image name

NOTE: If the semaphore number is specified as 0, it means semaphore is not used.
      Core number specifies the star core number, ranges 0-5.

7. Run IPC tests:
         $ ./ipc_test -r 0 -i 10
         $ ./ipc_test -r 1 -i 10
         $ ./ipc_test67 -r 0 -i 10
         $ ./ipc_test67 -r 1 -i 10
         $ ./ipc_test -r 0 -i 100

NOTE: When total numbers message exchanged is 100 on any channel,
       DSP generated a watchdog interrupt, after this failures can be seen on IPC channels.

8. Recover DSP cores with the help of test application (l1d_app).

     Test sends an ioctl call to the kernel, inside the kernel it waits on a waitqueue,
     the ioctl returns only if an interrupt is generated by the dsp core towards the PA core via
MPIC interface.
     This interrupt sets the WSRSR register, value set in this register is returned to the proccss
invoking the ioctl
     and this register is cleared.

   Format
   ------
   L1 defense with IPC is use
   $ ./l1d_app 1 1
   Usage:
     ./l1d_app <single core/multi core> <ipc in use>
   Where as,
      0: single core
```

```
       1: multi core
       0: IPC not used
       1: IPC used

   OR
   Usage:
     ./l1d_app
   Where as,
     "./l1d_app" means <single core> <ipc not used>
     Same as "./l1d_app 0 0"

NOTE: This test requires user inputs,which are mentioned below:

     for Eg:
        Enter your choice
          0 means not in use for all Parameters
          Only Values mentioned below are valid, rest all values are invalid

        WARM_RESET_MODE <1 or 2 or 3> Enter value as <0x1, 0x2, 0x4>
        MAPLE_RESET_MODE <0x0,0x2,0x4,0x8,0x6,0xA,0xC,0xE>
        Debug_print <0x0,0x1>
        HW_SEM_NUM <0x0,0x1,0x2,0x3,0x4,0x5,0x6,0x7>
        Number of Shared images <0x0,0x1,0x2,0x3,0x4>

        4 0 1 1 0

        Is it B4420 ? <0x0, 0x1>
        0

        NR_DSP_CORE <0x2,0x6>
        6
    configure watchpoint ? (0/1)
    0

    Use Default DSP safe virtual address ? (0/1)
    1

    DSP safe virtual address used are:
    0x80000000  0x80000000  0x80000000  0x80000000  0x80000000  0x80000000

    Run it for infinite loop? (y/n)
    y

NOTE: SDOS images should be located in /ipc/ directory, with the names as
      c0.bin, c1.bin, c2.bin, c3.bin, c4.bin, c5.bin.

NOTE: Step 9 and Step 10 are reuired only for SDOS imagw which has both IPC and L1d together.

9. Kill the l1d_app when you see Warm reset success (ctrl+c)
         == DSP Booted up ==
         Still at BEGIN_WARM_RESET_OS_INIT or BEGIN_WARM_RESET_APP_INIT sleep 2 sec
         Warm reset success on core_id = 0x1
         sleep 5 sec

10. Rerun IPC tests to see that dsp cores are recovered.
```

SDOS IMAGE FORMAT

```
Dsp loader(dsp_bt) expects the SDOS image in the below mentioned format.

       ENDIANESS_BYTE (1Byte)
       <ADDRESS - 8Bytes><SIZE_IN_BYTES - 8Bytes><data_payload>
       <ADDRESS - 8Bytes><SIZE_IN_BYTES - 8Bytes><data_payload>
       <ADDRESS - 8Bytes><SIZE_IN_BYTES - 8Bytes><data_payload>
       ........
       <ADDRESS =0xFFFF_FFFF_FFFF_FFFF ><SIZE = 8><__crt0_start address>

       __crt0_start address should be 8k aligned.
```

Limitations

IPC support for B4 platforms is available only for 32-bit user space.

9.4 L2Switch (T1040)

9.4.1 Overview

NXP T1040 and T1020 SoC have an 8-port gigabit Ethernet switch integrated on the device.

T1040 Hardware Support

Linux User Space
L2Switch (T1040)

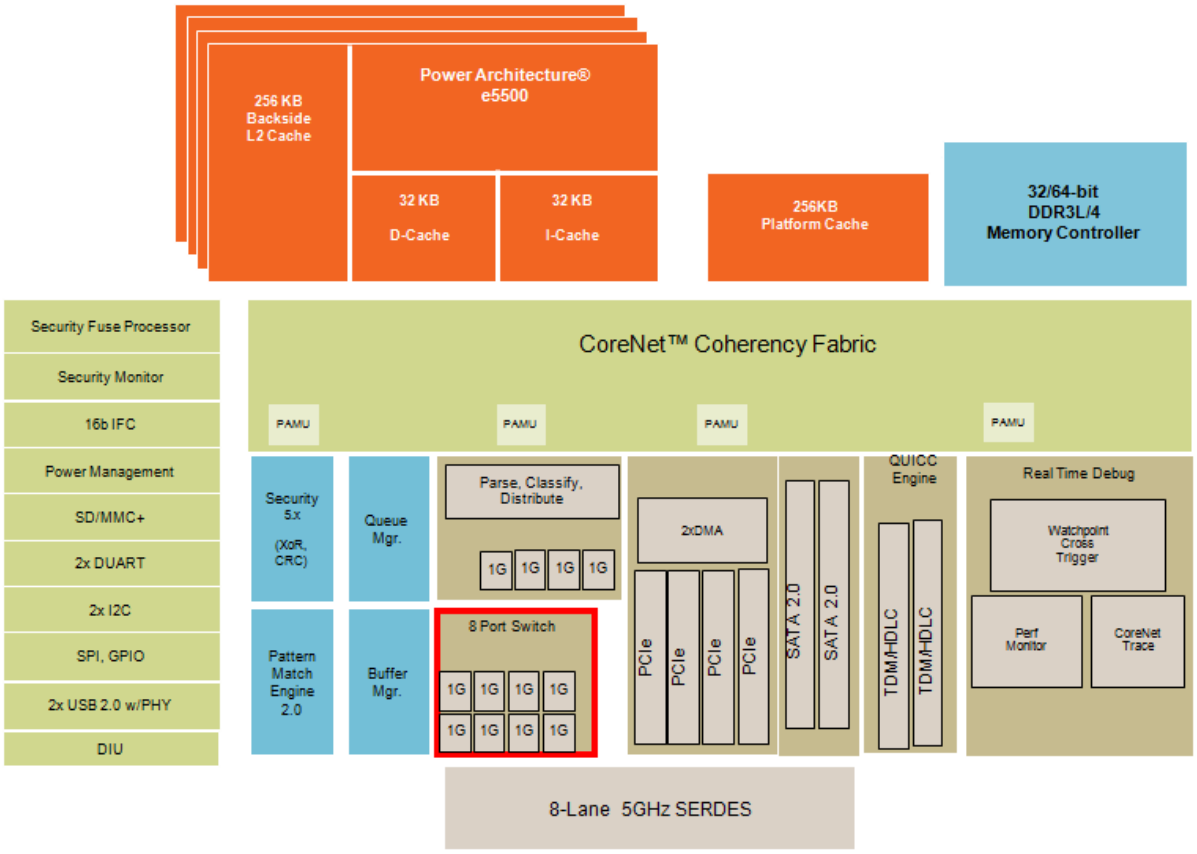

Figure 210. T1040 Architecture

The integrated 8-port gigabit Ethernet switch supports the following features:

- 8192 MAC addresses
  - Static Address provisioning
  - Dynamic learning of MAC addresses and aging
- 4096 VLANs
  - Independent VLAN learning (IVL)
  - VLAN editing, translation and remarking
- Link aggregation (IEEE Std 802.3ad)
- Policing with storm control and MC/BC protection
- Spanning Tree Protocol (STP, RSTP and MSTP) - IEEE 802.1w/IEEE 802.1s
- IPv4 and IPv6 multicast
- Jumbo frames (9.6 KB)
- Access Control List (ACLs)
- Hierarchical QoS with DWRR scheduling at different levels between the following:
  - Ingress ports
  - Priorities

- Services
- RMON counters per port

Switch interfaces:

- 8 Gigabit switch ports are external ports and are connected to external Phys
- 2 switch ports (2.5G) are connected to FMan ports

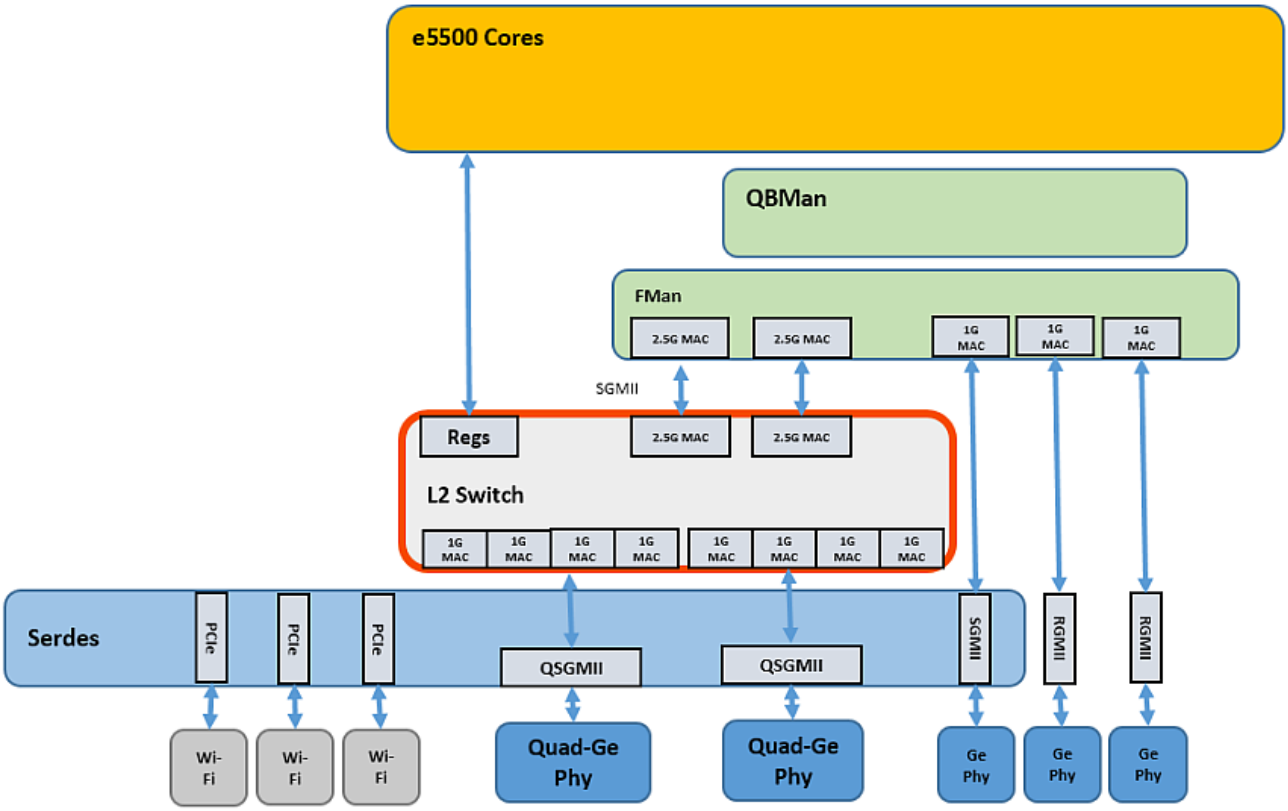

Figure 211. T1040 Port Connectivity

For more details check the T1040 Reference Manual.

Software Support

The Software Architecture of the NXP SDK enablement software is:

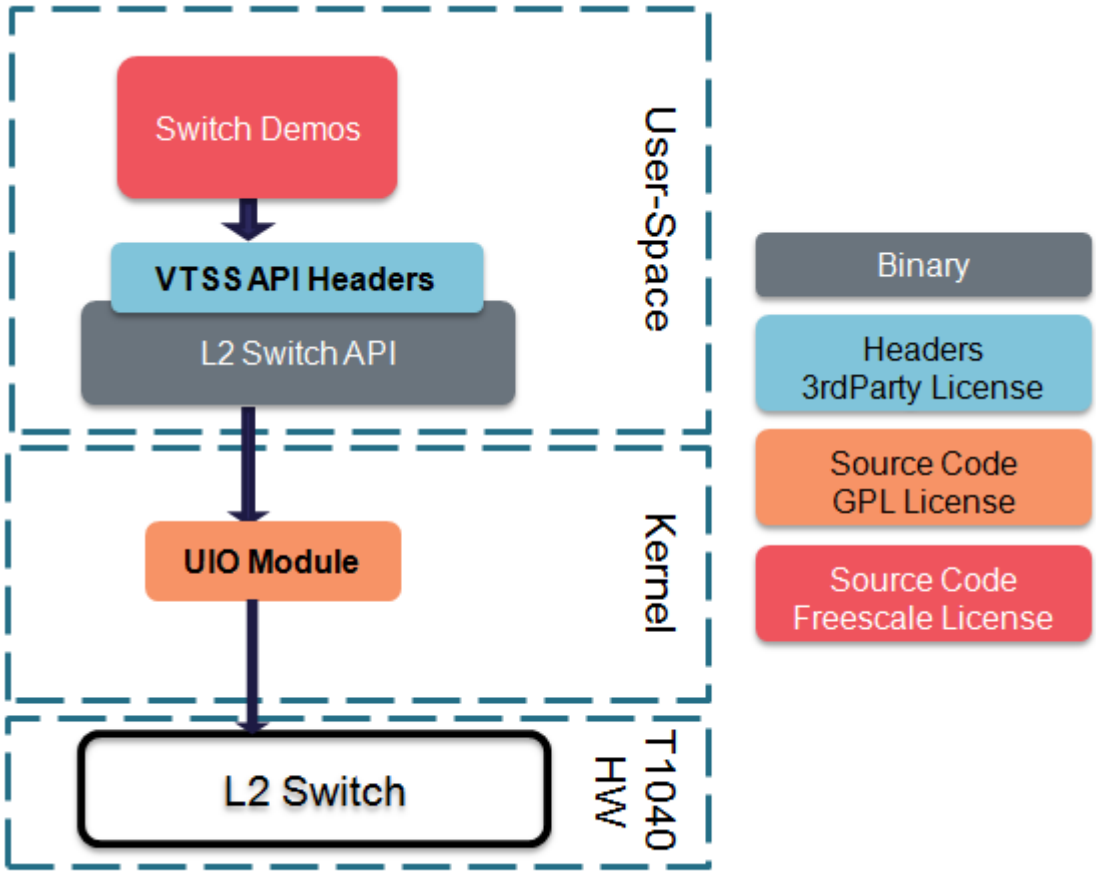

Figure 212. SW Architecture

NXP SDK includes an L2 Switch user space driver and a small demo application that uses the API provided by the switch driver.

L2 Switch protocol termination stack is not included in NXP SDK and can be provided through external means.

Features Supported

Functionalities supported by L2Switch API:

- Forwarding
  - Dynamic MAC Learning
  - Static MAC Forwarding
- Port Control & Statistics
- Link Aggregation
  - Static Link Aggregation
- VLAN
  - VLAN Configuration
  - Port Based VLAN
  - Private VLAN
  - Protocol based VLAN

- IP Subnet based VLAN
- MAC based VLAN
- Q-in-Q (IEEE-802.1ad Provider Bridge)
- Voice VLAN
- Port isolation

- BPDU Handling
- QoS
  - Classification
  - Policing
  - Scheduling and Shaping
  - Tag Remarking
  - DSCP based QoS (e.g. classification/translation, remarking)
  - PFC (Priority Based Flow Control IEEE 802.1qbb)
  - WRED
- 802.3x Flow control
- ACLs
  - ACE Configuration
  - ACL Port Configuration
- Port Mirroring
- Storm control
- 802.1X
  - Port-based 802.1X
  - Single 802.1X
  - Multiple 802.1X
- Port Mirroring
- sFlow

Functionalities supported by Demo Application

- Port Control
- Port Statistics
- MAC address table operations
- Configuration options for:
  - Static Link Aggregation
  - VLANs
  - VLAN Classification Entries
  - Private VLANs
  - Isolated ports
  - Storm control
  - Port Mirroring

- QoS
- Q-in-Q (IEEE-802.1ad Provider Bridge)
- Flow control

9.4.2 Build and Installation Summary

The driver and demo application is included by default in the rootfs generated by the NXP SDK. Demo application is configured to start at boot.

L2Switch components can also be built and installed manually.

Building L2Switch Driver with Yocto

The L2Switch driver can be built from a Yocto recipe included in NXP SDK:

```
> bitbake uio-seville
```

This will build and package a kernel module containing the driver.

Building L2Switch Demo Application with Yocto

The L2Switch demo application is a simple sample application that exercises the API to control the switch. It offers basic commands, like port control, port aggregation and port statistics information.

The L2Switch demo application can be built from a Yocto recipe included in NXP SDK:

```
> bitbake l2switch
```

This will build several packages containing the demo application, the shared library with the user-space driver and the API headers.

Installation

The packages obtained in the previous steps have to be installed on the rootfs:

1. Install the kernel module package and insert the module into the kernel:

   ```
   root@t1040rdb:~# insmod /lib/modules/`uname -r`/extra/uio_seville.ko
   ```

   If the insertion is successful the console will display this message:

   ```
   seville ffe800000.l2switch: Found Seville Switch, UIO device - IRQ 26, id 0x099530e9.
   ```

2. Install the shared object user-space driver package:

   ```
   root@t1040d4rdb:~# rpm –i libvtss-api0-0.1-r0.ppc64e5500.rpm
   ```

3. Install the L2Switch demo application:

   ```
   root@t1040d4rdb:~# rpm –i l2switch-0.1-r0.ppc64e5500.rpm
   ```

The switch demo application is started with the following command:

```
root@t1040rdb:~# /etc/init.d/l2switch start
```

This allows also stopping the application and restarting it.

```
root@t1040rdb:~# /etc/init.d/l2switch {start|stop|restart|reload|status}
```

Demo application default configuration:

- L2 switch is started with all ports enabled
- Internal ports are configured as fixed links at 2.5Gbps
- External ports have autonegotiation at 1Gbps
- Ports are in VLAN 1
- Maximum frame size is 10k
- Switch performs hardware MAC learning
- Flow Control is disabled by default

NOTE: Some L2 protocols require a MAC address for each switch port for proper functioning. An address can be specified in u-boot, that will serve as a seed for generating MAC addresses for each port:

```
setenv l2switchaddr 00:11:22:33:44:55
saveenv
```

This address will be available as a sysfs entry:

```
root@t1040d4rdb:~# cat /sys/bus/platform/devices/ffe800000.l2switch/mac_address
00:11:22:33:44:55
```

9.4.3 l2switch-cfg Command Reference

This section details the list of commands and parameters supported by the L2Switch demo application

Interaction with the L2 Switch is possible via l2switch-cfg script:

```
root@t1040d4rdb:~# l2switch-cfg
Usage: /usr/bin/l2switch-cfg [options] - basic script to configure the L2 switch

Options:
dscp <option>                  - Configure DSCP mode
                                 where option can be translate|remap|trust
isolated member(s) <option>    - Configure isolated members list
mac <option>                   - Configure MAC address table
port <option>                  - Configure a specific port where option
                                 can be stats|all|port_no
private vlan <option>          - add/remove port from/to private VLANs or
                                 show private VLANs
qos <option>                   - Configure QoS
set <option>                   - Set mirroring or max frame length or lag mode
                                 where option can be mirror|max_frame_length|
```

```
                                  lag
storm control <option>          - Set storm control rate or disable
vlan <option>                   - VLAN configuration:
                                  - add/remove port to/from VLAN
                                  - show VLANs
                                  - configure VLAN translation
                                  - show isolated VLANs
vce <add|remove> <option>       - VCE configuration(MAC,OUI,Type,Subnet)
control traffic <option>        - Control traffic configuration where option can
                                  be conf|stats|verbose|receive|reflect|ena|dis
show version                    - shows software version
poll <on|off>                   - enable/disable PHY polling
check                           - check for dropped or invalid frames;
                                  if any, a debug file will be generated
```

Note: In order to be able to use link aggregation on the internal ports (8 and 9) the bonding module has to be inserted in the kernel. See Appendix - Bonding configuration for internal ports on page 1405

9.4.4 U-Boot Command Reference

U-Boot is able to initialize the switch. The following message is displayed in logs:

```
VSC9953 L2 switch initialized
```

This enables using switch ports in unmanaged mode for access to network (TFTP file transfer, connectivity checks). FM1@DTSEC1 and FM1@DTSEC2 are connected to switch port 8 and 9 at 2.5Gbps.

Note: Switch does not have any loop protection mechanism running, so the user must take care not to create any network loops.

Switch configuration is maintained in Linux, if demo application is not loaded.

Limited configuration commands are available in U-Boot:

```
=> ethsw
ethsw - vsc9953 l2 switch commands

Usage:
ethsw port <port_nr> enable|disable
    - enable/disable an l2 switch port
      port_nr=0..9; use "all" for all ports
ethsw port <port_nr> show
    - show an l2 switch port's configuration
      port_nr=0..9; use "all" for all ports
```

Example: displaying L2 switch ports status

```
=> ethsw port all show
    Port    Status     Link    Speed   Duplex
       0  enabled       up     1000     full
       1  enabled       up     1000     full
       2  enabled       up     1000     full
       3  enabled     down       10     half
       4  enabled     down       10     half
       5  enabled     down       10     half
       6  enabled       up     1000     full
       7  enabled       up     1000     full
       8  enabled       up     2500     full
       9  enabled       up     2500     full
```

9.4.5 l2switch-cfg How To's

9.4.5.1 How to control Ports and Statistics

Port control:

```
root@t1040d4rdb:/# l2switch-cfg port <port_no> state enable
root@t1040d4rdb:/# l2switch-cfg port <port_no> state disable
```

Port status:

```
root@t1040d4rdb:/# l2switch-cfg port all config show
Port 0 state: enabled  link: up        mode: auto      speed: 1G       duplex: full
Port 1  state: enabled  link: up        mode: auto      speed: 1G       duplex: full
Port 2  state: enabled  link: up        mode: auto      speed: 1G       duplex: full
Port 3  state: enabled  link: up        mode: auto      speed: 1G       duplex: full
Port 4  state: enabled  link: down      mode: auto      speed: ???      duplex: half
Port 5  state: enabled  link: down      mode: auto      speed: ???      duplex: half
Port 6  state: enabled  link: down      mode: auto      speed: ???      duplex: half
Port 7  state: enabled  link: down      mode: auto      speed: ???      duplex: half
Port 8  state: enabled  link: down      mode: static    speed: 2.5G     duplex: full
Port 9  state: enabled  link: down      mode: static    speed: 2.5G     duplex: full
```

Port statistics:

```
root@t1040d4rdb:~# l2switch-cfg port stats all clear

root@t1040d4rdb:~# l2switch-cfg port stats all packets
Port 0 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 1 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 2 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 3 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 4 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 5 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
---------------------------------------------------------
Port 6 statistics:
---------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
```

```
-------------------------------------------------------
Port 7 statistics:
-------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
-------------------------------------------------------
Port 8 statistics:
-------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
-------------------------------------------------------
Port 9 statistics:
-------------------------------------------------------
Rx Packets:          0   Tx Packets:          0
-------------------------------------------------------
```

9.4.5.2 How to control Link Aggregation

Commands for setting LAG between two ports:

```
root@t1040d4rdb:/# l2switch-cfg set lag mode
root@t1040d4rdb:/# l2switch-cfg set lag no 1 members 5 6
       LAG NO 1 members: 5 6
```

9.4.5.3 How to configure port based VLAN

- By default all ports belong to VLAN 1:

```
root@t1040d4rdb:~# l2switch-cfg vlan show
Printing all VLANs...

VLAN 1: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
```

- Adding a port to a specific VLAN:

```
root@t1040d4rdb:~# l2switch-cfg vlan 10 add 3
Adding port 3 as member for VLAN 10
VLAN 10: 3,

root@t1040d4rdb:~# l2switch-cfg vlan 11 add 4
Adding port 4 as member for VLAN 11
VLAN 11: 4,

root@t1040d4rdb:~# l2switch-cfg vlan show
Printing all VLANs...

VLAN 1: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
VLAN 10: 3,
VLAN 11: 4,
```

- Removing a port from a specific VLAN:

```
root@t1040d4rdb:~# l2switch-cfg vlan 10 remove 3
Removing port 3 from VLAN 10 members

root@t1040d4rdb:~# l2switch-cfg vlan show
Printing all VLANs...
```

```
VLAN 1: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
VLAN 11: 4,
```

9.4.5.4 How to control MAC table

Commands available for MAC table operations:

```
mac add <mac> <port< [<vid>]           - add static entry to FDB
mac del <mac> [<vid<]                  - delete static entry from FDB
mac lookup <mac> [<vid>]               - lookup for specficic entry in FDB
mac dump                               - dump FDB entries content
mac flush [port <port>] [vlan <vid>]   - flush dynamic entries
mac agetime [<age_time>]               - get/set agetime
mac learn <auto|off>                   - enable/disable hardware MAC learning
```

1. Adding a static entry:

```
root@t1040d4rdb:~# l2switch-cfg mac add 00:11:22:33:44:55 4 12

root@t1040d4rdb:~# l2switch-cfg mac dump
Type    VID  MAC Address        Ports
------  ---  -----------------  -----
Static  12   00:11:22:33:44:55  4

Static  entries: 1
Dynamic entries: 0
```

2. Deleting a static entry:

```
root@t1040d4rdb:~# l2switch-cfg mac del 00:11:22:33:44:55

root@t1040d4rdb:~# l2switch-cfg mac dump
Type    VID  MAC Address        Ports
------  ---  -----------------  -----

Static  entries: 0
Dynamic entries: 0
```

3. lookup for specific MAC address:

```
root@t1040d4rdb:~# l2switch-cfg mac dump
Type    VID  MAC Address        Ports
------  ---  -----------------  -----
Static  1    00:11:22:33:44:66  5
Static  1    00:11:22:33:44:67  5
Static  1    00:11:22:33:44:68  5
Static  10   00:11:22:33:44:60  3

Static  entries: 4
Dynamic entries: 0

root@t1040d4rdb:~# l2switch-cfg mac lookup 00:11:22:33:44:67
```

```
Type    VID  MAC Address        Ports
------  ---  -----------------  -----
Static  1    00:11:22:33:44:67  5

root@t1040d4rdb:~# l2switch-cfg mac lookup 00:11:22:33:44:50
No entries found
```

9.4.5.5 How to check for errors

Command to gather extra info in case of dropped/invalid frames. This is a diagnose command that indicates if frames are dropped by the switch. In case of dropped frames, errors are showed on the console and a file is created that gathers additional information.

```
root@t1040d4rdb:~# l2switch-cfg check
No dropped or invalid frames reported
```

9.4.5.6 How to control PHY polling

If no interrupts are present in device-tree for Seville PHYs, by default application polls for PHY status. Deactivating PHY polling is useful mainly for benchmarking scenarios where l2switch-cfg needs to consume 0 CPU cycles.

```
root@t1040d4rdb:~# l2switch-cfg poll on
polling is already turned on
```

To disable PHY polling:

```
root@t1040d4rdb:~# l2switch-cfg poll off
polling disabled
```

9.4.6 Use Cases

9.4.6.1 Using L2Switch as Port Extender

The LAN ports of the L2 Switch make forwarding decisions based only on L2 switch logic, with no involvement from FMAN or CPU (CPU can't track the packets that are switched between the 8 external L2 Switch ports). Depending on the use case, this behavior might not be desirable. In order to direct all traffic received on external ports to CPU, maintaining ingress port information and avoid switching in L2Switch IP the Port-based VLAN functionality needs to be used.

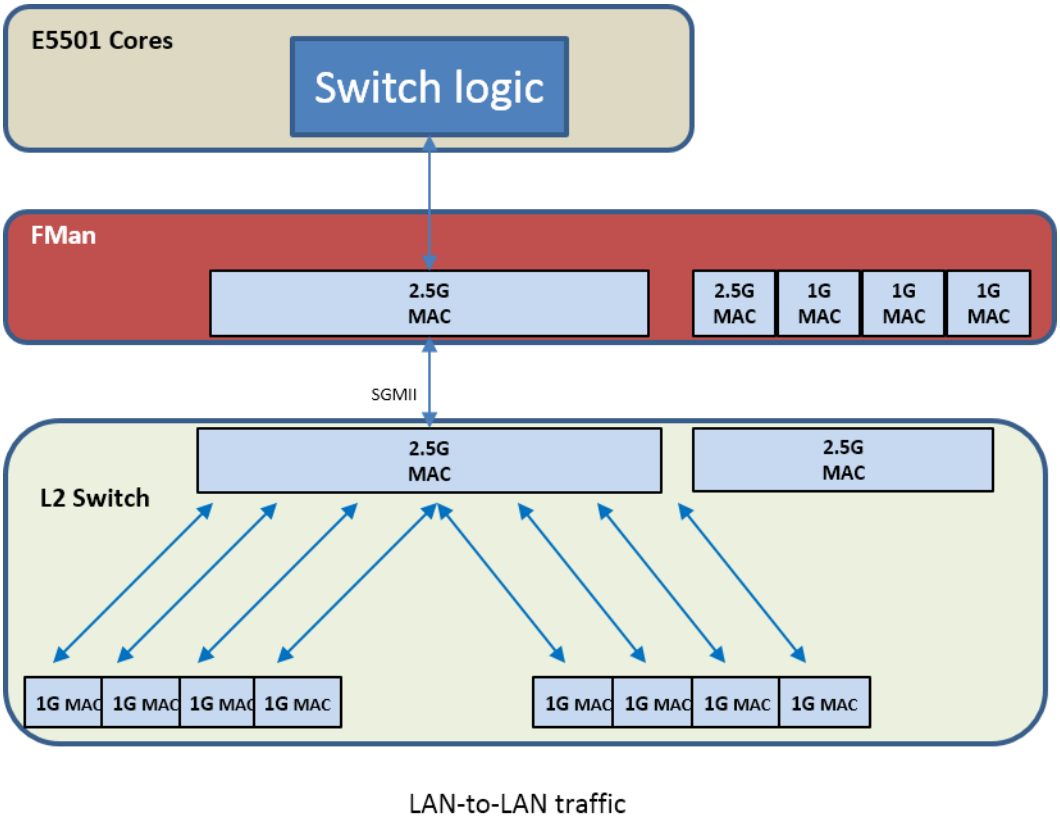

Figure 213. Port extender

Note: In the first example only one L2 Switch internal port (port 8) is used, ensuring a throughput of 2.5 Gbps, full duplex mode. The FMAN port corresponding to the second internal port (port 9) won't be used.

If the throughput is not enough, the second internal port (port 9) is required for increasing the throughput to 5 Gbps, full duplex.

Configuration when using one FMan Port

The following commands will add each external port <port_nr> as a member of VLAN 10 + <nr_port> to create a separate VLAN for each external port:

```
root@t1040d4rdb:~# l2switch-cfg vlan 10 add 0
Adding port 0 as member for VLAN 10
VLAN 10: 0,

root@t1040d4rdb:~# l2switch-cfg vlan 11 add 1
Adding port 1 as member for VLAN 11
VLAN 11: 1,

root@t1040d4rdb:~# l2switch-cfg vlan 12 add 2
Adding port 2 as member for VLAN 12
VLAN 12: 2,

root@t1040d4rdb:~# l2switch-cfg vlan 13 add 3
Adding port 3 as member for VLAN 13
VLAN 13: 3,

root@t1040d4rdb:~# l2switch-cfg vlan 14 add 4
```

```
Adding port 4 as member for VLAN 14
VLAN 14: 4,

root@t1040d4rdb:~# l2switch-cfg vlan 15 add 5
Adding port 5 as member for VLAN 15
VLAN 15: 5,

root@t1040d4rdb:~# l2switch-cfg vlan 16 add 6
Adding port 6 as member for VLAN 16
VLAN 16: 6,

root@t1040d4rdb:~# l2switch-cfg vlan 17 add 7
Adding port 7 as member for VLAN 17
VLAN 17: 7,
```

To add the internal port 8 as a member to all the previous created VLANs use the following commands:

```
root@t1040d4rdb:~# l2switch-cfg vlan 10 add 8
Adding port 8 as member for VLAN 10
VLAN 10: 0, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 11 add 8
Adding port 8 as member for VLAN 11
VLAN 11: 1, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 12 add 8
Adding port 8 as member for VLAN 12
VLAN 12: 2, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 13 add 8
Adding port 8 as member for VLAN 13
VLAN 13: 3, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 14 add 8
Adding port 8 as member for VLAN 14
VLAN 14: 4, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 15 add 8
Adding port 8 as member for VLAN 15
VLAN 15: 5, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 16 add 8
Adding port 8 as member for VLAN 16
VLAN 16: 6, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 17 add 8
Adding port 8 as member for VLAN 17
VLAN 17: 7, 8,
```

The Rx traffic for the L2 Switch external ports has to be classified and tagged with the proper VLAN, so that the application which will make the forwarding decision will be aware of the packet's ingress port by looking at the VID from the VLAN tag.

This can be done using Port-based VLAN L2 Switch functionality:

```
root@t1040d4rdb:~# l2switch-cfg port 0 vlan 10
0 - VID 10
```

```
root@t1040d4rdb:~# l2switch-cfg port 1 vlan 11
1 - VID 11

root@t1040d4rdb:~# l2switch-cfg port 2 vlan 12
2 - VID 12

root@t1040d4rdb:~# l2switch-cfg port 3 vlan 13
3 - VID 13

root@t1040d4rdb:~# l2switch-cfg port 4 vlan 14
4 - VID 14

root@t1040d4rdb:~# l2switch-cfg port 5 vlan 15
5 - VID 15

root@t1040d4rdb:~# l2switch-cfg port 6 vlan 16
6 - VID 16

root@t1040d4rdb:~# l2switch-cfg port 7 vlan 17
7 - VID 17
```

With the above commands ingress traffic on port <port_nr> is classified to VLAN 10 + <port_nr>. This traffic will be sent to internal port since there is no other member of the classified VLAN to forward the packet to. Notice that the default Port-based VLAN was not changed for port 8 (VLAN 1). This means that packets that are classified to a VLAN different than VLAN 1 will be tagged on the egress of port 8 with the classified VLAN ID. Also, when injecting a packet from the application to internal port 8, the packet must be tagged with the VLAN corresponding to the external port on which we want to send to. The VLAN tag will be removed on the egress of the external port.

Configuration output:

```
root@t1040d4rdb:~# l2switch-cfg vlan show
Printing all VLANs...

VLAN 1: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
VLAN 10: 0, 8,
VLAN 11: 1, 8,
VLAN 12: 2, 8,
VLAN 13: 3, 8,
VLAN 14: 4, 8,
VLAN 15: 5, 8,
VLAN 16: 6, 8,
VLAN 17: 7, 8,

root@t1040d4rdb:~# l2switch-cfg port all vlan show
Vlan port-based configuration (port - VID):
0 - VID 10
1 - VID 11
2 - VID 12
3 - VID 13
4 - VID 14
5 - VID 15
6 - VID 16
7 - VID 17
8 - VID 1
9 - VID 1
```

Using VLANs for creating a Port Extender scenario is straight forward, easy to configure, there is no custom header involved.

The limitations are:

- VLAN functionality is reserved to the Port Extender use case and can't be used properly for any other configuration. If a packet arrives at an external port already tagged, it will be classified to the VID specified in the VLAN tag, not to its Port-based VLAN. In a future release, the VLAN Unaware functionality of a port will be added, which will always classify a packet to the Port-based VLAN, even if the packet is already tagged with a VLAN;
- Throughput of all 8 external ports can't be higher than 2.5 Gbps;
- One L2 switch port (port 9) and one FMAN internal port unused;

Configuration when using two FMan Ports

In the previous configuration, only one L2 Switch internal port has been used and the throughput to CPU is limited to 2.5 Gbps.

Using both internal ports the throughput is doubled and in order to do this, the traffic needs to be split on the external ports.

This may be done by grouping external ports 0…3 with internal port 8 and external ports 4..7 with internal port 9.

The commands for this scenario are:

```
root@t1040d4rdb:~# l2switch-cfg vlan 10 add 8
Adding port 8 as member for VLAN 10
VLAN 10: 0, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 11 add 8
Adding port 8 as member for VLAN 11
VLAN 11: 1, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 12 add 8
Adding port 8 as member for VLAN 12
VLAN 12: 2, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 13 add 8
Adding port 8 as member for VLAN 13
VLAN 13: 3, 8,

root@t1040d4rdb:~# l2switch-cfg vlan 14 add 9
Adding port 9 as member for VLAN 14
VLAN 14: 4, 9,

root@t1040d4rdb:~# l2switch-cfg vlan 15 add 9
Adding port 9 as member for VLAN 15
VLAN 15: 5, 9,

root@t1040d4rdb:~# l2switch-cfg vlan 16 add 9
Adding port 9 as member for VLAN 16
VLAN 16: 6, 9,

root@t1040d4rdb:~# l2switch-cfg vlan 17 add 9
Adding port 9 as member for VLAN 17
VLAN 17: 7, 9,

root@t1040d4rdb:~# l2switch-cfg vlan show
Printing all VLANs...

VLAN 1: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
VLAN 10: 0, 8,
```

```
VLAN 11: 1, 8,
VLAN 12: 2, 8,
VLAN 13: 3, 8,
VLAN 14: 4, 9,
VLAN 15: 5, 9,
VLAN 16: 6, 9,
VLAN 17: 7, 9,
```

9.4.7 Troubleshooting

1. How to verify user-space driver status:

```
root@t1040d4rdb:~# /etc/init.d/l2switch status
   l2sw_bin is stopped
```

2. Check the uio-seville module is inserted:

```
root@t1040d4rdb:~# lsmod
Module                  Size  Used by
uio_seville            1589      1
```

9.4.8 Limitations

Switch driver:

- For Link Aggregation, only mode 2 is supported
- When link aggregation is enabled between FMAN ports and L2 switch internal ports, ICMP requests get duplicated after recovering from a link failure

Demo application:

- For internal ports (8 and 9) the link status is incorrectly displayed as down. Those ports do not have PHYs so no information about status can be reported

9.4.9 Appendix - Bonding configuration for internal ports

Building the Linux Kernel

Linux kernel has to be rebuilt with bonding support. In NXP SDK this can be done by:

```
> bitbake -c menuconfig virtual/kernel
```

Select "Bonding driver support" in the "Network device support" section. Configure the driver as a module.

Build the kernel with the updated configuration and also the bonding module:

```
> bitbake -c deploy virtual/kernel
```

Installing the module

The kernel module can now be copied onto the board, installed and loaded. Note that the bonding module resides within a tgz archive in the same location as the kernel does.

```
root@t1040d4rdb:~# insmod /lib/modules/`uname -r`/kernel/drivers/net/bonding/bonding.ko mode=2
miimon=100 downdelay=200 updelay=200
bonding: Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)
```

```
bonding: MII link monitoring set to 100 ms
MODE parameter: specifies one of the bonding policies. 1 or active-backup provides fault tolerance
with only one slave in the bond being active; a different slave becomes active if the active slave
fails.
```

- MIIMON parameter: MII link monitoring frequency in milliseconds (how often the link state of each slave is inspected for link failures)
- DOWNDELAY parameter: time to wait before disabling a slave after a link failure has been detected.
- UPDELAY parameter: time to wait before enabling a slave after a link recovery has been detected.

Configuring the internal ports bonding

The L2Switch application has to be configured for ports bonding.

Enabling Link Aggregation on ports 8,9

```
root@t1040d4rdb:~# l2switch-cfg set lag mode

root@t1040d4rdb:~# l2switch-cfg set lag no 1 members 8, 9
LAG NO 1 members: 8 9
```

Disabling Link Aggregation on ports 8,9

```
root@t1040d4rdb:~# l2switch-cfg set lag no 1 members
```

The internal ports have two corresponding interfaces, named fm1-gb0 and fm1-gb1. The following commands have to be issued in order to configure them as bonded:

```
root@t1040d4rdb:~# ifconfig bond0 13.13.13.1 up
IPv6: ADDRCONF(NETDEV_UP): bond0: link is not ready
8021q: adding VLAN 0 to HW filter on device bond0
root@t1040d4rdb:~# ifenslave bond0 fm1-gb0 fm1-gb1
bonding: bond0: enslaving fm1-gb0 as an active interface with an up link.
bonding: bond0: enslaving fm1-gb1 as an active interface with an up link.
bonding: bond0: link status definitely up for interface fm1-gb0, 10 Mbps half duplex.
bonding: bond0: first active interface up!
IPv6: ADDRCONF(NETDEV_CHANGE): bond0: link becomes ready
bonding: bond0: link status definitely up for interface fm1-gb1, 10 Mbps half duplex.
```

9.5 Link Aggregation (T1040)

9.5.1 Introduction

LAG - Link Aggregation Overview

As defined in the IEEE 802.1AX-2014 Standard, Link Aggregation provides protocols, procedures, and managed objects that allow the following:

- One or more parallel instances of full-duplex point-to-point links to be aggregated together to form a Link Aggregation Group (LAG), such that a MAC Client can treat the LAG as if it were a single link.
- A resilient interconnect using multiple full-duplex point-to-point links among one to three nodes in a network and one to three nodes in another, separately administered, network, along with a means to ensure that frames belonging to any given service will use the same physical path in both directions between the two networks.

Link Aggregation allows the establishment of full-duplex point-to-point links that have a higher aggregate bandwidth than the individual links that form the aggregation, and the use of multiple systems at each end of the aggregation. This allows improved utilization of available links in bridged local area network (LAN) environments, along with improved resilience in the face of failure of individual links or systems.

LAG Topology Examples

For some topology examples for Link Aggregation, please refer to Figure 214. Topology Examples on page 1407 extracted from the IEEE 802.1AX-2014 Standard.

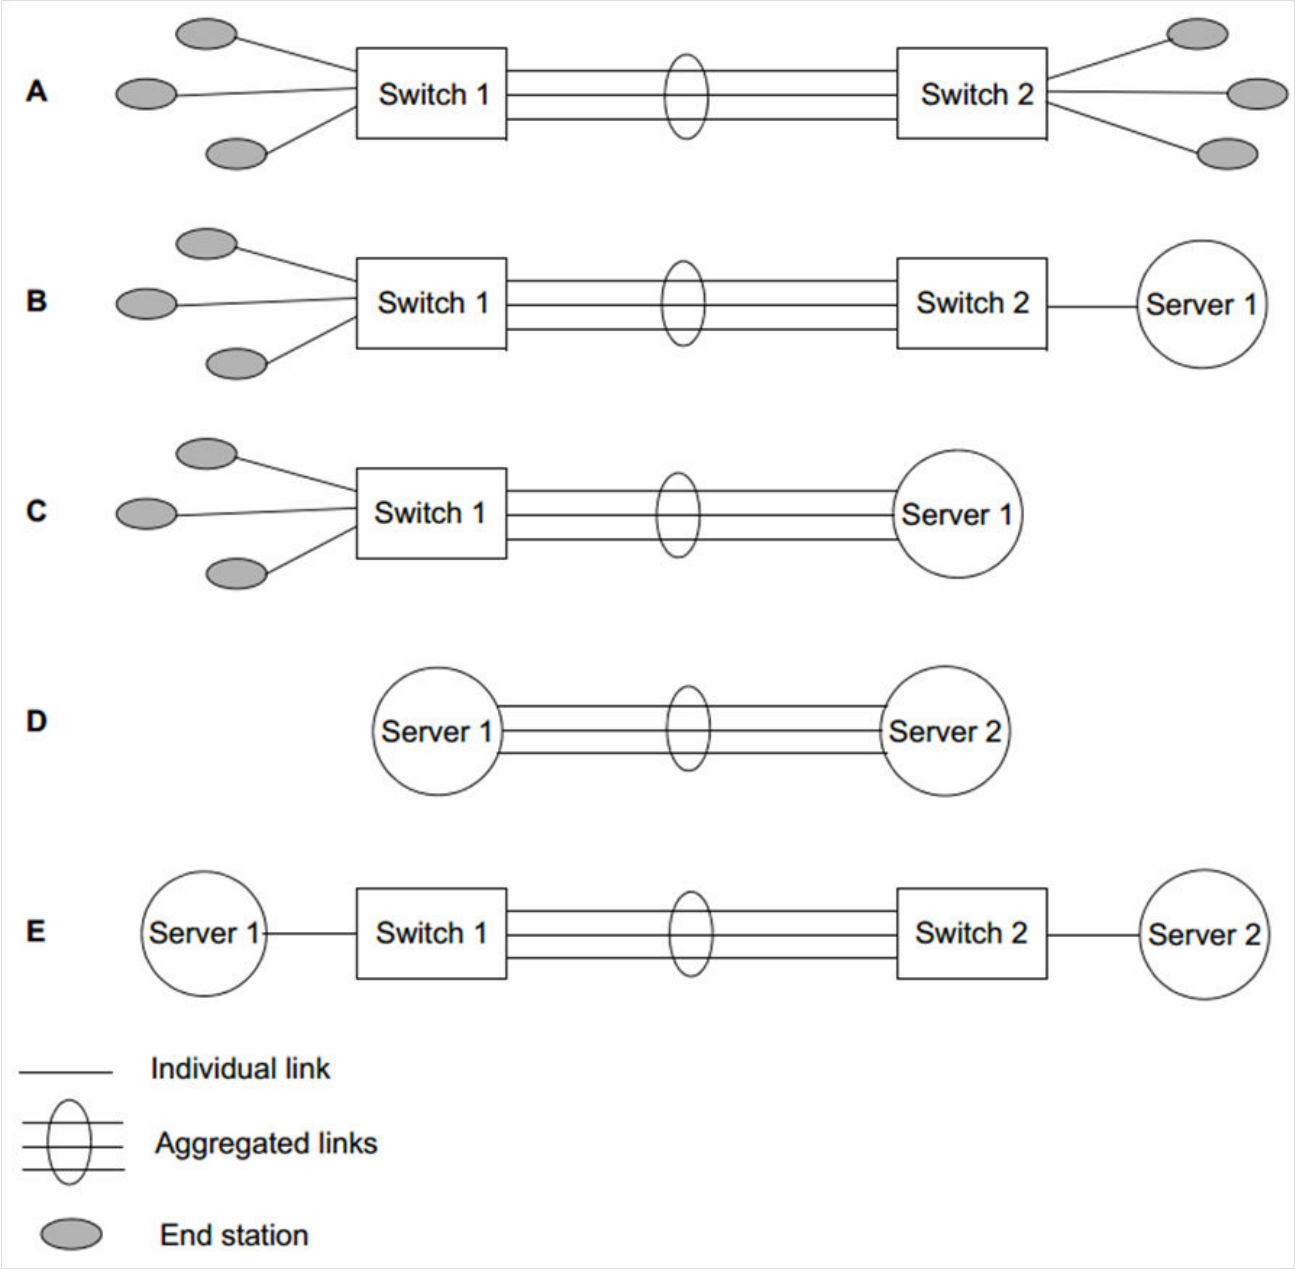

Figure 214. Topology Examples

T1040 Port Connectivity

There are 5 MAC ports in T1040 FMan, 3 of them can be pinout to Phys as 1Gbps RGMII/ SGMII links, others 2 of them can be pinout to Phys as 2.5G SGMII links or directly be connected to L2 Switch trunk ports via different RCW/ Serdes. Please refer to figure T1040 ports connectivity.

The L2 Switch has below interfaces:

- 8 Gigabit switch ports are external ports and are connected to external Phys
- 2 switch ports (2.5G) are connected to FMan ports

Please refer to figure T1040 Port Connectivity.

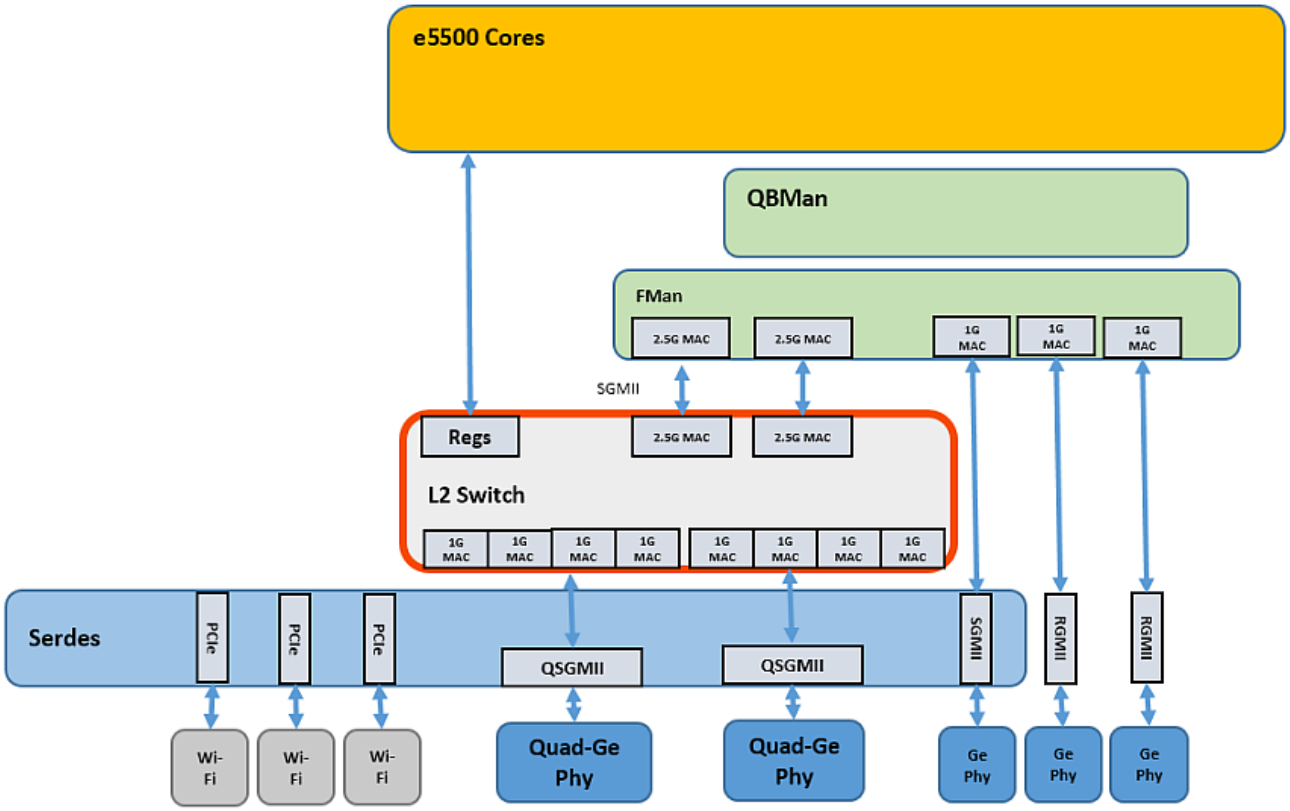

Figure 215. T1040 ports connectivity

For more details check the T1040 Reference Manual and T1040 L2 Switch Manual.

T1040 WAN ports and LAN ports

There are 3 WAN ports and 8 LAN ports in T1040, which look like figure T1040 WAN ports and LAN ports.

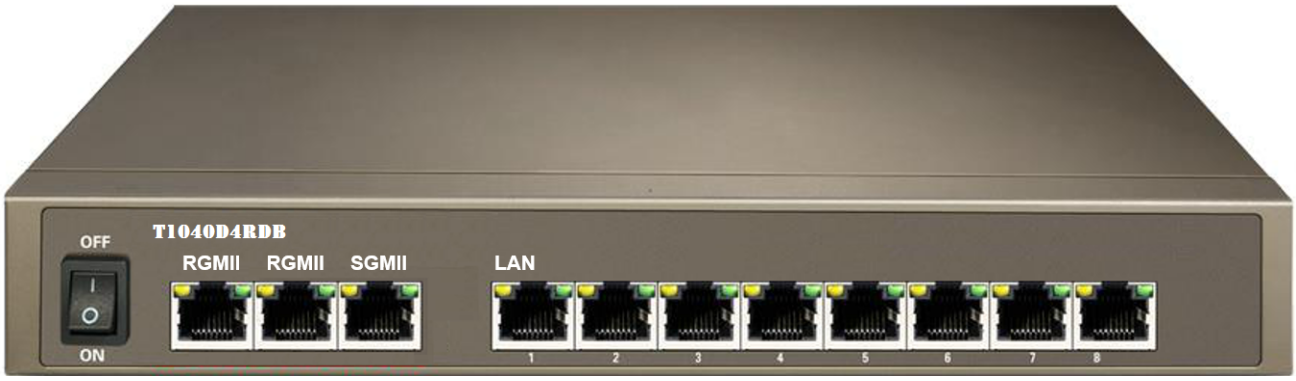

Figure 216. T1040D4RDB WAN ports and LAN ports

Why NXP style LAG is needed

NXP provides Data Path Acceleration Architecture (DPAA) which can offload CPU in network device driver. Linux bonding driver is at the same network device layer, in order to offload CPU while slave device selecting calculation for outgoing traffic with FSL DPAA value added – PCD (Parse, Classify, Distribute), FSL style LAG is introduced. For more detail information, please refer to FSL DPAA UM and Linux Documentation bonding.txt

Now, only T1040D4RDB board has this FSL style LAG feature.

9.5.2 Objectives

This document is based on NXP DPAA platform (T1040D4RDB) and introduces how to setup a LAG environment on NXP QorIQ DPAA system (T1040D4RDB). Hardware environment, software environment, various scenarios and Spirent Test Center (STC) ports setting are introduced. The purpose of this document is to make FAE/customers/ testing team can easily reproduce LAG cases.

9.5.3 NXP Style LAG (Link Aggregation) Features

There are 7 mode (policies) in Linux kernel bonding driver. NXP Style LAG supports mode 2 (balance-xor) and mode 4 (IEEE 802.1ax or the previous IEEE 802.3ad), here is the feature list:

- FMan 1G MAC ports: 2x1Gbps RGMII/SGMII WAN link aggregation
- FMan 2.5G MAC ports for L2 Switch: 2x2.5Gbps SGMII link aggregation
- Multi-cast/broad-cast forwarding on aggregated links
- traffics over IPv4 forwarding on aggregated links: TCP/UDP/ ICMP Destination unreachable/ICMP Echo Reply/ICMP Echo request/ICMP Info Reply/ICMP Info request/ICMP parameter problem/ICMP redirect/ICMP source quench/ICMP time exceeded/ICMP timestamp reply/ICMP timestamp requestIGMP v1 message/IGMP v2 query message/IGMP v2 report message/IGMP v3 query message/IGMP v3 report message/IPv6/IPv4 (My Test)
- traffics over IPv6 forwarding on aggregated links: TCP/ UDP/ MLDv1 Listener Done/LMDv1 Listener Report/ My Test / ICMPv6 Dest Unreachable/ ICMPv6 Echo Reply/ICMPv6 Echo Request/ICMPv6 packet Too Big/ ICMPv6 Parameter Problem/ ICMPv6 Time Exceeded/IPv4/ IPv6 Hop By Hop Header/IPv6 Authentication Header/IPv6 Authentication Header/IPv6 Routing Header /IPv6 Fragment Header/ IPv6 Encapsulation Header/ MLDv1/MLDv2 Query/MLDv2 Report /Neighbor Advertisement/ Neighbor Solicitation /Redirect/ Router Advertisement/ Router Solicitation/UDP-DHCP Ack/ UDP-DHCP Decline /UDP-DHCP Inform/ UDP-DHCP Discover/ UDP-DHCP Inform /UDP-DHCP Nak/ UDP-DHCP Offer/UDP-DHCP Release /UDP-DHCP Request/ UDP-VxLAN
- Supports both 32 bit and 64 bit Linux kernel

9.5.4 Test environment

Test environment includes hardware environment and software environment.

9.5.4.1 Hardware environment

- RCW/Serdes: RR_P_66, which means: RGMII@mac4 + RGMII@mac5 + One PCIe slot, SERDES1 Protocol is 0x66
- Switch: use the default switch, please see T1040d4rdb platform UM
- ucode: use fsl_fman_ucode_t1040_r1.1 version, please see T1040d4rdb platform UM

9.5.4.2 Software environment

9.5.4.2.1 Test benches software environment

In different test cases, software environment of test benches (end stations) are nearly the same. In most cases, any Linux machines like x86 PC/ PowerPC/ ARM with TCP/IP stack can work well as test benches. But in order to save the total count of test benches (end stations), network name space are required in test benches' Linux kernel and DUT's Linux kernel. Name space can isolate network links of one test bench, after add individual links to different network name spaces, those links seem like different links in different test benches (end stations). while aggregate 1 Gbps RGMII/SGMII WAN ports, in order to reply LACPDU, at least one test bench needs Linux bonding driver.

9.5.4.2.2 DUT software environment

9.5.4.2.2.1 Device tree

NXP Style LAG utilizes PCD function of offline port of FMan to distribute traffics. To enable offline port 2 and buffer pool 6 both which will be attached to the bundle link, please add below contents (offline port node) in the T1 board LAG dts. If they are not in, recompile the dts to get the dtb file. However the dts file has already been integrated into the NXP SDK.

Terms

```
  PCD - Parser, Classification, Distribution
  Offline ports - NXP FMan components which have PCD functionality
  Buffer pools - NXP BMan components which have buffer management functionality
```

The SDK includes the following contents in T1040 LAG dts file:

```
arch/powerpc/boot/dts/fsl/t1040d4rdb-usdpaa-lag.dts
#include "t1040d4rdb.dts"
{
    Bp6:buffer-pool@6 {
        compatible = "fsl,t1040-bpool", "fsl,bpool";
        fsl,bpid = <6>;
        fsl,bpool-ethernet-cfg = <0x0 0x0 0x0 0x6c0 0x0 0xfeedabba>;
        fsl,bpool-thresholds = <0x100 0x300 0x0 0x0>;
    };
    fsl,dpaa {
        dpa-fman0-oh@2 {
            compatible = "fsl,dpa-oh";
            /* Define frame queues for the OH port*/
            /* <OH Rx error, OH Rx default> */
            fsl,qman-frame-queues-oh = <0x68 0x1 0x69 0x1>;
```

```
            fsl,bman-buffer-pools = < &bp6>;
            fsl,qman-frame-queues-tx = <0x90 0x1>;
            fsl,fman-oh-port = <&fman0_oh2>;
        };
    };
};
```

9.5.4.2.2.2 Linux kernel options

Linux kernel option - bonding is not enabled as default, to enable it and NXP style LAG, HW_DISTRIBUTION_WITH_OH must be selected manually based on optimized kernel configuration files corenet32_fmanv3l_smp_defconfig, or corenet64_fmanv3l_smp_defconfig. See the example below:

- Enable Linux bonding driver:

```
Symbol: HW_DISTRIBUTION_WITH_OH [=y]
Type  : boolean
Prompt: Bonding driver with h/w based Tx traffic distribution support
Location:
 ->Device Drivers
    -> Network device support (NETDEVICES [=y])
      -> Network core driver support (NET_CORE [=y])
        -> Bonding driver support (BONDING [=y])
```

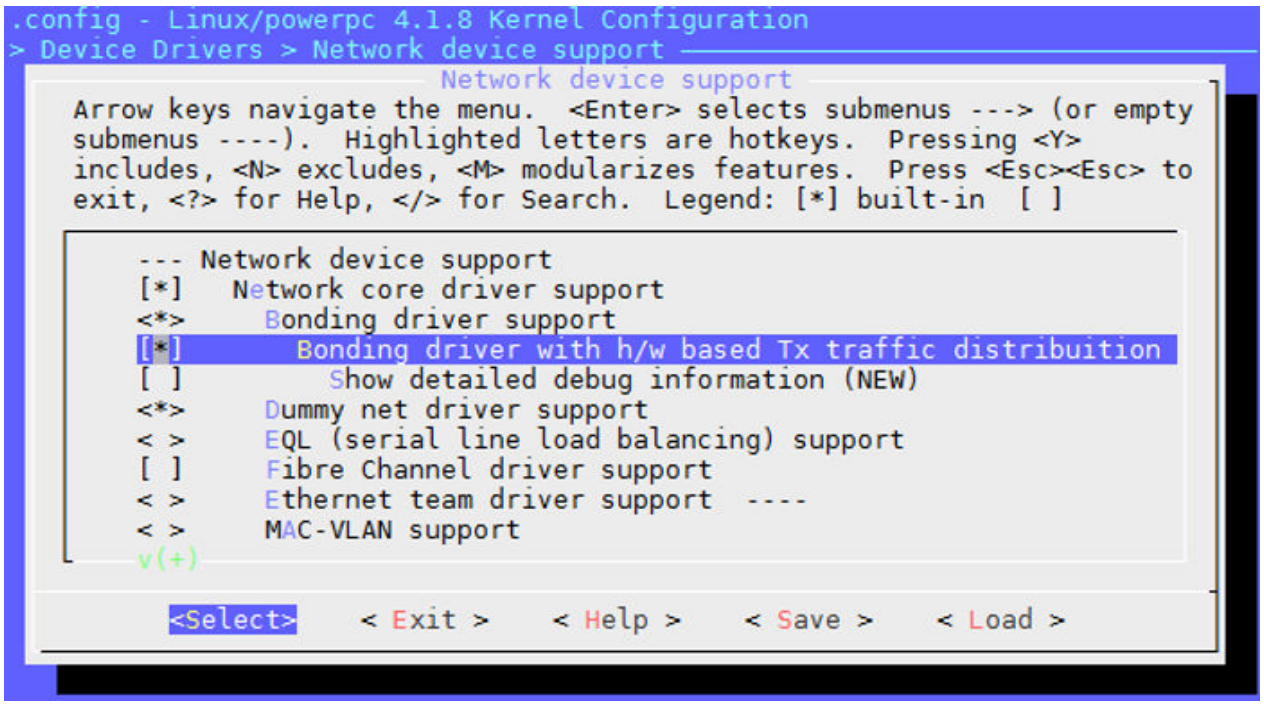

Figure 217. kernel-config-bonding

- To enable T1040 chip, FMan V3L option is required:

```
Symbol: FMAN_V3L [=y]
Type  : boolean
Prompt: FmanV3L
  Location:
```

```
    -> Device Drivers
      -> Network device support (NETDEVICES [=y])
        -> Ethernet driver support (ETHERNET [=y])
          -> Freescale devices (NET_VENDOR_FREESCALE [=y])
            -> Frame Manager support
              -> Freescale Frame Manager (datapath) support - SDK driver (FSL_SDK_FMAN [=y])
                -> FMAN Processor support
                  -> Processor Type (<choice> [=y])
```

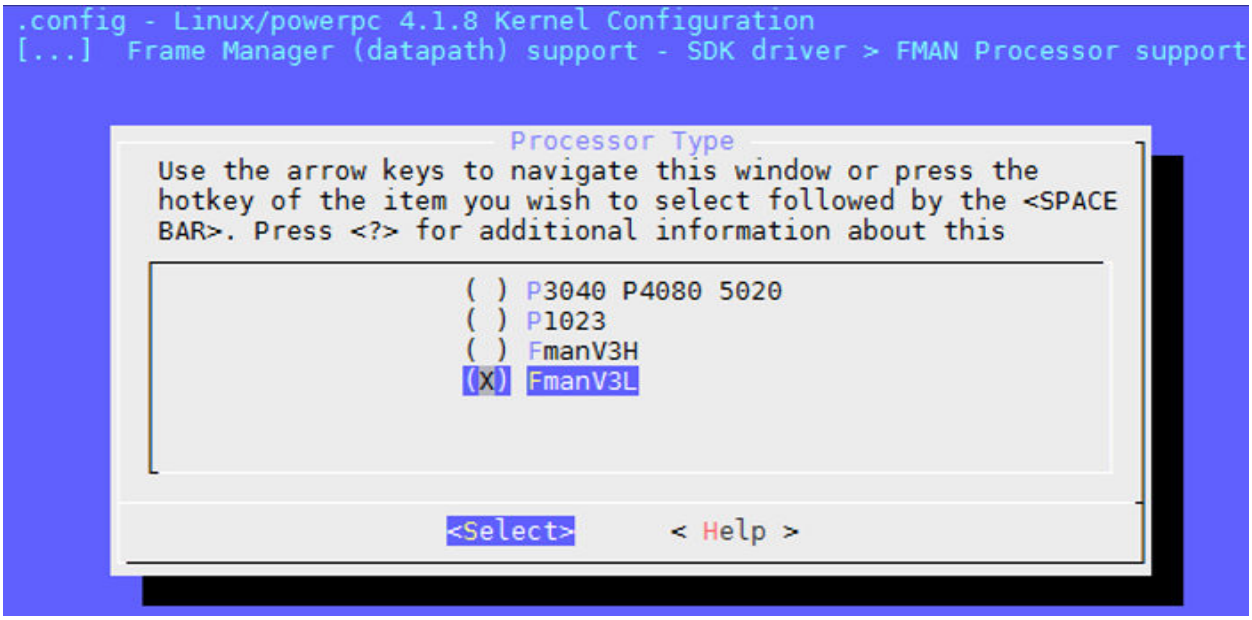

Figure 218. kernel-config-fman_v3l

- This feature also depends on the NXP DPAA Offline port; hence, offline ports driver should be enabled:

```
Symbol: FSL_DPAA_OFFLINE_PORTS [=y]
Type  : boolean
Prompt: Offline Ports support
  Location:
    -> Device Drivers
      -> Network device support (NETDEVICES [=y])
        -> Ethernet driver support (ETHERNET [=y])
          -> Freescale devices (NET_VENDOR_FREESCALE [=y])
            -> DPAA Ethernet (FSL_SDK_DPAA_ETH [=y])
```

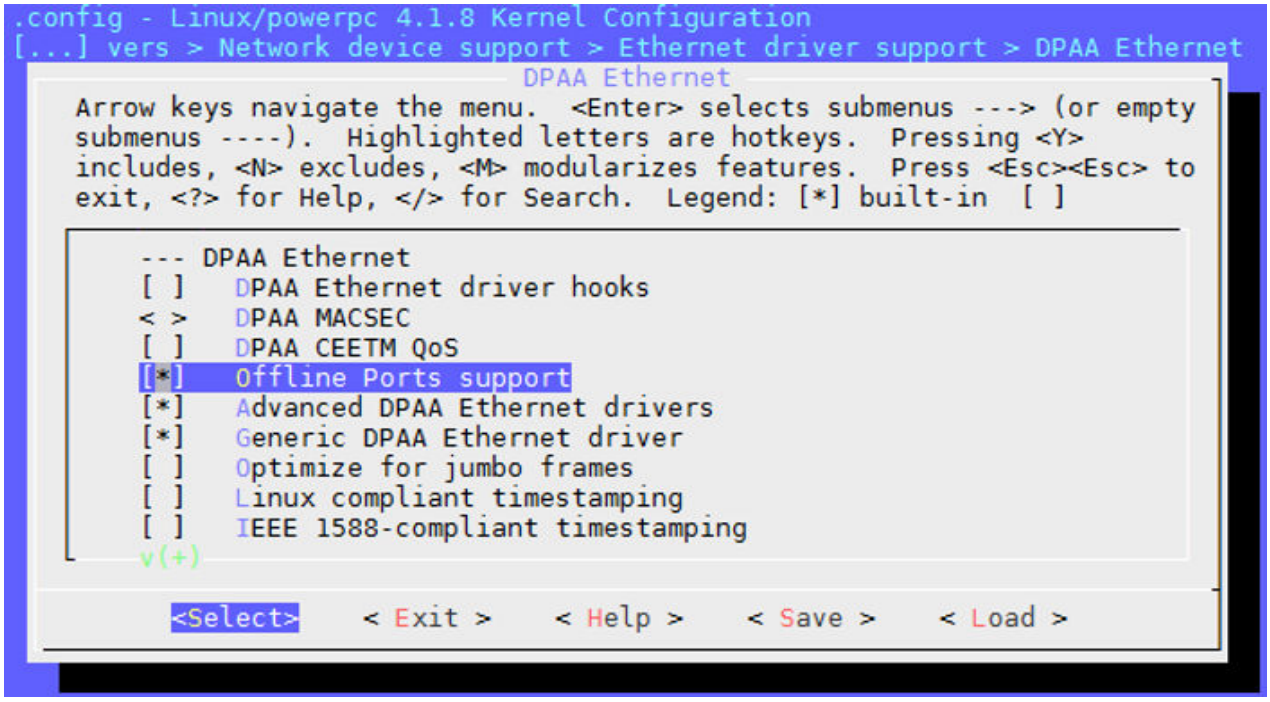

Figure 219. kernel-config-offline-ports

- Enable Network namespace to make full use of network links:

```
Symbol: NET_NS [=y]
Type  : boolean
Prompt: Network namespace
  Location:
    -> General setup
      -> Namespaces support (NAMESPACES [=y])
```

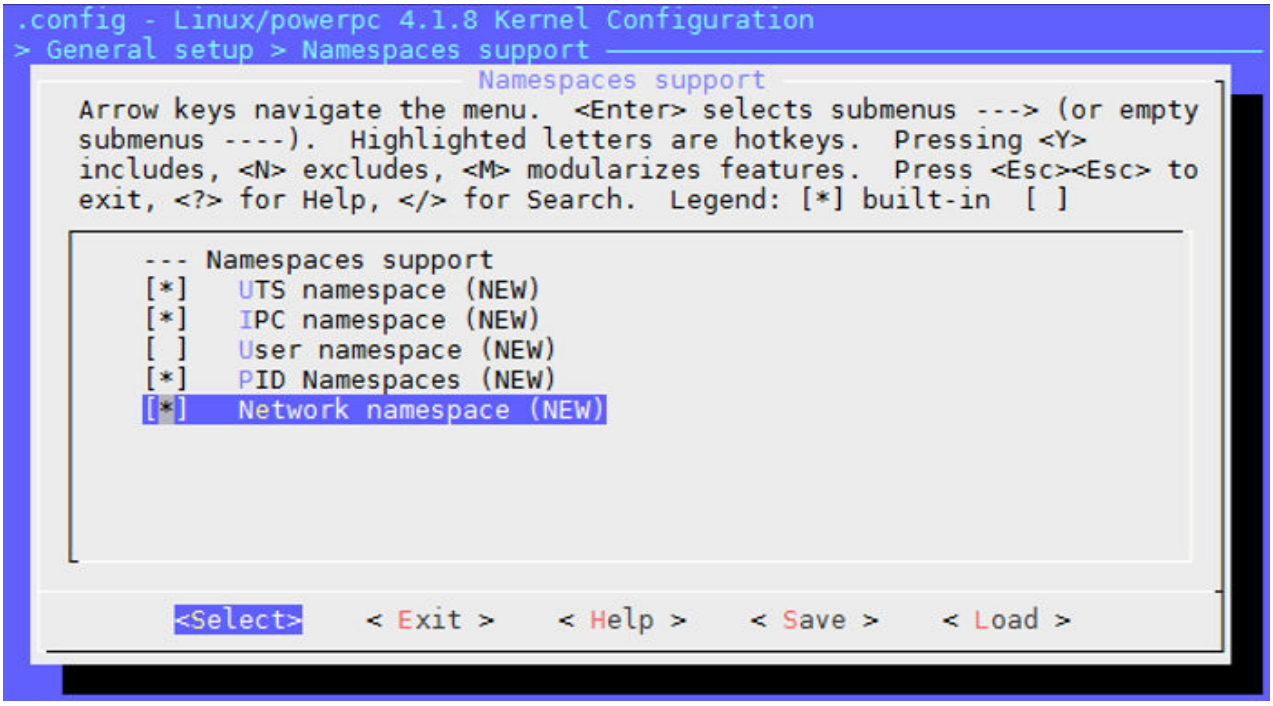

Figure 220. kernel-config-ns

9.5.4.2.2.3 File system

In normal scenario, any changes to file system are unnecessary . File system built by yocto from fsl-image-core.bb in NXP SDK can fit all of below cases. For LACP (802.3ad mode) verification, to support traditional software based LACP on L2 Switch FMan ports, the 3rd-Party L2 Switch Stack is required, which is not included in NXP SDK and can be delivered as a separate package. There are lots of L2 Switch features have already been supported in NXP SDK. For more details about Switch support and configuration, please refer to the chapter L2Switch Driver User Guide.

9.5.5 Verification method

Software based verification method

- Using ping IPv4 uni-cast/multi-cast/broad-cast address, or using ping6 an IPv6 address from one end-station to others end-stations on the other side of the DUT (router/switch). If echos are received, which means traffics can pass the aggregated link of the DUT.
- Optionally, traceroute is for print the route packets trace to network host, and tracepath can help trace path to a network host discovering MTU along this path
- Netperf can be run from one end-station to others end-stations on the other side of the DUT (router/switch), which method can help verify TCP shake hands information.

STC (Spirent Test Center) traffics generator based verification method

Spirent traffics generator has many powerful functions, including traffics generation, receiving frames dump and so on. For any details, please refer to Spirent user manual.

In this user manual, only traffics flow with special traffics types are needed, which traffics types are listed in the features section above.

The required count of traffics flows and the required type of the traffics will be described alone with the following topics of test cases.

9.5.6 Test Procedure

In order to simplify test environment and save end stations (test benches), below 8 main test cases are selected for function verification of LAG. There are 2 method to verify LAG: Software based (ping/ tracerouth/ tracepath/ Netperf) and Spirent Test Center (STC) traffics generators.

9.5.6.1 Aggregation on 2x1G Links

9.5.6.1.1 Traffics over IPv4 forwarding verification

9.5.6.1.1.1 Verification with software

DUT and Test Benches Setting

Set network ports connections

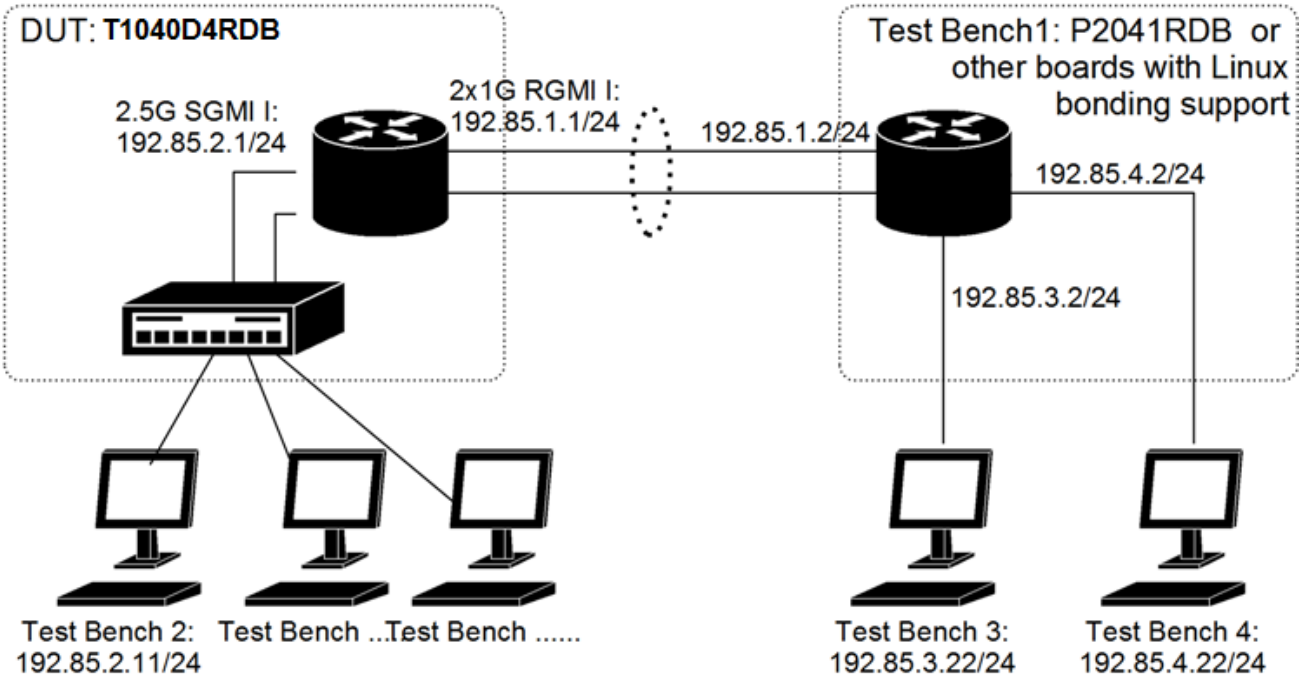

Figure 221. 2x1G-IPv4-software

Set hardware environment as above, in a real case with NXP board farm, all boards and links connections look like below:

```
T1040RDB-4_RGMII1          P2041RDB-2_RGMII1
T1040RDB-4_RGMII2          P2041RDB-2_RGMII2
T1040RDB-4_SGMII1          NW_2:39
T1040RDB-4_SW-P1           P1022DS-2_eTSEC1

P2041RDB-2_RGMII1          T1040RDB-4_RGMII1
```

```
P2041RDB-2_RGMII2           T1040RDB-4_RGMII2
P2041RDB-2_SGMII1           P2041RDB-2_SGMII2
P2041RDB-2_SGMII2           P2041RDB-2_SGMII1
P2041RDB-2_Slot1_PCIe_NIC   NW_2:41
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt "#":

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg mac learn auto
```

Enable mode 4, (IEEE 802.1ax or the previous IEEE 802.3ad):

```
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb3 >slaves
#echo +fm1-gb4 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface with an IP address:

```
#ifconfig bond0 192.85.1.1/24 up
#route add default gw 192.85.1.2
```

Configure other network interface with an IP address to help test:

```
#ifconfig fm1-gb0 192.85.2.1/23 up
```

Enable multi-cast forwarding:

```
#cd /proc/sys/net/ipv4
#ls -l icmp_*
#cat icmp_*
#cat icmp_echo_ignore_broadcasts
#echo 0 > icmp_echo_ignore_broadcasts
#ip route add 224.0.0.0/4 dev bond0
#cd
```

Wait till others test benches setting finish:

```
#echo "Wait till others test benches setting finish:"
```

Commands in test bench1 and in the test bench4 (network name space ns1 of test bench1):

```
#ifconfig -a
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
#echo +fm1-gb3 > slaves
```

```
#echo +fm1-gb4 > slaves
#cat slaves

#ifconfig bond0 192.85.1.2/24 up
#route add default gw 192.85.1.1
#ip route add 224.0.0.0/4 dev bond0
#ifconfig fm1-gb0 192.85.4.2/22 up

#cd /proc/sys/net/ipv4
#ls -l icmp_*
#cat icmp_*
#echo 0 > icmp_echo_ignore_broadcasts
#cat icmp_echo_ignore_broadcasts
#cd

#killall -9 netserver
#netserver

#ifconfig
#arp -a
#route

#history
```

Wait till others test benches and DUT setting finish:

```
#echo "Wait till others test benches and DUT setting finish:"
```

Commands will be in network name space ns1 of test bench1:

```
#echo "=======below commands will be run in network namespace ns1===="
#ip netns add ns1
#ip link set fm1-gb1 netns ns1
#ip netns exec ns1 bash
```

Commands in test bench 4 (network name space ns1 of test bench1):

```
#echo $SHELL
#cat > ~/sshtest << 'EOF'
#hello, ssh test.................
#EOF

#ifconfig -a
#ifconfig fm1-gb1 192.85.4.22/22 up
#route add default gw 192.85.4.2
#ip route add 224.0.0.0/4 dev fm1-gb1

#killall -9 dropbear
#/usr/sbin/dropbear -r /etc/dropbear/dropbear_rsa_host_key -p 22 -B
#netserver -p 20000

#cd /proc/sys/net/ipv4
#ls -l icmp_*
#cat icmp_*
#cat icmp_echo_ignore_broadcasts
#echo 0 > icmp_echo_ignore_broadcasts
#cd
```

```
#echo "====wait for others testbench setting========="
```

Commands in test bench 2:

```
#ifconfig eth0 192.85.2.11/23 up
#route add default gw 192.85.2.1

#echo "======= multicast and broadcast forwarding setting====="
#cd /proc/sys/net/ipv4/
#ls -l icmp_*
#cat icmp_*
#echo 0 > icmp_echo_ignore_broadcasts
#cat icmp_echo_ignore_broadcasts
#ip route add 224.0.0.0/4 dev eth0
#cd

#echo "======create a file for ssh test====="
#cat > sshtest2 <<'EOF'
#hello, ssh test2.................
#EOF

#echo "=====wait for other testbench and DUT setting======"
#ifconfig
#arp -a
#route
```

Verification

Simple test in DUT:

```
#ping 192.85.2.11 -c 5
#ping 224.0.0.1 -c 5
```

Status checking and logs recording in DUT:

```
#ifconfig
#l2switch-cfg mac dump
#arp -a
#route

#history
```

Multi-cast and broadcast verification in test bench 1:

```
#ping -b 255.255.255.255 -c 5
#ping 224.0.0.1 -c 5
```

Verification in ns1 of testbench1

```
#traceroute 192.85.2.11
#tracepath -l 60 192.85.2.11
#ping -b 255.255.255.255 -c 5
#ping -b 192.85.3.255 -c 5
#ping 224.0.0.1 -c 5

#cd
#scp root@192.85.2.11:/home/root/sshtest2 ~/
```

```
#cat ~/sshtest2

9.5.6.1.1.2 Verification with STC

DUT and Test Benches Setting

Set network ports connections

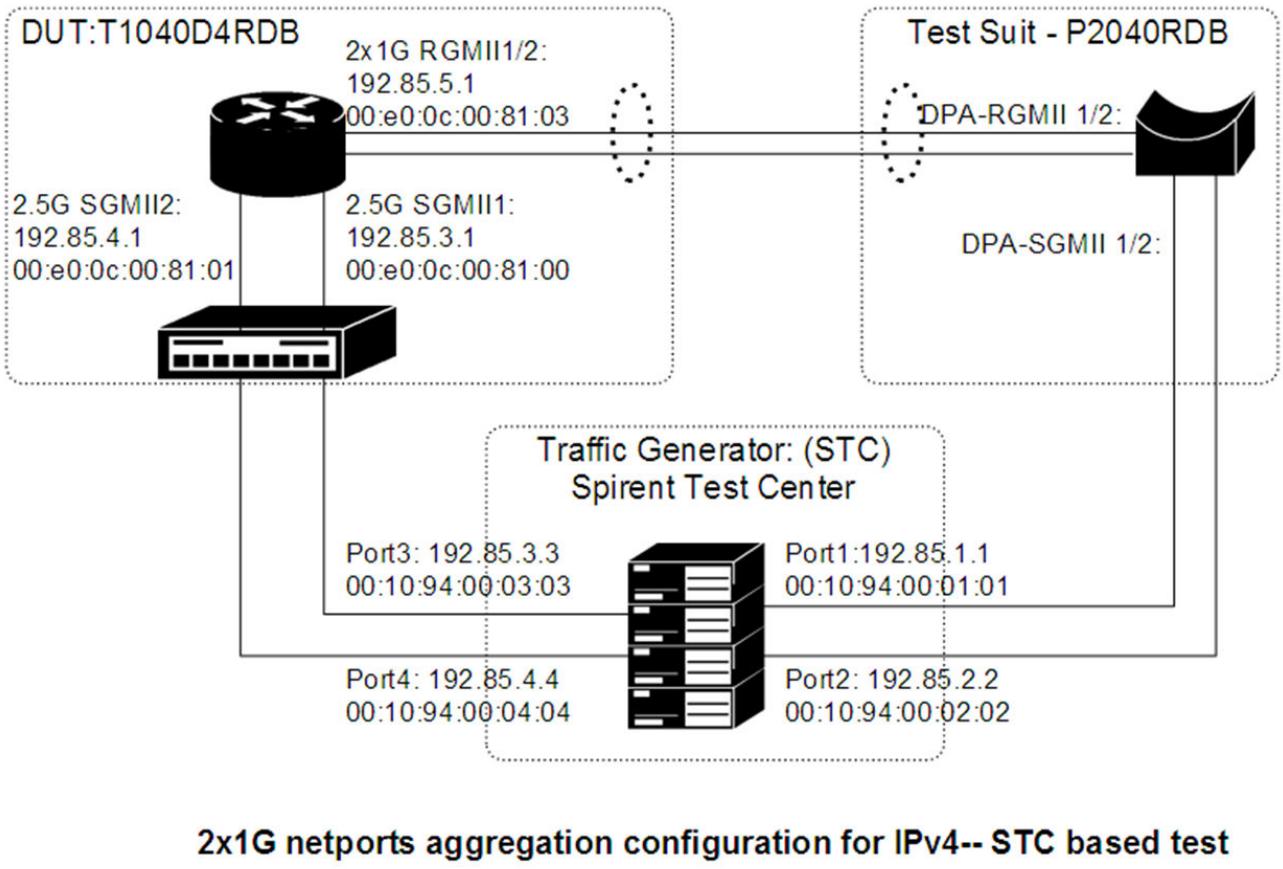

Figure 222. 2x1G-IPv4-STC

Set network ports connections as above, in a real case with NXP board farm, all boards and links connections look like below:

```
#bft map -m P2040RDB-1_RGMII1,T1040D4RDB-2_RGMII1,board -c
#bft map -m P2040RDB-1_RGMII2,T1040D4RDB-2_RGMII2,board -c
#bft map -m P2040RDB-1_SGMII1,Spirent_3:1,board -c --force
#bft map -m P2040RDB-1_SGMII2,Spirent_3:2,board -c --force
#bft map -m T1040D4RDB-2_SW-P3,Spirent_3:3,board -c --force
#bft map -m T1040D4RDB-2_SW-P4,Spirent_3:4,board -c --force

#bft port -l P2040RDB-1
 P2040RDB-1_RGMII1           T1040D4RDB-2_RGMII1
 P2040RDB-1_RGMII2           T1040D4RDB-2_RGMII2
 P2040RDB-1_SGMII1           Spirent_3:1
 P2040RDB-1_SGMII2           Spirent_3:2

#bft port -l T1040D4RDB-2
 T1040D4RDB-2_QSGMII1        MRV4_2:24
 T1040D4RDB-2_QSGMII2        T1040D4RDB-2_QSGMII1
 T1040D4RDB-2_RGMII1         P2040RDB-1_RGMII1
 T1040D4RDB-2_RGMII2         P2040RDB-1_RGMII2
 T1040D4RDB-2_SW-P3          Spirent_3:3
 T1040D4RDB-2_SW-P4          Spirent_3:4
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt “#”:

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg mac learn auto
```

Enable mode 4, (IEEE 802.1ax or the previous IEEE 802.3ad):

```
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb3 >slaves
#echo +fm1-gb4 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP address:

```
#ifconfig fm1-gb0 192.85.3.1/22
#ifconfig fm1-gb1 192.85.4.1/21
#ifconfig bond0 192.85.5.1/20
#route add default gw 192.85.3.1
#route
#arp -s 192.85.1.1 00:10:94:00:01:01
#arp -s 192.85.2.2 00:10:94:00:02:02
#free -l
#free -l -m
#route
#arp -a
#cat offline_port_xmit_statistics
#ps axu
#l2switch-cfg mac dump
```

Enable multi-cast forwarding:

```
#cd /proc/sys/net/ipv4
#ls -l icmp_*
#cat icmp_*
#cat icmp_echo_ignore_broadcasts
#echo 0 >icmp_echo_ignore_broadcasts
#cd -
```

Monitor frames from STC traffics generator:

```
#tcpdump -vvv -e -n
```

Utilize a develop board with multi network ports to create a bridge to emulate L2 Switch with full feature of LACP

```
Boot up into Linux with a bridge support then input below commands:
#ifconfig
#cat /proc/version
#cat /proc/cmdline
#ifconfig -a
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
#echo +fm1-gb3 > slaves
#echo +fm1-gb4 > slaves
```

```
        #brctl addbr brhelper
        #brctl addif brhelper fm1-gb0
        #brctl addif brhelper fm1-gb1
        #brctl addif brhelper bond0
        #echo "wait for another peer setting finish"
        #ifconfig brhelper up
        #ifconfig bond0 up
        #ifconfig fm1-gb0 up
        #ifconfig fm1-gb1 up
        #ifconfig
        #arp -a
        #route
        #brctl showmacs brhelper
```

Create traffic flows according above figure in this section:

```
4 traffic flows will be created in STC:
        STC1 --->STC3
        STC2 --->STC4
        STC3 --->STC1
        STC4 --->STC2

Above 4 traffic flows information look like below:
STC1<--->00:10:94:00:01:01,192.85.1.1 <---> STC3:192.85.3.3: 00:e0:0c:00:81:03 (neigh of the bridge
helper)
STC2<--->00:10:94:00:02:02,192.85.2.2 <---> STC4:192.85.4.4: 00:e0:0c:00:81:03 (neigh of the bridge
helper)
STC3<--->00:10:94:00:03:03,192.85.3.3 <---> STC1:192.85.1.1: 00:e0:0c:00:81:00 (L2 Switch FMan
port1)
STC4<--->00:10:94:00:04:04,192.85.4.4 <---> STC2:192.85.2.2: 00:e0:0c:00:81:01 (L2 Switch FMan
port2)
```

Verification

1.
```
Select Layer 4 type of frames among below, then send some frames, STC receiving port will receive
the same type of traffics as  expected:

TCP/UDP/ ICMP Destination unreachable/ICMP Echo Reply/ICMP Echo request/ICMP Info Reply/ICMP
Info request/ICMP parameter problem/ICMP redirect/ICMP source quench/ICMP time exceeded/ICMP
timestamp reply/ICMP timestamp requestIGMP v1 message/IGMP v2 query message/IGMP v2 report
message/IGMP v3 query message/IGMP v3 report message/IPv6/IPv4 (My Test)
```
2. In the DUT terminal, tcpdump will also output the same type of traffics as expected.
3. Frames received in STC are also captured/recorded by STC software, which can be played in the 3rd party software like wireshark.

For more detailed information, please refer to Spirent Test Center user manual.

9.5.6.1.2 Traffics over IPv6 forwarding verification

9.5.6.1.2.1 Verification with software

DUT and Test Benches Setting

Set network ports connections

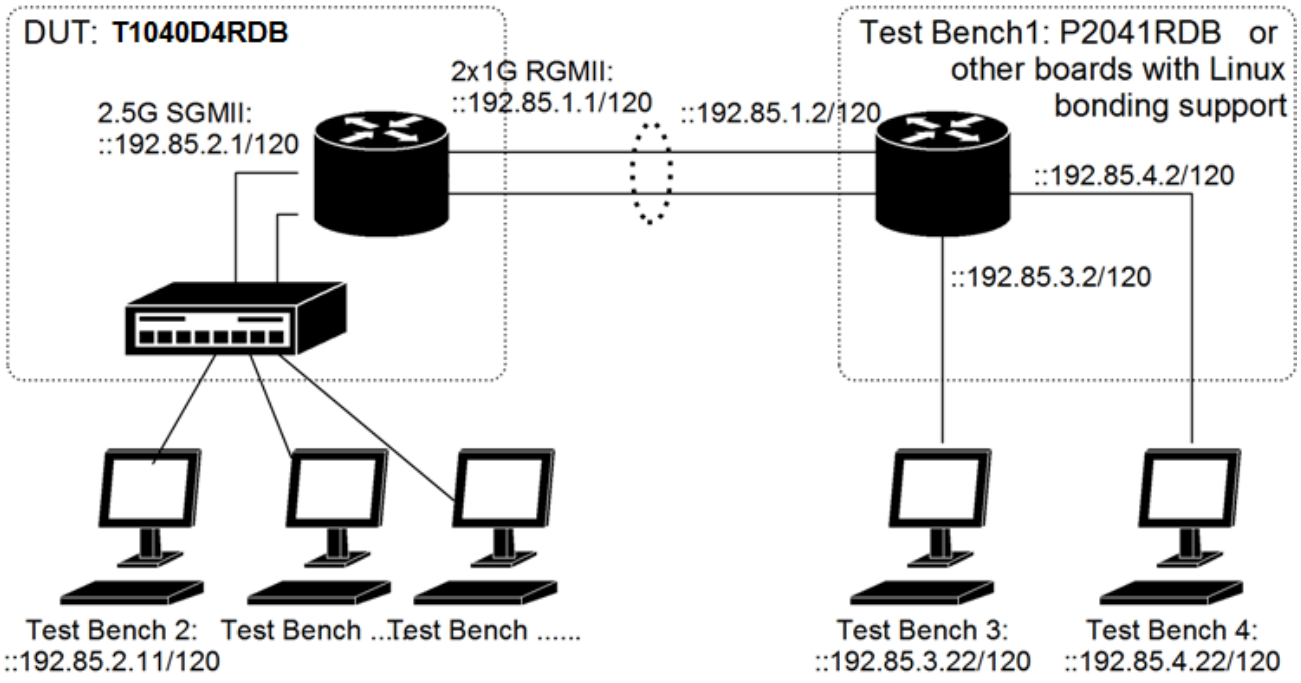

Figure 223. 2x1G-IPv6-software

Set hardware environment as above, in a real case with NXP board farm, all boards and links connections look like below:

```
T1040RDB-4_RGMII1           P2041RDB-2_RGMII1
T1040RDB-4_RGMII2           P2041RDB-2_RGMII2
T1040RDB-4_SGMII1           NW_2:39
T1040RDB-4_SW-P1            P1022DS-2_eTSEC1

P2041RDB-2_RGMII1           T1040RDB-4_RGMII1
P2041RDB-2_RGMII2           T1040RDB-4_RGMII2
P2041RDB-2_SGMII1           P2041RDB-2_SGMII2
P2041RDB-2_SGMII2           P2041RDB-2_SGMII1
P2041RDB-2_Slot1_PCIe_NIC   NW_2:41
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt “#”:

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg mac learn auto
```

Enable mode 4, (IEEE 802.1ax or the previous IEEE 802.3ad):

```
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb3 >slaves
#echo +fm1-gb4 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP addresses:

```
#ip -6 addr add  dev bond0 0::192.85.1.1/120
#ip -6 addr add  dev fm1-gb0 0::192.85.2.1/119
#ip link set bond0 up
#ip link set fm1-gb0 up
#ip -6 route add default via  0::192.85.1.2 dev bond0
#ip -6 route show
#ip -6 neigh show
#ip link show
#ip -6 addr show
#history
```

Wait till others test benches setting finish:

```
#echo "Wait till others test benches setting finish:"
```

Commands in test bench1 and in the test bench4 (network name space ns1 of test bench1):

```
#cd /sys/class/net/bond0/bonding/
#echo 4 >mode
#echo 1 >/proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
#echo +fm1-gb3 >slaves
#echo +fm1-gb4 >slaves
#cat slaves
#cat xmit_hash_policy
#ip -6 addr add 0::192.85.1.2/120 dev bond0
#ip -6 addr add 0::192.85.4.2/118 dev fm1-gb0
#ip link set bond0 up
#ip link set fm1-gb0 up
#ip -6 route add default via ::192.85.1.1 dev bond0
#ip link show
#ip -6 addr show
#ip -6 route show
#ip -6 neigh show
#killall -9 netserver
#netserver -6
#ps aux
#history
```

Wait till others test benches and DUT setting finish:

```
#echo "Wait till others test benches and DUT setting finish:"
```

Commands will be in network name space ns1 of test bench1:

```
#echo "=====below commands will be run in ns1======="
#ip netns help
#ip netns add ns1
#ip netns list
#ip link set fm1-gb1 netns ns1
```

```
#ip netns exec ns1 bash
```

Commands in test bench 4 (network name space ns1 of test bench1):

```
#ip link show
#ifconfig fm1-gb1 inet6 add 0::192.85.4.22/118 up
#echo 1 >/proc/sys/net/ipv6/conf/all/forwarding
#cat /proc/sys/net/ipv6/conf/all/forwarding
#ip -6 route add default via   ::192.85.4.2 dev fm1-gb1
#ip link show
#ip -6 addr show
#ip -6 route show
#ip -6 neigh show
#netserver -6 -p 20000
```

Commands in test bench 2:

```
#ip link show
#ip -6 addr add  dev eth0 0::192.85.2.11/119
#ip link set eth0 up
#ip -6 route add default via  0::192.85.2.1 dev eth0
#ip link show
#ip -6 addr show
#ip -6 route show
#ip -6 neigh show
#killall -9 netserver
#netserver -6
#ps aux
#history

#echo "=====wait for other testbench and DUT setting======"
```

Verification

Verification in ns1 of testbench1

```
#ping6 ::192.85.2.11 -c 5
#netperf -6 -H ::192.85.2.11 -l 10 -t TCP_STREAM
#ps aux
#history
#exit
```

Verification in test bench 2

```
#ping6 ::192.85.1.1 -c 5

9.5.6.1.2.2 Verification with STC

DUT and Test Benches Setting

Set network ports connections

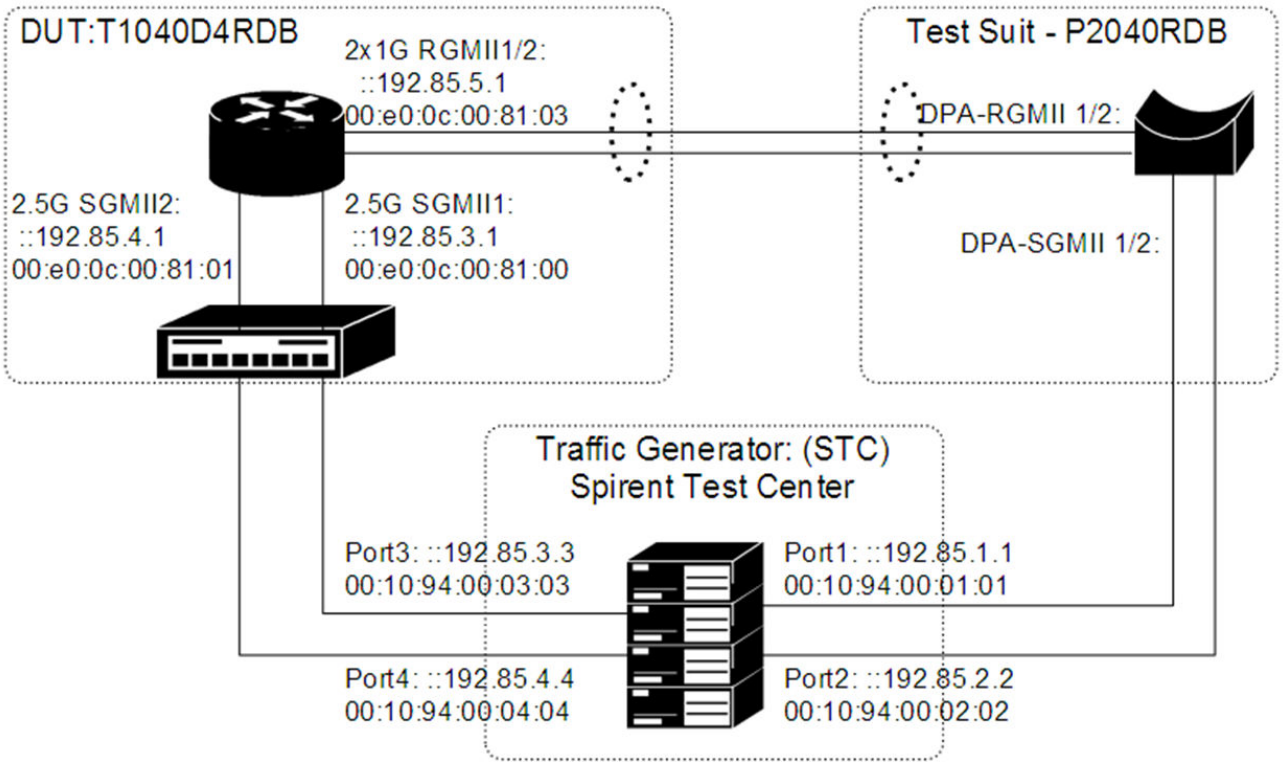

Figure 224. 2x1G-IPv6-STC

Set network ports connections as above, in a real case with NXP board farm, all boards and links connections look like below:

```
#bft map -m P2040RDB-1_RGMII1,T1040D4RDB-2_RGMII1,board -c
#bft map -m P2040RDB-1_RGMII2,T1040D4RDB-2_RGMII2,board -c
#bft map -m P2040RDB-1_SGMII1,Spirent_3:1,board -c --force
#bft map -m P2040RDB-1_SGMII2,Spirent_3:2,board -c --force
#bft map -m T1040D4RDB-2_SW-P3,Spirent_3:3,board -c --force
#bft map -m T1040D4RDB-2_SW-P4,Spirent_3:4,board -c --force

#bft port -l P2040RDB-1
 P2040RDB-1_RGMII1           T1040D4RDB-2_RGMII1
 P2040RDB-1_RGMII2           T1040D4RDB-2_RGMII2
 P2040RDB-1_SGMII1           Spirent_3:1
 P2040RDB-1_SGMII2           Spirent_3:2

#bft port -l T1040D4RDB-2
 T1040D4RDB-2_QSGMII1        MRV4_2:24
 T1040D4RDB-2_QSGMII2        T1040D4RDB-2_QSGMII1
 T1040D4RDB-2_RGMII1         P2040RDB-1_RGMII1
 T1040D4RDB-2_RGMII2         P2040RDB-1_RGMII2
 T1040D4RDB-2_SW-P3          Spirent_3:3
 T1040D4RDB-2_SW-P4          Spirent_3:4
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt “#”:

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg mac learn auto
```

Enable mode 4, (IEEE 802.1ax or the previous IEEE 802.3ad):

```
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb3 >slaves
#echo +fm1-gb4 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP address:

```
#ifconfig fm1-gb0 inet6 add 0::192.85.3.1/120 up
#ifconfig fm1-gb1 inet6 add 0::192.85.4.1/120 up
#ifconfig bond0   inet6 add 0::192.85.5.1/120 up
#ifconfig
#ip -6 route add default via 0::192.85.5.1 dev bond0
#route
#ip -6 neigh add 0::192.85.3.3 lladdr 00:10:94:00:03:03 dev fm1-gb0
#ip -6 neigh add 0::192.85.4.4 lladdr 00:10:94:00:04:04 dev fm1-gb1
#ip -6 neigh add 0::192.85.1.1 lladdr 00:10:94:00:01:01 dev bond0
#ip -6 neigh add 0::192.85.2.2 lladdr 00:10:94:00:02:02 dev bond0
#ip -6 neigh show
#free -l
#free -l -m
#route
#arp -a
#ip -6 route show
#ip -6 neigh show
#cat offline_port_xmit_statistics
#l2switch-cfg mac dump
#ps axu
```

Monitor frames from STC traffics generator:

```
#tcpdump -vvv -e -n
```

Utilize a develop board with multi network ports to create a bridge to emulate L2 Switch with full feature of LACP:

```
Boot up into Linux with a bridge support then input below commands:
#ifconfig
#cat /proc/version
#cat /proc/cmdline
#ifconfig -a
#cd /sys/class/net/bond0/bonding/
#echo 4 > mode
#echo +fm1-gb3 > slaves
#echo +fm1-gb4 > slaves
#brctl addbr brhelper
#brctl addif brhelper fm1-gb0
#brctl addif brhelper fm1-gb1
#brctl addif brhelper bond0
```

```
        #echo "wait for another peer setting finish"
        #ifconfig brhelper up
        #ifconfig bond0 up
        #ifconfig fm1-gb0 up
        #ifconfig fm1-gb1 up
        #ifconfig
        #arp -a
        #route
        #brctl showmacs brhelper
```

Create traffic flows according above figure in this section:

```
4 traffic flows will be created in STC:
        STC1 --->STC3
        STC2 --->STC4
        STC3 --->STC1
        STC4 --->STC2
Above 4 traffic flows information look like below:

STC1<--->00:10:94:00:01:01, ::192.85.1.1 <---> STC3: ::192.85.3.3: 00:e0:0c:00:81:03 (neigh of the
bridge helper)
STC2<--->00:10:94:00:02:02, ::192.85.2.2 <---> STC4: ::192.85.4.4: 00:e0:0c:00:81:03 (neigh of the
bridge helper)
STC3<--->00:10:94:00:03:03, ::192.85.3.3 <---> STC1: ::192.85.1.1: 00:e0:0c:00:81:00 (L2 Switch
FMan port1)
STC4<--->00:10:94:00:04:04, ::192.85.4.4 <---> STC2: ::192.85.2.2: 00:e0:0c:00:81:01 (L2 Switch
FMan port2)
```

Verification

1.
```
Select Layer 4 type of frames among below, then send some frames, STC receiving port will receive
the same type of traffics as  expected:

TCP/ UDP/ MLDv1 Listener Done/LMDv1 Listener Report/ My Test /ICMPv6 Dest Unreachable/ ICMPv6
Echo Reply/ICMPv6 Echo Request/ICMPv6 packet Too Big/ ICMPv6 Parameter Problem/ ICMPv6 Time
Exceeded/IPv4/ IPv6 Hop By Hop Header/IPv6 Authentication Header/IPv6 Authentication Header/IPv6
Routing Header /IPv6 Fragment Header/ IPv6 Encapsulation Header/ MLDv1/MLDv2 Query/MLDv2 Report /
Neighbor Advertisement/ Neighbor Solicitation /Redirect/ Router Advertisement/ Router
Solicitation/UDP-DHCP Ack/ UDP-DHCP Decline /UDP-DHCP Inform/ UDP-DHCP Discover/ UDP-DHCP
Inform /UDP-DHCP Nak/ UDP-DHCP Offer/UDP-DHCP Release /UDP-DHCP Request/ UDP-VxLAN
```

2. In the DUT terminal, tcpdump will also output the same type of traffics as expected.
3. Frames received in STC are also captured/recorded by STC software, which can be played in the 3rd party software like wireshark.

For more detailed information, please refer to Spirent Test Center user manual.

9.5.6.2 Aggregation on 2x2.5G Links

9.5.6.2.1 Traffics over IPv4 forwarding verification

9.5.6.2.1.1 Verification with software

DUT and Test Benches Setting

Set network ports connections

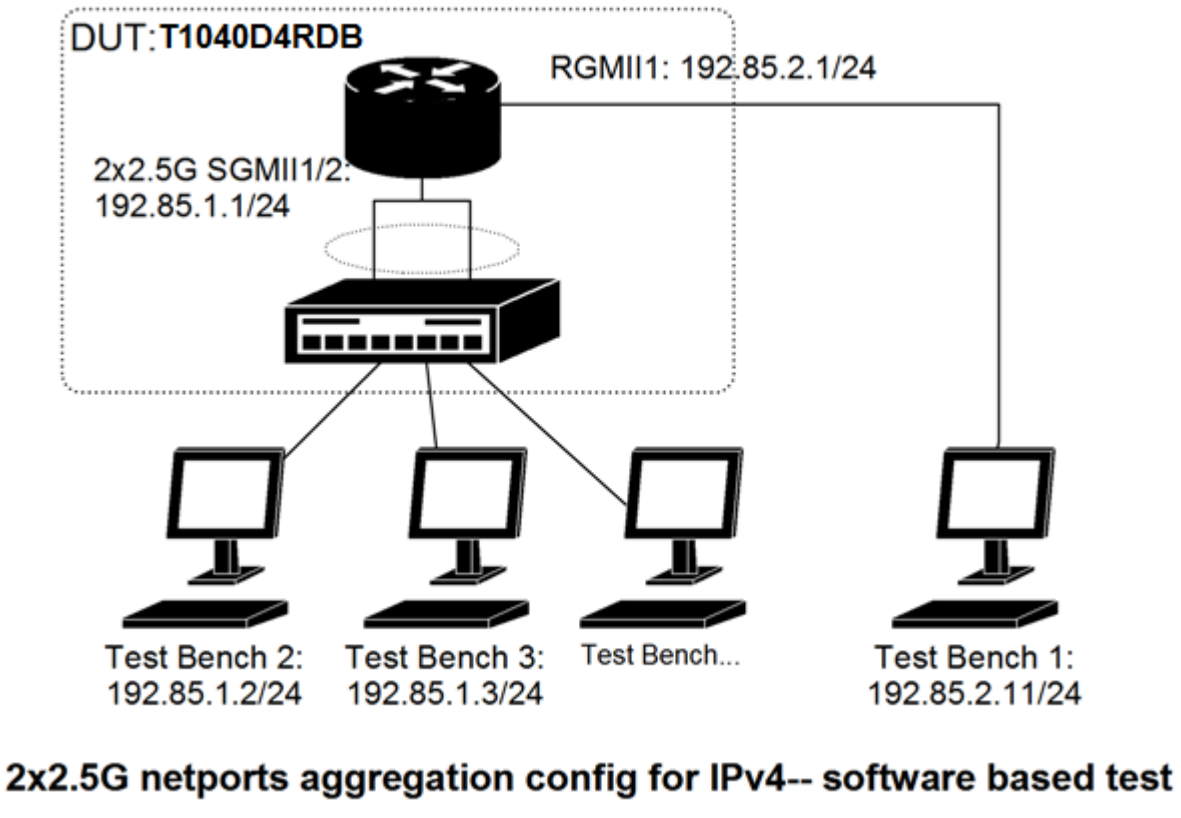

Figure 225. 2x2.5G-IPv4-software

Set hardware environment as above, in a real case with NXP board farm, all boards and links connections look like below:

```
T1040RDB-4_RGMII1          P1022DS-2_eTSEC1
T1040RDB-4_SW-P1           P2041RDB-2_SGMII1
T1040RDB-4_SW-P2           P2041RDB-2_SGMII2
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt "#":

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status

#l2switch-cfg set lag mode
#l2switch-cfg set lag no 1 members 8 9

#l2switch-cfg mac learn auto
```

Enable mode 2, (balance-xor 2 as default, IEEE 802.1ax or the previous IEEE 802.3ad while L2 Switch full feature stack supported):

```
#cd /sys/class/net/bond0/bonding/
#echo 2 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb0 >slaves
#echo +fm1-gb1 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP addresses:

```
#ifconfig bond0 192.85.1.1/24 up
#ifconfig fm1-gb3 192.85.2.1/23 up
#route add default gw 192.85.1.1
```

Enable multi-cast forwarding:

```
#cd /proc/sys/net/ipv4
#ls -l icmp_*
#cat icmp_*
#cat icmp_echo_ignore_broadcasts
#echo 0 > icmp_echo_ignore_broadcasts
#ip route add 224.0.0.0/4 dev bond0
#cd
```

Wait till others test benches setting finish:

```
#echo "Wait till others test benches setting finish:"
```

Commands in test bench 1:

```
#echo 0 > /proc/sys/net/ipv4/icmp_echo_ignore_broadcasts
#ifconfig eth0 192.85.2.11/23 up
#route add default gw 192.85.2.1
#killall -9 netserver
#netserver
#route

#echo "====wait for others testbench setting========="
```

Commands in test bench2 and in the net name space of the test bench2:

```
#ifconfig fm1-gb0 192.85.1.2/24 up
#route add default gw 192.85.1.1
#killall -9 netserver
#netserver

#ip netns add ns1
#ip netns list
#ip link set dev fm1-gb1 netns ns1
#ip netns exec ns1 ifconfig fm1-gb1 192.85.1.3/24 up
#ip netns exec ns1 route add default gw 192.85.1.1
#route
#ip netns exec ns1 bash
#netserver -p 20000
```

Wait till others test benches and DUT setting finish:

```
#echo "Wait till others test benches and DUT setting finish:"
```

Verification

Simple test in DUT:

```
#ping 224.0.0.1 -c 5
#ping -b 192.85.1.255 -c 5
#ping -b 192.85.3.255 -c 5
#ping -b 255.255.255.255 -c 5
#history
```

Status checking and logs recording in DUT:

```
#ifconfig
#l2switch-cfg mac dump
#arp -a
#route

#history
```

Multi-cast and broadcast verification in DUT:

```
please refer to above "Simple test in DUT"
```

Verification in testbench1:

```
#ping 192.85.1.1 -c 5
#ping 192.85.1.2 -c 5
#ps aux

#echo Verify shake hands between test bench 1 and test bench 2
#netperf -H 192.85.1.2 -l 10 -t TCP_STREAM
#netperf -H 192.85.1.2 -l 10 -t TCP_SENDFILE
#netperf -H 192.85.1.2 -l 10 -t TCP_MAERTS
#netperf -H 192.85.1.2 -l 10 -t TCP_RR

#history
```

9.5.6.2.1.2 Verification with STC

DUT and Test Benches Setting

Set network ports connections

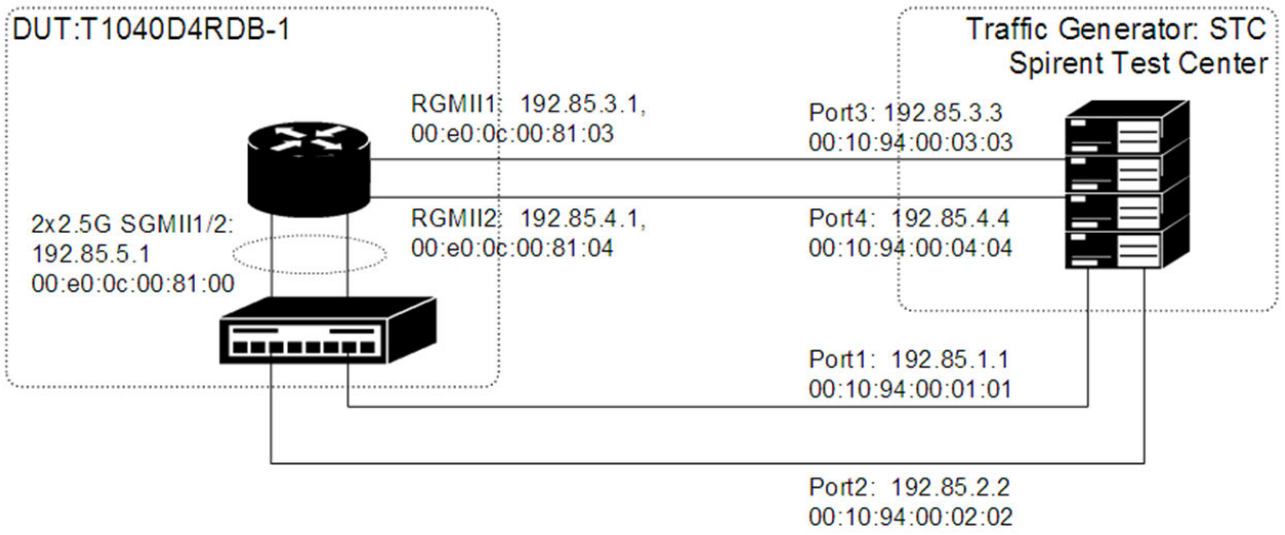

Figure 226. 2x2.5G-IPv4-STC

Set network ports connections as above, in a real case with NXP board farm, all boards and links connections look like below:

```
#bft map -m T1040RDB-4_SW-P1,Spirent_3:1,board -c --force
#bft map -m T1040RDB-4_SW-P2,Spirent_3:2,board -c --force
#bft map -m T1040RDB-4_RGMII1,Spirent_3:3,board -c --force
#bft map -m T1040RDB-4_RGMII2,Spirent_3:4,board -c --force

#bft port -l t1040rdb-4
T1040RDB-4_RGMII1           Spirent_3:3
T1040RDB-4_RGMII2           Spirent_3:4
T1040RDB-4_SGMII1           NW_2:39
T1040RDB-4_SW-P1            Spirent_3:1
T1040RDB-4_SW-P2            Spirent_3:2
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt “#”:

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
```

```
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg set lag mode
#l2switch-cfg set lag no 1 members 8 9
#l2switch-cfg mac learn auto
```

Enable mode 2, (balance-xor 2 as default, IEEE 802.1ax or the previous IEEE 802.3ad while L2 Switch full feature stack supported):

```
#cd /sys/class/net/bond0/bonding/
#echo 2 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb0 >slaves
#echo +fm1-gb1 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
        #ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP address:

```
        #ifconfig fm1-gb3 192.85.3.1/22
        #ifconfig fm1-gb4 192.85.4.1/21
        #ifconfig bond0 192.85.5.1/20
        #ifconfig fm1-gb2 192.168.2.69/24
        #route add default gw 192.85.5.1
        #route
        #ping 192.168.2.1 -c 5
        #
        #arp -s 192.85.1.1 00:10:94:00:01:01
        #arp -s 192.85.2.2 00:10:94:00:02:02
        #arp -s 192.85.3.3 00:10:94:00:03:03
        #arp -s 192.85.4.4 00:10:94:00:04:04
        #
        #free -l
        #free -l -m
        #route
        #arp -a
        #cat offline_port_xmit_statistics
        #ps axu
        #l2switch-cfg mac dump
```

Enable multi-cast forwarding:

```
        #cd /proc/sys/net/ipv4
        #ls -l icmp_*
        #cat icmp_*
        #cat icmp_echo_ignore_broadcasts
        #echo 0 >icmp_echo_ignore_broadcasts
        #cd -
```

Monitor frames from STC traffics generator:

```
        #tcpdump -vvv -e -n
```

Create traffic flows according above figure in this section:

```
4 traffic flows will be created in STC:
        STC1 --->STC3
        STC2 --->STC4
        STC3 --->STC1
        STC4 --->STC2

Above 4 traffic flows information look like below:

STC1<--->00:10:94:00:01:01,192.85.1.1 <---> STC3:192.85.3.3: 00:e0:0c:00:81:00 (bond0 ports' MAC)
STC2<--->00:10:94:00:02:02,192.85.2.2 <---> STC4:192.85.4.4: 00:e0:0c:00:81:00 (bond0 ports' MAC)
STC3<--->00:10:94:00:03:03,192.85.3.3 <---> STC1:192.85.1.1: 00:e0:0c:00:81:03 (RGMII1 ports' MAC)
STC4<--->00:10:94:00:04:04,192.85.4.4 <---> STC2:192.85.2.2: 00:e0:0c:00:81:04 (RGMII2 ports' MAC)
```

Verification

1.
```
Select Layer 4 type of frames among below, then send some frames, STC receiving port will receive
the same type of traffics as  expected:

TCP/UDP/ ICMP Destination unreachable/ICMP Echo Reply/ICMP Echo request/ICMP Info Reply/ICMP
Info request/ICMP parameter problem/ICMP redirect/ICMP source quench/ICMP time exceeded/ICMP
timestamp reply/ICMP timestamp requestIGMP v1 message/IGMP v2 query message/IGMP v2 report
message/IGMP v3 query message/IGMP v3 report message/IPv6/IPv4 (My Test)
```

2. In the DUT terminal, tcpdump will also output traffics in the same type as expected.
3. Frames received in STC are also captured/recorded by STC software, which can be played in the 3rd party software like wireshark.

For more detailed information, please refer to Spirent Test Center user manual.

9.5.6.2.2 Traffics over IPv6 forwarding verification

9.5.6.2.2.1 Verification with software

DUT and Test Benches Setting

Set network ports connections

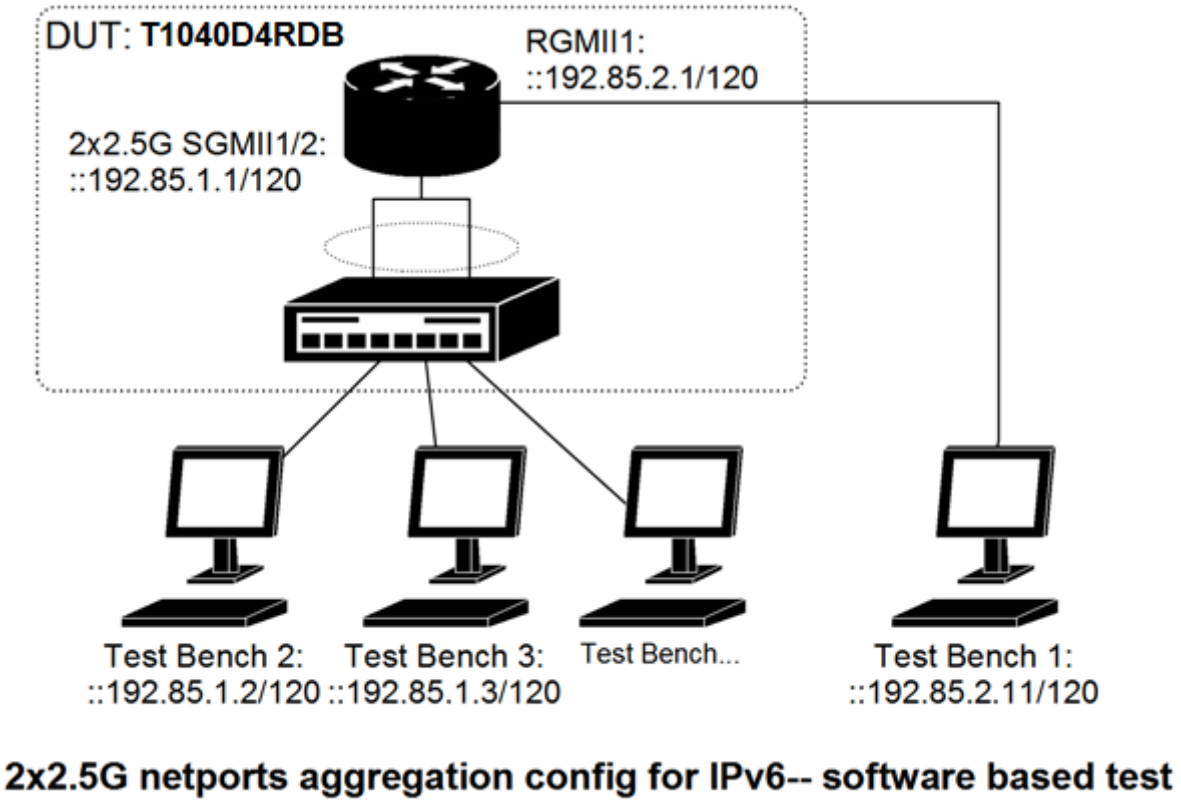

Figure 227. 2x2.5G-IPv6-software

Set hardware environment as above, in a real case with NXP board farm, all boards and links connections look like below:

```
T1040RDB-4_RGMII1           P1022DS-2_eTSEC1
T1040RDB-4_SW-P1            P2041RDB-2_SGMII1
T1040RDB-4_SW-P2            P2041RDB-2_SGMII2
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt "#":

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status

#l2switch-cfg set lag mode
#l2switch-cfg set lag no 1 members 8 9

#l2switch-cfg mac learn auto
```

Enable mode 2, (balance-xor 2 as default, IEEE 802.1ax or the previous IEEE 802.3ad while L2 Switch full feature stack supported):

```
#cd /sys/class/net/bond0/bonding/
#echo 2 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
#cat oh_en
#echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
#cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
#echo +fm1-gb0 >slaves
#echo +fm1-gb1 >slaves
#cat slaves
#cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
#ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP addresses:

```
#ip -6 addr add  dev bond0 0::192.85.1.1/120
#ip -6 addr add  dev fm1-gb3 0::192.85.2.1/119
#ip link set bond0 up
#ip link set fm1-gb3 up

#ip -6 route show
#ip -6 neigh show
#ip link show
#ip -6 addr show
#ps aux
#history
```

Wait till others test benches setting finish:

```
#echo "Wait till others test benches setting finish:"
```

Commands in test bench1:

```
#ip -6 addr add  dev eth0 0::192.85.2.11/119
#ip -6 route add default via 0::192.85.2.1 dev eth0
#ip link set eth0 up
#killall -9 netserver
#netserver -6
```

```
        #echo "====wait for others testbench setting========="
```

Commands in test bench2 and in the net name space of the test bench2:

```
        #ip -6 addr add  dev fm1-gb0 ::192.85.1.2/120
        #ip -6 route add default via  0::192.85.1.1 dev fm1-gb0
        #ip link set fm1-gb0 up
        #ip -6 route show
        #ip -6 neigh show
        #ip link show
        #ip -6 addr show
        #killall -9 netserver
        #netserver -6

        #ip netns add ns1
        #ip netns list
        #ip link set dev fm1-gb1 netns ns1
        #ip netns exec ns1 ip -6 addr add  dev fm1-gb1 0::192.85.1.3/119
        #ip netns exec ns1 ip -6 route add default via  0::192.85.1.1 dev fm1-gb1
        #ip netns exec ns1 ip link set fm1-gb1 up
        #netserver -6 -p 20000
```

Wait till others test benches and DUT setting finish:

```
        #echo "Wait till others test benches and DUT setting finish:"
```

Verification

Verification in testbench1

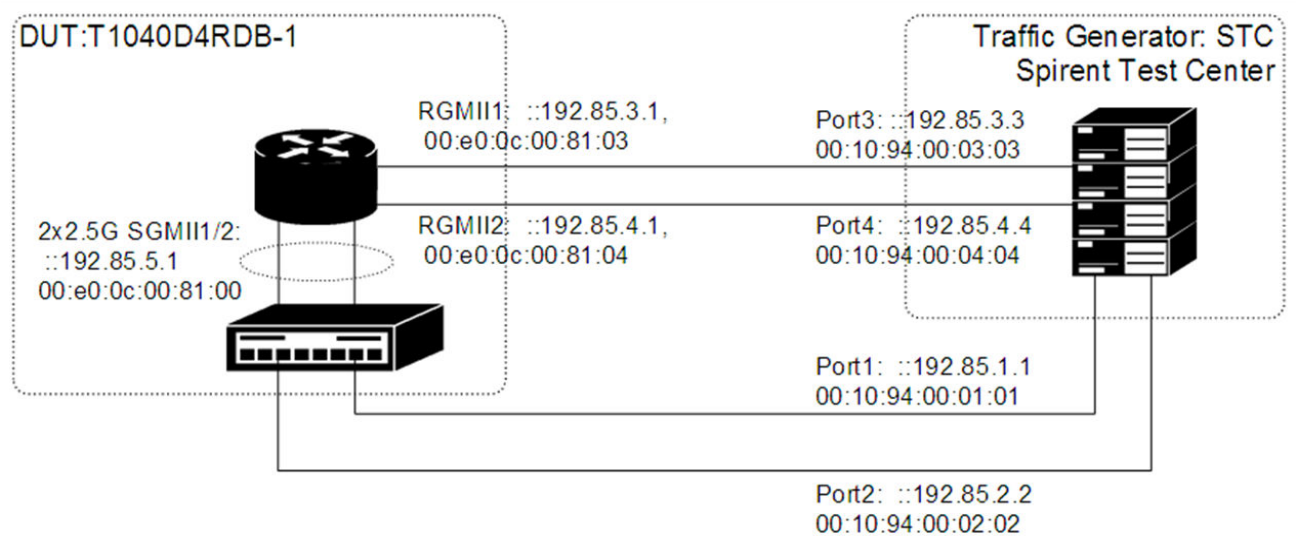
9.5.6.2.2.2 Verification with STC

DUT and Test Benches Setting

Set network ports connections



2x2.5G netports aggregation config for IPv6-- STC based test

Figure 228. 2x2.5G-IPv6-STC

Set network ports connections as above, in a real case with FSL board farm, all boards and links connections look like below:

```
#bft map -m T1040RDB-4_SW-P1,Spirent_3:1,board -c --force
#bft map -m T1040RDB-4_SW-P2,Spirent_3:2,board -c --force
#bft map -m T1040RDB-4_RGMII1,Spirent_3:3,board -c --force
#bft map -m T1040RDB-4_RGMII2,Spirent_3:4,board -c --force

#bft port -l t1040rdb-4
T1040RDB-4_RGMII1           Spirent_3:3
T1040RDB-4_RGMII2           Spirent_3:4
T1040RDB-4_SGMII1           NW_2:39
T1040RDB-4_SW-P1            Spirent_3:1
T1040RDB-4_SW-P2            Spirent_3:2
```

Boot up DUT:

Boot up DUT into Linux with right binaries like dtb, kernel uImage and rootfs, then get the prompt "#":

Commands in DUT

Check kernel version:

```
#uname -a
#cat /proc/version
```

Optional, kill irrelevant daemon

```
#killall -9 netserver
```

However, in order to avoid reset MAC table or STC ports mac addresses and reuse STC configuration file in other cases, below commands are plus, which can fit all DUT boards even they have different MAC addresses.

```
#ifconfig fm1-gb0 hw ether 00:e0:0c:00:81:00
#ifconfig fm1-gb1 hw ether 00:e0:0c:00:81:01
#ifconfig fm1-gb2 hw ether 00:e0:0c:00:81:02
#ifconfig fm1-gb3 hw ether 00:e0:0c:00:81:03
#ifconfig fm1-gb4 hw ether 00:e0:0c:00:81:04
```

Ensure L2 Switch driver enabled:

```
#lsmod
#insmod /lib/modules/xxx_kernel_version/extra/uio_seville.ko
#/etc/init.d/l2switch status
#/etc/init.d/l2switch help
#/etc/init.d/l2switch start
#/etc/init.d/l2switch status
#l2switch-cfg set lag mode
#l2switch-cfg set lag no 1 members 8 9
#l2switch-cfg mac learn auto
```

Enable mode 2, (balance-xor 2 as default, IEEE 802.1ax or the previous IEEE 802.3ad while L2 Switch full feature stack supported):

```
#cd /sys/class/net/bond0/bonding/
#echo 2 > mode
```

Enable IP Forwarding:

```
#echo 1 > /proc/sys/net/ipv4/ip_forward
#echo 1 > /proc/sys/net/ipv6/conf/all/forwarding
```

Check which offline ports are probed:

```
#cat offline_ports
```

Attach one offline port to current bond as a hardware based traffic distribution helper:

```
#echo fman0-oh@2 > oh_needed_for_hw_distribution
```

Check whether they bind each other successfully or not:

```
#cat oh_needed_for_hw_distribution
```

Allow this offline port help this bond to do hardware based traffics distribution:

```
        #cat oh_en
        #echo 1 > oh_en
```

Check whether offline port agree to help the bond to do hardware based traffics distribution:

```
        #cat oh_en
```

Add slave devices to the bond. if different version of file system is used, the name of the Ethernet may be different, maybe fmXX-gbYY or maybe fmXX-macYY, or maybe ethxxx:

```
        #echo +fm1-gb0 >slaves
        #echo +fm1-gb1 >slaves
        #cat slaves
        #cat xmit_hash_policy
```

Disable slave devices advanced features, which a bond is not aware or a bundle has not method to check, since FSL style LAG is bypassing slave devices driver:

```
        #ethtool -K bond0 gso off sg off tx off
```

Configure the bonding interface and other network interface with IP address:

```
        #ifconfig fm1-gb3  inet6 add  ::192.85.3.1/120 up
        #ifconfig fm1-gb4  inet6 add  ::192.85.4.1/120 up
        #ifconfig bond0    inet6 add  ::192.85.5.1/120 up
        #ifconfig fm1-gb2 192.168.2.69/24 up
        #route -A inet6 add default gw ::192.85.5.1 dev bond0
        #ping 192.168.2.1 -c 5
        #l2switch-cfg mac dump
        #route
        #
        #arp -a
        #ip -6 route show
        #ip -6 neigh show
        #
        #free -l
        #free -l -m
        #cat offline_port_xmit_statistics
        #ps axu
        #history
```

Monitor frames from STC traffics generator:

```
        #tcpdump -vvv -e -n
```

Create traffic flows according above figure in this section:

```
4 traffic flows will be created in STC:
        STC1 --->STC3
        STC2 --->STC4
        STC3 --->STC1
        STC4 --->STC2

Above 4 traffic flows information look like below:
STC1<--->00:10:94:00:01:01, ::192.85.1.1 <---> STC3: ::192.85.3.3: 00:e0:0c:00:81:00 (bond0 ports'
```

```
MAC)
STC2<--->00:10:94:00:02:02, ::192.85.2.2 <---> STC4: ::192.85.4.4: 00:e0:0c:00:81:00 (bond0 ports'
MAC)
STC3<--->00:10:94:00:03:03, ::192.85.3.3 <---> STC1: ::192.85.1.1: 00:e0:0c:00:81:03 (RGMII1 ports'
MAC)
STC4<--->00:10:94:00:04:04, ::192.85.4.4 <---> STC2: ::192.85.2.2: 00:e0:0c:00:81:04 (RGMII2 ports'
MAC)
```

Verification

1.
```
Select Layer 4 type of frames among below, then send some frames, STC receiving port will receive
the same type of traffics as  expected:

TCP/ UDP/ MLDv1 Listener Done/LMDv1 Listener Report/ My Test /ICMPv6 Dest Unreachable/ ICMPv6
Echo Reply/ICMPv6 Echo Request/ICMPv6 packet Too Big/ ICMPv6 Parameter Problem/ ICMPv6 Time
Exceeded/IPv4/ IPv6 Hop By Hop Header/IPv6 Authentication Header/IPv6 Authentication Header/IPv6
Routing Header /IPv6 Fragment Header/ IPv6 Encapsulation Header/ MLDv1/MLDv2 Query/MLDv2 Report /
Neighbor Advertisement/ Neighbor Solicitation /Redirect/ Router Advertisement/ Router
Solicitation/UDP-DHCP Ack/ UDP-DHCP Decline /UDP-DHCP Inform/ UDP-DHCP Discover/ UDP-DHCP
Inform /UDP-DHCP Nak/ UDP-DHCP Offer/UDP-DHCP Release /UDP-DHCP Request/ UDP-VxLAN
```

2. In the DUT terminal, tcpdump will also output the same type of traffics as expected.
3. Frames received in STC are also captured/recorded by STC software, which can be played in the 3rd party software like wireshark.

For more detailed information, please refer to Spirent Test Center user manual.

9.5.6.3 Note

Note:

1. As default, valid Netperf testnames are not always compiled-in. For more detail Netperf testing, please refer to the Netperf UM.
2. When slow in lacp_rate as default, ping sometimes fail for a couple of seconds while a slave link quits the aggregation group from the other peer, which is normal phenomenon.
3. There are many free sshd programs, for example: dropbear, openssh and etc,. If the rootfs of current sdk version excludes dropbear, please refer to your sshd user manual accordingly for start or restart the ssh daemon.

9.5.7 Known Bugs, Limitations, or Technical Issues

1. Performance limitation: NXP style LAG performance depends on Offline port forwarding speed. By now, it is lower than the idea speed of FMan v3 version:3.75Mpps, need an enhancement in subsequent release.
2. Linux bonding is using XOR L2/L3/L4 header information to calculate slave device. But FMan supports neither XOR nor bi-directional SHIFT operator. NXP style LAG uses CRC-64 based hashing to instead.
3. Current design is bypassing DPA-Eth driver, so good features of the DPA-Eth driver are not available, such as SG-GSO, IEEE1588, etc..
4. Current NXP LAG only support 2 DPA slaves per bundle, this limitation dues to current Keygen hardware, which is requiring hashDistributionNumOfFqids" to be a power of 2, which implies the count of slave device has to be 2, 4, 8, 16.
5. Current NXP style LAG only support one bundle, other bundles are based on software, this limitation dues to lack of available count of Offline ports. By now, there are only 3 Offline ports in T104x/T102x. So far, OP 3# and OP 4# are reserved for oNIC and CAPWAP, OP 2# for LAG. This limitation will be eliminated in the future.

6. L3/4 header information have not been calculated in when xmit_hash_policy changes for current version, will be enhanced in the future version.
7. Non-reconfigurable: This release support attach/detach slave devices to/from a bundle only once, dues to design limitation. If a bond does not need offline port's help for traffics, below command maybe a workaround while a bundle is in inactive status : "echo 0 > /sys/class/net/bond0/bonding/ oh_en". NXP internal CRS: ENGR00326388, ENGR00326299, ENGR00326297 are tracking this.
8. Termination based functionalities and hardware L4 CSUM by offline ports are not available for this release. For forwarding path, L4 CSUM for xmit path is not necessary. L4 CSUM is only required in termination cases. These functionalities will be done in subsequent releases.
9. Jumbo Frame is not supported yet, DPA driver does this by FMan MAC ports. NXP style LAG will do this by FMan Offline ports while this is required.
10. The 3rd party L2 Switch protocol: For 2x2.5G L2 Switch FMan ports aggregation, the 3rd party full feature stack of L2 Switch is needed to support IEEE802.3ad/IEEE802.1ax LAG, because if the protocol stack is not available, 2.5G L2 Switch FMan ports can't reply LACP signalling. From SDK-v2.0, balance-xor mode Link Aggregation is provied.

9.6 Linux HugeTLBFS User Guide

9.6.1 Introduction

Instructions for using large pages for networking application performance improvement with Linux HugeTLBFS.

It is becoming customary for user-level applications to have large memory requirements in embedded systems. Even so, the default page size in Linux is 4KB while the amount of memory mappable in TLB0 with 4KB pages is small. Small TLBs may result in many TLB misses for large applications. This document illustrates, with examples, how to properly configure a QorIQ device for large page sizes.

9.6.2 Objectives

These are results expected for the method outlined:

- Baseline understanding of Linux HugeTLBFS.
- Identify any optimizations that have been discovered and ensure they are implemented.
- Investigate other changes that may improve performance.
- Compare these results with end product performance objectives.

9.6.3 TLBFS Basics

The amount of memory mappable in TLB0 with 4KB pages is small:

Table 214. Mappable Memory of e500 Versions

Processor	No. TLB Entries	Mappable by TLB0
e500 v1	256	1MB
• e500 v2 • e500MC • e5500	512	2MB

9.6.3.1 4KB TLB0 Miss Issues

The salient contributors to TLB0 miss issues:

- TLB0 is shared between multiple processes.
- TLB0 is used for mapping both instructions and data.
- Thrashing - A single MMU-hogging process in the system can have performance inpact on smaller processes running in the system.
- A single process may use significantly more than 2M.

For the case of conflict miss, TLB0 is 4-way set associative (2-way on e500v1), which has a higher potential for conflict miss than a fully-associative TLB cache. Another concern is latency issues caused by e500 reloads of TLB entries using software which has a latency of at least 100-200 cycles per TLB.

9.6.3.2 e500 Family TLB1

The e500 processor family provides a second software-visible TLB structure, the TLB1. This is sometimes referred to as the TLBCAM. Because the TLB1 is fully associative, new mappings may be placed in any entry.

TLB1 supports a number of large page sizes but has a small number of entries:

Table 215. e500 Family TLB1 Characteristics

Processor	TLB1 Entries	Page Size
e500 v1	16	4KB, 16KB, 64KB, 256KB, 1MB, 4MB, 16MB, 64MB, 256MB
e500 v2	16	Same as e500 v1, also, 1GB, 4GB
e500MC, e5500	64	Same as e500 v2

9.6.3.3 HugeTLB Basics

Hugetlbfs allows the Linux kernel to use large pages mapped by TLB1 for user processes:

- The kernel itself does not use “hugetlbfs”; it uses a few large TLB1 entries to map some amount of memory using large mappings
- Drivers that run as part of the kernel cannot use hugetlbfs (may be a short-term restriction)

The kernel will not allocate hugepages unless requested:

- This is intentional - the number of TLB1 entries is limited so they should be used with care.
- Hugepages can cause performance problems if misused.

Hugetlb for BookE supports 4MB, 16MB, 64MB, 256MB, and 1GB pages:

- This is a subset of the hardware page sizes supported by TLB1.
- We cannot easily support a page size less than 4MB due to the current page table architecture of the 32-bit Linux kernel.

Hugepages can be used for:

- program
- .text
- .data

- .bss
- `malloc()`
- `mmap()`
- `shmget()`

Using hugepages may or may not require application modification and/or rebuild.

9.6.3.4 Normal vs. Gigantic hugepages

Page sizes larger than 16MB are called **Gigantic** pages. This depends on `CONFIG_FORCE_MAX_ZONEORDER` in Linux and may vary on different kernels; this value is for the FSL BSP. There are differences in how normal hugepages and gigantic hugepages are allocated in the kernel:

Table 216. (Normal) Huge vs. Gigantic Pages

Type	Sizes	Allocation	Deallocation
Normal	4MB, 16MB	At boot, or while system is running	Allowed
Gigantic	64MB, 256MB, 1GB	Only at boot time	Not allowed

The table below lists several limiting cases for Gigantic pages:

Table 217. Gigantic Page Limitations

Limiting Case	Description
Gigantic pages should be allocated with care since they cannot be deallocated.	Has the effect of removing RAM from the system if the hugepages are not used.
Virtual and physical addresses in the TLB must be aligned to the huge page size requested.	• May not be possible for the kernel to allocate many gigantic pages because of alignment requirements • example: The user's virtual address space is limited to 3GB total on 32-bit Linux, so at most one or two 1GB pages and eight or so 256MB pages may be used by a single process

9.6.4 Building and Booting Linux with Hugetlb

Linux must be built with CONFIG_HUGETLBFS and CONFIG_HUGETLB_PAGE set; CONFIG_FORCE_MAX_ZONEORDER should be set to 13.

- Upcoming FSL BSPs have these options enabled
- The publicly available Linux trees do not yet contain the Hugetlb support; this update is pending publication.

Specify the default hugepage size to allocate hugepages via the kernel boot command line:

- `default_hugepagesz=16m hugepagesz=16m hugepages=25 hugepagesz=4m hugepages=25`
- Once allocated, hugepages are removed from the available memory pool and will only be used for huge mappings. Avoid allocating hugepages that you don't expect to use.

9.6.4.1 Booting Linux for HugeTLB

Once Linux is booted, follow these steps:

Table 218. Step 1: The hugetlbfs filesystem must be mounted by root.

Description	Action
Check that hugetlb is enabled:	• `grep hugetlbfs /proc/filesystems` • `grep HugePages_Total /proc/meminfo` (look for a non-zero number)
Mount the default huge page size:	`mount -t hugetlbfs none /mnt/hugetlbfs`
Mount a secondary page size:	`mount -t hugetlbfs none –opagesize=16m /mnt/hugetlbfs-16M`
To allow non-root to use hugepages:	mount point perms = 1777; or use `hugeadm` to create a user or group-specific mount point

Step 2: Build and install libhugetlbfs

- simple `make; make install`
- Will be included in the BSP.
- Specific version from NXP required.

Step 3: Use `hugeadm` utility to query/change huge page parameters:

- Change the number of non-gigantic huge pages available.
- Query the size of the current huge page pool.
- View supported page sizes.
- Create hugepage mount points.

Step 4: Use `HUGETLB_DEBUG=yes` in environment to help debug applications linked with the library when there are issues

9.6.4.2 Setting Up Mount Points with hugeadm

4 commands are provided for creating mount points:

Table 219. Rev. History Table

Command Line	Description
--create-mounts	Creates a mount point for each available huge page size on this system under `/var/lib/hugetlbfs`
--create-user-mounts [user]	Creates a mount point for each available hugepage size under `/var/lib/hugetlbfs/[user]` usable by [user] [user]
--create-group-mounts [group]	Creates a mount point for each available huge page size under `/var/lib/hugetlbfs/[group]` usable by group [group]
--create-global-mounts	Creates a mount point for each available huge page size under `/var/lib/hugetlbfs/global` usable by anyone

9.6.4.3 Running Hugepage mount/query Example

Each result of each action in the example is shown in the tables

```
-bash-3.2# mount -t hugetlbfs none /mnt/hugetlbfs
```

```
-bash-3.2# hugeadm --pool-list
```

Table 220. Pool List

Size	Minimum	Size	Minimum	Default
4194304	25	25	25	
16777216	25	25	25	*
67108864	0	0	0	
268435456	0	0	0	
1073741824	0	0	0	

```
-bash-3.2# hugeadm –pool-pages-min 4M:100
```

```
-bash-3.2# hugeadm --pool-list
```

Table 221. Pool List

Size	Minimum	Size	Minimum	Default
4194304	100	100	100	
16777216	25	25	25	*
67108864	0	0	0	
....				

9.6.5 Hugepage Allocation in User Programs

User applications can request hugepages several ways:

Table 222. Pool List

Method	Steps
Shared memory	• `shmget()` call specifies `MAP_HUGETLB` • Link application with libhugetlbfs to override all `shmget()` calls
Heap-based allocations	Causes all `malloc()` calls (and C++ `new` operator) to allocate in a huge page heap region.

Table continues on the next page...

Table 222. Pool List (continued)

Method	Steps
`mmap()`	• Anonymous `mmap() (MAP_ANONYMOUS)` with `MAP_HUGETLB mmap()` • `mmap()` file on the hugetlbfs mount point.
Back program segments with hugepages	.text, .data, and .bss segments

9.6.5.1 Using Shared Memory Hugepages: SHM_HUGETLB

Specify `SHM_HUGETLB` in `shmget()` flags inapplication code

- Requires application modification to add SHM_HUGETLB to shmget() arguments.
- Application must be rebuilt.
- Libhugetlbfs is not required to use this method (no special linking needed).
- Can specify exactly which shmget() calls use hugepages.
- Can only use the systemwide default hugepage size.
- The size requested must be a multiple of the huge page size.

9.6.5.2 Running the SHM_HUGETLB Example

The code below illustrates several of the concepts discussed so far:

```
    #define LENGTH 4 * 1024 * 1024

/* Create shared memory region */
if ((shmid = shmget(2, LENGTH, SHM_HUGETLB | IPC_CREAT | SHM_R | SHM_W)) < 0)
    exit(1);

    shmaddr = shmat(shmid, 0, 0); /* Attach the region to the process */
if (shmaddr == (char *)-1) {
    shmctl(shmid, IPC_RMID, NULL);
    exit(2);
}

for (i = 0; i < LENGTH; i++)         /* Example write to the region */
    shmaddr[i] = (char)(i);

if (shmdt((const void *)shmaddr) != 0) { /* Detach the region */
    shmctl(shmid, IPC_RMID, NULL);
    exit(3);
}
shmctl(shmid, IPC RMID, NULL); /* Remove the shmid */
```

9.6.5.3 Using Shared Memory Hugepages: Link with libhugetlbfs

Instead of specifying `SHM_HUGETLB`, link application with libhugetlbfs to override all `shmget()` calls

- No application modification required.
- With dynamic linking, can use an existing binary.

- Can only use the systemwide default hugepage size.
- Simply invoke the application as follows (dynamic link):
  - `LD_PRELOAD=libhugetlbfs.so HUGETLB_SHM=yes [your app command line]`
- These variables can be set in the user's shell, but they will then apply to all binaries executed in this shell, which is usually not desired.
- The size requested will automatically be rounded up to the huge page size.

9.6.6 Manipulating Shared Memory System Tunables

Hugepage `shmget()` requests can fail due to limits placed on process shared memory by 4 system tunables:

- **shmmax**: Limit on shared memory size for a single process, in bytes.
- **shmall**: System-wide limit on total shared memory "pages"; in this context a "page" is 4k.
- **shmmin**: Minimum size of a shared memory segment.
- **shmmni**: System-wide maximum number of shared memory segments.

Low shmmax usually the cause of `shmget()` failure. It should be adjusted to the max size required by a single process on the system. For example, to allow any process to have 256MB of shared memory:

- `echo 268435456 > /proc/sys/kernel/shmmax`

shmall will rarely require change; the others need modification extremely rarely.

9.6.6.1 Allocating hugepages for Heap Memory

Link application with libhugetlbfs to use hugepages for all malloc() calls and the C++ new operator

- Requires no application modification.
- With dynamic linking, can use an existing binary.
- Any available and mounted hugepage size can be used via the HUGETLB_MORECORE environment variable.

All malloc()calls and the C++ new operator will use hugepages provided by kernel.

- C library malloc() code is the same as without libhugepages; the underlying interface to kernel (known as morecore()) is what is changed by libhugetlbfs
- Total amount of hugepages is limited by system configuration
- malloc() or new requests smaller than the hugepage size will be rounded up by the kernel; multiple small requests can end up being mapped by a single hugepage.

9.6.6.2 Invoking Applications with Huge Heap (mallock()/new)

To use the default hugepage size:

- `LD_PRELOAD=libhugetlbfs.so`
- `HUGETLB_MORECORE=yes` [your app command line]

To use a different hugepage size:

- `LD_PRELOAD=libhugetlbfs.so`
- `HUGETLB_MORECORE=16M` [your app command line]

If the libhugetlbfs library is not installed in the normal system library directory, use LD_LIBRARY_PATH to specify the location::

- `LD_PRELOAD=libhugetlbfs.so`
- `LD_LIBRARY_PATH=~/mylibdir`

- `HUGETLB MORECORE=yes` [your app command line]

9.6.6.3 Moving the Heap for Hugepage Allocations

By default, the heap is located after the program image and can continue until it runs into a mmap. The program image typically resides at text/data/bss. Addresses for mmap are normally chosen by the kernel, starting from TASK_UNMAPPED_BASE. The result is a large portion of address space, sometimes larger than the default heap, unused. The HUGETLB_MORECORE_HEAPBASE option can be used to start the heap after the mmap area, rather than before it, so as to provide more space for the heap.

There may not be enough address space at the default heap location for hugepage malloc() and new requests to succeed.

- The 32-bit kernel uses `0x48000000` as TASK_UNMAPPED_BASE, which causes failures when trying to map > about 832MB of memory

The library provides HUGETLB_MORECORE_HEAPBASE to allow the user to specify the heap location.

- Use pmap or set HUGETLB_DEBUG=yes to get more information on the process' heap allocations
- Find a hole in the map large enough for your allocation and set HUGETLB_MORECORE_HEAPBASE to this when you run.

Example:

- LD_PRELOAD=libhugetlbfs.so HUGETLB_MORECORE=yes HUGETLB_MORECORE_HEAPBASE=`0x4C000000` [your app command line]

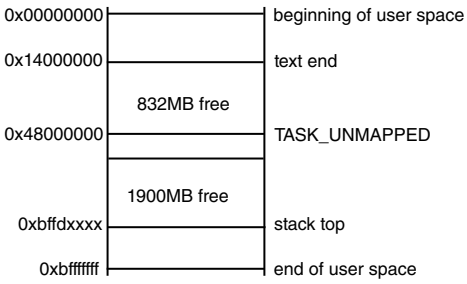

Figure 229. Heap Example:

9.6.7 Using Hugepages for .text, .data, and/or .bss (gnu ld 2.17+)

Specify –hugetlbfs-align option to GNU ld.

- Requires no application modification.
- Application needs to be relinked.
- libhugetlbfs wrapper script and linker script must be installed.
- Quite flexible – can specify exactly which segment types should use hugepages.
- Causes segments to be properly aligned for hugepage use.

Hugeedit utility

- Change the default segment-specific behavior without relinking the program.
- Default behavior is no hugepage mapping.
- The settings are used when HUGETLB_ELFMAP is not specified.

Run application with HUGETLB_ELFMAP.

Table 223. Environment variable that controls which segments use hugepages

Variable	Description
HUGETLB_ELFMAP=R	Read-only segments (text)
HUGETLB_ELFMAP=W	`Writable segments (data/BSS)`
HUGETLB_ELFMAP=RW	All segments (text/data/BSS)
HUGETLB_ELFMAP=no	`No segments`

The HUGETLB_ELFMAP application can specify specific page sizes for the different segment types:

- HUGETLB_ELFMAP=[R[=[pagesize]]:[W[=[pagesize]]]

Example: program invocation (dynamic link):

- LD_PRELOAD=libhugetlbfs.so HUGETLB_ELFMAP=R=4M:W=16M [your app command line]

If you are **not** using HUGETLB_ELFMAP:

- The default settings for the binary (set via hugeedit) will be used.
- The system-wide hugepage size will be used.

9.6.8 Performing mmap on a Hugepage-backed File

The option exists for an alternative to hugetlb-backed memory. This option is appropriate for these cases:

- To have some things hugetlb-backed without making the heap huge-tlb backed.
- To Share huge-tlb backed memory.
- To make use of address space above TASK_UNMAPPED_BASE without moving heap and thereby losing use of the address space above TASK_UNMAPPED_BASE.

Create and mmap() files on the hugetlbfs mount point.

- Can use any mounted huge page size.
- The huge page size will be the page size supported by the mount point.
- Files on the hugetlb file system are not regular files – they represent memory. You cannot copy a regular file onto the hugetlb file system mount point.
- Do not specify MAP_HUGETLB for this type of mapping – files on the hugetlb mount point are automatically backed by hugepage memory
- Files on a hugetlb mount point should be created as a multiple of the huge page size for that particular mount point; otherwise mmap() fails.

9.6.8.1 Exercising the mmap() File Example

The following example demonstrates a 4M hugetlbfs mount point.

```
#define LENGTH 4*1024*1024
#define FILE_NAME "/var/lib/hugetlbfs/global/pagesize-4MB/my_hugefile"

/* Open/create the file on the 4m mountpoint */
fd = open(FILE_NAME, O_CREAT | O_RDWR, 1777);
if (fd < 0) exit(1);
```

```
/* map in the file and check that the mmap succeeded */
addr = mmap(NULL, LENGTH, PROT_READ | PROT_WRITE, MAP_SHARED, fd, 0);
if (addr == MAP_FAILED) {
perror("mmap");
unlink(FILE_NAME);
exit(1);

}
/* unmap file, check for error */
if (munmap(addr, LENGTH) < 0) {
perror("munmap");
exit(2);

}
close(fd);
unlink(FILE NAME);
```

9.6.8.2 Requesting Anonymous mmap() with Hugepages

The user can directly request hugepages with MAP_HUGETLB flag to anonymous (no file descriptor specified) mmap

- Libhugetlbfs is not required.
- This method can only use the default hugepage size
- No mount points required.

Example:

```
mmap(NULL, 4*1024*1024, PROT_READ | PROT_WRITE,
    MAP_ANONYMOUS | MAP_HUGETLB | MAP_SHARED, 0, 0);
```

NOTE

MAP_ANONYMOUS and MAP_HUGETLB are both required

9.6.8.3 Using HugeTLB mmap(): Arguments and Error Checking

If specified, the address argument passed to mmap() must be aligned to the huge page size.

- Address may be NULL; the system will pick one for you.

For non-anonymous mmap() calls, the "offset" should be a multiple of the huge page size, if specified as non-zero.

The length of a mmap() should be a multiple of the huge page size.

- mmap() calls that use a fd (i.e. non-anonymous) must follow this rule.
- This is not required for anonymous mmaps, but is recommended to avoid munmap() problems.

Always check mmap() return codes.

9.6.8.4 Using HugeTLB munmap(): Arguments and Error Checking

Exercise caution with this process step, munmap() calls must specify a length that is a multiple of the huge page size.

- This is not optional.
- The munmap() will fail if this rule is broken.

Programs should always check the return code of munmap().

- It is common coding practice to check the return code from mmap() but not from munmap(). This is incorrect. Check the return code of both mmap() and munmap() to properly catch errors.

9.6.9 Running the Test

After two boards boot up, login linux and run following commands:

Table 224. sRIO Test Procedure

Memory Allocation Type	Code Mod	Reuse Binary	Huge Page Size	Need Lib?	Notes
heap (malloc()/ new)	No	Yes*	Any>	Yes	* If dynamically linked.
anonymous (mmap()/new)	Yes	No	Default Only>	No	
file mmap()	Yes	No	Any*>	Yes	* Page size used is that supported by the mount
shared memory (shmget() with SHM_HUGETLB)	Yes	No	Default Only	No	
shared memory (shmget() without SHM_HUGETLB)	No	Yes*	Default Only	Yes	*If dynamically linked.
.text, .data, .bss	No	No	Any	Yes	

9.6.9.1 When to Use Hugepages

In order to calculate whether a program will benefit from using huge pages, count the L2 MMU miss rate using core performance monitors.

- If (# L2 MMU misses * 200 cycles) represents a large percentage of the program's total number of cycles, it is possibly a good candidate for hugepages

Use "top" or "ps" on a running process to determine its resource usage.

- For a long-running process, `/usr/bin/time -v` can be used to get the "Maximum resident set size", but it can return values that are 4x the actual usage.

Look at pattern of mmap()calls in a program trace.

- Large calls lend themselves more easily to using hugepages. Programs with lots of small calls can also benefit from code change to consolidate the calls into a multiple of the huge page size.
- Also look at munmap() calls – the program must be able to munmap() in multiples of the huge page size.

Generate an instruction trace of the program and look at load/store addresses

- If the top 20 bits of load/store addresses change often and have more than 512 distinct values, then the program may be using a lot of data and bss.
- Also see if the same is true for instruction addresses

Programs with malloc() or new requests whose sum is large may benefit.

- When the library sees one of these requests it will allocate a large heap region that is the size of the hugepage specified by the HUGETLB_MORECORE environment variable.
- Future malloc() or new requests will allocate from that same region until it is fully utliized.
- The smallest hugepage that encompasses all the requests should be used when possible.

Smaller heap requests can also benefit.

- If the number of hugepages needed in the system is smaller than the number of entries in TLB1, the application may see fewer TLB misses with a hugepage.

9.6.10 Matching Hugetlb Methods with Program Characteristics

Table 225. sRIO Protocol Efficiency

Program Characteristic	HugeTLB usage
Large `malloc()` or new requests.	HUGETLB_MORECORE = [hugepage size]
Large program segments (.text, hugetlbfs align .data, .bss)	--hugetlbfs-align, HUGETLB_ELFMAP=[specify segments/size]
Large MAP_ANONYMOUS `mmap()`	`mmap()` on hugetlb mount point.
Large shared memory	SHM_HUGETLB or link with library and specify HUGETLB_SHM.

9.6.11 Using Multiple Types of Hugepage Allocation Methods

HugeTLB allocation methods are not mutually exclusive.

- Example: HUGETLB_MORECORE + HUGETLB_ELFMAP
- Example: shmget(SHM_HUGETLB) + HUGETLB_MORECORE

All combinations are allowed; but care should be taken.

- Poor choice of options can result in less-than optimal hugepage allocations.
- Can run out of hugepages in the system.
- TLB1 can end up oversubscribed.
- Can waste process virtual address space and have failed program allocations.

9.6.12 Hugetlb Benefits and Limitations

Benefits:

- Fewer TLB misses in large processes.
- Other processes can benefit because their 4k pages aren't getting evicted by memory hog processes.
- Potential for significant performance gains.

Limitations:

- Limited number of TLB1 entries.
- Adds minor latency to critical kernel paths for 4k pages.
- Hugepages are more costly for the kernel to manage.
- Allocating hugepages removes them from the available memory pool, causing less memory to be available.

9.6.13 Understand the Differences Between Applications

Some applications convert easily to hugepages. In many cases, only slight modifications, or none at all, are required. Other applications may benefit, but with more work:

- Some huge page usage models can only operate on multiples of a huge page size.
- Applications that map and unmap large amounts of memory using a lot of small mmap() and/or munmap() calls will likely require significant modifications in order to use hugepages efficiently.
- Code that doesn't properly check system call return codes may have unexpected fails later in the program execution.

There are programs that will not benefit from huge pages. Either the memory footprint is too small or it may be the case that a low percentage of cycles are spent in TLB miss handling.

9.6.14 HugeTLB Status and Support

The current status of HugeTLB features and future goals for this effort includes these items:

- Some huge page usage models can only operate on multiples of a huge page size.
- Applications that map and unmap large amounts of memory using a lot of small mmap() and/or munmap() calls will likely require significant modifications in order to use hugepages efficiently.
- Code that doesn't properly check system call return codes may have unexpected fails later in the program execution.

There are programs that will not benefit from huge pages. Either the memory footprint is too small or it may be the case that a low percentage of cycles are spent in TLB miss handling.

4-part LWN.net series on HugeTLB

Running Applications with Libhugetlbfs

Libhugetlbfs HOWTO:

NOTE

These supporting documents don't have specifics for FSL Power Architecture such as page size but are included for general understanding.

9.7 OpenSSL Offload User's Guide

9.7.1 Overview

The Secure Socket Layer (SSL) protocol is the most widely deployed application protocol to protect data during transmission by encrypting the data using popular cipher algorithms such as AES, DES and 3DES.

Apart from encryption it also provides message authentication services using popular hash/digest algorithms such as SHA1 and MD5. SSL is widely used in application web servers (HTTP) and other applications such as SMTP POP3, IMAP, Proxy servers etc., where protection of data in transit is essential for data integrity.

There are various version of SSL protocol such as SSLv3, TLSv1.0, TLSv1.1, TLSv1.2, TLSv1.3 and DTLS (Datagram TLS). Of all the SSL protocol versions, TLSv1.0 and SSLv3 are in commonly in use, the other versions seeing more adoption as well.

This document introduces NXP SSL acceleration solution on QorIQ platforms using OpenSSL:

1. OpenSSL software architecture
2. Building OpenSSL with hardware offload support
3. Examples of OpenSSL Offloading

9.7.1.1 OpenSSL Software architecture

The SSL protocol is implemented as a library in OpenSSL - the most popular library distribution in Linux and BSD systems. The OpenSSL library has several sub-components such as:

1. SSL protocol library
2. Crypto library (Symmetric and Asymmetric cipher support, digest support etc.)
3. Certificate Management

The following figure presents the general interconnect architecture for OpenSSL. Each relevant layer is represented with a clear separation between Linux User Space and Linux Kernel Space.

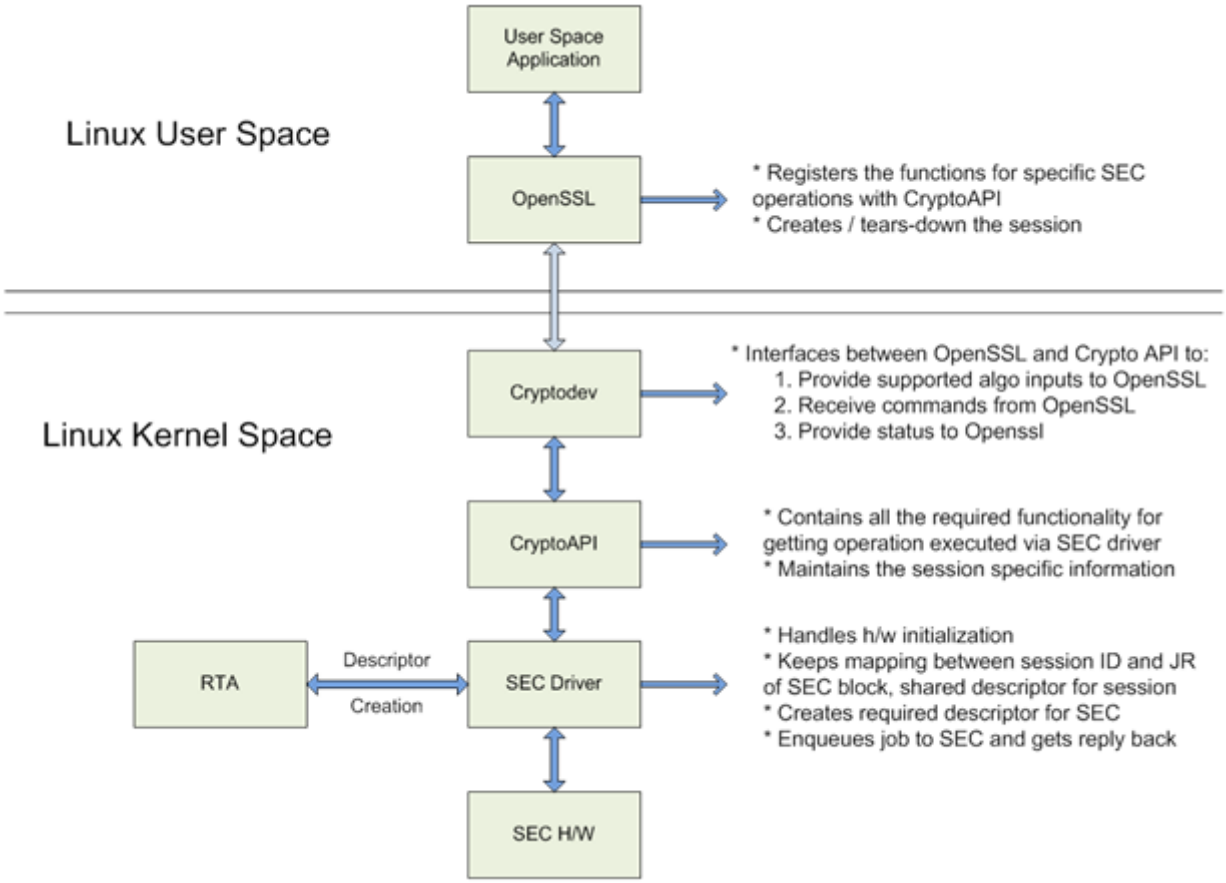

Figure 230. OpenSSL interface with Linux kernel

9.7.1.1.1 OpenSSL's ENGINE Interface

OpenSSL Crypto library provides Symmetric and Asymmetric (PKI) cipher support that is used in a wide variety of applications such as OpenSSH, OpenVPN, PGP, IKE, XML-SEC etc. The OpenSSL Crypto library provides software support for:

1. Cipher algorithms
2. Digest algorithms
3. Random number generation
4. Public Key Infrastructure

Apart from the software support, the OpenSSL can offload these functions to hardware accelerators via the ENGINE interface. The ENGINE interface provides callback hooks that integrate hardware accelerators with the crypto library. The callback hooks provide the glue logic to interface with the hardware accelerators. Generic offloading of cipher and digests algorithms through Linux kernel is possible with cryptodev engine.

9.7.1.1.2 NXP solution for OpenSSL hardware offloading

The following layers can be observed in NXP's solution for OpenSSL hardware offloading:

- OpenSSL (user space) - implements the SSL protocol
- cryptodev-engine (user space) - implements the OpenSSL ENGINE interface; talks to cryptodev-linux (/dev/crypto) via ioctls, offloading cryptographic operations in kernel
- cryptodev-linux (kernel space) - Linux module that translates ioctl requests from cryptodev-engine into calls to Linux Crypto API
- Linux Crypto API (kernel space) - Linux kernel crypto abstraction layer
- CAAM driver (kernel space) - Linux device driver for the CAAM (Cryptographic Acceleration and Assurance Module) crypto engine

The following are offloaded in hardware in current SDK:

- protocols: TLS v1.0
- cipher modes:
  - one-shot (a single ioctl for both encryption and authentication): AES128-SHA, AES256-SHA
  - two-shot (two ioctls - one for encryption, the other for authentication): all combinations of AES with SHA1, all combinations of DES and 3DES with SHA1

9.7.2 Building OpenSSL with hardware offloading support

1. Build the `fsl-image-core` rootfs for P4080DS (similar for other platforms); this will automatically deploy OpenSSL with cryptodev-engine support:

```
$ bitbake fsl-image-core
```

2. Boot the board and load the cryptodev kernel module:

```
root@p4080ds:~# modprobe cryptodev
cryptodev: driver 1.8 loaded.
```

3. Check that OpenSSL detected cryptodev:

```
root@p4080ds:~# openssl engine
(cryptodev) BSD cryptodev engine
(dynamic) Dynamic engine loading support
```

9.7.3 Nginx offloading with OpenSSL

In this section, a client-server example will be presented. There are two options of testing and validating the OpenSSL TLS 1.0 Offloading:

- Web Server running on the NXP QorIQ Board and client (e.g. HTTPS browser) on another equipment
- Client running on the NXP QorIQ board and the web server on another equipment

The examples below use "nginx" web server and "openssl s_client" utility as client.

Building a custom OpenSSL and a web server

Both openssl and nginx are build by default with NXP SDK full image. These packages can be added to other images with minor modifications of he image recipes. For example, to add nginx package to the fsl-minimal image add this line to fsl-image-minimal.bb file:

```
IMAGE_INSTALL += "nginx"
```

Nginx does not use any openssl engines by default. Cryptodev must be explicitely mentioned in nginx configuration file to enable hardware offloading:

`/etc/nginx/nginx.conf:`

```
ssl_engine cryptodev;
worker_processes 4;
worker_cpu_affinity 0001 0010 0100 1000; #for 4 Core CPU; For 2 Core CPU worker_cpu_affinity 01
10;
...
    # HTTPS server
    #
    server {
        listen       443;
        server_name  localhost;

        ssl                  on;
        ssl_certificate      server.crt;
        ssl_certificate_key  server.key;
        ssl_session_timeout  5m;
        ssl_protocols  TLSv1;
        ssl_ciphers AES128-SHA:AES256-SHA;
        ssl_prefer_server_ciphers   on;

        location / {
            root   /var/www/localhost/html;
            index  index.html index.htm;
        }
    }
...
```

Worker processes and affinity should be set according to the number of CPU cores available on the platform. Refer to nginx documentation for more details.

Insert cryptodev module and run basic checks

Cryptodev must be probed into the kernel before running crypto acceleration code. Both nginx and s_client will notice cryptodev presence only during their initialization phase.

```
$ modprobe cryptodev
cryptodev: driver 1.8 loaded.
```

```
$ openssl version
OpenSSL (...)
$ openssl engine
(cryptodev) BSD cryptodev engine
(dynamic) Dynamic engine loading support
```

If cryptodev driver is not loaded, openssl will report only dynamic engine support and all operations will be done in software.

Linux kernel can check and report ciphers availability with the help of tcrypt module. After probing tcrypt, crypto algorithms will be listed in /proc/crypto:

```
$ modprobe tcrypt
$ grep tls /proc/crypto
name         : tls10(hmac(sha1),cbc(aes))
driver       : tls10-hmac-sha1-cbc-aes-caam
```

Offloading operations can be monitored with the interrupt counters for CAAM JR and QI interfaces:

```
root@p4080ds:~# cat /proc/interrupts | grep -i qman
108: 0 0 0 0 0 0 0 7508   OpenPIC   108 Level     QMan portal 7
110: 0 0 0 0 0 0 7524 0   OpenPIC   110 Level     QMan portal 6
112: 0 0 0 0 0 7542 0 0   OpenPIC   112 Level     QMan portal 5
114: 0 0 0 0 7565 0 0 0   OpenPIC   114 Level     QMan portal 4
116: 0 0 0 7576 0 0 0 0   OpenPIC   116 Level     QMan portal 3
118: 0 0 7524 0 0 0 0 0   OpenPIC   118 Level     QMan portal 2
120: 0 7535 0 0 0 0 0 0   OpenPIC   120 Level     QMan portal 1
122: 7521 0 0 0 0 0 0 0   OpenPIC   122 Level     QMan portal 0
470: 0 0 0 0 0 0 0 0      OpenPIC   2006 Edge      qman-err
```

The interrupt counters are also incremented on networking operations. Further analysis is required to understand the source of their modification. Some algorithms implemented in CAAM use only the JR interface. For example, these are the JR counters after "openssl speed aes-128-cbc" when using cryptodev:

```
root@p4080ds:~# cat /proc/interrupts | grep jr
 88: 0 0 0 0 26 0 0 0   OpenPIC    88 Level     ffe301000.jr
 89: 0 0 0 0 0 1117204 0 0   OpenPIC    89 Level     ffe302000.jr
 90: 0 0 0 0 0 0 24 0   OpenPIC    90 Level     ffe303000.jr
 91: 0 0 0 0 0 0 0 24   OpenPIC    91 Level     ffe304000.jr
```

Testing TLS

To verify TLS record offload, the minimum setup requires a testing board and a web server with support for TLS1.0, either nginx, apache, lighttpd. We will run the SSL client on the NXP QorIQ board and and download one 100MB file over the network from a web-server.

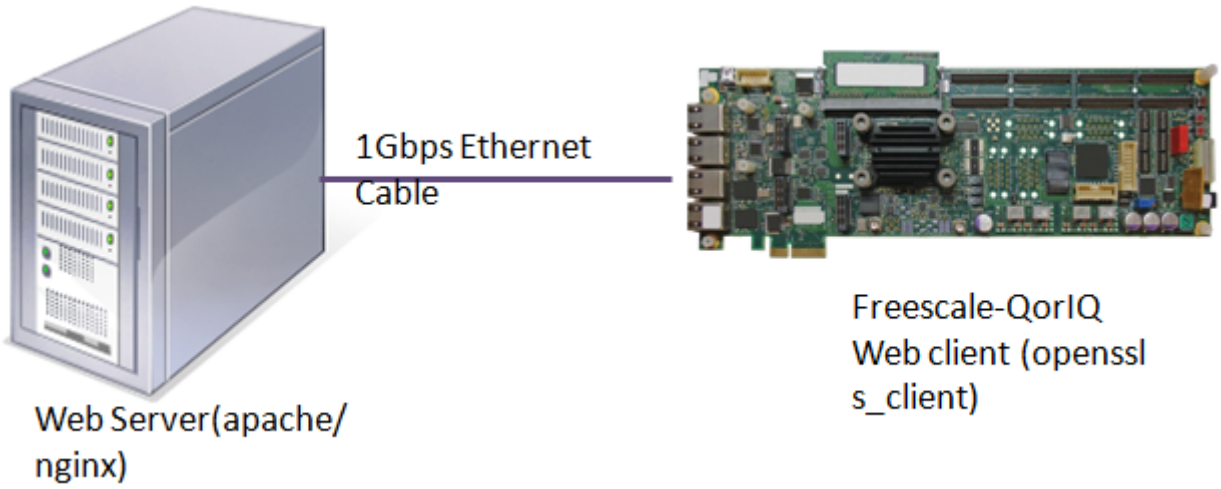

Figure 231. Test setup

Openssl s_client command will be used on the NXP board to make the connection with the server:

```
$ openssl s_client
```

The command can be scripted and run without further intervention:

```
$ echo GET /index.html | openssl s_client -connect <server_ip>:443 -cipher AES128-SHA -tls1 -quiet
```

The option "-quiet" can be removed to see more details about the TLS session.

OpenSSL will transparently use HW acceleration if cryptodev module is loaded in the kernel. If cryptodev module is removed, openssl will not initialize cryptodev engine and will use software implementation.

9.7.4 OpenSSH offloading with OpenSSL

This section describes the steps to enable OpenSSH offloading:

- Configure OpenSSH for QorIQ devices
- Test OpenSSH with OpenSSL Acceleration

Configure OpenSSH for QorIQ devices

By default the SSH server used in NXP images is Dropbear. Dropbear does not have support for hardware acceleration of cryptographic operations. For this reason, a customized QorIQ image have to be built in which we replace Dropbear with OpenSSH. Add the following code to the bitbake file for your image of choice (e.g. fsl-image-minimal.bb):

```
DEPLOY_PKGS = " \
    fm-ucode \
    hv-cfg \
    rcw \
    hypervisor \
    hypervisor-partman \
    openssl \
    openssh \
    openssh-ssh \
    openssh-sftp-server \
    openssh-sshd \
"
IMAGE_INSTALL_append = " ${DEPLOY_PKGS}"
```

```
IMAGE_INSTALL_append = " cryptodev-linux"
IMAGE_INSTALL_append = " cryptodev-module"
```

The bitbake recipe for OpenSSH and the server configuration file must be modified as well:

poky/meta/recipes-connectivity/openssh/openssh_7.1p1.bb

```
EXTRA_OECONF = "'LOGIN_PROGRAM=${base_bindir}/login' \
                ${@base_contains('DISTRO_FEATURES', 'pam', '--with-pam', '--without-pam', d)} \
                --without-zlib-version-check \
                --with-privsep-path=/var/run/sshd \
                --sysconfdir=${sysconfdir}/ssh \
                --with-xauth=/usr/bin/xauth \
                --with-ssl-engine"
```

poky/meta/recipes-connectivity/openssh/openssh/sshd_config

```
Protocol 2
Ciphers aes128-cbc,aes256-cbc
MACs hmac-sha1
```

After completing these steps the customized boot image can be created:

```
$ bitbake fsl-image-minimal
```

Test OpenSSH with OpenSSL Acceleration

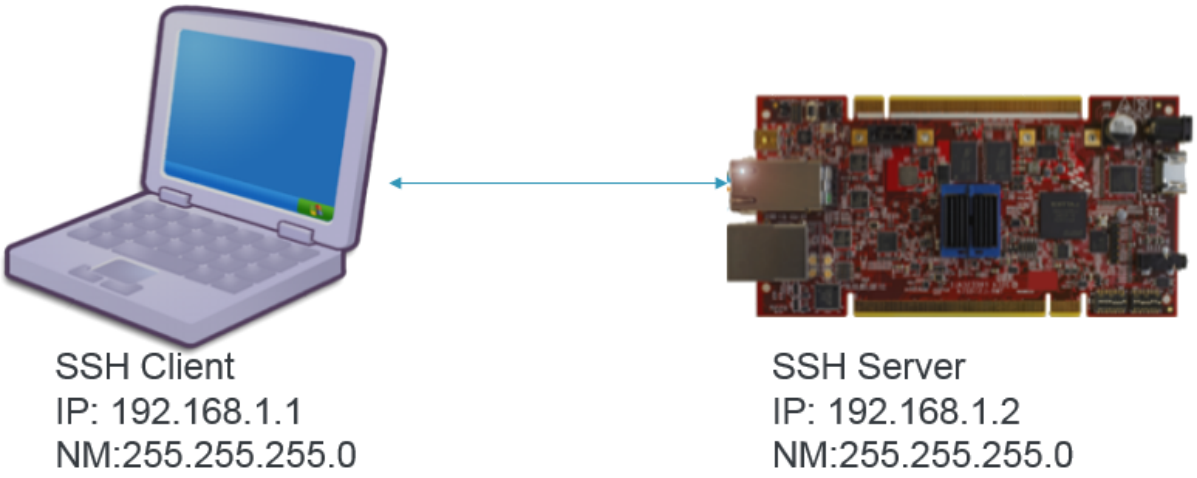

Figure 232. OpenSSH Test setup

Operations to be executed on the QorIQ device:

```
root@p4080ds:~# modprobe cryptodev
cryptodev: driver 1.8 loaded.
root@p4080ds:~# openssl version
OpenSSL (...)
root@p4080ds:~# openssl engine
(cryptodev) BSD cryptodev engine
(dynamic) Dynamic engine loading support
```

If cryptodev driver is not correctly loaded, OpenSSH will not be able to use the hardware acceleration. Cryptographic operations will be executed using the OpenSSL software implementation.

Start the OpenSSH server on the QorIQ device after loading cryptodev kernel module. The OpenSSH server will automatically use cryptodev if available, without any further configuration:

```
root@p4080ds:~# /usr/sbin/sshd -f /etc/ssh/sshd_config
```

Test connectivity between computer and board.

```
[user@host temp] ping 192.168.1.2
PING 192.168.1.2 (192.168.1.2) 56(84) bytes of data.
64 bytes from 192.168.1.2: icmp_seq=1 ttl=64 time=0.234 ms
64 bytes from 192.168.1.2: icmp_seq=2 ttl=64 time=0.104 ms
```

Initial connection to QorIQ Board IP 192.168.1.2.

```
[user@host temp] ssh root@192.168.1.2
The authenticity of host '192.168.1.2 (192.168.1.2)' can't be established.
ECDSA key fingerprint is dc:83:0d:91:d8:e4:bb:f4:76:66:54:6d:52:03:c7:a3.
Are you sure you want to continue connecting (yes/no)?yes
```

Create a test file for SCP on SSH client and transfer the file to board:

```
[user@host temp] dd if=/dev/zero of=file.out bs=1MB count=500
500+0 records in
500+0 records out
500000000 bytes (500 MB) copied, 11.9799 s, 41.7 MB/s
[user@host temp]scp file.out root@192.168.1.2:/var/volatile
file.out            100%  477MB  68.1MB/s   00:07
```

Special Case: If the board gets rebooted, the server key will change. For this reason you will have to delete the initial key that have been stored on the client. Delete the line and restart the SSH Connection:

```
[user@host temp] vi .ssh/known_hosts
[...]
[user@host temp] ssh root@192.168.1.2
The authenticity of host '192.168.1.2 (192.168.1.2)' can't be established.
ECDSA key fingerprint is dc:83:0d:91:d8:e4:bb:f4:76:66:54:6d:52:03:ff:ff.
Are you sure you want to continue connecting (yes/no)?yes
root@p4080ds:~#
```

Offloading operations can be monitored with the interrupt counters for CAAM JR and QI interfaces:

```
root@p4080ds:~# cat /proc/interrupts | grep -i qman
108: 0 0 0 0 0 0 0 7508   OpenPIC   108 Level     QMan portal 7
110: 0 0 0 0 0 0 7524 0   OpenPIC   110 Level     QMan portal 6
112: 0 0 0 0 0 7542 0 0   OpenPIC   112 Level     QMan portal 5
114: 0 0 0 0 7565 0 0 0   OpenPIC   114 Level     QMan portal 4
116: 0 0 0 7576 0 0 0 0   OpenPIC   116 Level     QMan portal 3
118: 0 0 7524 0 0 0 0 0   OpenPIC   118 Level     QMan portal 2
120: 0 7535 0 0 0 0 0 0   OpenPIC   120 Level     QMan portal 1
122: 7521 0 0 0 0 0 0 0   OpenPIC   122 Level     QMan portal 0
470: 0 0 0 0 0 0 0 0      OpenPIC   2006 Edge      qman-err
```

The interrupt counters are also incremented on networking operations. Further analysis is required to understand the source of their modification. Some algorithms implemented in CAAM use only the JR interface. For example, these are the JR counters after "openssl speed aes-128-cbc" when using cryptodev:

```
root@p4080ds:~# cat /proc/interrupts | grep jr
88: 0 0 0 0 26 0 0 0           OpenPIC    88 Level     ffe301000.jr
89: 0 0 0 0 0 1117204 0 0   OpenPIC    89 Level     ffe302000.jr
90: 0 0 0 0 0 0 24 0           OpenPIC    90 Level     ffe303000.jr
91: 0 0 0 0 0 0 0 24           OpenPIC    91 Level     ffe304000.jr
```

9.7.5 TLS Ciphersuites vs TLS protocol version

Table 226. OpenSSL CipherSuite Compatibility

9.8 USDPAA

9.8.1 USDPAA User Guide

9.8.1.1 Introduction

The NXP Data Path Acceleration Architecture comprises a set of hardware components which are integrated via a hardware queue manager and use a common hardware buffer manager. Software accesses the DPAA via hardware components called "software portals". These directly provide queue and buffer manager operations such as enqueues, dequeues, buffer allocations, and buffer releases and indirectly provide access to all of the other DPAA hardware components via the queue manager.

This document describes the User Space Datapath Acceleration Architecture (USDPAA) software. USDPAA is a software framework that permits Linux user space applications to directly access the DPAA queue and buffer manager software portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

9.8.1.1.1 Intended audience

This document is intended for software developers and system architects who work with the USDPAA framework.

The material is technical in nature. The reader is assumed to be familiar with

- General Linux software development, operation, and configuration-- for Power architecture devices in particular.
- The concept of device drivers and their role in operating systems.
- Linux network administration and use.
- The NXP Linux SDK for DPAA-based SoCs.
- At least broadly, the DPAA hardware blocks.

The P4080 was the first NXP SoC to incorporate the DPAA. As such, it is used in many examples. However, USDPAA is intended to apply in the same manner to all DPAA-based SoCs.

9.8.1.1.2 USDPAA overview

As mentioned above, USDPAA is an environment that allows the development of Linux user space applications that have direct access to software portals for the DPAA buffer manager (BMan) and the DPAA queue manager (QMan).

Software portals are memory mapped hardware components. The items within them (message ring, dequeue ring, etc.) have specific addresses in the SoC's physical address map just like regular memory does. USDPAA works by permitting the physical address ranges that correspond to software portals to be mapped into the virtual (technically "effective" in the Power architecture nomenclature) address space of user space processes.Thus, the user space application can use normal load and store instructions to perform operations on the portals.

Portals must be accessed using correct instruction sequences, and also the memory range for the portals must be mapped using the correct cache attributes. For this reason, the USDPAA software includes both the user space driver for the portals and also an access and control API packaged as a user space library.

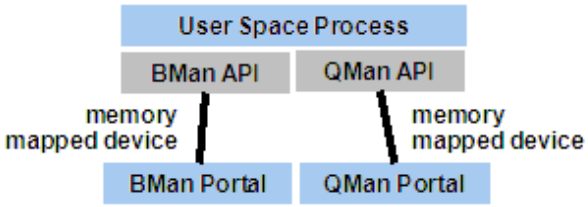

Figure 233. C-Language APIs access memory-mapped devices

The USDPAA framework assumes the context of a single SMP Linux instance on an SoC such as the P4080 . There is no dependence on the NXP Embedded Hypervisor, and this document assumes that it is not used.

Specifically, the SMP Linux instance may contain many user spaces processes. These processes can be (and normally are) multi-threaded using the pthreads facility of Linux. Define a "USDPAA thread" as a thread that has been allocated a BMan and a QMan software portal for its use via direct access. A "USDPAA process" is a Linux user space process that contains at least one USDPAA thread.

Clearly, the number of USDPAA threads is limited by the number of software portals that the particular SoC provides. The P4080 provides 10 QMan and 10 BMan software portals. The available portals must be divided into two sets: portals for use by the Linux kernel and portals for use by USDPAA threads.

9.8.1.1.3 USDPAA and legacy Linux software

This section describes the relationship between USDPAA and various types of legacy software.

9.8.1.1.3.1 Legacy user space applications

USDPAA provides user space processes access to DPAA functionality via user space device drivers and device-oriented C-language APIs layered upon them. Legacy applications must be modified in order to use these APIs. USDPAA's primary goal is to provide these APIs.

As an example, it is possible to offload cryptographic operations to the DPAA Security Engine (SEC) using USDPAA drivers, but this does not imply that all applications that use a cryptography-related legacy Linux facility are automatically accelerated. Software someplace (in user space) must explicitly use the USDPAA functions.

It is possible that some legacy user space facilities could be accelerated in a manner that automatically applies to legacy user space applications if means other than or in addition to USDPAA are used. This topic is, however, beyond the scope of the document.

9.8.1.1.3.2 Relationship to conventional kernel-based drivers

Conventional device drivers reside in the Linux kernel and are accessed via system calls such as read and write. These often (but not always) involve copying data between the application's address space and the kernel's address space. These types of drivers are desirable in many situations.

The existence of USDPAA neither implies nor excludes the existence of conventional drivers. It also implies nothing about whether or not conventional drivers copy data. Mostly, the topic of conventional drivers is beyond the scope of this document. Details will vary among DPAA IP blocks. A few points follow:

- SEC has a job queue interface that can be used concurrently with its QMan interface. The DPAA SDK contains kernel code that does this.
- As figure QMan driver overview on page 1481 shows, The DPAA's Buffer Manager and Queue Manager in-kernel portal drivers support access by multiple entities such as the DPAA kernel ethernet driver. It is possible to create custom conventional kernel drivers that layer on top of the in-kernel portal drivers. These can provide traditional kernel-mediated device access.

9.8.1.2 USDPAA assumptions and use cases

The primary purpose of USDPAA is application performance. User space drivers can provide substantial performance improvement over traditional kernel-mediated access to devices.

- No system calls are needed to do I/O.
- This implies no need to switch into and out of the kernel's execution context.
- User space applications directly access data buffers, thus providing zero copy I/O in all cases.

Because the goal is performance, USDPAA provides simple but low-level access to I/O functionality. It does not employ complex and costly abstractions. Applications deal directly with QMan and BMan via their software APIs. These form a thin but helpful layer between the application and the hardware.

9.8.1.2.1 Assumptions

The USDPAA software makes certain assumptions and supports multiple use-cases. These are detailed in the sections that follow.

9.8.1.2.1.1 General assumptions

- USDPAA threads should be made affine to a core. This is due to support for stashing to per-core caches. (Nothing breaks if this is not the case, but performance will be sub-optimal.)
- Every USDPAA thread has its own BMan and QMan software portals. No other thread or entity accesses these portals. Within the drivers, these are stored as thread-local variables and the locking assumptions depend on them being thread-private.
- USDPAA threads may make use of arbitrary Linux system calls. For example, they can do file I/O.
- USDPAA threads are compatible with general Linux services such as debuggers like gdb.
- Threading is via standard Linux pthreads and the standard Linux GNU C library.

9.8.1.2.2 Use cases

USDPAA is intended to support multiple use-cases, and the supported use-case set will grow with time.

9.8.1.2.2.1 Run-to-completion

The full run-to-completion use case is defined by the following characteristics:

- The number of USDPAA threads per core must not exceed the number of QMan and BMan portals assigned to that core (and reserved for USDPAA use) within the device-tree. Note however that testing with more than one thread per core has been minimal. Not all cores need have a USDPAA thread, however.
- Cores hosting USDPAA threads may be configured to run nothing in user space other than that core's USDPAA thread. For example the kernel parameter "isolcpus" could be used - see CPU isolation on page 1485 for more on this topic.
- The /proc/irq mechanism may be used to limit interrupts for miscellaneous peripherals to non-isolated cores. Again, USDPAA does not require this architecturally, but it is often done.
- In run-to-completion, USDPAA threads poll their portals. Polling generally implies that the USDPAA threads will always be running or ready to run. It would be unusual to have other threads scheduled on the same core when USDPAA threads are in this "non-interactive" mode.

- Often, one thinks of the USDPAA threads as "workers" able to process any form of "work" delivered via QMan messages. In this model, the QMan scheduler can be used as a general "work" scheduler rather than relying on the Linux scheduler for this purpose.

9.8.1.2.2.2 Interrupt-driven

USDPAA supports an interrupt-driven model that allows benefits such as cooperating with other threads on the same core, potential power-saving by not polling all of the time, and so on. This model introduces more operating system overheads and thus trades performance and latency for these benefits.

- The user space drivers for BMan and QMan software portals are implemented using a Linux character device. It permits USDPAA threads to await interrupts from software portals by doing file operations (like "select()") using a file descriptor associated with the user space device. See section QMan and BMan drivers and C API. on page 1481 for more details.
- USDPAA threads process dequeued frames from portals (as much as they like) after an interrupt indicates that data are available. When dequeue processing is complete, the thread re-enables the interrupt.
- This interrupt mechanism allows USDPAA threads to sleep awaiting I/O. Thus, other threads can execute while a particular USDPAA thread sleeps. In this model, it is normal it have multiple threads, USDPAA or otherwise, execute on the same core.
- This use-case is compatible with SCHED_FIFO Linux scheduling. USDPAA is independent of scheduling policy. It is also independent of real-time policy and patches such as PREEMPT_RT.

Application developers may chose the model, run-to-completion or interrupt-driven that best fits their need. The PPAC-based example applications in USDPAA (eg. reflector) implement a hybrid of both modes, where an interrupt-driven mode is used whenever the packet-processing has been idle for a short period of time, and switching back to run-to-completion once processing resumes.

9.8.1.3 USDPAA components

USDPAA consists of several components which may used in the context of standard SMP Linux on the NXP family of DPAA-based SoCs. These components are described below.

9.8.1.3.1 Device-tree handling

Many configuration and resource details are defined within the "device-tree" used to boot Linux. The kernel itself uses this data structure to determine the system's devices and attributes, and USDPAA applications are dependent on the same information. As will be seen, the QMan and BMan portals that are available to USDPAA (and their attributes such as channel IDs) are declared within the device-tree, as are the ethernet interfaces and related attributes from the FMan side of things.

The USDPAA "of" driver[16] parses the device-tree information from the procfs filesystem exported by the Linux kernel (as found at /proc/device-tree/) and constructs an internal data-structure representation of the tree, including interrelationships between device-nodes (eg. portals and CPUs, pool-channels and portals, etc). This information is then used by driver and application-configuration layers where required to obtain device information.

9.8.1.3.1.1 Device-tree initialization requirements

In the current "of" driver implementation, it is the application's responsibility to initialize this driver layer prior to initializing or using any other driver layers that may be dependent on it. This is achieved by calling the of_init() API. To satisfy leak-checkers or to support the use of persistent/reusable processes, an application can also undo all allocations and driver state by calling of_finish().

The "Queue Manager, Buffer Manager API Reference Manual" cover these APIs in more detail, if the above description (and the <usdpaa/of.h> header) are insufficient.

[16] "OF" refers to Open Firmware, the specification behind device-trees, a subject beyond the scope of this document.

9.8.1.3.2 QMan and BMan drivers and C API.

The Queue Manager (QMan) and Buffer Manager (BMan) drivers are the heart of USDPAA. The two drivers are structurally similar in the broadest sense. This discussion will focus on QMan, but the material also applies to BMan.

9.8.1.3.2.1 QMan driver overview

The QMan driver serves two roles:

1. Initialization and management of all aspects of QMan that are not per-portal, i.e. are global.
2. Initialization and management of per software portal QMan operations, i.e. operations that are local to the system component to which the portal is dedicated.

It is reasonable to think of the QMan driver as being split into parts: a QMan global driver and QMan software portal driver. There is only one instance of the global driver per SoC. It is always a kernel-level driver. There is an instance of the software portal driver for every QMan software portal that exists physically on the SoC. For example, P4080 provides 10 QMan software portals. Thus, there are 10 instances of the portal driver available.

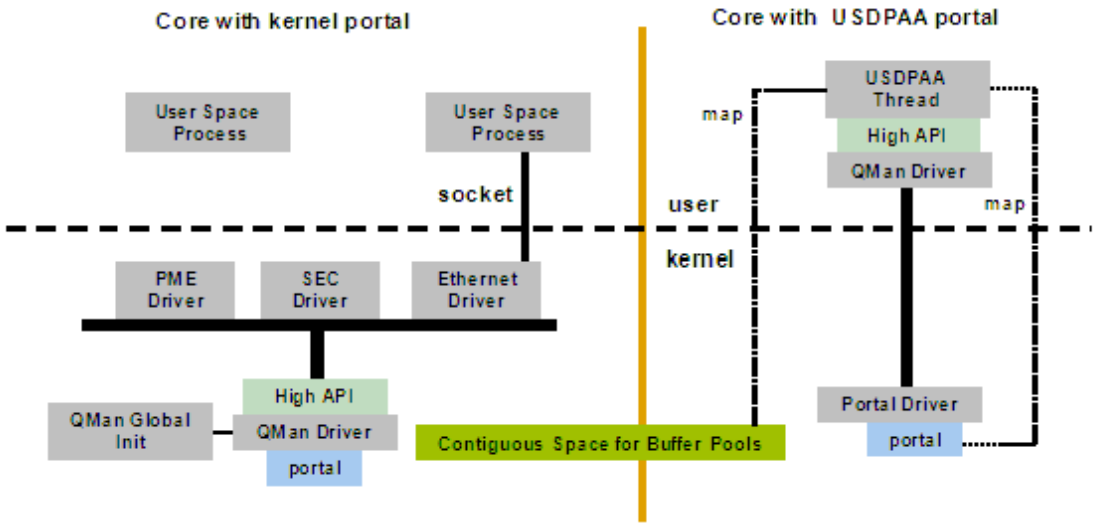

Figure 234. QMan Driver Architecture

As the figure above shows, the software portals (and hence their driver instances) may be dedicated for kernel or or user space use. Essentially the same QMan portal API is presented for both the kernel and the user space instances. Indeed, the same software is used in user space and the kernel.

The kernel driver instances have existing "users" in the kernel. For example, the ethernet driver, the PME driver and (though not in the current release) the SEC driver all use the QMan API to share access to the same physical portal on a core. They all enqueue and queue on the same portal using the API associated with the portal's driver instance. Kernel developers are free to add additional users in the form of additional kernel-level components that share the same portal.

As an aside, the SEC is a special case because it has two interfaces that software can use: the job queue interface, and the QMan interface. With current versions of the DPAA SDK, kernel software uses the job queue interface. User space processes can use the SEC via QMan using their portals.

User space processes access QMan using software portals that are dedicated to user space. To a great extent the QMan API abstracts it, but this access is implemented using standard Linux character devices for user space drivers. It provides /dev entries for devices to be accessed from user space. A user space process opens such a device and requests that the device be mapped directly into the process's address space. The assumption is that the physical device is a conventional memory mapped peripheral - as QMan software portals are. At this point, the process can access the device hardware via normal load and store instructions.

QMan's hardware design requires that portals be mapped with the correct caching attributes for each part of the portal. In addition, careful instruction sequences are needed to ensure that portal operations are carried out correctly. This is due to the hardware's cache stashing support, which provides low-latency access to portals and data dequeued from portals.

The QMan API mentioned above abstracts this and provides software with a convenient method to perform portal operations such as enqueues and dequeues. The QMan API in user space is a library that is layered on top of the USDPAA character device infrastructure. For the user space driver instances, there is

- In user space:
  - The QMan API
  - Direct access to the portal hardware
- In the kernel:
  - The character device code to establish mappings
  - Handle interrupts

This C-callable API is documented in the "Queue Manager, Buffer Manager API Reference Manual" that is distributed with the DPAA SDK software.

One difference in usage of portals in user space versus the kernel is that kernel portals are expected to be persistent. They are brought into service and remain in service so upper layer kernel services such as the ethernet driver can assume that they are there. User space portals are, in contrast, dedicated to an application thread and need to be in service only as long as that thread is running. Thus, the time during which the portal is in service is determined by the application and all uses of the portal are determined by the application.

9.8.1.3.2.2 QMan portals and the Linux device-tree

Since QMan software portals can be dedicated to either the Linux kernel or user space, there must be a mechanism to indicate how each portal will be used.

Linux device trees describe physical resources that are available to Linux and provide information that allows Linux to select drivers for those devices. As such, there are entries in the device tree for all QMan software portals.

The device tree property "fsl,usdpaa-portal" indicates that a given portal is to be made available to user space; the absence of this property implies that the portal will be used only within the Linux kernel.

A listing of two QMan software portal device tree nodes follows. The first portal is used by the kernel. The second is made available to user space.

```
qportal0: qman-portal@0 {
        cell-index = <0x0>;
        compatible = "fsl,p4080-qman-portal", "fsl,qman-portal";
        reg = <0x0 0x4000 0x100000 0x1000>;
        cpu-handle = <&cpu0>;
        interrupts = <104 0x2 0 0>;
        fsl,qman-channel-id = <0x0>;
        fsl,qman-pool-channels = <&qpool1 &qpool2 &qpool3>;
};
qportal1: qman-portal@4000 {
        cell-index = <0x1>;
        compatible = "fsl,p4080-qman-portal", "fsl,qman-portal";
        fsl,usdpaa-portal;
        reg = <0x4000 0x4000 0x101000 0x1000>;
        cpu-handle = <&cpu1>;
        interrupts = <106 0x2 0 0>;
        fsl,qman-channel-id = <0x1>;
        fsl,qman-pool-channels = <&qpool4 &qpool5 &qpool6
                                  &qpool7 &qpool8 &qpool9
                                  &qpool10 &qpool11 &qpool12
                                  &qpool13 &qpool14 &qpool15>;
};
```

There is no mechanism provided to determine what, if anything, user space software will do with a given user space portal. Initially, these portals are present but not initialized. Each user space portal has a /dev entry. It is a USDPAA driver decision as to which portals a given process or thread will use. A portal is placed into use when a user space process or thread requests it via the QMan API.

9.8.1.3.2.3 Note on the current implementation

In the current implementation, portals are bound to cores via the cpu-handle in the portal device tree node. Most commonly, a thread will make itself affine to its portal's core, because stashing for the portal will be targeting that core's cache. Functionality will not break if the thread executes on a different core, because coherency will be maintained, but at the expense of sub-optimal performance (and increased contention between the cores).

Expect more flexibility in this respect in later releases of the QMan software.

9.8.1.3.2.4 Portal initialization requirements

As described in Device-tree initialization requirements on page 1480, the USDPAA "of" driver must be initialised prior to trying to initialize or use QMan or BMan. Once this is done, a pthread that wishes to be initialized with access to a QMan portal should call the qman_thread_init() API, which is defined in the <usdpaa/fsl_usd.h> header along with all other USDPAA-specific QMan/BMan APIs.

Please consult the "Queue Manager, Buffer Manager API reference" for more information.

9.8.1.3.2.5 Buffer Manager (BMan)

The BMan driver and its software support is very similar to QMan's. BMan software portals may be used in the kernel or in user space just like QMan portals. Just as with QMan, the same BMan software API is available in both the kernel and in user space. This API also is defined in the "Queue Manager, Buffer Manager API Reference Manual."

9.8.1.3.2.6 Raw Portal APIs

Raw portal APIs are available to allow USDPAA process to allocate QMan and BMan portals on behalf of another processor. The portals allocated by these APIs are not configured, it is the responsibility of the allocator to do any configuration of the portal that may be needed. The APIs are as follows:

- int qman_allocate_raw_portal(struct usdpaa_raw_portal *portal) - Allocates an unconfigured QMan Portal
- int qman_free_raw_portal(struct usdpaa_raw_portal *portal) - Releases a raw QMan portal that was previously allocated
- int bman_allocate_raw_portal(struct usdpaa_raw_portal *portal) - Allocates an unconfigured BMan portal
- int bman_free_raw_portal(struct usdpaa_raw_portal *portal) - Releases a raw BMan portal that was previously allocated

For detailed information on then usdpaa_raw_portal struct refer to the fsl_usd.h header file.

9.8.1.3.3 DMA memory management

The NXP DPAA hardware provides several peripherals such as FMan, SEC, and PME that read and write memory directly using DMA. Buffers used for peripherals' DMA must be allocated from memory with special properties:

- The memory must be physically contiguous since the peripheral does not access memory via the core's MMU (or any page-mode I/O MMU).
- The memory must be addressable by the peripheral.
- The memory must not be swapped out by Linux while the device is accessing it.
- For user space drivers, there must be an efficient mechanism to convert the physical addresses used by the peripheral hardware to and from the effective addresses used in a user space process or thread's address space.
- For BMan and DPAA usage, it is often convenient for software to allocate memory from physically contiguous regions that are quite large.

- It is desirable to use the Power core's TLB1 mechanism to map large physically contiguous memory regions of this sort. This increases performance by reducing the number of MMU-related interrupts that must be processed. A single TLB0 entry can map only a single 4K page. A single TLB1 entry, in contrast, can map a large (but variable-sized) page. One TLB1 entry can do the work of many TLB0 entries in circumstances such as this one.

Memory that meets the criteria above is called DMA memory. Drivers for all DMA-capable devices must use DMA memory for buffers. This is true for both conventional in-kernel drivers and user space drivers. It is a hardware implication of peripherals' relationships to cores and MMUs.

9.8.1.3.3.1 Current USDPAA solution

The USDPAA Linux kernel reserves a contiguous region of memory very early in the kernel boot process for use as DMA memory. This is done prior to full initialization of the kernel's memory-management subsystem that subsequently inhibits such allocations. This memory reservation is of a size and alignment that is hard-coded into the kernel via the Kconfig option "CONFIG_FSL_USDPAA_SHMEM". Within the kernel's "make menuconfig" interface, this can be found under "Device Drivers" -> "Misc devices" -> "NXP USDPAA shared memory driver". The default is for a 64MB memory reservation.

This same USDPAA kernel driver exposes the reserved memory range via a "/dev/fsl_usdpaa_shmem" character device, which allows the USDPAA application to mmap() the physically-contiguous memory range to a corresponding contiguous range in its virtual address space, thus facilitating trivial virtual/physical address conversions. Additionally, a hook is placed into the memory-management code to "catch" page faults within this memory range and ensure that they are resolved by a single TLB1 mapping that spans the entire memory reservation (rather than the usual 4KB TLB0 mappings). That is, once the USDPAA application has accessed any address within the DMA memory range, no more page faults should occur for any other access within the entire region. Given that USDPAA datapaths of less than 200 processor cycles per packet have been demonstrated, for traffic rates that can consume over 1MB of buffer space in less than a millisecond, we consider that incurring the overhead of page-fault handlers in the kernel when iterating across thousands of pages of memory would likely be too high a price to pay for high performance applications.

The 'fsl_usdpaa_shmem' driver does not automatically constrain the mmap() alignment, so due to the alignment requirements of TLB1 entries, the USDPAA application has to propose virtual base addresses to the kernel rather than letting it allocate them. This will be fixed in a future release. However all of this is encapsulated within the USDPAA "dma_mem" driver. This driver is initialized via the dma_mem_setup() API, which handles the loading and mapping of the DMA memory region. Furthermore, a hard-coded subset of the DMA memory is reserved for buffer pool usage in the USDPAA demo applications, and the rest of it is exposed for general purpose DMA-able memory allocation via the dma_mem_memalign() and dma_mem_free() APIs.

Implementation Note

The USDPAA QMan and BMan APIs always refer to buffers by physical address, as these are what are passed to and from DMA-enabled devices within the Datapath Architecture. So ultimately, any mechanism can be used to provide "DMA memory" to a USDPAA application so long as it allows the application easy access to the memory and an efficient mechanism for converting to and from physical addresses.

Performance considerations will probably also require that page-faults be minimized or eliminated in performance-critical scenarios. The USDPAA "dma_mem" driver (and underlying character device and TLB1 kernel hook) is just one way to achieve this. In future USDPAA releases, it is likely that this will be deprecated in favour of a HugeTLB-based mechanism. In particular, this would help eliminate a limitation of the current USDPAA release, that prevents more than one application instance running at once-- the DMA memory region can only be safely mapped into one process at a time.

9.8.1.3.3.2 DMA memory API

See the <usdpaa/dma_mem.h> header for a simple user space DMA memory API.

- dma_mem_memalign - dynamic allocation of DMA memory from within the large physically contiguous region.
- dma_mem_free - free allocated memory.
- dma_mem_ptov - convert physical to virtual (effective) address within user space process address space.
- dma_mem_vtop - convert virtual (effective) address to physical address.

Expect this API to be expanded in future software releases.

9.8.1.3.4 Network configuration

The USDPAA QMan and BMan drivers do not, in and of themselves, dictate which resources such as frame queues or buffer pools are used. In some cases, they can be dynamically allocated. In other cases, the specific resource is determined by a factor that is external to the USDPAA application itself.

The most common examples relate to the frame manager (FMan) and are discussed in section Relationship to SDK Linux ethernet subsystem on page 1486.

The PPAC-based USDPAA applications ("reflector" and "ipfwd") use the usdpaa_netcfg_acquire() APIto determine the specific resources needed for a network interface. This configuration information is collected from several external sources:

- FMC policy file
- FMC configuration file
- the device-tree

9.8.1.3.4.1 Network configuration initialisation requirements

As described in Device-tree initialization requirements on page 1480, the USDPAA "of" driver must be initialised prior to network configuration being extracted from it. Once this is done, the usdpaa_netcfg_acquire() API, as defined in the <usdpaa/usdpaa_netcfg.h> header, can be used to extract the network configuration. In addition to initialisation of the USDPAA "of" driver layer, this API also requires the path to the two FMC XML files described above (policy and configuration), which are passed as parameters.

To satisfy leak-checkers or to support the use of persistent/reusable processes, an application can also undo all allocations and state by calling usdpaa_netcfg_release(), passing the "info" structure previously returned from usdpaa_netcfg_acquire() as a parameter.

9.8.1.3.5 CPU isolation

USDPAA provides no non-standard Linux features to provide CPU isolation, but the topic is important enough to merit some discussion. Standard Linux features may be use to achieve CPU isolation.

Especially in the run-to-completion use case, it can make sense to dedicate an entire core (which Linux would call a "cpu") to a single USDPAA process or thread. In other words, one wishes to reduce or eliminate any other software use of that particular core.

First, consider user space processes and threads. Linux provides a helpful kernel parameter called "isolcpus". This parameter indicates to the Linux kernel which cores should not have any user space process or thread scheduled onto them by default. The only way that a user space process or thread can execute on an isolated core is by explicit request.

For example, booting the kernel with "isolcpus=1-7" will isolate cores 1 through 7 as shown in the figure below. Note that this isolation is not architecturally required for functionality.

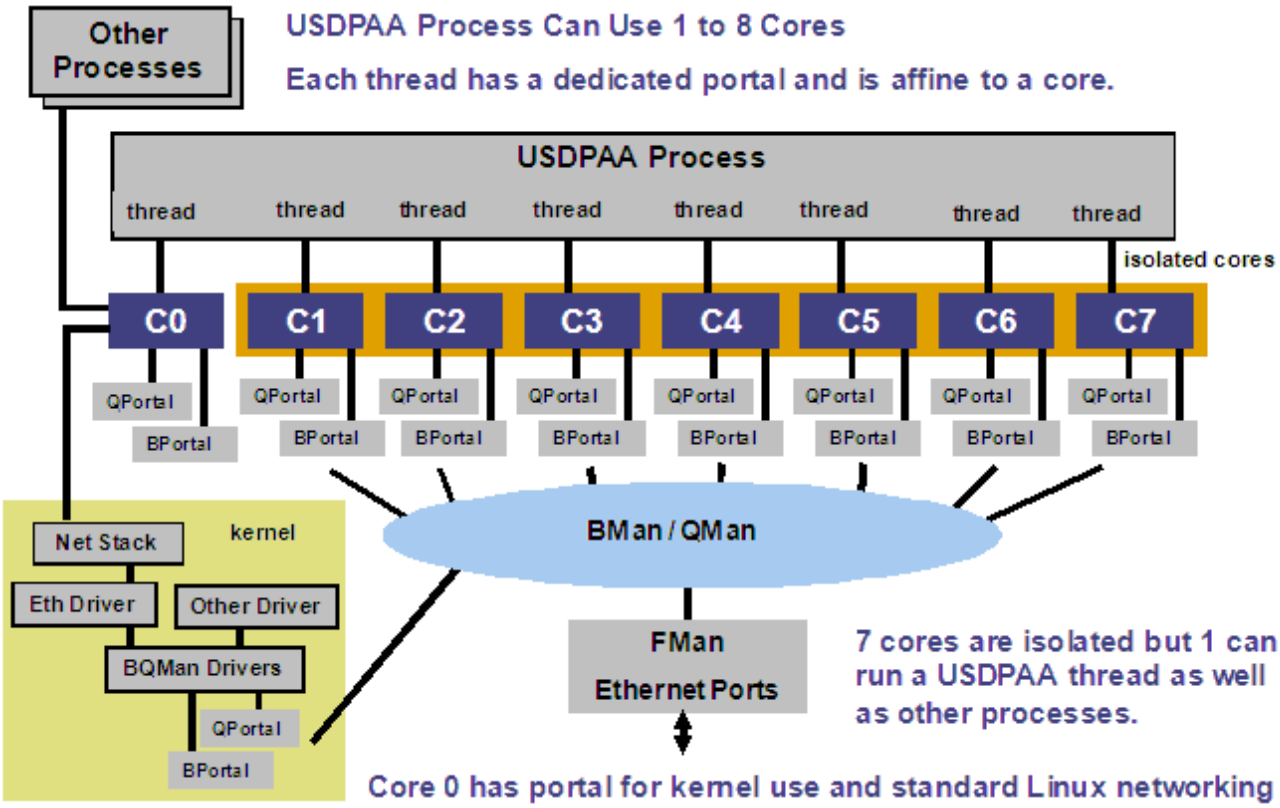

Figure 235. Portal allocation, affinity, and core-isolation

The "isolcpus" kernel parameter is documented (along with others) in the kernel source documentation directory, Documentation/kernel-parameters.txt.

The most convenient way to cause a USDPAA thread to be scheduled on an isolated to core is to use the function pthread_setaffinity_np(). This is a standard Linux pthreads function and "man pthread_setaffinity_np" should give documentation on it. (The "_np", for "non-portable", simply implies that it is not necessarily available in other pthreads implementations on other operating systems.)

The USDPAA example applications also provide an example of this function's use. It is used not only to allow the USDPAA thread to be executed on an isolated core, it makes the thread affine to that core. Recall that affinity is recommended when using the user space QMan and BMan drivers.

Isolation is also a kernel topic. Users who wish to maximize isolation should use the standard Linux interrupt core binding mechanism, /proc/irq to bind interrupts to cores other than those that are isolated. Of course, interrupts associated with portals bound to cores should be bound to that core.

9.8.1.4 Relationship to SDK Linux ethernet subsystem

The DPAA SDK FMan and Linux kernel ethernet driver software is defined as external to the USDPAA software for this release. However, USDPAA, the ethernet driver in the kernel, and the FMan software are all interrelated. The figure below shows four use cases involving the three components.

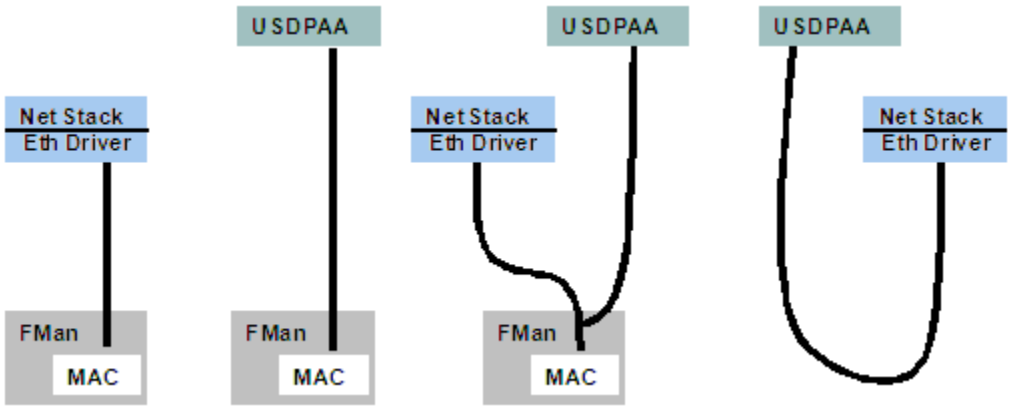

Figure 236. USDPAA, FMan, ethernet use cases

1. QMan connects FMan MAC only to the kernel ethernet driver, which exchanges frames with the Linux network stack.
2. QMan connects an FMan MAC only to a USDPAA application.
3. QMan connects an FMan MAC to both the kernel driver and to a USDPAA application. On ingress, FMan selects the destination for each frame and enqueues it onto a particular frame queue accordingly. Different frame queues make the connections between the MAC and the ethernet driver and the MAC and the USDPAA application. This use case can be generalized by assuming multiple USDPAA applications, multiple ethernet driver instances, or both.
4. QMan connects an ethernet driver to a USDPAA application. FMan is not involved. Note that it is possible to accomplish this via the standard Linux facility TUN/TAP rather than using QMan.

The current release of USDPAA demonstrates cases 1 and 2.

9.8.1.4.1 Selecting ethernet interfaces for USDPAA

As will be discussed below, the ethernet driver is always involved in configuring FMan. This is true even for the second use case above in which the ethernet driver does not directly use FMan. Instead, the ethernet driver is creating an interface for another entity to use. Historically in the SDK that other entity was the LWE. In the current release, that other entity is a USDPAA application. The FMan and ethernet subsystem is actually unchanged from the standard DPAA SDK.

It is ethernet-related Linux device tree entries that determine the use case. This is documented in the "P4080 DPAA Device Bindings" distributed with the DPAA SDK. The sub-topic is "Data-Path Acceleration Assist".

The following device tree snippet shows a Linux private interface and also an interface used privately by USDPAA.

```
ethernet@0 {
   compatible = "fsl,p4080-dpa-ethernet-init", "fsl,dpa-ethernet-init";
   fsl,bman-buffer-pools = <&bp7 &bp8 &bp9>;
   fsl,qman-channel = <&qpool4>;
   fsl,qman-frame-queues-rx = <0x50 1 0x51 1>;
   fsl,qman-frame-queues-tx = <0x70 1 0x71 1>;
   fsl,fman-mac = <&enet0>;
};
ethernet@1 {
   compatible = "fsl,p4080-dpa-ethernet", "fsl,dpa-ethernet";
   fsl,qman-channel = <&qpool1>;
   fsl,fman-mac = <&enet1>;
};
```

The first ethernet is used by USDPAA. The second is used by the Linux ethernet driver.

Table 227. P4080DS ethernet interfaces

Deice Tree Name	U-boot Name	U-Boot MAC Environment Variable	Linux Name (udev)	SerDes 0xe Physical Position
ethernet@0	FM1@DTSEC1	ethaddr	fm1-gb0	not used
ethernet@1	FM1@DTSEC2	eth1addr	fm1-gb1	Motherboad RGMII
ethernet@2	FM1@DTSEC3	eth2addr	fm1-gb2	not used
ethernet@3	FM1@DTSEC4	eth3addr	fm1-gb3	not used
ethernet@4	FM1@TGEC1	eth4addr	fm1-10g	slot 5 XAUI
ethernet@5	FM2@DTSEC1	eth5addr	fm2-gb0	not used
ethernet@6	FM2@DTSEC2	eth6addr	fm2-gb1	not used
ethernet@7	FM2@DTSEC3	eth7addr	fm2-gb2	slot 3 SGMII 2nd closest to motherboard
ethernet@8	FM2@DTSEC4	eth8addr	fm2-gb3	slot 3 SGMII closest to motherboard
ethernet@9	FM2@TGEC1	eth9addr	fm2-10g	slot 4 XAUI

The DPAA SDK uses different names for different physical ethernet interfaces in different contexts. This is due to long-standing decisions on naming conventions, many not made by NXP. It can be confusing. See table above for a list of all of the ethernet interfaces on the P4080 and their names in all of the important contexts. For P4080, no single SerDes protocol number provides access to all of the ethernets at the same time. This is due to pin multiplexing reasons.

The example defaults assume the use of the SerDes 0xe because it gives a total of 23 Gbps of ethernet connectivity on the P4080DS. The table shows which ethernet interfaces are used in SerDes 0xe.

9.8.1.4.2 FMC, FMD, and the ethernet Driver

The Frame Manager (FMan) software in the DPAA SDK is divided into a user space component (FMC) and a kernel component (FMD). The latter is the FMan driver in the conventional sense. FMD provides a capable API to support FMan configuration.

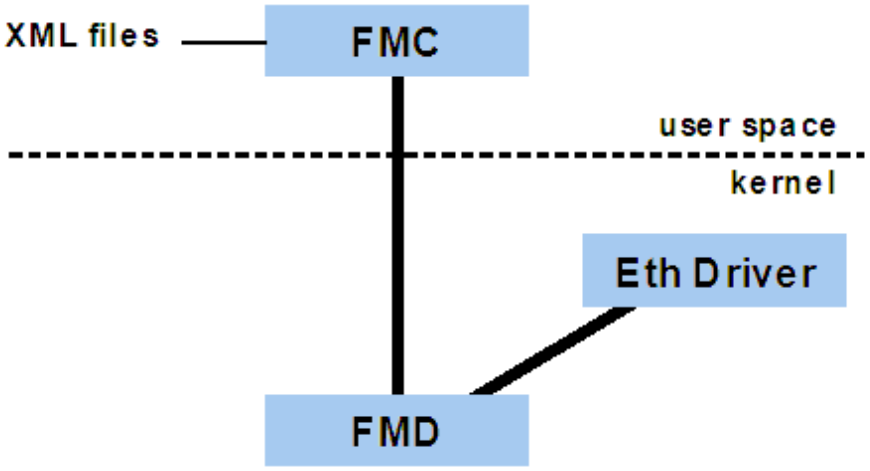

Figure 237. FMC, FMD, and ethernet

By itself, the ethernet driver uses FMD to configure only very simple FMan use cases. Basically, it configures only the default and error frame queues for ingress and egress. Doing more requires running the "fmc" user space application.

This application reads xml files as input and can establish more complex use-cases such as parsing incoming frames and hashing them into a set of frame queues for distribution to multiple cores (meaning USDPAA threads in the context of this document).

Various USDPAA example applications provide XML files and assume that fmc will be run. This usage is described in the application user guides.

9.8.1.5 Supported hardware platforms

This USDPAA release is tested in the following environments:

9.8.1.5.1 P4080DS

- P4080 revision 2 SoC. (Revision 1 is not supported.)
- The main test configuration
  - SGMII card in slot 3 with two interfaces used.
  - XAUI card in slot 4 (but the reflector example will work without it)
  - XAUI card in slot 5 (but the reflector example will work without it)
- SerDes protocol 0xe is the main test case. It provides
  - 1 x 1G ethernet port (via RGMII) used by the Linux kernel network stack.
  - 2 x 1G ethernet ports (via SGMII) used by USDPAA.
  - 2 x 10G ethernet ports (via XAUI) used by USDPAA.
- Testing is done with P4080 high bin clocking:
  - 1500 MHz core, 800 MHz platform, 1300 MHz DDR rate, 600 MHz FMan and PME
- Memory, 4 GB (but 8 GB should work also).
- Linux 8-way SMP.
- All caches (core-private L1/L2 and shared L3) are enabled. No locking or cache partitioning is used.

9.8.1.5.2 P3041DS

- SerDes protocol 0x36 (RR_HXAPNSP_0x36) is the main test case. It provides
  - 2 x 1G ethernet port (via RGMII) used by USDPAA.
  - 3 x 1G ethernet ports (via SGMII) used by USDPAA.
  - 2 x 10G ethernet ports (via XAUI) used by USDPAA.
- no interfaces used/available for the Linux kernel network stack.
- Testing is done with the rcw_15g_1500mhz:
  - 1500 MHz core, 750 MHz platform, 1333 MHz DDR rate, 583 MHz FMan and 375 MHz PME

9.8.1.5.3 P5020DS

- SerDes protocol 0x36 (RR_HXAPNSP_0x36) is the main test case. It provides
  - 2 x 1G ethernet ports (via RGMII) used by USDPAA.
  - 3 x 1G ethernet ports (via SGMII) used by USDPAA.
  - 1 x 10G ethernet port (via XAUI) used by USDPAA.
  - no interfaces used/available for the Linux kernel network stack.
- Testing is done with the rcw_15g_2000mhz:
  - 2000 MHz core, 800 MHz platform, 1333 MHz DDR rate, 600 MHz FMan and 400 MHz PME

9.8.1.5.4 P5040DS

- SerDes protocol 0x02 (RR_XXSNSpP_0x02) is the main test case. It provides
  - 2 x 1G ethernet ports (via RGMII) used by USDPAA.
  - 4 x 1G ethernet ports (via SGMII) used by USDPAA.
  - 2 x 10G ethernet port (via XAUI) used by USDPAA.
  - no interfaces used/available for the Linux kernel network stack.
- Testing is done with the rcw_26g_2267mhz.bin:
  - 2267 MHz core, 800 MHz platform, 1600 MHz DDR rate, 600 MHz FMan and 400 MHz

9.8.1.5.5 P2041RDB

- SerDes protocol 0x09 (RR_PX_0x09) is the main test case. It provides
  - 2 x 1G ethernet ports (via RGMII) used by USDPAA.
  - 2 x 1G ethernet ports (via SGMII) used by USDPAA.
  - 1 x 10G ethernet port (via XAUI) used by USDPAA.
  - no interfaces used/available for the Linux kernel network stack.
- Testing is done with the rcw_14g_1500mhz:
  - 1500 MHz core, 750 MHz platform, 1333 MHz DDR rate, 583 MHz FMan and 400 MHz PME

9.8.1.5.6 B4860QDS

- SerDes protocol 2a and 49 (N_NNSS_0x2A_0x49) is the main test case. It provides
  - 4 x 1G ethernet port (via SGMII) used by USDPAA.

- 1 x 1G ethernet port (via SGMII) used/available for the Linux kernel network stack.

- Testing is done with the rcw_5sgmii_1600mhz.bin:
  - 1600 MHz core, 666.667 MHz platform, 800 MHz DDR rate, 666.667 MHz FMan and 333.333 MHz QMan.

9.8.1.5.7 T4240QDS

- SerDes protocol RR_XXXXPRPR_1_1_6_6 is the main test case. It provides
  - 2 x 1G ethernet ports (via SRIO) used by USDPAA.
  - 4 x 10G ethernet port (via XAUI) used by USDPAA.
  - 2 x 1G ethernet ports (via PCIe) used/available for the Linux kernel network stack.
- Testing is done with the rcw_1_1_6_6_1666MHz.bin:
  - 1666.667 MHz core, 666.667 MHz platform, 800 MHz DDR rate, 400 MHz FMan and 333.333 MHz PME

9.8.1.6 Example applications

USDPAA will be distributed with a set of example applications that is expected to grow over time.

The current set is

- A packet reflector application, "reflector".
- An IP forwarding performance demonstration, "ipfwd".
- A cryptographic accelerator example, "simple_crypto".
- A pattern-matching accelerator example, "pme_loopback_test".
- An IPFwd application based upon Longest Prefix Match methodology, "lpm_ipfwd".
- An application to route IPv4 packets after performing encryption/decryption, "IPSecfwd".
- A non-PPAC based stand-alone application, "hello_reflector".

Each example has its own user manual.

9.8.1.7 USDPAA installation and execution

The USDPAA software is contained within the SDK release, and should be compiled and installed by default by following the general instructions accompanying the release. Those instructions will not be reproduced here in their entirety. All that should be required to bring up and run the USDPAA environment, compared to booting the "standard" Linux system from the SDK, is to use the USDPAA-specific device tree. Eg. on the P4080DS system, one should use "uImage-p4080ds-usdpaa.dtb" instead of "uImage-p4080ds.dtb". Other than that, please follow the steps prescribed in the SDK installation notes. The following sections reproduce some of these steps (for the P4080DS case only), but primarily to ensure that USDPAA-relevant information is correctly identified.

9.8.1.7.1 Files needed to boot Linux on the P4080DS system

To run the USDPAA software, one must first boot Linux with the correct files;

- R_PPSXX_0xe/**rcw_2sgmii_1500mhz.bin**

  Reset configuration word (rcw) that selects the SerDes Protocol, suitable to program into the P4080DS NOR flash.

- **u-boot-P4080DS.bin**

  U-Boot bootloader image suitable to program into the P4080DS NOR flash.

- **fsl_fman_ucode.bin**

  FMan microcode for appropriate P4080 silicon suitable to program into the P4080DS NOR flash.

- **uImage-p4080ds.bin**

  Linux kernel supporting USDPAA.

- **uImage-p4080ds-usdpaa.dtb**

  Device tree file configured for USDPAA usage.

- **fsl-image-core-p4080ds.ext2.gz.u-boot**

  File system (used in RAM disk) that contains the needed user space files including USDPAA example application binaries. Linux must be booted using this file system.

All six of the files listed above are needed to run USDPAA. The first three must be programmed into the P4080DS NOR flash. The last three may be programmed into the NOR flash, but also may be loaded into RAM by u-boot using the tftp protocol.

U-boot is also capable of loading files into RAM via tftp and then programming them into the NOR flash. In all cases, you must have access to a tftp server, ideally on your Linux development host.

Copy the six files listed above to a directory from which they can be accessed via your tftp server. U-boot on the P4080DS must use tftp to access them. Details of installing and configuring a tftp server on your development host are specific to your host Linux distribution.

9.8.1.7.2 About U-Boot and network interfaces

U-boot is a bootloader. It is very flexible. but its main job is to do quite a bit of system configuration and then to load an operating system image (mainly Linux) into RAM and transfer control to it.

One of the simplest ways of transferring images (and other files) to the P4080DS running u-boot is to use tftp. For this to work, you must configure a network interface in u-boot.

Specifically, we assume that the 1 Gbps ethernet interface on the P4080DS motherboard will be used, and that the RCW file used causes this interface to correspond to the 2nd DTSEC in the P4080's first FMan instance.

At this point, we list for reference the text that U-boot should print when it runs. Note that there can be some variation in what U-boot prints.

```

FM1@DTSEC2, FM1@TGEC1, FM2@DTSEC3, FM2@DTSEC4, FM2@TGEC1
```

In the above text, notice the final line;

```
FM1@DTSEC2, FM1@TGEC1, FM2@DTSEC3, FM2@DTSEC4, FM2@TGEC1
```

It lists the available network interfaces, which is determined by the RCW file and the SerDes protocol that it selects. This document assumes that SerDes 0xe is used. It provides the interfaces above. They will be used as follows.

- FM1@DTSEC2, U-boot MAC "eth1addr"

  This is the 1 GBps ethernet interface on the P4080DS motherboard. It will be used by U-Boot to transfer images and also is available in Linux as a standard ethernet interface. The "ifconfig" command will show it as "fm1-gb1" because the "gb's" are counted from zero.

- FM1@TGEC1 (slot 5 XAUI), U-boot MAC "eth4addr"
- FM2@DTSEC3 (slot 3 SGMII, 2nd closest to motherboard), U-boot MAC "eth7addr"
- FM2@DTSEC4 (slot 3 SGMII, closest to motherboard), U-boot MAC "eth8addr"
- FM2@TGEC1 (slot 4 XAUI), U-boot MAC "eth9addr"

  These other 4 interfaces, 2 x 1 GB and 2 x 10 GB, are dedicated to user space access via USDPAA.

This provides the USDPAA application with 22 Gbps of full-duplex ethernet capacity, assuming that an SGMII card is in P4080DS slot 3, and 10G XAUI cards are in slots 4 and 5. The USDPAA "reflector" application will function if the XAUI cards are not present, but only two GB of capacity will be available.

The P4080 has many ethernet interfaces. See Selecting ethernet interfaces for USDPAA on page 1487 for a complete summary of the names of these interfaces in different software contexts and for a statement of their use by the SerDes 0xe protocol on the P4080DS.

Returning to u-boot, selection of the network interface and networking parameters is done via u-boot environment variables. These are set using the "setenv" command that can be entered at the u-boot prompt. The network parameters include MAC addresses for the interfaces. Set them for all ten of the P4080 interfaces even though only a subset will be used.

Here is a complete list of the needed setenv commands. You will have to adjust the IP addresses and netmask to match your network. The addresses shown below are examples only.

```
setenv ethact FM1@DTSEC2
setenv ethaddr 00:04:9F:77:4E:00
setenv eth1addr 00:04:9F:77:4E:01
setenv eth2addr 00:04:9F:77:4E:02
setenv eth3addr 00:04:9F:77:4E:03
setenv eth4addr 00:04:9F:77:4E:04
setenv eth5addr 00:04:9F:77:4E:05
setenv eth6addr 00:04:9F:77:4E:06
setenv eth7addr 00:04:9F:77:4E:07
setenv eth8addr 00:04:9F:77:4E:08
setenv eth9addr 00:04:9F:77:4E:09
setenv ipaddr 10.82.146.151
setenv serverip 10.82.146.150
setenv gatewayip 10.82.146.150
setenv netmask 255.255.255.0
saveenv
```

In summary, U-boot will use the motherboard ethernet and will give it IP address 10.82.146.151. The tftp server has IP address 10.82.146.150. The "saveenv" saves all environment variable values into flash so they are retained after a reboot.

After entering the values above, you can test the U-boot network connection via ping and a trial tftp transfer. If this does not work, check the variables and network cables. This must work. Here is a text capture showing a successful test. You may need to adjust the path usdpaa/u-boot.bin per your tftp server configuration.

```
=> ping $serverip
Using FM1@DTSEC2 device
host 10.82.146.150 is alive
=> tftpboot 01000000 usdpaa/u-boot.bin
Using FM1@DTSEC2 device
TFTP from server 10.82.146.150; our IP address is 10.82.146.151
Filename 'usdpaa/u-boot.bin'.
Load address: 0x1000000
Loading: ###################################
done
Bytes transferred = 524288 (80000 hex)
```

9.8.1.7.3 P4080DS NOR flash banks

The P4080DS board has a feature that uses address swizzling to make it appear that the NOR flash is divided into multiple parts-- this document will assume two. The parts are called "bank 0" and "bank 4".

When you power-on or reset, u-boot will boot from bank 0. U-boot in bank 0 can program images into bank 4. Then, you can enter "pixis altbank" from the bank 0 u-boot prompt to boot into bank 4.

It is very wise to leave the bank 0 images alone and simply use them to program images into bank 4. This is to ensure that you always have working images in bank 0. This document will assume that you have u-boot flashed in bank 0. Use it only to program bank 4.

Look at the u-boot output in About U-Boot and network interfaces on page 1492. The line

```
Board: P4080DS, Sys ID: 0x17, Sys Ver: 0x01, FPGA Ver: 0x0b, vBank: 4
```

shows the bank from which u-boot was booted. In this case it was bank 4 (per vBank).

9.8.1.7.4 Programming the P4080DS NOR flash bank 4

First, boot from bank 0 by doing a reset or power-on. Check that you see "vBank: 0" since this is very important. Then, set network parameters using the u-boot environment variables described in section About U-Boot and network interfaces on page 1492.

The following U-boot commands will flash all six of the needed files into bank 4. Remember that you may have to adjust the paths in the tftpboot commands per your tftp server.

```
# BE BOOTED FROM BANK 0; WE WILL FLASH THE ALT BANK, WHICH WILL BE BANK 4

# rcw altbank
tftpboot 0x01000000 usdpaa/rcw_2sgmii_1500mhz.bin
protect off 0xec000000 +$filesize && erase 0xec000000 +$filesize && cp.b 0x01000000 0xec000000
$filesize

# u-boot altbank
tftpboot 0x01000000 usdpaa/u-boot.bin
protect off 0xebf80000 +$filesize && erase 0xebf80000 +$filesize && cp.b 0x01000000 0xebf80000
$filesize

# Delete altbank the u-boot env-- use default
protect off 0xebf60000 +0x20000 && erase 0xebf60000 +0x20000

# FMan u-code altbank
tftpboot 0x01000000 usdpaa/fsl_fman_ucode.bin
protect off 0xeb000000 +$filesize && erase 0xeb000000 +$filesize && cp.b 0x01000000 0xeb000000
$filesize

# device tree alt bank
tftpboot 0x01000000 usdpaa/p4080ds-usdpaa.dtb
protect off 0xec800000 +$filesize && erase 0xec800000 +$filesize && cp.b 0x01000000 0xec800000
$filesize

# kernel altbank
tftpboot 0x01000000 usdpaa/uImage
protect off 0xec020000 +$filesize && erase 0xec020000 +$filesize && cp.b 0x01000000 0xec020000
$filesize

# rootfs altbank
tftpboot 0x01000000 usdpaa/initramfs.cpio.gz.uboot
protect off 0xed300000 +$filesize && erase 0xed300000 +$filesize && cp.b 0x01000000 0xed300000
$filesize
```

9.8.1.7.5 Boot into bank 4 and set more variables

Next, enter the command "pixis altbank" to boot into bank 4 and press "any key" to stop the boot. Check that u-boot prints "vBank: 4". It is important that it does. If not, there is probably a mistake in the previous steps.

At this point, you must enter all of the networking u-boot environment variables (see section About U-Boot and network interfaces on page 1492) again and also set variable bootcmd. The latter is shown below along with a "saveenv" to save the values.

```
setenv bootcmd setenv bootargs root=/dev/ram rw console=ttyS0,115200 usdpaa_mem=256M
bportals=s0-1 qportals=s0-1 \; bootm 0xe8020000 0xe9300000 0xe8800000
saveenv
```

It is important that you type the backslash (\) because semicolon (;) is a command separator in u-boot. Here is a "printenv bootcmd" in a larger font and with line wrap showing the correct value. Note that the printenv does not show the backslash.

```
=> printenv bootcmd
bootcmd=setenv bootargs root=/dev/ram rw console=ttyS0,115200 usdpaa_mem=256M bportals=s0-1
qportals=s0-1 ; bootm 0xe8020000 0xe9300000 0xe8800000
```

U-boot has an environment variable "bootdelay" that controls the number of seconds u-boot counts down before automatically running command "boot". If you prefer to run "boot" manually, set bootdelay to -1. This will cause u-boot to go directly to a command prompt. You can set bootdelay to whatever you want.

```
setenv bootdelay -1
saveenv
```

9.8.1.7.6 Environment variable hwconfig and optical 10G

At this point , enter the u-boot command "printenv hwconfig" as shown below.

```
=> printenv hwconfig
hwconfig=fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you see the value above, and you plan to use the 10G copper interfaces (or no 10G at all), then all is well. You may skip to the next section.

If you plan to use optical 10G interfaces, you must add information to hwconfig. This is important. The optical interface will operate erratically without it. It is easiest to do this using the u-boot "editenv" command. Whatever you type will be appended to hwconfig. The text you need to append is

```
;fsl_fm2_xaui_phy:xfi;fsl_fm1_xaui_phy:xfi
```

The leading semicolon is needed. Do another "printenv hwconfig" to ensure that the value is correct and then a saveenv as shown below.

```
=> printenv hwconfig
hwconfig=fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm2_xaui_phy:xfi;fsl_fm1_xaui_ph
y:xfi
=> saveenv
```

9.8.1.7.7 Booting Linux

At this point, you need to reset once again into bank 4 (u-boot command "pixis altbank") and run the u-boot "boot" command, either manually or by letting it happen automatically after the count-down.

Linux will boot and give you a login prompt.

Login as user "root" with password "root".

An "ifconfig -a" should show only one FMan (fm) ethernet interface, fm1-gb1. This is the P4080DS motherboard 1G ethernet interface. You can set its IP address and use it as an ordinary Linux network interface if you wish.

If you cat /root/SOURCE_THIS, you will see the commands needed to run the "reflector" example application. This is the first application you should examine. Please see its user manual for more information.

```
[root@p4080 /root]# cat /root/SOURCE_THIS
cd /usr/etc
fmc -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst.xml -a
reflector
```

9.8.1.7.8 Using tftp for the kernel, device-tree, and file-system

It can be slow to reflash the kernel, device tree, and file system every time you run ltib to change a USDPAA application (see section Known limitations on page 1498). As an alternative, you can use the following u-boot commands (from bank 4) to boot Linux.

```
tftpboot 01000000 usdpaa/uImage
tftpboot 02000000 usdpaa/p4080ds-usdpaa.dtb
tftpboot 02100000 pusdpaa/initramfs.cpio.gz.uboot
boot
```

However, in this case the addresses in the "bootm" run by bootcmd need to be different. So, set bootcmd as follows.

```
setenv bootcmd setenv bootargs root=/dev/ram rw console=ttyS0,115200 usdpaa_mem=256M
bportals=s0-1 qportals=s0-1 \; bootm 01000000 02100000 02000000
saveenv
```

9.8.1.8 Using configurations other than SerDes 0xe

Most NXP testing, examples, and discussion of examples in documentation assumes the use of SerDes 0xe and 22 Gbps of ethernet connectivity to USDPAA in the form of 2 x 1 Gbps + 2 x 10 Gbps.

It is possible to use USDPAA in other configurations and some examples will be summarized below.

See the document "NXP DPAA SDK <version>: Selecting Ethernet Interfaces" for background information. It is distributed with the NXP DPAA SDK.

9.8.1.8.1 SGMII (4 x 1 Gbps) card and one XAUI (10 Gbps) card

Goal (using Linux names for network interfaces, see Selecting ethernet interfaces for USDPAA on page 1487):

- fm1-gb1 used by Linux kernel
- fm2-gb2 used by USDPAA
- fm2-gb3 used by USDPAA
- fm2-10g used by USDPAA

Method:

- SGMII card goes in P4080DS slot 3.
- XAUI card goes in P4080DS slot 4.
- Continue to use SerDes 0xe and RCW file R_PPSXX_0xe/rcw_2sgmii_1500mhz.bin in the P4080DS NOR flash.
- Boot into bank 4 (assuming you are using bank 4 for USDPAA).
- Add text ";serdes:fsl_srds_lpd_b3=0xf" to u-boot environment variable hwconfig, saveenv, and reset the system again into bank 4. This disables fm1-10g. The leading ";" separates the information added to hwconfig from what was already there.

- Delete references to fm1-10g from the fmc configuration file you will use. For example, delete the following text from it:

```
<engine name="fm0">
          <port type="10G" number="0" policy="hash_ipv4_policy_4"/>
</engine>
```

Run the USDPAA application.

9.8.1.8.2 SGMII (4 x 1 Gbps) card and no XAUI (10 Gbps) card

Goal (using Linux names for network interfaces, see table Selecting ethernet interfaces for USDPAA on page 1487):

- fm1-gb1 used by Linux kernel
- fm2-gb0 used by USDPAA
- fm2-gb1 used by USDPAA
- fm2-gb2 used by USDPAA
- fm2-gb3 used by USDPAA

Method:

- SGMII card goes in P4080DS slot 3.
- Use SerDes 0x10 and RCW file: R_PPSXN_0x10/**rcw_5g_1500mhz.bin** in the P4080DS NOR flash. This is a different RCW file than the one discussed above.
- Boot into bank 4 (assuming you are using bank 4 for USDPAA).
- Add text ";serdes:fsl_srds_lpd_b2=0xf" to u-boot environment variable hwconfig, saveenv, and reset the system again into bank 4. This disables fm2-10g. The leading ";" separates the information added to hwconfig from what was already there. Note that fm1-10g is never available in SerDes 0x10.
- Delete references to any of the 10 Gbps interfaces and ensure references to all USDPAA 1 Gbps interfaces are present in the fmc configuration file. For example, it should like the following after you edit it:

```
<cfgdata>
    <config>
        <engine name="fm1">
                <port type="1G" number="0" policy="hash_ipv4_policy_5"/>
                <port type="1G" number="1" policy="hash_ipv4_policy_6"/>
                <port type="1G" number="2" policy="hash_ipv4_policy_7"/>
                <port type="1G" number="3" policy="hash_ipv4_policy_8"/>
        </engine>
    </config>
</cfgdata>
```

Run the USDPAA application.

9.8.1.9 Known limitations

- Interrupts for QMan and BMan portals used in user-space by USDPAA threads are not necessarily affine to the CPU to which the portal is assigned (ie. to the portal where stashing is performed and where the threads are advised to be affine). This is a current limitation of the UIO interface in the kernel which does not give the QMan/BMan drivers explict control over interrupt affinity. However given that interrupts are generally used to implement sleeping/blocking semantics (eg. when idle), this is not expected to have a significant impact. As a workaround, if the need arises, the user can manually override the interrupt-affinity via the procfs controls available at /proc/irq.
- Only 1 Gbps full-duplex operation is supported on 1 Gbps ethernet links. It is also true that 10 Gbps links may only be used at 10 Gbps, but in this case the reason is a P4080DS board-level hardware limitation.

- Present release does not permit working with all four SGMII 1 Gbps ethernet ports and a XAUI 10 Gbps ethernet port at the same time. This would appear possible using SerDes 0x10, but it is not due to FMan buffer size constraints and support for jumbo frames. This is, at heart, a P4080 SoC hardware limitation, but future releases will provide greater flexibility.

9.8.1.10 Document history

Table 228. Document history

Rev	Notes
1.0	Initial version.
1.1	FQID detail and more.
1.2	Description of proof-of-concept added.
1.3	Add TX FQIDs and discussion of application timing
1.4	Documentation of configuration files.
1.5	Instructions on running on the P4080DS. This version describes the first release of the proof-of-concept.
1.6	Corrected reserving 512 bytes in buffers.
1.7	Updated performance table for case when FMan automatically releases buffers.
1.8	Updated for 10G XAUI + 4x1G SGMII support and some optimizations.
1.9	Changed document title. Updated for phase 0 release.
1.10	Updated for USDPAA phase 1 release.
1.11	Late updates for phase 1 release including advice on non-22Gbps runs.
1.12	Add discussion of use cases beyond SerDes 0xe and 22 Gbps of ethernet connectivity for USDPAA.
1.13	Fixed minor typographical errors and made other small improvements.
1.14	Updated for SDK v1.0.
1.15	Updated for SDK v1.3.
1.16	Added T4 & B4 platforms for SDK v1.3.1.

9.8.2 USDPAA Multiple Processor Support User Guide

9.8.2.1 USDPAA Multiple Process Support

Describes the modifications done in the QorIQ SDK1.2 to provide USDPAA multiple process support.

The changes introduced in the SDK V1.2 release and are described in this document as a set of changes between SDK V1.1 and the SDK V1.2 releases. Concurrently, a set of interim releases (IRn) are being developed to provide DPAA Offload support

in the SDK. The IR2 release integrates support for multiple USDPAA processes. As such, the delta between SDK V1.1 and SDK V1.2 described in this document also applies as the delta between IR1 and IR2 releases.

9.8.2.2 USDPAA User/Kernel Device Interface

For SDK 1.1 most USDPAA resources were hard-coded into the USDPAA applications, there being only a single USDPAA process. For SDK 1.2 each process opens the “/dev/fsl_usdpaa” device once and uses this process driver for all that process's resource management.

SDK 1.1 QMan/BMan resources

Prior to the SDK 1.2 release, a simplifying assumption of a single process, together with assumptions about unused resources in the device tree led to hard-coded resources. This was the case for buffer pools, congestion groups, pool channels and frame queues.

SDK 1.1 DMA Memory

The only USDPAA resource that was kernel-managed was the mapping of DMA memory, via the

```
/dev/fsl_usdpaa_shmem
```

device. This also had the simplifying assumption that the entire memory region reserved by the kernel would always be mapped in its entirety by the unique USDPAA process, meaning that the functions in the USDPAA “dma_mem” API did not need any parameter to specify which DMA region was implied as there was only one region.

SDK 2.1 Process Driver

The “fsl_usdpaa_shmem” device has been renamed to simply “/dev/fsl_usdpaa” and is also referred to as the “process” device (within USDPAA, this is handled via the “process” driver), because the intention is for each process to open this device once and to use it for all that process's resource management.

SDK 2.1 QMan and BMan Resources

As of the 1.2 release, the process device supports ioctl() commands for (de)allocating resources to (and from) the kernel. So multiple USDPAA processes as well as any datapath logic in the kernel will all be using the same allocator for resources.

SDK 2.1 DMA Memory

The DMA mapping of the device remains but is enhanced to allow multiple regions and sub-regions to be allocated and mapped out of the total memory reservation. These regions are mapped independently and can be allocated by USDPAA apps, via the “dma_mem” driver, on the fly. The allocated regions have the same size and alignment limitations that come from the use of TLB1 entries to map them for fault-less access during datapath operations, but the kernel management of these regions is maximally optimal. Ie. any combination of regions that can conceivably fit within the total memory reservation will always be obtainable, independent of the order in which the USDPAA processes request the allocation of those regions.

Other features of the allocation and mapping of DMA regions:

- They can be process-private (“unnamed”) or shareable (“named”). Named regions can be mapped by multiple processes.
- For shared regions, the process driver in the kernel provides a sleep-based locking scheme that the USDPAA dma_mem driver uses to synchronise buffer allocations within a sub-region across multiple processes.

SDK 2.1 Resource Tracking

Because USDPAA processes open the /dev/fsl_usdpaa device and perform all resource management through that file-descriptor, the kernel device driver can track what resources are allocated and deallocated by those process. When such a process exits (intentionally or otherwise) the file-descriptor is cleaned up and this allows the device driver to check which resources had not been explicitly released by the application. If there are unreleased frame queues, buffer pools, pool channels or congestion groups, the kernel driver will issue leak warnings to the kernel log (and/or the serial console).Examples:

```
USDPAA process leaking 10 FQIDs
USDPAA process leaking 4 QPOOLs
```

Leaked resources are not automatically returned to the allocators, because the current drivers do not yet support automatic clean up and recovery of resources that are left in an undefined (and possibly volatile) state.

Even when applications explicitly deallocate resources back to the kernel-managed allocators (subsequently described here in the "Multi-process PPAC Applications" topic), there is no protection against applications that fail to first put those resources back into their expected “power-on” states. As such, an application that does not correctly clean up resources can, for the current version of the SDK (1.2), pollute the allocators with resources that will be allocated out to other users and lead to undefined results.

9.8.2.3 USDPAA Resource Management

Describes QMan and BMan resource availability and how to declare these resources at system initialization.

QMan and BMan Portals

In SDK 1.1, QMan and BMan portals were declared in the device-tree with properties that pre-determined whether they were for use in the kernel or USDPAA (the latter were marked by the “fsl,usdpaa-portal” property) as well as a pre-determined CPU-affinity (the “cpu-handle” property links to a CPU node).

For SDK 1.2 and later versions, portals are declared in the device-tree simply as hardware resources, with no specification of what the portals will be used for nor which CPU they will be used from. The kernel parses all portals into an internal list, from(/to) which they can be (de)allocated as required.

The QMan driver will, by default, try to allocate a distinct portal for each core and initialise it for kernel use. This behaviour can be influenced by the use of the “qportals” boot argument, to use fewer portals and share them between cores. The mechanism by which a portal can be shared involves cores that do not have their own portals being “slaves” to a core that does have its own portal. Portal processing (interrupts, polling, changing dequeue masks, [etc]) is still performed only on the core to which the portal has been assigned, but software running on slave cores can perform software-initiated commands (enqueues, management commands, [etc]) on the shared portal due.

Once the kernel has initialised portals for its own use, it will allocate and export all the remaining portals as UIO devices for USDPAA use. When a USDPAA application thread initialises a portal for use, the opening of the UIO device triggers kernel logic to configure the portal as affine to the CPU the USDPAA thread is executing on.

QMan Frame Queues (FQs) in SDK 1.1

The allocation of FQs was not coordinated between user-space and kernel-space. Kernel-space FQ allocations would, by default, acquire FQIDs from buffer pool zero, which was statically seeded (via device-tree entries) with a range of values from 0x100 (255) to 0x1ff (511) inclusive, though this behaviour could be overridden by the presence of a “fsl,fqid-range” node in the device-tree which would bypass the buffer pool allocator and instead implemented a software allocator using the given range.

User-space FQ allocations on the other hand always used a software allocator implementation whose range was hard-coded (in source code) to be from 0x200 (512) to 0x3ff (1023).

QMan FQs in SDK 1.2

In kernal-space, support for using buffer pool zero as a special case for FQ allocations has been entirely removed. Now, FQ allocations are only possible if the device-tree contains a “fsl,fqid-range” node. There are device-tree include files (arch/powerpc/boot/dts/fsl/qoriq-dpaa-res*.dtsi) that declare default allocation ranges.

User-space FQ allocations are now always handled by using the resource allocation ioctl() commands in the USDPAA “process” driver. Ie. user-space FQ allocations are sourced from the allocator residing in kernel-space, and so multiple user-space processes and kernel code are using a common allocator.

QMan Congestion Group Records (CGRs) for SDK 1.1

There was no facility at all for providing allocation of CGRs, and indeed there was no knowledge on the part of kernel or user-space as to how many CGRs were physically present in the hardware – any CGR-dependent software would simply be making its own assumptions about what CGRIDs were safe to use relative to the hardware and any other CGR-dependent software.

QMan CGRs for SDK 1.2

The kernel now implements a CGRID allocator which is seed by a “fsl,cgrid-range” node in the device-tree. The user-space has the same API, and its allocations are routed in the kernel via the “process” driver in the same way as was mentioned for frame queues.

QMan Pool Channels in SDK 1.1

There was no facility for providing allocations of pool-channels, however the device-tree did represent how many pool-channels were present in hardware (this was primarily to allow network devices to be statically configured to use particular pool-channels via device-tree linkage). The kernel-space driver could then enforce its knowledge of what pool-channels were available, but did not coordinate the resource so independent entities of software would need to avoid conflicts via its own means. The user-space driver also used the device-tree to determine the physically-available pool-channels, and provided no coordination of the resources.

QMan Pool Channels in SDK 1.2

The use of device-tree linkage between network nodes and pool-channels in previous versions is gone. The kernel network driver has been adjusted to dynamically allocate its pool-channel instead. As with the other resource types, the USDPAA driver now has the same pool-channel allocation API as the kernel, with user-space allocation operations going via the “process” driver to be handled by the allocator in the kernel.

BMan Buffer Pools in SDK 1.1

The kernel used to determine the number of buffer pools available by looking at the SoC version. Some buffer pools would be represented by device-tree nodes in order to support device-tree linkage with network nodes and in doing so could optionally be seed with ranges of values specified by node properties. The kernel would, by default, implement a BPID allocator that would automatically include all physically available buffer pools that were not explicitly mentioned in device-tree nodes (ie. device-tree nodes acted as reservations against being allocated). An optional “fsl,bpool-range” node could be used to override this behaviour, implementing a software allocator in the same way as “fsl,fqid-range” does.

BMan Buffer Pools in SDK 1.2

If the device-tree contains a “fsl,bpid-range” node (previously named “fsl,bpool-range”). There are device-tree include files

```
arch/powerpc/boot/dts/fsl/qoriq-dpaa-res*.dtsi
```

that declare default allocation ranges. User-space FQ allocations are now always handled by using the resource allocation ioctl() commands in the USDPAA “process” driver. Ie. user-space FQ allocations are sourced from the allocator residing in kernel-space, and so multiple user-space processes and kernel code are using a common allocator.

Changes for FMan Resources

The only change to FMan resource management caused by the SDK 1.2 changes for USDPAA multi-process support is the removal of statically-assigned pool channels for ethernet interfaces. The “dpaa_eth” kernel driver now dynamically allocates a pool-channel during initialisation, and uses it for all the network interfaces it instantiates.

USDPAA DMA Memory for SDK 1.1

The kernel driver used an early-boot hook to reserve a memory region of a hard-coded size (configurable at the expense of a kernel recompile), and the USDPAA “dma_mem” driver would open the “/dev/fsl_usdpaa_shmem” device on behalf of the unique application process and mmap() all the of reserved memory. It was not possible to map less memory than that, it was not possible to create named/shared mappings, and so this was one of the reasons it was not possible to run multiple USDPAA processes.

USDPAA DMA Memory for SDK 1.2

The kernel driver now requires a boot-argument (“usdpaa_mem=<size>[,<num_tlb1>”) to trigger the reservation of USDPAA memory early during the kernel boot, otherwise no memory is reserved. The reservation of multiple TLB1 indices for use by USDPAA is also possible by passing a comma-separated argument. Using multiple TLB1 indices allows simultaneous mappings from USDPAA processes to DMA regions without any risk of fault handling overheads (note that if two processes map the same shared region, that requires 2 TLB1 indices). See section 2.2.3 for information on the device that exposes this memory to mapping from USDPAA applications.

9.8.2.4 BMan and QMan API

SDK 1.2 USDPAA processes performs resource management through the /dev/fsl_usdpaa file-descriptor .

BMan Modifications - fsl_bman.h

The changes described in this section apply to the BMan API in kernel-space and user-space unless otherwise specified. For more information on specific APIs (eg. the “partial” parameter to allocation functions or API return values) please see the comments in the header file that declares the interface (or consult the API reference manual).

Removal of “recovery” API

bman_recovery_cleanup_bpid() and bman_recovery_exit() have been removed, as they were never more than non-functional stubs and were conflicting with ongoing development.

New BPID allocation API

```
int bman_alloc_bpid_range(u32 *result, u32 count, u32 align, int partial);
static inline int bman_alloc_bpid(u32 *result)
{
       int ret = bman_alloc_bpid_range(result, 1, 0, 0);
       return (ret > 0) ? 0 : ret;
}

void bman_release_bpid_range(u32 bpid, unsigned int count);
static inline void bman_release_bpid(u32 bpid)
{
       bman_release_bpid_range(bpid, 1);
}
```

QMan Modifications - fsl_qman.h

The changes described here apply to the QMan API in kernel-space and user-space unless otherwise specified.

Removal of "recovery" API for SDK 1.2

qman_recovery_cleanup_fq() and qman_recovery_exit() have been removed, as they were never more than non-functional stubs and were conflicting with ongoing development.

Removal of Buffer-Pool Based FQ Allocator API

qm_fq_new(), qm_fq_free(), and the QM_FQ_FREE_* flags have been removed, as they were rendered unnecessary and awkward, in particular as they used to support “wait” options that were useful when deallocating FQIDs to a buffer pool but have no sane interpretation with the software-implemented allocator.

Removal of 'struct qman_portal_config::has_stashing' for SDK 1.2

Stashing can now be assumed as enabled in all environments (kernel-space, user-space, with Linux running natively, under the topaz hypervisor, or under KVM), so support for stashing-disabled operation has been removed for the sake of optimisation.

Removal of 'struct qman_fq_cb::dc_ern' for SDK 1.2

The callbacks associated with a frame queue object no longer support a DC_ERN handler (as these never worked properly because the concept is fundamentally unworkable). The lowest level at which DC_ERN messages can meaningfully be handled is at the portal level.

New API for handling DC_ERNs in SDK 1.2

It is possible to register a handler for DC_ERN messages with the portal affine to the running CPU, or as a global fallback for any portals that don't have their own handler.

```
void qman_set_dc_ern(qman_cb_dc_ern handler, int affine);
```

Removal of “NULL FQ” API in SDK 1.2

qman_get_null_cb(), qman_set_null_cb(), and QMAN_INITFQ_FLAG_NULL flag have been removed, as this functionality was considered marginal, had no known use-case, and was conflicting with ongoing development.

New API to Obtain Portal Channel for SDK 1.2

As portals are dynamically allocated, initialised, and assigned to CPUs during boot up, it became necessary for a user to be able to determine the channel ID for the portal associated with a given CPU, eg. in order to schedule frame queues such that dequeues would be handled on that CPU core.

```
enum qm_channel qman_affine_channel(int cpu);
```

New Pool-Channel Allocation API for SDK 1.2

For QMan pool-channel allocation:

```
int qman_alloc_pool_range(u32 *result, u32 count, u32 align, int partial);
static inline int qman_alloc_pool(u32 *result)
{
       int ret = qman_alloc_pool_range(result, 1, 0, 0);
       return (ret > 0) ? 0 : ret;
}

void qman_release_pool_range(u32 id, unsigned int count);
static inline void qman_release_pool(u32 id)
{
       qman_release_pool_range(id, 1);
}
```

New QMan CGR allocation API for SDK 1.2

```
int qman_alloc_cgrid_range(u32 *result, u32 count, u32 align, int partial);
static inline int qman_alloc_cgrid(u32 *result)
{
       int ret = qman_alloc_cgrid_range(result, 1, 0, 0);
       return (ret > 0) ? 0 : ret;
}

void qman_release_cgrid_range(u32 id, unsigned int count);
static inline void qman_release_cgrid(u32 id)
{
       qman_release_cgrid_range(id, 1);
}
```

9.8.2.5 USDPAA Thread and Global API

The API changes described apply to user-space (USDPAA).

fsl_d.h -- Thread Initialization simplified

The SDK 1.1 Thread initialization was verbose:

```
int qman_thread_init(int cpu, int recovery_mode);   /* remove for SDK 1.2 */
int bman_thread_init(int cpu, int recovery_mode);   /* remove for SDK 1.2 */
int qman_thread_init(void);
int bman_thread_init(void);
```

The SDK 1.2 Thread initialization is compact:

```
int qman_thread_init(void);
int bman_thread_init(void);
```

Recovery support (which was non-functional) has been removed so 'recovery_mode' is no longer a parameter. As for the 'cpu' parameter, portals are now dynamically bound to CPUs, so these functions will allocate any unused portal and it will be automatically bound to the CPU on which the caller is executing.

fsl_d.h -- Global Initialization

The SDK 1.1 Global initialization was verbose:

```
int qman_global_init(int recovery_mode);           /* remove for SDK 1.2 */
int bman_global_init(int recovery_mode);           /* remove for SDK 1.2 */
int qman_global_init(void);
int bman_global_init(void);
```

The SDK 1.2 Global initialization is compact:

```
int qman_global_init(void);
int bman_global_init(void);
```

As before, the 'recovery_mode' parameter is removed because the non-functional recovery interfaces have been removed.

9.8.2.6 USDPAA DMA API

The API changes described apply to DMA user-space (USDPAA).

dma_mem.h

The key change to this interface is that there can now be more than one DMA region available to each USDPAA process, so there is support for creating multiple such mappings, and as such most of the functions require that the DMA region be supplied as a parameter where there was no such need before.

Setup, or creation of DMA maps

The dma_mem driver used to initialise in a parameterless manner, creating the unique DMA map via dma_mem_setup(void), which has been removed. Instead, maps are created by the application using the following interfaces:

```
struct dma_mem;
#define DMA_MAP_FLAG_SHARED   0x01
#define DMA_MAP_FLAG_ALLOC    0x08
#define DMA_MAP_FLAG_NEW      0x02
#define DMA_MAP_FLAG_LAZY     0x04
#define DMA_MAP_FLAG_READONLY 0x10
struct dma_mem *dma_mem_create(uint32_t flags, const char *map_name,
                               size_t len);
```

The significance of the flags is described in more detail within the dma_mem.h header. To summarise, the SHARED flag creates a mapping to a new or existing DMA region that can be mapped by multiple USDPAA processes ('map_name' is the identifier for the region), otherwise a new region and mapping created that remains private to the process. If NEW is not specified the DMA region must already exist, whereas if NEW is specified the region must not already exist unless LAZY is also specified. LAZY refers to “lazy initialisation”, meaning that multiple processes can independently issue the same API call with the same name and specifying both the NEW and LAZY flags, with the result being that the named region will be allocated only once (by whichever process “wins the race”) and mapped into all the requesting processes.

If ALLOC is specified, then all processes that map the same region can use the dma_mem_memalign() and dma_mem_free() interfaces to allocate blocks from the region in a coordinated way. Without ALLOC, the region is created “raw”, meaning the user manipulates the entire region directly without any allocator functionality provided by the dma_mem driver.

Raw Memory Regions

If a DMA region and mapping is created with the RAW flag, it can then be accessed via;

```
void *dma_mem_raw(struct dma_mem *map, size_t *len);
```

Memory allocation

These functions are similar to those in SDK 1.1, with the exception that they require a parameter to indicate which DMA map to use. For SDK 1.1:

```
void *dma_mem_memalign(size_t boundary, size_t size);    /* SDK 1.1 version */
void dma_mem_free(void *ptr, size_t size);               /* SDK 1.1 version */
```

Additional parameter for SDK 1.2:

```
void *dma_mem_memalign(struct dma_mem *map, size_t boundary, size_t size);
void dma_mem_free(struct dma_mem *map, void *ptr);
```

Distinguishing DMA regions

```
struct dma_mem *dma_mem_findv(void *v);
struct dma_mem *dma_mem_findp(dma_addr_t p);
```

Physical/virtual address conversion

As with memory allocation, these functions require a parameter to indicate which DMA map to use, but are otherwise similar to those in SDK 1.1. In the case where the DMA map is not known, use the functions mentioned in “Distinguishing DMA regions” first. Note, these functions are actually implemented as inlines with some nasty details involving casts that should be ignored, this is simply because these routines are performance critical in packet-processing processing;

```
static inline void *dma_mem_ptov(struct dma_mem *map, dma_addr_t p) { … }
static inline dma_addr_t dma_mem_vtop(struct dma_mem *map, void *v) { … }
```

Legacy interfaces, “dma_mem_generic”

In order to facilitate porting of legacy applications to the new dma_mem API, the following mechanism is provided. A global variable within the dma_mem driver, dma_mem_generic, is NULL by default but can be set by the application once it has created a DMA mapping. From that point on, it could use the following __dma_mem_*() functions, which do not require a DMA map parameter.

```
extern struct dma_mem *dma_mem_generic;
static inline void *__dma_mem_ptov(dma_addr_t p)
{
       return dma_mem_ptov(dma_mem_generic, p);
}
static inline dma_addr_t __dma_mem_vtop(void *v)
{
       return dma_mem_vtop(dma_mem_generic, v);
}
static inline void *__dma_mem_memalign(size_t boundary, size_t size)
{
       return dma_mem_memalign(dma_mem_generic, boundary, size);
}
static inline void __dma_mem_free(void *ptr)
{
       return dma_mem_free(dma_mem_generic, ptr);
}
```

That is, in order to port a legacy application (which worked on the assumption of there being a unique, canonical DMA mapping for all DMA operations), it should suffice to;

1. During application initialisation, create a default DMA map using dma_mem_create(), and assign that to dma_mem_generic,
2. Change all the legacy dma_mem_*() calls in the application to __dma_mem_*().

9.8.2.7 USDPAA netcfg.h

The API changes described apply to user-space (USDPAA).

For SDK 1.1 and previous versions:

```
struct usdpaa_netcfg_info {
       uint8_t num_cgrids;             /* SDK 1.1 and previous */
       uint32_t *cgrids;               /* SDK 1.1 and previous */
       uint8_t num_pool_channels;      /* SDK 1.1 and previous */
       enum qm_channel *pool_channels; /* SDK 1.1 and previous */
       uint8_t num_ethports;           /* Number of ports */
       [...]
```

For SDK 1.2 and subsequent versions:

```
struct usdpaa_netcfg_info {
       uint8_t num_ethports;           /* Number of ports */
       [...]
```

'struct usdpaa_netcfg_info' no longer specifies CGR and pool-channel resources to applications. There are now allocators in the QMan API for both these resource types, and they no longer need to come from the network configuration. Note that these resources were previously coming from hard-coded work-arounds if present at all.

See the "USDPAA Resource Management Modifications for SDK 1.2" topic for details on CGRs and QMan Pool Channels.

9.8.2.8 Kernel configuration

Kconfig settings for the fsl_qbman driver have changed.

SDK 1.2 Kconfig changes:

- CONFIG_FSL_DPA_HAVE_IRQ is removed, IRQ support is always enabled.
- CONFIG_FSL_BMAN_PORTAL is removed, support for BMan portals is always enabled.
- CONFIG_FSL_QMAN_PORTAL is removed, support for QMan portals is always enabled.
- CONFIG_FSL_QMAN_PORTAL_DISABLEAUTO_DCA is removed, QMan portals are always enabled for DCA consumption of DQRR (dequeue response ring) entries.
- CONFIG_FSL_QMAN_NULL_FQ_DEMUX is removed, see the BMan and QMan API Modifications topic, Removal of “NULL FQ” API heading.
- CONFIG_FSL_QMAN_DQRR_PREFETCHING is removed, the driver is now optimised to always assume stashing is always enabled, so support for pre-fetching is removed. This removes a run-time check from the critical path.

9.8.2.9 Device Tree (Excluding QMan/BMan Resource Ranges)

Device tree changes, excluding the QMan/BMan resource ranges.

QMan/BMan portals

Portals no longer have “fsl,usdpaa-portal” or “cpu-handle” properties.

```
       qportal1: qman-portal@4000 {
               cell-index = <0x1>;
               compatible = "fsl,p4080-qman-portal", "fsl,qman-portal";
               reg = <0x4000 0x4000 0x101000 0x1000>;
               interrupts = <106 0x2 0 0>;
               fsl,qman-channel-id = <0x1>;
               cpu-handle = <&cpu1>;
```

```
        };
```

BPID 0 FQ-allocator

No buffer pool device tree node for BPID 0, because we no longer support that legacy mechanism for FQID allocation.

QMan Pool channels

Pool channel nodes have been removed and replaced by “pool channel range” nodes.

BMan buffer pools

Buffer pool nodes have not been removed, because they are still linked to by network-related nodes. However they are now ignored by the fsl_qbman driver and so no longer contain the “fsl,bpool-cfg” property type. Eventually, network configuration will obtain buffer pools dynamically, at which point there should be no more need for individual buffer pol nodes in the device-tree. (There is no current plan for when this deprecation will occur.)

Ethernet Interfaces

Ethernet nodes no longer have “fsl,qman-channel” properties linking them to pool channels.

```
        ethernet@2 {
                compatible = "fsl,p4080-dpa-ethernet", "fsl,dpa-ethernet";
                fsl,fman-mac = <&enet2>;
```

9.8.2.10 Device Tree (QMan/BMan Resource Ranges)

These device tree resource properties share a common format.

QMan and BMan Portals

Portals no longer have “fsl,usdpaa-portal” or “cpu-handle” properties. For SDK 1.1 and previous:

```
qportal1: qman-portal@4000 {
             cell-index = <0x1>;
             compatible = "fsl,p4080-qman-portal", "fsl,qman-portal";
             reg = <0x4000 0x4000 0x101000 0x1000>;
             interrupts = <106 0x2 0 0>;
             fsl,qman-channel-id = <0x1>;
             fsl,usdpaa-portal;                                    /* SDK 1.1 only */
             cpu-handle = <&cpu1>;
             fsl,qman-pool-channels = <&qpool4 &qpool5 &qpool6
                                       &qpool7 &qpool8 &qpool9
                                       &qpool10 &qpool11 &qpool12
                                       &qpool13 &qpool14 &qpool15>; /*SDK 1.1 only */
        };
```

For SDK 1.2 and later versions:

```
qportal1: qman-portal@4000 {
             cell-index = <0x1>;
             compatible = "fsl,p4080-qman-portal", "fsl,qman-portal";
             reg = <0x4000 0x4000 0x101000 0x1000>;
             interrupts = <106 0x2 0 0>;
             fsl,qman-channel-id = <0x1>;
             cpu-handle = <&cpu1>;
        };
```

BPID 0 FQ-allocator

No buffer pool device tree node for BPID 0, because we no longer support that legacy mechanism for FQID allocation. See section 3.2.

QMan Pool Channels

Pool channel nodes have been removed (and replaced by “pool channel range” nodes, see the corresponding item below). See section 3.4.

BMan Buffer Pools

Buffer pool nodes have not been removed, because they are still linked to by network-related nodes. However they are now ignored by the fsl_qbman driver and so no longer contain the “fsl,bpool-cfg” property type. Eventually, network configuration will obtain buffer pools dynamically, at which point there should be no more need for individual buffer pol nodes in the device-tree. There is no precise plan for when this deprecation will occur though.

QMan and BMan Resource Ranges (Allocation)

The following resource properties share a common format, with a 2-tuple specifying a base+count pair. Eg. if the pool-channel range property specifies “<0x21 0xf>”, that corresponds to a range of pool channel IDs ranging from 33 (0x21) to 47 (0x21+0xf-1), inclusive.

FQID

“FQID range” nodes have been added to specify FQs that are available for dynamic allocation. These do not yet include all the FQs that are available in the system, because there are still some legacy requirements for pre-configured FQIDs that have not been updated to use dynamic allocation. These nodes were previously supported but were not enabled by the default device trees, whereas they are now used in all cases, via the including of arch/powerpc/boot/dts/fsl/qoriq-dpaa-res*.dtsi files (which did not exist in SDK 1.1) as follows:

```
        qman-fqids@0 {
               compatible = "fsl,fqid-range";
               fsl,fqid-range = <256 256>;
             };
```

CGRID Dynamic Allocation

“CGRID range” nodes have been added to specify CGRs that are available for dynamic allocation. Example:

```
        qman-cgrids@0 {
               compatible = "fsl,cgrid-range";
               fsl,cgrid-range = <0 256>;
             };
```

Pool Channel

“Pool channel range” nodes have been added to specify pool channels that are available for dynamic allocation. Example:

```
       qman-pools@0 {
               compatible = "fsl,pool-channel-range";
               fsl,pool-channel-range = <0x21 0xf>;
       };
```

BPID

“BPID range” nodes have been added to specify buffer pools that are available for dynamic allocation. Example:

```
       bman-bpids@0 {
               compatible = "fsl,bpid-range";
               fsl,bpid-range = <32 32>;
       };
```

9.8.2.11 USDPAA Boot Arguments

Without this boot-argument, no memory is reserved by the “fsl_usdpaa” driver and so no memory will be available for creating DMA mappings in USDPAA applications.

usdpaa_mem

The usdpaa_mem argument is not set by default by u-boot, device-trees or any other resource. The user must add it explicitly to boot commands in order to be able to run USDPAA applications. The size can be expressed using the standard suffixes for memory size notation (“256M”, “1G”, etc).

A second (and optional) argument allows multiple TLB1 indices to be reserved for mapping regions within the memory reservation. Without this extra argument, the default behaviour is to reserve only 1 TLB1 entry. Ie. “usdpaa_mem=64M,1” is equivalent to “usdpaa_mem=64M”. Note that the handling of page faults for software access to these resources will be satisfied by using the reserved TLB1 entries in a round-robin fashion, so if there are more mappings between user-space processes and DMA regions than there are TLB1 entries, and all of those mappings are being actively used at run-time, then performance will degenerate.

Since single TLB1 entries can only map power of 4 memory sizes a set of 1 or more TLB1 entries is required in to map a DMA region into each process. The USDPAA driver will use the minimum number of TLB1 entries possible to map each DMA region.

If a single process maps to two DMA regions, that would require two sets of TLB1 entries. But the same is true if two distinct processes map to one private DMA region each. So the number of TLB1 entries required is really the number of pairings between user-space processes and distinct DMA regions, or “the number of mappings”, to put it another way. The total number of TLB1 entries available depends on the SoC version, so one should check this when determining how many TLB1 entries to dedicate to USDPAA.

Note that a typical kernel would internally only use 3 or so TLB1 entries, and all the remaining entries are normally reserved by the “hugetlb” driver for a similar kind of large-page fault-handling algorithm as that implemented for USDPAA – indeed, the reason USDPAA does not just use “hugetlb” directly is that it has no mechanisms to support user-space obtaining physical addresses and performing DMA.

One must also determine whether HugeTLB support is required. This decision determines the number of TLB1 entries for USDPAA use and, in turn, how many processes and active DMA mappings used. The USDPAA could use most of the TLB1 entries if HugeTLB support is not used.

"qportals" and "bportal;s"

By default, the kernel will attempt to allocate portals for each online core. If however the “qportals” (for QMan portals) and/or “bportals” (for BMan portals) boot-arguments are specified, this behaviour will be overridden. These boot-arguments specify cores that should be assigned portals to them, with the implication being that cores that are not specified will need to “slave” off the cores that are assigned.

Table 229. boot-argument: "qportals=1,s3-4"

Core	Portal	Association
0	B	slave
1	A	affine unshared
2	C	slave
3	B	affine shared
4	C	affine shared
5	B	slave
7	B	slave

9.8.2.12 USDPAA Virtualisation and Partitioning

In a partitioned system, it is necessary to assign each partition non-conflicting subsets of the hardware resources.

All the resources mentioned in section 3 can and should be divided up, with each instance of Linux receiving distinct portals and other dynamically-allocated resources via their respective device-trees.

Some use-cases may intentionally share resources between partitions, in which coordination of the corresponding resource IDs is up to the application. The resources provided to the partitions by the device-tree are inherently managed by the drivers themselves, and these must be mutually-exclusive because the drivers in the distinct partitions have no innate coordination.

9.8.2.13 Multi-process PPAC Applications

A description of how the networking applications are affected by, and have been adapted for, multi-process support.

The USDPAA toolkit provides a template called “PPAC” (Packet Processing Application Core) for simple networking applications, together with some applications called “PPAM”s (Packet Processing Application Module) that are written on top of this template. These networking applications notably include “reflector” and “ipfwd”.

Running multiple distinct PPAM application processes (or “instances” as they are sometimes described) requires that each process have its own dedicated set of FMAN interfaces, buffer pools, and cores.

FMan Interfaces

By default, a PPAM application will automatically configure and use all available FMan interfaces, unless a specific set of interfaces is specified via the “-i” option. For example:

```
<app1> -i fm1-10g,fm2-10g
<app2> -i fm2-gb2,fm2-gb3
```

The names of FMAN interfaces that can be used with “-i” option are as follows.

Table 230. FMan "-i" Options

FMAN1	Fman2
fm1-gb0	fm2-gb0
fm1-gb1	fm2-gb1
fm1-gb2	fm2-gb2
fm1-gb32	fm2-gb3
fm1-gb4	fm2-gb4
fm1-10g	fm2-10g

As per SERDES protocol, a set of FMAN interfaces can be chosen to run with an application.

Buffer pool restrictions

The device tree specifies the ethernet nodes such that each has a set of buffer pools for FMan to use when receiving frames. One restriction of the PPAC multi-process support is that the buffer pools used by FMan interfaces in one process must not also be used by any FMan interfaces in any other process. As such the device tree may need to be adjusted to ensure that any reuse of a buffer pool by more than one FMan interface must only occur when those FMan interfaces will always belong

to the same process. For example, if one application wants to use fm1-10g and fm2-10g and another application is going to use fm2-gb2 and fm2-gb3, then corresponding ethernet nodes might look like:

```
ethernet@4 {
                        compatible = "fsl,p4080-dpa-ethernet-init", "fsl,dpa-ethernet-init";
                        fsl,bman-buffer-pools = <&bp9>;
                        fsl,qman-frame-queues-rx = <0x5a 1 0x5b 1>;
                        fsl,qman-frame-queues-tx = <0x7a 1 0x7b 1>;
                };

ethernet@9 {
                        compatible = "fsl,p4080-dpa-ethernet-init", "fsl,dpa-ethernet-init";
                        fsl,bman-buffer-pools = <&bp9>;
                        fsl,qman-frame-queues-rx = <0x66 1 0x67 1>;
                        fsl,qman-frame-queues-tx = <0x86 1 0x87 1>;
                };
ethernet@7 {
                        compatible = "fsl,p4080-dpa-ethernet-init", "fsl,dpa-ethernet-init";
                        fsl,bman-buffer-pools = <&bp8>;
                        fsl,qman-frame-queues-rx = <0x60 1 0x61 1>;
                        fsl,qman-frame-queues-tx = <0x80 1 0x81 1>;
                };
ethernet@8 {
                        compatible = "fsl,p4080-dpa-ethernet-init", "fsl,dpa-ethernet-init";
                        fsl,bman-buffer-pools = <&bp8>;
                        fsl,qman-frame-queues-rx = <0x62 1 0x63 1>;
                        fsl,qman-frame-queues-tx = <0x82 1 0x83 1>;
                };
```

Seeding buffer pools

Each PPAC-based application process will initialise the (usually 3) buffer pools used by each FMan interface that belongs to it. (If a buffer pool is used by more than one interface, it will only be initialised once.) By default the number of buffers to allocate for the triplet of pools used by an FMan interface is 0 for the first two pools and 1728 for the third. The default allocation triplet can be overridden via the “–b” option. For example, to continue the earlier example of a two-process scenario, and to have each process allocate 1600 buffers for the first pool used by any network interface and 0 for the second and third pools, they would use the following arguments :

```
<app1> -b 1600:0:0 -i fm1-10g,fm2-10g
<app2> -b 1600:0:0 -i fm2-gb2,fm2-gb3
```

Cores

By default, each PPAC-based application process will start a single thread running on core 1. Additional threads can be started and stopped on arbitrary cores using the interactive CLI, but the first/primary thread can not be removed without ending the process. So for multi-process scenarios, it is better for each application instance to specify a core or set of cores as part of the command line. For example, to split 8 cores in half between our two hypothetical application processes;

```
<app1> 0..3 -b 1600:0:0 -i fm1-10g,fm2-10g
<app2> 4..7 -b 1600:0:0 -i fm2-gb2,fm2-gb3
```

9.8.2.14 Limitations

The use of dynamic allocation of resources does not address the appropriate state of an allocation.

A resource that is deallocated by one user can subsequently be allocated by another and it will be in the same state it was left, for better or worse. As such, stability and integrity of (and between) datapath applications is entirely a matter of cooperation. Future releases will implement measures to quiesce and recover such resources to make the system more robust in the face of individual application failures.

For the reasons explained above, most types of resources can be leaked by USDPAA applications that exit (or crash) before deallocating them. Although an application can explicitly deallocate a resource in a bad state, the risk of a resource being in a bad state when an application exits without having deallocated it is considered too great – so it is leaked rather than allowing it lead to undefined behaviour in future uses.

An exception to the last comment is for QMan and BMan portals, which due to them being UIO-based means they are implicitly “deallocated” when a process exits. In a future release, portals will likely no longer be UIO-based, and in any case, they will likely be “cleaned up” on process-exit.

9.9 USDPAA Applications

9.9.1 USDPAA ceetm Demo User Guide

9.9.1.1 Introduction

This document describes the usage of "ceetm_demo" application which is built on USDPAA PPAC architecture. User can experience the functionality of QMan CEETM with this application and can also learn how to use user space CEETM driver API from source code of this application.

The concept of QMan CEETM is beyond scope of this document. The user should refer to QMan user manual for this part.

9.9.1.2 Overview of ceetm demo

ceetm_demo is an USDPAA application built on PPAC architecture. It works in a way like reflector – the traffic sent to one ethernet interface will be reflected back from the same interface. Please refer to reflector user guide for details. Besides, ceetm_demo enables traffic management on Tx side and differentiates traffic flows according to TOS value in IPv4 header.

In order to provide flexibility at most, we use a xml-format configuration file to depict configuration of CEETM which can be parsed by ceetm_demo at initialization phase. User can experience different cases of traffic management just by changing configuration file before launching ceetm_demo.

If users want to learn how to utilize CEETM driver APIs for their own case, please see function 'net_if_ceetm_init' in ceetm_demo.c as reference.

The ceetm_demo application is currently supported on all B-series and T-series NXP platforms.

9.9.1.3 Features of ceetm demo

ceetm_demo application has following features that provide flexibility to user to experience functionality of QMan CEETM:

- Shaping on LNI and Channel is configurable
- Number of CQs and weighted groups(A and B) is configurable
- SP CQ and Group can be configured for CR/ER eligible or both
- The weight of CQ is configurable
- Distinguish flows by TOS field in IPv4 protocol which is used to identify unique CQ on egress

9.9.1.4 CEETM use case

CEETM configuration may vary from case to case. Here we only show the way to implement one case which is described in QMan 3.x document. Other scenarios could be easily implemented by changing configuration file only.

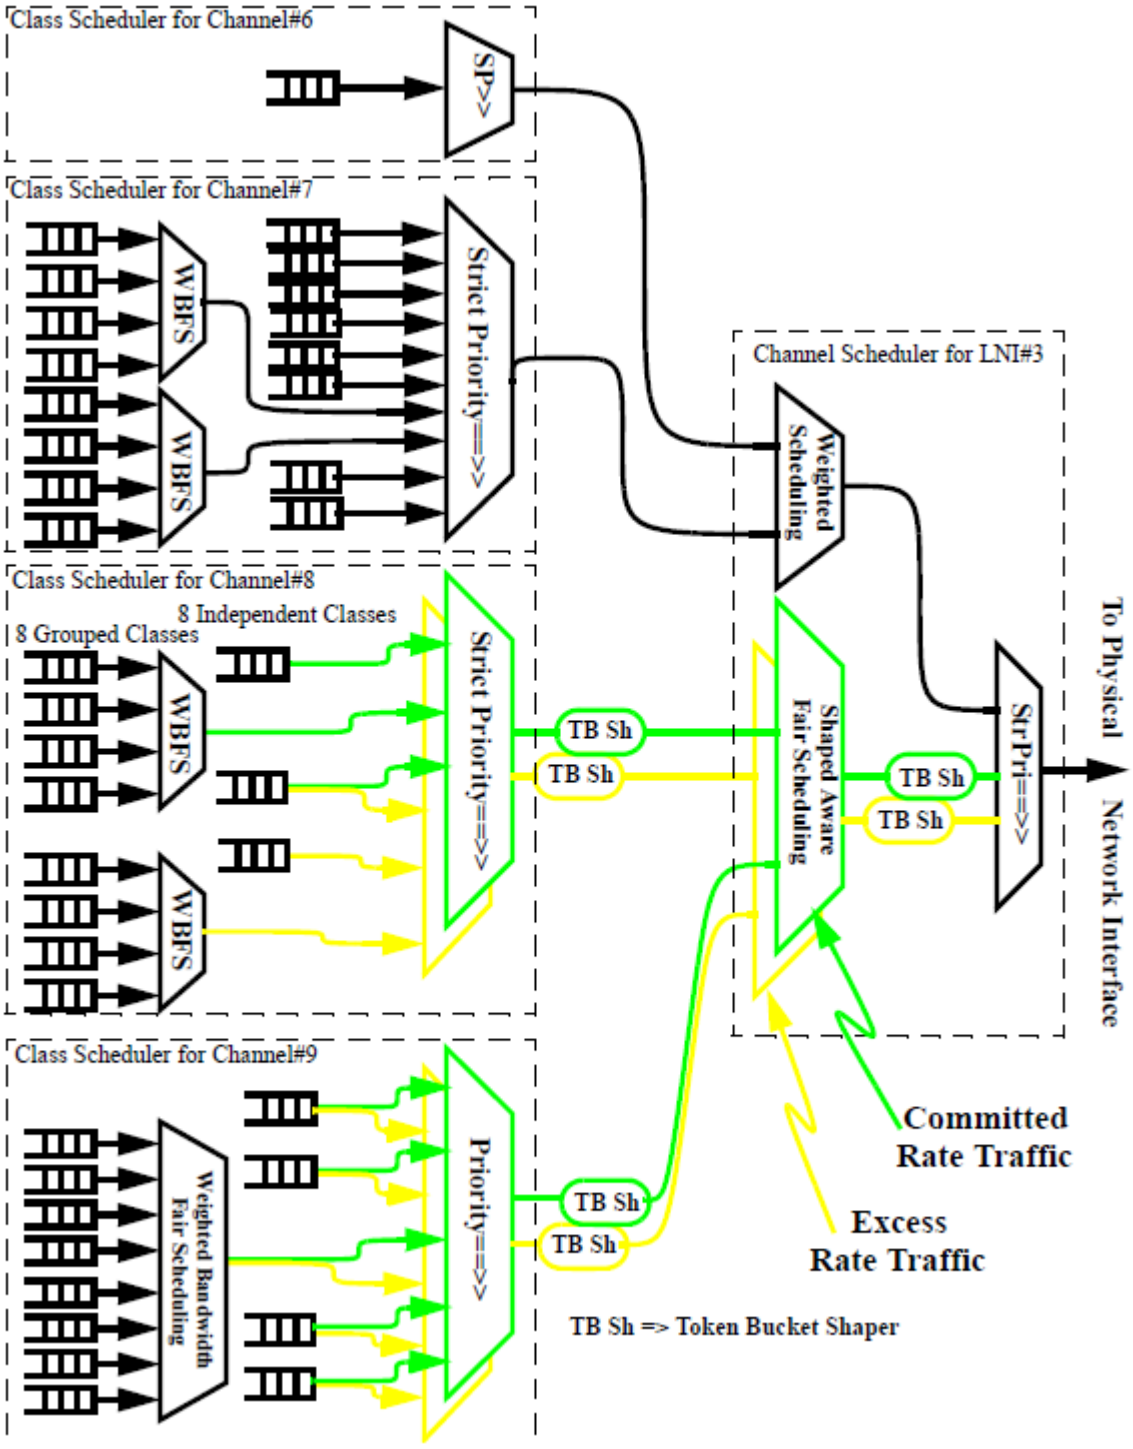

Figure 238. CEETM use case

This scenario depicts the following:

- Channels #6,#7,#8 and #9 have been configured to be scheduled by the channel scheduler for LNI#3 (i.e. all packets from these channels are directed via LNI#3 to the physical network interface coupled by configuration to LNI#3).
- Channels #6 and #7 have been configure to be “unshaped”. Packets from these channels will not be subjected to shaping at the channel level and will feed the top priority level within the LNI which is also not subjected to shaping. Their class schedulers will not distinguish between CR and ER opportunities.

- Channels #8 and #9 have been configured to be “shaped”. Their class schedulers will distinguish between CR and ER opportunities. The CR/ER packets to be sent form each channel shall be subjected to a pair of CR/ER token bucket shapers specific to that channel. The aggregate of CR/ER packet from these channels shall be subject to a pair of CR/ER token bucket shapers specific to LNI#3.
- Channels #6 has only one class in use. That class queue will behave as if it were a channel queue and a peer to channel #7. Unused classes do not have to be configured as such - simply not used.
- Channel #7 has all 16 classes in use
  - The group classes have been configured as 2 groups (A and B) of 4 classes.
  - The priority of the groups A and B have both been set to be immediately below independent class 5. In a case of similar configuration group A has higher priority than group B.
- Channels #8 has 3 independent classes and 2 groups of 4 grouped classes in use.
  - The priorities of the class groups A and B have been set to be immediately below independent class 0 and class 2 respectively.
  - Independent class 0 and class group A have been configured to request and fulfill only CR packet opportunities.
  - Independent class 1 has been configured to request and fulfill both CR and ER packet opportunities.
  - Independent class 2 and class group B have been configured to request and fulfill only ER packet opportunities.
- Channels #9 has 4 independent classes and 1 groups of 8 grouped classes in use.
  - The group classes have been configured as 1 group (A) of 8 classes.
  - All independent classes and the class group (A) have been configured to request and fulfill both CR and ER packet opportunities.

9.9.1.5 CEETM configuration file

CEETM configuration file is used to depict a model of traffic management in xml format which can then be parsed by ceetm_demo application. User could experience the effect of dual-shaper and dual-scheduler of CEETM by changing this configuration file.

```
<ceetm>
    <lni control="shaped" cr="2g" er="2g">
        <channel control="unshaped" group="0">
            <cq idx='0'/>
        </channel>
        <channel control="unshaped" group="2">
            <groupA idx="6" />
            <groupB idx="6" />
            <cq idx='0' />
            <cq idx='1' />
            <cq idx='2' />
            <cq idx='3' />

  - er: bandwidth for Excess Rate of interface
- <channel>
  - control: ‘shaped’ if shaping is placed on this interface; ‘unshaped’ otherwise
  - grou: '0' – no group; '1' – only groupA enabled; '2' – both groupA/B are enabled
  - cr: bandwidth for Commit Rate of channel
  - er: bandwidth for Excess Rate of channel
- <cq>
  - idx: CQ id, ranging from 0 to 15
  - op: 'cr' – cr eligible; 'er' – er eligible; or 'both'. Only applicable for SP CQ
  - weight: the weight of CQ. Only applicable for grouped CQ

9.9.1.6 Running ceetm_demo

User should boot board with USDPAA mode. After logging into the board as 'root', run following command

```
          login: root
          Password:
          root@t2080qds:~# cd /usr/etc
          root@t2080qds:/usr/etc# fmc -c usdpaa_config_t2_serdes_66_16.xml -p
usdpaa_policy_hash_ipv4.xml -a
          root@t2080qds:/usr/etc# ceetm_demo -c usdpaa_config_t2_serdes_66_16.xml -p
usdpaa_policy_hash_ipv4.xml -f ceetm_cfg.xml
          Found /fsl,dpaa/dpa-fman0-oh@2, Tx Channel = 80a, FMAN = 0, Port ID = 1
          Found /fsl,dpaa/ethernet@0, Tx Channel = 802, FMAN = 0, Port ID = 2
          Found /fsl,dpaa/ethernet@1, Tx Channel = 803, FMAN = 0, Port ID = 3
          Found /fsl,dpaa/ethernet@2, Tx Channel = 804, FMAN = 0, Port ID = 2
          Found /fsl,dpaa/ethernet@3, Tx Channel = 805, FMAN = 0, Port ID = 3
          Found /fsl,dpaa/ethernet@8, Tx Channel = 800, FMAN = 0, Port ID = 0#
          Found /fsl,dpaa/ethernet@9, Tx Channel = 801, FMAN = 0, Port ID = 1
          Configuring for 4 network interfaces
          Allocated DMA region size 0x1000000
          Released 0 bufs to BPID 7
          Released 0 bufs to BPID 8
          Released 8192 bufs to BPID 9
          Thread uid:0 alive (on cpu 1)
          ceetm> add 2..7
          Thread uid:1 alive (on cpu 2)
          Thread uid:2 alive (on cpu 3)
          Thread uid:3 alive (on cpu 4)
          Thread uid:4 alive (on cpu 5)
          Thread uid:5 alive (on cpu 6)
          Thread uid:6 alive (on cpu 7)
          ceetm>
```

When application starts, only 1 thread runs. User can add more threads by 'add' command to improve throughput, or specify cpu range on which thread runs. For example

```
          root@t2080qds:/usr/etc# ceetm_demo 2..7 -c usdpaa_config_t2.xml -p
usdpaa_policy_hash_ipv4.xml -f ceetm_cfg.xml
```

In this case, 6 threads run after application starts.

The PCD configuration file may vary from board to board, here is summary of file name for boards that support CEETM.

```
          B4860QDS: usdpaa_config_b4_serdes_0x2a_0x98.xml
          T4240QDS: usdpaa_config_t4_serdes_1_1_6_6.xml
          T2080QDS: usdpaa_config_t2_serdes_66_16.xml
```

9.9.1.7 Generate trafflic flows

ceetm_demo works in a way like 'reflector'. It enhances traffic differentiation on egress side. The egress flow will be forwarded to class queue according to ‘tos’ value in IPv4 header.

TOS is a 8-bit value, 4 msb in this case means CHANNEL id within a LNI while 4 lsb means CQ id (0 – 0xf) within a CHANNEL. So if you want to egress traffic flow through CQ 10 in channel 2, the tos vaule should be 0x2a.

User can see the effect of packet scheduling by sending traffic flows with different TOS values.

Currently QMan CEETM supports dual-rate shapers and dual-scheduler on two levels. Please refer to QMan user guide for elaboration about them.

9.9.2 DPAA Offloading Applications Users Guide

9.9.2.1 Introduction

This document supplies several methods for modifying the QorIQ USDPAA offloading applications using the DPA offloading driver API.

The document explores the following target use cases providing detailed and interactive examples. These include:

- USDPAA classifier demo application
- USDPAA IP fragmentation demo application
- USDPAA IP reassembly demo application
- USDPAA IPSec offloading application
- USDPAA IPSec & IP Forwarding offloading application using Network Function Layer

See Appendix A of the DPAA Offloading Applications User Guide for list of supported processors.

The following table provides a short summary of each example.

Table 231. Summary of USDPAA offloading applications

Application	Description
USDPAA classifier demo application	Provides an example on how to use basic frame manager features such as parse, classify, distribution and header manipulation.
USDPAA IP fragmentation demo application	Illustrates how to configure basic IP fragmentation provided by the Frame Manager. For frame manager version 3 devices the reassembly application also demonstrates the Virtual Storage Profile configuration and selection for reassembled flows.
USDPAA IP reassembly demo application	Explains how to configure basic IP reassembly provided by the Frame Manager. For Frame Manager version 3 devices the reassembly application also demonstrates the Virtual Storage Profile configuration and selection for reassembled flows.
USDPAA IPSec offloading application	Reveals how to use standard Linux tools to configure IPSec offloading using the DPA offloading driver.
USDPAA IPSec & IP forwarding offloading application using Network Function Layer	Demonstrates how IPSec and IP forwarding services can be offloaded using the DPAA offloading *Network Function Layer*

Before using any of the applications in this document, you need to build and install the DPAA offloading drivers as described in section "*Appendix B - Enabling DPA Offloading Drivers in the Linux Kernel*".

9.9.2.2 Altering the classifier_demo application

This application demonstrates how packet classification can be offloaded to the frame manager by using the DPA offloading driver. It shows several functionalities of the classifier, traffic manager(on CEETM capable platforms) and statistics components.

9.9.2.2.1 Overview

The application performs the following operations on the created resources (a set of three DPA Classifier Exact Match tables managed by key and a group of DPA Stats counters):

- Create an Exact Match Table
- Insert entry in an Exact Match Table
- Delete entry by Key in an Exact Match Table
- Flush an Exact Match Table
- Free an Exact Match Table
- Dynamically create header manipulations
- Set up header manipulation on a table entry
- Free the header manipulation associated with a table entry
- Create a DPA Stats class counter for the entire Exact Match Table for each table created
- Retrieve synchronously and asynchronously the DPA Stats counters
- Remove all created DPA Stats counters

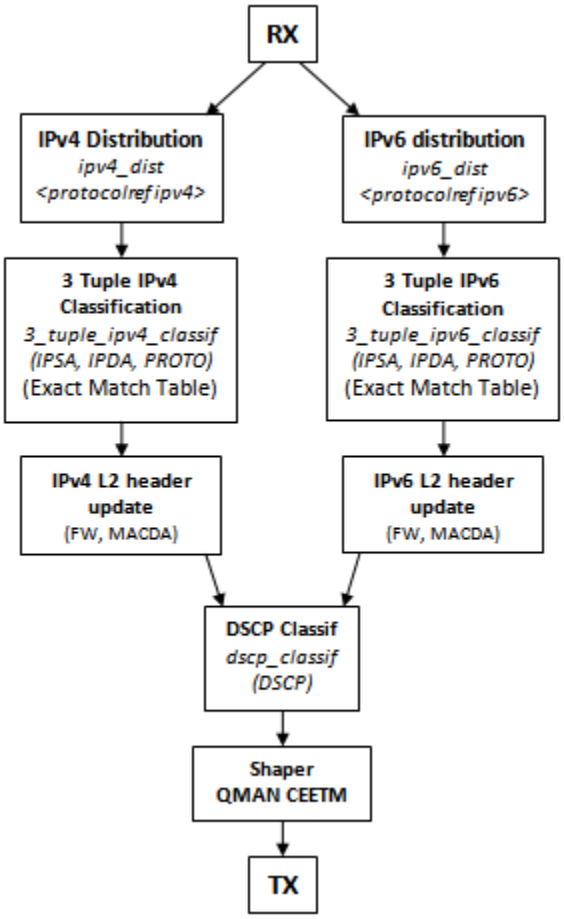

Figure 239. Classifier Demo Application Scheme

The application has defined a number CLI commands, each is meant to validate different functionalities. The user can add or remove classification entries by typing the command “add4” for IPv4, respectively “add6” for IPv6. For removing the inserted entries, the commands “rem4”, or “rem6” must be used in the USDPAA PPAM command line.

When a frame is received, it is first distributed based on protocol, then if the table lookup process results in a HIT condition, the frame is sent to the next classifier table where, based on DSCP value, the frame is forwarded to a logical frame queue corresponding to a traffic manager class queue in case of CEETM capable platforms. At the traffic manager level, based on priorities, the frame is forwarded or not to the TX port. On P platforms the frame is enqueued on the first fqid configured for the TX port.

A header manipulation chain is attached to each of the entries which are inserted in the IPv4/IPv6 Exact Match table. Each header manipulation chain consists of a TTL decrement, a PAT (Port Address Translation) and a forwarding header manipulation (L2 header update). The values in each header manipulation operation are updated at runtime based on the information passed by the user along with the add4/6 command.

During the life cycle of the application, the user has the possibility to perform insert or delete classification keys or to read values of the DPA Stats class counters by entering the following commands in the USDPAA PPAM command line:

Table 232. Application

Command Line	Description
add4 <IPSA><IPDA><PROTO><new-MACDA><new-SPORT><new-DPORT>	dynamically insert a new entry in 3_tuple_ipv4_classif Exact Match table.
add6 <IPSA><IPDA><PROTO><new-MACDA><new-SPORT><new-DPORT>	dynamically insert a new entry in 3_tuple_ipv6_classif Exact Match table.
rem4 <IPSA><IPDA><PROTO>	dynamically remove an entry from 3_tuple_ipv4_classif Exact Match table.
rem6 <IPSA><IPDA><PROTO>	dynamically remove an entry from 3_tuple_ipv6_classif Exact Match table.
get_classif_stats	retrieve the statistics for the created classifier table counters in asynchronous mode and print the returned values.
get_classif_stats_sync	retrieve the statistics for the created classifier table counters in synchronous mode and print the returned values.
get_traffic_stats	retrieve the statistics for the created traffic manager/ethernet counters in asynchronous mode and print the returned values.
get_traffic_stats_sync	retrieve the statistics for the created traffic manager/ethernet counters in synchronous mode and print the returned values.
reset_stats	reset the statistics for all created DPA Stats counters.

In order to have a successful operation, the user must verify that the returned values of the counters statistics matches the number of sent frames.

Classifier demo is a USDPAA application that requires the following resources:

- `classif_demo_config.xml` - config file
- `classif_demo_policy.xml` - policy file

This user space application initializes the classification schemes using the FMC library, and afterwards it manages the DPA Classifier table.

The application receives traffic on the configured Ethernet port. The traffic is split in IPv4 and IPv6 flows, and then lookups are performed in the DPA Classifier table. If the result is HIT, the frame is sent to the next configured classifier table, the dscp_classif.

On B4 platforms, at this point, based on DSCP, the frame is enqueued to the appropriate logical frame queue. The traffic manager based on its internal algorithms decides to send or not the packet back to be transmitted on the interface from which it was received.

On the other hand, in case of P4 platforms, the traffic is classified based on the DSCP table entries, shown in the tables below, and then enqueued on the fqid configured for the TX port used by the application.

If the result is MISS, the frame is silently dropped in both cases.

The application creates a two Exact Match tables managed by key, none of them contains prefilled entries, but the user can dynamically insert or remove keys with add4/6 or rem4/6 PPAM CLI commands. Each table supports a maximum of 64 keys. Each key is composed from the following parts: IPSA, IPDA and protocol. The add commands have an additional field MACDA that is used for the forwarding header manipulation.

Another Exact Match table is populated by the application with 12 entries that represent the main QOS traffic classes AFxy. Those entries are static, defined in the application and cannot be modified. For each traffic class a CEETM channel is defined, each channel has three CEETM class queues (corresponding to the level of drop precedence) and a class congestion group (that aggregates all dropped traffic) defined. Due to lack of CEETM support on P4 platforms all traffic is sent from the DSCP classification table to the first fqid configured on the TX port and the table structure is the same as represented bellow.

Table 233. Application QOS Table (Classifier Exact Match Table)

Channel	Class Queue	QOS	DSCP	TOS	Entry
CH0	CQ0	AF11	0x0A	0x28	0
CH0	CQ1	AF12	0x0C	0x30	1
CH0	CQ2	AF13	0x0E	0x38	2
CH1	CQ0	AF21	0x12	0x48	3
CH1	CQ1	AF22	0x14	0x50	4
CH1	CQ2	AF23	0x16	0x58	5
CH2	CQ0	AF31	0x1A	0x68	6
CH2	CQ1	AF32	0x1C	0x70	7
CH2	CQ2	AF33	0x1E	0x78	8
CH3	CQ0	AF41	0x22	0x88	9
CH3	CQ1	AF42	0x24	0x90	10
CH3	CQ2	AF43	0x26	0x98	11

NOTE

Classifier demo application does not use the cores or the IP stack for performing classification (look-up actions) or header manipulation operation (protocol operations). It uses the frame manager features for traffic classification and header manipulation.

9.9.2.2.2 Running classifier_demo

Classifier_demo application supports the following platforms:

- P2041
- P4080
- B4860
- B4420
- T4240
- T2080
- LS1043A

To run the application, you may need to use a specific device tree file that comes with the Linux DPA offloading driver. The following shows you how to produce this device tree file for your platform.

9.9.2.2.2.1 Application environment specifications

This application uses the setup pictured bellow with the following connections:

Table 234. Port Connections

SoC	Traffic Port
P4080	`fm1-mac0`
P2041	`fm0-mac1`
B4860	`fm0-mac5`
B4420	`fm0-mac3`
T4240	`fm0-mac4`
T2080	`fm0-mac3`
LS1043A	`fm0-mac0`

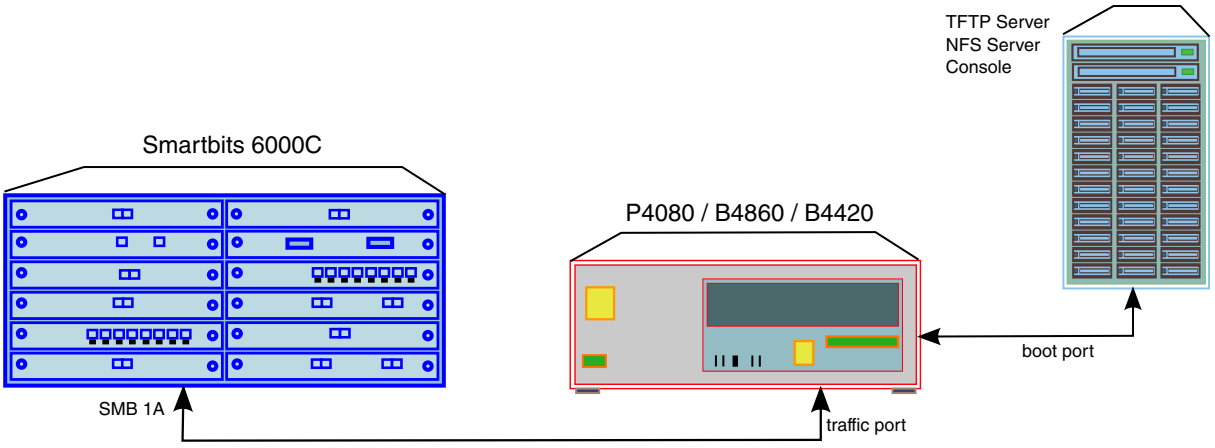

Figure 240. Use Case Set-up

If you want *classifier_demo* application to use a different traffic port than the ones listed above, you need to update the XML port configuration file for your platform and to use the proper command line arguments for your new traffic port. Please refer to the paragraph **Application start-up and configuration** for further details.

9.9.2.2.2.2 Application start-up and configuration

Use the steps described later in **Compiling the Device Tree for USDPAA Applications** to generate a device tree binary file. Boot the board with the compiled kernel, `arch/powerpc/boot/uImage`, and the `DTB` file.

To enable the scatter-gather support in the DPAA Ethernet driver add the following to the boot arguments:

```
setenv othbootargs "fsl_fm_max_frm=9600"
```

The following commands assume that the application runs on a B4860QDS board. When running on a different supported platform, please use the proper configuration file and the parameters listed in the section above. Run these commands to set up the USDPAA network configuration and PCD resources used by the application:

```
export DEF_CFG_PATH=/usr/etc/classifier_demo_config-b4860.xml
export DEF_PCD_PATH=/usr/etc/classifier_demo_policy.xml
export DEF_PDL_PATH=/etc/fmc/config/hxs_pdl_v3.xml
```

First ensure that the following device files have been created:

- `/dev/dpa_classifier`
- `/dev/dpa_stats`

The `classifier_demo` can be run with the following command:

```
/usr/bin/classifier_demo -f 0 -t 6
```

The following arguments specify the frame manager ports used by the application:

- `-f [FMan index]`
- `-t [Traffic Port index]`

The output displayed by the application would be something similar with the following:

```
Found /fsl,dpaa/dpa-fman0-oh@2, Tx Channel = 80a, FMAN = 0, Port ID = 1
Found /fsl,dpaa/dpa-fman0-oh@3, Tx Channel = 80b, FMAN = 0, Port ID = 2
Found /fsl,dpaa/dpa-fman0-oh@4, Tx Channel = 80c, FMAN = 0, Port ID = 3
Found /fsl,dpaa/ethernet@4, Tx Channel = 806, FMAN = 0, Port ID = 4
```

```
Found /fsl,dpaa/ethernet@5, Tx Channel = 807, FMAN = 0, Port ID = 5
Found /fsl,dpaa/ethernet@16, MAC-LESS node
Found /fsl,dpaa/ethernet@17, MAC-LESS node

9.9.2.2.2.3 Running the application

At this point the user can start sending traffic with the traffic generator.

By running a set of add4 and add6 commands after the application is started, the user can populate the IPv4 and IPv6. The commands for populating the IPv4 table are:

```
➢ add4 192.168.1.1 128.224.10.10 tcp 44:00:00:00:00:01 881 921
```

```
➢ add4 192.168.25.1 128.224.20.10 udp 44:00:00:00:00:02 882 922
```

```
➢ add4 192.168.50.1 128.224.30.10 TCP 44:00:00:00:00:03 883 923
```

```
➢ add4 192.168.75.1 128.224.40.10 UDP 44:00:00:00:00:04 884 924
```

```
➢ add4 192.168.100.1 128.224.50.10 6 44:00:00:00:00:05 885 925
```

```
➢ add4 192.168.125.1 128.224.60.10 17 44:00:00:00:00:06 886 926
```

The commands for populating the IPv6 table are:

```
➢ add6 3ffe:1944:0100:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:010b TCP
66:00:00:00:00:01 6011 501
```

```
➢ add6 3ffe:1944:0200:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:020b UDP
66:00:00:00:00:02 6012 502
```

```
➢ add6 3ffe:1944:0300:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:030b 6
66:00:00:00:00:03 6013 503
```

```
➢ add6 3ffe:1944:0400:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:040b 17
66:00:00:00:00:04 6014 504
```

```
➢ add6 3ffe:1944:0500:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:050b tcp
66:00:00:00:00:05 6015 505

➢ add6 3ffe:1944:0600:000a:0000:00bc:2500:0d0b 1ffe:2044:ba00:320a:1100:00bc:25a1:060b udp
66:00:00:00:00:06 6016 506
```

After entering those commands the content of the DPA Classifier Exact Match tables will be:

Table 235. IPv4 Classification Table (Classifier Exact Match Table)

Flow	IP SRC	IP DST	Protocol
1	192.168.1.1	128.224.10.10	TCP
2	192.168.25.1	128.224.20.10	UDP

6	3ffe:1944:0600:000a: 0000:00bc:2500:0d0b	1ffe:2044:ba00:320a: 1100:00bc:25a1:060b	UDP

By sending with a traffic generator flows identically to the ones described in the tables above, the user will notice that the traffic is received back with the TTL decremented and the MACDA, L3 source port and destination ports updated as specified in the *add4* / *add6* command that inserted the entry. On P4 platforms, all traffic is received back. If additional flows are defined in the traffic generator configuration, the miss statistics will also be increased. Based on the traffic sent the user can read the statistics by running the *get_classif_stats*/*get_classif_stats_sync* or *get_traffic_stats*/*get_traffic_stats_sync* commands. In order to have a successful operation, the user must verify that the returned values of the counter statistics matches the number of sent frames.

In order to shut down the application you can type *quit* in the application console.

9.9.2.3 Adapting the fragmentation_demo application

The application demonstrates how IP fragmentation can be offloaded to the FMan by using the direct XML configuration and the DPA offloading driver.

9.9.2.3.1 Overview

The IP fragmentation function works strictly on offline ports and performs fragmentation of IPv4 and IPv6 packets into IP fragments according to RFC 791 and RFC 2460. The DPA Stats component usage is highlighted in the same application by creating single and class counters for the IP Fragmentation packet header manipulation.

The application initializes the IP fragmentation and the Parse-Classify-Police-Distribute (PCD) description through the use of the FMC Library.

Traffic is received on a backhaul Rx port (BP) by USDPAA fragmentation_demo application. IP packets that pass the Parse-Classify and Distribute descriptor configured on the Rx port are received in the application. The application swaps the Ethernet MAC addresses and enqueue the traffic in the offline port. This port performs a classification based on VLAN and, depending on the value, it performs IP fragmentation if the frame size is larger than a pre-configured value. Afterwards it forwards the obtained fragments back to the Tx queue of the BP port.

The user has the possibility of performing a number of actions on the DPA Stats counters by typing the following commands in the USDPAA PPAM command line:

Table 237. USDPAA PPAM commands

Command Line	Description
get_stats	retrieve the statistics for the created counters in an asynchronous mode and print the returned values.
get_stats_sync	retrieve the statistics for the created counters in a synchronous mode and print the returned values.
reset_stats	reset the statistics for the created counters.

To have a successful operation, you should verify that the returned values of the counters statistics matches the number of sent frames.

NOTE

The fragmentation demo application is different from the fragmentation performed in the Linux IP stack because the demo does not use the cores or the IP stack for performing fragmentation operation. It uses the frame manager for fragmentation processing.

9.9.2.3.2 Running fragmentation_demo

fragmentation_demo application supports the following platforms:

- P2041
- P4080
- B4860
- B4420
- T4240
- T2080
- LS1043A

In order to run it you may need to use a specific device tree file that comes with the DPA offloading driver. Please read below about how to produce this device tree file for your platform.

9.9.2.3.2.1 Application environment specifications

The environment is the same as described for the classifier_demo application. Please see **Classifier_demo: Application environment specifications.**

If you need the *fragmentation_demo* application to run on a different traffic port than the defaults, you will need to adapt the XML port configuration file for your platform and use the proper command line arguments for your new traffic port. Please refer to the paragraph **Application start-up and configuration** for further details.

9.9.2.3.2.2 Application start-up and configuration

Use the steps described later in **Appendix A: Compiling the Device Tree for IP Offloading** to generate a device tree binary file. Boot the board with the compiled kernel, `arch/powerpc/boot/uImage`, and the `DTB` file.

To enable the scatter-gather support in the DPAA Ethernet driver add the following to the boot arguments:

```
setenv othbootargs "fsl_fm_max_frm=9600"
```

The following commands assume that the application runs on a B4860QDS board. When running on a different supported platform, please use the proper parameters listed in **Running Classifier_demo: Application environment specifications**. For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH=/usr/etc/fragmentation_demo_config-b4860.xml
export DEF_PCD_PATH=/usr/etc/fragmentation_demo_policy.xml
export DEF_PDL_PATH=/etc/fmc/config/hxs_pdl_v3.xml
```

First ensure that the following device files have been created:

- `/dev/dpa_stats`

The `fragmentation_demo` can be run with the following command:

```
/usr/bin/fragmentation_demo -f 0 -t 6 -o 2
```

The following arguments specify the FMan ports used by the application:

- `-f [FMan index]`
- `-o [Offline Port index]`
- `-t [BP Rx port index]`

The output displayed by the application would be something similar with the following:

```
Found /fsl,dpaa/dpa-fman0-oh@2, Tx Channel = 80a, FMAN = 0, Port ID = 1
Found /fsl,dpaa/ethernet@0, Tx Channel = 802, FMAN = 0, Port ID = 0
Found /fsl,dpaa/ethernet@1, Tx Channel = 803, FMAN = 0, Port ID = 1
Found /fsl,dpaa/ethernet@2, Tx Channel = 804, FMAN = 0, Port ID = 2
Found /fsl,dpaa/ethernet@5, Tx Channel = 807, FMAN = 0, Port ID = 5
Configuring for 2 network interfaces
Allocated DMA region size 0x1000000
Released 0 bufs to BPID 4
fragmentation_demo is assuming FMan:0 and eth:6 and offline port:2
Released 0 bufs to BPID 7
Released 0 bufs to BPID 8
Warn: drained 8192 bufs from BPID 9
Released 8192 bufs to BPID 9
```

```
Thread uid:0 alive (on cpu 1)
fragmentation_demo >
```

9.9.2.3.2.3 Running the application

The user should send IPv4 or IPv6 frames generated by an external traffic generator. The following example of IPv4 frames was used to validate the IPv4 Fragmentation:

Table 238. fragmentation_demo IPv4 Input Traffic

MAC SA	VLAN TCI	IP Source	Protocol	Size	IP Fragment Offset
00:00:00:00:00:29	0x2614	192.168.1.1	UDP	1280	0
00:00:00:00:00:2a	0x2615	192.168.1.2	UDP	1280	0
00:00:00:00:00:2b	0x2616	192.168.1.3	UDP	1280	0
00:00:00:00:00:2c	0x2617	192.168.1.4	UDP	1280	0

IPv4 frames that have the VLAN TCI value equal to 0x2614 or 0x2616 are fragmented into fragments of maximum 256 bytes in size, while frames that have the VLAN TCI value equal to 0x2615 or 0x2617 are fragmented into fragments of maximum 512 bytes in size.

IPv6 frames that have the VLAN TCI value equal to 0x6800 or 0x6802 are fragmented into fragments of maximum 256 bytes in size, while frames that have the VLAN TCI value equal to 0x6801 or 0x6803 are fragmented into fragments of maximum 512 bytes in size.

The following example of IPv6 frames was used to validate the IPv6 fragmentation:

Table 239. fragmentation_demo IPv6 input traffic

MAC SA	VLAN TCI	IP Source	Protocol	Size
00:00:00:00:00:2d	0x6800	3FFE:1944:0400:000A:0000:00BC:2500:0D01	UDP	1024
00:00:00:00:00:2e	0x6801	3FFE:1944:0400:000A:0000:00BC:2500:0D02	UDP	1024
00:00:00:00:00:2f	0x6802	3FFE:1944:0400:000A:0000:00BC:2500:0D03	UDP	1024
00:00:00:00:00:30	0x6803	3FFE:1944:0400:000A:0000:00BC:2500:0D04	UDP	1024

After sending the traffic, the user can see the statistics values for the IP fragmentation process. The counter “OH_FRAG1” stands for a single counter of type Fragmentation with MTU of 256 bytes, the counter “OH_FRAG2” stands for single counter of type Fragmentation with MTU of 512 bytes and both objects are also grouped in a class counter of type Fragmentation.

```
STATISTICS:       FRAG_TOTAL_FRAMES FRAG_FRAMES FRAG_GEN_FRAGS
OH_FRAG1        :                 0           0             0
OH_FRAG2        :                 0           0             0
CLS_MBR_OH_FRAG1:                 0           0             0
CLS_MBR_OH_FRAG1:                 0           0             0
```

In order to shut down the application you can type *quit* in the application console.

9.9.2.4 Manipulating the reassembly_demo application

This application demonstrates how IP reassembly can be offloaded to the FMan by using the direct XML configuration and the DPA offloading driver.

9.9.2.4.1 Overview

This application demonstrates how IP reassembly can be offloaded to the FMan by using the direct XML configuration and the DPA offloading driver. The IP Reassembly feature can be configured on an RX port or an Offline port and performs reassembly on detected IPv4 and IPv6 protocol fragments. For B4 platforms, the application also provides Virtual Storage Profile support. The DPA Stats component usage is highlighted in the same application by creating single counters for Ethernet and Reassembly, and both single and class counters for Classification Nodes.

The application initializes the Reassembly functionality and the Parse-Classify-Police-Distribute (PCD) description through the use of the FMC Library.

Traffic is received on a backhaul Rx port (BP) by USDPAA reassembly_demo application. IP fragments are detected and reassembled before arriving into the application. The application swaps Ethernet MAC addresses and enqueues the traffic back to the Tx queue of the same port.

The user has the possibility of performing a number of actions on the DPA Stats counters by typing the following commands in the USDPAA PPAM command line:

Table 240. DPA Stats class counter actions

Command Line	Description
get_stats	retrieve the statistics for the created counters in an asynchronous mode and print the returned values.
get_stats_sync	retrieve the statistics for the created counters in a synchronous mode and print the returned values.
reset_stats	reset the statistics for the created counters.

To have a successful operation, the user must verify that the returned values of the counters statistics matches the number of sent frames for each stage of the test.

9.9.2.4.1.1 Virtual storage profiles

The virtual storage profile is only available on frame manager v3. The configuration is transparent to the user. Three storage profiles are defined in the policy file `reassembly_demo_policy-v3.xml`:

```
<vsp name="Default_VSP" base="0"/>
<vsp name="IPv4_Reass_VSP" base="1"/>
<vsp name="IPv6_Reass_VSP" base="2"/>
```

The first storage profile, Default_VSP is also the default storage profile of the port. The second and the third storage profiles are used for IPv4 and IPv6 flows. Each of the storage profiles described above has a set buffer pool associated with it (up to four buffer pools can be defined per vsp)

The buffer pools are dynamically allocated and initialized by reassembly_demo.

When an IPv4 flow is reassembled / classified on inbound port, the IPv4_Reass_VSP is used and the buffers are selected from one of the buffer pools available for this VSP. When an IPv6 flow is reassembled/classified on inbound port, the

IPv6_Reass_VSP with buffers from one of the buffer pools available for this VSP is used. For any other flows the Default_VSP is selected.

The VSP selection mechanism described in this paragraph is totally transparent to the user and doesn't affect the use case behavior in any way.

In order to test the non-consistent storage profile functionality the user needs to take into consideration that if a fragment that enters the reassembly distribution is not the first fragment, de default VSP of the port is selected. Otherwise according to the classification, if the fist fragment has the L4 destination port equal to a specific value, the IPv4 VSP is selected. If the reassembled frame has fragments in buffers from different buffer pools, then there is a NCSP event triggered and the frame is enqueued to the NCSP queue. For testing this particular case the user has to take care sending the first fragment of the IPv4 frame (the one with the Fragment Offset flag with value 0) after any other fragment (Ex: fragment3, fragment2, fragment1, fragment4). For the moment the NCSP could be tested only with IPv4 frames.

9.9.2.4.1.2 Differences from Linux IP stack

Reassembly_demo application does not use the cores or the IP stack for performing reassembly operation. It uses the frame manager for processing the reassembly.

9.9.2.4.2 Running reasembly_demo

reasembly_demo application supports the following platforms:

- P2041
- P4080
- B4860
- B4420
- T4240
- T2080
- LS1043A

In order to run it you may need to use a specific device tree file that comes with the DPA offloading driver. Please read below about how to produce this device tree file for your platform.

9.9.2.4.2.1 Application environment specifications

The environment is the same as described for the classifier_demo application. Please see **Classifier_demo: Application environment specifications.**

If you need the *reassembly_demo* application to run on a different traffic port than the defaults, you will need to

1. adapt the XML port configuration file for your platform
2. adapt the DTS file that Linux kernel boots up with and
3. use the proper command line arguments for your new traffic port.

Please refer to the paragraph **Application start-up and configuration** for further details.

9.9.2.4.2.2 Application start-up and configuration

Use the steps described later in **Appendix A: Compiling the Device Tree for IP Reassembly** to generate a device tree binary file. Boot the board with the compiled kernel, `arch/powerpc/boot/uImage`, and the `DTB` file.

To enable the scatter-gather support in the DPAA Ethernet driver add the following to the boot arguments:

```
setenv othbootargs "fsl_fm_max_frm=9600"
```

The following commands assume that the application runs on a B4860QDS board. When running on a different supported platform, please use the proper parameters listed in **Running Classifier_demo: Application environment**

specifications. For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH=/usr/etc/reassembly_demo_config-b4860.xml
export DEF_PCD_PATH=/usr/etc/reassembly_demo_policy.xml
export DEF_PDL_PATH=/etc/fmc/config/hxs_pdl_v3.xml
```

First ensure that the following device files have been created:

- `/dev/dpa_stats`

The `reassembly_demo` can be run with the following command:

`/usr/bin/reassembly_demo –f 0 –t 6`

The following arguments specify the FMan ports used by the application:

- `-f [FMan index]`
- `-t [Traffic Port index]`

The output displayed by the application would be something similar with the following:

```
Loading configuration
Found /fsl,dpaa/dpa-fman0-oh@2, Tx Channel = 80a, FMAN = 0, Port ID = 1
Found /fsl,dpaa/dpa-fman0-oh@3, Tx Channel = 80b, FMAN = 0, Port ID = 2
Found /fsl,dpaa/dpa-fman0-oh@4, Tx Channel = 80c, FMAN = 0, Port ID = 3
Found /fsl,dpaa/ethernet@0, Tx Channel = 802, FMAN = 0, Port ID = 0

CLS_CLASSIF: IPv6_KEY0 IPv6_KEY1 IPv6_KEY2 IPv6_KEY3 MISS
                0          0         0         0       0
CNT_CLASSIF: IPv4_KEY0 IPv4_KEY1 IPv4_KEY2 IPv4_KEY3 MISS
                0          0         0         0       0
CLS_CLASSIF: IPv4_KEY0 IPv4_KEY1 IPv4_KEY2 IPv4_KEY3 MISS
                0          0         0         0       0
```

In order to shut down the application you can type *quit* in the application console.

9.9.2.5 Customizing the ipsec_offload application

USDPAA ipsec_offload is a multi-threaded application which applies a subset of IPsec transformations to the IPv4/IPv6 traffic.

9.9.2.5.1 IPSec_offload application overview

The IPv4/IPv6 traffic is processed between two Ethernet ports. The inbound port expects encrypted/tunneled traffic while the outbound port expects clear-text traffic. The classification, encryption/decryption, authentication, encapsulation/decapsulation is accomplished using the DPA offload driver which connects and configures DPAA traffic processing accelerators (Fman, SEC) to completely offload IPSec processing based on common Linux configuration tools (setkey, ip xfrm, arp, ip neigh). The following features are currently supported:

- ESP tunnel mode.
- TOS/ECN/DSCP propagation.

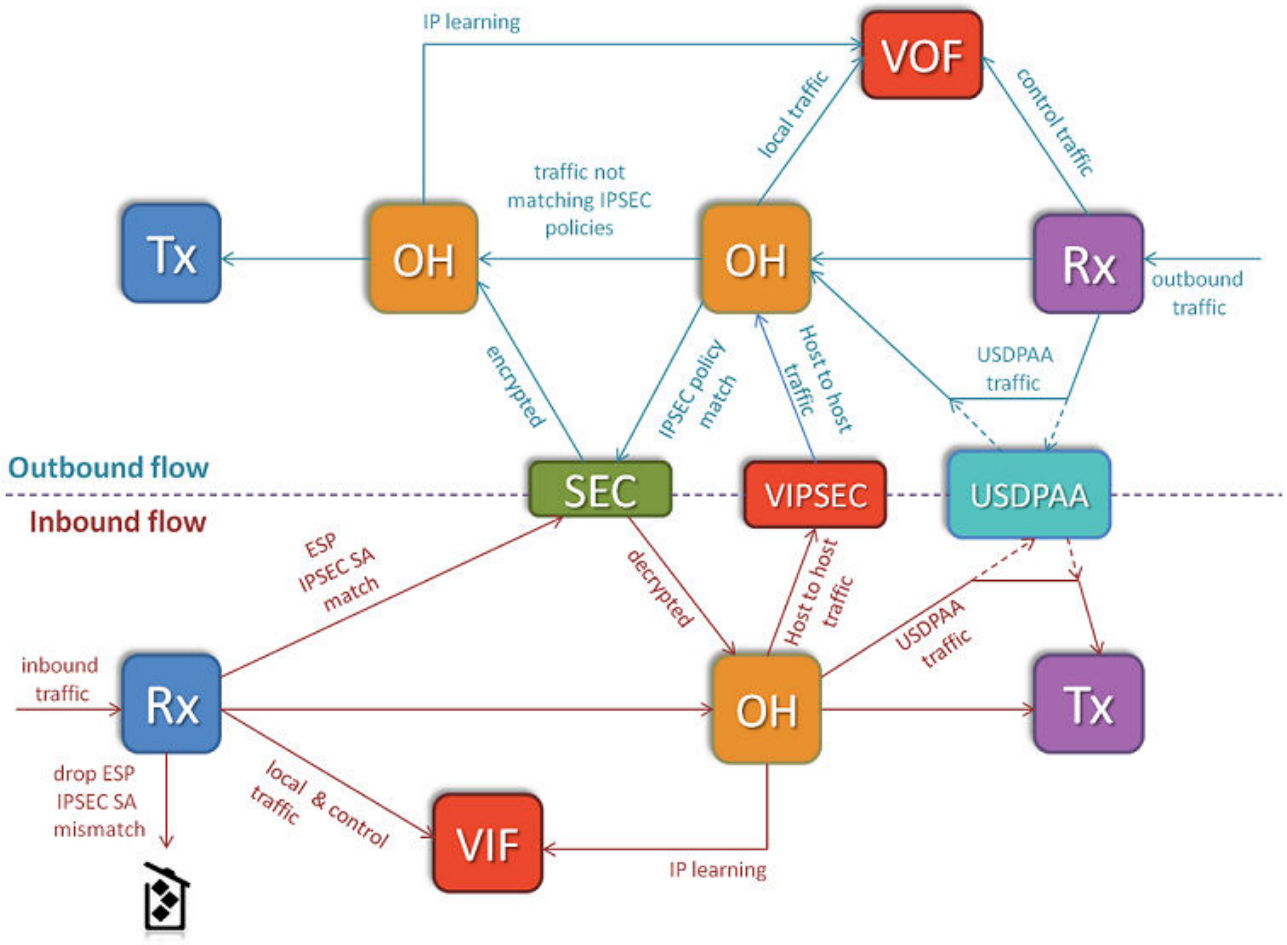

Figure 241. IPSec_offload flows

9.9.2.5.1.1 IPSec_offload outbound flows

The clear text traffic is received on the **outbound Rx** and classified based on UDP destination port. Frames matching UDP destination port 2152 are received by USDPAA frame processing threads.The rest of the frames are sent directly to **pre-encryption OH** port. On this port the traffic is classified according to configured IPSec traffic selectors. Frames for which IPsec policy is applicable are sent to SEC for security processing. Optionally, this port performs IP fragmentation for frames matching IPsec policy if frame size is larger than a configured value (`mtu_pre_enc`). Traffic not matching IPsec policy bypass security processing and are enqueued directly to post-encryption OH port. The SEC output frames are enqueued to **post-**

encryption OH port. On this port the Ethernet source and destination addresses are updated with Tx port MAC address and next hop MAC address respectively.

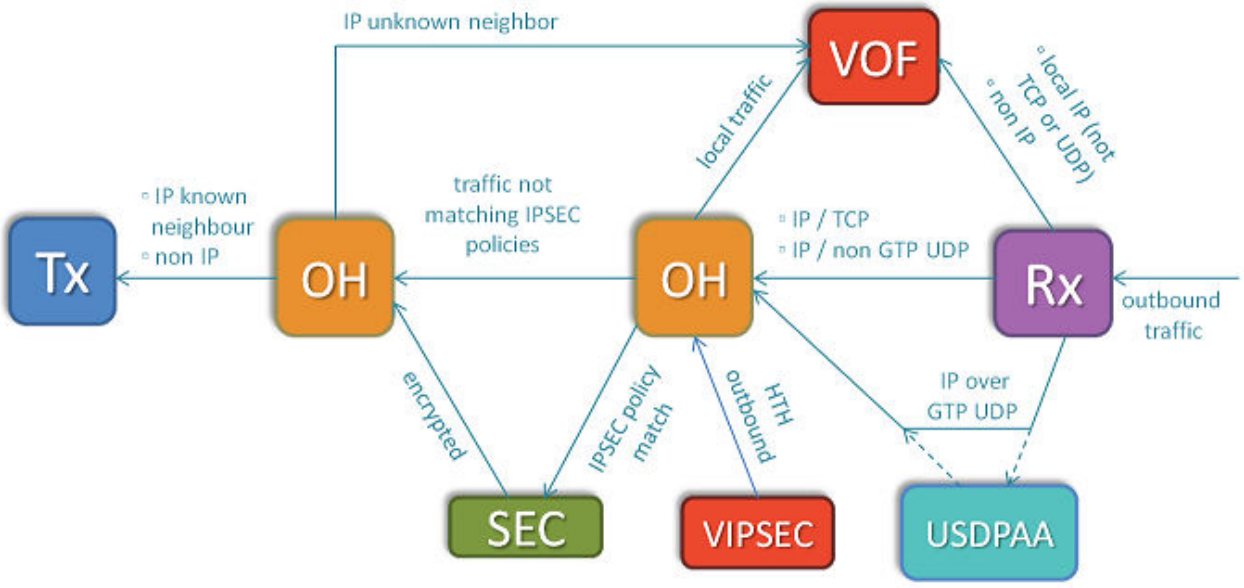

Figure 242. Outbound processing

Below are some flow diagrams that explain (as per the application's PCD) how frames are being processed at each node.

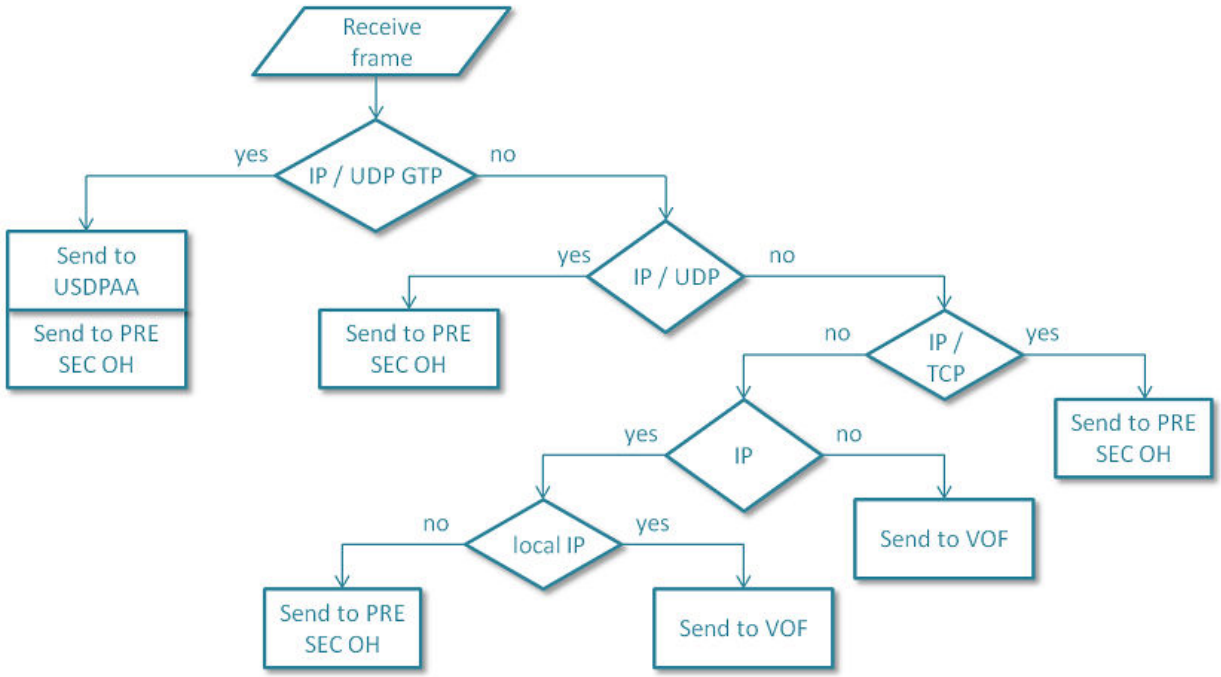

Figure 243. Outbound Rx

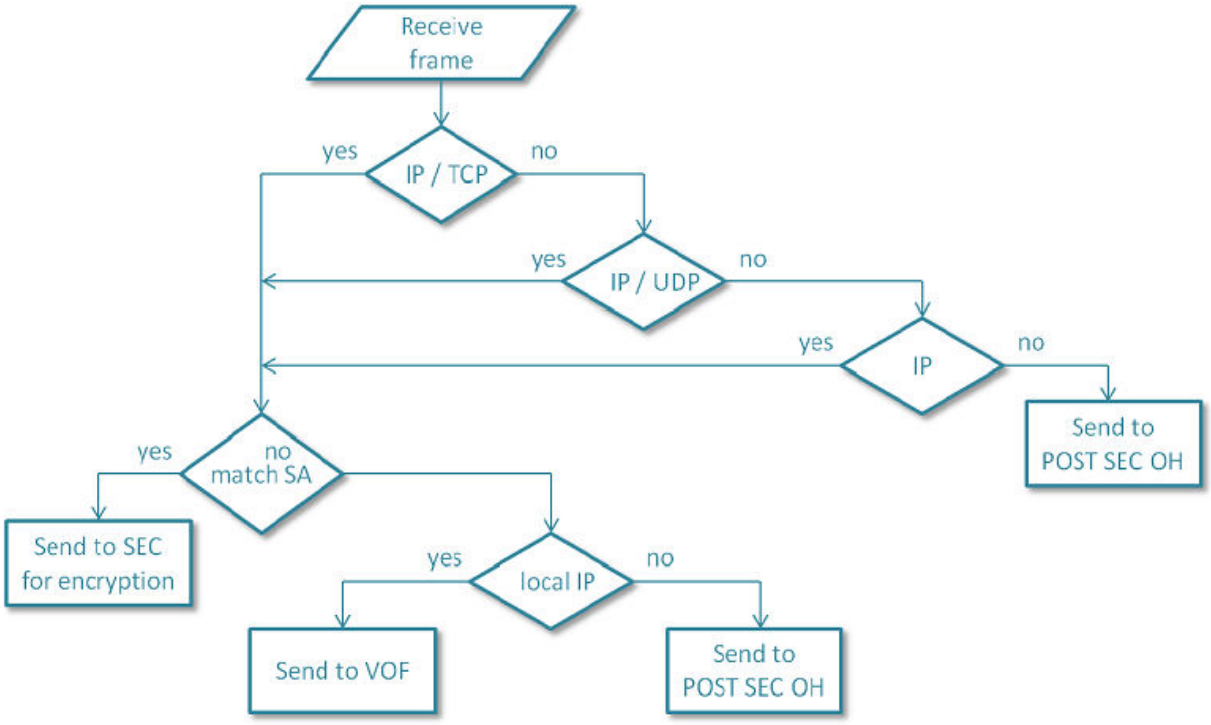

Figure 244. Outbound Pre SEC OH

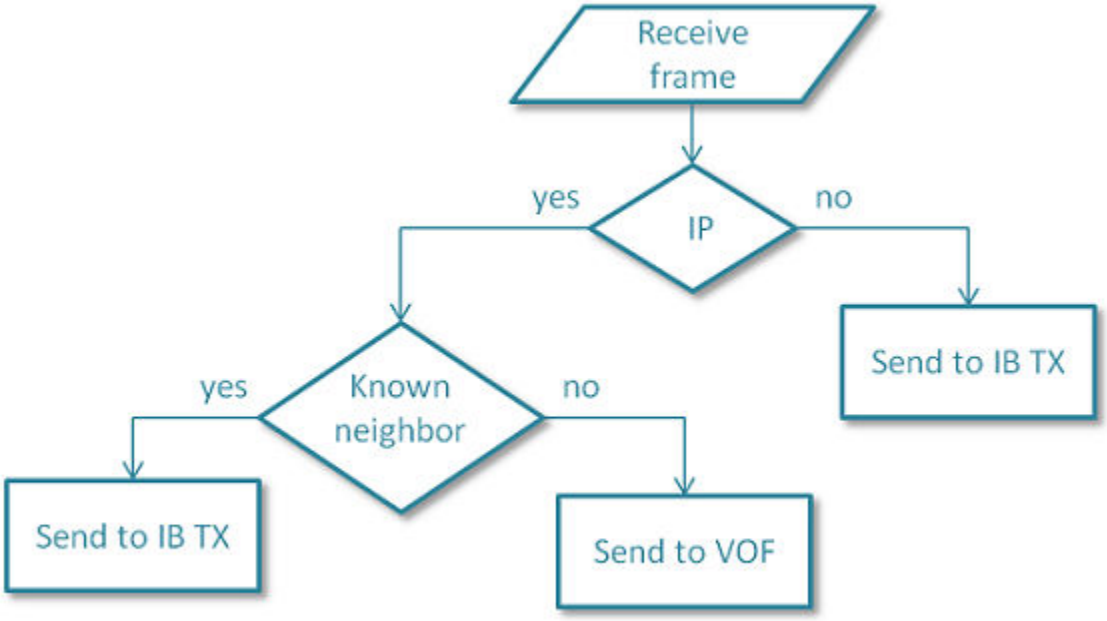

Figure 245. Outbound Post SEC OH

9.9.2.5.1.2 IPSec_offload inbound flows

IPsec traffic (IPv4/IPv6 ESP and UDP-encap ESP) received on the inbound port is classified according to offloaded security associations. Frames for which a security association is found are sent to the appropriate SEC engine input queues for

decryption/decapsulation; traffic for which a security association is not found is dropped. Non-IPsec traffic is directly sent to **inbound** OH port. Decrypted and non-IPsec traffic is reassembled if fragmented, optionally passes inbound policy verification and further a post IPsec classification which sends frames matching UDP destination port 2152 to USDPAA frame processing threads. Frames not matching UDP destination port 2152 have their Ethernet source and destination MAC addresses updated with Tx port MAC address and next hop MAC address respectively.

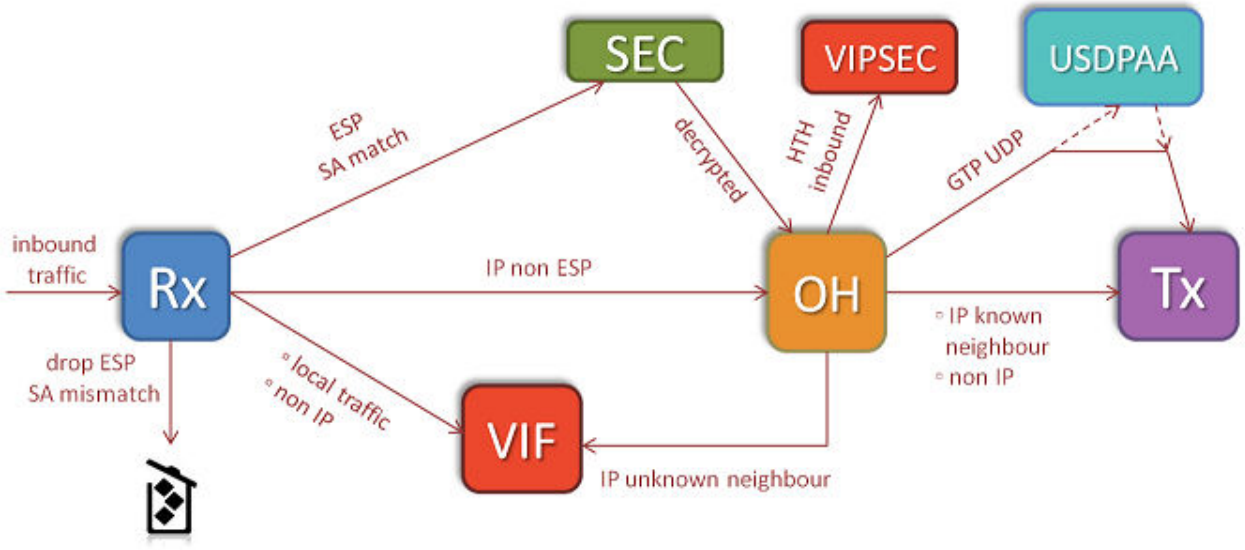

Figure 246. Inbound processing

Below are some flow diagrams that explain (as per the application's PCD) how frames are being processed at each node.

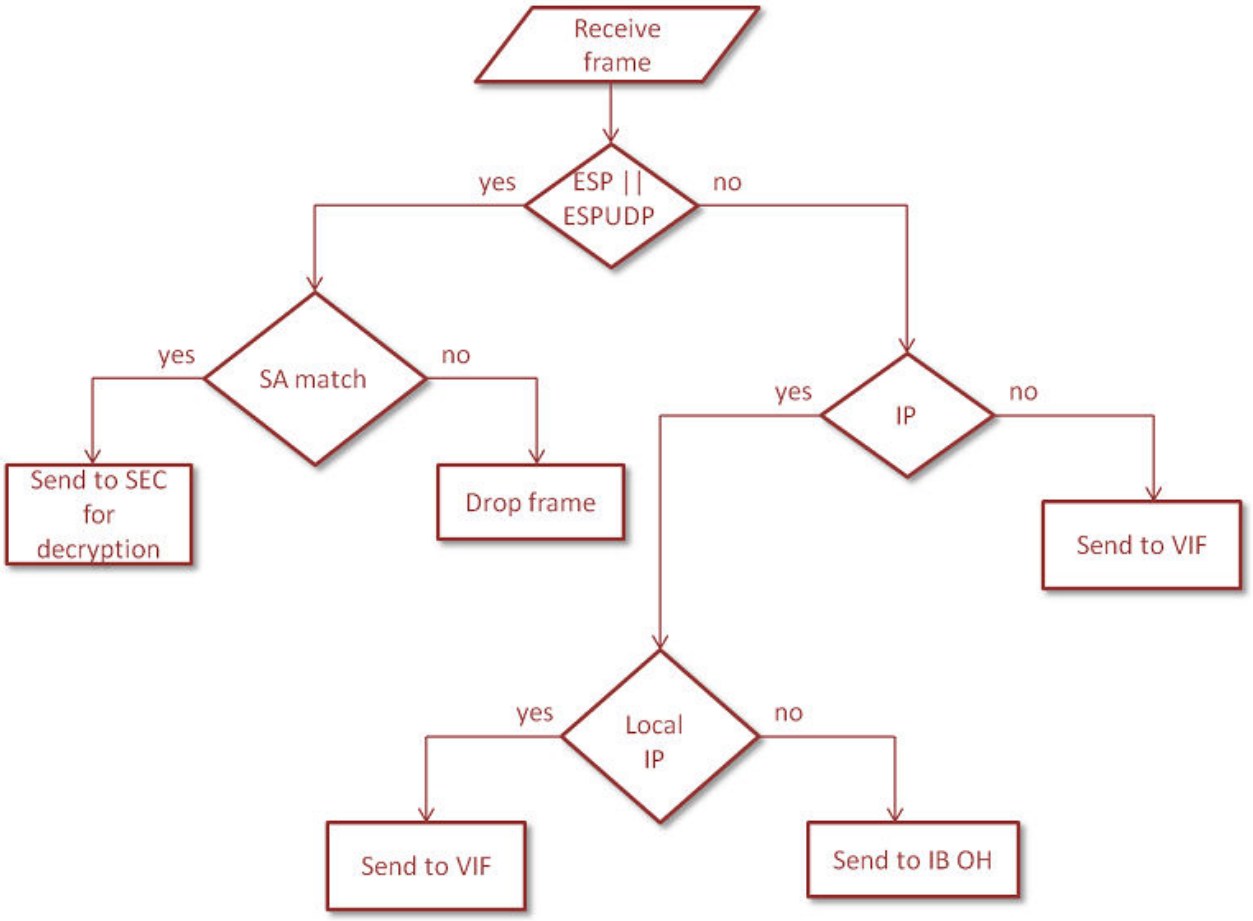

Figure 247. Inbound Rx

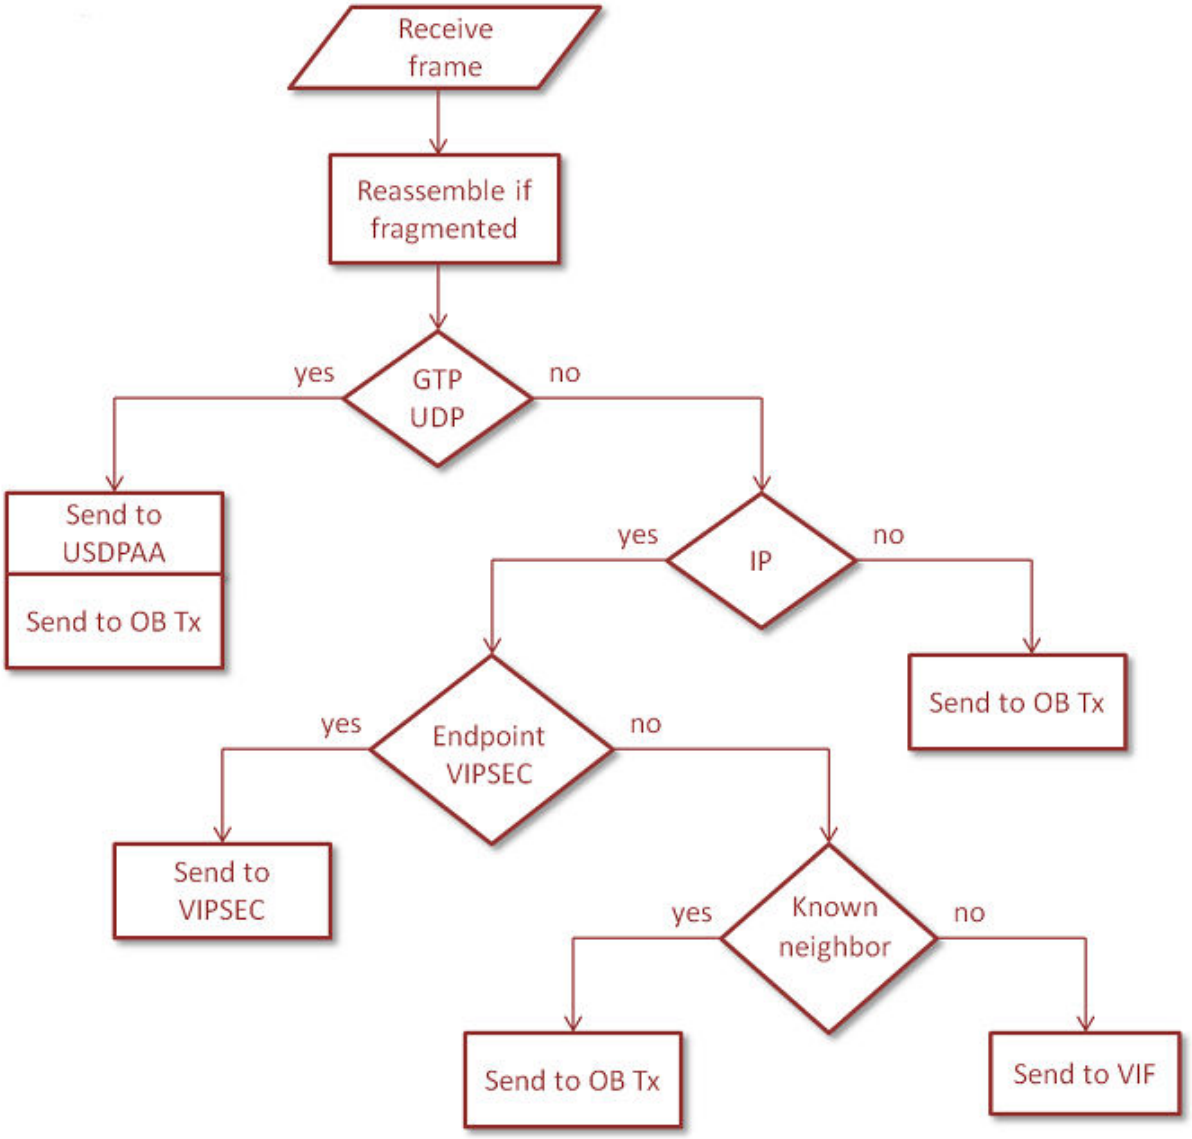

Figure 248. Inbound OH

9.9.2.5.1.3 Differences from existing ipsecfwd application

This USDPAA application allows complete offload of IPSec data paths, thus relieving the cores from the tasks of submitting/ receiving frames to/from the SEC engine prior or after tunnel payload processing nd from frame forwarding after IPsec processing. Core intervention is performed only for tasks related to application specific processing. Also, the application supports standard Linux tools for configuration.

9.9.2.5.2 Running the Application

The procedures for configuring the environment, starting up and configuring the Ipsec_offload application are discussed.

9.9.2.5.2.1 Application environment specifications

The application can run in a real network setup configuration and inter-operate with other IPSec gateways. There is also an option to put the inbound port in loopback mode and return IPSec traffic to the inbound port. The details on how to run the application refers to this mode.

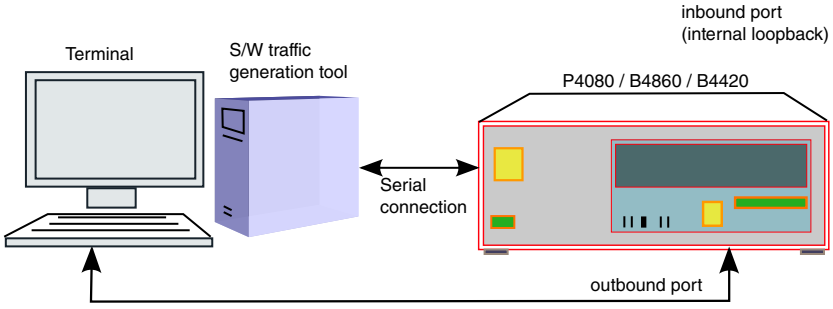

Figure 249. Use case set-up in loopback mode

Table 243. Port connections

SoC	Inbound Port	Outbound Port
P4080	`fm1-mac1`	`fm1-mac0`
P2041	`fm0-mac2`	`fm0-mac1`
B4860	`fm0-mac4`	`fm0-mac5`
B4420	`fm0-mac2`	`fm0-mac3`
T4240	`fm0-mac1`	`fm0-mac0`
T2080	`fm0-mac2`	`fm0-mac3`

If you need the *ipsec_offload* application to run on different traffic ports than the ones listed above, you will need to

1. adapt the XML port configuration file for your platform and
2. adapt the DTS file that Linux kernel boots up with.

Please refer to the paragraph **Application start-up and configuration** for further details.

9.9.2.5.2.2 Application Start-up and Configuration

In this section you will find out how to run the ipsec_offload application. All the examples below are given for a B4860QDS board and assume the standard SDK environment is being used (with the standard RCW, u-boot, *-usdpaa-shared-interfaces.dts).

Note: When running on a different platform, please modify the parameters accordingly as shown in the tables below. **Custom scenarios that alter the default configurations involve changes that are out of the scope of this document.**

Setup the environment

Use the steps described in Appendix A - **Compiling the device tree for IPSec offload** to generate a device tree binary file. Boot the board with the compiled kernel (`arch/powerpc/boot/uImage`) and the DTB file.

To enable the scatter-gather support in the DPAA Ethernet driver add the following boot arguments in uBoot:

```
setenv othbootargs "fsl_fm_max_frm=9600"
```

Setup USDPAA configurations and PCD resources

The configuration xml and the PCD xml vary according to platform. Choose the appropriate files for your platform as per the table below. For running the application in single mode or with multiple instances consult the corresponding sections of the user guide.

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_b4860.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_b4.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
```

Table 244. XML config files

SOC	DEF_CFG_PATH	DEF_PCD_PATH
P4080	/usr/etc/ ipsec_offload_config_p4080.xml	/usr/etc/ipsec_offload_pcd_p4.xml
P2041	/usr/etc/ ipsec_offload_config_p2041.xml	/usr/etc/ipsec_offload_pcd_p2.xml
B4860	/usr/etc/ ipsec_offload_config_b4860.xml	/usr/etc/ipsec_offload_pcd_b4.xml
B4420	/usr/etc/ ipsec_offload_config_b4420.xml	/usr/etc/ipsec_offload_pcd_b4.xml
T4240	/usr/etc/ ipsec_offload_config_t4240.xml	/usr/etc/ipsec_offload_pcd_t4.xml
T2080	/usr/etc/ ipsec_offload_config_t2080.xml	/usr/etc/ipsec_offload_pcd_t2.xml

Start the application

Following is a brief description of ipsec_offload's parameters and an explanantion on how to set them:

-c: the configuration file for the platform (platform specific - see table above)

-p: policy file

--vif: virtual inbound interface index

--vof: virtual outbound interface index

--vipsec: virtual interface for host to host tunnels

These interfaces are used by Linux to receive and send local traffic - IP traffic matching Linux IP addresses and non-IP traffic like ARP.

The VIF and VOF parameters are always macless nodes. To choose what interfaces to use, look for interfaces with one of the following ethernet addresses:

```
00:11:22:33:44:55 or 00:11:22:33:44:66 or 00:11:22:33:44:77
```

Any combination of these nodes can be used.

The VIPSEC can be either a macless interface or an oNIC interface (for B4 and T4 platforms only). The ipsec_offload oNIC interface always has 00:11:22:33:44:88 as an ethernet address.

Note: the virtual interfaces parameters have to be provided in the following order: vif, vof, vipsec.

--ib-loop: configures the inbound port in loop mode - all frames received on the Tx port will be fed back to the Rx port

To run the application on B4860QDS, execute the following command:

```
/usr/bin/ipsec_offload -c /usr/etc/ipsec_offload_config_b4860.xml -p /usr/etc/
ipsec_offload_policy.xml --vif macless0 --vof eth1 --vipsec eth2 --ib-loop
```

To shut down the application you can type the command *quit* in the application console. At shutdown the application flushes its offloading tables, but it does not flush the items that were configured in the Linux kernel. Therefore, in case you have performed additional route, neighbor or IPSec configurations using the Linux tools it is more than a good idea to revert/flush them as well using the appropriate commands once the application was shut down.

IMPORTANT NOTE: Multiple SA's can be configured but if the VIF interface is UP and has an IP on it, all the SA's for outbound direction should have that IP as tunnel source, and all the SA's for inbound should have that VIF IP as destination. It is possible to create multiple SA's in which the IP has to be identical but vary the SPI, encryption or authentication keys or algorithm and so on. This constraint comes from the fact that VIF IP has to be the tunnel IP and this information is used to distribute SA's on diffrent IPSec instances.

EXAMPLE:

```
VIF eth3
ifconfig eth3 192.168.60.1 netmask 255.255.255.0 up

add 192.168.60.1 192.168.50.1 esp 0x901 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabplX" -A hmac-
sha1 "abcdefghipqrstuvwxyO";
add 192.168.60.1 192.168.50.2 esp 0x902 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabplY" -A hmac-
sha1 "abcdefghipqrstuvwxyM";
add 192.168.60.1 192.168.50.3 esp 0x903 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabplZ" -A hmac-
sha1 "abcdefghipqrstuvwxyP";

Outbound
spdadd 172.13.0.1/32[any] 172.14.0.1/32[any] udp -P out ipsec esp/tunnel/192.168.60.1-192.168.50.1/
require;
spdadd 172.13.0.2/32[any] 172.14.0.2/32[any] udp -P out ipsec esp/tunnel/192.168.60.1-192.168.50.2/
require;
spdadd 172.13.0.3/32[any] 172.14.0.3/32[any] udp -P out ipsec esp/tunnel/192.168.60.1-192.168.50.3/
require;

Inbound
spdadd 172.14.0.1/32[any] 172.13.0.1/32[any] udp -P in ipsec esp/tunnel/192.168.50.1-192.168.60.1/
require;
spdadd 172.14.0.2/32[any] 172.13.0.2/32[any] udp -P in ipsec esp/tunnel/192.168.50.2-192.168.60.1/
require;
spdadd 172.14.0.3/32[any] 172.13.0.3/32[any] udp -P in ipsec esp/tunnel/192.168.50.3-192.168.60.1/
require;
```

Following script can be used as an example:

```
#!/bin/sh
echo "flush;" | setkey -c
echo "spdflush;" | setkey -c

for i in `seq $1`
do
        spi=`expr 201 + $i`
```

```
        echo "spdadd 172.16.0.$i/32[any] 172.17.0.$i/32[any] udp
                -P out ipsec esp/tunnel/192.168.100.1-192.168.200.$i/require; " | setkey -c

        echo "spdadd 172.17.0.$i/32[any] 172.16.0.$i/32[any] udp
                -P in ipsec esp/tunnel/192.168.200.$i-192.168.100.1/require;" | setkey -c

        echo "add 192.168.100.1 192.168.200.$i esp 0x$spi
                -E 3des-cbc \"abcdefghipqrstuvwxyabcde\"
                -A hmac-sha1 \"abcdefghipqrstuvwxya\";" | setkey -c

        echo "add 192.168.200.$i 192.168.100.1 esp 0x$spi
                -E 3des-cbc \"abcdefghipqrstuvwxyabcde\"
                -A hmac-sha1 \"abcdefghipqrstuvwxya\";" | setkey -c
done
```

Application configuration for IPsec

IPSec can be configured for offloading using setkey tool. To add an SA and two corresponding SPs add the following lines in a setkey.conf file:

```
flush;
spdflush;
add 192.168.100.1 192.168.200.1 esp 0x201
        -E 3des-cbc "abcdefghipqrstuvwxyabcde"
        -A hmac-sha1 "abcdefghipqrstuvwxya";
spdadd 172.16.0.1/32[any] 172.17.0.1/32[any] udp
        -P out ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
spdadd 172.17.0.1/32[any] 172.16.0.1/32[any] udp
        -P in ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
```

Now run the command:

```
setkey –f setkey.conf
```

These commands create an ESP tunnel with the following endpoints: IP src 192.168.100.1 – IP dst 192.168.200.1, SPI 0x201, 3DES-CBC encryption and HMAC-SHA1 authentication. The UDP traffic coming from 172.16.0.1 going to 172.17.0.1 will be tunneled using the defined tunnel.

To configure Linux interfaces, neighboring and routing for the loopback setup run the following commands:

```
#enable IP forwarding
echo "1" > /proc/sys/net/ipv4/ip_forward
#inbound interface
ifconfig macless0 192.168.100.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/macless0/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/macless0/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/macless0/accept_local
#outbound interface
ifconfig eth1 172.16.0.254 netmask 255.255.0.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth1/accept_local
#route to tunnel destination
route add -net 192.168.200.0/24 gw 192.168.100.254 dev macless0
#route to tunneled traffic destination - outbound interface in loop mode
route add -net 172.17.0.0/16 gw 172.16.0.1 dev eth1
#static neigh entry for loopback mode
```

```
ip neigh add 192.168.100.254 lladdr <inbound_port_mac_addres> dev macless0
```

9.9.2.5.2.3 Running Traffic

Assuming that the traffic is generated with a directly connected Linux box, you need to configure the Linux box to output frames for `172.16.0.1` on the connected interface (ethX):

```
ifconfig <ethX> 172.16.0.2 netmask 255.255.0.0 up
```

You can use the hping tool to generate UDP packets and tcpdump to capture traffic on interface ethX. Each sent frame should be returned by the application.

```
hping -2 -s 2152 -p 2152 -c 1 172.17.0.1
```

At any point you can use the following commands to show packet and byte statistics.

- ```
  sa_stats <sa-id>
  ```

  This command shows the statistics for a particular SA.
- ```
  ipsec_stats <ipsec-instance-id>
  ```

  This command shows the global IPSec statistics for the specified IPSec instance. This includes the miss counters for the inbound and outbound direction.

9.9.2.5.3 ipsec_offload application flow

The application follows PPAC/PPAM design. PPAM is responsible for initialization and for forwarding received frames (UDP destination port 2152) between outbound port and outbound/inbound offline ports. The following tasks are part of the initialization:

- Get command line configuration parameters
- Allocate memory and create buffer pools for additional required buffer pools (i.e – IP fragmentation, IP reassembly)
- Compile and apply PCD model for the application
- Init IPsec offloading component
- Start XFRM and neighbouring notification processing
- Mappings required by USDPAA to forward frames between ports

Offloading work is performed by XFRM and neighbour notifications processing threads. Each thread listens on a specific Netlink socket and receives messages containing the event and associated information. This information is used to configure IPsec offloading datapath.

9.9.2.5.4 IPSEC tunnel setup using ipsec offload application and Strongswan with IKEv2

The application can work in conjunction with stongswan client using IKEv2 protocol. The figure below ilustrates a possible setup that creates a tunnel between DUT and REF devices.

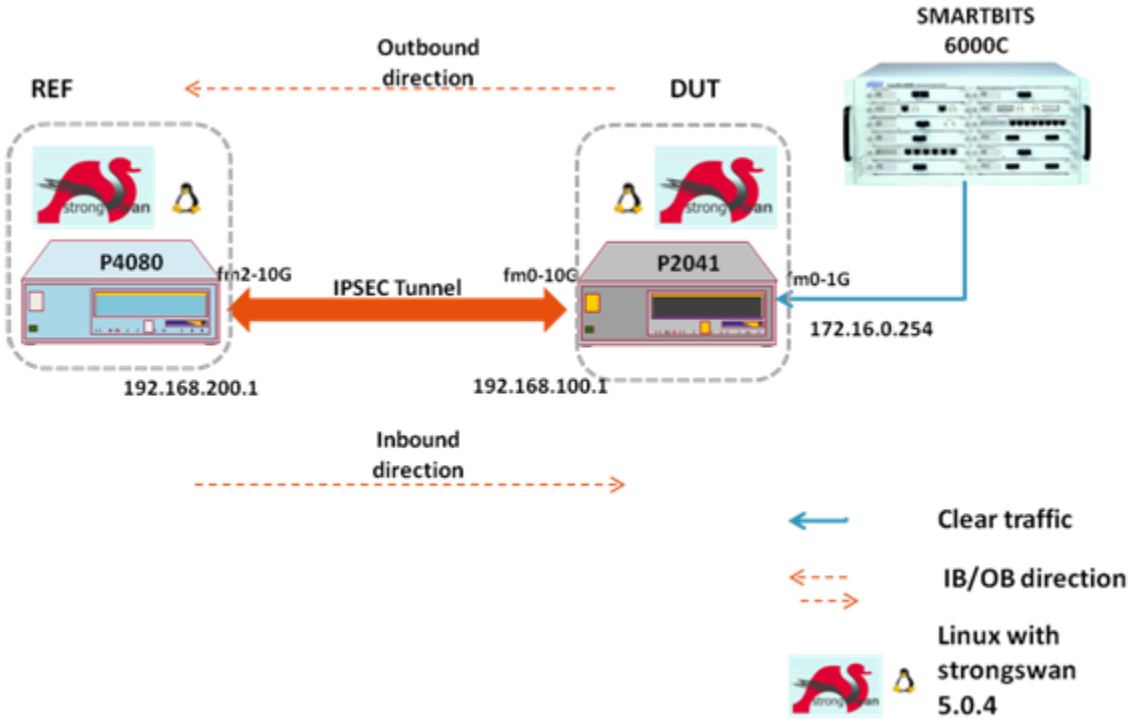

Figure 250. IPSEC tunnel setup with Strongswan and IKEv2

REF can be any client machine and DUT can be any board with **DPAA capabilities**. The **smartbit** can also be replaced by another client machine.

The tunnel is negotiated by both machines and the security associations created on DUT, are offloaded. On **outbound direction,** traffic is sent from **SMARTBITS**, encrypted on DUT and then decrypted on the REF.

On **inbound direction** traffic can be sent from REF using for instance *wget* application:

wget http://172.16.0.1

9.9.2.5.4.1 REF (Linux with Strongswan 5.0.4) configuration

- ipsec.conf (configuration file used by strongswan):

```
 conn %default
        ikelifetime=60m
        keylife=20m
        rekeymargin=3m
        keyingtries=1
        authby=secret
        keyexchange=ikev2
        mobike=no

conn ref
        left=192.168.200.1
        leftsubnet=172.17.0.0/16
        right=192.168.100.1
        rightsubnet=172.16.0.0/16
        auto=add
        reauth=no
        esp=3des-sha1
```

- ipsec.secrets(pre shared secret used by strongswan):

```
 # /etc/ipsec.secrets - strongSwan IPsec secrets file

192.168.100.1 192.168.200.1 : PSK 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
```

To start the IKEv2 daemon on REF, the following command will be executed:

ipsec start

Notes:

No tunnels are created yet.

The interfaces and route configuration for REF machine is the following (it can be different according to the needs):

```
fm2-10g   Link encap:Ethernet  HWaddr 00:04:9f:00:03:09
          inet addr:192.168.200.1  Bcast:192.168.200.255  Mask:255.255.255.0

```

9.9.2.5.4.2 DUT (Linux with Strongswan 5.0.4) configuration

- ipsec.conf (configuration file used by trongswan):

```
conn %default
        ikelifetime=120m
        keylife=60m
        rekeymargin=3m
        keyingtries=1
        authby=secret
        keyexchange=ikev2
        mobike=no

conn dut
 left=192.168.100.1
        leftsubnet=172.16.0.0/16
        reauth=no
        right=192.168.200.1
        rightsubnet=172.17.0.0/16
        auto=start
```

```
        #lifetime=360s
        #rekeyfuzz=0%
        #margintime=330s
        #rekey=yes
        esp=3des-sha1
```

- ipsec.secrets(pre shared secret used by strongswan):

```
 # /etc/ipsec.secrets - strongSwan IPsec secrets file

192.168.100.1 192.168.200.1 : PSK 0sv+NkxY9LLZvwj4qCC2o/gGrWDF2d21jL
```

To start the IKEv2 daemon on DUT, the following command will be executed:

ipsec start

Notes:

Tunnels will be created -due to *auto=start* option.

The daemon must be started after the ipsec offload application

The interfaces and route configuration for DUT machine is the following (it can be different according to the needs):

```
eth0      Link encap:Ethernet  HWaddr 00:04:9f:02:09:fe
          inet addr:192.168.100.1  Bcast:192.168.100.255  Mask:255.255.255.0
          inet6 addr: fe80::204:9fff:fe02:9fe/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
          RX packets:0 errors:0 dropped:0 overruns:0 frame:0

```

9.9.2.5.4.3 Running ipsec offload application on DUT using 10G port setup

In the proposed setup, DUT and REF have a 10G connection. In this situation the ipsec offload application must be started using a **1G port for outbound** and a **10G port for inbound**.

Before starting the application, the xml configuration file that defines the ethernet ports, must be modified - in order to contain the 10G port.

The code snippet from below shows the modification:

```
diff --git a/apps/ipsec_offload/ipsec_offload_config_p2041.xml b/apps/ipsec_offload/
ipsec_offload_config_p2041.xml
index 61bfdac..1d34bb1 100644
--- a/apps/ipsec_offload/ipsec_offload_config_p2041.xml
+++ b/apps/ipsec_offload/ipsec_offload_config_p2041.xml
@@ -38,9 +38,9 @@

<cfgdata>
        <config>
-       <engine name="fm1">
-               <port type="1G" number="2" policy="ib_rx_policy"/>
+       <engine name="fm0">
+               <port type="10G" number="0" policy="ib_rx_policy"/>
                <port type="OFFLINE" number="1" policy="ib_oh_post_policy"/>
                <port type="OFFLINE" number="2" policy="ob_oh_pre_policy"/>
                <port type="OFFLINE" number="3" policy="ob_oh_post_policy"/>
```

Note:

The port numbers may change due to different hardware configuration.

The ipsec offload application will be started using the following commands:

```
 export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p2041.xml"
 export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p2.xml"
 export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
 export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"

/usr/bin/ipsec_offload \
-c /usr/etc/ipsec_offload_config_p2041.xml \
-p /usr/etc/ipsec_offload_policy.xml \
-s /usr/etc/ipsec_offload_swp.xml \
--fm 0 \
--ob_eth 1,1 --ib_eth 0,2  \
--ib-oh 1 --ob-oh-pre 2 --ob-oh-post 3 \
--max-sa 16 --vif eth0 --vof eth1 --vipsec eth2 --mtu-pre-enc 500
```

Notes:

max-sa parameter must reflect the number of SA pairs. Looking in the pcd file, there are defined 16 entries for inbound esp_cc classification table. In this case there will be 16 security associations. Interfaces vif, vof and vipsec may change due to different hardware configuration.

From another console, after ipsec offload startup, the following commands will be executed:

```
echo "1" > /proc/sys/net/ipv4/ip_forward
ifconfig eth0 192.168.100.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth0/accept_local
ifconfig eth1 172.16.0.254 netmask 255.255.0.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth1/accept_local
```

```
route add -net 192.168.200.0/24 gw 192.168.100.254 dev eth0
route add -net 172.17.0.0/16 gw 192.168.100.254 dev eth0
```

Start strongswan:

ipsec start

Note:

A tunnel will be negotiated between DUT and REF.

9.9.2.5.4.4 Rekeying process with Strongswan and ipsec offload

This chapter shortly presents how to enable the rekey process using strongswan.(For more details please consult *strongswan wiki page*)

When a security association expires (after a period of time or after a number of processed packets/bytes) the operating system will notify strongswan. The expired security associations will be updated(new key material will be generated).

Ipsec offload application is able to catch the notifications and will update the offloaded SAs. The DPAA offload function used for rekeying, guarantees that no packets will be lost during this process.

To enable rekeying on DUT (see **DUT configuration** chapter), uncomment (remove "#") the following lines:

```
        #lifetime=360s
        #rekeyfuzz=0%
        #margintime=330s
        #rekey=yes
```

before starting strongswan and ipsec offload application.

The above lines will cause the created tunnels to expire at every 30 seconds (For more details please consult *strongswan wiki page* for rekeying process).

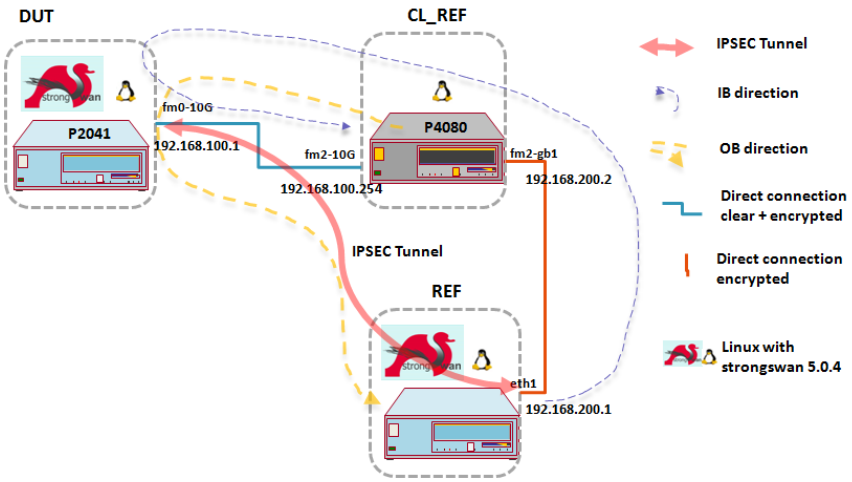
Notes:.

On inbound direction, traffic must be injected before the 30 seconds interval expires. Otherwise the security association that has expired, will stay in rekey process.

9.9.2.5.4.5 Ipsec offload application in single port configuration

Configuration setup

The figure below represents the ipsec tunnel setup using one port - for inbound and outbound directions.



REF can be any machine and DUT can be any board with **offload capabilities**. CL_REF can be any machine with a 10G port available. The difference between this setup and the previous depicted setup is that the DUT machine has only one port available on the offload path, on which will be applied both policies - for inbound and outbound directions.

On outbound direction traffic is sent from CL_REF with a traffic generator application (e.g wget or hping), encrypted on DUT sent back on CL_REF, forwarded to REF where is decrypted.

On inbound direction traffic is sent from REF with a traffic generator application (e.g wget or hping), encrypted on REF, forwarded by CL_REF , decrypted on DUT and sent back to CL_REF

Note that the tunnel is created between DUT and REF. CL_REF will be used for forwarding.

Strongswan daemon is configured in the same way as in the previous setup - both for DUT and REF.

DUT configuration

The following commands will be run on DUT after application start up but before starting strongswan:

```
echo "1" > /proc/sys/net/ipv4/ip_forward
ifconfig eth0 192.168.100.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth0/accept_local
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth1/accept_local
route add -net 192.168.200.0/24 gw 192.168.100.254 dev eth0
route add -net 172.16.0.0/16 gw 192.168.100.254 dev eth0
ip neigh add 192.168.100.254 lladdr [CL_REF mac addr] dev eth0
```

CL_REF mac addr represents the ethernet address of the CL_REF interface that is connected with DUT port

Route configuration on DUT:

```
root@p2041rdb:/root# route
Kernel IP routing table
Destination     Gateway         Genmask         Flags Metric Ref    Use Iface
default         192.168.1.1     0.0.0.0         UG    0      0        0 eth2
172.16.0.0      192.168.100.254 255.255.0.0     UG    0      0        0 eth0

```

Notes:

Forwarding must be enabled between fm2-10g and fm2-gb1.

Running the ipsec offload applicaion in single port configuration

For this setup, the single port xml files will be used.

The config xml for single port is like the snippet below:

```
<cfgdata>
        <config>
        <engine name="fm0">
-                 <port type="1G" number="2" policy="ib_ob_rx_policy"/>
+                <port type="10G" number="0" policy="ib_ob_rx_policy"/>
                <port type="OFFLINE" number="1" policy="ib_oh_post_policy"/>
                <port type="OFFLINE" number="2" policy="ob_oh_pre_policy"/>
                <port type="OFFLINE" number="3" policy="ob_oh_post_policy"/>
        </engine>
        </config>
</cfgdata>
```

Note:

The port numbers may change due to different hardware configuration.

The ipsec offload application will be started using the following commands:

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p2041_1p.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p2_1p.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
/usr/bin/ipsec_offload \
-c /usr/etc/ipsec_offload_config_p2041_1p.xml \
-p /usr/etc/ipsec_offload_policy_1p.xml \
-s /usr/etc/ipsec_offload_swp.xml \
--vif eth0 --vof eth0 --vipsec eth3
```

Notes:

Interfaces vif, vof and vipsec may change due to different hardware configuration.

The number of maximum SA pairs can be determined by looking in the pcd file, there are defined 16 entries for inbound esp_cc classification table. In this case there will be 16 security associations.

From another console, after ipsec offload startup, the following commands will be executed:

```
echo "1" > /proc/sys/net/ipv4/ip_forward
ifconfig eth0 192.168.100.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth0/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth0/accept_local
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth1/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth1/accept_local
route add -net 192.168.200.0/24 gw 192.168.100.254 dev eth0
route add -net 172.16.0.0/16 gw 192.168.100.254 dev eth0
ip neigh add 192.168.100.254 lladdr 00:10:18:BA:E4:05 dev eth0
```

Start strongswan:

ipsec start

Note:

A tunnel will be negotiated between DUT and REF.

Sending traffic on outbound direction

wget was used for sending traffic. Any other application that can generate tcp/udp packets, can be used.

```
wget --no-proxy http://172.17.0.1/
```

The tcpdump output on CL_REF will be similar to this:

```
8:12:14.823907 00:10:18:ba:e4:05 (oui Unknown) > 00:04:9f:02:09:fb (oui Unknown), ethertype IPv4
(0x0800), length 74: 172.16.0.1.52699 > 172.17.0.1.http
18:12:14.823988 00:04:9f:02:09:fb (oui Unknown) > 00:10:18:ba:e4:05 (oui Unknown), ethertype IPv4
(0x0800), length 126: 192.168.100.1 > 192.168.200.1: ESP(spi=0xc718bd51,seq=0x13), length 92
```

On REF the tcpdump output will be similar to:

```
18:23:18.829555 00:10:18:ba:e4:04 (oui Unknown) > a0:36:9f:19:fe:14 (oui Unknown), ethertype IPv4
(0x0800), length 126: 192.168.100.1 > 192.168.200.1: ESP(spi=0xc115218e,seq=0xe), length 92
18:23:18.829555 00:10:18:ba:e4:04 (oui Unknown) > a0:36:9f:19:fe:14 (oui Unknown), ethertype IPv4
(0x0800), length 74: 172.16.0.1.51413 > 172.17.0.1.http
```

Sending traffic on inbound direction

wget was used for sending traffic. Any other application that can generate tcp/udp packets, can be used.

```
wget --no-proxy http://172.16.0.1
```

The tcpdump output on REF will be similar to this:

```
Connecting to 172.16.0.1:80... 18:22:34.220792 a0:36:9f:19:fe:14 (oui Unknown) > 00:10:18:ba:e4:04
(oui Unknown), ethertype IPv4 (0x0800), length 126: 192.168.200.1 > 192.168.100.1:
ESP(spi=0xc4163da8,seq=0x2), length 92
```

On CL_REF the tcpdump output will be similar to:

```
18:09:07.192481 00:10:18:ba:e4:05 (oui Unknown) > 00:04:9f:02:09:fb (oui Unknown), ethertype IPv4
(0x0800), length 126: 192.168.200.1 > 192.168.100.1: ESP(spi=0xc0ce4d0a,seq=0x12), length 92
18:09:07.192625 00:04:9f:02:09:fb (oui Unknown) > 00:10:18:ba:e4:05 (oui Unknown), ethertype IPv4
(0x0800), length 74: 172.17.0.2.39485 > 172.16.0.1.http
```

Single port with aggregation option

In single port configuration, ipsec offload application supports an operating mode called aggregation.

Let's suppose there are three SAs on inbound direction: SAi1, SAi2 and SAi3 and one SA on outbound: SAo1. Encrypted traffic received on inbound, would match one of the previous SAs- SAi1 to SAi3. Consider that the decrypted traffic have the following selectors:

```
for SAi1:: 172.16.0.0/16 172.17.0.0/16 udp
for SAi2: 172.18.0.0/16 172.19.0.0/16 udp
for SAi3: 172.20.0.0/16 172.21.0.0/16 udp
```

Consider that on outbound direction the policies corresponding to SAo1 will have the above selectors.

If aggregation is enabled, decrypted traffic from SAi1 to SAi3 will be forwarded to the outbound offline port pre-encryption. The forwarded traffic will match the outbound policies , will be encrypted with the SAo1 and sent on the Tx port.

For **aggregation mode**, the ipsec offload application will be started using the following commands:

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p2041_1p.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p2_1p.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
/usr/bin/ipsec_offload \
-c /usr/etc/ipsec_offload_config_p2041_1p.xml \
-p /usr/etc/ipsec_offload_policy_1p.xml \
-s /usr/etc/ipsec_offload_swp.xml \
--vif eth0 --vof eth0 --vipsec eth3 --aggreg
```

Note:

Aggregation is available only in single port configuration. In this situation, the decrypted traffic must match the configured policies on outbound direction.(see aforementioned explanation)

Sample setkey configuration file:

```
#!/usr/sbin/setkey -f

# Flush the SAD and SPD
flush;
spdflush;

9.9.2.5.5 Ipsec offload application in multiple instances configuration

Steps to initialize first instance - for FMAN 1

The following commands assume that the application runs on a P4080 board. Altering the presented port configurations involves various changes, including device tree updates, and that is not covered by this document.

For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p4080_1p_fman1_instance.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p4_1p.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
```

Start the application with the following command:

```
/usr/bin/ipsec_offload \
-c /usr/etc/ipsec_offload_config_p4080_1p_fman1_instance.xml \
-p /usr/etc/ipsec_offload_policy_1p_fman1_instance.xml \
-s /usr/etc/ipsec_offload_swp.xml \
--vif eth4 --vof eth4 --vipsec macless0
```

Configure interfaces:

```
echo "1" > /proc/sys/net/ipv4/ip_forward
ifconfig eth4 192.168.100.1 netmask 255.255.255.0 up
```

```
echo "1" > /proc/sys/net/ipv4/conf/eth4/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth4/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth4/accept_local
route add -net 192.168.200.0/24 gw 192.168.100.254 dev eth4
route add -net 172.17.0.0/16 gw 192.168.100.254 dev eth4
ip neigh add 192.168.100.254 lladdr  00:e0:0c:00:93:05 dev eth4
arp -s 172.16.0.1 00:11:22:22:11:00 dev eth4
```

Create tunnels and policies for the first instance:

```
add 192.168.100.1 192.168.200.1 esp 0x201 -m tunnel -E 3des-cbc "kabcdefghipqrstuvwxyabcde" -A hmac-
sha1 "abcdefghipqrstuvwxya";
add 192.168.200.1 192.168.100.1 esp 0x201 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabcde" -A hmac-
sha1 "abcdefghipqrstuvwxya";
spdadd 172.16.0.1/32[any] 172.17.0.1/32[any] udp -P out ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
spdadd 172.17.0.1/32[any] 172.16.0.1/32[any] udp -P in ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
spdadd 172.16.0.1/32[any] 172.17.0.1/32[any] icmp -P out ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
spdadd 172.17.0.1/32[any] 172.16.0.1/32[any] icmp -P in ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
```

Validate ESP operation

```
Send traffic that matches the outbound policies and see that ESP packets are
created. Verify also that statistics on the outbound SA increment with the
number of ESP created packets.

Send ESP packets to the board and see that they are decapsulated correctly
and check also the statistics.
```

Stept to initialize the second instance - for FMAN 0

The following commands assume that the application runs on a P4080 board. Altering the presented port configurations involves various changes, including device tree updates, and that is not covered by this document.

For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p4080_1p_fman0_instance.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p4_1p.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
```

Start the application with the following command:

```
/usr/bin/ipsec_offload \
-c /usr/etc/ipsec_offload_config_p4080_1p_fman0_instance.xml \
-p /usr/etc/ipsec_offload_policy_1p_fman0_instance.xml \
-s /usr/etc/ipsec_offload_swp.xml \
```

```
--vif eth3 --vof eth3 --vipsec eth5
```

Configure interfaces:

```
echo "1" > /proc/sys/net/ipv4/ip_forward
ifconfig eth3 192.168.60.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/eth3/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth3/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth3/accept_local
route add -net 192.168.50.0/24 gw 192.168.60.254 dev eth3
route add -net 172.13.0.0/16 gw 192.168.60.254 dev eth3
ip neigh add 192.168.60.254 lladdr  00:e0:0c:00:93:05 dev eth3
arp -s 172.14.0.1 00:11:22:22:11:00 dev eth3
```

Create tunnels and policies for the second instance:

```
add 192.168.60.1 192.168.50.1 esp 0x901 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabplX" -A hmac-
sha1 "abcdefghipqrstuvwxyO";
add 192.168.50.1 192.168.60.1 esp 0x901 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabplm" -A hmac-
sha1 "abcdefghipqrstuvwxya";
spdadd 172.13.0.1/32[any] 172.14.0.1/32[any] udp -P out ipsec esp/tunnel/192.168.60.1-192.168.50.1/
require;
spdadd 172.14.0.1/32[any] 172.13.0.1/32[any] udp -P in ipsec esp/tunnel/192.168.50.1-192.168.60.1/
require;
spdadd 172.13.0.1/32[any] 172.14.0.1/32[any] icmp -P out ipsec esp/tunnel/
192.168.60.1-192.168.50.1/require;
spdadd 172.14.0.1/32[any] 172.13.0.1/32[any] icmp -P in ipsec esp/tunnel/192.168.50.1-192.168.60.1/
require;
```

Validate ESP operation

Send traffic that matches the outbound policies and see that ESP packets are created. Verify also that statistics on the outbound SA increment with the number of ESP created packets. Send ESP packets to the board and see that they are decapsulated correctly and check also the statistics.

IMPORTANT NOTE: Multiple SA's can be configured but if the VIF interface is UP and has an IP on it, all the SA's for outbound direction should have that IP as tunnel source, and all the SA's for inbound should have that VIF IP as destination. It is possible to create multiple SA's in which the IP has to be identical but vary the SPI, encryption or authentication keys or algorithm and so on. This constraint comes from the fact that VIF IP has to be the tunnel IP and this information is used to distribute SA's on diffrent IPSec instances.

9.9.2.5.6 Host to host tunnels

Overview

The ipsec_offload usecase can be used to protect data flows between a pair of hosts. An IPsec tunnel can be setup to provide end to end encryption / decryption between the two hosts. The interface that the ipsec_offload uses for host to host tunnels is the one provided via the ‘vipsec’ command line argument.

Configuration and start-up

This section details the configuration sequence needed to enable host to host tunnels on a P4080DS board

- Run the usecase:

```
export DEF_CFG_PATH="/usr/etc/ipsec_offload_config_p4080.xml"
export DEF_PCD_PATH="/usr/etc/ipsec_offload_pcd_p4.xml"
export DEF_SWP_PATH="/usr/etc/ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
/usr/bin/ipsec_offload \
--vif macless0 --vof eth3 --vipsec eth4
```

- Configure the ethernet interfaces:

```
echo "1" > /proc/sys/net/ipv4/ip_forward

ifconfig macless0 192.168.100.1 netmask 255.255.255.0 up
echo "1" > /proc/sys/net/ipv4/conf/macless0/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/macless0/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/macless0/accept_local

route add -net 192.168.200.0/24 gw 192.168.100.254 dev macless0
ip neigh add 192.168.100.254 lladdr 00:04:9f:02:87:26 dev macless0

ifconfig eth4  172.20.0.1 up
echo "1" > /proc/sys/net/ipv4/conf/eth4/disable_policy
echo "1" > /proc/sys/net/ipv4/conf/eth4/disable_xfrm
echo "1" > /proc/sys/net/ipv4/conf/eth4/accept_local

echo "1" > /proc/sys/net/ipv4/conf/macless0/arp_accept
echo "1" > /proc/sys/net/ipv4/conf/macless0/proxy_arp
```

- Create IPsec tunnels using the following setkey script:

```
flush;
spdflush;
add 192.168.100.1 192.168.200.1 esp 0x201 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabcde" -A
hmac-sha1 "abcdefghipqrstuvwxya";
add 192.168.200.1 192.168.100.1 esp 0x201 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabcde" -A
hmac-sha1 "abcdefghipqrstuvwxya";
spdadd 172.20.0.1/32[any] 172.21.0.1/32[any] icmp -P out ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
spdadd 172.21.0.1/32[any] 172.20.0.1/32[any] icmp -P in ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
spdadd 172.20.0.1/32[any] 172.21.0.1/32[any] udp -P out ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
spdadd 172.21.0.1/32[any] 172.20.0.1/32[any] udp -P in ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
```

UDP and ICMP traffic going out of eth4 will be encrypted and sent via the 192.168.100.1-192.168.200.1 tunnel. UDP and ICMP traffic coming out of the 192.168.200.1-192.168.100.1 tunnel will be decrypted and the frames addressed to the vipsec interface will be forwarded accordingly.

Traffic

Connect the other end-point of the tunnel by configuring the following on a test station which is linked to the inbound port of the board.

- Configure the interfaces:

```
ifconfig eth1 172.21.0.1/16 up
ifconfig eth1:0 192.168.200.1/24 up
route add -net 172.20.0.0/16 dev eth1
route add -net 192.168.100.0/24 dev eth1
```

- Configure IPSec tunnels by running the following setkey script:

```
flush;
spdflush;
add 192.168.100.1 192.168.200.1 esp 0x201 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabcde" -A
hmac-sha1 "abcdefghipqrstuvwxya";
add 192.168.200.1 192.168.100.1 esp 0x201 -m tunnel -E 3des-cbc "abcdefghipqrstuvwxyabcde" -A
hmac-sha1 "abcdefghipqrstuvwxya";
spdadd 172.21.0.1/32[any] 172.20.0.1/32[any] icmp -P out ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
spdadd 172.20.0.1/32[any] 172.21.0.1/32[any] icmp -P in ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
spdadd 172.21.0.1/32[any] 172.20.0.1/32[any] udp -P out ipsec esp/tunnel/
192.168.200.1-192.168.100.1/require;
spdadd 172.20.0.1/32[any] 172.21.0.1/32[any] udp -P in ipsec esp/tunnel/
192.168.100.1-192.168.200.1/require;
```

Outbound traffic

On the P4080 board, configure a route to the test station – all traffic destined to that network will go through the vipsec interface:

```
route add -net  172.21.0.0/16 dev eth4
```

Send an ICMP request from the board to the test station:

```
ping 172.21.0.1 –c 1
```

Check the Tx statistics on the inbound port (eth_stats 1 1) and the outbound SA stats (sa_stats 0). They will each be incremented by one.

On the test station run a tcpdump on the eth1 interface:

```
15:33:16.196378 IP 192.168.100.1 > 192.168.200.1: ESP(spi=0x00000201,seq=0x6), length 116
15:33:16.196378 IP 172.20.0.1 > 172.21.0.1: ICMP echo request, id 1864, seq 0, length 64
15:33:16.196448 IP 192.168.200.1 > 192.168.100.1: ESP(spi=0x00000201,seq=0x14), length 116
```

The ICMP request is seen as both encrypted and then decrypted. Also the encrypted ICMP reply can be seen.

Inbound traffic

Send a ICMP request from the test station to the board:

```
ping 172.20.0.1 -c 1
```

Check the inbound SA stats (sa_stats 1). They will be incremented by one.

On the P4080 run tcpdump on the vipsec interface:

```
17:11:05.282030 IP 172.21.0.1 > 172.20.0.1: ICMP echo request, id 11607, seq 1, length 64
17:11:05.282050 IP 172.20.0.1 > 172.21.0.1: ICMP echo reply, id 11607, seq 1, length 64
```

Only clear traffic will be seen on this interface.

Host to host tunnels via oNIC

oNIC is a new Ethernet driver which is an improved solution (with CSUM offload and zero-copy) for macless. Currently it is available only on the T4 and B4 platforms.

An oNIC device has been integrated in the ipsec_offload usecase – the vipsec device can now be oNIC instead of macless. This transition is seemingly transparent - the only thing the user needs to do is to specify an oNIC node instead of a macless node as the vipsec command line parameter.

The oNIC interface can be identified from the DTS (it has the "fsl,dpa-ethernet-generic" attribute). For example for a B4 board:

```
ethernet@19 {
    compatible = "fsl,b4860-dpa-ethernet-generic", "fsl,dpa-ethernet-generic";
    fsl,qman-frame-queues-rx =  <7000 2>;
    fsl,qman-frame-queues-tx = <7008 1>;
    fsl,oh-ports = <&oh2 &oh3>;
    local-mac-address = [00 11 22 33 44 88];
    };
```

When running ipsec_offload pass the corresponding ethernet interface as the vipsec:

```
eth6   Link encap:Ethernet  HWaddr 00:11:22:33:44:88
          BROADCAST MULTICAST  MTU:1500  Metric:1
          RX packets:0 errors:0 dropped:0 overruns:0 frame:0
          TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:0 (0.0 B)  TX bytes:0 (0.0 B)
```

9.9.2.6 Using the dpa_offload - the NF API offloading demo application

This application demonstrates how IPSec and IP forwarding services can be offloaded to the DPAA using the *Network Function Layer* DPAA offloading drivers extension.

9.9.2.6.1 Overview

This application shows how IPSec services, as defined by the *RFC 4301*, and IP forwarding services can be offloaded from the Linux user space by using the USDPAA, the *Network Function Layer* and the DPAA offloading drivers. It equally

demonstrates how the *Network Function Layer* offloading services can be integrated with a standard operating system's IP forwarding and IPSec configuration tools.

This application overrides the Linux operating system's data path configuration and it offloads into DPAA:

- IPSec tunnels that the user configures by using the *setkey* tool
- IP routes that are configured by the use of the *ip route* and *ip neigh* tools
- inbound ingress rules configured by the use of the application command line interface (CLI)

NOTE

This application is a pilot and has the following limitations:

Table 245. DPAA Offloading Application Limitations

Limitation Description
This application does not yet support IPv6 IPSec tunnels & policies offloading.
This application does not yet support IPSec *red side fragmentation* offloading.
This application currently supports offloading only IPSec tunnels with one policy per direction.
This application does not yet support the IPSec DSCP/ECN copy feature.
This application does not yet support IPSec *inbound policy verification*.
This application currently supports only IPSec policies with specific L4 ports. It does not yet support the *ANY* specifier or L4 port ranges in the IPSec policy.
The application does not yet support IPSec *host-to-host tunnels*.
The application does not yet support IPSec and IP forwarding offloading using multiple instances in parallel.

9.9.2.6.2 Running dpa_offload

The dpa_offload demo application supports the following platforms:

- B4860

In order to run it you will need to use a specific device tree file that comes with the DPA offloading driver. Please read below about how to produce this device tree file for your platform.

9.9.2.6.2.1 Application environment specifications

The application can run in a real network setup configuration and inter-operate with other IPSec gateways. There is also an option to put the inbound port in loopback mode and return IPSec traffic to the outbound port. The details on how to run the application refers to this mode.

The simplest hardware setup is the one described in the **ipsec_offload Application environment specifications** section.

Table 246. Port connections

SoC	Inbound Port	Outbound Port
B4860	`fm1-mac5`	`fm1-mac6`

9.9.2.6.2.2 Application start-up and configuration

Use the steps described later in **Appendix A: Compiling the device tree for Network Function Layer offloading** to generate a device tree binary file. Boot the board with the compiled kernel, `arch/powerpc/boot/uImage`, and the `DTB` file.

To enable the scatter-gather support in the DPAA Ethernet driver add the following to the boot arguments:

```
setenv othbootargs "fsl_fm_max_frm=9600"
```

The following commands assume that the application runs on a B4860QDS board. When running on a different supported platform, please use the proper parameters listed in **Running dpa_offload: Application environment specifications**. For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH="/usr/etc/dpa_offload_config_b4860.xml"
export DEF_POL_PATH="/usr/etc/dpa_offload_policy.xml"
export DEF_PCD_PATH="/usr/etc/dpa_offload_pcd_b4.xml"
export DEF_SWP_PATH="/usr/etc/dpa_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
```

First ensure that the following device files have been created:

- `/dev/dpa_classifier`
- `/dev/dpa_stats`
- `/dev/dpa_ipsec`

Following is a brief description of dpa_offload application's parameters and an explanantion on how to set them:

- `--vif`, virtual inbound interface name;
- `--vof`, virtual outbound interface name;
- `--vipsec`, virtual interface for host-to-host IPSec tunneling; this needs to be provided, but it is not currently used due to an application limitation;
- `--ib-loop`, set the inbound interface in loopback mode;
- `--disable-ib-ecn`, disable inbound DSCP/ECN field copy; you should always use this due to the current limitation of the application;
- `--disable-ob-ecn`, disable outbound DSCP/ECN field copy; you should always use this due to the current limitation of the application.

The *VIF* and *VOF* arguments are the names of the shared interfaces that the application is using as inbound and outbound interfaces. These are the Ethernet interface names mentioned in the **Application environment specifications** section above for the platform that you are running on.

The *VIPSEC* interface is a macless interface. Please select the interface with the following Ethernet address:

```
00:11:22:33:44:55
```

The dpa_offload application can be run with the following command:

```
/usr/bin/dpa_offload --vif fm1-mac5 --vof fm1-mac6 --vipsec macless0 --disable-ib-ecn --disable-ob-ecn
--ib-loop
```

The output displayed by the application would be something similar with the following:

```
Found /fsl,dpaa/dpa-fman0-oh@2, Tx Channel = 80a, FMAN = 0, Port ID = 1

```

To shut down the application you can type the command *quit* in the application console. At shutdown the application flushes its offloading tables, but it does not flush the items that were configured in the Linux kernel. Therefore, in case you have performed additional route, neighbor or IPSec configurations using the Linux tools it is more than a good idea to revert/flush them as well using the appropriate commands once the application was shut down.

Typing *help* in the application console will display the available application CLI commands.

9.9.2.6.2.3 Running the application

First step to take is to configure the IP addresses on the inbound and outbound interfaces of the host. For example:

```
ip addr add 192.168.100.1/24 dev fm1-mac5

ip addr add 172.16.0.254/16 dev fm1-mac6
```

Before continuing, you need to bring down the VIF interface so that it doesn't interfere with the IPSec policies setup:

```
ip link set dev fm1-mac5 down
```

IPSec can be configured for offloading using the *setkey* tool. To create an IPSec tunnel (SA) and two security policies (one for inbound and one for outbound) add the following lines to a `setkey.conf` text file:

```
flush;
spdflush;

add 192.168.100.1 192.168.200.1 esp 0x201
-E 3des-cbc "abcdefghipqrstuvwxyabcde"
-A hmac-sha1 "abcdefghipqrstuvwxya";

spdadd 172.16.0.1/32[1230] 172.17.0.1/32[2600] udp
    -P out ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
spdadd 172.17.0.1/32[2600] 172.16.0.1/32[1230] udp
    -P in ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
```

To execute the script and set up the tunnels, you can run the command:

```
setkey -f setkey.conf
```

These commands will create an ESP tunnel with the following endpoints: IP src 192.168.100.1 - IP dst 192.168.200.1, SPI 0x201, 3DES-CBC encryption and HMAC-SHA1 authentication. The UDP traffic coming from 172.16.0.1, with UDP source port 2130 and going to 172.17.0.1, with UDP destination port 2600 will be directed through the defined tunnel.

Once the IPSec tunnels are set up, we can bring the VIF interface back up:

```
ip link set dev fm1-mac5 up
```

You are ready now to add your IP gateways and IP routes using commands like:

```
ip neigh add 172.16.0.1 lladdr 00:10:18:BA:E4:04 dev fm1-mac6
ip neigh add 192.168.100.254 lladdr 68:05:ca:12:2f:0f dev fm1-mac5
```

When running in loopback mode you should configure the next hop on the inbound port with its own Ethernet address (marked in bold in the example above).

IP routes can be configured using the *ip route* tool as in:

```
ip route add 192.168.200.0/24 via 192.168.100.254 table 13 dev fm1-mac5
ip route add 172.17.0.0/16 via 172.16.0.1 table 14 dev fm1-mac6
```

The route table numbers can be found in the application startup information by looking after the *Initializing IP route tables* section. The first table in the section is always the outbound route table, while the second is the inbound route table. Please note that there are different initialization sections for IPv4 and IPv6 routing tables.

IP ingress rules can currently be configured for the inbound direction only. For this purpose you have the *ib_rule_add4*, *ib_rule_add6*, *ib_rule_del4* and *ib_rule_del6* commands available. These rules apply to the clear traffic received on the unprotected (inbound) interface. The usual syntax of an *add rule* command is:

```
ib_rule_add4 <src_ip>/<prefix> <dst_ip>/<prefix> <priority> <dest_route_table_no> [ <hex_tos> ]
```

where

- *src_ip*/*prefix* is the source net IP address;
- *dst_ip*/*prefix* is the destination net IP address;
- *priority* is the priority level that you want this rule to have relative to the other rules in the ingress IP rule table; please note that there cannot be two rules with the same priority;
- *dest_route_table_no* is the number of the **outbound** route table that this flow will be directed to; identification of the IP route tables was described earlier in this paragraph;

- *hex_tos* is an optional argument specifying the *Type Of Service* or *Traffic Class* in hexadecimal representation.

IP rules apply to inbound clear traffic allowing it to be propagated to the specified outbound IP routing tables. All inbound clear traffic flows that does not match any of the configured ingress IP rules is silently discarded.

The application also supports displaying IPSec statistics. You can get SA related statistics using the *sa_stats* CLI command and also global IPSec statistics using the *ipsec_stats* CLI command.

9.9.2.8 Appendix A – Preparing DPA Offloading DTB Files

Detailed reference for compiling the device tree for the following DPAA offloading scenarios:

1. USDPAA
2. IP Offloading
3. IP Reassembly
4. Shared interfaces
5. NF Offloading

For these SoC products:

1. P2041
2. P4080
3. B4860
4. B4420
5. T4240
6. T2080
7. LS1043A (only USDPAA, IP Offloading and IP Reassembly scenarios)

9.9.2.8.1 Compiling the device tree for USDPAA applications

Compiling the device tree for P4080

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/p4080ds-usdpaa.dts
   arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p4080ds-usdpaa.dtb
   arch/powerpc/boot/dts/p4080ds-usdpaa.dts
```

The DTB file `p4080ds-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for P2041

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/p2041rdb-usdpaa.dts
   arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p2041rdb-usdpaa.dtb
   arch/powerpc/boot/dts/p2041rdb-usdpaa.dts
```

The DTB file `p2041rdb-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for B4860

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa.dts
   arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4860qds-usdpaa.dtb
   arch/powerpc/boot/dts/b4860qds-usdpaa.dts
```

The DTB file `b4860qds-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for B4420

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/b4420qds-usdpaa.dts
   arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4420qds-usdpaa.dtb
   arch/powerpc/boot/dts/b4420qds-usdpaa.dts
```

The DTB file `b4420qds-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for T4240

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/t4240qds-usdpaa.dts
   arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t4240qds-usdpaa.dtb
   arch/powerpc/boot/dts/t4240qds-usdpaa.dts
```

The DTB file `t4240qds-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for T2080

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/t2080qds-usdpaa.dts
   arch/powerpc/boot/dts
```

```
scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t2080qds-usdpaa.dtb
   arch/powerpc/boot/dts/t2080qds-usdpaa.dts
```

The DTB file `t2080qds-usdpaa.dtb` will be built in the current directory.

Compiling the device tree for LS1043A

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/fsl-ls1043a-rdb-usdpaa.dts arch/arm64/boot/dts/freescale

make freescale/fsl-ls1043a-rdb-usdpaa.dtb
```

The DTB file `fsl-ls1043a-rdb-usdpaa.dtb` will be generated in the `arch/arm64/boot/dts/freescale` subdirectory. LS1043A boot up mechanism may require also that you build an *ITB* file which aggregates your Linux kernel image, *DTB* file and your root file system (in case you are using RAMBOOT). This file can be generated using the *mkimage* tool.

9.9.2.8.2 Compiling the device tree for IP offloading

Compiling the device tree for P4080

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/p4080ds-usdpaa.dts
arch/powerpc/boot/dts/

cp drivers/staging/fsl_dpa_offload/dts/p4080si-pre.dtsi
arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/p4080si-chosen-offld.dtsi
arch/powerpc/boot/dts/fsl/p4080si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p4080ds-usdpaa-offload.dtb
arch/powerpc/boot/dts/p4080ds-usdpaa.dts
```

The DTB file `p4080ds-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for P2041

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/p2041rdb-usdpaa.dts
arch/powerpc/boot/dts/

cp drivers/staging/fsl_dpa_offload/dts/p2041si-pre.dtsi
arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/p2041si-chosen-offld.dtsi
arch/powerpc/boot/dts/fsl/p2041si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p2041rdb-usdpaa-offload.dtb
arch/powerpc/boot/dts/p2041rdb-usdpaa.dts
```

The DTB file `p2041rdb-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for B4860

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa.dts
 arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/b4860si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4860si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/b4860si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o
 b4860qds-usdpaa-offload.dtb
arch/powerpc/boot/dts/b4860qds-usdpaa.dts
```

The DTB file `b4860qds-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for B4420

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/b4420qds-usdpaa.dts
 arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/b4420si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4420si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/b4420si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o
 b4420qds-usdpaa-offload.dtb
arch/powerpc/boot/dts/b4420qds-usdpaa.dts
```

The DTB file `b4420qds-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for T4240

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/t4240qds-usdpaa.dts
 arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/t4240si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/t4240si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/t4240si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o
 t4240qds-usdpaa-offload.dtb arch/powerpc/boot/dts/t4240qds-usdpaa.dts
```

The DTB file `t4240qds-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for T2080

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/t2080qds-usdpaa.dts
 arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/t208xsi-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/t2080si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/t2080si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o
 t2080qds-usdpaa-offload.dtb arch/powerpc/boot/dts/t2080qds-usdpaa.dts
```

The DTB file `t2080qds-usdpaa-offload.dtb` will be built in the current directory.

Compiling the device tree for LS1043A

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/fsl-ls1043a-rdb-usdpaa.dts arch/arm64/boot/dts/freescale

cp drivers/staging/fsl_dpa_offload/dts/fsl-ls1043a.dtsi arch/arm64/boot/dts/freescale

cp drivers/staging/fsl_dpa_offload/dts/ls1043a-chosen-offload.dtsi arch/arm64/boot/dts/freescale/
ls1043a-chosen.dtsi

make freescale/fsl-ls1043a-rdb-usdpaa.dtb
```

The DTB file `fsl-ls1043a-rdb-usdpaa.dtb` will be genereted in the `arch/arm64/boot/dts/freescale` subdirectory. LS1043A boot up mechanism may require also that you build an *ITB* file which aggregates your Linux kernel image, *DTB* file and your root file system (in case you are using RAMBOOT). This file can be generated using the *mkimage* tool.

9.9.2.8.3 Compiling the device tree for IP reassembly

Compiling the device tree for P4080

On P4080 there is no specific device tree building process for IP reassembly. You can use the one described in **Compiling the Device Tree for USDPAA Applications**.

Compiling the device tree for P2041

On P2041 there is no specific device tree building process for IP reassembly. You can use the one described in **Compiling the Device Tree for USDPAA Applications**.

Compiling the device tree for B4860

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa.dts
arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/b4860si-pre.dtsi
```

```
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4860si-chosen-reass.dtsi
 arch/powerpc/boot/dts/fsl/b4860si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4860qds-usdpaa-reass.dtb
arch/powerpc/boot/dts/b4860qds-usdpaa.dts
```

The DTB file `b4860qds-usdpaa-reass.dtb` will be built in the current directory.

Compiling the device tree for B4420

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4420qds-usdpaa.dts
arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/b4420si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4420si-chosen-reass.dtsi
 arch/powerpc/boot/dts/fsl/b4420si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4420qds-usdpaa-reass.dtb
arch/powerpc/boot/dts/b4420qds-usdpaa.dts
```

The DTB file `b4420qds-usdpaa-reass.dtb` will be built in the current directory.

Compiling the device tree for T4240

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/t4240qds-usdpaa.dts
arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/t4240si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/t4240si-chosen-reass.dtsi
 arch/powerpc/boot/dts/fsl/t4240si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t4240qds-usdpaa-reass.dtb
arch/powerpc/boot/dts/t4240qds-usdpaa.dts
```

The DTB file `t4240qds-usdpaa-reass.dtb` will be built in the current directory.

Compiling the device tree for T2080

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/t2080qds-usdpaa.dts
arch/powerpc/boot/dts

cp drivers/staging/fsl_dpa_offload/dts/t208xsi-pre.dtsi
 arch/powerpc/boot/dts/fsl
```

```
cp drivers/staging/fsl_dpa_offload/dts/t2080si-chosen-reass.dtsi
 arch/powerpc/boot/dts/fsl/t2080si-chosen.dtsi

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t2080qds-usdpaa-reass.dtb
arch/powerpc/boot/dts/t2080qds-usdpaa.dts
```

The DTB file `t2080qds-usdpaa-reass.dtb` will be built in the current directory.

Compiling the device tree for LS1043A

Go to your Linux kernel source code directory and run the following commands:

```
cp drivers/staging/fsl_dpa_offload/dts/fsl-ls1043a-rdb-usdpaa.dts arch/arm64/boot/dts/freescale

cp drivers/staging/fsl_dpa_offload/dts/fsl-ls1043a.dtsi arch/arm64/boot/dts/freescale

cp drivers/staging/fsl_dpa_offload/dts/ls1043a-chosen-reass.dtsi arch/arm64/boot/dts/freescale/
ls1043a-chosen.dtsi

make freescale/fsl-ls1043a-rdb-usdpaa.dtb
```

The DTB file `fsl-ls1043a-rdb-usdpaa.dtb` will be genereted in the `arch/arm64/boot/dts/freescale` subdirectory. LS1043A boot up mechanism may require also that you build an *ITB* file which aggregates your Linux kernel image, *DTB* file and your root file system (in case you are using RAMBOOT). This file can be generated using the *mkimage* tool.

9.9.2.8.4 Compiling the device tree for ipsec offload

Compiling the device tree for P4080

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/p4080si-pre.dtsi
 arch/powerpc/boot/dts/fsl
```

```
cp drivers/staging/fsl_dpa_offload/dts/p4080si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/p4080si-chosen.dtsi
```

```
cp drivers/staging/fsl_dpa_offload/dts/p4080ds-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts
```

```
scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p4080ds-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/p4080ds-usdpaa-shared-interfaces.dts
```

The DTB file `p4080ds-usdpaa-shared-mac.dtb` will be built in the current directory.

Compiling the device tree for P2041

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/p2041si-pre.dtsi
 arch/powerpc/boot/dts/fsl
```

```
cp drivers/staging/fsl_dpa_offload/dts/p2041si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/p2041si-chosen.dtsi
```

```
cp drivers/staging/fsl_dpa_offload/dts/p2041rdb-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts
```

```
scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o p2041rdb-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/p2041rdb-usdpaa-shared-interfaces.dts
```

The DTB file `p2041rdb-usdpaa-shared-mac.dtb` will be built in the current directory.

Compiling the device tree for B4860

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4860si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4860si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/b4860si-chosen.dtsi

cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4860qds-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/b4860qds-usdpaa-shared-interfaces.dts
```

The DTB file `b4860qds-usdpaa-shared-mac.dtb` will be built in the current directory.

Compiling the device tree for B4420

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4420si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4420si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/b4420si-chosen.dtsi

cp drivers/staging/fsl_dpa_offload/dts/b4420qds-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4420qds-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/b4420qds-usdpaa-shared-interfaces.dts
```

The DTB file `b4420qds-usdpaa-shared-mac.dtb` will be built in the current directory.

Compiling the device tree for T4240

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/t4240si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/t4240si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/t4240si-chosen.dtsi

cp drivers/staging/fsl_dpa_offload/dts/t4240qds-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t4240qds-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/t4240qds-usdpaa-shared-interfaces.dts
```

The DTB file `t4240qds-usdpaa-shared-mac.dtb` will be built in the current directory.

Compiling the device tree for T2080

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/t208xsi-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/t2080si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/t2080si-chosen.dtsi

cp drivers/staging/fsl_dpa_offload/dts/t2080qds-usdpaa-shared-interfaces.dts
 arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o t2080qds-usdpaa-shared-mac.dtb
 arch/powerpc/boot/dts/t2080qds-usdpaa-shared-interfaces.dts
```

The DTB file `t2080qds-usdpaa-shared-mac.dtb` will be built in the current directory.

9.9.2.8.5 Compiling the device tree for Network Function Layer offloading

Compiling the device tree for B4860

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4860si-pre.dtsi
 arch/powerpc/boot/dts/fsl

cp drivers/staging/fsl_dpa_offload/dts/b4860si-chosen-offld.dtsi
 arch/powerpc/boot/dts/fsl/b4860si-chosen.dtsi

cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa-nf-offload.dts
 arch/powerpc/boot/dts

scripts/dtc/dtc -f -b 0 -p 1024 -I dts -O dtb -o b4860qds-usdpaa-nf-offload.dtb
 arch/powerpc/boot/dts/b4860qds-usdpaa-nf-offload.dts
```

The DTB file `b4860qds-usdpaa-nf-offload.dtb` will be generated in the current directory.

9.9.2.9 Appendix B - Enabling DPA Offloading Drivers in the Linux Kernel

DPA offloading works only with the DPA offloading Linux kernel drivers. In order to build the DPA offloading Linux drivers, you need to follow the steps presented in this paragraph.

Go to your Linux kernel source code directory and type the command

```
make menuconfig
```

In the build menu that is presented, enable the following option

```
Device Drivers
    Staging Drivers
        <*> Freescale Datapath Offloading Driver
```

In this example the driver is built into the Linux kernel. If you would rather use a loadable module, then you can select the "M" option.

```
Device Drivers
    Staging Drivers
        <M> Freescale Datapath Offloading Driver
```

You also need to remember to insmod the driver at runtime before running the DPA offloading applications.

Some of the DPA offloading applications require that the FMan driver resource allocation algorithm be disabled. In order to do that, in the build menu make sure the option

```
Device Drivers
    Network device support
        Ethernet driver support
            Freescale devices
                Frame Manager support
                    Freescale Frame Manager (datapath) support
                        [ ] Enable FMan dynamic resource allocation algorithm
```

is disabled.

The last step is to actually launch the kernel build using the make command.

9.9.2.10 Revision history

This table summarizes revisions to this document.

Table 247. Revision history

Revision	Date	Description
0	08/2013	Initial public release.

9.9.3 DPAA Offloading Drivers Reference Manual

9.9.3.1 Introduction

This document covers some components implementation details, but the main focus is the programming interfaces (APIs) exposed by these components.

9.9.3.2 DPA Classifier

The DPA Classifier is a module which allows software to accelerate lookups and decisions based on frame content using DPA.

The software must provide the initial FMan coarse classification nodes to be managed by the Classifier tables and must set up a set of **classification rules** . Rules can be added, edited or removed at any time. The DPA Classifier table will manage the provided FMan resource (coarse classification node) and may extend it if necessary during runtime.

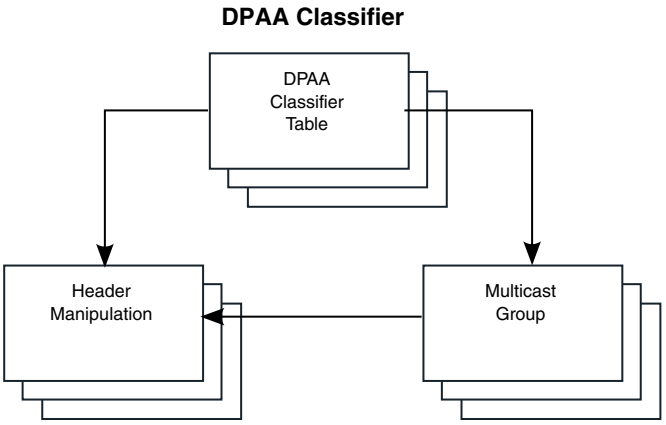

Figure 251. DPA Classifier control objects

9.9.3.2.1 Table

The DPA Classifier's main control object is the DPA Classifier Table. A general functional diagram of the DPA Classifier table is shown below.

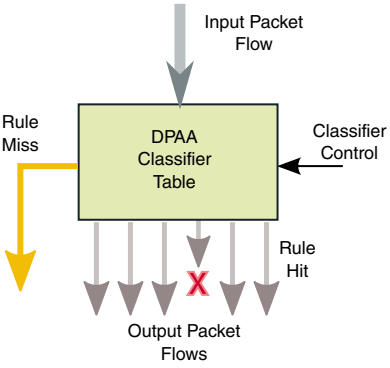

Figure 252. DPA Classifier control objects

Before using the DPA Classifier, the software must create a PCD skeleton. The easiest way to create the PCD skeleton is by using the Fman Configuration tool (FMC).

The user software is responsible for keeping the synchronization between the static FMan resources that it creates at init time and the way it uses DPA Classifier. For instance, it is responsible for properly configuring and linking the FMan KeyGen schemes and the FMan Coarse classification nodes so that the proper keys are extracted from the frames. The DPA Classifier will only assume that the key generation process is correct and fit for that type of table.

A classification rule (also called a classifier entry) is an action that will be executed when the entry is hit. The entries in the table are indexed by lookup key, which can have different formats depending on the table.

The result of a table lookup for an input packet is either:

- a hit condition, which means that the key generated from the input packet data (usually header fields) has matched with the key description associated with a rule in the table or

- a miss condition, which means that the key generated from the input packet data did not match the key description of any entry (rule) in the table.

Depending on the type of the lookup, the miss condition might exist or not. For certain types of lookup (e.g. indexed lookup), the miss condition cannot be defined. The DPA classifier supports the following types of lookups:

Table 248. Port Connections

Lookup Type	Description
Exact match lookup	The hardware will search the table for a key which is an exact sequence of bytes. The key can be used as is, or can be masked. If the key matches exactly over the key of an entry, a hit occurs. If there is no match with any of the keys in the table, a miss situation occurs.
Indexed lookup	The hardware will use a sequence of bits from the key to create an index. The index will be used as a direct index in the table and the action from the entry with that index will be executed. For this type of table there cannot be any miss as the index table is required to be filled with all entries at initialization time. Also, keys from an indexed table cannot be (ever) removed. They can only be modified.
HASH lookup	The hardware will calculate a HASH value out of the key generated from the input packet data, and it will use this masked HASH value as a first index for a table lookup. This will result in finding a HASH set. In the second phase, an exact match lookup is performed among the rules in that particular HASH set to find the exact table entry which matches the lookup key. If a match is found, a lookup hit occurs and the associated action is executed. Otherwise, a lookup miss condition occurs.

Exact match lookup is offering more performance on tables with few entries, while HASH tables offer more performance on densely populated tables. However, the memory consumption for exact match tables is lower and more efficient than for HASH tables, hence it is recommended to use this type of table whenever possible.

The action associated with a table entry falls into 3 possible categories:

1. **Drop frame** action;
2. **Enqueue frame** action - send the frame to a specified frame queue; this action has several options such as enable policing, enable statistics, header manipulation operations;
3. Send frame to a**new lookup** - the frame is directed towards a new DPA Classifier table;
4. **Multicast** - replicate the frame and send it to multiple destinations by using a multicast group.

The DPA Classifier table has two possible ways to manage entries. If entry management **by key** is selected, the DPA Classifier keeps internally a **shadow table** for the entries. This allows it to offer features which are additional to those offered by the low level driver alone, such as lookups and transparent entry index management.

If entry management **by reference** is selected, the DPA Classifier will identify the entries only by their Id (reference), and not by their key. The shadow table is not created in this case. The application will keep the mapping between the keys and their table entry Ids and this will help DPA Classifier to provide more performance for runtime operations.

The DPA Classifier can work with certain *prefilled tables*, which are

- prefilled HASH tables,

- prefilled exact match tables.

Prefilled tables are tables which are populated by the user application before DPA Classifier takes control of the FMan coarse classification node. This is not applicable for indexed tables, where the user always provides all the entries at initialization time. The user application must communicate to the DPA Classifier how many static entries are present in the table at initialization time. If the number of static entries is n, the DPA Classifier module will consider that the static entries are the first n entries in the table and with the highest priority (when priorities are enabled). Working with prefilled tables comes with certain limitations listed below.

- DPA Classifier can only work in key management mode with prefilled tables. Prefilled tables managed by reference are not supported.
- Prefilled classifier HASH tables do not support adding entries with header manipulations.

9.9.3.2.1.1 Table API

There are four selections for the DPA Classifier table API:

- Create and Remove Tables
- Insert, Remove or Update Tables
- Update Default Table Policy
- Table Look-up

9.9.3.2.1.1.1 Create and Remove Tables

Table 249. API to Create and Remove Tables

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_create`	Creates a DPA Classifier table using a coarse classification node. This call does not allocate MURAM.	• handle of the initial Cc node; • the type of table to create; • the table size; • other table params.	Descriptor of the newly created DPA Classifier table.
`dpa_classif_table_free`	Releases all resources associated with a DPA Classifier table and destroys it.	• descriptor of the DPA Classifier table to destroy.	None.

9.9.3.2.1.1.1.1 Function: dpa_classif_table_create

Syntax

```
 int dpa_classif_table_create(const struct dpa_cls_tbl_params *params,
int *td);

struct dpa_cls_tbl_params
{
 void      *cc_node;
 void      *distribution;
 void      *classification;
 enum dpa_cls_tbl_type   type;
 enum dpa_cls_tbl_entry_mgmt  entry_mgmt;
 union
```

```
 {
  struct dpa_cls_tbl_hash_params  hash_params;
  struct dpa_cls_tbl_indexed_params  indexed_params;
  struct dpa_cls_tbl_exact_match_params exact_match_params;
 };
 unsigned int    prefilled_entries;
};

enum dpa_cls_tbl_type
{
 DPA_CLS_TBL_HASH = 0,  /**< HASH table */
 DPA_CLS_TBL_INDEXED,  /**< Indexed table */
 DPA_CLS_TBL_EXACT_MATCH /**< Exact match table */
};

struct dpa_cls_tbl_hash_params
{
 unsigned int num_sets;
 unsigned int max_ways;
 unsigned int hash_offs;
 uint8_t  key_size;
};

struct dpa_cls_tbl_indexed_params
{
 unsigned int entries_cnt;
};

struct dpa_cls_tbl_exact_match_params
{
 unsigned int entries_cnt;
 uint8_t  key_size;
 bool   use_priorities;
};

enum dpa_cls_tbl_entry_mgmt
{
 DPA_CLS_TBL_MANAGE_BY_KEY = 0,
 DPA_CLS_TBL_MANAGE_BY_REF
};
```

Parameters

- **params** - data structure containing the parameters of the table to create;
  - **cc_node** - handle of the Cc node to start with; please refer to the function description for more information;
  - **distribution** - handle of a FMan distribution to send frames to instead of enqueuing them. If this handle is provided (not NULL) the enqueue action will only select the frame queue, but it will not actually enqueue the frame to the selected frame queue. Instead it will send the frame to the indicated distribution for further processing.
  - **classification** - handle of a FMan classification to send frames after distribution. For FMan v3 previously determined frame queue will be retained as frame destination. This parameter may be used to perform header manipulations operations such as fragmentation after the enqueue decision has been made.
  - **type** - the type of table to create; configured using dpa_cls_tbl_type enum;
  - **entry_mgmt** - table entry management mechanism for runtime; configured using dpa_cls_tbls_entry_mgmt enum;

NOTE

Not all types of tables support all types of entry management. Indexed tables can only be managed by key, because table entry insert doesn't make any sense on this type of table. Only entry modification is available for this type of tables. In this case there is no way for the classifier to provide the user an entry reference for the entry management by reference mechanism to work.

- **hash_params**
  - num_sets – the number of sets in the HASH table; this controls the table size;
  - max_ways – the maximum number of ways (depth) of the HASH table; this controls the capability of the HASH to resolve conflicts;
  - hash_offs – lets the user control how the HASH value is used to determine the HASH set; this is the offset in bits from the MSB of the calculated HASH value where DPA Classifier should start applying the mask to get the index for HASH set lookup;
  - key_size - the size of the lookup keys in bytes.
- **indexed_params**
  - entries_cnt - the number of entries to be stored in the indexed table;
- **exact_match_params**
  - entries_cnt - maximum number of entries expected to be stored in the table;
  - key_size – the size of the keys in bytes;
  - use_priorities - Use priorities for each entry in table if set to true.
- **prefilled_entries** - Number of entries in the table which are pre-filled (already used). The assumption is always that these entries are the first entries in the table and with the highest priority. There are several limitations for prefilled tables relative to the normal (blank) tables: a) prefilled HASH tables cannot be managed by ref; b) header manipulations created using the DPA Classifier header manipulation API cannot be used on prefilled tables.

- **td** - a location where the function will return the descriptor of the newly created table, in case of success; this descriptor will be further used by the application to refer to this DPA Classfier table in other API function calls.

Description

Configures and initializes a DPA Classifier table using a coarse classification node generated with the FMan Configuration tool. This function never allocates new MURAM space.

Once the DPA Classifier takes control of a FMan Cc node, all management must be performed through its API. If applications use different APIs to modify the Cc node's properties in the same time while the DPA Classifier has ownership of the node, unpredictable behavior and data inconsistency can occur. Each type of DPA Classifier table requires a coarse classification node of a special type as its initial Cc node. The types of the initial Cc nodes relative to the types of DPA classifier tables are specified below.

Table 250.

DPA Classifier table type	Required initial FMan Cc node type
Exact Match Table	Match Table Cc Node
Indexed Table	Indexed Cc Node
HASH Table	HASH Table Cc Node

Depending on the value of the **entry_mgmt** parameter, the behavior of the runtime functions changes. In a table created with `DPA_CLS_TBL_MANAGE_BY_KEY`, runtime modify / delete / stats operations can be accomplished using any of the runtime

function versions. For tables which use DPA_CLS_TBL_MANAGE_BY_REF, only the runtime function versions with the suffix "by_ref" are supported for modification / deletion / stats.

The DPA_CLS_TBL_MANAGE_BY_REF is an entry management mode which is optimized in terms of speed and memory consumption of the DPA Classifier. Management by reference (Id), however, needs the application to take care of the mapping between lookup keys and entry Ids, because the Classifier only uses the entry Ids.

If DPA_CLS_TBL_MANAGE_BY_KEY is selected, the DPA Classifier will keep an internal shadow table for the mapping between the lookup keys and the actual table entries. This way, the user can specify entries also by their key and the DPA Classifier will do the (software) mapping to determine the entry Id.

For the HASH and exact match DPA classifier tables, the miss action of the table is stored separately and is not included in the number of entries requested by the user. Indexed tables never have miss action.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- -EINVAL, if one of the function arguments or parameters of the table was incorrect;
- -ENOSYS, if a feature selected by the table parameters is not supported;
- -ENOMEM, if there is no more memory to create a new DPA classifier table; this may mean that either the internal management data structures of the table could not be allocated, or the shadow table (if one was requested) could not be allocated;
- -EBUSY, if a FMan low level driver function call has failed.

9.9.3.2.1.1.1.2 Function: dpa_classif_table_free

Syntax

```
int dpa_classif_table_free(int td);
```

Parameters

- **td** - descriptor of the DPA Classifier table to destroy.

Description

Releases all resources associated with a DPA Classifier table and destroys it.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- -EINVAL, if the provided table descriptor is not valid;
- -EBUSY, if a FMan low level driver function call has failed.

9.9.3.2.1.1.2 Insert, Remove or Update Table Entries

Table 251. API to Insert, Remove or Update Table Entries

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_insert_entry`	Adds an entry (classification rule) in the specified DPA Classifier table.	• descriptor of the DPA Classifier table where the entry needs to be added; • the key description (its format depends on the type of table); • the action description in case of hit. • entry priority (if necessary).	The new entry's reference (or entry Id) in case of success.
`dpa_classif_table_delete_entry_by_key`	Removes an entry in the specified DPA Classifier table. The entry is identified by the lookup key.	• descriptor of the DPA Classifier table containing the entry to be removed; • the key description of the entry to be removed.	None.
`dpa_classif_table_delete_entry_by_ref`	Removes an entry in the specified DPA Classifier table. The entry is identified by its reference (Id).	• descriptor of the DPA Classifier table containing the entry to be removed; • the reference of the entry to be removed.	None.
`dpa_classif_table_modify_entry_by_key`	Modifies an entry in the specified DPA Classifier table. The entry is identified by the lookup key.	• descriptor of the DPA Classifier table containing the entry to be modified; • the key description of the entry to be modified; • the new key description to replace the existing key description; • the new action description in case of hit.	None.

Table continues on the next page...

Table 251. API to Insert, Remove or Update Table Entries (continued)

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_modify_entry_by_ref`	Modifies an entry in the specified DPA Classifier table. The entry is identified by reference (Id).	• descriptor of the DPA Classifier table containing the entry to be modified; • the reference of the entry to be modified; • the new key description to replace the existing key description; • the new action description in case of hit.	None.
`dpa_classif_table_get_entry_stats_by_key` **NOTE** As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.	Returns statistics for a specified entry in a specified table. Optionally reset the statistics once they are read. The entry is identified by the lookup key.	• descriptor of the DPA Classifier table containing the entry to return statistics for; • the key description of the classification rule to return statistics for; • indication whether the statistics should be reset once they are read.	The requested entry statistics.
`dpa_classif_table_get_entry_stats_by_ref` **NOTE** As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.	Returns statistics for a specified entry in a specified table. Optionally reset statistics once they are read. The entry is identified by its reference (Id).	• descriptor of the DPA Classifier table containing the entry to return statistics for; • reference of the classification rule to return statistics for; • indication whether the statistics should be reset once they are read.	The requested entry statistics.

Table continues on the next page...

Table 251. API to Insert, Remove or Update Table Entries (continued)

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_get_miss_stats` **NOTE** As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.	Returns miss statistics for a specified table. The table is identified by its descriptor (td).	descriptor of the DPA Classifier table to return statistics for.	The requested table miss statistics.

9.9.3.2.1.1.2.1 Function: dpa_classif_table_insert_entry

Syntax

```
int dpa_classif_table_insert_entry(
 int       td,
 const struct dpa_offload_lookup_key  *key,
 const struct dpa_cls_tbl_action  *action,
 int       priority,
 int       *entry_id);

struct dpa_cls_tbl_action
{
 enum dpa_cls_tbl_action_type    type;
 bool        enable_statistics;
 union
 {
  struct dpa_cls_tbl_enq_action_desc  enq_params;
  struct dpa_cls_tbl_next_table_desc  next_table_params;
  struct dpa_cls_tbl_mcast_group_desc  mcast_params;
 };
};

enum dpa_cls_tbl_action_type
{
 DPA_CLS_TBL_ACTION_NONE = 0,
 DPA_CLS_TBL_ACTION_DROP,
 DPA_CLS_TBL_ACTION_ENQ,
 DPA_CLS_TBL_ACTION_NEXT_TABLE,
 DPA_CLS_TBL_ACTION_MCAST
};

struct dpa_cls_tbl_enq_action_desc
{
 bool      override_fqid;
 uint32_t     new_fqid;
```

```
 struct dpa_cls_tbl_policer_params *policer_params;
 int      hmd;
 uint8_t     new_rel_vsp_id;
};

struct dpa_cls_tbl_next_table_desc
{
 int  next_td;
 int  hmd;
};

struct dpa_cls_tbl_mcast_group_desc
{
 int  grpd;
 int  hmd;
};

struct dpa_cls_tbl_policer_params
{
 bool   modify_policer_params;
 bool   shared_profile;
 unsigned int new_rel_profile_id;
};
```

Parameters

- **td** - descriptor of the DPA Classifier table to insert in;
- **key** - pointer to the key description (its format depends on the type of table);
- **action** - the action description in case of hit;
  - **type** – the type of action to take: drop, enqueue, send to next table, send to multicast group; the drop action descriptor type doesn't need any further parameters; selected from the dpa_cls_tbl_action_type enum; action type NONE is not accepted;
  - **enable_statistics** – true to enable statistics for this action; this attribute is ignored if the action is of type send to next table;
  - **enq_params**
    - **override_fqid** – true if the attribute new_fqid will override the KeyGen selected frame queue;
    - **new_fqid** – if override_fqid is true, this holds the explicit frame queue Id where to place the frame;
    - **policer_params** – policing parameters; if NULL, no policing is performed during the enqueue operation
      - **modify_policer_params** – true if the default policer parameters will be overridden;
      - **shared_profil** - true if this policer profile is shared between ports; relevant only if modify_policer_params is also true;
      - **new_rel_profile_id** - this parameter should indicate the policer profile offset within the port's policer profiles or from the SHARED window; relevant only if modify_policer_params is true;
    - **hmd** – header manipulation object descriptor, or DPA_OFFLD_DESC_NONE if no header manipulation is required for the enqueue action; the header manipulation object defined by the provided descriptor must be a header manipulation chain head;
    - **new_rel_vsp_id** – new virtual storage profile Id. This parameter is mandatory when override_fqid is set to true and the port has virtual storage profiles defined. Otherwise it is not used..
  - **mcast_params** – this parameter is used when the action is multicast.

  - **grpd** – multicast group descriptor. This value identifies an existing multicast group.
  - **hmd** – header manipulation object descriptor, or DPA_OFFLD_DESC_NONE if no header manipulation is required. The header manipulation object defined by the provided descriptor must be a header manipulation chain head. The header manipulation operation will be performed before sending the frame to the multicast group.
- **next_table_params**
  - **next_td** – descriptor of the next DPA Classifier table where the frame will be sent for further classification.
  - **hmd** - descriptor of the header manipulation chain to use before sending the frames to the next table, or DPA_OFFLD_DESC_NONE if no header manipulation is required. The header manipulation object defined by the provided descriptor must be a header manipulation chain head.
- **priority** - the priority of the entry. This parameter is meaningful only if td is an exact match table with priority per entries. The priority value of the entry influences the position of the entry in the table relative to the other entries. Entries with lower priority values go to the top of the table. Priority values can be negative. If two entries with the same priority are inserted in the table, they will be positioned one after the other in the table, with the older one first.
- **entry_id** - reference to the newly created entry returned by this function on success.

Description

Adds an entry (classification rule) in the specified DPA Classifier table. If the MURAM for the table was pre-allocated, this operation doesn't consume MURAM.

NOTE

The hardware currently doesn't support longest prefix match on the exact match or HASH tables. If there are more entries in the table that match the lookup (e.g. because of their mask) the first one will always be returned by the hardware lookup.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EEXIST`, if the specified table entry already exists;
- `-EINVAL`, if there is an error in the provided entry parameters;
- `-EBUSY`, if a FMan low level driver function call has failed;
- `-ENOMEM`, if there is no more memory for adding or managing a new table entry;
- `-ENOSPC`, if there is no more room to add a new table entry (table is full).

9.9.3.2.1.1.2.2 Function: dpa_classif_table_delete_entry_by_key

Syntax

```
int dpa_classif_table_delete_entry_by_key(
 int      td,
 const struct dpa_offload_lookup_key *key);
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to be removed;
- **key** - the key description of the entry to be removed.

Description

Removes an entry in the specified DPA Classifier table. The entry is identified by the lookup key. If the MURAM for the table was pre-allocated, this function doesn't free up any MURAM space.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;;
- - `ENOSYS`, if the function was illegally called for a table `DPA_CLS_TBL_MANAGE_BY_REF`;
- `-ENODEV`, if the entry with the specified key was not found in the table;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.1.1.2.3 Function: dpa_classif_table_delete_entry_by_ref

Syntax

```
int dpa_classif_table_delete_entry_by_ref(int td, int entry_id);
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to be removed;
- **entry_id** - the reference (Id) of the entry to be removed.

Description

Removes an entry in the specified DPA Classifier table. The entry is identified by its reference (Id). If the MURAM for the table was pre-allocated, this function doesn't free up any MURAM space.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.1.1.2.4 Function: dpa_classif_table_modify_entry_by_key

Syntax

```
int dpa_classif_table_modify_entry_by_key(
    int                             td,
const struct dpa_offload_lookup_key        *key,
    const struct dpa_cls_tbl_entry_mod_params    *mod_params);

enum dpa_cls_tbl_modify_type
{
    DPA_CLS_TBL_MODIFY_KEY = 0,
    DPA_CLS_TBL_MODIFY_ACTION,
    DPA_CLS_TBL_MODIFY_KEY_AND_ACTION
};
```

```
struct dpa_cls_tbl_entry_mod_params
{
    enum dpa_cls_tbl_modify_type        type;
    struct dpa_offload_lookup_key        *key;
    struct dpa_cls_tbl_action       *action;
};
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to be modified;
- **key** - the key description of the entry to be modified;
- **mod_params** - the new parameters to replace the existing key descriptor and/or action descriptor;
  - **type** - specifies the desired modification; can be either key descriptor modification only, action descriptor modification only, or both; configured using the dpa_cls_tbl_modify_type enum;
  - **key** - new key descriptor to replace the descriptor that is indexing this entry; this is ignored if the type of modification is `DPA_CLS_TBL_MODIFY_ACTION`;
  - **action** - the new action description in case of hit; this is ignored if the type of modification is `DPA_CLS_TBL_MODIFY_KEY`.

Description

Modifies an entry in the specified DPA Classifier table. The entry is identified by the lookup key. This function never allocates new MURAM space.

The entry modification types `DPA_CLS_TBL_MODIFY_KEY` and `DPA_CLS_TBL_MODIFY_KEY_AND_ACTION` are only available for exact match tables.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the required type of modification is not supported or if the function was illegally called for a table `DPA_CLS_TBL_MANAGE_BY_REF`;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.1.1.2.5 Function: dpa_classif_table_modify_entry_by_ref

Syntax

```
int dpa_classif_table_modify_entry_by_ref(
    int                             td,
    int                             entry_id,
    const struct dpa_cls_tbl_entry_mod_params    *mod_params);
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to be modified;
- **entry_id** - the reference (Id) of the entry to be modified;
- **mod_params** - the new parameters to replace the existing key descriptor and/or action descriptor;

Description

Modifies an entry in the specified DPA Classifier table. The entry is identified by its reference (Id). This function never allocates new MURAM space. The entry modification types `DPA_CLS_TBL_MODIFY_KEY` and `DPA_CLS_TBL_MODIFY_KEY_AND_ACTION` are only available for exact match tables.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the required type of modification is not supported;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.1.1.2.6 Function: dpa_classif_table_flush

Syntax

```
int dpa_classif_table_flush(int td);
```

Parameters

- **td** - descriptor of the DPA Classifier table to flush;

Description

Removes all the entries in a DPA Classifier Table. After this operation is completed the entries cannot be recovered.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;;
- `-EBUSY`, if a FMan low level driver call has failed.

9.9.3.2.1.1.2.7 Function: dpa_classif_table_get_entry_stats_by_key

Syntax

NOTE

As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.

```
int dpa_classif_table_get_entry_stats_by_key(
 int       td,
 const struct dpa_offload_lookup_key  *key,
 struct dpa_cls_tbl_entry_stats  *stats);

struct dpa_cls_tbl_entry_stats
{
    uint32_t    pkts;
    uint32_t    bytes;
};
```

Parameters

- **td** - of the DPA Classifier table containing the entry to return statistics for;
- **key** - key description of the classification rule to return statistics for;
- **stats** - pointer to a structure allocated especially to receive the requested statistics;
  - **pkts** - the total number of packets that have hit the entry;
  - **bytes** - the total number of bytes in all the packets that have hit the entry.

Description

Returns the statistics for a specified entry in a specified table. The entry is identified by the lookup key.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the function was illegally called for a table `DPA_CLS_TBL_MANAGE_BY_REF`;
- `-ENODEV`, if the entry with the specified key was not found in the table.

9.9.3.2.1.1.2.8 Function: dpa_classif_table_get_entry_stats_by_ref

Syntax

NOTE

As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.

```
int dpa_classif_table_get_entry_stats_by_ref(
    int                         td,
    int                         entry_id,
    struct dpa_cls_tbl_entry_stats    *stats);
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to return statistics for;
- **entry_id** - reference (Id) of the classification rule to return statistics for;
- **stats** - pointer to a structure allocated especially to receive the requested statistics.

Description

Returns the statistics for a specified entry in a specified table. The entry is identified by its reference (Id).

Return Value

The function returns zero on success or a negative error code otherwise. The returned error code is the following:

- `-EINVAL`, if there are errors in the parameters provided to the function.

9.9.3.2.1.1.2.9 Function: dpa_classif_table_get_miss_stats

Syntax

NOTE

As statistics will be further handled by the DPA Stats component, this function is now obsolete. Please take into account that it will be removed in the next releases of DPA Classifier.

```
int dpa_classif_table_get_miss_stats(
    int                         td,
    struct dpa_cls_tbl_entry_stats    *stats);
```

Parameters

- **td** - descriptor of the DPA Classifier table containing the entry to return statistics for;
- **stats** - pointer to a structure allocated especially to receive the requested statistics.

Description

Returns the statistics for a specified table identified by its descriptor (td).

Return Value

The function returns zero on success or a negative error code otherwise. The returned error code is the following:

- `-EINVAL`, if there are errors in the parameters provided to the function.
- `-EPERM`, if there are errors while retrieving the statistics.

9.9.3.2.1.1.3 Update Default Table Policy

Table 252. API to Update Default Table Policy

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_modify_miss_action`	Modifies the action taken in case of lookup miss condition.	• descriptor of the DPA Classifier table to modify the miss action for; • pointer to the new action description in case of lookup miss.	None.

9.9.3.2.1.1.3.1 Function: dpa_classif_table_modify_miss_action

Syntax

```
int dpa_classif_table_modify_miss_action(
int                         td,
const struct dpa_cls_tbl_action    *miss_action);
```

Parameters

- **td** - descriptor of the DPA Classifier table to modify the miss action for;
- **miss_action** - pointer to the new action description in case of lookup miss;

Description

Modifies the action taken in case of lookup miss condition.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the user requested an unsupported modification of the miss action;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.1.1.4 Table Lookup

Table 253. API for Table Lookup

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_table_lookup_by_key`	Performs a software lookup in the specified table. If successful (i.e. the entry exists in that table) the action descriptor for that entry is returned. The entry is identified by the lookup key.	• descriptor of the DPA Classifier table to search in; • pointer to the key descriptor of the entry to search for.	The action descriptor properties in case the entry is found in the table.
`dpa_classif_table_lookup_by_ref`	Performs a software lookup in the specified table. If successful (i.e. the entry exists in that table) the action descriptor for that entry is returned. The entry is identified by its reference (Id).	• descriptor of the DPA Classifier table to search in; • the reference of the entry to search for;	The action descriptor properties in case the entry is found in the table.

9.9.3.2.1.1.4.1 Function: dpa_classif_table_lookup_by_key

Syntax

```
int dpa_classif_table_lookup_by_key(
int                             td,
    const struct dpa_offload_lookup_key        *key,
struct dpa_cls_tbl_action            *action);
```

Parameters

- **td** - descriptor of the DPA Classifier table to search in;
- **key** - pointer to the key descriptor of the entry to search for;
- **action** - pointer to a specially allocated structure to receive the action descriptor properties in case the entry is found in the table; this structure is to be considered valid only when the function returns zero.

Description

Performs a lookup in the specified table for an entry specified by a key. If successful (i.e. the entry exists in that table) the action descriptor for that entry is returned. This function works only if entry management by key was selected for the table.

Please be aware that this is not a hardware accelerated lookup. This lookup is performed by the DPA Classifier in its internal shadow tables. It is recommended to use this function with consideration.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the function was illegally called for a table `DPA_CLS_TBL_MANAGE_BY_REF`;
- `-ENODEV`, if the entry with the specified key was not found in the table.

9.9.3.2.1.1.4.2 Function: dpa_classif_table_lookup_by_ref

Syntax

```
int dpa_classif_table_lookup_by_ref(
int                     td,
    int                     entry_id,
    struct dpa_cls_tbl_action    *action);
```

Parameters

- **td** - descriptor of the DPA Classifier table to search in;
- **key** - pointer to the key descriptor of the entry to search for;
- **action** - pointer to a specially allocated structure to receive the action descriptor properties in case the entry is found in the table; this structure is to be considered valid only when the function returns zero.

Description

Returns the action descriptor for an entry specified by a reference (Id) existing in a specified table. This function is using the internal shadow tables of the DPA Classifier, hence it can be called only for tables created with the `DPA_CLS_TBL_MANAGE_BY_KEY` flag.

Return Value

The function returns zero on success or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOSYS`, if the function was illegally called for a table `DPA_CLS_TBL_MANAGE_BY_REF`;

9.9.3.2.2 Header Manipulation

Header manipulation can be performed on any frame in the following situations:

- when it hits the enqueue action,
- when it is sent to a multicast group or
- when it is sent to a new classification (new lookup).

The available header manipulations are designed based on specific network processes and are listed below.

- NAT (Network Address and Port Translation)
- Forwarding
- Remove header manipulation
- Insert header manipulation
- Update L3/L4 header manipulation
- VLAN specific header manipulation
- MPLS specific header manipulation

Each of these header manipulations can consist of one or more header manipulation **operations**, but this is transparent to the DPA Classifier user. Some of the header manipulation operations may be optional and can be disabled. Header manipulations can be chained in sequence to create more complex actions however, care must be taken at the order of operations. Certain operations may be impacted by previous insert or remove operations which modify the offsets of the headers in the frame.

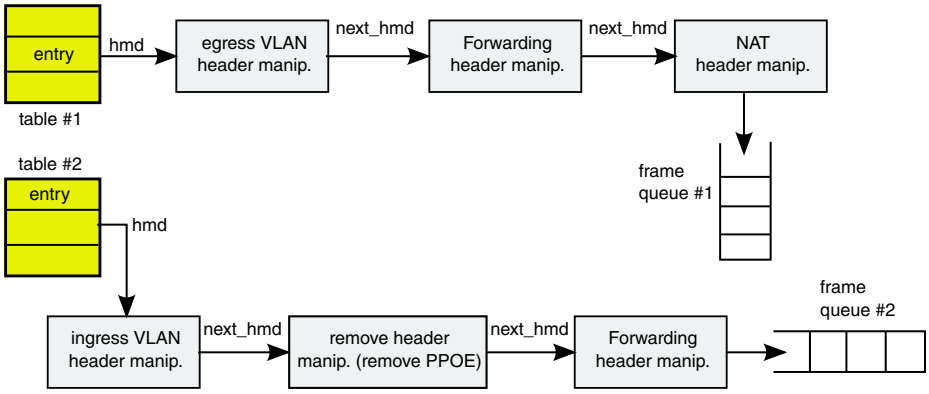

Figure 253. Header manipulation operations chain example

A header manipulation operations chain is always created starting from the tail and working your way towards the head of the chain. The last header manipulation in the chain is identified by passing `next_hmd=DPA_OFFLD_DESC_NONE` (no other header manipulations are beyond it). The chain head is identified by calling the appropriate header manipulation operation create function using the argument `chain_head=true`. When DPA Classifier identifies the chain head, it initializes the low level driver resources for the entire header manipulation chain. The header manipulation operations chain is now ready to be attached to a DPA Classifier table entry.

To attach an existing header manipulation chain to a DPA Classifier table entry, one needs to set the hmd attribute of the enqueue parameters (`dpa_cls_tbl_enq_action_desc`) related to the new table entry (`dpa_cls_tbl_action`) to point to the descriptor of the header manipulation chain head. Setting the hmd to point to any other header manipulation operation different from a chain head will result in an error. Once the table insert function is called, the table entry and the header manipulation chain enter effect. It is **not possible** to use header manipulations in tables created in different PCDs. It is possible to share the same header manipulation operations **chain** on multiple table entries.

When there is no more need for the header manipulation chain, the header manipulation operations that make it up can be removed in any order. The DPA Classifier will refuse to free header manipulation operations belonging to chains which are in use (i.e. still attached to table entries). One must delete all table entries or detach the header manipulation chain from all entries in order to be able to remove operations from the chain. The low level driver resources are removed only when the chain head operation is removed. It is **not possible** to reuse parts of a header manipulation chain. Header manipulation operation parameters can be modified at runtime using a set of “modify” functions. However, the user application cannot change the **type** of the header manipulation operation. The proper modify function must be called for the type of the existing header manipulation operation. If the header manipulation operation type is not matched to the **modify** function, an error is returned by the **modify** function.

9.9.3.2.2.1 Header Manipulation API

There are two selections for the DPA Classifier table API:

9.9.3.2.2.1.1 Create and Remove Operations

Table 254. API to Create and Remove Header Manipulation Operations

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_set_nat_hm`	Creates / imports a NAT type header manipulation object.	• NAT header manipulation parameters; • descriptor of the next header manipulation object in chain; • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.
`2 dpa_classif_set_fwd_hm`	Creates / imports a forwarding type header manipulation object.	• forwarding header manipulation parameters; • descriptor of the next header manipulation object in chain. • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.

Table continues on the next page...

Table 254. API to Create and Remove Header Manipulation Operations (continued)

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_set_remove_hm`	Creates / imports a remove type header manipulation object.	• ingress (remove) header manipulation parameters; • descriptor of the next header manipulation object in chain. • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.
`dpa_classif_set_insert_hm`	Creates / imports an insert type header manipulation object.	• egress insert header manipulation parameters; • descriptor of the next header manipulation object in chain; • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.
`dpa_classif_set_update_hm`	Creates / imports an update type header manipulation object.	• egress update header manipulation parameters; • descriptor of the next header manipulation object in chain. • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.

Table continues on the next page...

Table 254. API to Create and Remove Header Manipulation Operations (continued)

Function Name	Description	Input Parameters	Output Parameters
dpa_classif_set_vlan_hm	Creates / imports a VLAN specific header manipulation (either ingress or egress) object.	• VLAN specific header manipulation parameters; • descriptor of the next header manipulation object in chain. • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.
dpa_classif_set_mpls_hm	Creates / imports a MPLS specific header manipulation object..	• MPLS specific header manipulation parameters; • descriptor of the next header manipulation object in chain. • indication whether this header manipulation object is the head of the header manipulation chain; • optional low level resources in case they need to be imported instead of created.	The descriptor of the current header manipulation object once it is created.
dpa_classif_free_hm	Releases a header manipulation object.	• descriptor of the header manipulation object to destroy.	None.

9.9.3.2.2.1.1.1 Function: dpa_classif_set_nat_hm

Syntax

```
int dpa_classif_set_nat_hm(const struct dpa_cls_hm_nat_params *nat_params,
     int next_hmd, int *hmd, bool chain_head,
const struct dpa_cls_hm_nat_resources *res);

/* Definition of a NAT related header manipulation */
struct dpa_cls_hm_nat_params {
 int        flags;
 enum dpa_cls_hm_nat_proto    proto;
 enum dpa_cls_hm_nat_type     type;
```

```
 union {
        struct dpa_cls_hm_traditional_nat_params nat;
        struct dpa_cls_hm_nat_pt_params  nat_pt;
 };
 uint16_t       sport;
 uint16_t       dport;
 /*
  * More attributes may be added to this structure when ICMP NAT
  * support will be available.
  */
 void        *fm_pcd;
 bool        reparse;
};

/* NAT header manipulation low level driver resources */
struct dpa_cls_hm_nat_resources {
 void *l3_update_node;
 void *l4_update_node;
};

/* Supported protocols for NAT header manipulations */
enum dpa_cls_nat_proto {
 DPA_CLS_NAT_PROTO_UDP,
 DPA_CLS_NAT_PROTO_TCP,
 DPA_CLS_NAT_PROTO_ICMP,
 DPA_CLS_NAT_PROTO_LAST_ENTRY
};

/* NAT operation type */
enum dpa_cls_hm_nat_type {
 DPA_CLS_HM_NAT_TYPE_TRADITIONAL,
 DPA_CLS_HM_NAT_TYPE_NAT_PT,
 DPA_CLS_HM_NAT_TYPE_LAST_ENTRY
};

/*
 * Flag values indicating the possible fields to be updated with the
 * NAT header manipulation
 */
enum dpa_cls_hm_nat_flags {
 DPA_CLS_HM_NAT_UPDATE_SIP = 0x01,
 DPA_CLS_HM_NAT_UPDATE_DIP = 0x02,
 DPA_CLS_HM_NAT_UPDATE_SPORT  = 0x04,
 DPA_CLS_HM_NAT_UPDATE_DPORT  = 0x08,
};

/* Traditional NAT parameters */
struct dpa_cls_hm_traditional_nat_params {
 struct dpa_offload_ip_address  sip;
 struct dpa_offload_ip_address  dip;
};

/* NAT-PT parameters */
struct dpa_cls_hm_nat_pt_params {
 enum dpa_cls_hm_nat_pt_type  type;
 union {
  struct ipv4_header  ipv4;
  struct ipv6_header  ipv6;
 } header;
};
```

```
/* Type of protocol translation for NAT */
enum dpa_cls_hm_nat_pt_type {
 DPA_CLS_HM_NAT_PT_IPv6_TO_IPv4,
 DPA_CLS_HM_NAT_PT_IPv4_TO_IPv6
};
```

Parameters

- **nat_params** - NAT header manipulation parameters:
  - **flags** – NAT operation flags specify which fields in the packet should be updated; this is a combination of the values in the dpa_cls_hm_nat_flags enum; combine the values using the or logical operand;
  - **proto** – protocol to perform NAT for; selected from dpa_cls_nat_proto enum ;
  - **type** – selects the flavor of NAT to configure; selected from the dpa_cls_hm_nat_type enum;
  - **nat** – traditional NAT header manipulation parameters; used only when traditional NAT is selected using the type attribute;
    - **sip** - new source IP address; used only when selected using the flags attribute;
    - **dip** - new destination IP address; used only when selected using the flags attribute;
  - **nat_pt** - NAT-PT header manipulation parameters; used only when NAT-PT is selected using the type attribute;
    - **type** - specifies the protocol replacement for NAT-PT: either IPv4-to-IPv6 or IPv6-to-IPv4;
    - **header** - data for protocol header replacement:
      - **ipv4** - IPv4 header data to replace IPv6 with;
      - **ipv6** - IPv6 header data to replace IPv4 with;
  - **sport** - new L4 protocol source port number; used when selected using the flags attribute;
  - **dport** - new L4 protocol destination port number; used only when selected using the flags attribute;

NOTE

More attributes may be added to this structure when ICMP NAT support will be available.

  - **fm_pcd** - handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irrelevant;
  - **reparse** - *TRUE* to force re-parsing of the packet after this NAT;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; `DPA_OFFLD_DESC_NONE` can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;
- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;

NOTE

When using external resource allocation it is the responsibility of the user to ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. There is no way for the DPA Classifier to verify the header manipulation parameters.

- **l3_update_node** – a handle to a header manipulation node which may combine a local IPv4/IPv6 update header manipulation with an IP protocol replace. This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed;
- **l4_update_node** - handle to the local TCP/UDP update header manipulation node. This is a FMan driver header manipulation node handle and it is optional (can be NULL in case no L4 header updates are necessary for this NAT flow);

Description

Creates or imports a NAT type header manipulation object. If the function is successful it returns at the hmd location the descriptor of the created header manipulation object.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the fm_pcd handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM.

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when chain_head parameter is provided as true). When working in this mode the fm_pcd handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.2.1.1.2 Function: dpa_classif_set_fwd_hm

Syntax

```
int dpa_classif_set_fwd_hm(
 const struct dpa_cls_hm_fwd_params  *fwd_params,
 int       next_hmd,
 int       *hmd,
bool       chain_head
const struct dpa_cls_hm_fwd_resources *res);

struct dpa_cls_hm_fwd_params {
 enum dpa_cls_hm_out_if_type   out_if_type;
 union {
  struct dpa_cls_hm_fwd_l2_param eth;
  struct dpa_cls_hm_fwd_pppoe_param pppoe;
  struct dpa_cls_hm_fwd_ppp_param ppp;
 };
 struct dpa_cls_hm_ip_frag_params  ip_frag_params;
 void       *fm_pcd;
 bool       reparse;
};

enum dpa_cls_hm_out_if_type {
 DPA_CLS_HM_IF_TYPE_ETHERNET,
 DPA_CLS_HM_IF_TYPE_PPPoE,
 DPA_CLS_HM_IF_TYPE_PPP,
```

```
 DPA_CLS_HM_IF_TYPE_LAST_ENTRY
};

struct dpa_cls_hm_ip_frag_params {
 uint16_t     mtu;
 uint8_t     scratch_bpid;
enum dpa_cls_hm_frag_df_action df_action;
};

enum dpa_cls_hm_frag_df_action {
 DPA_CLS_HM_DF_ACTION_FRAG_ANYWAY,
 DPA_CLS_HM_DF_ACTION_DONT_FRAG,
 DPA_CLS_HM_DF_ACTION_DROP
};

struct dpa_cls_hm_fwd_l2_param {
 uint8_t    macda[ETH_ALEN];
 uint8_t    macsa[ETH_ALEN];
};

struct dpa_cls_hm_fwd_pppoe_param {
 struct dpa_cls_hm_fwd_l2_param l2;
 struct pppoe_header   pppoe_header;
};

struct dpa_cls_hm_fwd_ppp_param {
 uint16_t     ppp_pid;
};

/* IP forwarding header manipulation low level driver resources */
struct dpa_cls_hm_fwd_resources {
 void *fwd_node;
 void *pppoe_node;
 void *ip_frag_node;
};
```

Parameters

- **fwd_params** - IP forwarding header manipulation parameters:
  - **out_if_type** – output interface type; based on this selection the DPA Classifier decides which header manipulations are needed to perform forwarding; selected from dpa_cls_hm_out_if_type enum;
  - **eth** – necessary parameters for an Ethernet output interface:
    - **macda** – new Ethernet destination MAC address to update the L2 header;
    - **macsa** – new Ethernet source MAC address to update the L2 header;
  - **pppoe** – necessary parameters for a PPPoE output interface:
    - **l2** – L2 header update parameters;
    - **pppoe_header** – PPPoE header to be inserted in the packets. The PPPoE payload length field is updated automatically (you can set it to zero).
  - **ppp** – necessary parameters for a PPP output interface:
    - **ppp_pid** – PPP PID value to use in the PPP header to be inserted.
  - **ip_frag_params** – parameters related to optional IP fragmentation:

- **mtu** – interface Maximum Transfer Unit in bytes. Use zero if no IP fragmentation should be performed (disable IP fragmentation);
- **scratch_bpid** – scratch buffer pool ID. This is necessary for the IP fragmentation on FMan v2 devices only. On FMan v3 or newer devices this parameter is ignored. It is also ignored if IP fragmentation is disabled;
- **df_action** - specifies how to deal with packets with DF flag on;

NOTE

Note: IP fragmentation is not supported in this context. Please use the “update” type header manipulation instead if IP fragmentation is needed.

- **fm_pcd** – handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irelevant;
- **reparse** - *TRUE* to force re-parsing of the packet headers after this forwarding header manipulation;

- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; DPA_OFFLD_DESC_NONE can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;
- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;

NOTE

When using external resource allocation it is the responsibility of the user to ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. There is no way for the DPA Classifier to verify the header manipulation parameters.

- **fwd_node** - handle to the forwarding header manipulation node. In case of an Ethernet or PPPoE output interface this is a local header replace header manipulation node (for Ethernet MAC addresses). In case of a PPP output interface this is a header manipulation node which combines a protocol specific header removal (for Ethernet and VLAN tags) with a local header insert manipulation. This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed.

NOTE

PPPoE protocol specific header manipulation is not supported yet.

- **pppoe_node** - Handle to the PPPoE specific node. This is an internal protocol specific insert PPPoE header manipulation node. This is a FMan driver header manipulation node handle and it is optional (can be NULL in case the output interface type is not PPPoE).
- **ip_frag_node** - handle to the IP fragmentation node. This is a FMan driver header manipulation node handle and it is optional (can be NULL in case no IP fragmentation is enabled for this IP forwarding flow).

Description

Creates or imports a forwarding type header manipulation object. This type of header manipulation can be configured to do either of the following:

- L2 header update
- L2 header update + IP fragmentation

L2 header update operation is performed according to the output port type:

- for Ethernet ports = MAC address update
- for PPPoE ports = PPPoE header insert
- for PPP ports = PPP header insert

DPA Classifier takes into account an Ethernet/IP frame to start with and, depending on the selection of output interface type, it decides what header manipulations are necessary.

IP fragmentation cannot be enabled all alone in the forwarding header manipulation context. If only IP fragmentation is needed on a packet flow (without any other header manipulation ops), the “update” type header manipulation is recommended instead of the “forwarding” type header manipulation. For additional details, please refer to `dpa_classif_set_update_hm`.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the `fm_pcd` handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM.

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when `chain_head` parameter is provided as true). When working in this mode the `fm_pcd` handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.2.1.1.3 Function: dpa_classif_set_remove_hm

Syntax

```
int dpa_classif_set_remove_hm(
 const struct dpa_cls_hm_remove_params *remove_params,
 int       next_hmd,
 int       *hmd,
bool       chain_head,
const struct dpa_cls_hm_remove_resources *res);

struct dpa_cls_hm_remove_params {
 enum dpa_cls_hm_remove_type   type;
 struct dpa_cls_hm_custom_rm_params  custom;
 void       *fm_pcd;
 bool       reparse;
};

enum dpa_cls_hm_remove_type {
 DPA_CLS_HM_REMOVE_ETHERNET,  /* removes ETH and all QTags */
 DPA_CLS_HM_REMOVE_PPPoE,  /* removes ETH, all QTags and PPPoE */
 DPA_CLS_HM_REMOVE_PPP,
 DPA_CLS_HM_REMOVE_CUSTOM,
 DPA_CLS_HM_REMOVE_LAST_ENTRY
};

 struct dpa_cls_hm_custom_rm_params {
 uint8_t      offset;
 uint8_t      size;
```

```
};

/* Ingress remove header manipulation low level driver resources */
struct dpa_cls_hm_remove_resources {
 void *remove_node;
};
```

Parameters

- **remove_params** - ingress (remove) header manipulation parameters:
  - **type** - selects the type of the remove header manipulation operation to perform. Protocol specific header removals don't need any further parameters; selected from dpa_cls_hm_remove_type enum.

    NOTE

    Protocol specific PPPoE header removal is not yet supported by the FMan microcode.

  - **custom** - parameters for the custom remove header manipulation. If type is anything else than "custom remove", these parameters are ignored;
    - **offset** - offset in bytes, relative to the start of the packet, to start removing data from;
    - **size** - the size in bytes of the section to remove;
  - **fm_pcd** - handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irelevant;
  - **reparse** - *TRUE* to force re-parsing of packet headers after this header remove;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; `DPA_OFFLD_DESC_NONE` can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;
- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;

  NOTE

  When using external resource allocation it is the responsibility of the user to ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. There is no way for the DPA Classifier to verify the header manipulation parameters.

  - **remove_node** - handle to either a header removal node or a protocol specific header removal node (for Ethernet and all VLAN tags). This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed.

Description

Creates or imports a remove type header manipulation object.

The `REMOVE_CUSTOM` header manipulation action is a raw data remove operation using an offset (relative to the start of the packet) and a size (in bytes of the area to remove) and it doesn't involve any checksum updates to the frame. The operation is not aware of any protocols that may exist in the frame. The offset and removal size restrictions that apply here are those of the FMan microcode.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the `fm_pcd` handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM.

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when chain_head parameter is provided as true). When working in this mode the `fm_pcd` handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if a FMan low level driver function call has failed.

9.9.3.2.2.1.1.4 Function: dpa_classif_set_insert_hm

Syntax

```
int dpa_classif_set_insert_hm(
 const struct dpa_cls_hm_insert_params *insert_params,
 int       next_hmd,
 int       *hmd,
bool       chain_head,
const struct dpa_cls_hm_insert_resources *res);

struct dpa_cls_hm_insert_params {
 enum dpa_cls_hm_insert_type   type;
 union {
  struct dpa_cls_hm_eth_ins_params eth;
  struct dpa_cls_hm_pppoe_ins_params pppoe;
  uint16_t     ppp_pid;
  struct dpa_cls_hm_custom_ins_params custom;
 };
 void       *fm_pcd;
 bool       reparse;
};

enum dpa_cls_hm_insert_type {
 DPA_CLS_HM_INSERT_ETHERNET, /* Insert Ethernet + QTags */
 DPA_CLS_HM_INSERT_PPPoE, /* Insert PPPoE, ETH and QTags */
 DPA_CLS_HM_INSERT_PPP,
 DPA_CLS_HM_INSERT_CUSTOM, /* General insert */
 DPA_CLS_HM_INSERT_LAST_ENTRY
};

/*
 * Maximum number of VLAN tags supported by the insert header manipulation
 */
#define DPA_CLS_HM_MAX_VLANs      6

/* Ethernet header insert params */
struct dpa_cls_hm_eth_ins_params {
 struct ethhdr   eth_header;
 unsigned int   num_tags;
```

```
 struct vlan_header  qtag[DPA_CLS_HM_MAX_VLANs];
};

struct dpa_cls_hm_pppoe_ins_params {
 struct dpa_cls_hm_eth_ins_params eth;
 struct pppoe_header   pppoe_header;
};

struct dpa_cls_hm_custom_ins_params {
 uint8_t    offset;
 uint8_t    size;
 const uint8_t   *data;
};

/* Egress insert header manipulation low level driver resources */
struct dpa_cls_hm_insert_resources {
 void *insert_node;
};
```

Parameters

- **insert_params** - egress insert header manipulation parameters:
  - **type** - specifies the type of insert header manipulation; selected from the `dpa_cls_hm_egress_ins_type` enum;
  - **eth** - Ethernet header insert parameters if **type** is “insert Ethernet”:
    - **eth_header** - Ethernet header to insert;
    - **num_tags** - number of VLAN tags to insert; if zero, no VLAN tags will be inserted in the packet;
    - **qtag** – relevant only if num_tags is not zero; contains an array with the data of the VLAN tags to insert;
  - **pppoe** - PPPoE header insert parameters if **type** is “insert PPPoE”;
    - **eth** - parameters of the Ethernet header to insert together with PPPoE header;
    - **pppoe_header** – PPPoE header to insert;
  - **ppp_pid** - PPP PID value to use in the PPP header if **type** is “insert PPP”;
  - **custom** - custom insert header manipulation operation parameters. These are relevant only if a custom insert header manipulation operation is selected.
    - **offset** – the offset in bytes relative to the start of the packet where the new header will be inserted;
    - **size** – the size in bytes of the new header to be inserted;
    - **data** – pointer to the buffer containing the data of the new header to be inserted.
  - **fm_pcd** - handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), **fm_pcd** is irelevant;
  - **reparse** - *TRUE* to force re-parsing of the packet headers after this header insert;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; `DPA_OFFLD_DESC_NONE` can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;

- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;

> **NOTE**
> When using external resource allocation the user shall ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. The DPA Classifier cannot verify the header manipulation parameters.

- **insert_node** - handle to either an internal header insert or an internal protocol specific header insert node. This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed.

Description

Creates or imports an insert type header manipulation object.

The `INSERT_CUSTOM` header manipulation action is a raw data insert operation using an offset (relative to the start of the packet), a size (in bytes of the area to insert) and a data pointer and it doesn't involve any checksum updates to the frame. The operation is not aware of any protocols that may exist in the frame. The offset and insert size restrictions that apply here are those of the FMan microcode.

If the **res** parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the `fm_pcd` handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM.

If the **res** parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when `chain_head` parameter is provided as true). When working in this mode the `fm_pcd` handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.1.5 Function: dpa_classif_set_update_hm

Syntax

```
int dpa_classif_set_update_hm(
 const struct dpa_cls_hm_update_params  *update_params,
 int        next_hmd,
 int        *hmd,
bool        chain_head,
const struct dpa_cls_hm_update_resources  *res);

struct dpa_cls_hm_update_params {
 int       op_flags;
 union {
  struct ipv4_header    new_ipv4_hdr;
  struct ipv6_header    new_ipv6_hdr;
 } replace;

 union {
```

```
  struct dpa_cls_hm_l3_update_params l3;
  struct dpa_cls_hm_l4_update_params l4;
 } update;

 struct dpa_cls_hm_ip_frag_params  ip_frag_params;
 void       *fm_pcd;
 bool       reparse;
};

/* Op flags */
enum dpa_cls_hm_update_op_flags {
 DPA_CLS_HM_UPDATE_NONE    = 0,

 DPA_CLS_HM_UPDATE_IPv4_UPDATE   = 0x01,
 DPA_CLS_HM_UPDATE_IPv6_UPDATE   = 0x02,
 DPA_CLS_HM_UPDATE_UDP_TCP_UPDATE  = 0x04,

 DPA_CLS_HM_REPLACE_IPv4_BY_IPv6  = 0x08,
 DPA_CLS_HM_REPLACE_IPv6_BY_IPv4  = 0x10
};

/* Field flags */
enum dpa_cls_hm_l3_field_flags {
 DPA_CLS_HM_IP_UPDATE_IPSA   = 0x01,
 DPA_CLS_HM_IP_UPDATE_IPDA   = 0x02,
 DPA_CLS_HM_IP_UPDATE_TOS_TC   = 0x04,
 DPA_CLS_HM_IP_UPDATE_ID    = 0x08,
 DPA_CLS_HM_IP_UPDATE_TTL_HOPL_DECREMENT = 0x10
};

enum dpa_cls_hm_l4_field_flags {
 DPA_CLS_HM_L4_UPDATE_SPORT   = 0x01,
 DPA_CLS_HM_L4_UPDATE_DPORT   = 0x02,
 DPA_CLS_HM_L4_UPDATE_CALCULATE_CKSUM = 0x04
};

/* L3 protocols field update parameters */
struct dpa_cls_hm_l3_update_params {
 struct dpa_offload_ip_address  ipsa;
 struct dpa_offload_ip_address  ipda;
 uint8_t     tos_tc;
 uint16_t     initial_id;

 /* select a combination from enum dpa_cls_hm_l3_field_flags */
 int      field_flags;
};

/* L4 protocols field update parameters */
struct dpa_cls_hm_l4_update_params {
 uint16_t sport; /* new L4 source port value */
 uint16_t dport; /* new L4 destination port value */

 /* select a combination from enum dpa_cls_hm_l4_field_flags */
 int  field_flags;
};

/* Update header manipulation low level driver resources */
struct dpa_cls_hm_update_resources {
 void *update_node;
```

```
 void *ip_frag_node;
};
```

Parameters

- **update_params** - egress update header manipulation parameters:
  - **op_flags** - flags defining the header manipulation operations to perform. They are a combination of the flags defined in the dpa_cls_hm_update_op_flags enum; only one flag from each group (e.g, update group, replace group, etc) can be selected; combine the values using the or logical operand;enum;
  - **replace** - parameters for header replace operations:
    - **new_ipv4_hdr** - IPv4 header data. This header can be used either for IPv4 field updates or for IPv6 to IPv4 header replace.
    - **new_ipv6_hdr** – IPv6 header data. This header can be used either for IPv6 field updates or for IPv4 to IPv6 header replace
  - **update** – parameters for protocol specific header update operations:
    - **l3** – L3 protocol field values. This data is used for L3 protocol header updates:
      - **ipsa** – new source IP address;
      - **ipda** – new destination IP address;
      - **tos_tc** – new TOS (for IPv4) or Traffic Class (for IPv6);
      - **initial_id** – initial IPv4 ID; this is used only if op_flags selected IPv4 update;
      - **field_flags** - a combination of flags designating the header fields to replace; the available options are defined in the `dpa_cls_hm_l3_field_flags` enum; combine the values using the or logical operand;
    - **l4** – L4 protocol field values. This data is used for L4 protocol header updates:
      - **sport** – new L4 source port value;
      - **dport** – new L4 destination port value;
      - **field_flags** - a combination of flags designating the header fields to replace; the available options are defined in the `dpa_cls_hm_l4_field_flags` enum; combine the values using the or logical operand;
  - **ip_frag_params** – IP fragmentation parameters. This is an optional operation and can be disabled if op_flags is not `DPA_CLS_HM_UPDATE_NONE`.

    NOTE

    There is currently a limitation when using IP fragmentation. IP fragmentation cannot be combined with other header manipulations, hence it can be used only as single update by setting the op_flags to DPA_CLS_HM_UPDATE_NONE.

  - **fm_pcd** – handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irelevant;
  - **reparse** - *TRUE* to force re-parsing of packet headers after this header update;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; `DPA_OFFLD_DESC_NONE` can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;

- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, he low level resources will be automatically allocated and managed by the DPA Classifier;

NOTE

When using external resource allocation it is the responsibility of the user to ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. There is no way for the DPA Classifier to verify the header manipulation parameters.

- **update_node** - handle to a header manipulation node with different header manipulations enabled, depending on the options selected in the parameters: local IPv4/IPv6 update header manipulation, a local TCP/UDP update header manipulation or an internal IP header replace. This is a FMan driver header manipulation node handle and it is optional (can be NULL in case no L3 or L4 field updates or header replace features are enabled for this flow);
- **ip_frag_node** - handle to the IP fragmentation node. This is a FMan driver header manipulation node handle and it is optional (can be NULL in case no IP fragmentation is enabled for this flow).

Description

Creates or imports an update type header manipulation object.

The updates performed by this type of header manipulation are protocol specific updates. The FMan is aware of the protocols being manipulated, hence the following checksums are also updated:

Table 255. Checksum updates

op_flags	Updated checksums
IPv4_UPDATE	IPv4 header checksum
UDP_TCP_UPDATE	TCP/UDP checksum only if it is not zero
IPv6_UPDATE	no checksums updated
REPLACE_IPv4_BY_IPv6	no checksums updated
REPLACE_IPv6_BY_IPv4	IPv4 header checksum

TCP/UDP checksum calculation can also be forced using the op_flags set to **UDP_TCP_UPDATE** and the L4 field_flags enabling **CALCULATE_CKSUM** option.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the `fm_pcd` handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when chain_head parameter is provided as true). When working in this mode the `fm_pcd` handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.1.6 Function: dpa_classif_set_vlan_hm

Syntax

```
int dpa_classif_set_vlan_hm(

};

struct dpa_cls_hm_ingress_vlan_params {
 enum dpa_cls_hm_vlan_count  num_tags;
};

/* VLAN specific header manipulation low level resources */
struct dpa_cls_hm_vlan_resources {
 void *vlan_node;
};
```

Parameters

- **vlan_params** - VLAN specific header manipulation parameters:
  - **type** - selects the type of the VLAN specific header manipulation: either “ingress” or “egress”; selected from `dpa_cls_hm_vlan_type` enum;
  - **ingress** - parameters for ingress VLAN header manipulations:
    - **num_tags** – number of VLAN tags to remove;

      NOTE

      Only the num_tags=none and num_tags=all are currently supported.
  - **egress** - parameters for egress VLAN header manipulations:
    - **update_op** – the type of desired VLAN tag update operation (if any); update operations are performed only on the outer most VLAN tag; selected from the `dpa_cls_hm_vlan_update_type` enum;
    - **num_tags** – number of VLAN tags to insert; if zero, no VLAN tags will be inserted in the packet and only update operations will be performed on existent VLAN tags; the combination num_tags=0 and update_op=none (nothing to do) doesn't make sense and it is rejected;
    - **qtag** – relevant only if num_tags is not zero; contains an array with the data of the VLAN tags to insert:
    - **update_params** – VLAN tag update parameters if an update_op was selected;
      - **vpri** – new VPri field value if update_op selects manual VPri update;
      - **dscp_to_vpri** – DSCP-to-VPri mapping table to use for VPri field update if update_op selects VPri update by mapping to DSCP;
  - **fm_pcd** - handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irrelevant;
  - **reparse** - *TRUE* to force re-parsing of packet headers after this VLAN header update;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; `DPA_OFFLD_DESC_NONE` can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;
- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;

NOTE

When using external resource allocation it is the responsibility of the user to ensure consistency between the header manipulation parameters provided here and those used when the resources were allocated. There is no way for the DPA Classifier to verify the header manipulation parameters.

- **vlan_node** - handle to a header manipulation node with different operations depending on the selected type of VLAN specific header manipulation. In case of VLAN ingress header manipulation this is a VLAN protocol specific removal node. In case of VLAN egress header manipulation this is a header manipulation node which may combine an internal header insert (in case there are VLANs to insert) with a protocol specific VLAN update operation. This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed.

Description

Creates or imports a VLAN specific header manipulation (either ingress or egress) object. VLAN header manipulations apply to both IPv4 as well as IPv6 frames. VLAN tags are added to the Ethernet frame header hence it will work with any type of L3 protocol (even different from IP).

Removal of VLAN tags is performed based on VLAN tag availability in the incoming packet. If the user configured to remove a specific number of VLAN tags and the incoming packets don't have that many VLAN tags, the FMan will remove as many tags as it finds up to the configured number of VLAN tags to remove. If the incoming packet is untagged, no action will be taken and the packet will remain unchanged. This is considered normal operation and no error or other notification will be issued in this case.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the `fm_pcd` handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn't allocate MURAM.

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when **chain_head** parameter is provided as true). When working in this mode the `fm_pcd` handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.1.7 Function: dpa_classif_set_mpls_hm

Syntax

```
int dpa_classif_set_mpls_hm(const struct dpa_cls_hm_mpls_params
*mpls_params, int next_hmd, int *hmd, bool chain_head,
const struct dpa_cls_hm_mpls_resources *res);

struct dpa_cls_hm_mpls_params {
 enum dpa_cls_hm_mpls_type  type;
 struct mpls_header  mpls_hdr[DPA_CLS_HM_MAX_MPLS_LABELS];
 unsigned int    num_labels;
 void      *fm_pcd;
 bool      reparse;
};
```

```
/*
 * Maximum number of MPLS labels supported by the insert header
 * manipulation
 */
#define DPA_CLS_HM_MAX_MPLS_LABELS    6

enum dpa_cls_hm_mpls_type {
 DPA_CLS_HM_MPLS_INSERT_LABELS,
 DPA_CLS_HM_MPLS_REMOVE_ALL_LABELS,
 DPA_CLS_HM_MPLS_LAST_ENTRY
};

/* MPLS specific header manipulation low level driver resources */
struct dpa_cls_hm_mpls_resources {
 void *ins_rm_node;
};
```

Parameters

- **mpls_params** - MPLS specific header manipulation parameters;
  - **type** - specifies the type of header manipulation; selected from dpa_cls_hm_mpls_type enum; the “remove all MPLS labels” operation type doesn’t need any other parameters;
  - **mpls_hdr** - the MPLS labels to insert if the operation type is “insert MPLS labels”;
  - **num_labels** - number of MPLS labels to insert; this is relevant only if the operation type is “insert MPLS labels”;
  - **fm_pcd** - handle to the low level driver PCD to use when creating the header manipulation object. This is necessary only when the header manipulation object is created. If the header manipulation low level driver resources are imported (i.e. res argument is provided), fm_pcd is irelevant;
  - **reparse** - *TRUE* to force reparsing of packet headers after this MPLS header update;
- **next_hmd** - descriptor of the next header manipulation object in chain; used only when creating a new header manipulation object; DPA_OFFLD_DESC_NONE can be provided as next HM if this header manipulation object is not chained to other header manipulation objects;
- **hmd** - the location where the function will return the descriptor of the current header manipulation object once it is created;
- **chain_head** - true if this header manipulation operation is the head of this header manipulations chain. This notifies the DPA classifier that the low level driver resources can be initialized for this header manipulations chain;
- **res** - optional low level driver resources in case the low level header manipulation infrastructure is allocated externally and should be only imported. If this pointer is NULL, the low level resources will be automatically allocated and managed by the DPA Classifier;
  - **ins_rm_node** - handle to the protocol specific header insert (MPLS) or to the protocol specific header removal (MPLS) node. This is a FMan driver header manipulation node handle and it is mandatory for the import to succeed.

Description

Creates or imports a MPLS specific header manipulation object.

If the res parameter is provided, the function will import the low level driver resources specified therein rather than create them. In this case the **fm_pcd** handle in the parameters structure is not used and can be provided as NULL. When working in this mode the function doesn’t allocate MURAM.

If the res parameter is not provided (i.e. is NULL) the function will create the low level resources which may result in MURAM allocation. Low level driver resources for the entire header manipulation chain are allocated only for the chain head (i.e. when chain_head parameter is provided as true). When working in this mode the **fm_pcd** handle in the parameters structure is necessary for the function to succeed.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.1.8 Function: dpa_classif_free_hm

Syntax

```
int dpa_classif_free_hm(int hmd);
```

Parameters

- **hmd** - descriptor of the header manipulation object to destroy.

Description

Releases a header manipulation object and frees up all related resources allocated for it. The header manipulation operations can be removed in any order. The low level driver resources are removed only when the chain head operation is removed.

The function fails if the header manipulation object is in use (i.e. if it is part of a header manipulation chain which is still attached to an existing DPA Classifier entry action descriptor).

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-EBUSY`, if the header manipulation operation is still in use, or if an FMan low level driver function call has failed.

9.9.3.2.2.1.2 Modify Operations at Runtime

Table 256. API to Modify Header Manipulation Operations at Runtime

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_modify_nat_hm`	Modify the parameters of an existing NAT header manipulation.	• new NAT header manipulation parameters; • flags indicating which parameters of the NAT header manipulation must be modified.	None.

Table continues on the next page...

Table 256. API to Modify Header Manipulation Operations at Runtime (continued)

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_modify_fwd_hm`	Modify the parameters of an existing forwarding type header manipulation.	• new forwarding header manipulation parameters; • flags indicating which parameters of the forwarding header manipulation must be modified.	None.
`dpa_classif_modify_remove_hm`	Modify the parameters of an existing remove type header manipulation.	• new remove header manipulation parameters; • flags indicating which parameters of the remove header manipulation must be modified.	None.
`dpa_classif_modify_insert_hm`	Modify the parameters of an existing insert header manipulation.	• new insert header manipulation parameters; • flags indicating which parameters of the insert header manipulation must be modified.	None.
`dpa_classif_modify_update_hm`	Modify the parameters of an existing update header manipulation.	• new update header manipulation parameters; • flags indicating which parameters of the update header manipulation must be modified.	None.
`dpa_classif_modify_vlan_hm`	Modify the parameters of an existing VLAN specific header manipulation.	• new VLAN specific header manipulation parameters; • flags indicating which parameters of the VLAN specific header manipulation must be modified.	None.
`dpa_classif_modify_mpls_hm`	Modify the parameters of an existing MPLS specific header manipulation.	• new MPLS specific header manipulation parameters; • flags indicating which parameters of the MPLS specific header manipulation must be modified.	None.

9.9.3.2.2.1.2.1 Function: dpa_classif_modify_nat_hm

Syntax

```
int dpa_classif_modify_nat_hm(int    hmd,
const struct dpa_cls_hm_nat_params  *new_nat_params,
int       modify_flags);

enum dpa_cls_hm_nat_modify_flags {
 DPA_CLS_HM_NAT_MOD_FLAGS   = 0x01,
 DPA_CLS_HM_NAT_MOD_SIP    = 0x02,
 DPA_CLS_HM_NAT_MOD_DIP    = 0x04,
 DPA_CLS_HM_NAT_MOD_SPORT   = 0x08,
 DPA_CLS_HM_NAT_MOD_DPORT   = 0x10,
 DPA_CLS_HM_NAT_MOD_IP_HDR   = 0x20
};
```

Parameters

- **hmd** - descriptor of the NAT header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not a NAT header manipulation, the function will fail;
- **new_nat_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the `new_nat_params` data structure are valid). Select the flag values from the `dpa_cls_hm_nat_modify_flags` enum and combine them using the "or" logical operand. There are some flag combinations which are illegal:
  - `DPA_CLS_HM_NAT_MOD_IP_HDR` cannot be used in combination with either of:
    1. `DPA_CLS_HM_NAT_MOD_SIP` or
    2. `DPA_CLS_HM_NAT_MOD_DIP`.

Description

Modify the parameters of an existing NAT header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.2 Function: dpa_classif_modify_fwd_hm

Syntax

```
int dpa_classif_modify_fwd_hm(int    hmd,
const struct dpa_cls_hm_fwd_params  *new_fwd_params,
int       modify_flags);

enum dpa_cls_hm_fwd_modify_flags {
 DPA_CLS_HM_FWD_MOD_ETH_MACSA   = 0x01,
 DPA_CLS_HM_FWD_MOD_ETH_MACDA   = 0x02,
 DPA_CLS_HM_FWD_MOD_PPPoE_HEADER  = 0x04,
 DPA_CLS_HM_FWD_MOD_PPP_PID   = 0x08,
```

```
 DPA_CLS_HM_FWD_MOD_IP_FRAG_MTU  = 0x10,
 DPA_CLS_HM_FWD_MOD_IP_FRAG_SCRATCH_BPID = 0x20,
 DPA_CLS_HM_FWD_MOD_IP_FRAG_DF_ACTION = 0x40
};
```

Parameters

- **hmd** - descriptor of the forwarding header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not a forwarding header manipulation, the function will fail;
- **new_fwd_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the `new_fwd_params` data structure are valid). Select the flag values from the `dpa_cls_hm_fwd_modify_flags` enum and combine them using the "or" logical operand. There are some flag combinations which are illegal:
  - `DPA_CLS_HM_FWD_MOD_PPP_PID` cannot be used in combination with either of:
    - `DPA_CLS_HM_FWD_MOD_ETH_MACSA`,
    - `DPA_CLS_HM_FWD_MOD_ETH_MACDA` or
    - `DPA_CLS_HM_FWD_MOD_PPPoE_HEADER`.

Description

Modify the parameters of an existing forwarding type header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.3 Function: dpa_classif_modify_remove_hm

Syntax

```
int dpa_classif_modify_remove_hm(int            hmd,
const struct dpa_cls_hm_remove_params    *new_remove_params,
int                          modify_flags);

enum dpa_cls_hm_remove_modify_flags {
    DPA_CLS_HM_RM_MOD_TYPE            = 0x01,
    DPA_CLS_HM_RM_MOD_CUSTOM_OFFSET    = 0x02,
    DPA_CLS_HM_RM_MOD_CUSTOM_SIZE        = 0x04
};
```

Parameters

- **hmd** - descriptor of the remove header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not a remove header manipulation, the function will fail;

- **new_remove_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the new_remove_params data structure are valid). Select the flag values from the dpa_cls_hm_remove_modify_flags enum and combine them using the "or" logical operand.

Description

Modify the parameters of an existing remove type header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.4 Function: dpa_classif_modify_insert_hm

Syntax

```
int dpa_classif_modify_insert_hm(int            hmd,
const struct dpa_cls_hm_insert_params    *new_insert_params,
int                           modify_flags);

enum dpa_cls_hm_insert_modify_flags {
    /* Ethernet and PPPoE insert group */
    DPA_CLS_HM_INS_MOD_ETH_HEADER        = 0x01,
    DPA_CLS_HM_INS_MOD_QTAGS_ARRAY    = 0x02,
    DPA_CLS_HM_INS_MOD_PPPoE_HEADER    = 0x04,

    /* PPP insert group */
    DPA_CLS_HM_INS_MOD_PPP_PID        = 0x08,

    /* Custom insert group */
    DPA_CLS_HM_INS_MOD_CUSTOM_OFFSET    = 0x10,
    DPA_CLS_HM_INS_MOD_CUSTOM_DATA    = 0x20
};
```

Parameters

- **hmd** - descriptor of the insert header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not an insert header manipulation, the function will fail;
- **new_insert_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the new_insert_params data structure are valid). Select the flag values from the `dpa_cls_hm_insert_modify_flags` enum and combine them using the "or" ogical operand. The user can only combine flags from a single group (either only Ethernet and PPPoE insert group flags or PPP insert group flags, and so on).

Description

Modify the parameters of an existing insert header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.5 Function: dpa_classif_modify_update_hm

Syntax

```
int dpa_classif_modify_update_hm(int            hmd,
const struct dpa_cls_hm_update_params    *new_update_params,
int                          modify_flags);

enum dpa_cls_hm_update_modify_flags {
    DPA_CLS_HM_UPDATE_MOD_IPHDR            = 0x0001,

    /* L3 protocol flags group */
DPA_CLS_HM_UPDATE_MOD_SIP            = 0x0002,
    DPA_CLS_HM_UPDATE_MOD_DIP            = 0x0004,
    DPA_CLS_HM_UPDATE_MOD_TOS_TC            = 0x0008,
    DPA_CLS_HM_UPDATE_MOD_IP_ID            = 0x0010,
    DPA_CLS_HM_UPDATE_MOD_L3_FLAGS        = 0x0020,

    /* L4 protocol flags group */
    DPA_CLS_HM_UPDATE_MOD_SPORT            = 0x0040,
    DPA_CLS_HM_UPDATE_MOD_DPORT            = 0x0080,
    DPA_CLS_HM_UPDATE_MOD_L4_FLAGS        = 0x0100,

    DPA_CLS_HM_UPDATE_MOD_IP_FRAG_MTU        = 0x0200,
    DPA_CLS_HM_UPDATE_MOD_IP_FRAG_SCRATCH_BPID = 0x0400,
    DPA_CLS_HM_UPDATE_MOD_IP_FRAG_DF_ACTION    = 0x0800
};
```

Parameters

- **hmd** - descriptor of the update header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not an update header manipulation, the function will fail;
- **new_update_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the new_update_params data structure are valid). Select the flag values from the `dpa_cls_hm_update_modify_flags` enum and combine them using the "or" logical operand. Avoid combinations between flags from the L3 protocol group with flags from the L4 protocol group.

Description

Modify the parameters of an existing update header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;

- -EBUSY, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.6 Function: dpa_classif_modify_vlan_hm

Syntax

```
int dpa_classif_modify_vlan_hm(int                hmd,
const struct dpa_cls_hm_vlan_params        *new_vlan_params,
int                           modify_flags);

enum dpa_cls_hm_vlan_modify_flags {
    DPA_CLS_HM_VLAN_MOD_INGRESS_NUM_QTAGS    = 0x01,

    DPA_CLS_HM_VLAN_MOD_EGRESS_QTAGS    = 0x02,
    DPA_CLS_HM_VLAN_MOD_EGRESS_UPDATE_OP    = 0x04,
    DPA_CLS_HM_VLAN_MOD_EGRESS_VPRI        = 0x08,
    DPA_CLS_HM_VLAN_MOD_EGRESS_DSCP_TO_VPRI_ARRAY = 0x10
};
```

Parameters

- **hmd** - descriptor of the VLAN specific header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not a VLAN specific header manipulation, the function will fail;
- **new_vlan_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the new_vlan_params data structure are valid). Select the flag values from the dpa_cls_hm_vlan_modify_flags enum and combine them using the "or" logical operand. The flag DPA_CLS_HM_VLAN_MOD_INGRESS_NUM_QTAGS cannot be combined with any other flags.

Description

Modify the parameters of an existing VLAN specific header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- -EINVAL, if there are errors in the parameters provided to the function;
- -ENOMEM, if dynamic memory allocations have failed;
- -EBUSY, if an FMan low level driver function call has failed.

9.9.3.2.2.1.2.7 Function: dpa_classif_modify_mpls_hm

Syntax

```
int dpa_classif_modify_mpls_hm(int    hmd,
const struct dpa_cls_hm_mpls_params  *new_mpls_params,
int       modify_flags);

enum dpa_cls_hm_mpls_modify_flags {
 DPA_CLS_HM_MPLS_MOD_NUM_LABELS = 0x01,
 DPA_CLS_HM_MPLS_MOD_HDR_ARRAY  = 0x02,
```

```
};
```

Parameters

- **hmd** - descriptor of the MPLS specific header manipulation object to modify parameters for; if the header manipulation designated by this descriptor is not a MPLS specific header manipulation, the function will fail;
- **new_mpls_params** - data structure containing the header manipulation attributes to modify;
- **modify_flags** - combination of flags indicating which header manipulation attributes to modify (and hence indicating which of the attributes in the `new_mpls_params` data structure are valid). Select the flag values from the `dpa_cls_hm_mpls_modify_flags` enum and combine them using the or logical operand.

Description

Modify the parameters of an existing MPLS specific header manipulation.

Return Value

Zero if successful or a negative error code otherwise. The returned error codes are the following:

- `-EINVAL`, if there are errors in the parameters provided to the function;
- `-ENOMEM`, if dynamic memory allocations have failed;
- `-EBUSY`, if an FMan low level driver function call has failed.

9.9.3.2.3 Multicast

The multicast module allows creation and management of specific entries into the classifier tables, entries identified as **multicast groups**. A group has **at least one member** identified as an enqueue action. The user can define a maximum number of members inside a group. Members can also have header manipulation chains attached. Header manipulations on any member, except the last member, **must not change the frame's header protocol stack and size**. No such limitation exists on the last member from a group. A virtual storage profile Id can also be set on each member of a group.

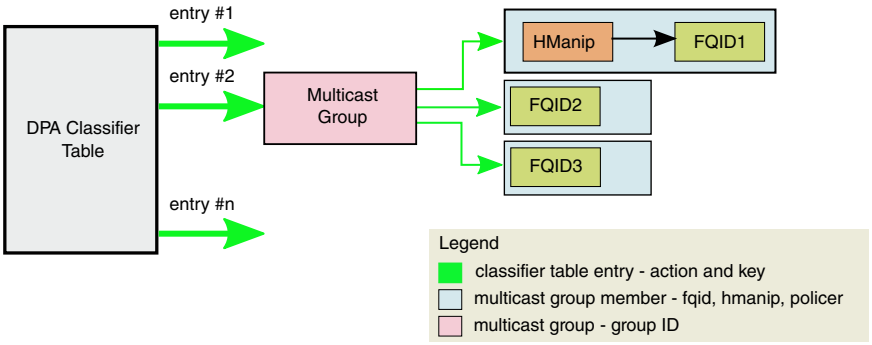

Figure 254. Multicast example

After creating a multicast group, new members can be added by filing the `membr_params`. The newly created member is identified by the `md` descriptor. Up to 64 members can be added in a group. Another step after creating a group is to create an entry of type multicast in a classification table. When calling `dpa_classif_table_insert_entry` the group descriptor (`grpd`) will be provided as input parameter for the new entry. If an entry of type multicast is no longer needed it can be removed using the `entry_id` or the call `dpa_classif_table_delete_entry_by_key` (the entry is identified by key). Members of the multicast group can be individually removed by calling `dpa_classif_mcast_remove_member`. The group can be removed by calling `dpa_classif_mcast_free_group`.

9.9.3.2.3.1 Multicast API

There are two selections for the DPA Multicast API:

9.9.3.2.3.1.1 Create and Remove Multicast Groups

Table 257. API to Create and Remove Multicast Groups

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_mcast_create_group`	Creates a multicast group with one initial member. If external group handle is given the function imports an existing group from preallocated resources	• max number of members in multicast group; • handle of the PCD needed to create the group • enqueue parameters of the initial member. • prefilled members – number of members in the imported group.	Descriptor of the newly created multicast group.
`dpa_classif_mcast_free_group`	Removes an existing group.	• group descriptor identifying the multicast group to remove.	None.

9.9.3.2.3.1.1.1 Function: dpa_classif_mcast_create_group

Syntax

```
int dpa_classif_mcast_group_create(struct dpa_cls_mcast_group_params
       *mcast_group_params, int *grpd);

/* Multicast group parameters */
struct dpa_cls_mcast_group_params {
 uint8_t     max_members;
 void      *fm_pcd;
 struct dpa_cls_tbl_enq_action_desc first_member_params;
unsigned int    prefilled_members;
void      *group;
void      *distribution;

};
```

Parameters

- **mcast_group_params** - group parameters
  - **max_members** - maximum number of members in group.
  - **fm_pcd** - handle of the PCD needed when creating a group.
  - **member_params** – enqueue parameters for the member (fqid, policer, header manipulation descriptor, storage profile id).
    - **override_fqid** – nonzero if the action descriptor corresponding to the member is of type new classification result and zero if the action descriptor is of type keep classification result;

- **new_fqid** – if override_fqid is nonzero, this holds the explicit frame queue Id where to place the frame;
- **policer_params** – policing parameters; if NULL, no policing is performed during the enqueue operation.
  - **modify_policer_params** – nonzero if the default policer parameters will be overridden;
  - **shared_profile** - nonzero if this policer profile is shared between ports; relevant only if modify_policer_params is nonzero;
  - **new_rel_profile_id** - this parameter should indicate the policer profile offset within the port's policer profiles or from the SHARED window; relevant only if modify_policer_params is nonzero;
- **hmd** – header manipulation object descriptor, or -1 if no header manipulation is required for the enqueue action; the header manipulation object defined by the provided descriptor must be a header manipulation chain head;
- **spid** – storage profile id. This parameter will specify the storage profile, in order to allocate new external buffers for the frame descriptor received on the member.

- **prefilled_members** – Number of members that already exist in the imported group.
- **group** – External group handle given as input parameter for an import operation.
- **distribution** – External distribution handle. When provided, replicated frames are not enqueued to members' frame queues. They are sent to this distribution.

- **grpd** - Address of an integer variable in which the function will return the group descriptor. This value will be used in other function calls, to identify the group on which operations will be performed.

Description

This function creates or imports a multicast group. The new group is identified by the group descriptor - **grpd**. It can be assigned to a new entry in the classification table using the function `dpa_classif_table_insert_entry`, which will have the type `DPA_CLS_TBL_ACTION_MCAST` for action parameter. If external group handle is provided, preallocated resources will be used – and the existing group will be used to add new members to it. Prefilled members will specify the number of existing members in the imported group.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- `-EINVAL`, if `mcast_group_params` parameter is NULL;
- `-EINVAL`, if `grpd parameter` is NULL;
- `-EINVAL`, if `max_member` is 0 or has a value greater than maximum number of supported members (64);
- `-EINVAL`, if invalid header manip descriptor (`hmd`) for the member defined in the new group. (A new group has at least one member);
- `-EINVAL`, if header manipulation descriptor of the member (`hmd`) is not a chain head;
- `-EINVAL`, if the group could not be created when low level function was invoked;
- `-ENOMEM`, if no more memory for the new multicast group;
- `-ENOMEM`, if no more memory for descriptor table when allocating descriptor for the new group;
- `-ENOMEM`, if no more memory for the member index array used to assign member ids;
- `-ENOSYS`, if policing params were provided for the first group member.

9.9.3.2.3.1.1.2 Function: dpa_classif_mcast_free_group

Syntax

```
int dpa_classif_mcast_free_group(int grpd);
```

Parameters

- **grpd** - Multicast group descriptor. This value identifies a group that was created before this function call.

Description

This function removes an existing group identified by the **grpd** parameter.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- `-EINVAL`, if Invalid group descriptor grpd provided to the function;
- `-EINVAL`, if the group could not be removed when low level function was invoked.

9.9.3.2.3.1.2 Add and Remove Multicast Group Members

Table 258. API to Add and Remove Multicast Group Members

Function Name	Description	Input Parameters	Output Parameters
`dpa_classif_mcast_add_member`	Adds a new member to an existing group	• group descriptor • enqueue parameters of the new member (fqid, policer, header manip desc, spid)	Descriptor of the newly created member.
`dpa_classif_mcast_remove_member`	Removes an existing member from an existing group. The member is identified by its member descriptor.	• group descriptor • member descriptor identifying the member to be removed from the group.	None.

9.9.3.2.3.1.2.1 Function: dpa_classif_mcast_add_member

Syntax

```
int dpa_classif_mcast_add_member(int grpd,
                   struct dpa_cls_tbl_enq_action_desc member_params, int *md);
```

Parameters

- **grpd** - Multicast group descriptor. This value identifies a group that was created before this function call.
- **member_params** - enqueue parameters for the member (fqid, policer, header manipulation descriptor, storage profile.
  - **override_fqid** – nonzero if the action descriptor corresponding to the member is of type new classification result and zero if the action descriptor is of type keep classification result;
  - **new_fqid** – if override_fqid is nonzero, this holds the explicit frame queue Id where to place the frame;

- **policer_params** – policing parameters; if NULL, no policing is performed during the enqueue operation.
  - **modify_policer_params** – nonzero if the default policer parameters will be overridden;
  - **shared_profile** - nonzero if this policer profile is shared between ports; relevant only if modify_policer_params is nonzero;
  - **new_rel_profile_id** - this parameter should indicate the policer profile offset within the port's policer profiles or from the SHARED window; relevant only if modify_policer_params is nonzero;
- **hmd** – header manipulation object descriptor, or -1 if no header manipulation is required for the enqueue action; the header manipulation object defined by the provided descriptor must be a header manipulation chain head;
- **spid** – storage profile id. This parameter will specify the storage profile, in order to allocate new external buffers for the frame descriptor received on the member.
- **md** - Address of an integer variable in which the function will return the member descriptor. This is a reference to an internal index updated by the FMD driver when a member is added or removed from the group.

Description

This function adds a new member to an existing group identified by the **grpd** parameter. The new created member will be identified by the member descriptor md.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- `-EINVAL`, if an invalid group descriptor (grpd) was provided to the function;
- `-EINVAL`, if `member_params` parameter is NULL;
- `-EINVAL`, if `md` is NULL;
- `-EINVAL`, if invalid header manip descriptor (`hmd`) for the new member;
- `-EINVAL`, if header manipulation descriptor (`hmd`) of the member is not a chain head;
- `-EINVAL`, if the multicast member could not be added when low level function was invoked;
- `-ENOSPC`, if the current number of members reached maximum value max_members (defined when the group was created);
- `-ENOSYS`, if policing params were provided.

9.9.3.2.3.1.2.2 Function: dpa_classif_mcast_remove_member

Syntax

```
int dpa_classif_mcast_remove_member(int grpd, int md);
```

Parameters

- **grpd** - Multicast group descriptor. This value identifies a group that was created before this function call.
- **md** - member descriptor which identifies the member inside a group

Description

This function removes an existing member from a group identified by the **grpd** parameter. The member is identified by member descriptor.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- `-EINVAL`, if an invalid group descriptor (`grpd`) was provided to the function;
- `-EINVAL`, if an invalid member descriptor `md` (value is negative or greater than `max_members`) was provided to the function;
- `-EINVAL`, if the multicast member could not be removed when low level function was invoked.

9.9.3.3 DPA IPSec

The DPA IPSec module exports a set of functions which can be used to:

- initialize the DPA IPSec module internal data structures;
- create and configure full inbound IPSec hardware accelerated paths;
- create and configure full outbound IPSec hardware accelerated paths;
- replace expired SAs (after rekeying) without packet loss.

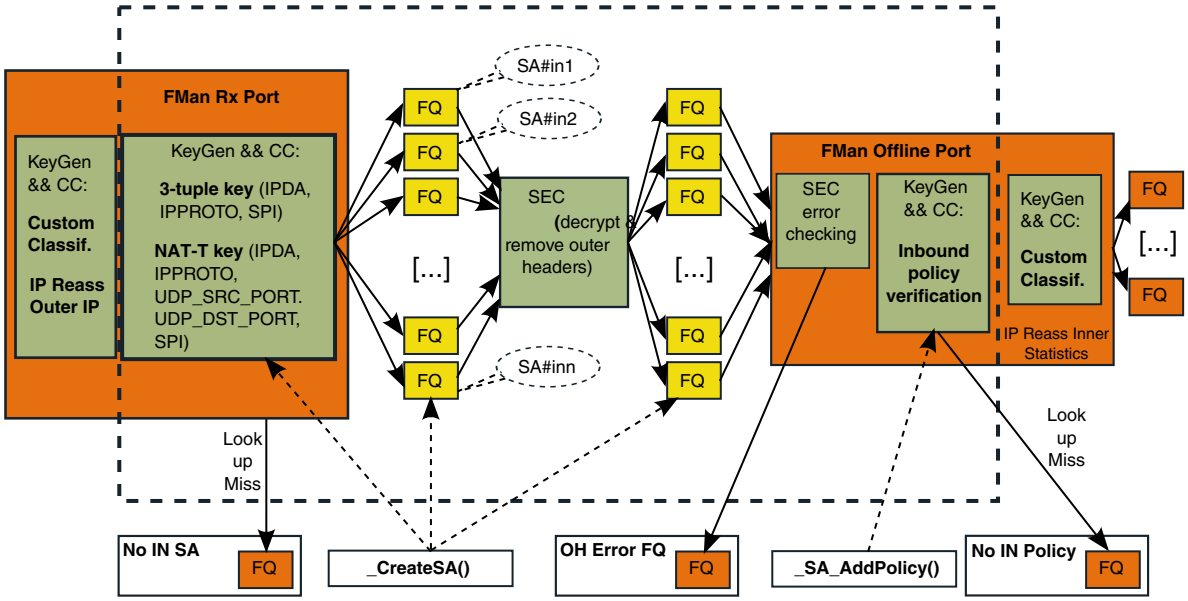

Figure 255. DPA IPSec inbound path architecture overview

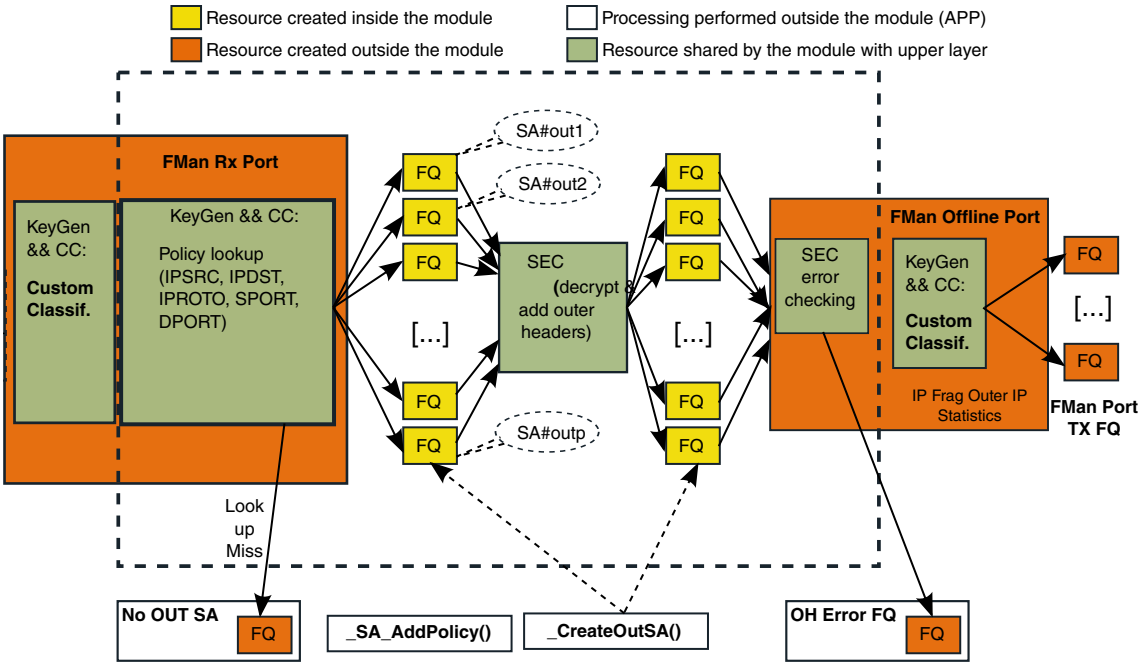

Figure 256. DPA IPSec outbound path architecture overview

After the accelerated paths for the inbound (figure above) and the outbound (figure above) are configured, the calling application can send and receive IPSec protected packets just by enqueuing and dequeueing frames. Although, from the calling applications perspective, all paths (inbound or outbound) are configured using similar function calls, the implementation of these hardware accelerated paths differs substantially. The DPA IPSec API is responsible for hiding these implementation details.

9.9.3.3.1 Initialization

Inbound path creation

Initialization is a mandatory step for enabling IPSec offloading. The initialization functions are designed to create and initialize the internal data structures of the module, which will later be used as a base for creating inbound or outbound accelerated IPSec processing paths. These configuration tasks are performed only once and are meant to enable the required hardware blocks, apply an initial configuration and initialize features that do not require dynamic configuration.

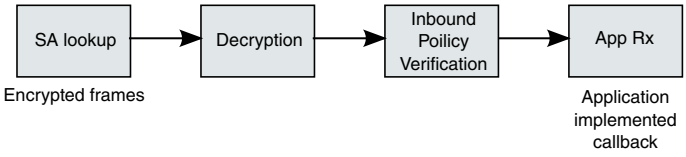

Figure 257. Inbound processing decomposition

Creating an inbound accelerated IPSec path means configuring the hardware blocks to classify the encrypted packets, decapsulate and decrypt them, perform required policy checks on the decrypted packet (as stated in the RFCs) and finally deliver the resulting packet to the calling application. The hardware blocks that process the packets before and after decryption and decapsulation, can also be configured to perform IP reassembly. Before decryption IP reassembly acts on the encrypted packets, while after decryption it acts on the inner, decrypted packets.

Because IP reassembly can (presently) only be enabled on a per port basis in FMan, it is beyond the scope of the DPA IPSec API to provide a means to configure and enable this feature. It is the responsibility of the upper layer applications to enable and configure IP reassembly when it initializes the PCD skeleton.

Outbound path creation

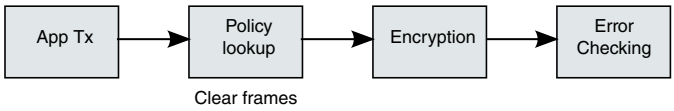

Figure 258. Outbound processing decomposition

An accelerated outbound IPSec path is supposed to use the hardware blocks to speed up the processing of an IP packet from the point where it is delivered for IPSec processing by the calling application and till a correct IPSec encapsulated packet has been constructed. Different hardware blocks have to be configured to classify the supplied packet and identify the correct outbound SA, encrypt and encapsulate the packet and finally check for errors and deliver the packet to an offline port. The calling application must implement on this offline port the classification needed to forward the packet. This processing is outside the scope of the DPA IPSec module.

9.9.3.3.2 DPA IPSec API

There are several selections for the DPA IPSec API:

9.9.3.3.2.1 IPSec Engine Startup and Shutdown

Table 259. API for IPSec Engine Startup and Shutdown

Function Name	Description
dpa_ipsec_init	The model's layout is fixed so most of the required configuration parameters are held internally. The function builds the necessary infrastructure for managing future runtime operations.
dpa_ipsec_free	Releases all the resources allocated previously by this module and also the managed (run-time added) ones.

9.9.3.3.2.1.1 Function: dpa_ipsec_init

Syntax

```
int dpa_ipsec_init(const struct dpa_ipsec_params *params,
    int *dpa_ipsec_id);

#define DPA_IPSEC_KEY_FIELD_SIP  0x01
#define DPA_IPSEC_KEY_FIELD_DIP  0x02
#define DPA_IPSEC_KEY_FIELD_PROTO  0x04
#define DPA_IPSEC_KEY_FIELD_DSCP  0x08
#define DPA_IPSEC_KEY_FIELD_SPORT  0x10
#define DPA_IPSEC_KEY_FIELD_ICMP_TYPE 0x10
#define DPA_IPSEC_KEY_FIELD_DPORT  0x20
#define DPA_IPSEC_KEY_FIELD_ICMP_CODE 0x20

enum dpa_ipsec_proto {
 DPA_IPSEC_PROTO_TCP_IPV4 = 0,
DPA_IPSEC_PROTO_TCP_IPV6,
 DPA_IPSEC_PROTO_UDP_IPV4,
 DPA_IPSEC_PROTO_UDP_IPV6,

 uint16_t       qm_sec_ch;
unsigned int   max_sa_pairs;
      struct dpa_ipsec_fqid_range  *fqid_range;
      unsigned int   max_sa_manip_ops;
};
```

Parameters

- **params** - structure containg all the parameters required for initializing a DPA IPSec instance:
  - **pre_sec_in_params** – structure containing the parameters required to configure and initialize the inbound SA lookup block:
    - **dpa_cls_td[..]** – array of descriptors for DPA Classifier tables, indexed by SA type (i.e. IPv4, IPv4 with NAT-T support, IPv6 – `dpa_ipsec_sa_type` enum), which will be used for identifying the SA that should process an incoming frame; the mechanisms used by the DPA IPSec instance to choose the table in which a policy will be inserted.
    - **gw_change_en** – enable the remote gateway address change detection mechanism (currently not supported)
  - **post_sec_in_params** - structure containing the parameters required to configure and initialize the inbound policy verification block:
    - **data_off** – the data offset that will be configured in the frame descriptor of all decrypted frames; configured using the dpa_ipsec_data_off enum; please refer to function description for details;
    - **tx_ch** – the qman channel id associated to the post decryption offline port
    - **dpa_cls_td** - the DPA IPSec module expects to receive from the upper layer a table descriptor for a DPA Classifier Indexed Table object which it will use to determine on which SA a frame was decrypted; it is mandatory that the table descriptor provided here is that of an indexed table
    - **do_pol_check** – enable the inbound policy verification
    - **key_fields** – the policy key structure (which fields of the policy parameters structure should be included in the policy key); relevant only if do_pol_check is TRUE; configured using the DPA_IPSEC_KEY_FIELD_* macros;
    - **use_ipv6_pol** - activate support for IPv6 policies. Allows better MURAM management. Relevant only if do_pol_check = TRUE.
    - **base_flow_id** – the base value from which inbound SA flow ID values can be allocated incrementally;
  - **pre_sec_out_params** - structure containing the parameters required to configure and initialize the outbound policy lookup block:
    - **table[..]** – array of structures defining the parameters for the DPA Classifier tables that will be used for offloading policy lookup; this array is indexed by policy protocol type and IP header version (dpa_ipsec_proto enum); the mechanisms used by the DPA IPSec instance to choose the table in which a policy will be inserted:
    - **dpa_cls_td** – table descriptors for DPA Classifier Exact Match Table objects, which will be used to determine which SA should be used for encrypting the frame;
    - **key_fields** – defines the policy key structure (which fields of the policy parameters structure should be included in the key) used in the table identified by the `dpa_cls_td` parameter; configured using the DPA_IPSEC_KEY_FIELD_* macros;
  - **post_sec_out_params** - structure containing the parameters required to configure and initialize the outbound error checking block:
    - **data_off** – the data offset that will be configured in the frame descriptor of all encrypted frames; configured using the `dpa_ipsec_data_off` enum; please refer to function description for details;
    - **tx_ch** – the qman channel id associated to the post encryption offline port;

- **fm_pcd** - handle to the low level driver PCD
- **qm_sec_ch** – the qman channel id associated to the SEC;
- **max_sa_pairs** – the maximum number of SAs pairs supported by the DPA IPSec module;
- **fqid_range** – pointer to a structure defining the boundaries of a FQID range from which the DPA IPSec instance should allocate fqids for the frame queues it creates internally; if this parameter is NULL, then the DPA IPSec instance will try to acquire fqids using the default allocation mechanism;
- **max_sa_manip_ops** – maximum number of manipulation objects (used for variable IP header length support or DSCP / ECN propagation support) to be preallocated at initialization; this value should be incremented with the number of header manipulations per every outbound policy; if 0, the required manipulation objects will be allocated at runtime;

- **dpa_ipsec_id** - upon successful initialization, this parameter will contain the identifier of this DPA IPSec instance; this identifier must be passed to all the other runtime functions when they are called (currently not supported).

Description

This function is used to initialize a DPA IPSec instance. When this function exits all the required internal structures of the DPA IPSec instance will be initialize and the other API functions can be used to configure offloading for outbound and inbound IPSec flows.

Some of the parameters of this function are handles to DPA Classifier Table objects. These tables must be initialized before this function is called.

The DPA IPSec instance expects to receive from the upper layer one or more table descriptors for DPA Classifier Table objects which it will use to perform SA lookup. Usually a hash table is used for this purpose, because it supports a large number of entries, but an exact match table can also be used.

If not all the tables for SA lookup are necessary (e.g. no IPv6 or NAT-T support is required), then the upper layer can pass invalid descriptors for the tables that will not be used, thus saving resources.

If more than one classifier table is used for SA lookup, the `max_sa_pairs` field will represent the sum of all the SAs that can be classified on the inbound path using all of the tables identified by valid descriptors (see the fields of the `pre_sec_in_params`structure)

If DPA Classifier Hash Tables are used for SA lookup (this is recommended), the value of the `max_sa_pairs` field should be smaller than the sum of the maximum number of entries supported by each hash table (`dpa_cls_td_*`in the `pre_sec_in_params`), because a hash table does not offer a uniform distribution of entries in its buckets. Also, the size of the indexed table in the `post_sec_in_params` structure must be greater or equal to the value of `max_sa_pairs field`.

The order in which the fields of the policy parameters structure should be place in the key is given by the values of the key fields identifiers (the `DPA_IPSEC_KEY_FIELD_*` macros) used for configuring the key structure in the key_fields members of the `pre_sec_out_params` and `post_sec_in_params` structures. The field the lowest identifier value is the first in the key and the field whith the highest identifier value is the last in the key.

The data_off is important to be configured correctly, especially when further processing of the encrypted / decrypted frames is expected to take place. Some of the modules, that will process the frames after they have been encrypted / decrypted by the SEC, require that extra space be available in the data buffers, in front of the actual data (e.g. IP Frag., IP Reass.).

The SEC can be configured not to place the output data at the beginning of the output buffer, but it restricts the values of the offset to be used. The data_off parameter is represented as a multiple of the SEC burst size, the maximum burst size used by the SEC when performing memory accesses. The SEC burst size can be either 32 or 64 bytes and it is controlled by a bit in the SEC control register. The default value for the SEC burst size is 64 bytes. Based on this, the following guidelines must be considered when configuring the `data_off` parameter:

- if classification is to be performed on the frames, after the SEC finishes encrypting / decrypting them a minimum offset of 64 bytes must be configured;
- if IP fragmentation / reassembly is to be performed on the frames, after the SEC finishes encrypting / decrypting them, an offset of 192 bytes should be configured;

- in any other situation an offset of 0 should be configured or a value consistent with the requirements of other applications / modules that are known to process the frames after SEC.

The value of the `base_flow_id` is important to be set correctly when the post decryption offline port is also used to perform other classifications based on flow ID. In these cases, it is recommended that a range of values for flow ID be reserved for all other classifications not related to IPSec, starting from flow ID value 0 and the `base_flow_id` to be equal to the number of flow ID values in that range. In all other cases the value of this field should be 0.

If the gw_change_en field value is FALSE, the remote gateway address change detection mechanism will be disabled. If the value is TRUE, this mechanism will be enabled and the calling application will be notified if an event of this type occurs through the special callback provided at SA creation time. If not callback is provided and such an event occurs, the frame that generated this event will be processed according to the miss action of the inbound SA lookup table.

The max_sa_manip_ops field can be used to preallocate a number of manipulation objects that will be used later (when an SA is offloaded) for the variable IP header length, variable IP version and DSCP / ECN propagation features and thus eliminate the need to allocate MURAM memory at runtime. The preallocated objects are placed in an internally managed pool and the implementation will extract objects from this pool whenever a SA that requires one is offloaded and put an object back into the pool whenever a SA that uses one is removed.

When calculating the value of this field the following aspects should be taken into consideration:

- for each outbound policy with header manipulation enabled one such manipulation object is required;
- for each inbound SA with or without the DSCP / ECN propagation or IP header length or variable IP version feature enabled one such manipulation object is required;
- for each inbound SA with the varianle IP header length feature enabled one such manipulation objet is required;
- for an inbound SA that has enabled both the DSCP / ECN propagation and the variable IP header length features only one manipulation object is required.

If the value of this field is 0 and one of those features is enabled, the IPSec implementation will allocate the required manipulation objects at runtime.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- `-EPERM`, , if a DPA IPSec instance is already initialized (multiple DPA IPSec instances are not supported yet) or the circular queue for inbound flow ID management could not be initialized;
- `-EINVAL`, if invalid function arguments or DPA IPSec initialization parameters were provided;
- `-ENOMEM`, if memory could not be allocated for one of the internal structures;
- `-ENOMEM`, if the internal ID management queues could not be initialized;
- `-EFAULT`, if a bad argument was passed to a internal function;
- `-EDOM`, if the size of the internal ID management queues was exceeded while trying to populate them;
- `-EBUSY`, , if the creation of the CCNodes required for inbound policy verification has failed (as a result of an error in FMD function call);
- all the error codes returned by the `dpa_classifier_create_table` function, which is used for creating tables for inbound policy verification;
- `-ENOSPC`, if the deferred work workqueue used in the rekeying process could not be initialized.

9.9.3.3.2.1.2 Function: dpa_ipsec_free

Syntax

```
int dpa_ipsec_free(int dpa_ipsec_id);
```

Parameters

- **dpa_ipsec_id** - identifier of the DPA IPSec instance that should be freed - (currently not supported).

Description

Releases all the resources allocated previously for this instance of the DPA IPsec API.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- all the error codes returned by the `dpa_ipsec_flush_all_sa function`.

9.9.3.3.2.2 Create, Remove and Manage SAs

Table 260. API for Creating, Removing and Managing SAs

Function Name	Description
`dpa_ipsec_create_sa`	Prepares the accelerated path for IPSec flows that will use this SA to encrypt or decrypt packets. Specific packets will be directed through this flow using policies (outbound) or specific SA selectors (inbound)
`dpa_ipsec_remove_sa`	Releases resources used by an SA.
`dpa_ipsec_flush_all_sa`	Removes all offloaded SAs from the DPA IPsec module
`dpa_ipsec_disable_sa`	Disables an SA before removal. No other packets will be processed using this SA. Resources associated to this SA will not be freed.
`dpa_ipsec_sa_modify`	Modifies all or just a part of the parameters of a previously offloaded SA.
`dpa_ipsec_sa_get_stats`	Returns statistics for a specified SA.
`dpa_ipsec_get_sa_context`	Retrieves information about a SA based on the packet that was processed by that SA.
`dpa_ipsec_sa_get_out_path`	Retrieves information which can be used to apply IPSec processing to a packet without performing the outbound policy lookup.

9.9.3.3.2.2.1 Function: dpa_ipsec_create_sa

Syntax

```
int dpa_ipsec_create_sa(int dpa_ipsec_id,
struct dpa_ipsec_sa_params *sa_params,
int *sa_id);

#define DPA_IPSEC_HDR_COPY_TOS 0x01
#define DPA_IPSEC_HDR_COPY_DF  0x02
#define DPA_IPSEC_HDR_DEC_TTL  0x04
#define DPA_IPSEC_HDR_COPY_DSCP 0x08
#define DPA_IPSEC_HDR_COPY_ECN 0x10

enum dpa_ipsec_direction {

        struct dpa_ipsec_sa_out_params sa_out_params;
    };
};
```

Parameters

- **dpa_ipsec_id** - identifier of the DPA IPSec instance - (**currently not supported**)
- **sa_params** - structure holding the parameters for this SA:
  - **spi** – the IPSec security parameter index for this SA
  - **use_ext_seq_num** – specify whether extended sequence numbers should be used
  - **start_seq_num** – the current sequence number for this SA; this value will be automatically be incremented for each packet processed using this SA
  - **l2_hdr_size** – the size of the Ethernet header, including any VLAN information
  - **sa_mode** – transport or tunnel mode; configured using `dpa_ipsec_sa_mode enum` - (currently not supported)
  - **sa_proto** – IPSec protocol used for protecting data (ESP or AH); configured using `dpa_ipsec_sa_proto enum` - (currently not supported)
  - **hdr_upd_flags** – a set of flags describing what header fields should be propagated from the inner header to the outer header and vice versa; these flags can be used to control the copying of the entire TOS field or the DSCP bits or the ECN bits from inner to outer header and vice versa, the copying of the DF bit (only) from the inner header to the outer header and the automatic update (decrement) of the TTL in the outer / inner header; configured using the `DPA_IPSEC_HDR_*` macros;
  - **sa_wqid** - work queue ID for all the queues of this SA
  - **sa_bpid** – the buffer pool from which the SEC should acquire buffers for encrypted / decrypted frames
  - **sa_bufsize** – SEC output frames buffer pool buffer size
  - **enable_stats** – enable support for gathering traffic statistics on this SA
  - **enable_extended_stats** - enable input traffic (extended) statistics on this SA. If *enable_stats* is set to *false*, this setting is ignored.
  - **crypto_params** – protection used by this SA
    - **alg_suite** – identifier for the encryption and authentication algoritms used by this SA; configured using the `dpa_ipsec_cipher_alg enum`;
    - **cipher_key** – address of the IPSec cipher key
    - **cipher_key_len** - length in bytes of the cipher key
    - **auth_key** – address of the IPSec authentication key
    - **auth_key_len** – length in bytes of the authentication key
  - **sa_dir** – SA type (inbound / outbound); configured using the `dpa_ipsec_direction` enum;

- **sa_in_params** – parameters specific for inbound SAs:
  - **arw** - type of anti replay protection requested; configured using the `dpa_ipsec_arw` enum;
  - **use_var_iphdr_len** – enable support for variable IP header length
  - **src_addr** – source IP address in the outer header
  - **dest_addr** – destination IP address in the outer header
  - **use_udp_encap** – specify whether this is a NAT-T SA;
  - **src_port** – source udp port value in the UDP encapsulation header; relevant only if useUdpEncap is true
  - **dest_port** – destination udp port value in the UDP encapsulation header; relevant only if useUdpEncap is true
  - **policy_miss_action** – action descriptor specyfing the action that will be performed for frames that fail inbound policy verification; relevant only if inbound policy verification is enabled;
  - **post_ipsec_action** – action descriptor specifying the default action for frames that have passed inbound policy verification; if inbound policy verification is disabled this is the default action for decrypted frames on this SA
  - **gw_change_cb** – pointer to a callback used by the DPA IPSec module to signal to the upper layer that a remote gateway change event has occurred on this SA - (currently not supported)
- **sa_out_params** – parameters specific for outbound SAs:
  - **init_vector** – address of the initialization vector to be used; if this parameter is NULL the internal random number generator of the SEC will be used to generate an IV
  - **ip_ver** – type of addresses in the outer header (IPv4 or IPv6); configured using the version number (4 or 6);
  - **ip_hdr_size** – size of the outer IP header that will be used to encapsulate the encrypted frames; this must include all IP options
  - **outer_ip_header** – pointer to the buffer containing the IP encapsulation header
  - **outer_udp_header**- pointer to the buffer containing the UDP encapsulation header, used for enabling NAT-T; if this pointer is NULL UDP encapsulation will not be used
  - **post_sec_flow_id** – this value will be attached to this SAs frame queue that comes from the SEC; the upper layer can configure classification based on this value on the post encryption offline port.
  - **dscp_start** – this value represents DSCP range start value. Will be ignored if the DSCP selector is not enabled for this SA
  - **dscp_end** – this value represents DSCP range end value. Will be ignored if the DSCP selector is not enabled for this SA
- **sa_id** - address of an integer variable in which the function will return the SA identifier if it succeeds in offloading the SA; this identifier will be used in further calls to DPA IPSec functions to refer to this particular SA.

Description

This function performs all the necessary steps required to set up a pair of frame queues that can be used to encrypt or decrypt frames according to the parameters of the SA.

For outbound SAs, the calling application must also call the `dpa_ipsec_sa_add_policy` function in order to have a fully functional IPSec hardware accelerated path.

For inbound SAs the function is also responsible for adding an entry in the pre decryption table in order to identify frames that should be decrypted using this SA and direct them to the correct frame queue. A call to this function is sufficient to create a functional inbound hardware accelerated IPSec path, if the use of inbound policy verification is not desired.

In case of error the implementation of this function will attempt to automatically rollback any changes it has performed and free all resources. If this attempt is successful the sa_id parameter will contain an invalid ID (e.g. the value -1). If this attempt fails then the `sa_id` parameter will contain the actual ID which was reserved for this SA and it is the responsibility of the

calling application to call dpa_ipsec_remove_sa with this ID, in order to release any resources that were allocated by dpa_ipsec_create_sa, but could not be released during the automatic rollback process.

In case the SA per DSCP feature needs to be enabled for an outbound SA, dscp_start and dscp_end should be specified. The values will be used to configure each selector that will have the feature enabled.

When configuring the automatic update of inner header fields or outer header fields, functionalities enabled by setting different bits in the hdr_upd_flags field, the following restrictions must be taken into consideration:

- The copying of the entire TOS / DiffServ fields, the automatic decrement of the TTL filed and the copying of the DF bit , enabled by setting the DPA_IPSEC_HDR_COPY_TOS, the DPA_IPSEC_HDR_DEC_TTL and the DPA_IPSEC_HDR_COPY_DF flags, in the hdr_upd_flags field, can be performed only when using the same type of IP header for the inner and outer headers (i.e. IPv4 and IPv4 or IPv6 and IPv6)
- Propagation of the DSCP and / or ECN fields cannot be configured together with the copying of the TOS / DiffServ fields, but this option is available regardless of the IP version of inner and outer.headers.

Return Value

The function will return 0 on success and a negative value otherwise. The returned error codes are the following:

- -EPERM, if no DPA IPSec instance is initialized;
- -EINVAL, if:
  - invalid function arguments or SA initialization parameters were provided;
  - the calling application requested activation of NAT-T support for an IPv6 SA;
  - the maximum number of inbound SAs that can be offloaded was reached;
  - a bad argument was passed to a internal function;
  - authentication and encryption keys could not be mapped to a job ring device;
  - the size of the calculated key for SA lookup is greater than the maximum key size of the classifier table in which it should be placed;
- -EDOM, if:
  - the maximum number of SAs that can be offloaded was reached;
  - an unused flow ID value could not be retrieved from the internal pool;
- -ERANGE, a new FQID could not be allocated using the default fqid allocation mechanism;
- -ENODEV, if no job ring device could be retrieved for generating the authentication split key;
- -EFAULT, if a bad argument was passed to a internal function;
- -EAGAIN, if the FMD manipulation object required for implementing variable header length support, could not be initialized;
- -ENOMEM, if:
  - there are no more available classifier tables for implementing inbound policy verification;
  - an error occurred during preparation for split key generation;
  - a new FQID could not be allocated from the fqid pool;
- error codes returned by caam_jr_enqueue function;
- error codes returned by the qman_create_fq and qman_init_fq functions;
- error codes returned by the dpa_classif_table_insert_entry (used for inserting inbound SA lookup keys, linking indexed table and inbound policy verification table and configuring the default inbound SA action), dpa_classif_table_get_params and dpa_classif_table_modify_miss_action functions.

9.9.3.3.2.2.2 Function: dpa_ipsec_remove_sa

Syntax

```
int dpa_ipsec_sa_remove(int sa_id);
```

Parameters

- **sa_id** - id of the SA that is to be deleted, as returned by the dpa_ipsec_sa_create function.

Description

This function destroys all the objects associated with the SA including all the policies. In case of error, the calling application can reuse the ID to try again to destroy this SA and all associated resources, by calling the function multiple times. It is the responsibility of the calling application to decide when it should give up on trying to release this SA's resources (if all previous calls to this function have failed).

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `-EPERM`, if no DPA IPSec instance is initialized;
- `-EINVAL`, if invalid function arguments were provided;
- `-EAGAIN`, if:
  - a lock on the SA could not be acquired;
  - a lock on the SA's child could not be acquired;
  - one of the policies attached to the SA could not be removed;
- `-EINPROGRESS`, if the SA is a child in the rekeying process;
- `-ENOTRECOVERABLE`, if the SA lookup key cannot be removed from the classifier table;
- `-EFAULT`, if a bad argument was passed to a internal function;
- `-EDOM`, if an error occurred while trying to release the SA's ID;
- `-ETIME`, if the SA is in the rekeying process and a timeout occurred while waiting for the SA's FQ TO SEC to be drained;
- `-EIO` , if, the SA is in the rekeying process and the child;s SA FQs could not be scheduled;
- `-EUCLEAN` , if, the SA is in the rekeying process and its resources could not be freed (FQs);
- `-EDQUOT` , if, the SA is in the rekeying process and its resources could not be recycled;
- `-EBUSY`, if a timeout occurred while waiting for the SA's FQs to be drained;
- error codes returned by `dpa_classif_table_delete_entry_by_ref`, if an error occurred during the inbound SA lookup table update process or an error occurred while trying to unlink the policy verification table form the indexed table;
- error codes returned by the `dpa_ipsec_sa_flush_policies`, if an error occurred while trying to remove the policies associated with this SA;
- error codes returned by the `qman_retire_fq` and `qman_oos_fq` functions.

9.9.3.3.2.2.3 Function: dpa_ipsec_flush_all_sa

Syntax

```
int    dpa_ipsec_flush_all_sa(int dpa_ipsec_id);
```

Parameters

- **dpa_ipsec_id** - identifier of the DPA IPSec instance.

Description

This function is used to remove all the SAs offloaded in the specified DPA IPSec instance. The internal resources are recycled. In case of error, the calling application can call this function multiple times until it is successful or it decides to give up on trying to release the resources associated to the SAs that have not been already destroyed by previous calls.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `-EPERM`, if no DPA IPSec instance is initialized.
- `-EAGAIN`, if one or more SAs could not be removed.

9.9.3.3.2.2.4 Function: dpa_ipsec_disable_sa

Syntax

```
int    dpa_ipsec_sa_disable(int sa_id);
```

Parameters

- **sa_id** - id of the SA that is to be disabled, as returned by the `dpa_ipsec_sa_create` function

Description

This function prepares a SA for removal. After this function returns the SA can no longer be used, because the hardware components were reconfigured in order to deactivate packet processing using this SA.

The frames that have already been classified and placed in the DPA IPSec internal queues, awainting processing, will not be dropped and will continue to be processed in the order they arrived until the queues become empty.

The resources associated with this SA, including the internal queues must be, afterwards, destroyed by the calling application using the `dpa_ipsec_remove_sa` function.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `-EINVAL`, if invalid function arguments were provided
- `-EAGAIN`, if, a lock on the SA could not be acquired
- `-EINPROGRESS`, if the SA is currently in the rekeying process
- `-ENOTRECOVERABLE`, if the SA lookup key cannot be removed from the classifier table.
- `-EBADSLT`, if not all the policies associated to an outbound SA could be removed.

9.9.3.3.2.2.5 Function: dpa_ipsec_sa_modify

Syntax

```
int dpa_ipsec_sa_modify(int sa_id,
  struct dpa_ipsec_sa_modify_prm *modify_prm);

enum dpa_ipsec_sa_modify_type {
 DPA_IPSEC_SA_MODIFY_ARS = 0,
DPA_IPSEC_SA_MODIFY_SEQ_NUM,
 DPA_IPSEC_SA_MODIFY_EXT_SEQ_NUM,
DPA_IPSEC_SA_MODIFY_CRYPTO
};

struct dpa_ipsec_sa_modify_prm {
 enum dpa_ipsec_sa_modify_type   type;
 union {
  enum dpa_ipsec_arw    arw;
  uint64_t      seq_num;
  struct dpa_ipsec_sa_crypto_params  crypto_params;
 };
};

enum dpa_ipsec_sa_operation_code {
    DPA_IPSEC_SA_MODIFY_ARS_DONE = 0,
    DPA_IPSEC_SA_MODIFY_SEQ_NUM_DONE,
    DPA_IPSEC_SA_MODIFY_EXT_SEQ_NUM_DONE,
    DPA_IPSEC_SA_MODIFY_CRYPTO_DONE,
    DPA_IPSEC_SA_GET_SEQ_NUM_DONE
};
```

Parameters

- **sa_id** - identifier of the SA for which to modify parameters.
- **modify_prm** - used to define what changes must be done to this SA.
  - **type** – type of parameters; configured using the `dpa_ipsec_sa_modify_prm enum`; currently we support only the `DPA_IPSEC_SA_MODIFY_ARS`.
  - **arw** – anti replay type to change to; relevant only if type is `DPA_IPSEC_SA_MODIFY_ARS`
  - **seq_num** – 32 bit or extended sequence number depending on how the SA was created by dpa_ipsec_create_sa. Only the least significant word is used for 32 bit SEQ
  - **crypto_params** – change the crypto parameters for this SA to the ones specified by this structure; relevant only if type is `DPA_IPSEC_SA_MODIFY_CRYPTO`

Description

This function can be used to modify the parameters of an already offloaded SA while running.

This function is asynchronous basically when returning with error code 0 means that the operation was triggered but not actually finished. When it is finished the post SEC offline port will enqueue to its error frame queue a frame descriptor having user error status (`0x38402102`) and in the payload the SA id of the security association that has been modified allong with the modify operation code. This status is set by the SEC engine when the modify operation is finished and being a user error no other SEC errors have this status.

The upper layer should periodically check the frames from post SEC offline port error frame queue, searching for frames that have SEC user error status (`0x38402102`). Basically when a frame with this status is received for sure the modify operation was finished. Another check can be done by calling again the `dpa_ipsec_sa_modify` function with the SA id set in the frame descriptor's payload and with the same `modify_prm` parameter. If all when well the function should return an –EALREADY error code signifying that the SA has been changed to the specified parameters.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `-EINVAL`, if invalid function arguments were provided:
  - invalid function arguments were provided
  - invalid type for modify parameters
  - SA id does not refer to an inbound SA
- `-ENXIO`, could not dma map an addres used by SEC engine.
- `-ETXTBSY`, Failed to enqueue frames to the 'TO SEC FQ' of the SA represented by SA id.
- `-EBUSY`, could not acquire the lock for SA structure represented by the SA id.
- `-EALREADY`, the proposed change is already in place for this SA.
- `-EOPNOTSUPP`, Operation not supported, currently we support changes only of DPA_IPSEC_SA_MODIFY_ARS type.

9.9.3.3.2.2.6 Function: dpa_ipsec_sa_get_stats

Syntax

```
int dpa_ipsec_sa_get_stats(int sa_id, struct dpa_ipsec_sa_stats *sa_stats);

struct dpa_ipsec_sa_stats {
 uint32_t packets_count;
 uint32_t bytes_count;
 uint32_t input_packets;
};
```

Parameters

- **sa_id** - identifier of the SA for which to remove all policies.
- **sa_stats** - pointer to a structure allocated especially to receive the requested statistics:
  - **packets_count** – number of packets processed through this SA
  - **bytes_count** – total number of bytes in all packets that were processed by this SA
  - **input_packets** - the total number of packets (including bad frames) that entered this SA. This statistic information is available only if you have set the *enable_extended_stats* attribute of the SA to *true*. Otherwise this is reported as zero. For an inbound SA this counter translates into the number of packets that were received by this SA, including frames that were later discarded due to decryption errors. For an outbound SA this translates into the total number of packets that were sent on this SA, including packets that failed due to encryption errors.

Description

In case of success the `sa_stats` will be filled with valid statistics information. In order to be able to retrieve statistical information using this function, the `enable_stats flag` must be set when the SA is created. Otherwise statistical information will not be available for the SA and this function will always return an error.

Return Value

The function returns 0 on success or an error code otherwise. The returned error codes are the following:

- `-EINVAL`, if invalid function arguments were provided.
- `-EBUSY`, if a lock on the SA could not be acquired.
- `-EPERM`, if the SA was created without statistics support enabled.

9.9.3.3.2.2.7 Function: dpa_ipsec_get_sa_context

Syntax

TBD

Parameters

TBD

Description

This function will be used to retrieve information about the SA that was used to process a packet.

This information can be useful when an error has occurred during IPSec processing and the control application receives the affected packet in a offline port's error frame queue. In this case the control application needs to identify the SA which was used to process that packet.

The function can also be called when inbound policy verification is performed outside the DPA IPSec module (e.g. in software). The module that will perform the inbound policy verification will use the function to retrieve information about what SA was used for decrypting the packet.

Return Value

TBD

9.9.3.3.2.2.8 Function: dpa_ipsec_sa_get_out_path

Syntax

```
int dpa_ipsec_sa_get_out_path(int sa_id, uint32_t *fqid);
```

Parameters

- **sa_id** - identifier of the SA for which to retrieve the frame queue.
- **fqid** - identifier of the frame queue to SEC for the specified SA in order to bypass outbound policy verification and apply IPSec processing.

Description

This function will be used to retrieve information which will allow the upper layer to bypass outbound policy lookup and directly apply IPSec processing on a packet using the SA provided as a parameter to the function. In this case it is the responsibility of the calling application to ensure that the correct SA is used to process the packets.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `-EINVAL`, if invalid function arguments were provided.
- `-EBUSY`, if, a lock on the SA could not be acquired.
- `-ENODEV`, if the SA is not used.
- `-EPERM`, if the SA is not an outbound SA.

9.9.3.3.2.2.9 Function: dpa_ipsec_get_stats

Syntax

```
int dpa_ipsec_get_stats(int dpa_ipsec_id, struct dpa_ipsec_stats *stats);

struct dpa_ipsec_stats {
 uint32_t inbound_miss_pkts;
 uint32_t inbound_miss_bytes;
 uint32_t outbound_miss_pkts;
 uint32_t outbound_miss_bytes;
};
```

Parameters

- **dpa_ipsec_id** - *dpa_ipsec* instance Id returned by a previous call to *dpa_ipsec_init*
- **stats** - pointer to a structure allocated especially to receive the global IPSec statistics
  - **inbound_miss_pkts** – number of packets that missed the inbound SA lookup
  - **inbound_miss_bytes** – total number of bytes in all packets that missed the inbound SA lookup
  - **outbound_miss_pkts** - number of packets that missed the outbound policy lookup
  - **outbound_miss_bytes** - total number of bytes in all packets that missed the outbound policy lookup

Description

This function returns the IPSec global statistics for the specified IPSec instance. In case of success the `stats` will be populated with valid statistics information.

Return Value

The function returns 0 on success or an error code otherwise. The returned error codes are the following:

- `-EINVAL`, if invalid function arguments were provided.

9.9.3.3.2.3 Add and Remove Policies

Table 261. API to Add and Remove Policies

Function Name	Description
dpa_ipsec_sa_add_policy	Adds a new policy (for inbound or outbound) policy verification. It adds keys and directs packets through a certain flow (SA).
dpa_ipsec_sa_remove_policy	Removes a previously added policy.
dpa_ipsec_sa_flush_policies	Removes all policies associated to a SA.
dpa_ipsec_sa_get_policies	Retrieves all the policies linked to a specified SA.

9.9.3.3.2.3.1 Function: dpa_ipsec_sa_add_policy

Syntax

```
   int dpa_ipsec_sa_add_policy(int sa_id,
                    struct dpa_ipsec_policy_params *policy_params);

struct dpa_ipsec_l4_params {
    uint16_t       src_port;
    uint16_t       src_port_mask;
    uint16_t       dest_port;
    uint16_t       dest_port_mask;
};

struct dpa_ipsec_icmp_params {
    uint8_t      icmp_type;
    uint8_t      icmp_type_mask;
    uint8_t      icmp_code;
    uint8_t      icmp_code_mask;
};

enum dpa_ipsec_df_action {
 DPA_IPSEC_DF_ACTION_DISCARD = 0,
DPA_IPSEC_DF_ACTION_OVERRIDE,
 DPA_IPSEC_DF_ACTION_CONTINUE
};

enum dpa_ipsec_pol_dir_params_type {
 DPA_IPSEC_POL_DIR_PARAMS_NONE = 0,
 DPA_IPSEC_POL_DIR_PARAMS_MANIP,
DPA_IPSEC_POL_DIR_PARAMS_ACT,
};

struct dpa_ipsec_pol_dir_params {
 enum dpa_ipsec_pol_dir_params_type  type;
 union {
  struct     int manip_desc;
  struct dpa_cls_tbl_action  in_action;
 };
```

```
};

struct dpa_ipsec_policy_params {
    struct dpa_ipsec_ip_address    src_addr;
    uint8_t      src_prefix_len;
    struct dpa_ipsec_ip_address    dest_addr;
    uint8_t        dest_prefix_len;
    uint8_t        protocol;
    bool      masked_proto;
    bool      use_dscp;
    union {
      struct dpa_ipsec_l4_params  l4;
  struct dpa_ipsec_icmp_params icmp;
    };
    struct dpa_ipsec_pol_dir_params dir params;
    int      priority;
};
```

Parameters

- **sa_id** - id of the SA that this policy is linked
- **policy_params** - structure containing the selectors for the offloaded policy:
  - **src_addr** – source IP address
  - **src_prefix_len** - the length of the mask to be applied on the source IP address
  - **dest_addr** – destination IP address
  - **dest_prefix_len** - the length of the mask to be applied on the destination IP address
  - **protocol** - the expected value in the IP header protocol field
  - **masked_proto** – enable / disable masking of the protocol field in the policy key;
  - **use_dscp** – enable / disable DSCP value in policy selector;
  - **l4** – structure containing parameters for layer 4 type of policies:
    - **src_port** – source port value; relevant only for selectors for L4 protocols
    - **src_port_mask** – mask to be applied on the source port value;
    - **dest_port** – destination port value; relevant only for selectors for L4 protocols
    - **dest_port_mask** – mask to be applied on the destination port value;
  - **icmp** – structure containing parameters for icmp policies:
    - **icmp_type** – the type field in the ICMP header; relevant only if protoco field is of type ICMP
    - **icmp_type_mask** – mask to be applied on the ICMP type field value value;
    - **icmp_code** – the code field in the ICMP header; relevant only if protocol field is of type ICMP
    - **icmp_code_mask** – mask to be applied on the ICMP code field value;
  - **dir_params** – direction specific parameter for the security policy:
    - **type** – type of parameters; configured using the `dpa_ipsec_pol_dir_params_type` enum; if equal to `DPA_IPSEC_POL_DIR_PARAMS_NONE`, the other fields' values are ignored;
    - **manip_desc** – fragmentation descriptor or header manipulation chain descriptor for policies attached to outbound SAs; relevant only if type is equal to `DPA_IPSEC_POL_DIR_PARAMS_MANIP`:

- **in_action** – the action that should be performed if the decrypted frames match the policy key; if this filed is NULL, the frames that pass inbound policy verification will be handled according to the default SA action configured at SA creation time; if this field is not NULL, it will override, for this policy only, the SA default action; this field is relevant only for policies attached to inbound SAs and if the type field is equal to `DPA_IPSEC_POL_DIR_PARAMS_ACT`;

- **priority** – the priority of this policy.

Description

This function can be used to configure the policies for a SA.

For outbound paths, the use of this function is mandatory, because the policy selectors passed as parameters to it will be used to classify frames and identify the correct SA that should be used for encryption.

For inbound paths the use of this function is mandatory if inbound policy verification was activated for this DPA IPSec instance and is prohibited if it was not activated. In case the inbound policy verification was activated, the policy selectors received as parameters will be used to check if the decrypted frames arrived on the correct SA.

In case the SA per DSCP feature needs to be enabled for an outbound SA selector, use_dscp must be set as true. In this case a number of selectors will be created according to DSCP range specified for the SA.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- EINVAL, if:
  - invalid function arguments were provided
  - the parameters of the classifier table could not be retrieved
  - no classifier table was configured for this type of policy
- EFAULT, if a bad argument was passed to a internal function.
- EBUSY , if a lock on the SA could not be acquired.
- EPERM, if:
  - othe SA is a parent in the rekeying process and is of type outbound
  - othe SA is a child in the rekeying process and is of type inbound
- ENOMEM, if memory could not be allocated for the new policy.
- EAGAIN, if the FMD header manipulation object for fragmentation could not be created.
- error codes returned by the `dpa_classif_table_insert_entry` (used for inserting policy keys).

9.9.3.3.2.3.2 Function: dpa_ipsec_sa_remove_policy

Syntax

```
int dpa_ipsec_sa_remove_policy(int sa_id,
                               struct dpa_ipsec_policy_params *policy_params);
```

Parameters

- **sa_id** - id of the SA that this policy is linked.

- **policy_params** - structure with policy selectors, used for identify the policy that must be deleted; for detailed information regarding the policy selectors please see the description of the parameters for `dpa_ipsec_sa_add_policy` function

Description

This function is used to remove a previously offloaded policy. The policy to be removed is identified by a policy parameters structure that is identical to the one that was passed in the `dpa_ipsec_sa_add_policy` function when the policy was offloaded.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if invalid function arguments were provided.
- `EBUSY`, if:
  - a lock on the SA could not be acquired
  - the FMD manipulation object used for fragmentation could not be removed
- `EFAULT`, if a bad argument was passed to a internal function
- `EPERM`, if:
  - the SA is a parent in the rekeying process and is of type outbound
  - the SA is a child in the rekeying process and is of type inbound
- `EDOM`, if a corresponding policy was not found in the SA's list of associated policies.
- error codes returned by the `dpa_classif_table_delete_entry_by_ref` (used for removing policy keys).

9.9.3.3.2.3.3 Function: dpa_ipsec_sa_flush_policies

Syntax

```
int    dpa_ipsec_sa_flush_policies(int sa_id);
```

Parameters

- **sa_id** - identifier of the SA for which to remove all policies..

Description

This function is used to remove all the policies for the given SA. The internal resources are recycled.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if invalid function arguments were provided.
- `EBUSY`, if, a lock on the SA could not be acquired.
- `EFAULT`, if a bad argument was passed to a internal function.
- `EAGAIN`, if one or more policies could not be removed.
- error codes returned by the `dpa_classif_table_delete_entry_by_ref` (used for removing policy keys).

9.9.3.3.2.3.4 Function: dpa_ipsec_sa_get_policies

Syntax

```
int    dpa_ipsec_sa_get_policies(int sa_id,
           struct dpa_ipsec_policy_params *policy_params,
           int    *num_pol);
```

Parameters

- **sa_id** - identifier of the SA for which to retrieve all policies.
- **policy_params** - placeholder for the array of policy structures associated to the specified SA; the array of policy parameters will be allocated internally by this function.
- **num_pol** - number of policy parameters structures in the returned policy array.

Description

This function is used to retrieve all the policies associated to a given SA. The array that will hold the retrieved policies must be allocated by the calling application.

In order to determine the correct size for this array, the calling application must first call the function with the `policy_params` parameter set to NULL. In this case the function will return in the `num_pol` parameter the number of policies that are linked to the specified SA. Then the calling application can allocated a policy array in which there is enough space for all the policies linked to the SA. After calling the function again, this time passing the address of the newly allocated array as the `policy_params` parameter, it will receive the information about all the policies linked to the specified SA.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if invalid function arguments were provided.
- `EBUSY`, if, a lock on the SA could not be acquired.
- `EFAULT`, if a bad argument was passed to a internal function.
- `EAGAIN`, if there are more policies in the SA list than the maximum number of policies that can be copied in the provided buffer.

9.9.3.3.2.4 Rekeying

Table 262. API for IPSec Rekeying

Function Name	Description
`dpa_ipsec_sa_rekeying`	Performs all the required actions for changing and expired SA with a newly negotiated SA, while ensuring no packets are lost during this process.

9.9.3.3.2.4.1 Function: dpa_ipsec_sa_get_rekeyings

Syntax

```
int     dpa_ipsec_sa_rekeying(int sa_id,
                              struct dpa_ipsec_sa_params *sa_params,
dpa_ipsec_rekey_event_cb *rekey_event_cb,
bool auto_rmv_old_sa, int *new_sa_id);

typedef int (*dpa_ipsec_rekey_event_cb)
(int dpa_ipsec_id,
                   int sa_id,
                   int error);
```

Parameters

- **sa_id** - id of the SA that has expired and needs to be replaced.
- **sa_params** - structure containing the parameters of the new SA; for a detailed description of these parameters see the description of `dpa_ipsec_create_sa`;
- **rekey_event_c** - callback used to report the status of the rekeying process, when it is completed; this callback is only supported in Kernel space
  - **dpa_ipsec_id** – id of the IPSec instance in which the SA rekeying process is performed;
  - **sa_id** – id of the SA for which the rekeying process was started;
  - **error** – status of the rekeying process;
- **auto_rmv_old_sa** - valid only for inbound rekeying. Auto remove old SA when encrypted traffic starts flowing on the new SA.
- **new_sa_id a** - address of an integer variable where the id of the newly created SA will be stored.

Description

This function is used to replace an expired SA with a new valid SA.

The rekeying procedure was designed in such a way that there is no service interruption, no packets are lost and the links between the policies and the old SA are automatically transferred to the new SA. Furthermore the rekeying process ensures that the packet order is preserved.

The `auto_rmv_old_sa` option has meaning only when rekeying an inbound SA as follows:

- If TRUE the DPA IPSEC will create the new SA and remove the old SA when it has received a frame encrypted with the new SA. This is done disregarding that the SA might be in its lifetime period.
- If FALSE the DPA IPSEC will create the new SA and let the old SA in place. Practically the two SA's will run in parallel. It is the responsibility of the user to call `dpa_ipsec_remove_sa` when the old SA expires (hardlimit reached). This option may be used when the user wants to receive frames encrypted with old SA which were reordered by the network and arrive after the new SA is already in use.

This function is the only one that uses an asynchronous error reporting mechanism. If an error occurs during the process of replacing the old SA with the new SA, which is an asynchronous process, the function will use the `dpa_ipsec_rekey_event_cb` to report the error to the calling application. If no error occurred during the rekeying process, the same callback will be used to signal successful completion of this task (i.e. error = 0).

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- -EINVAL, if:
  - no DPA IPSec instance is initialized
  - invalid function arguments or SA initialization parameters were provided
  - the calling application requested activation of NAT-T support for an IPv6 SA
  - authentication and encryption keys could not be mapped to a job ring device
  - the size of the calculated key for SA lookup is greater than the maximum key size of the classifier table in which it should be placed
- -EBUSY , if a lock on the SA could not be acquired.
- -EEXIST, if a bad argument was passed to a internal function.
- -EDOM, if a bad argument was passed to a internal function.
- -ERANGE, if a bad argument was passed to a internal function.
- -ENODEV, if a bad argument was passed to a internal function.
- -EFAULT, if a bad argument was passed to a internal function.
- -ENOMEM, if a bad argument was passed to a internal function.
  - an error occurred during preparation for split key generation
  - a new FQID could not be allocated from the fqid pool
- -EAGAIN, if there are more policies in the SA list than the maximum number of policies that can be copied in the provided buffer.
- error codes returned by caam_jr_enqueue function.
- error codes returned by the qman_create_fq and qman_init_fq functions.
- error codes returned by the dpa_classif_table_insert_entry (used for inserting inbound SA lookup keys) and dpa_classif_table_get_params functions
- -EUSERS, if the function dpa_classif_table_modify_entry_by_ref, used for modifying the actions associated to the outbound security policies, failed and only some of the security policies were transferred to the new SA
- error codes returned by the qman_schedule_fq function

The following error codes can be returned in the error parameter of the dpa_ipsec_rekey_event_cb callback:

- for outbound SAs:
  - –EUCLEAN, if during the rekeying process the removal of the TO SEC FQ of old SA failed. The upper layer has to call the dpa_ipsec_remove_sa at a later time (not from callback) to try again to free the old SA resources. The new SA is active.
  - –EDQUOT, if recycling of old SA's memory resources failed. The upper layer has to call the dpa_ipsec_remove_sa function at a later time (not from callback) to try again to recycle these resources.
- for inbound SAs:
  - –ENOTRECOVERABLE, if the removal of the old SA's table entry in in the SA lookup classifier table has failed. If this error is received the upper layer must take into consideration that the system is in a vulnerable state, because it will still accept packets that match the old SA's parameters, and it should consider rebooting the system.
  - –EUCLEAN, if during the rekeying process the removal of the TO SEC FQ of old SA failed. The upper layer has to call the dpa_ipsec_remove_sa at a later time (not from callback) to try again to free the old SA resources. The new SA is active.
  - –EDQUOT, if recycling of old SA's memory resources failed. The upper layer has to call the dpa_ipsec_remove_sa function at a later time (not from callback) to try again to recycle these resources.

9.9.3.4 DPA Statistics

The DPA Stats module exports a set of functions that can be used to:

- initialize the DPA Stats module;
- create a DPA Stats single counter;
- create a DPA Stats class counter;
- retrieve the values for a series of counters.

9.9.3.4.1 Initialization

Initialization is a mandatory step in using the DPA Stats component. The initialization function has the purpose of creating and initializing internal data structures that will be further used at runtime. The allocated internal structures will be later

Counter creation

Counter creation is an important step, as the counter is the basic element used to retrieve specific information. There are two types of counters that can be created: a single counter and a class counter.

A **single counter** is meant to retrieve information from one source, which can be either a hardware resource or a software resource.

A **class counter** has the purpose of retrieving information from multiple sources of the same type.

Counters are of different types; as such counter creation is responsible of configuring the interface with different hardware blocks or software components in order to be able to obtain the corresponding values.During counter creation no hardware block or software component is initialized, that is the responsibility of the user software. The counter relies on an already initialized hardware or software component and will only configure the mechanism it needs to gain the desired information. It is also the user responsibility to insure synchronization between the initialized hardware and software components and the created counters. As such a counter needs to be removed if the underlying hardware or software component was destroyed.

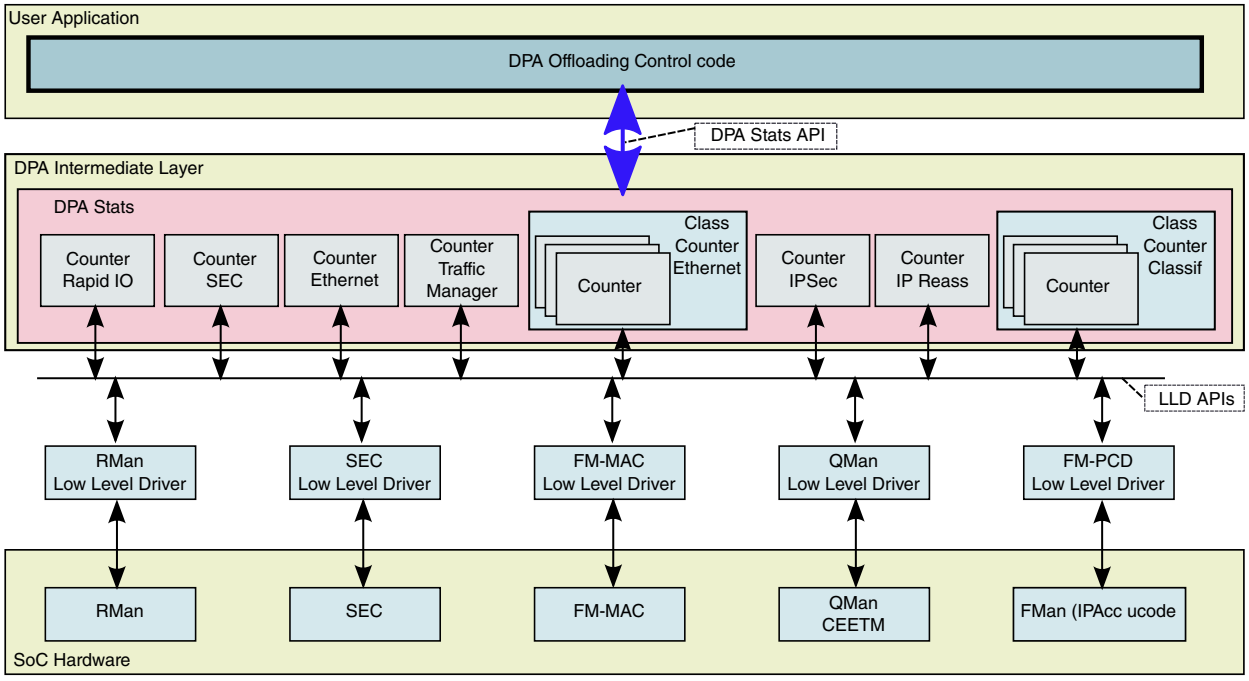

Figure 259. DPA Stats architecture

Counter retrieve

The user has the possibility of retrieving the values for one or multiple counters. For each counter, the retrieve operation means a direct interaction with the hardware or software component. As such, the response time of the retrieve operation depends on the number of counters the request is made of and the underlying hardware or software component response time.

The result of a retrieve operation is written by the DPA Stats component in a memory area provided by the user application and the user application will be informed on the number of bytes written either when the calling function returns or via a callback function.

9.9.3.4.2 DPA Statistics API

There are several selections for the DPA Statistics API:

9.9.3.4.2.1 Initialize and Free Statistics

Table 263. API to Initialize and Free Statistics

Function Name	Description	Input Parameters	Output Parameters
`dpa_stats_init`	Configures and initializes a DPA Stats instance.	• maximum number of counters that will be managed by the DPA Stats instance. • pointer to the memory area where the values of the counters will be written by the DPA Stats instance. • length of the memory area expressed in number of bytes.	Identifier of the newly created DPA Stats instance.
`dpa_stats_free`	Releases all resources associated with a DPA Stats instance and destroys it.	• identifier of the DPA Stats instance to destroy.	None.

9.9.3.4.2.1.1 Function: dpa_stats_init

Syntax

```
int dpa_stats_init(const struct dpa_stats_params *params, int
                   *dpa_stats_id);

struct dpa_stats_params
{
 unsigned int max_counters;
 void    *storage_area;
 unsigned int storage_area_len;
};
```

Parameters

- **params** - data structure containing the parameters needed to initialize the DPA Stats;
  - max_counters: maximum number of counters supported by the DPA Stats module.
  - storage_area: pointer to the memory area where the values of the counters will be written by the DPA Stats instance after a retrieve operation was successful.
  - storage_area_len: length of the memory area expressed in number of bytes.
- **dpa_stats_id** - a location where the function will return the identifier of the DPA Stats instance, in case of success; this id will be further used to create counters that are attached to the DPA Stats instance.

Description

This function is used to initialize a DPA Stats instance. The purpose of the function is to allocate and initialize all the internal structures that will be further needed by the DPA Stats instance.

The storage area can be a pointer to a memory allocated using C programming standard library routines or a pointer to a memory area allocated using NXP's "shmem" application programming interface. Memory allocated using "shmem" is a contiguous physical memory that is accessible both in user-space application and in kernel-space driver implementation through corresponding user-space and kernel space virtual addresses. This type of memory allows the DPA Stats driver to write the statistics values in the storage area using a "zero copy" approach and is an optimized solution to transfer information from kernel-space to user-space.

Memory area allocated in user-space using C programming routines is not mapped in kernel-space so the transfer between kernel-space DPA Stats driver and user-space application is performed using memory copy from kernel-to-user space and vice-versa.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if one of the function arguments or parameters was incorrect;
- `ENOMEM`, if there is no more memory to create an internal data structure needed by the DPA Stats module.
- `EPERM`, if the component is already initialized.
- `ENOSPC`, if the operation of creating a single threaded workqueue failed.
- `EDOM`, if the number of provided counters is above the maximum allowed.

9.9.3.4.2.1.2 Function: dpa_stats_free

Syntax

```
int dpa_stats_free(int dpa_stats_id);
```

Parameters

- **id** - identifier of the DPA Stats instance to destroy.

Description

Releases all resources associated with a DPA instance and destroys the instance.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if the provided instance identifier is not valid;
- `EDOM`, if the provided counter identifier could not be released.

9.9.3.4.2.2 Create, Remove or Modify Counters

Table 264. API to Create Remove or Modify Counters

Function Name	Description	Input Parameters	Output Parameters
`dpa_stats_create_counter`	Configures and initializes a DPA Stats counter. The counter will be used to address a single hardware or software resource.	• identifier of the DPA Stats instance the counter will belong to. • the type of counter that needs to be created • parameters needed to create the counter, depending of the counter type • pointer to a location where the function will return an unique identifier for the counter in case of success.	Identifier for the counter. The returned identifier will be further used to address the counter.
`dpa_stats_create_class_counter`	Configures and initializes a DPA Stats counter. The counter will be used to address multiple hardware or software resources of the same time.	• identifier of the DPA Stats instance the class counter will belong to. • the type of class counter that needs to be created. • parameters needed to create the class counter, depending of the class counter type. • pointer to a location where the function will return an unique identifier for the class counter in case of success.	Identifier for the class counter in case of success. The returned identifier will be further used to address the class counter.

Table continues on the next page...

Table 264. API to Create Remove or Modify Counters (continued)

Function Name	Description	Input Parameters	Output Parameters
`dpa_stats_modify_class_counter`	Modifies a member of a certain class counter. The class member can be invalidated or updated, by providing a new source.	• identifier of the DPA Stats class counter for which the member will be updated. • the type of the member that needs to be modified. • parameters needed to modify the class member. • the index of the member in the class counter.	None.
`dpa_stats_remove_counter`	Removes a single counter or a class counter. The resources occupied by the counter are marked as empty.	• identifier of the DPA Stats counter or class counter that will be removed.	None.

9.9.3.4.2.2.1 Function: dpa_stats_create_counter

};
```

Parameters

- **dpa_stats_id** - identifier of the DPA Stats instance the counter belongs to.
- **params** - structure holding the parameters needed to create a counter:
  - **type**: the type of the counter that needs to be created: Ethernet counter, Reassembly counter, Fragmentation Counter, Policer Counter, Classifier Table counter, Classification Node Counter, IPSec counter, Traffic Manager counter or RapidIO counter (selected from `dpa_stats_cnt_type` enum).
  - **eth_params**: structure holding the parameters needed to create an Ethernet counter
    - **src**: structure holding the parameters needed to identify the source of the Ethernet counter
      - **engine_id**: identifier of the engine the Ethernet interface belongs to
      - **eth_id**: identifier of the Ethernet interface, identifier that is relative to the engine the interface belongs to
    - **cnt_sel**: selection from Ethernet available counters: enum `dpa_stats_cnt_eth_sel`
  - **reass_params**: structure holding the parameters needed to create an IP Reassembly counter
    - **reass**: handle of IP Reassembly object
    - **cnt_sel**: selection from Reassembly available counters, enum `dpa_stats_cnt_reass_gen_sel`, `dpa_stats_cnt_reass_ipv4_sel` or `dpa_stats_cnt_reass_ipv6_sel`
  - **frag_params**: structure holding the parameters needed to create an IP Fragmentation counter
    - **frag**: handle of IP Fragmentation object
    - **cnt_sel**: selection from Fragmentation available counters, enum `dpa_stats_cnt_frag_sel`
  - **plcr_params**: structure holding the parameters needed to create a Policer counter
    - **plcr**: handle of Policer object
    - **cnt_sel**: selection from Policer available counters, enum `dpa_stats_cn_plcr_sel`
  - **classif_tbl_params**: structure holding the parameters needed to create a Classifier Table counter
    - **td**: descriptor of the table used to perform the Classification
    - **key**: pointer to the key descriptor. If *key* is NULL, DPA Stats will provide the table *miss* condition statistics in this counter.
      - **byte**: pointer to an array of bytes representing the key
      - **mask**: the mask to store for this key
      - **size**: the size of the key
    - **cnt_sel**: selection from Classifier Table available counters, enum `dpa_stats_cnt_classif_sel` or enum `dpa_stats_cnt_frag_sel`
  - **classif_node_params**: structure holding the parameters needed to create a Classification Node counter
    - **cc_node**: handle of the Cc node used to perform the Classification
    - **ccnode_type**: the type of FMAN Classification Node

- **key**: pointer to the key descriptor. If *key* is NULL, DPA Stats will provide the CC node's *miss* condition statistics in this counter.
  - **byte**: pointer to an array of bytes representing the key
  - **mask**: the mask to store for this key
  - **size**: the size of the key
- **cnt_sel**: selection from Classification Node available counters, enum `dpa_stats_cnt_classif_sel`

- **ipsec_params**: structure holding the parameters needed to create an IPSec counter
  - **sa_id**: identifier of the Security Association
  - **cnt_sel**: single selection from IPSec available counters, enum `dpa_stats_cnt_sel`
- **traffic_mng_params**: structure holding the parameters needed to create a Traffic Manager counter
  - **src**: the type of the source used for the Traffic Manager counter
  - **traffic_mng**: depending on the Traffic Manager source, the 'traffic_mng' has a different meaning: it represents a pointer to a structure of type 'qm_ceetm_cq' in case the traffic source is a "Class Queue" or a pointer to a structure of type 'qm_ceetm_ccg' in case the traffic source is a "Class Congestion Group"
  - **cnt_sel**: single selection from Traffic Manager counter, `dpa_stats_cnt_sel` enum
- **rapidio_params**: structure holding the parameters needed to create a RapidIO counter

- **dpa_stats_cnt_id** - address of an integer variable in which the function will return the counter identifier if it succeeds in creating it; this identifier will be used in further calls to DPA Stats functions to refer to this particular counter.

Description

This function performs all the necessary steps required to create and initialize a single counter. A single counter means a counter that is used to retrieve information from one source, source that can be either a hardware resource or a software resource.

During counter creation no memory is allocated, but instead the function uses internal structures that were allocated during DPA Stats instance initialization. On success, the function returns a unique counter identifier that should be further used on calls that refer to that counter.

The first parameter of the structure used to create a counter is the type of the counter. Depending on the type of the counter, the user needs to provide the parameters necessary for that type of counter.

For the Ethernet counter, the user can select any combinations of counters from the enumeration `dpa_stats_cnt_eth_sel`.

For the Reassembly counter, the user can have combination of selections from the three groups of counters: counters that are common both to IPv4 and IPv6 protocols, counters specific to IPv4 protocol and counters specific to IPv6 protocol: `dpa_stats_cnt_reass_gen_sel`, `dpa_stats_cnt_reass_ipv4_sel` and `dpa_stats_cnt_reass_ipv6_sel`.

For the Fragmentation and Policer counter, the user can have combination of selections from the corresponding enumerations: `dpa_stats_cnt_frag_sel` and `dpa_stats_cnt_plcr_sel`.

In terms of Classification, there are two types of Classification counters: a Classification Table counter and a Classification Node counter. For a Classification Table counter, the user can retrieve the statistics values for a specific table entry, statistics values that can be any selection or combination of selection from `dpa_stats_cnt_frag_sel` or `dpa_stats_cnt_classif_sel`. The user should be aware that when the same fragmentation object is applied on more than one Classifier Table entries, the statistics values represent the values for the entire number of entries on which the same fragmentation object is applied.

For IPSec and Traffic Manager counters, the user has the possibility of selection from the enum `dpa_stats_cnt_sel`, which return the number of bytes, number of frames or both of them but the returned value has a different meaning, depending on the type of counter and source of the counter.

The DPA Stats component verifies every valid source provided during counter creation by trying to retrieve the corresponding statistics.

The value for a single statistics value is of 4 bytes, but in case multiple statistics values were selected by combining them the value returned will be 4 bytes multiplied with the number of statistics selected.

Return Value

This function returns 0 for success or an error code otherwise. The returned error codes are the following:

- `EPERM`, if no DPA Stats instance is initialized.
- `EINVAL`, if one of the function arguments or parameters was incorrect.
- `EDOM`, if the number of previously created counters reached the maxium preconfigured number of counters.

9.9.3.4.2.2.2 Function: dpa_stats_create_class_counter

Syntax

```
int dpa_stats_create_class_counter(int dpa_stats_id,
  const struct dpa_stats_cls_cnt_params *params, int *dpa_stats_cnt_id);

struct dpa_stats_cls_cnt_params
{
 int     class_members;
 enum dpa_stats_cnt_type type;
 union
{
  struct dpa_stats_cls_cnt_eth     eth_params;

struct dpa_stats_cls_cnt_classif_tbl  cls_tbl_params;
struct dpa_stats_cls_cnt_classif_node cls_node_params;
  struct dpa_stats_cls_cnt_classif    cls_params;
  struct dpa_stats_cls_cnt_ipsec    ipsec_params;
  struct dpa_stats_cls_cnt_traffic_mng  traffic_mng_params;
  struct dpa_stats_cls_cnt_rapidio    rapidio_params;
 };
};

struct dpa_stats_cls_cnt_eth
{
 struct dpa_stats_cnt_eth_src  *src;
 unsigned int    cnt_sel;
};

struct dpa_stats_cls_cnt_reass
{
 void   **reass;
 unsigned int cnt_sel;
};

struct dpa_stats_cls_cnt_frag
{
 void   **frag;
 unsigned int cnt_sel;
};

struct dpa_stats_cls_cnt_plcr
{
```

```
 void   **plcr;
 unsigned int cnt_sel;
};

enum dpa_stats_classif_key_type
{
 DPA_STATS_CLASSIF_SINGLE_KEY = 0,
 DPA_STATS_CLASSIF_PAIR_KEY
};

struct dpa_offload_lookup_key_pair
{
 struct dpa_offload_lookup_key *first_key;
 struct dpa_offload_lookup_key *second_key;
};

struct dpa_stats_cls_cnt_classif_tbl
{
 int td;
 enum dpa_stats_classif_key_type   key_type;

 union {
  struct dpa_offload_lookup_key      **keys;
  struct dpa_offload_lookup_key_pair **pairs;
 };
 unsigned int cnt_sel;
};

enum dpa_stats_classif_node_type
{
 DPA_STATS_CLASSIF_NODE_HASH = 0,
 DPA_STATS_CLASSIF_NODE_INDEXED,
 DPA_STATS_CLASSIF_NODE_EXACT_MATCH
};

struct dpa_stats_cls_cnt_classif_node
{
 void              *cc_node;
enum dpa_stats_classif_node_type    ccnode_type;
 struct dpa_offload_lookup_key      **keys;
 unsigned int       cnt_sel;
};

struct dpa_stats_cls_cnt_ipsec
{
 int     *sa_id;
 enum dpa_stats_cnt_sel  cnt_sel;
};

struct dpa_stats_cls_cnt_traffic_mng
{
 enum dpa_stats_cnt_traffic_mng_src  src;
 void       **traffic_mng;
 enum dpa_stats_cnt_sel        cnt_sel;
};

struct dpa_stats_cls_cnt_rapidio;
```

Parameters

- **dpa_stats_id** - identifier of the DPA Stats instance the class counter belongs to.
- **params** - structure holding the parameters needed to create a counter:
  - **class_members**: the number of members or sources of the same type the class counter provides information for
  - **type**: the type of the class counter that needs to be created: Ethernet counter, Reassembly counter, Fragmentation Counter, Policer Counter, Classification Table, Classification Node counter, IPSec counter, Traffic Manager counter or RapidIO counter (selected from dpa_stats_cnt_type enum).
  - **eth_params**: structure holding the parameters needed to create an Ethernet class counter
    - **src**: an array of structures holding the parameters needed to identify multiple sources. Each structure identifies one Ethernet source:
      - **engine_id**: identifier of the engine the Ethernet interface belongs to
      - **eth_id**: identifier of the Ethernet interface, identifier that is relative to the engine the interface belongs to
    - **cnt_sel**: selection of Ethernet available counters, `dpa_stats_cnt_eth_sel enum`
  - **reass_params**: structure holding the parameters needed to create an IP Reassembly counter
    - **reass**: an array of IP Reassembly objects
    - **cnt_sel**: selection of counters from Reassembly available counters, `dpa_stats_cnt_reass_gen_sel`, `dpa_stats_cnt_reass_ipv4_sel` and `dpa_stats_cnt_reass_ipv6_sel` enums
  - **frag_params**: structure holding the parameters needed to create an IP Fragmentation counter
    - **frag**: an array of IP Fragmentation objects
    - **cnt_sel**: selection of counters from Fragmentation available counters, dpa_stats_cnt_frag_sel enum
  - **plcr_params**: structure holding the parameters needed to create a Policer counter
    - **plcr**: an array of Policer objects
    - **cnt_sel**: selection of counters from Policer available counters, dpa_stats_cn_plcr_sel enum
  - **cls_tbl_params**: structure holding the parameters needed to create a Classification Table counter
    - **td**: descriptor of the table used to perform the Classification
    - **key_type**: the type of the key used to identify an entry in the Classification
    - **keys**: Pointer to an array of keys, where each element of the array can be either a key that identifies a specific entry or NULL in order to obtain the statistics for the *miss* entry.
    - **pairs**: Pointer to an array of "pair-keys" where each element of the array can either be a "pair-key" that identifies a specific entry, or NULL. It is allowed to specify a *miss* table relationship in each of the key pairs by providing NULL for that specific key (i.e. first or second key). If one wants to get statistics for the *miss-miss* pair, you can provide NULL for both keys inside the key pair, or you can simply provide NULL for the pair itself in this array.
    - **cnt_sel**: selection from Classification Table available counters, dpa_stats_cnt_classif_sel and dpa_stats_cnt_frag_sel enums
  - **cls_node_params**: structure holding the parameters needed to create a Classification Node counter
    - **cc_node**: handle of the Cc node used to perform the Classification
    - **ccnode_type**: the type of FMAN Classification Node
    - **keys**: Pointer to an array of keys, where each element of the array can be either a key that identifies a specific entry or NULL in order to obtain the statistics for the *miss* entry.
    - **cnt_sel**: selection from Classification Node available counters, `dpa_stats_cnt_classif_sel` enum
  - **ipsec_params**: structure holding the parameters needed to create an IPSec counter

  - **sa_id**: identifier of the Security Association
  - **cnt_sel**: single selection from IPSec available counters, dpa_stats_cnt_sel enum
- **traffic_mng_params**: structure holding the parameters needed to create a Traffic Manager counter
  - **src**: the type of the source used for the Traffic Manager counter
  - **traffic_mng**: depending on the Traffic Manager source, the 'traffic_mng' has a different meaning: it represents an array of pointers to structures of type 'qm_ceetm_cq' in case the traffic source is a "Class Queue" or an array of pointers to structures of type 'qm_ceetm_ccg' in case the traffic source is a "Class Congestion Group"
  - **cnt_sel**: single selection from Traffic Manager counter, `dpa_stats_cnt_sel` enum
- **rapidio_params**: structure holding the parameters needed to create a RapidIO counter

- **dpa_stats_cnt_id** - address of an integer variable in which the function will return the counter identifier if it succeeds in creating it; this identifier will be used in further calls to DPA Stats functions to refer to this particular counter.

Description

This function performs all the necessary steps required to create and initialize a class counter. A class counter means a counter that is used to retrieve information from multiple sources of the same type, source which can be either a hardware resource or a software resource.

During class counter creation no memory is allocated but instead the function uses internal structures that were allocated during DPA Stats instance initialization. On success, the function returns a unique counter identifier that should be further used on calls that refer to that counter.

The first parameter of the structure used to create a counter is the type of the counter. Depending on the type of the counter, the user needs to provide the parameters necessary for that type of counter.

For the Ethernet counter, the user can select any combinations of counters from the enumeration `dpa_stats_cnt_eth_sel`.

For the Fragmentation and Policer counter, the user can have combination of selections from the corresponding enumerations: `dpa_stats_cnt_frag_sel` and `dpa_stats_cnt_plcr_sel`.

In terms of Classification, there are two types of Classification counters: a Classification Table counter and a Classification Node counter. For a Classification Table counter, the user can retrieve the statistics values for multiple table entries, statistics values that can be any selection or combination of selection from `dpa_stats_cnt_frag_sel` or `dpa_stats_cnt_classif_sel`. The user should be aware that when the same fragmentation object is applied on more than one Classifier Table entries, the statistics values represent the values for the entire number of entries on which the same fragmentation object is applied. In order to identify multiple table entries, the user application needs to provide an array of keys, keys which can be either single keys or pair of keys. When a pair of keys is used, the first key will identify one entry from the table, while the second key identifies an entry connected with the first entry on a “next” action.

For IPSec and Traffic Manager counters, the user has the possibility of selection from the enum `dpa_stats_cnt_sel`, which return the number of bytes, number of frames or both of them but the returned value has a different meaning, depending on the type of counter and source of the counter.

For two types of class counter, meaning Classification Table and IPSec, the user can provide an invalid source, in which case the returned value of the associated statistics will be 0. In this way, the user application can provide during creation only a subset of valid sources and update the rest of the sources during run-time. For a Classication Table counter an invalid source means a NULL pointer for a specific key, in case the key type is single, or a NULL pointer for the first key, in case the key type is pair of keys. For an IPSec counter, an invalid source means an invalid security association identifier, whose value is equal to -1.

The DPA Stats component verifies every valid source provided during counter creation by trying to retrieve the corresponding statistics.

The value for a single statistics value is of 4 bytes, but in case multiple statistics values were selected by combining them, the value returned will be 4 bytes multiplied with the number of statistics selected.

Return Value

This function returns 0 for success or an error code otherwise. The returned error codes are the following:

- `EPERM`, if no DPA Stats instance is initialized.
- `EINVAL`, if one of the function arguments or parameters was incorrect.
- `EDOM`, if the number of previously created counters reached the maxium preconfigured number of counters.

9.9.3.4.2.2.3 Function: dpa_stats_modify_class_counter

Syntax

```
int dpa_stats_modify_class_counter(int dpa_stats_cnt_id,
 const struct dpa_stats_cls_member_params *params, int member_index)

struct dpa_stats_cls_member_params
{
 enum dpa_stats_cls_member_type type;
 union
{
  struct dpa_offload_lookup_key *key;
  struct dpa_offload_lookup_key_pair *pair;
  int sa_id;
 };
};
```

Parameters

- **dpa_stats_cnt_id** - identifier of the class counter the member belongs to.
- **params** - structure holding the parameters needed to update a member of a class:
  - **type**: the type of the class member that needs to be updated: single key, pair key or security association identifier (selected from `dpa_stats_cls_member_type` enum)
  - **key**: a key descriptor to identify a specific table entry, or NULL to identify the table *miss* counter
  - **pair**: a pair of key descriptors to identify a specific table entry. It is allowed to specify a miss table relationship in each of the key pairs by providing NULL for that specific key (i.e. first or second key). If one wants to get statistics for the *miss-miss* pair, you can provide NULL for both keys inside the key pair, or you can simply provide NULL for the pair.
  - **sa_id**: a security association identifier
- **member_index** - the position of the member in the counter's class.

Description

This function is used to modify a member of a class counter of type Classification Table or IPSec, identified through the position of the member in the class. The user application can invalidate a specific member, in which case the returned statistics value is 0, can set a valid source (key, pair or sa id) in case the member of the class was created with an invalid source or can even update a valid source.

A source is considered invalid in the following cases:

- single key: if the provided key byte and key mask are NULL
- pair key: if the provided first key byte and mask are NULL
- sa id: if the provided security association identifier is -1

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if the provided class counter identifier is not valid;

9.9.3.4.2.2.4 Function: dpa_stats_remove_counter

Syntax

```
int dpa_stats_remove_counter(int dpa_stats_cnt_id);
```

Parameters

- **dpa_stats_cnt_id** - of the counter (single or class counter) it needs to be removed.

Description

This function is used to remove a previously created DPA Stats single or class counter. The memory occupied by the internal structures of this counter is not released, but instead it is marked as empty and can be used the next time a counter is created. After a counter is removed, it can no longer be used to retrieve values for it.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if the provided instance identifier is not valid;
- `EDOM`, if the provided counter identifier could not be released.

9.9.3.4.2.3 Retrieve or Reset Counters

Table 265. API to Retrieve or Reset Counters

Function Name	Description	Input Parameters	Output Parameters
dpa_stats_get_counters	Retrieves the values for multiple single or class counters.	• an array of single or class counters identifiers for which to retrieve values. • the size of the array of requested counters. • flag to specify if requested counters should be reset after their values are retrieved. • offset in the memory area provided at DPA Stats initialization where to write the counter values. • pointer to a location where the function will return the number of bytes that should be written by the DPA Stats in the storage area in case the operation was successful • pointer to a callback function to be called by the DPA Stats module when counter values were written in the storage area or NULL in case the request is a synchronous operation	The number of bytes written by the DPA Stats in the storage area in case the operation was successful.
dpa_stats_reset_counters	Reset the values for multiple single or class counters.	• an array of single or class counters identifiers for which to reset the statistics. • the size of the array of counters to be reset.	None.

9.9.3.4.2.3.1 Function: dpa_stats_get_counters

Syntax

```
int dpa_stats_get_counters(struct dpa_stats_cnt_request_params params,
 int *cnts_len, dpa_stats_request_cb request_done);

typedef void (*dpa_stats_request_cb)(int dpa_stats_id, unsigned int   storage_area_offset, unsigned
int cnts_written, int bytes_written);

struct dpa_stats_cnt_request_params
```

```
{
 int    *cnts_ids;
 unsigned int cnts_ids_len;
 bool    reset_cnts;
 unsigned int storage_area_offset;
};
```

Parameters

- **params** structure holding the parameters needed to retrieve the values for a group of counters
  - **cnts_ids**: pointer to an array of counter identifiers for which to retrieve values
  - **cnts_ids_len**: the size of array of counters to retrieve values
  - **reset_cnts**: flag to specify if counters provided in the cnts_ids array should be reset after the retrieve operation
  - **storage_area_offset**: offset in the storage area where to receive the values of the counters
- **cnts_len**: address of an integer variable in which the function will return the number of bytes occupied by the requested counters values
- **request_done** - pointer to a callback function that will be called by the DPA Stats module when the retrieve operation finished writing the counter values in the storage area or NULL in case the retrieve operation is synchronous
  - **dpa_stats_id**: DPA Stats instance identifier
  - **storage_area_offset**: offset in the storage area where the retrieve operation wrote the counter values
  - **cnts_written**: number of counters that were written in the storage area
  - **bytes_written**: number of bytes that were written in the storage area or the error code in case an error occurred

Description

This function is used to retrieve values for a group of counters. The statistics will be retrieved in the order given by the counter identifiers position in the array cnts_ids.

Each counter statistics value represents cumulative counters and is stored on 4 bytes. The user application has the possibility of resetting the counters values after the retrieve operation, by enabling the reset_cnts flag.

For a counter of type Classification Table or IPSec, in case the user application explicitly provided an invalid source, the corresponding statistics value will be 0 and the retrieve operation is considered successful.

A counters retrieve request can be either synchronous or asynchronous. The difference between them is made through the `request_done` callback. In case the corresponding parameter is NULL, the request will be synchronous and the counters values will be available in the storage area when the function returns. In case an error occurred during the retrieve operation, the function will return the corresponding error. If the user application provided the request_done callback, the retrieve operation is asynchronous and the callback will be called by the DPA Stats module as soon as the counters values are written in the storage area. In case of an error, the number of bytes_written will have a negative value and it will the store the error code.

The user application needs to be aware of the length of the counters values before making the call to the retrieve operation. The only check the DPA Stats module performs is to verify if the offset provided by the call and the size of the counters goes beyond the length of the storage area. If that is not the case, the counters values are written starting with the storage_area_offset and will override any information that might be available in the memory area it needs to write.

Return Value

The function returns 0 on success and an error code otherwise. The returned error codes are the following:

- `EINVAL`, if invalid function arguments were provided;

- ENOENT, if an error occurred during statistics retrieve for an Ethernet counter;
- ESRCH, if an error occurred during statistics retrieve for a Reassembly counter;
- EINTR, if an error occurred during statistics retrieve for a Fragmentation counter;
- EIO, if an error occurred during statistics retrieve for a Classifier Table counter;
- ENXIO, if an error occurred during statistics retrieve for a Classification Node counter;
- E2BIG, if an error occurred during statistics retrieve for an IPSec counter.

9.9.3.4.2.3.2 Function: dpa_stats_reset_counters

Syntax

```
int dpa_stats_reset_counters(int *cnts_ids, unsigned int cnts_ids_len);
```

Parameters

- **cnts_ids** - pointer to an array of counter identifiers for which to reset the statistics.
- **cnts_ids_len** - the size of array of counters identifiers to reset.

Description

This function is used to reset the statistics for multiple single or class counters.

Return Value

The function returns 0 on success and an error code otherwise. The returned error code is the following:

- **EINVAL**, if invalid function arguments were provided;

9.9.3.4.2.4 Create or Remove Sampling Group

Table 266. API to Create or Remove Sampling Group

Function Name	Description	Input Parameters	Output Parameters
dpa_stats_create_sampling_group	Create a sampling group.	TBD	None.
dpa_stats_remove_sampling_group	Remove a sampling group.	TBD	None.

9.9.3.4.2.4.1 Function: dpa_stats_create_sampling_group

Syntax

TBD

Parameters

TBD

Description

This function will allow creating a sampling group for a number of counters. The purpose of a sampling group is to perform counters sampling at a specific frequency in order to assure counter rollover. By creating sampling groups, the application will always receive cumulative counters that take in account also the number of rollovers.

Return Value

TBD

9.9.3.4.2.4.2 Function: dpa_stats_create_sampling_group

Syntax

TBD

Parameters

TBD

Description

This function is used to remove a previously created sampling group.

Return Value

TBD

9.9.3.5 Network Function Layer

The *Network Function Layer* is a DPAA offloading driver extension which provides a service level API in Linux user space to enable NXP customers to easily configure hardware acceleration for specific standard network services on different NXP devices directly from their user space applications. The Network Function API is **platform agnostic** and is presently available for two families of NXP devices:

- the **Layerscape** family - LS2085A
- the **QorIQ** family equipped with DPAA 1.x network functions accelerator - P devices, B devices and T devices

On QorIQ devices the Network Function Layer (a.k.a. **NF Layer** is based on the current DPAA 1.x offloading drivers.

The Network Function Layer includes the following types of network sevices. The network services supported on DPAA 1.x devices are marked in the table below.

Table 267. Network Function Layer Services

Service Name	Supported on DPAA 1.x?
Firewall	
IP Forwarding (IPv4 and IPv6)	yes
IPSec	yes
Interface and Network Namespace Management	

Network Function API runtime services work identically across the entire list of supported NXP devices.

As far as the initialization is concerned, each NXP devices family has its specific mechanism for initializing its network hardware accelerator. Due to the major differences in design and concepts, NF API could not align the initialization across device families in a clear and easy-to-use way. As a consequence, each type of device has its own initialization sequence before starting to use NF API.

In QorIQ DPAA 1.x based devices, the offloading application / integration layer is in charge of the platform initialization. The following is a most commonly used initialization sequence.

1. Interpret PCD configuration file and create PCD model (using *fmclib*, for instance)
2. Initialize network interfaces (typically using *USDPAA*)
3. Initialize the acceleration infrastructure (queues, buffer pools, classification tables, etc.) (typically using *USDPAA*)
4. Update the PCD model with runtime information
5. Apply the PCD model and configure FMan (using *fmclib* and *fmlib*, for instance)
6. Provide initialization data to the NF Layer
7. Use the NF Layer for runtime network function services offloading configuration

9.9.4 USDPAA PPAC User Manual

9.9.4.1 USDPAA PPAC Users Manual

The Packet Processing Application Core (PPAC), as a component of the USDPAA software framework that directly access queue manager (QMan) and buffer manager (BMan), helps develop and maintain common packet processing code between multiple USDPAA sample applications developed by NXP.

This document provides the following information.

- PPAC and PPAM detail.
- Layout of a PPAC/PPAM application.
- User controls to alter PPAC/PPAM application behavior.

Common packet processing code reduces maintenance costs, keeping common packet processing centralized and supporting updates done once rather than per application. Application-specific packet processing code is part of the application Packet Processing Application Module (PPAM). Together, the application specific PPAM and the common PPAC make up the complete application.

Users of USDPAA are not required to use the PPAC/PPAM model. Indeed, NXP only intends to extend PPAC capabilities to meet needs for sample USDPAA applications rather than for other generic usage.

This document assumes familiarity with the following concepts and documentation.

- QMan/BMan API Reference Manual
- USDPAA User Guide
- Linux user-space programming (POSIX, pthreads, etc.)

9.9.4.2 Overview of PPAC

The “reflector” application, developed as a small, stand-alone application for the USDPAA driver components, converted to a PPAC/PPAM application.

Origins of PPAC.

Early in USDPAA development, the “reflector” application was developed as a small, stand-alone application written on top of the USDPAA driver components. This application was eventually converted to a PPAC/PPAM application. Currently, there exists in the SDK another application, called hello_reflector, which is a new version of that stand-alone application.

the reflector application is very simple in terms of its packet processing logic (it flips Ethernet and IPv4 headers in regular IPv4 packets and forwards them back out the interface they arrive on, whilst discarding everything else), it facilitated and continues to facilitate the development, testing, and benchmarking of many generic aspects of packet-processing applications, not least of which are:

- parsing and enacting device configuration.
- driver initialisation.

Goals of the PPAC Users Manual.

With the extension of configurability and addition of features to the basic reflector application, and the requirement for other USDPAA packet-processing applications that share many of the same “general” requirements mentioned above, it was determined that the generic packet-processing application logic in reflector should be separated from the logic implementing the reflector-specific packet-processing “decision”.

Definition of PPAC and PPAM

The division of the packet-processing applications into a common, general infrastructure and application-specific components gives rise to the following two acronyms that now make up any PPAC-based application.

- PPAC: Packet-Processing Application Core. This is the generic application framework, implementing all of the “generic aspects of packet-processing applications” listed above. In the simplest case (the reflector application), this is essentially everything except the logic that flips the packet headers and selects the input interface as the forwarding destination. In particular, this includes the main() function .
- •PPAM: Packet-Processing Application Module This specialises PPAC into a “real application” by implementing the missing piece – namely the “packet-processing” specifics of the desired application. Each PPAM is compiled and linked with the PPAC component, but produces a stand-alone (and PPAM-specific) application binary.

Object Orientation

For some of the discussion that will follow, it may be helpful to use an object-oriented metaphor where PPAC is a base-class for packet-processing applications such that the packet-processing function is a pure virtual method (which is to say, non-existent and so must be implemented by derived classes). In this metaphor, PPAC-based applications are instantiations of derived classes, called PPAMs. Now all of this is implemented in C and the object-oriented metaphor should not be taken too literally, but it may help as an illustrative tool.

Limitation of Scope

PPAC supports a limited set of features; the application framework does not provide a solution for all conceivable USDPAA-based applications. PPAC provides as much consistency as possible for the packet-processing applications that are bundled with the USDPAA component of the SDK. That is, PPAC delivers a consistent user experience in both the look-and-feel and the elimination of code duplication. The scope and complexity of PPAC is intentionally limited to the current development, testing, and benchmarking requirements of USDPAA and the applications bundled with it. In particular, it is more important that PPAC (and PPAM) code be sufficiently comprehensible that application authors can understand how it works, than to provide a complete infrastructural solution for all potential USDPAA-based applications. With this in mind, please see the

"Chronology of a DPAA application" section, which attempts to provide pointers to key sections of PPAC code specifically to help with the development of non-PPAC applications.

Performance Challenges

Any abstraction underlying USDPAA applications needs to avoid imposing additional levels of function calls or other indirection. Eg. for 64 byte packets, when using between 1 and 4 CPUs on a p4080 DS, the peak processing rate of reflector application averages out to approximately 170 CPU cycles per-packet. An ad-hoc experiment to add just one extra level of indirection to that processing path introduced an additional overhead of ~20 cycles, causing a 12% performance degradation.

The same concern for function calls also applies to the data structure relationships between the PPAC and PPAM components. Use of pointers to relate discontiguous data-structures would necessarily lead to additional indirection and latency in the fast-path processing logic.

As it happens, splitting the fast-path logic of a data-path application into an abstraction layer (PPAC) and an application-specific layer (PPAM) whilst unifying the corresponding data-structures and without introducing any additional level of function calls is not impossible, but nor is it trivial.

9.9.4.3 Overview of PPAC Method and Implementation

the PPAC/PPAM interface is implemented by a strategic use of inlining.

Method

The reasons mentioned above should help explain why the PPAC/PPAM interface is implemented by a strategic use of inlining. It has been kept as simple as reasonably possible, but is clearly less straightforward than it would be if the afore-mentioned performance considerations were not a factor. The resulting implementation is organized in such a way that the compiler is able to inline the fast-path code of PPAC and PPAM together, as though they were written as a single (or "flat") application. As such, the PPAM version of reflector has no performance degradation relative to earlier non-PPAM versions, despite the PPAC/PPAM split. Note that all non-performance-critical code is compiled and linked conventionally within the PPAC library, without inlining. The application PPAM determines for itself how much code to implement within the inlining scope.

From both the data-structure and function-call points of view, the inlining relationship between PPAC and PPAM needs to resolve a circular dependency:

- PPAM within PPAC: the fast-path PPAC packet-processing logic needs to "compile in" the PPAM packet-processing logic – i.e. to have the compiler expand the PPAM-specific packet-processing logic "inline". Similarly the PPAC data-structure representing the interface and FQ state being handled needs to encompass any corresponding PPAM-specific state. I.e. the combined data-structures need to be declared statically rather than linked via indirection.
- PPAC within PPAM: the PPAM packet-processing logic will invariably need to issue one or more enqueue/transmit operations (or a release/drop operation) as a result of its packet-processing decision, and these operations must necessarily be coordinated by PPAC (otherwise generic mechanisms like buffer-management, flow-control, [etc] cannot be coordinated). So any PPAC-provided functions to be used by the PPAM packet-processing logic will need to be expanded "inline".

Thus, for at least a subset of the PPAC and PPAM code, there will be two layers of inlining; PPAC within PPAM within PPAC. The following diagram shows the behaviour of a PPAC-based application where maximum inlining of the packet-processing code is used (this is the case with the reflector application).

By way of example, the reflector application presents a very minimal PPAM component, essentially the "header-flipping" function, and so it presents only the one C source file that is used to inline the PPAC machinery and compile within that "inlining" scope. The IPFwd application on the other hand implements significant components of a network stack and routing logic, so much of its logic (including some that is used in the packet-processing fast-path) is conventional C code without inlining. The fact remains that the PPAC abstraction itself does not contribute any additional functional indirection, in order to retain the property of providing no performance overhead relative to an equivalent application written without the use of such an abstraction.

The following diagram illustrates a PPAC-based application where only a subset of the packet-processing code is inlined. This example proposes that each FQ carries packets for one or more network flows (due to classification and hashing in FMan), and that the PPAM associates each such FQ with state to implement a "recently-processed flow cache" (or "RPFC" as we'll call it for the purposes of this illustration), which in its simplest form would be a single-entry. It's worth noting that if

network traffic is classified/hashed into multiple Rx FQs, then the probability increases that consecutive packets on a given FQ are from the same flow. If the packet matches a flow in the RPFC then packet-processing will complete entirely within the inlined/optimised code. Furthermore, if FQ context-stashing is enabled, then this RPFC state would be pre-positioned in the CPU's L1 or L2 cache and so packet-processing would complete without any memory latencies. The “slow path” is the case where the packet does not match in the RPFC, the processing of the packet will then involve code that is not inlined into the packet-handler, and will likewise use state that is not necessarily present in processor cache.

Implementing a New PPAM

The upcoming sections provide a guide to the noteworthy PPAC files, data-structures, and interfaces, and also enumerate those required of a minimal PPAM application. Additionally, the “reflector” application should be used as a reference example to understanding this interface and for starting out new PPAM applications, and indeed could be copied and modified to begin doing such work due to its simplicity.

As was mentioned at the start of this document, such descriptions are provided to enable creation of quick sample applications that require the same common packet processing as other USDPAA sample applications. The following sections also help users understand the implementation of PPAC/PPAM sample applications so that they can extract any useful capability there into their own non-PPAC application.

About the Upcoming Document Sections

In the upcoming sections of this document, the PPAC/PPAM specifics will be introduced in the following order;

- PPAC files: this section will document the files that make up PPAC and describe their characteristics.
- PPAM files: this section documents the minimal set of files that a PPAM (i.e. PPAC-based application) needs to provide.
- Packet-processing data structures: this section documents the data types used in PPAC-based applications, which necessarily includes the sub-types to be implemented by PPAMs.
- PPAM-provided functions: this section describes how PPAM can implement its data-types and the corresponding handler functions that are invoked by the PPAC infrastructure.
- PPAC-provided functions: this section describes those PPAC functions that can be called from within PPAM implementations. Most interestingly, this describes the interfaces available to PPAM packet-handling logic for the transmitting or dropping of frames.

9.9.4.4 PPAC Files

The PPAC abstraction comprises the following five (5) files.

File: apps/include/ppac_interface.h

This header declares the network interface structure, “struct ppac_interface”, which combines the PPAC and PPAM structures into one, thus it requires that the PPAM declarations already be defined. This type encompasses all Rx and Tx FQs.

File: apps/include/ppac.h

This header declares a variety of definitions required by both PPAC and PPAM logic, which includes:

- pre-compiler symbols controlling parameters and options for PPAC compilation.
- pre-declarations of PPAM functions to be called by PPAC code.
- pre-declarations of PPAC functions to be called by PPAM code.
- pre-declarations of PPAC functions called between the code that is inlined into PPAM and the code that is compiled in to the PPAC library.
- PPAC inline code that needs to be available at a wider scope than that of apps/include/ppac.c.
- pre-declarations of global variables required by inline functions.
- pre-declarations of global variables representing weakly-linked PPAC constants (ie. that a PPAM can override).

File: 3.3apps/include/ppac.c

This “header” contains the fast-path PPAC code that needs to be expanded/inlined with the corresponding fast-path PPAM code. It also contains any other code that needs to exist at the same scope as the fast-path code. The main characteristic of this file is that it must be included exactly one time, by the PPAM code, and it must be included after PPAM has declared its own fast-path hooks (the included PPAC fast-path logic calls these PPAM hooks). This file includes:

- PPAC-defined QMan callbacks for handling dequeued frames from each class of Rx FQ. (These invoke PPAM-specific hooks which are thereby inlined into a single function by the compiler.)
- the interface manipulation code (setup, teardown, enable, disable) that binds these fast-path callbacks to their corresponding FQ objects and provides fast-path as well as setup and teardown hooks to PPAM.

File: apps/ppac/main.c

This file contains the PPAC code that can be compiled independently of PPAM and made available as a linkable library (libusdpaa_ppac.a). This includes:

- global constants and variables that are not required directly from inline fast-path logic.
- FQ, buffer pool, and CGR manipulation code (setup, teardown, etc).
- thread management (including IPC).
- buffer pool management.
- global setup and teardown (invokes the per-interface setup/teardown logic contained within apps/include/ppac.c)

File: apps/ppac/ppac.lds

This file is a linker script to be used when compiling PPAM applications. The CLI implementation in PPAC allows both PPAC and PPAM code to declare and implement commands to be added to the interface, and the underlying definitions compile these into a dedicated linker section. By linking the resulting application with this linker-script, the location and length of this linker section is known to PPAC CLI code. (The alternative to using this approach is to have PPAC and PPAM dynamically build a list of CLI command handlers, which requires a coordinated initialisation phase, whereas this linker-based mechanism is static.)

Use of this linker script is shown in the PPAM section covering <app-dir>/Makefile.am.

9.9.4.5 PPAM Files

The PPAM application may be composed of as little as one C file, and of course may be significantly more complex. The main requirement is that exactly one C file include the PPAC inline machinery contained in apps/include/ppac.c.

Other C files may include the other headers in order to share PPAC definitions as widely as required.

The three (3) files listed here correspond to those implemented by the reflector PPAM (which uses two files in order to separate some definitions into a header for the sake of clarity). A far more elaborate PPAM example can be found in the case of the IPFwd PPAM.

File: <app-dir>/ppam_interface.h

This file is defined by reflector and IPFwd PPAMs for the sake of clarity - there is no technical or other reason for such a header to exist separately from any other PPAM files. In reflector, this header contains the PPAM-specific data-structures that are pre-requisites for the definition of PPAC data-types contained in ppac_interface.h. i.e. the PPAM code includes ppam_interface.h prior to including ppac.c (which is what requires and includes ppac_interface.h). PPAM code can just as easily implement the same definitions elsewhere, so long as they are defined prior to the one-off inclusion of ppac.c.

File: <app-dir>/*.c

This section refers to the primary PPAM C file that includes the PPAC inline machinery. It must ensure that the required data-structures are defined prior to the inclusion of ppac_interface.h, and it must ensure that the required PPAM hooks are declared before inclusion of ppac.c. In the case of reflector, the data-structures are defined in ppam_interface.h as explained above, and apps/reflector/reflector.c defines and implements the PPAM hooks as inline functions prior to including ppac.c. (They only need to be pre-declared before inclusion of ppac.c if you prefer to implement them afterwards. If you don't wish to use inline functions to save function jumps, then they can be implemented in other C files and resolved by the linker.)

The PPAM must also define the symbols that are required by PPAC in order to link, though this does not necessarily need to be done within the primary PPAM C file that is including the PPAC inline machinery. In the reflector case however, these symbols are in fact instantiated in the same C file, for simplicity's sake. These symbols relate to the CLI, and as reflector adds no commands to the base commands implemented within PPAC, so the required PPAM symbols have trivial implementations.

File: <app-dir>/Makefile.am

This section presumes that the PPAM application is being built by the USDPAA build system. This need not be the case, but an external build-system would still need to address the same requirements in its own way. The following definitions are used to build and link the reflector application;

```
bin_PROGRAMS = reflector

AM_CFLAGS := -I$(TOP_LEVEL)/apps/include

reflector_SOURCES := reflector.c
reflector_LDADD := usdpaa_ppac usdpaa_syscfg usdpaa_qbman usdpaa_fman \
                   usdpaa_dma_mem usdpaa_of
reflector_LDFLAGS := $(LIBXML2_LDFLAGS) $(LIBEDIT_LDFLAGS) \
                     -T $(TOP_LEVEL)/apps/ppac/ppac.lds
```

The key points here are:

- the PPAC logic contained in apps/include/ needs to be accessible via includes of <ppac.c>, <ppac.h>, and <ppac_interface.h>.
- the application needs to link with libusdpaa_ppac.a, and by dependence needs to link with the other named libraries that provide USDPAA configuration parsing and driver functionality.
- the linker flags need to provide any dependencies for linking with Gnome Libxml2. In the SDK containing USDPAA, this is set to point to the installation directory for system libraries and to resolve with the “xml2”, “z” (zip), and “m” (math) libraries.
- the linker flags need to provide any dependencies for linking with Editline. In the SDK containing USDPAA, this is set to point to the installation directory for system libraries and to resolve with the “edit”, and “curses” (ncurses) libraries.
- the ppac.lds linker script should be used to add the array-delimitation definitions required by the PPAC CLI implementation.

When implementing a new PPAM application, the above model can be followed – simply create a new sub-directory within the build-tree, add that directory's name to the SUBDIRS definition in parent directory's Makefile.am file, and copy-paste-and-modify the above “reflector” definitions to your requirements:

- if your directory is in fact to host sub-directories with their own libraries and/or applications, then add a SUBDIRS definition to your Makefile.am file (for further information about this, look at the IPFwd reference application).
- change all occurrences of “reflector” to the name of your desired application (or if your directory is only going to host sub-directories with their own targets, then remove everything except the SUBDIRS definition described in the preceding point).
- change the “..._SOURCES” attribute to describe the C files that need to be compiled. The above example for reflector only lists one C file because that's all it contains, but less trivial applications will have more (the list should be space-separated, with back-slashes for multi-line entries).
- Extend “..._LDADD” and “..._LDFLAGS” attributes if required.

9.9.4.6 Packet-processing data structures

A descriotion of the data-structures that are used within PPAC (and PPAM) for handling network interfaces and the FQs they contain.

Within each such PPAC type, the data-structure contains a PPAM-specific equivalent, allowing PPAM to “sub-class” PPAC types for its application-specific purposes (to use the object-oriented metaphor mentioned in section 2.2.2). In section 6, these PPAM types will be described, as will the handler functions PPAM can provide for them (i.e. the “pure virtual methods” that can be implemented in “derived classes”, to continue the object-orientation imagery).

File: struct ppac_interface

(Defined in apps/include/ppac_interface.h.) This structure represents a network interface and associated state. In keeping with the object-oriented metaphor, this structure includes a PPAM-defined structure within it, “struct ppam_interface”, which the PPAM can use to define and maintain interface-wide state of its own.

This structure contains the following state:

- a pointer to information about the configuration of the FMan ethernet port corresponding to this “interface”.
- a PPAM-defined “struct ppam_interface” object for use by PPAM processing.
- an array of QMan FQ objects representing the Tx FQs for the interface.
- objects representing the unique Rx FQs associated with the interface . These structures are described subsequently.
- a linked-list of PCD ranges, each represented by the "struct ppac_pcd_range" type. Each PCD range is an array of objects representing the "hashed" Rx FQs for a policy of the interface. In high-performance datapath applications, FMan distributes most traffic to this range of FQs based on parse and classification processing.

File: struct ppac_rx_{error|default|hash}

These structures represent individual FQs that FMan enqueues frames to during Rx processing and that are dequeued to software portals for application processing. The “error” FQ receives frames due to any errors in FMan Rx processing, otherwise frames are either enqueued to one of many “hash” FQs (due to FMan parse and classify processing) or to the “default” FQ. For each structure type, the PPAC structure includes a PPAM-defined structure within it, “struct ppam_rx_*”, which the PPAM can use to define and maintain FQ-wide state of its own.

These structures contain the following state:

- the “struct qman_fq” object used with the QMan driver for manipulating the hardware FQ object as well as handling dequeued frames. The nature of the QMan driver API is such that this object is also the “FQ context” that gets stashed to processor cache if the FQ is configured for any stashing at all. This object is intentionally the first element in the per-FQ PPAC structure, because the application can control how many cache lines of “FQ context” should be stashed during dequeue operations, so any adjacent state following this object can also benefit from dequeue stashing.
- a PPAM-defined “struct ppam_rx_*” object for use by PPAM processing. As mentioned in the previous item, QMan dequeue processing can be configured to stash this state to processor cache during the dequeue operation in hardware, potentially avoiding or minimising the possibility for cache-misses in fast-path processing.

File: struct ppac_tx_{error|confirm}

These structures are similar to those described for “struct ppac_rx_*”, so the details will not be repeated here. The key difference is that these FQs are enqueued to by FMan during Tx processing and so represent the consequence of an attempt by software to forward already-processed traffic, rather the consequence of Rx processing of frames that software has not yet seen.

The “error” FQ naturally will receive any frames where FMan or QMan encountered an error during transmit (implying that the packet was not transmitted successfully).

The “confirm” FQ is intended to return frames back to software that have been successfully transmitted, but this is not a mode of operation that PPAC currently enables (nor are there currently any options to turn this on).

For current PPAC application purposes, all transmitted frames are composed of buffers sourced from BMan pools, and so the Tx FQs are configured to make FMan autonomously release all buffers from the transmitted frames back to the pools they belong to. Use of a “confirm” FQ is unnecessary here and would just degrade system performance. If an application is going to transmit traffic from buffers that do not originate from BMan buffer pools, then it may be necessary to reconfigure the Tx FQs to use the confirmation feature.

9.9.4.7 PPAM-provided Functions

PPAC/PPAM-based applications are driven by PPAC itself which implements the main() function as well as the run-to-completion functions that execute in the worker threads.

Here are listed the functions that can be implemented by a PPAM application. Application-specific behaviour of PPAM applications is determined by the way in which PPAMs implemen the interfaces that PPAC expects to exist. A subset of these interfaces are performance-critical, so as previously described they can be implemented so as to benefit from compiler inlining

When considering the object-oriented metaphor, these PPAM-provided functions correspond to pure virtual methods in the PPAC base-class that the PPAM derived class should implement

Many of these functions naturally map to the PPAM-specific structures that are embedded in each of the corresponding PPAC data structures defined in the previous section, so will be documented in the same sequence. The exceptions are the “global initialisation” and “polling” handlers, which are not scoped to any particular interface or FQ. (In object-oriented language, these latter handlers would be considered “class methods”.)

Global Initialisation

The handlers described in this section are called when initialising and cleaning the application process itself and the individual worker threads created within that process. The PPAC library declares weakly-linked versions of these interfaces, so a PPAM is not required to implement its own versions unless it needs such hooks (though if it does the PPAM-provided versions will be called instead of the PPAC-provided fallbacks).

Process Initialization and Cleanup

The “init” function is called when the application starts up (prior to creation of any network interface structures or any worker threads) and the “finish” function is called when the application is exiting (after all worker threads and network interfaces are destroyed). Any state managed by these hooks should be implemented using (non-thread-local) global variables.

```
int ppam_init(void) ;
void ppam_finish(void);
```

If ppam_init() returns non-zero, that is considered failure and application initialisation will be abandoned.

Worker Thread Initialisation and Cleanup

These functions are called when a worker thread starts up or is being destroyed. Any state managed by these hooks should be implemented using thread-local global variables, i.e. using the “__thread” gcc attribute.

```
int ppam_thread_init(void);
void ppam_thread_finish(void);
```

As usual, if the initialisation function returns non-zero, that is considered failure and so creation of the worker thread will be abandoned. Note also that thread-local QMan/BMan portals are already initialised when ppam_thread_init() is called and are not destroyed until after ppam_thread_finish() has returned, so it is safe to use portal-dependent QMan/BMan APIs within these functions.

Polling Handlers

The run-to-completion loop of each worker thread (implemented by PPAC) can optionally call a PPAM-provided polling function to allow PPAM applications t perform general-purpose processing. E.g. to implement background processing tasks, generate frames for transmit that are not in reaction to a received frame (IPC), etc. As with the global initialisation handlers, PPAC defines a weakly-linked version of this polling function, so PPAMs are not required to implement it unless they need it. There is also a thread-local global variable that PPAM code can be set non-zero whenever it wishes the run-to-completion loop to call this polling handler.

```
extern __thread int ppam_thread_poll_enabled;
int ppam_thread_poll(void);
```

If ppam_thread_poll_enabled is zero (the default), the ppam_thread_poll() function is not called from within the run-to-completion loop (minimising overhead in the case that no polling hook is required). Note that the weakly-linked version of

ppam_thread_poll() implemented by PPAC will intentionally kill the application, because it is illegal to set ppam_thread_poll_enabled non-zero unless the PPAM application implements its own ppam_thread_poll() function.

File: struct ppam_interface

This is the PPAM-specific object representing a network interface. It and its PPAC-wrapper form the “parent” for the objects that representing the individual FQs A PPAM must implement the following hooks for this object;

Initialisation

This function is called as the network interface is initialised but prior to all Rx or Tx FQ objects being initialised, so this hook is called before all ppam_rx_*_init() or ppam_tx_*_init() hooks are called for object that belong to the this interface. The parameters provide a pointer to the PPAM-specific interface state (which is uninitialised on entry and should be initialised to the PPAM's requirements), a pointer to the configuration information for this network interface, and also indicates to PPAM the numbe of Tx FQs that will be initialised for this interface;

```
int ppam_interface_init(struct ppam_interface *p,
                        const struct fm_eth_port_cfg *cfg,
                        unsigned int num_tx_fqs);
```

If this function returns non-zero, it will be interpreted as an error code and initialisation of the interface will be abandoned.

Cleanup

This function is called as the network interface is being cleaned up and after all Rx and Tx FQ objects have been destroyed, so this hook is called after all ppam_rx_*_finish() and ppam_tx_*_finish() hooks are called for objects that belong to this interface.

```
void ppam_interface_finish(struct ppam_interface *p);
```

Tx FQ Enumeration

The ppam_interface_init() function described earlier notifies the PPAM of the number of Tx FQs that will be initialised for this interface. So the purpose of this function is to notify the PPAM as each individual Tx FQID is (dynamically) allocated and initialised for this purpose. I.e. the PPAM can use the initial ppam_interface_init() hook to know how many Tx FQs the interface will have (e.g. in order to allocate a sufficiently large array, or to verify that an existing static array is large enough) and then use the subsequent ppam_interface_tx_fqid() hooks to obtain each such FQID. This process preceeds all the Rx FQ hooks described below.

```
void ppam_interface_tx_fqid(struct ppam_interface *p,
                            unsigned idx,
                            uint32_t fqid);
```

9.9.4.8 PPAM Rx and Tx

These are the PPAM-specific objects representing the Rx-related FQs of a network interface. A PPAM must implement the following hooks for these objects;

PPAM Rx Initialization

These functions are called just prior to the corresponding Rx-related FQ being initialised by PPAC. The parameters provide a pointer to the PPAM-specific FQ state (which is uninitialised on entry and should be initialised to the PPAM's requirements), a pointer to the PPAM-specific state for the interface this FQ belongs to (which will have already been initialised by the PPAM's own ppam_interface_init() function), and a pointer to the QMan dequeue-stashing configuration that will be used to initialise the FQ (the PPAM can modify this structure before returning in order to modify the stashing configuration to be applied to the FQ). Note that the “hash” function also provides an index parameter, as the “rx_hash” FQs form arrays called "PCD ranges". If the PPAM logic needs to know the number (and order) of these ranges, and the number of "hash" FQs within each of them, it can determine that from the ::list field of the "cfg" parameter passed to the ppam_interface_init() hook.

```
int ppam_rx_error_init(struct ppam_rx_error *p,
                       struct ppam_interface *_if,
```

```
                        struct qm_fqd_stashing *stash_opts);
int ppam_rx_default_init(struct ppam_rx_default *p,
                         struct ppam_interface *_if,
                         struct qm_fqd_stashing *stash_opts);
int ppam_rx_hash_init(struct ppam_rx_hash *p,
                      struct ppam_interface *_if,
                      unsigned idx,
                      struct qm_fqd_stashing *stash_opts);
```

If these functions return non-zero, it will be interpreted as an error code and initialisation of the interface will be abandoned.

PPAM Rx Cleanup

These functions are called as the network interface is being cleaned-up, each such hook is called just prior to the corresponding FQ object being destroyed. The interface-wide ppam_interface_finish() hook is last to be called once all FQs belonging to the interface have been cleaned up. The parameters match those to the corresponding _init() functions, with the exception that no stashing configuration is provided (because the FQ is being destroyed, not initialised).

```
void ppam_rx_error_finish(struct ppam_rx_error *p,
                          struct ppam_interface *_if);
void ppam_rx_default_finish(struct ppam_rx_default *p,
                            struct ppam_interface *_if);
void ppam_rx_hash_finish(struct ppam_rx_hash *p,
                         struct ppam_interface *_if,
                         unsigned idx);
```

PPAM Rx Packet Processing

These functions essentially represent the PPAM's “fast-path”, particular in the “hash” case. When processing dequeued frames, the QMan driver invokes the callback associated with the FQ object, which is implemented by PPAC as part of the “inlined” component of the code. These PPAC-implemented callbacks handle any “infrastructure” responsibilities for processing the dequeued frame and the FQ it was dequeued from (e.g. providing support for order preservation or restoration, flow-control, etc), but they defer to these PPAM-specific packet-processing hooks to examine the packets and determine what to do with them. The parameters provide a pointer to the PPAM-specific FQ state, a pointer to the PPAM-specific state for the interface this FQ belongs to (except in the “hash” case), and a pointer to the QMan DQRR entry containing the frame descriptor and other status about the dequeue operation for the frame (and the FQ it was dequeued from, e.g. whether the dequeue left empty).

If these hooks are implemented as inlines, then the compiler is able expand the PPAC and PPAM packet-processing logic into a single function layer, and many also make other optimisations possible (such as not having to prepare and pass parameters to the PPAM hooks if they're unused, etc).

```
void ppam_rx_error_cb(struct ppam_rx_error *p,
                      struct ppam_interface *_if,
                      const struct qm_dqrr_entry *dqrr);
void ppam_rx_default_cb(struct ppam_rx_default *p,
                        struct ppam_interface *_if,
                        const struct qm_dqrr_entry *dqrr);
void ppam_rx_hash_cb(struct ppam_rx_hash *p,
                     const struct qm_dqrr_entry *dqrr);
```

Note that the “hash” callback hook does not provide the PPAM-specific state for the interface, nor does it provide the index of the hash callback. These two omissions are primarily justified by the observation that this is the most performance-defining code-path and so should not include any potentially-unnecessary overheads, whether or not the packet-processing is fully inlined. Also, the “error” and “default” FQs are global to the interface and so packets that arrive on them represent events that are in some way “exceptional”, whereas packet-processing on the “hash” FQs should be the normal case and less likely to depend on interface-global state. If this is not the case and the “hash” callback does require the interface state and/or the index, then that state should be added to the “struct ppam_rx_hash” type and initialised during the ppam_rx_hash_init() hook,

ensuring that it does not need to be “computed” by PPAC for passing as a parameter, and may also benefit from stashing of the “struct ppam_rx_hash” structure during dequeue operation.

It is the responsibility of these callbacks to determine what to do with the frame and in doing so should commit to the corresponding action before returning. The APIs available for this are described in a later section called “PPAC-provided functions”, but in essence they provide “drop” and “forward” mechanisms.

PPAM Tx

As with the description of these data-structures in the previous section (“Packet-processing data structures”), the PPAM-specific functions for them are very similar to those described for “struct ppac_rx_*” and so will not be repeated here. As mentioned in the data-structure discussion, the key difference is that these FQs are enqueued to by FMan during Tx processing and so represent the consequence of an attempt by software to forward already-processed traffic, rather the consequence of Rx processing of frames that software has not yet seen. Please see that data-structure discussion for more specifics.

PPAM Tx Initialization

```
int ppam_tx_error_init(struct ppam_tx_error *p,
                       struct ppam_interface *_if,
                       struct qm_fqd_stashing *stash_opts);
int ppam_tx_confirm_init(struct ppam_tx_confirm *p,
                         struct ppam_interface *_if,
                         struct qm_fqd_stashing *stash_opts);
```

PPAM Tx Cleanup

```
void ppam_tx_error_finish(struct ppam_tx_error *p,
                          struct ppam_interface *_if);
void ppam_tx_confirm_finish(struct ppam_tx_confirm *p,
                            struct ppam_interface *_if);
```

PPAM Packet Processing

```
void ppam_tx_error_cb(struct ppam_tx_error *p,
                      struct ppam_interface *_if,
                      const struct qm_dqrr_entry *dqrr);
void ppam_tx_default_cb(struct ppam_tx_confirm *p,
                        struct ppam_interface *_if,
                        const struct qm_dqrr_entry *dqrr);
```

9.9.4.9 PPAC Provided Functions

Describes the functions that PPAC makes available for use from PPAM application code.

PPAC Packet Processing

The PPAM packet-processing hooks must adhere to a simple set of rules when processing dequeued frames in order to ensure sane functioning of the system. For every packet examined, exactly one of two mutually-exclusive actions must be taken prior to returning from the packet-processing hook; “drop” or “forward”. (The “forward” APIs are called “send”, for the sole reason that the latter has fewer letters.) The “drop” case is very simple, while the “forward” case presents some options..

Note that these APIs assume that no intermediary processing of the frame is required, and in particular do not prescribe any way of dealing with accelerator hardware (cryptographic, pattern-matching, or otherwise). See section 7.2 for more information.

PPAC Packet Processing - Drop a Frame

If a PPAM packet-processing hook has examined a frame and determined that it should not be transmitted, it must drop it using the following API. The parameter is the frame-descriptor to be dropped, which would usually be “&dqrr->fd”, where “dqrr” is the parameter passed to the packet-processing hook.

```
void ppac_drop_frame(const struct qm_fd *fd);
```

Note that this function is actually implemented as part of the PPAC inline machinery, and so just as the PPAM hook can be inlined into the PPAC packet-processing code, this “drop” action will likewise be inlined into the processing chain, and permit the compiler to look for any possible optimisations.

PPAC Packet Processing - Forward a Frame

If a PPAM packet-processing hook has examined a frame and determined that it should be forwarded, it must use the following API exactly once. The parameters specify the frame-descriptor to be forwarded (see the ppac_drop_frame() description above for more info about this parameter), as well as the FQID of the Tx FQ to which it should be forwarded. Please refer back to the “PPAM-provided functions”, and specifically the “Tx FQ enumeration” subsection to recall how a PPAM is notified of the Tx FQIDs for each of the network interfaces. This information provided during initialisation should be organised by the PPAM implementation in order for it to be able to determine target FQIDs when processing packets.

```
void ppac_send_frame(u32 fqid, const struct qm_fd *fd);
```

As with dropping a frame, this function is also implemented by PPAC as an inline, ensuring that it can be compiled (and potentially optimised) into the packet-processing logic.

PPAC Packet Processing - Forwarding Multiple Frames

If a frame needs to be forwarded multiple times (e.g. for multicast), ppac_send_frame() must still be called exactly once. Supplementary transmit actions are achieved by using the following API;

```
void ppac_send_secondary_frame(u32 fqid, const struct qm_fd *fd);
```

The parameters are the same as for ppac_send_frame().

PPAC Packet Processing - Dealing with Accelerators

As mentioned in the previous section, the current packet-processing functionality in PPAC provides no support for accelerators. It is likely that future versions of PPAC will provide something in this regard, but for now interactions with accelerators is presumed to be outside the scope of the PPAC infrastructure, and so PPAMs will communicate with accelerators via their driver interfaces. The upshot of this is that any flow-control or other infrastructural support within PPAC will be “blind” to frames and frame queues going between the application and the accelerator hardware.

If a PPAM packet-processing function chooses not to make a drop-or-forward decision immediately, then it must do so at a later time in order to avoid leaking the frame (and all buffer resources associated with it). This delayed transmit action will presumably occur from within the dequeue callback for the FQ that brings the accelerator's response back from the accelerator.

PPAC Packet Processing - Accelerator Limitations

The use of accelerators, or indeed any other deferral by the PPAM packet-handler to issue a drop-or-forward action “at a later time” infers some limitations on PPAC functions.

- ORP (Order Restoration) support must be disabled in PPAC, the infrastructure for ORP relies on the drop or forward PPAC interfaces being called from within the PPAM's packet-handling function.
- Order-preservation support must also be disabled in PPAC, for much the same reasons as for ORP.

PPAC Packet Processing - Application Generated Frames

It is possible for applications to generate new frames for transmission rather than strictly forwarding received frames. E.g. the polling hooks available to PPAM (see section 6.2) might be used by the PPAM application to generate test traffic, send work-items to accelerators, respond to IPC requests from other threads or applications, or manage the migration of traffic between USDPAA and non-USDPAA interfaces (e.g. wireless). The limitations described in section 7.2.1 with respect to

accelerators apply here if the transmissions are to go out the USDPAA-managed network interfaces. Moreover, if the transmissions are targeted to those network interfaces, then the frame descriptors must reference buffers that are sources from BMan buffer pools (as the network hardware will autonomously release them back to BMan post-transmission).

PPAC Packet Processing - Application Terminated Frames

Frames that are received via the PPAC-provided packet-handling interface may be fully-consumed by the PPAM application, the assumption is not that they are strictly for forwarding. However, the current PPAC implementation does present some limitations in this regard;

- the frames that are not forwarded must instead be "dropped" from the PPAC perspective (by calling the ppac_drop_frame() function), meaning that the BMan buffers within them will be deallocated back to their respective buffer pools.
- if the application intends to use the packet contents after the packet has been "dropped", its contents must be copied to other memory before doing so. (It is possible that future PPAC enhancements will provide a means to avoid this limitation.)
- if the application intends to delay dropping the frame until it has finished with it, meaning that it will not be dropped before returning from the packet-handling routine, then the same limitations that are mentioned in section 7.2.1 apply here (for the same reasons).

9.9.4.10 PPAC Setting

PPAC-based applications are compiled using a certain set of options that are, for the most part, defined in the header located at apps/include/ppac.h. The following sections describe the most useful options for modification, if alternative application behaviour is desired.

PPAC Order Preservation

Order preservation is a functionality of the QMan software portal interface that allows processing of Rx FQs across multiple portals to retain order when transmitted corresponding Tx FQs. The technique only applies to frames dequeued from a given Rx FQ that are all transmitted out the same Tx FQ (which is the case for "reflector", and also the case for "IPFwd" when frames are from the same flow). The mechanism requires two QMan features, "HOLDACTIVE" and "enqueue DCA". The former ensures that a FQ that has been dequeued to a software portal from should remain bound to that portal until all the corresponding DQRR entries have been consumed. The latter ensures that a DQRR entry is consumed by QMan itself once it has dispatched the corresponding enqueue (Tx) command. Together, for any given Rx/Tx FQ pair, the processing via pool-channels and multiple CPUs does not allow frame processing to get out of order. (For more information on this feature, consult the QMan/BMan API Guide.)

Use of "HOLDACTIVE" is mutually exclusive with another QMan option "AVOIDBLOCK", which is selected by default in PPAC. So to enable order-preservation, one must change the settings from :

```
#undef PPAC_HOLDACTIVE
#undef PPAC_ORDER_PRESERVATION
#define PPAC_AVOIDBLOCK
to;
#define PPAC_HOLDACTIVE
#define PPAC_ORDER_PRESERVATION
#undef PPAC_AVOIDBLOCK
```

PPAC Order Restoration

Order restoration is a feature of the QMan hardware that allows frame enqueue operations to be re-assembled in an ORP ("Order Restoration Point") prior to enqueuing onto the destination FQ. (ORPs are in fact FQ objects in hardware that are configured for use as restoration contexts). The subject of ORP (and its various behavioural parameters) is beyond the scope of this document. Please consult the QMan Reference Manual for more detail.

To enable order restoration, one must change the setting from;

```
#undef PPAC_ORDER_RESTORATION
to;
#define PPAC_ORDER_RESTORATION
```

PPAC Monitoring Rx/Tx Fill-Levels via CGR

If CGR-based monitoring is enabled, then two Congestion Group Records will be configured, with all Rx FQs for all interfaces being subscribed to one, and all Tx FQs being subscribed to the other. The CGRs are not configured to perform any flow-control (i.e. no tail-drop nor WRED options are enabled), so this simply allows the user to monitor the overall fill-level of frame queues in the system, in particular to determine whether build-up is occurring before or after the software-processing phase. The thresholds used for the CGRs are determined from the two constants also defined in ppac.h, PPAC_CGR_RX_PERFQ_THRESH and PPAC_CGR_TX_PERFQ_THRESH. These constants, combined with the number of FQs, define the thresholds for CGR congestion-entry. QMan in turn defines the CGR exit-threshold to be 7/8 the entry-threshold (to provide hysteresis), and so these combined entry/exit events will be logged to stdout independently for the Rx and Tx CGRs.

An extra command, “cgr”, becomes available in the CLI when this feature is compiled in, which will query and display all the fields of both CGRs. Note however that this option introduces extra latency, and more critically, extra contention within the system. This is because QMan must lock the CGR for each enqueue and dequeue event that relates to it, meaning that the forwarding of a single packet through the system requires 2 lock/unlock pairs for each CGR (thus 4 lock/unlock pairs). A small but noticeable performance degradation should be expected when running in this mode. (Real-world use of CGRs would not subscribe all Rx/Tx FQs from all interfaces to a single CGR, so this scalability issue should not be a concern for production software usage of CGR-based congestion management.)

To enable this feature, change:

```
#undef PPAC_CGR
to;
#define PPAC_CGR
```

PPAC Other Settings

Many other settings used by PPAC (and thus PPAC-based apps) are defined in ppac.h but they are less intended for ad-hoc manipulation than those mentioned above. However a curious user may wish to examine some of these, and perhaps search out their usage within the source-code, in order to see how they are used and explore some of the driver interfaces and application design in this way.

9.9.4.11 PPAC Buffers

When starting up, PPAC applications seed the 3 buffer pools that the FMan is configured to use for Rx processing.

To improvement restartability, the pools are first drained of any stale contents, after which they are seeded using allocations from the “/dev/fsl_usdpaa_shmem” DMA device, which is described in the USDPAA User Guide. The buffer pool IDs that must be used, and the size of the buffers they must each hold, is required to match the settings in FMan – these are currently hardcoded in the include/internal/conf.h header, and must be kept in-sync with the FMan settings.

The three buffer pools initialized and used by PPAC (and the default USDPAA configuration of FMan) have the following attributes;

Table 269. Buffer Pool attributes

Buffer Pool ID (BPID)	Buffer Size (used by Fman)	Number of Buffers
7	320	0
8	704	0
9	1728	0x2000

When processing frames, buffers are allocated by FMan on Rx and then released by FMan after Tx.

The current default buffer pool settings from include/internal/conf.h follow;

```
#define DMA_MEM_PATH            "/dev/fsl-usdpaa-shmem"
#define DMA_MEM_BP1_BPID        7
#define DMA_MEM_BP1_SIZE        320
#define DMA_MEM_BP1_NUM         0 /* 0*320==0 (0MB) */
#define DMA_MEM_BP2_BPID        8
#define DMA_MEM_BP2_SIZE        704
#define DMA_MEM_BP2_NUM         0 /* 0*704==0 (0MB) */
#define DMA_MEM_BP3_BPID        9
#define DMA_MEM_BP3_SIZE        1728
#define DMA_MEM_BP3_NUM         0x2000 /* 0x2000*1728==13.5MB */
#define DMA_MEM_BPOOL \
        (DMA_MEM_BP1_SIZE * DMA_MEM_BP1_NUM + \
        DMA_MEM_BP2_SIZE * DMA_MEM_BP2_NUM + \
        DMA_MEM_BP3_SIZE * DMA_MEM_BP3_NUM) /* 13.5MB */
```

And the application implements the seeding of these buffers according to the following structure in apps/ppac/main.c;

```
/* Seed buffer pools according to the configuration symbols */
const struct ppac_bpool_static {
        int bpid;
        unsigned int num;
        unsigned int sz;
} ppac_bpool_static[] = {
        { DMA_MEM_BP1_BPID, DMA_MEM_BP1_NUM, DMA_MEM_BP1_SIZE},
        { DMA_MEM_BP2_BPID, DMA_MEM_BP2_NUM, DMA_MEM_BP2_SIZE},
        { DMA_MEM_BP3_BPID, DMA_MEM_BP3_NUM, DMA_MEM_BP3_SIZE},
        { -1, 0, 0 }
};
```

9.9.4.12 Chronology of a DPAA application

Provides pointers to key locations in the PPAC code where tasks are performed that any USDPAA-based application would need to implement, in particular for applications that will not be based on PPAC or anything similar.

For more information on each of the named APIs, such as parameters, return codes, semantics, [etc], please consult the relevant documentation (e.g. the “USDPAA User Guide”, the “Queue Manager, Buffer Manager API Reference Manual”, etc.).

DPAA Application - Global Initialization

This section covers the steps performed prior to initialising USDPAA threads, i.e. prior to binding pthreads to QMan and BMan portals.

DPAA Application - Global Initialization for Device Tree Parsing

The USDPAA “of” driver needs to parse the device-tree before any dependent driver or application layers are activated. This is performed via of_init(), as seen early in apps/ppac/main.c:main(). This does not do any configuration of devices, it simply parses the information in the device-tree in order to make it available for the various device drivers that will subsequently initialise. (Note that “of” refers to the “Open Firmware” standard upon which u-boot and linux device-tree handling is based, and the APIs for manipulating such device-trees are typically prefixed with “of_” in those environments too.)

DPAA Application - Global Initialization for Network Device Configuration Parsing

The application-level “usdpaa_netcfg” interface parses the device-tree and the two XML files used with FMC to program the FMan devices. This interface is in turn built on top of the lower-level interface associated with the USDPAA “FMan” driver (and initialisation of “usdpaa_netcfg” will implicitly initialise the “FMan” driver layer). See include/usdpaa/{usdpaa_netcfg.h,fman.h}, which is used by PPAC in apps/ppac/main.c:main() where it calls usdpaa_netcfg_acquire().

USDPAA apps should choose to bypass the “usdpaa_netcfg” layer and optionally the “FMan” driver layer too if it wishes to implement its own parsing of the configuration, or even obtain the configuration information from another source.

DPAA Application - Global Initialization for QMan and BMan

The USDPAA QMan and BMan drivers currently initialise some global resources using compiled-in constants. This setup is driven by the qman_global_init() and bman_global_init() APIs. This is done in apps/ppac/main.c:main().

DPAA Application - DMA Memory Initialization

The USDPAA “dma_mem” driver initialises and manages access to a memory-mapped region of physically-contiguous memory with trivial virtual/physical address conversion and no page-faulting. This is via the dma_mem_setup() API, as called in apps/ppac/main.c:main().

DPAA Application - Thread Initialization

This section covers the setup of USDPAA threads.

DPAA Application - Portal Interrupts

A running thread can request the allocation and configuration of a thread-affine QMan or BMan portal using the qman_thread_init()/bman_thread_init() APIs. This is done in apps/ppac/main.c:worker_fn(), after the thread has been spawned from apps/ppac/main.c:worker_new(). Note that this specifies to the QMan/BMan drivers the CPU that the portals need to be affine to, but it is up the application when (or even if) to bind the thread to the nominated CPU. In the case of PPAC, this is performed immediately prior to initialising the portals, via the pthread_setaffinity_np() API.

DPAA Applicaiton - Thread-local Enqueue Objects

Rather than using distinct QMan FQ objects for each FQID that it wishes to enqueue to, PPAC instead declares a thread-local, global FQ object for enqueuing to any FQID. This is done in apps/ppac/main.c:worker_fn(), search for “local_fq”. This means that PPAC and PPAM logic only needs to know and specify the FQIDs of the various Tx FQs for each interface rather than tracking objects for each such FQ. Moreover, it also avoids the sharing of Tx FQ objects across multiple threads (and thus across CPUs) unnecessarily, which is to avoid the potential for cache-coherency overheads. This has its disadvantages too – when PPAC performs an enqueue, it must directly substitute the FQID within the thread-local FQ object. Also, in the event of any ERNs (enqueue rejection notifications), the PPAC-implemented callback cannot rely on the FQ object to identify the FQID (or interface) which relates to the failed enqueue, so would have to interpret that information from the FQID contained in the notification. The PPAC currently does no such demuxing and simply drops any frames that are rejected.

DPAA Applicaiton - Portal dequeue mapping of pool-channels

The network interface configuration mentioned earlier, obtained via usdpaa_netcfg_acquire(), can be used to identify the QMan pool-channels that the network interfaces' Rx FQs are scheduled to. Using this information, the application can determine the pool-channels it wishes the initialised portal to dequeue from. The PPAC code computes this mask in apps/ppac/main.c:main() (search for “sdqcr”), and then each thread applies it to its QMan portal in apps/ppac/main.c:worker_fn() via the qman_static_dequeue_add() API.

DPAA Application - Thread run-to-completion loop

This section covers the run-to-completion loop of a USDPAA application thread once it has been initialised. For USDPAA, the QMan and BMan portals are usually set in run-to-completion mode, meaning that none of the portal interrupt sources are enabled and all portal duties are configured to be processed by polling instead of interrupt-handling. The expectation is therefore that the application thread will repeatedly “poll” the portals within the core-loop of its execution.

DPAA Application - Fast Path Processing

For QMan, the run-to-completion processing is split into two halves. The “fast” part deals with processing of the portal's dequeue ring (DQRR), because this is the most speed-critical mechanism and also the most hardware-optimised. In particular, with portal ring-stashing enabled (as it is by default in USDPAA), processing of this ring rarely involves any cache-stalls, whether there is dequeue work available to be processed or not, so it can be executed quickly and in a tight-loop without any large fixed overheads. (Processing that involves reading a cache-inhibited register, on the other hand, will always have a minimum overhead due to the latency of issuing a read to hardware and waiting for the response.)

So the core loop of PPAC-based application threads call qman_poll_dqrr() frequently, such that other kinds of processing are far less frequent. Or put another way, most iterations of the thread's run-to-completion loop do nothing except call qman_poll_dqrr(). See apps/ppac/main.c:main(), the calls to qman_poll_dqrr().

DPAA Application - Slow Path Processing

For QMan, the other side of run-to-completion processing encompasses “everything else”, i.e. all portal processing except DQRR. This is because polling for other processing duties, even if there is no work to be done, will require a minimal overhead in order to interrogate hardware. In the case of BMan, there is no “fast” path as such, as there is no analogy for DQRR. The speed-critical processing of releasing buffers to (and acquiring buffers from) buffer pools does not require maintenance from the run-to-completion loop (they are command based and self-maintaining).

So PPAC-based application threads calls qman_poll_slow() and bman_poll_slow() within the run-to-completion loop, but use a throttling scheme to ensure that their overheads are not incurred on every iteration. See apps/ppac/main.c:main().

DPAA Application - Packet Processing

The task of examining a packet (or frame) and determining the appropriate action is triggered by the “Fast path processing” mentioned above. When qman_poll_dqrr() is called and dequeued frames are discovered and handled, callbacks will be invoked for the FQ objects to which the dequeued frames belonged. So packet-processing occurs within callbacks registered with FQ objects. In the case of PPAC, the main example for the performance-critical case is in apps/include/ppac.c:cb_dqrr_rx_hash(). However, this handler defers all the significant work to the PPAM hook, as indeed that is what PPAMs are - they implement the packet-handling specifics. As can be seen from cb_dqrr_rx_hash(), it calls ppam_rx_hash_cb() to process the packet. See apps/reflector/reflector.c:ppam_rx_hash_cb(). This in turn defers all work to apps/reflector/reflector.c:reflect_cb() (because in some configurations, the same processing is performed on the “rx_default” FQ too, so the implementation is factored out).

This packet processing uses dma_mem_ptov(qm_fd_addr()) to extract the frame address from the frame-descriptor (whether the frame descriptor also specifies an offset or not) and converts it from a device-physical to a usable pointer/virtual address. The packet is then examined, and the outcome is either that the packet is dropped via ppac_drop_frame() or it is forwarded via ppac_send_frame().

Note also that in the case of the frame being forwarded, the FQID to which it is transmitted is derived from the PPAM's own FQ state that was initialised during the network interface initialisation phase. In particular, the Tx FQIDs for each interface are captured as the interface initialises, so that when the Rx FQs for the same interface are initialised, the PPAM-specific state immediately makes a fixed assignment for each Rx FQ to one of the Tx FQs. (As a “reflector” this is possible because all packets need to go back out the interface they come in on. This is quite different to “IPFwd” and other forwarding applications of course.)

9.9.4.13 A non-PPAC comparison, “hello_reflector”

A stand-alone version of reflector was created in order to illustrate how to move from a PPAM-based prototype to a stand-alone code-base for development of stand-alone user applications. To emphasise its “hello world” nature, this application is called “hello_reflector”.

"hello reflector" is located in apps/hello_reflector/. Many of the features of the PPAC/PPAM version are missing from the stand-alone version in order to keep it simple (and besides which, those features are provided from the PPAC infrastructure rather than from the reflector PPAM itself, so re-implementing those features in a new, stand-alone form would not illustrate anything useful). The “hello_reflector” code is also intended to be self-documenting, so there is no user guide for it nor will it be discussed in great deal here. However, comparing the reflector PPAM code with hello_reflector should make it clear that the packet-processing is fundamentally the same. Furthermore, the single hello_reflector C file implements all the initialisation described in section 10 outside of PPAC, so should be instructive for those looking to write stand-alone (non-PPAC) USDPAA applications.

9.9.5 USDPAA Reflector and PPAC User Guide SDK

9.9.5.1 Introduction

The User Space Datapath Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document describes the "reflector" application and the PPAC abstraction on which it is built, both contained in the USDPAA package. This application serves as a reference example for working with the USDPAA interface, as well as providing

a benchmark for USDPAA system performance. More elaborate PPAC-based applications (such as "ipfwd") have their own user guide documents, but do not repeat the PPAC discussion found here.

Furthermore, a stripped-down "hello_reflector" application exists within USDPAA that is implemented without using the PPAC abstraction. This application is missing many of the features of PPAC, but is intended to provide a usable comparison between PPAC-based and stand-alone applications, eg. for customers prototyping with PPAC and then looking to develop stand-alone production code. As "hello_reflector" is very simplistic, the source code is self-documenting and it will not be discussed in any detail here. A short guide to executing the "hello_reflector" application will be provided at the end of this document.

A variant of hello_reflector called hello_reflector "short circuit" is also provided which basically tests the sanity of the hardware path for the packet flow by this way without any processing by the core on the received packets.

9.9.5.1.1 Intended audience

This document is intended for software developers and system architects who work with the USDPAA framework.

The material is technical in nature. The reader is assumed to be familiar with:

- General Linux software development, operation, and configuration for Power architecture devices in particular.
- Familiarity with the concept of device drivers and their role in operating systems.
- Linux network administration and use.
- The NXP Linux SDK for DPAA-based SoCs.
- At least broadly, the DPAA hardware blocks.
- The USDPAA User Guide document (this document covers only the reflector application).
- Linux UIO (User space I/O) driver infrastructure (USDPAA drivers for QMan/BMan portals use the standard UIO mechanisms for memory-mapping and interrupt-handling).

The P4080 was the first NXP SoC to incorporate the DPAA. As such, it is used in many examples. However, USDPAA is intended to apply in the same manner to all DPAA-based SoCs.

9.9.5.1.2 Change history

Table 270. Change History

Version	Updates
1.0	Creation of reflector UG for phase1 release, based on the general UG prepared for the phase0 release. - tidy up of text - describe phase1-specific additions; PPAC/PPAM, IRQ mode, etc.
1.1	Add section on testing reflector using a Linux PC.
1.2	Fix minor typographical errors.
1.3	Updates for v1.0 release. - split PPAC-common material from reflector specifics - corrected and updated buffer pool descriptions

Table continues on the next page...

Table 270. Change History (continued)

Version	Updates
1.4	Updates for v1.1 release - document "hello_reflector" - document cmd-line args and environment-variables - update sample console output - update buffer definitions

9.9.5.2 Overview of reflector

The reflector application is a simple packet-processing USDPAA application. The main purpose of USDPAA's user space drivers (as opposed to more conventional kernel-mediated device access) is raw I/O performance, and the reflector application focuses on this. Reflector is basically all I/O - it receives and sends frames, but does very little processing on them. It demonstrates the I/O capabilities of the DPAA hardware and corresponding user-space drivers.

9.9.5.3 Overview of PPAC

The source code to reflector has been reorganized into two parts; the "PPAC" (Packet-Processing Application Core) and a "PPAM" (Packet-Processing Application Module). The idea behind this is that many packet-processing applications (particularly any variations on the theme of network forwarding) would likely only differ from reflector in the way they make their "forwarding decision". The essential difference is the logic that looks at the packet and determines what to do with it. The PPAM portion implements this application specific logic. On the other hand, the PPAC component represents the common infrastructure to support such PPAMs; initializing devices, handling flow-control, implementing a CLI (Command-Line Interface), managing threads and buffers, [etc]. For USDPAA demonstration applications, the use of a common PPAC component allows for easier code development and maintenance and a uniform application look and feel.

Users are not obliged to use PPAC for their USDPAA application development. Moreover users could choose to implement PPAC-based applications (eg. for quick prototyping) and then later port their work to a stand-alone product. A stand-alone version of reflector, called "hello_reflector", has been provided to illustrate this principle. Please note that the emphasis in "hello_reflector" is on simplicity, so it does not (re)implement stand-alone equivalents of all the features and flexibility of the PPAC environment.

Additionally, if the user only wants to first check the sanity of the hardware path for the packet flow and later wants to send the packets to the core for the processing, he can first run hello_reflector in "short circuit" mode and if the traffic is received back on the hardware path, he can now run hello_reflector and so involve the core in the packet processing.

In "short circuit" hello reflector, packets are dequeued from the interface and received on Rx FQs. These packets are then sent out from the QMAN channel on which Tx FQs are scheduled.

9.9.5.4 PPAC details

However at an implementation level, there is a limit to the degree of abstraction one can obtain. E.g. for 64 byte packets, using between 1 and 4 CPUs on a p4080 DS, reflector processing averages out to approximately 170 CPU cycles per-packet. Adding just one extra level of indirection to that processing path can add enough overhead to make a visible performance difference to the application (one such ad-hoc experiment showed an additional overhead of ~20 cycles, causing a 12% performance degradation). For this reason, the PPAC/PPAM interface is implemented by a strategic use of inlining. The resulting PPAC implementation and interface is organized in such a way that the compiler is able to inline the fast-path code of PPAC and PPAM together, as though they were written as a single (or "flat") application. Indeed, the PPAM version of reflector, despite the PPAC/PPAM split, has no performance degradation relative to earlier non-PPAM versions.

9.9.5.4.1 IRQ mode for sleeping when idle

A new feature of PPAC (and thus all PPAM applications like reflector and "ipfwd") is support for interrupts and sleeping. As USDPAA's QMan and BMan drivers use the standard Linux UIO subsystem, the behavior of interrupt-handling is in keeping with UIO semantics. Note that the qman_irqsource_*() and bman_irqsource_*() APIs must be used prior to entering a blocking read(), select(), poll(), [etc] to configure the relevant QMan/BMan portals to report activity via interrupt. Failure to do so may cause the application to block indefinitely waiting for interrupts that won't occur because the portals are configured for polling. Similarly, when leaving IRQ/blocking mode to run in polling mode (and in particular to post-process the events that caused interrupts), one must again use the "irqsource" APIs, this time to configure the portals to be processed by polling APIs rather than interrupts.

For an illustration of PPAC's use of IRQ mode, see apps/ppac/main.c, specifically the core loop of the worker_fn() function. This loop migrates from polling mode to a blocking "IRQ mode" built around select() whenever reflector has looped a certain number of times without any forward progress. If input traffic is significantly below processing capacity, then it should be possible to observe reflector going in to (and out of) blocking select()s, even if the traffic is never completely stopped. In such cases, any latency associated with sleeping and scheduling is absorbed by system buffering long enough for reflector to wake up and resume polling mode (and catch up on the buffered backlog). This mechanism allows reflector to share CPUs with other tasks more effectively (and consume less power) provided the throughputs are low or busty enough to make this acceptable.

9.9.5.4.2 Buffers

When starting up, PPAC applications seed the 3 buffer pools that the Fman is configured to use for Rx processing. To improvement restartability, the pools are first drained of any stale contents, after which they are seeded using allocations from the "/dev/fsl_usdpaa_shmem" DMA device, which is described in the USDPAA User Guide.

The three buffer pools initialized and used by PPAC (and the default USDPAA configuration of Fman) have the following attributes.

Table 271. Buffer Pool attributes

Pool ID	Buffer Size (used by Fman)	Number of Buffers
7	320	0
8	704	0
9	1728	0x2000

When processing IPv4 frames, buffers are allocated by FMan on Rx and then released by FMan after Tx.

The source code specifies the buffer pool requirements in include/internal/conf.h:

```
#define DMA_MEM_BP1_BPID        7
#define DMA_MEM_BP1_SIZE        320
#define DMA_MEM_BP1_NUM         0 /* 0*320==0 (0MB) */
#define DMA_MEM_BP2_BPID        8
#define DMA_MEM_BP2_SIZE        704
#define DMA_MEM_BP2_NUM         0 /* 0*704==0 (0MB) */
#define DMA_MEM_BP3_BPID        9
#define DMA_MEM_BP3_SIZE        1728
#define DMA_MEM_BP3_NUM         0x2000 /* 0x2000*1728==13.5MB) */
#define DMA_MEM_BPOOL \
          (DMA_MEM_BP1_SIZE * DMA_MEM_BP1_NUM + \
          DMA_MEM_BP2_SIZE * DMA_MEM_BP2_NUM + \
          DMA_MEM_BP3_SIZE * DMA_MEM_BP3_NUM) /* (13.5MB) */
```

And the application implements the seeding of these buffers according to the following structure in apps/ppac/main.c:

```
/* Seed buffer pools according to the configuration symbols */
const struct ppac_bpool_static {
          int bpid;
          unsigned int num;
          unsigned int sz;
} ppac_bpool_static[] = {
          { DMA_MEM_BP1_BPID, DMA_MEM_BP1_NUM, DMA_MEM_BP1_SIZE},
          { DMA_MEM_BP2_BPID, DMA_MEM_BP2_NUM, DMA_MEM_BP2_SIZE},
          { DMA_MEM_BP3_BPID, DMA_MEM_BP3_NUM, DMA_MEM_BP3_SIZE},
          { -1, 0, 0 }
};
```

9.9.5.4.3 Compile-time configuration

PPAC-based application are compiled using a certain set of options that are currently defined in the header located at apps/include/ppac.h. The following describes the most useful options for modification if alternative application behaviour is desired;

9.9.5.4.3.1 Order preservation

Order preservation is a functionality of the QMan software portal interface that allows processing of Rx FQs across multiple portals to retain order when transmitted corresponding Tx FQs. The technique only applies to frames dequeued from a given Rx FQ that are all transmitted out the same Tx FQ (which is the case for "reflector", and also the case for "ipfwd" when frames are from the same flow). The mechanism requires two QMan features, "HOLDACTIVE" and "enqueue DCA". The former ensures that a FQ that has been dequeued to a software portal from should remain bound to that portal until all the corresponding DQRR entries have been consumed. The latter ensures that a DQRR entry is consumed by QMan itself once it has dispatched the corresponding enqueue (Tx) command. Together, for any given Rx/Tx FQ pair, the processing via pool-channels and multiple CPUs does not allow frame processing to get out of order. (For more information on this feature, consult the QMan/BMan API Guide.)

Use of "HOLDACTIVE" is mutually exclusive with another QMan option "AVOIDBLOCK", which is selected by default in PPAC. So to enable order-preservation, one must change the settings from;

```
#undef PPAC_2FWD_HOLDACTIVE
#undef PPAC_2FWD_ORDER_PRESERVATION
#define PPAC_2FWD_AVOIDBLOCK
```

to;

```
#define PPAC_2FWD_HOLDACTIVE
#define PPAC_2FWD_ORDER_PRESERVATION
#undef PPAC_2FWD_AVOIDBLOCK
```

9.9.5.4.3.2 Monitoring Rx/Tx fill-levels via CGR

If CGR-based monitoring is enabled, then two Congestion Group Records will be configured, with all Rx FQs for all interfaces being subscribed to one, and all Tx FQs being subscribed to the other. The CGRs are not configured to perform any flow-control (ie. no tail-drop nor WRED options are enabled), so this simply allows the user to monitor the overall fill-level of frame queues in the system, in particularly to determine whether build-up is occuring before or after the software-processing phase. The thresholds used for the CGRs are determined from the two constants also defined in ppac.h, PPAC_CGR_RX_PERFQ_THRESH and PPAC_CGR_TX_PERFQ_THRESH. These constants, combined with the number of FQs, define the thresholds for CGR congestion-entry. Qman in turn defines the CGR exit-threshold to be 7/8 the entry-threshold (to provide hysteresis), and so these combined entry/exit events will be logged to stdout independently for the Rx and Tx CGRs.

An extra command, "cli", becomes available in the CLI when this feature is compiled in, which will query and display all the fields of both CGRs. Note however that this option introduces extra latency, and more critically, extra contention within the system. This is because Qman must lock the CGR for each enqueue and dequeue event that relates to it, meaning that the forwarding of a single packet through the system requires 2 lock/unlock pairs for each CGR (thus 4 lock/unlock pairs). A small but noticable performance degradation should be expected when running in this mode. (Real-world use of CGRs would not subscribe all Rx/Tx FQs from all interfaces to a single CGR, so this scalability issue should not be a concern for production software usage of CGR-based congestion management.)

To enable this feature, change;

```
#undef PPAC_CGR
```

to;

```
#define PPAC_CGR
```

9.9.5.4.3.3 Other settings

Many other settings used by PPAC (and thus PPAC-based apps) are defined in ppac.h but they are less intended for ad-hoc manipulation than those mentioned above. However a curious user may wish to examine some of these, and perhaps search out their usage within the source-code, in order to see how they are used and explore some of the driver interfaces and application design in this way.

9.9.5.5 Running reflector

The following comments about executing reflector apply to all PPAM applications - PPAMs may of course define new command-line (and environment-variable) behaviour, but the following behaviour is all generic to PPAC (reflector does not implement any extensions of its own).

After logging in to the p4080 DS environment as "root", the SOURCE_THIS file in the "/root" directory can be used to simplify running "fmc" (to configure FMan for the required network device configuration) and starting up reflector, as can be seen from the following:

```
login: root
Password:
[root@p4080 root]# cat /root/SOURCE_THIS
cd /usr/etc
fmc -c usdpaa_config_p4_serdes_0xe.xml -p usdpaa_policy_hash_ipv4.xml -a
reflector
[root@p4080 root]# source /root/SOURCE_THIS
Found /fsl,dpaa/dpa-fman0-oh@1, Tx Channel = 46, FMAN = 0, Port ID = 1
Found /fsl,dpaa/ethernet@4, Tx Channel = 40, FMAN = 0, Port ID = 0
Found /fsl,dpaa/ethernet@7, Tx Channel = 63, FMAN = 1, Port ID = 2
Found /fsl,dpaa/ethernet@8, Tx Channel = 64, FMAN = 1, Port ID = 3
Found /fsl,dpaa/ethernet@9, Tx Channel = 60, FMAN = 1, Port ID = 0
Qman: FQID allocator includes range 512:128
Bman: BPID allocator includes range 56:8
Configuring for 4 network interfaces and 4 pool channels
FSL dma_mem device mapped (phys=0xe0000000,virt=0x70000000,sz=0x1000000)
Thread uid:0 alive (on cpu 1)
Release 0 bufs to BPID 7
Release 0 bufs to BPID 8
Release 8192 bufs to BPID 9
reflector starting
Thread uid:0 alive (on cpu 1)
reflector>
```

Reflector starts up with a single thread running on CPU 1 by default, with all the network interfaces enabled. The CLI (Command-Line Interface) allows you to add and remove additional threads to enable the use of multiple CPUs, with the only restriction being that the primary thread on CPU 1 can not be removed (except by shutting down the application).

Reflector can alternatively be started as a single thread on a different CPU by executing it with the desired CPU as its sole argument:

```
[root@p4080 root]# reflector 5
```

Alternatively, multiple threads can be started by specifying a range of CPUs:

```
[root@p4080 root]# reflector 3..7
```

By default, reflector is compiled to load the XML configuration and PCD files passed to the "fmc" tool in the afore-mentioned SOURCE_THIS script. Indeed, it is important that reflector always load the same configuration as is passed to "fmc". If "fmc" is run with different XML inputs, eg. when running on another board than p4080ds and/or when using a different SERDES configuration, then reflector must be instructed to load non-default XML files to match. This can be achieved either by setting the DEF_PCD_PATH and DEF_CFG_PATH environment variables, or by using short or long command-line arguments: Eg. the following 3 examples achieve the same thing:

```
[root@p4080 root]# reflector -c my_cfg.xml -p my_pcd.xml

[root@p4080 root]# reflector --fm-config my_cfg.xml --fm-pcd my_pcd.xml

[root@p4080 root]# export DEF_CFG_PATH=my_cfg.xml
[root@p4080 root]# export DEF_PCD_PATH=my_pcd.xml
[root@p4080 root]# reflector
```

Note also that PPAC implements a CLI for all PPAM applications, which means that it expects a console to be present on 'stdin'. If the reflector process is backgrounded, or run as a daemon, then the process will pause waiting for it to receive control of console input. If the user wishes to launch reflector or any other PPAM without the use of the console, they should instruct it ignore input and not run the CLI by passing the "-n" or "--non-interactive" command-line arguments:

```
[root@p4080 root]# reflector --non-interactive &
```

9.9.5.6 PPAC (and reflector) CLI commands

The following commands are illustrated in the context of reflector (carrying on from the session started in the previous section), but the commands are common to all PPAC-based applications.

To add a thread on a single CPU (e.g. CPU 2):

```
reflector> add 2
```

To add threads on a range of CPUs:

```
reflector> add 3..6
```

To list the threads (this also queries each thread, verifying that they aren't blocked):

```
reflector> list
Thread uid:0 alive (on cpu 1)
Thread uid:1 alive (on cpu 2)
Thread uid:2 alive (on cpu 3)
Thread uid:3 alive (on cpu 4)
Thread uid:4 alive (on cpu 5)
Thread uid:5 alive (on cpu 6)
```

To remove a thread by its UID:

```
reflector> rm uid:2
Thread uid:2 killed (cpu 3)
```

To remove a thread running on a given CPU:

```
reflector> rm 4
Thread uid:3 killed (cpu 4)
```

If more than one thread is running on a given CPU (only possible if the device-tree has been updated to reserve multiple portals for USDPAA on the same CPU), then this removes the first thread found running on the named CPU. A range of CPUs can likewise be specified:

```
reflector> rm 5..6
Thread uid:4 killed (cpu 5)
Thread uid:5 killed (cpu 6)
```

To perform a controlled shutdown of reflector (this includes disabling the network ports):

```
reflector> quit
```

9.9.5.7 Running hello_reflector

The stand-alone "hello_reflector" application, which is not PPAC-based, can be executed in exactly the same environment as the PPAC-based "reflector". Instead of executing "reflector", one executes "hello_reflector" instead:

```
[root@p4080 root]# hello_reflector
```

Hello_reflector always starts up on CPU 0, and by default it only starts a single thread. Multiple threads can be started by providing the "-n" argument, in which case that many CPUs will be used starting with CPU 0 and counting upwards.

```
[root@p4080 root]# hello_reflector -n 5
```

Hello_reflector does not implement a CLI, so the only way to gracefully shut it down is to enter a Ctrl-C on the controlling console, or equivalently issue a SIGINT signal to the hello_reflector process.

Alternative configuration and PCD files can be provided to hello_reflector by using the "-c" and "-p" arguments respectively. These should always match the XML files that are passed to "fmc":

```
[root@p4080 root]# hello_reflector -p my_pcd.xml -c my_cfg.xml
```

9.9.5.8 Running hello_reflector (short circuit)

Issue following command to run hello_reflector in "short circuit" mode:

```
[root@p4080 root]# hello_reflector -c /usr/etc/usdpaa_config_p4_serdes_0xe.xml -
p /usr/etc/usdpaa_policy_hash_ipv4.xml –n 1 –sc
```

To test sc mode, stop the process (ctrl + Z) and feed the traffic to FMAN port (using spirent), you will still see the rx traffic due to the fact that the destination channel for RX queues is tx_channel.

Follow these steps precisely :

1. Hang up process by ctrl+z, this will avoid using cpu and will not impact traffic flow.

2. To quit process, you have to recover process by 'fg %1' then press 'ctrl+c' to quit.

9.9.5.9 Testing reflector

Functional testing of the "reflector" application is possible by connecting any subset of the P4080 USDPAA network interfaces to a conventional computer, assumed to be a Linux PC using an ethernet switch as shown in the figure below.

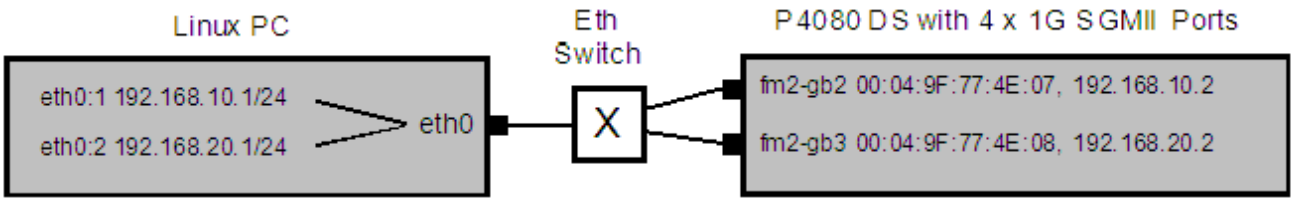

Figure 260. Testing Reflector

The figure assumes that the default USDPAA SerDes 0xe reset configuration word (RCW) is used. This configuration provides 2 x 10 Gbps and 2 x 1 Gbps ethernet interfaces to the USDPAA application. The test case in the figure assumes that only the 2 x 1 Gbps interfaces will be used. These are the two interfaces on the SGMII riser card that are closest to the P4080DS motherboard. This test will work even if 10 Gbps XAUI riser cards are not fitted in the P4080DS.

See the main USDPAA User Guide for more information on network interfaces.

To perform the test, boot the P4080 and run the example application as described in section Running reflector on page 1695.

The IP and ethernet MAC addresses used below are examples. You can change them as long as you are consistent. The most important thing is to be sure of the MAC addresses on the P4080DS board. Again, see the main USDPAA User Guide.

On the Linux PC, create eth0:1 through eth0:3 via, for example:

```
sudo ifconfig eth0:1 192.168.10.1 netmask 255.255.255.0
sudo ifconfig eth0:2 192.168.20.1 netmask 255.255.255.0
```

The reflector application does not respond to ARP requests, so static ARP entries for all of the P4080 USDPAA interfaces must be created on the Linux PC:

```
sudo arp -s 192.168.10.2 00:04:9F:77:4E:07
sudo arp -s 192.168.20.2 00:04:9F:77:4E:08
```

Then, from the Linux PC ping one of the P4080 interfaces, e.g. "ping 192.168.10.2". This causes the following sequence:

1. Linux PC sends ICMP echo request to the switch.
2. At least for the first ping, the switch will flood the request to all P4080 ports. It will be dropped by all but the correct one.
3. The P4080 receives the frame, swaps the IP and MAC addresses, and sends the frame back out the MAC it came in on.
4. The Linux PC receives the frame, an ICMP echo request.
5. The Linux PC responds to the request.
6. The response is received by the P4080 which swaps the IP and MAC addresses and sends the frame back out on the MAC it came in on.
7. The Linux receives the response.
8. The original ping is now complete. The Linux PC just "pinged itself via the P4080".

It is possible to also test with different packet types using this same technique. For example, have a telnet server running on the Linux PC and then do "telnet 192.168.10.2" from the Linux PC. The Linux PC will telnet to itself via the P4080. One can also use ssh in the same way.

To test performance, it is best to used dedicated ethernet traffic generation equipment such as a Spirent Test Center. Such equipment can inject packets into the P4080 at known and very high rates and measure the rate of the packets that egress from the P4080.

9.9.6 NXP USDPAA IPFWD User Manual Rev. 1.2

9.9.6.1 About this Book

The User Space Datapath Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document provides the following:

- A summary of the USDPAA IPFwd application
- Execution steps for USDPAA IPFwd application from the NXP yocto package on the P4080DS/P3041DS/P5020DS/ T4240QDS/B4860QDS/B4420QDS.

Conventions

This document uses the following conventions:

Courier is used to identify commands, explicit command parameters, code examples, expressions, data types, and directives.

9.9.6.2 Introduction

9.9.6.2.1 Purpose

This document describes the USDPAA IPv4 forwarding application. This application documents the USDPAA IPv4 demonstration applications forwarding flow and its performance measured on a P4080DS.

9.9.6.3 Overview

The USDPAA IPv4 forwarding (IPFwd) application is a multi-threaded application that routes IPv4 packets from one ethernet interface to another on all QorIQ platforms. The routing is done based on the source IP address and destination IP address in the frame. Any combination of the cores can run a USDPAA IPv4 Forwarding application thread in USDPAA SDK v1.1.

IPFwd packet-processing:

· Receives ethernet frames on all USDPAA ethernet interfaces.

· Discards (and deallocates buffers for) all non-IPv4 frames.

· For IPv4 frames processing takes place as defined in section Overview of packet flow: on page 1700

9.9.6.3.1 USDPAA IPv4 forwarding application flow

The IPFwd application has two main phases. There is an initial configuration phase and a subsequent packet processing phase.

The configuration phase executes when the application starts. Application threads are created and global initialization of resources is done which is the part of PPAC (see USDPAA PPAC User Guide for more details). The configuration phase also includes PPAM (i.e. IPFwd) related initialization. Once the configuration phase is completed the IPFwd application moves to the packet processing phase. This application provides a command-line interface to enable users to add and remove routing table and ARP cache entries at any given time. For each user input, the appropriate information is communicated to the IPFwd application via standard Posix IPC. Messages are placed onto the message queue till they are received by the IPfwd application. Note that the IPFwd application does not dynamically resolve ARP – missing ARP entries will result in the application dropping the packet.

In the packet processing phase, the loop migrates from polling mode to a blocking “IRQ mode” whenever IPFwd has looped a certain number of times without any forward progress. For more information on IRQ mode please refer to “USDPAA PPAC User Guide”. In polling mode – the application constantly looks for data to process on its dedicated QMan portal . Network traffic is classified and distributed by the FMan to frame queues based on source and destination IP address in the packet. There is an associated handler that processes the packets arriving on each frame queue.

9.9.6.3.1.1 Overview of packet flow:

1. Route table entries are populated using the IPFwd configuration commands at any given time.
2. Packet is received by the FMan, which uses 2-tuple (Src IP & Dest IP) to hash the packet to a Rx frame queue.
3. The classified packet is presented to the USDPAA IPFwd application thread running on one of the cores - the distribution is based on the portal and FQ setup done by the application during its portal and frame queue initialization. The packet is subjected to IPv4 Forwarding route lookup.
4. Based on the packet destination, the application transmits the packet by enqueueing it on a frame queue destined for the appropriate Tx interface.

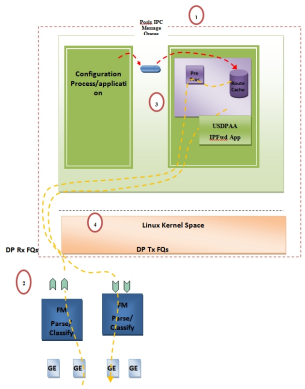

Figure 261. Packet flow for USDPAA IPv4 Forwarding

9.9.6.4 Overview of PPAC

The source code to IPFwd has been reorganized into two parts; the “PPAC” (Packet-Processing Application Core) and a “PPAM” (Packet-Processing Application Module). The PPAM portion implements the IPFWD application specific logic of processing the packet to forward it. On the other hand, the PPAC component represents the common infrastructure to support PPAM; initializing devices, handling flow-control, implementing a CLI (Command-Line Interface), managing threads and buffers. PPAC details can be found in the document “USDPAA PPAC User Guide”.

9.9.6.5 IPFwd related PPAC Details

9.9.6.5.1 Compile-time configuration

PPAC-based application are compiled using a certain set of options that are currently defined in the header located at apps/include/ppac.h. The following describes the most useful options for modification if alternative application behaviour is desired.

9.9.6.5.1.1 Order Preservation in IPFWD

This section describes how user can enable Order Preservation in IPFWD application. By default Order Preservation is disabled in IPFWD application and in order to enable it the user will have to re-compile the binary by making following changes to the source code.

In file, usdpaa/apps/include/ppac.h you can find these two lines.

/* Application options */

#undef PPAC_2FWD_HOLDACTIVE /* Process each FQ on one portal at a time */

#undef PPAC_2FWD_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */

Change the above to

#define PPAC_HOLDACTIVE /* Process each FQ on one portal at a time */

#define PPAC_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */

And then compile usdpaa once again. Now run the IPFWD application with Order Preservation.

9.9.6.5.1.2 Order Restoration in IPFWD

Oder restoration is the functionality of QMan software portal interface which restores the relative temporal order of a flow of frames (sequence of frames) to that observed before transmitting to the destination Frame Queue and Order Definition Point (ODP) takes note of the correct order of packets before start processing by using the sequence number. Use of "HOLDACTIVE" is mutually exclusive with another QMan option "AVOIDBLOCK", which is selected by default in PPAC. To enable order-restoration, the user will have to re-compile the binary by making following changes to the source code.

/* Application options */

#undef PPAC_2FWD_HOLDACTIVE /* Process each FQ on one portal at a time */

#undef PPAC_2FWD_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */

#undef PPAC_2FWD_ORDER_RESTORATION /* Use ORP */

#define PPAC_2FWD_AVOIDBLOCK /* No full-DQRR blocking of FQs */

Change the above to

#undef PPAC_HOLDACTIVE /* Process each FQ on one portal at a time */

#undef PPAC_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */

#define PPAC_ORDER_RESTORATION /* Use ORP */

#define PPAC_AVOIDBLOCK /* No full-DQRR blocking of FQs */

And then compile usdpaa once again. Now run the IPFWD application with Order Restoration. Implementation note: Order restoration has been implemented such that each PCD Frame queue has a corresponding ORP (order restoration point) frame queue associated with it. Each ORP is configured with default window settings as seen below

#define PPAC_ORP_WINDOW_SIZE 7 /* 0->32, 1->64, 2->128, ... 7->4096 */

#define PPAC_ORP_AUTO_ADVANCE 1 /* boolean */

#define PPAC_ORP_ACCEPT_LATE 3 /* 0->no, 3->yes (for 1 & 2->see RM) */

Here the ORP window size is set to be 4K, auto advance window size as 4K and accept late arrival window size as 8K. This ensures that no traffic is getting dropped but are always accepted below and at Zero loss throughput. Beyond zero loss throughput, as usual packets would be dropped and thus you can see mis-ordering.

ORP FQ descriptor attributes settings:

- Prefer in cache
- No " HOLDACTIVE "
- No " AVOIDBLOC K"
- ORP enabled

Assumption: To see the effect of Order Restoration in IPFwd application the user must use separate streamblocks as a source of traffic. If not done so, mis-ordering would be seen.

Key observation: It has been observed in IPFwd application that use of "HOLDACTIVE" with traffic generated using separate streamblocks, all the packets are IN sequence. Therefore, it is recommended that if user wants to see the real effect of Order

restoration in IPFwd application he should use “AVOIDBLOCK” with “RESTORATION” and not “HOLDACTIVE” with “RESTORATION”

9.9.6.5.1.3 Monitoring Rx/Tx fill-levels and flow-control via CGR

If CGR-based monitoring is enabled, then two Congestion Group Records will be configured, with all Rx FQs for all interfaces being subscribed to one, and all Tx FQs being subscribed to the other. This simply allows the user to monitor the overall fill-level of frame queues in the system, in particular to determine whether build-up is occuring before or after the software-processing phase. Refer to section “ Monitoring Rx/Tx fill-levels via CGR ” of USDPAA PPAC User Guide for more details. To enable this feature, in ppac.h change;

#undef PPAC_CGR

to;

#define PPAC_CGR

The CGRs can also be configured to perform flow-control using Congestion state tail drop by setting CSTD_EN bits . Each congestion group record can be configured to track either byte counts or frame counts in all frame queues in the Congestion Group. When the threshold set for each CGR is exceeded, the CS bit is set in the CGR, and the congestion group is said to have entered congestion. At this point the incoming frames are marked for discard and QMAN will generate enqueue rejections to the producer. When the group’s I_BCNT returns below the threshold (minus approximately 1/8 of the threshold to provide hysteresis), the CS bit is cleared, and the congestion group’s state exits congestion. To enable tail drop, in ppac.h change;

#undef PPAC_CGR /* Track rx and tx fill-levels via CGR */

#undef PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

to

#define PPAC_CGR /* Track rx and tx fill-levels via CGR */

#define PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

And then compile usdpaa once again. Now run the IPFWD application with CGR tail drop enabled. To test this feature PPAC CLI provides a command “cgr” which will query and display all the fields of both CGRs. On pumping the traffic to IPFWD application at full line rate, t he instantaneous group byte count value I_BCNT(Instantaneous frame/byte count) must be maintained lesser than the CGR threshold set for each congestion group. Here is one such cgr command output:

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 0

cscn_targ: 0x00800000

cstd_en: 1

cs: 0

cs_thresh: 0x00_0000_1000

mode: 1

i_bcnt: 0x00_0000_0e1e

a_bcnt: 0x00_0000_0e1e

Tx CGR ID: 11, selected fields;

cscn_en: 0

cscn_targ: 0x00800000

cstd_en: 1

cs: 0

cs_thresh: 0x00_0000_0200

mode: 1

i_bcnt: 0x00_0000_0002

a_bcnt: 0x00_0000_0004

On the other hand if this feature of Congestion Group tail drop is disabled in IPFWD application I_BCNT is never maintained below CGR threshold value with traffic at full line-rate. This can be checked by compiling the IPFWD application with;

#define PPAC_CGR /* Track rx and tx fill-levels via CGR */

#undef PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

Now on pumping traffic at full line-rate, atleast one of the CGRs must go into congestion state and its I_BCNT should be above CGR threshold value. Here is the sample output:

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 1

cscn_targ: 0x00800000

cstd_en: 0

cs: 0

cs_thresh: 0x00_0000_1000

mode: 1

i_bcnt: 0x00_0000_0006

a_bcnt: 0x00_0000_0004

Tx CGR ID: 11, selected fields;

cscn_en: 1

cscn_targ: 0x00800000

cstd_en: 0

cs: 1

cs_thresh: 0x00_0000_0200

mode: 1

i_bcnt: 0x00_0000_5fb7

a_bcnt: 0x00_0000_5fb8

Thus, the above test showcases the flow control achieved by enabling congestion group tail drop in IPFWD application.

9.9.6.6 PPAM related compile time configuration

9.9.6.6.1 One million route support

By default IPfwd application can work only with 1K routes. The user may want to run it for higher number of routes, so there is an option available in the header located at apps/ipfwd/include/app_common.h. To enable one million route support, the user will have to re-compile the binary by making following changes to the source code.

#undef ONE_MILLION_ROUTE_SUPPORT

Change the above line to

#define ONE_MILLION_ROUTE_SUPPORT

And then compile usdpaa once again. Now run the IPFWD application for one million routes. There is a sample shell script available at /usr/bin/ipfwd_20G_1Mroutes.sh in the rootfs. It creates one million routes using the 2 x 10G interfaces. It can assign ip addresses to the interfaces, add an ARP entry and assumes the netmask to be 255.255.255.0. The following table summarizes the setting done by this script.

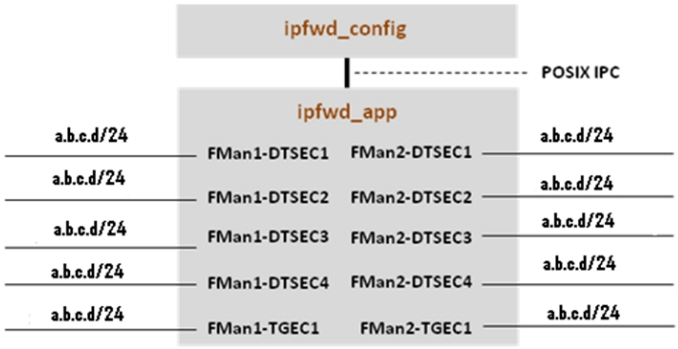
Port ID	Source IP Address	Destination IP Address (for each src IP addr)	Default Gateway IP Address
FM1:TGEC1	192.168.24.2 to 192.168.24.255	192.168.29.2 .. 255	192.168.29.2
	192.168.25.2 to 192.168.25.255	192.168.29.2 .. 255	192.168.29.2
	192.168.26.2 to 192.168.26.255	192.168.29.2 .. 255	192.168.29.2
	192.168.27.2 to 192.168.27.255	192.168.29.2 .. 255	192.168.29.2
	192.168.28.2 to 192.168.28.255	192.168.29.2 .. 255	192.168.29.2
	192.168.1.2 to 192.168.1.255	192.168.29.2 .. 255	192.168.29.2
	192.168.18.2 to 192.168.18.255	192.168.29.2 .. 255	192.168.29.2
	192.168.30.2 to 192.168.30.255	192.168.29.2 .. 255	192.168.29.2
	192.168.31.2 to 192.168.31.91	192.168.29.2 .. 91	192.168.29.2
FM2:TGEC2	192.168.29.2 to 192.168.29.255	192.168.24.2 .. 255	192.168.24.2
	192.168.2.2 to 192.168.2.255	192.168.24.2 .. 255	192.168.24.2
	192.168.3.2 to 192.168.3.255	192.168.24.2 .. 255	192.168.24.2
	192.168.4.2 to 192.168.4.255	192.168.24.2 .. 255	192.168.24.2
	192.168.5.2 to 192.168.5.255	192.168.24.2 .. 255	192.168.24.2
	192.168.6.2 to 192.168.6.255	192.168.24.2 .. 255	192.168.24.2
	192.168.17.2 to 192.168.17.255	192.168.24.2 .. 255	192.168.24.2
	192.168.19.2 to 192.168.19.255	192.168.24.2 .. 255	192.168.24.2

Table continues on the next page...

Table continued from the previous page...

	192.168.20.2 to 192.168.20.91	192.168.24.2 .. 91	192.168.24.2

9.9.6.7 IPFWD Application Suite



The figure above shows the structure of the IPFWD USDPAA application suite. Its purpose is to forward IPv4 packets between the interfaces shown. No IP address is assigned to any of the interfaces by default. Using ipfwd_config command as mentioned in section Assign IP address to interfaces on page 1722 IP address can be assigned to all these interfaces. Each interface has a fixed netmask shown in the figure. The notation "/24" refers to a netmask of 255.255.255.0. The MAC addresses of these interfaces are determined by u-boot environment variables ethaddr, eth1addr, eth2addr, etc.

The ipfwd application will respond to ARP requests on these interfaces. However, the application will not generate ARP requests to determine the destination MAC address of forwarded packets. An ipfwd_config command should be used to set these MAC addresses.

It is important to understand that the application can use only a subset of these interfaces at any one time. This is due to pin multiplexing rules on the P4080 SoC. The set of available interfaces is determined by a number of factors:

1. The interface set made available by the selected SerDes Protocol and u-boot variable "hwconfig". See the SDK document "NXP DPAA SDK X.Y: Selecting Ethernet Interfaces". This document is distributed with the DPAA SDK.
2. The Linux device tree determines which subset of the available interfaces is for use by USDPAA applications. See the USDPAA User Guide for more information.
3. Finally, the fmc configuration file passed by command line argument to ipfwd_app determines the subset of these interfaces that the application will attempt to initialize.

In the default SerDes 0xe example, the interfaces used by ipfwd_app are:

- FMan1-TGEC1
- FMan2-DTSEC3
- FMan2-DTSEC4
- FMan2-TGEC1

Running the ipfwd application suite involves four steps:

1. Run the fmc application to configure the FMan hardware instances.
2. Run ipfwd_app
3. Run ipfwd_config repeatedly to add routes to ipfwd's route cache.
4. Run "ipfwd_config -O" to start application processing.

Specific examples showing these steps are provided in other sections of this document.

9.9.6.8 Possible configuration scenario for IPFWD

IPfwd application can run in different configuration scenario. The table below shows the configuration files and corresponding sample shell script existing in the repository.

xml file	Sample shell script	Number of routes (as per sample shell script)
usdpaa_config_p4_serdes_0xe.xml (2x10G+2x1G)	ipfwd_20G.sh	1012 routes (2x10G)
	ipfwd_22G.sh	1022 routes (2x10G+2x1G)
usdpaa_config_p3_p5_serdes_0x36.xml (5x1G+10G)	ipfwd_15G.sh	1000 routes (5x1G+10G)

Figure 1: usdpaa_config_p4_serdes_0xe.xml

The figure above shows the ethernet interfaces available as per configuration file " usdpaa_config_p4_serdes_0xe.xml". It contains the 1 RGMII port (FMAN1, DTSEC 2), 2 SGMII ports (FMan2, DTSECs 3- 4) and 2 XAUI ports (FMAN1, TGEC1 and FMAN2-TGEC2). It is the user's wish to use any combination of ports available with the configuration file. The above table shows the sample shell scripts that user can use for this configuration. If user uses 2x10G, following is the flow configuration.

Test Center <-> P4080

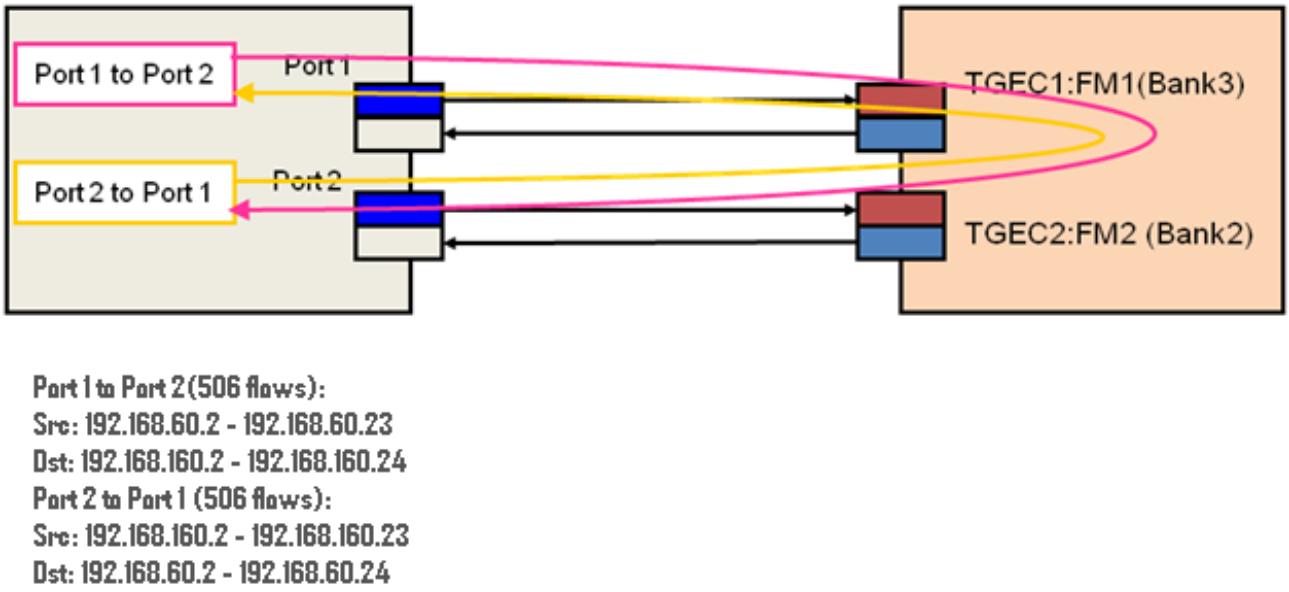


Figure 2 : Flow Configuration for 2x10G on P4080DS

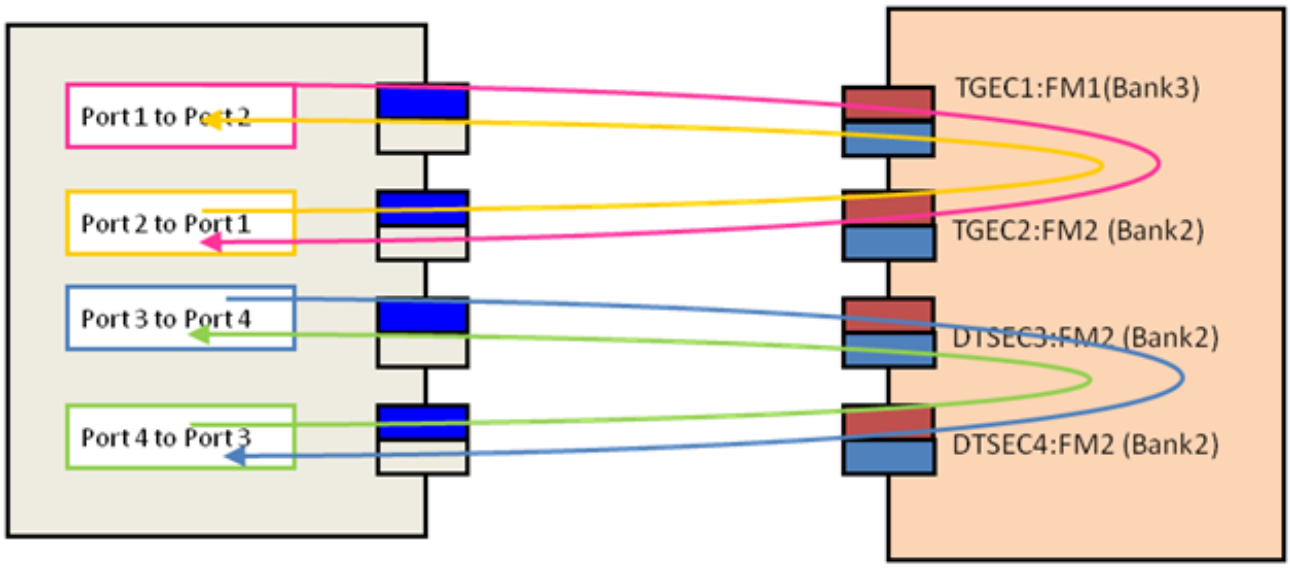
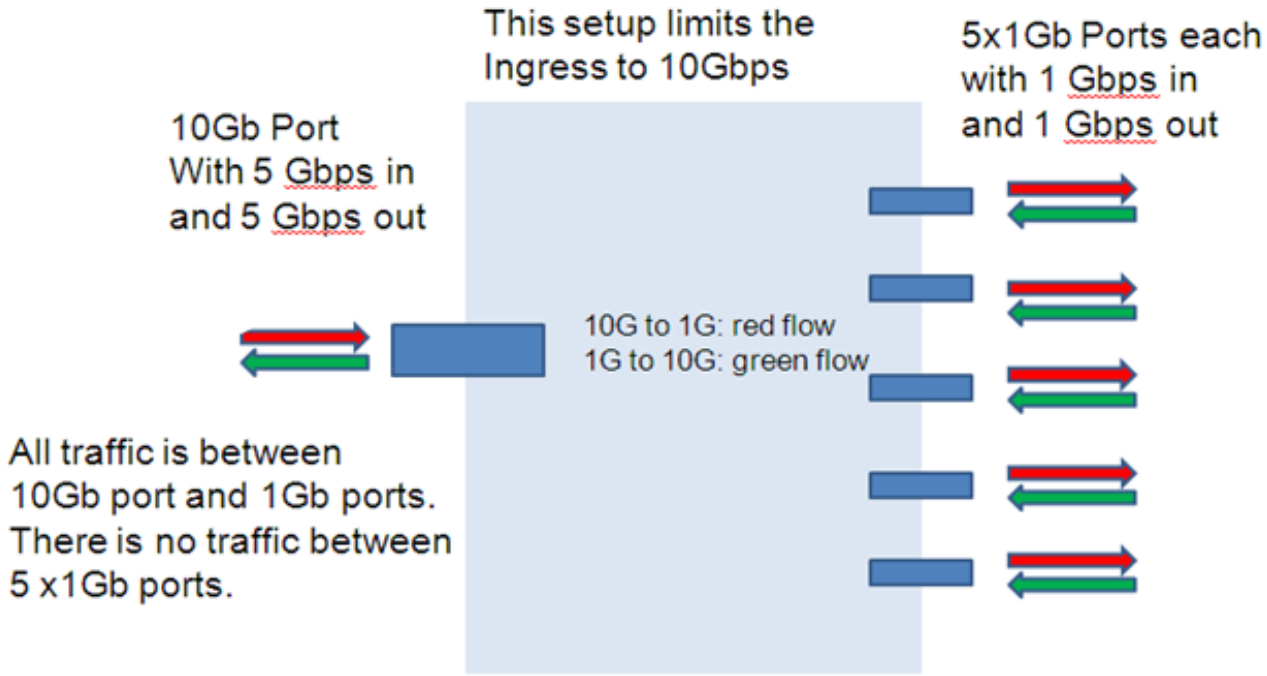


```
Port 1 to Port 2 (462 flows):
Source: 192.168.60.2 – 192.168.60.22
Destination: 192.168.160.2 – 192.168.160.23
Port 2 to Port 1 (462 flows) :
Source: 192.168.160.2 – 192.168.160.22
Destination: 192.168.60.2 – 192.168.60.23
Port 3 to Port 4 (46 flows):
Source: 192.168.130.2 – 192.168.130.22
Destination: 192.168.140.2 – 192.168.140.23
Port 2 to Port 1 (46 flows) :
Source: 192.168.140.2 – 192.168.140.22
Destination: 192.168.130.2 – 192.168.130.23
```

Figure 3 : configuration for 2x10G and 2x1G on P4080

For running IPFwd on P3041DS/P5020DS, the user can use " usdpaa_config_p3_p5_serdes_0x36.xml". Following is the flow configuration.



Left: 10G port (port6: fm1-10g)
Right: top-to-bottom: 1G port (port1-port6)

Figure 4 : Flow Configuration for 10G on P5020DS and P3041DS

```
Port 1 to Port 6 (100 flows):
                Src: 192.168.10.2 - 192.168.10.11
                Dst: 192.168.60.2 - 192.168.60.11

Port 2 to Port 6 (100 flows):
                Src: 192.168.20.2 - 192.168.20.11
                Dst: 192.168.60.2 - 192.168.60.11

Port 3 to Port 6 (100 flows):
                Src: 192.168.30.2 - 192.168.30.11
                Dst: 192.168.60.2 - 192.168.60.11

Port 4 to Port 6 (100 flows):
                Src: 192.168.40.2 - 192.168.40.11
                Dst: 192.168.60.2 - 192.168.60.11

Port 5 to Port 6 (100 flows):
                Src: 192.168.50.2 - 192.168.50.11
                Dst: 192.168.60.2 - 192.168.60.11
```

```
Port 6 to Port 1 (100 flows):
                Src: 192.168.60.2 - 192.168.60.11
                Dst: 192.168.10.2 - 192.168.10.11

Port 6 to Port 2 (100 flows):
                Src: 192.168.60.2 - 192.168.60.11
                Dst: 192.168.20.2 - 192.168.20.11

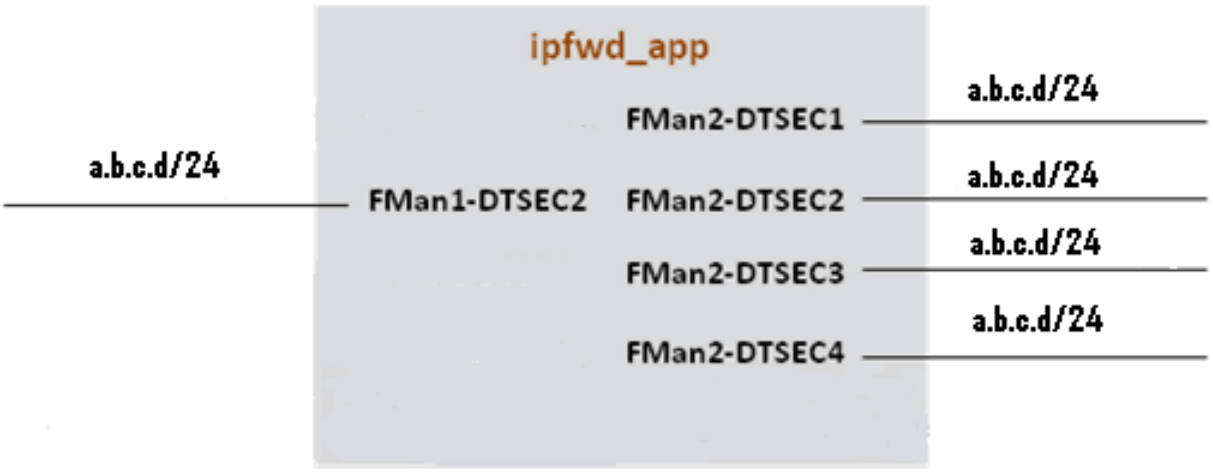
Port 6 to Port 3 (100 flows):
                Src: 192.168.60.2 - 192.168.60.11
                Dst: 192.168.30.2 - 192.168.30.11

Port 6 to Port 4 (100 flows):
                Src: 192.168.60.2 - 192.168.60.11
                Dst: 192.168.40.2 - 192.168.40.11

Port 6 to Port 5 (100 flows):
                Src: 192.168.60.2 - 192.168.60.11
                Dst: 192.168.50.2 - 192.168.50.11
```

How to run if user has no XAUI but only SGMII card?

Assume user does not have a XAUI card and wants to run IPFwd using only the SGMII ports as shown below.



This configuration contains the 1 RGMII port (FMAN1, DTSEC 2), 4 SGMII ports (FMan2, DTSECs 1- 4). The user can modify the configuration file and sample shell scripts as per requirement. The configuration file would contain the following

```
<cfgdata>
<config>
<engine name="fm1">
<port type="1G" number="0" policy="hash_ipsec_src_dst_spi_policy6"/>
<port type="1G" number="1" policy="hash_ipsec_src_dst_spi_policy7"/>
<port type="1G" number="2" policy="hash_ipsec_src_dst_spi_policy8"/>
<port type="1G" number="3" policy="hash_ipsec_src_dst_spi_policy9"/>
</engine>
</config>
</cfgdata>
```

User can create a new shell script which would make routes between the 4x1G. Here is the content of the script.

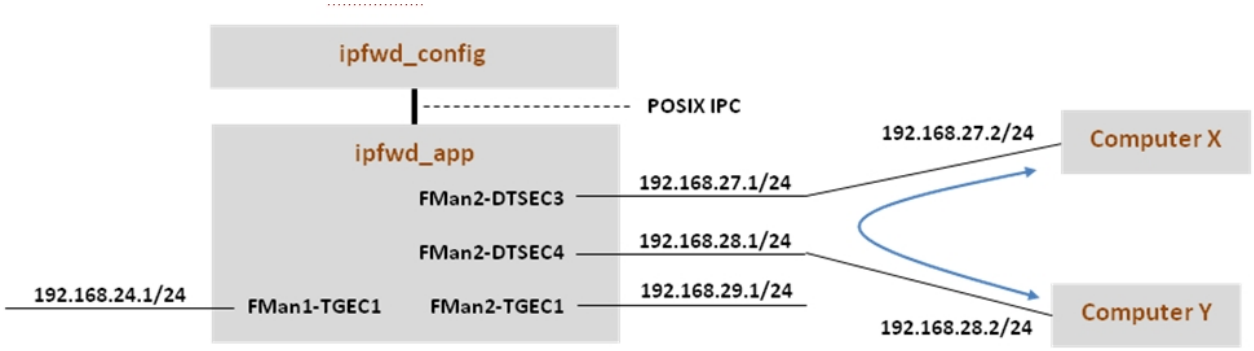
```
net_pair_routes()
{
for net in $1 $2
      do
ipfwd_config -P $pid -B -s 192.168.$net.2 -c $3 \
-d 192.168.$(expr $1 + $2 - $net).2 -n $4 -g \
192.168.$(expr $1 + $2 - $net).2
done
}
ipfwd_config -P $pid -F -a 192.168.110.1 -i 6
```

```
ipfwd_config -P $pid -F -a 192.168.120.1 -i 7
ipfwd_config -P $pid -F -a 192.168.130.1 -i 8
ipfwd_config -P $pid -F -a 192.168.140.1 -i 9
ipfwd_config -P $pid -G -s 192.168.110.2  -m 02:00:c0:a8:6e:02 -r true
ipfwd_config -P $pid -G -s 192.168.120.2 -m 02:00:c0:a8:78:02 -r true
ipfwd_config -P $pid -G -s 192.168.130.2 -m 02:00:c0:a8:82:02 -r true
ipfwd_config -P $pid -G -s 192.168.140.2 -m 02:00:c0:a8:8c:02 -r true
# 1024
net_pair_routes 110 120  16  16   # 2 *  16 *  16 =  512
net_pair_routes 130 140 16 16   # 2 * 16 * 16 = 512
echo IPFwd Route Creation completed
```

Now traffic can be run as per the routes created.

9.9.6.9 Using Two Computers to Test the IPFWD Application Suite

This section describes how to configure the IPFWD application suite to forward packets between two ordinary computers as shown in the following figure. It is assumed that the two 1 Gbps Ethernet interfaces provided by SerDes 0xe are used.



Assign IP addresses to all the interfaces. The IP addresses used here for Computer X and Computer Y are examples. Their MAC addresses must be known as they will be needed in the commands below.

Keep in mind that ipfwd_app has no default IP address assigned to the interfaces. This means that you must first assign IP addresses to the interfaces and then use IP addresses for Computer X and Computer Y that are on the subnets shown in the figure. Please be careful with the network parameters. Any mistake will prevent packets from flowing from end to end.

Follow these steps on Computer X:

1. Set the ip address for eth0 interface

```
ifconfig eth0 192.168.27.2 up
```

Set the default gateway for subnet 192.168.27.1

```
route add default gw 192.168.27.1 eth0
```

2. Add arp for gw

```
arp –s 192.168.27.1 “MAC address for 192.168.27.1 on P4080”
```

Follow these steps on Computer Y:

1. Set the ip address for eth0 interface

```
ifconfig eth0 192.168.28.2 up
```

Set the default gateway for subnet 192.168.28.1

route add default gw 192.168.28.1 eth0

2. Add arp for gw

arp –s 192.168.28.1 “MAC address for 192.168.28.1 on P4080”

The commands to perform on P4080 are:

Boot the P4080 and login as root.

Assign IP address to fm1-gb1

ifconfig fm1-gb1 <IPADD> up

cd /usr/etc

fmc -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_32_fq.xml -a

Assume use of cores 1 - 7 ipfwd_app 1..7

Now ssh to P4080 linux on other terminal

ssh root@<IPADD>

give IP address as assigned to fm1-gb1 in the beginning

Now assign ip address to the interfaces

First run command to check what all enabled interfaces are available

Note: check pid from application print "Message queue to send: /mq_snd_2536"

ipfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

PortID=1:3 is FMan interface node

with MAC Address

02:00:c0:a8:5b:fe

Interface number: 8

PortID=1:2 is FMan interface node

with MAC Address

02:00:c0:a8:51:fe

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces

Assign IP address to the interfaces.Use the same interface number displayed as an ouput on giving the above command

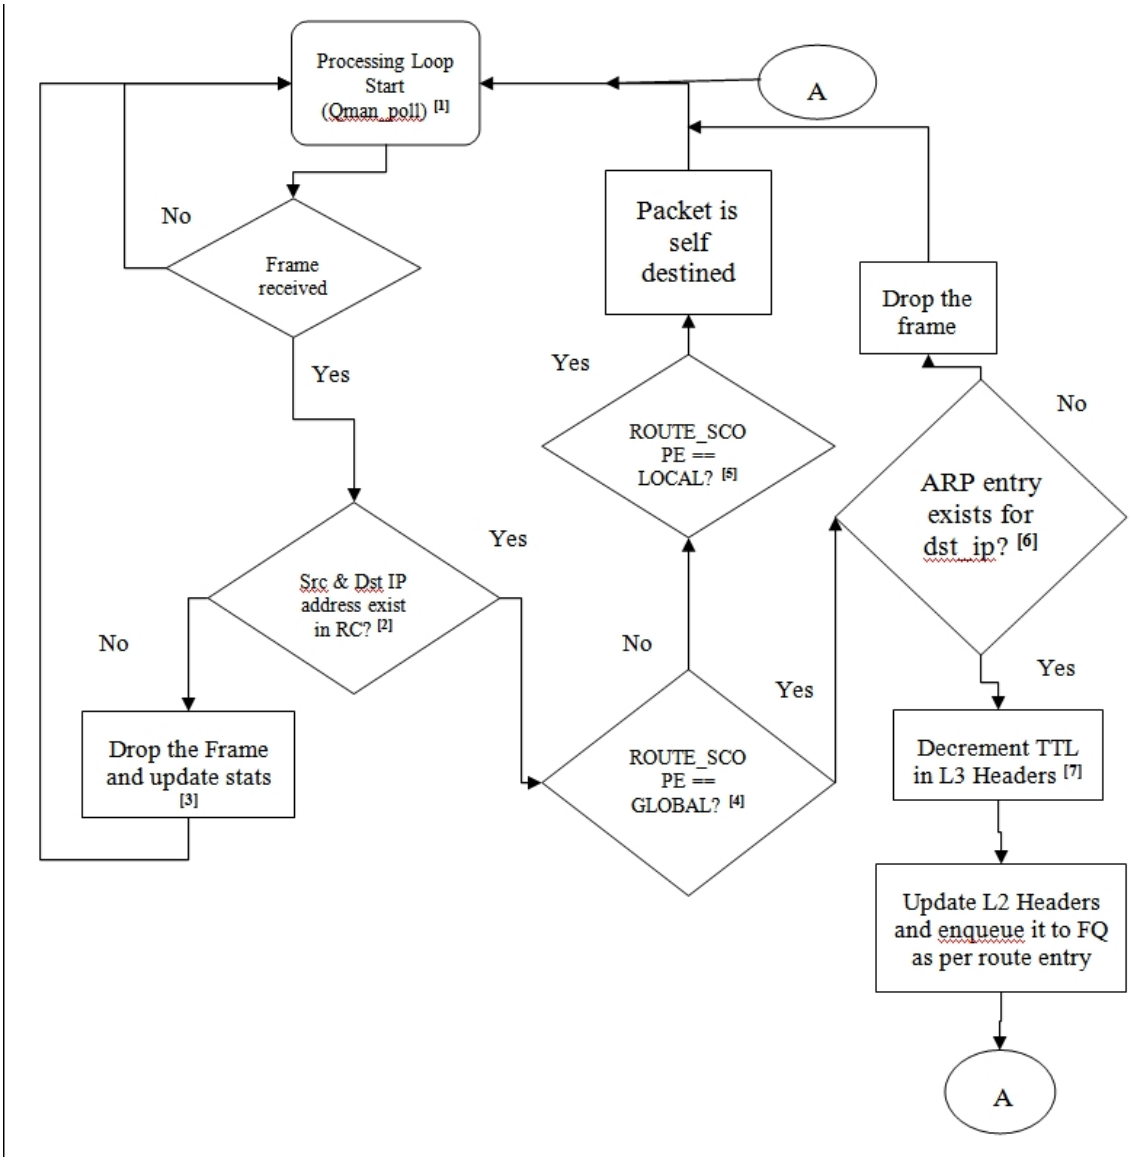
```
ipfwd_config -P 2536 -F -a 192.168.24.1 -i 5
ipfwd_config -P 2536 -F -a 192.168.28.1 -i 9
ipfwd_config -P 2536 -F -a 192.168.27.1 -i 8
ipfwd_config -P 2536 -F -a 192.168.29.1 -i 11

# Now enter routes and MAC addresses. Format of a MAC address is
# aa:bb:cc:dd:ee:ff where the letters are hexadecimal digits.

ipfwd_config -P 2536 -B -s 192.168.27.2 -d 192.168.28.2 -g 192.168.28.2
ipfwd_config -P 2536 -G -s 192.168.28.2 -m COMPUTER_Y_MAC_ADDRESS -r true
ipfwd_config -P 2536 -B -s 192.168.28.2 -d 192.168.27.2 -g 192.168.27.2
ipfwd_config -P 2536 -G -s 192.168.27.2 -m COMPUTER_X_MAC_ADDRESS -r true
# Computer X and Computer Y need to be told to route via the P4080.
# On Computer X (assuming it runs Linux), enter this command as root:
route add -net 192.168.28.0 netmask 255.255.255.0 gw 192.168.27.1
# On Computer Y (assuming it runs Linux), enter this command as root:
route add -net 192.168.27.0 netmask 255.255.255.0 gw 192.168.28.1
# Now, traffic can pass between Computer X and Computer Y. For example, on Computer X
# enter:
ping 192.168.28.2
```

9.9.6.10 Flowchart for packet processing

This topic provides a flowchart for packet processing.



9.9.6.10.1 Description of Flow chart

1. All of the threads enter the processing loop where they call Qman_poll till a frame is received.
2. If a frame is received, the application checks whether the source and destination IP address exist in the Route cache. For this it calls rc_entry_fast_lookup(), which does the fast route look up by using the hash value provided by the FMan. The hash value is indexed into the route table. The IPFWD application does not change its route cache in response to seeing the first packet in a flow. Instead the route cache is set only by commands, as mentioned in section IPv4 forward application Configuration command on page 1720.
3. If the route entry for this frame is not present in the Route cache, the frame is dropped and statistics are updated. It then continues with Qman_poll.
4. If the route entry for this frame exists in the Route cache, it checks for the scope of the frame. If the scope is GLOBAL, the frame is sent for forwarding.
5. If the scope is not GLOBAL but LOCAL, the frame is self-destined. It then continues with Qman_poll.

6. If the frame is to be forwarded, check if ARP entry exists in ARP table for destination IP address. IPFWD application will not dynamically resolve the ARP. So if sending packets to IPFWD using a regular computer, the user will have to create static ARP entries.
7. If ARP entry exists, TTL is decremented in L3 header.
8. Finally, the L2 header is updated, which includes changing the dst MAC address in L2 header. The frame is then enqueued to the TX FQ.

9.9.6.10.2 Running IPv4 forwarding on P4080DS board

The instructions below describe how to run IPFWD. Traffic should only be directed to the P4080DS once the application is running and configuration via the ipfwd_config application is completed.

- On linux prompt, assign IP address to fm1-gb1

$ ifconfig fm1-gb1 <IPADD> up

- Configure FMan PCD using fmc with the XML files in /usr/etc:

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_32_fq.xml -a

To setup the FMan to distribute traffic to 1024 ingress frame queues per port:

$ fmc -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_1024_fq.xml -a

- Run IPFWD application

The main IPFwd application binary is called **ipfwd_app** *. The application can run on multiple cores as specified by the first parameter to the application. To run it to handle traffic distributed over 32 ingress frame queues per port:*

$ ipfwd_app <m..n>

By default ipfwd_app uses us_config_serdes_0xe.xml and us_policy_hash_ipv4_src_dst_32_fq.xml files.

To run for scenario 1024 ingress frame queues per port

$ ipfwd_app <m..n> -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_1024_fq.xml

IPFWD application command syntax:

[root@p4080 etc]# ipfwd_app --usage

Usage: ipfwd_app [-n?V] [-c FILE] [-d SIZE] [-i FILE] [-p FILE] [--fm-config=FILE]

[--non-interactive] [--fm-pcd=FILE] [--cpu-range] [--help]

[--usage] [--version] [cpu-range]

IPFWD application run command:

[root@p4080 root]# cd /usr/etc

<_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_32_fq.xml -a

If the user wants to use all interfaces :

[root@p4080 etc]# ipfwd_app 1..7

If the user wants to use ONLY selective interfaces :

[root@p4080 etc]# ipfwd_app 1..7 -i fm1-10g,fm2-gb2

[1] 5363

[root@p4080 etc]# Found /fsl,dpaa/ethernet@9

Found /fsl,dpaa/ethernet@8

Found /fsl,dpaa/ethernet@7

Found /fsl,dpaa/ethernet@4

Qman: FQID allocator includes range 512:128

Bman: BPID allocator includes range 56:8

Configuring for 4 network interfaces and 4 pool channels

FSL dma_mem device mapped (phys=0xf8000000,virt=0x70000000,sz=0x4000000)

Thread uid:0 alive (on cpu 1)

Release 16384 bufs to BPID 7

Release 4096 bufs to BPID 8

Release 4096 bufs to BPID 9

ipfwd_app starting

Message queue to send: /mq_snd_2536

Message queue to receive: /mq_rcv_2536

Thread uid:1 alive (on cpu 2)

Thread uid:2 alive (on cpu 3)

Thread uid:3 alive (on cpu 4)

Thread uid:4 alive (on cpu 5)

Thread uid:5 alive (on cpu 6)

Thread uid:6 alive (on cpu 7)

If, in the run application command, cpu-range is given i.e. "ipfwd_app <*m..n*>" IPFWD application starts threads on cpu-range m..n. The main thread (by default on CPU 1) then does global initialization needed by the application, including starting other application threads.

If, on the other hand, run application command is given without any cpu-range i.e. "ipfwd_app" IPFWD application starts up with a single thread running on CPU 1 by default, which does global initialization needed by the application and enables all the network interfaces.

The CLI (Command-Line Interface) allows you to add and remove additional threads to enable the use of multiple CPUs, with the only restriction being that the primary thread on CPU 1 cannot be removed (except by shutting down the application).

To add a thread on a single CPU (e.g. CPU 2):

> add 2

To add threads on a range of CPUs:

> add 3..6

To list the threads (this also queries each thread, verifying that they aren't blocked):

> list

Thread alive on cpu 1

Thread alive on cpu 2

Thread alive on cpu 3

Thread alive on cpu 4

Thread alive on cpu 5

Thread alive on cpu 6

To enable all interfaces

> macs on

To disable all interfaces

> macs off

To perform a controlled shutdown of ipfwd (this includes disabling the network ports):

> quit

- Once the application starts, it can receive the configuration commands. Run application configuration script.

For creating route entries, the binary *ipfwd_config* is run. This binary processes the configuration request from the user (using the command line) and populates the configuration via Linux standard posix IPC messages to the IPFwd application.

The shell script mentioned below contains sample commands to add route entries. Detailed description of all ipfwd_config commands is provided in section IPv4 forward application Configuration command on page 1720.

SSH to p4080 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to fm1-gb1 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipfwd_20G.sh "pid"

$ ipfwd_20G.sh 2536

There are two example shell scripts available and those are "ipfwd_20G.sh" and "ipfwd_22G.sh". ipfwd_20G.sh creates routes for only the 2 x 10G interfaces and ipfwd_22G.sh creates routes for 2 x 10G and 2 x 1G interfaces. They can assign IP addresses to the interfaces, add an ARP entry and assumes the netmask to be 255.255.255.0. The following table summarizes the settings done by these scripts. Check sectionPossible configuration scenario for IPFWD on page 1706 for more details.

For the IPFwd application to forward traffic successfully, traffic destined for the P4080DS ports must have the appropriate source and destination addresses.

Console messages are printed for each entry added to the routing table. Once all configuration is completed, the application moves to the packet processing phase - the message "Application Started successfully" is printed on the console. At this point, traffic can be sent to the IPFWD application, which would do its processing on the cpu-range specified by the user on the application command-line.

9.9.6.10.3 Running IPv4 forwarding on P3041/P5020 board

The instructions below describe how to run IPFWD on P3041/P5020. Traffic should only be directed to P3041/P5020 once the application is running and configuration via the ipfwd_config application is completed. · On linux prompt, assign IP address to eth0

$ ifconfig eth0 <IPADD> up

Running IPFWD

· Configure FMan PCD using fmc with the XML files in /usr/etc:

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c usdpaa_config_p3_p5_serdes_0x36.xml -p usdpaa_policy_hash_ipv4.xml -a

· Run IPFWD application

If the user wants to use all interfaces :

$ ipfwd_app <m..n> -c usdpaa_config_p3_p5_serdes_0x36.xml -p usdpaa_policy_hash_ipv4.xml

If the user wants to use ONLY selective interfaces :

$ipfwd_app m..n -c usdpaa_config_p3_p5_serdes_0x36.xml -p usdpaa_policy_hash_ipv4.xml -i fm1-10g,fm1-gb4

For P3041, m..n can be 0..3. For P5020, m..n can be 0..1.

SSH to p4080 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipfwd_15G.sh "pid"

$ ipfwd_15G.sh 2536

There is an example shell script available named as ipfwd_15G.sh creates routes for only the 5 x 1G and 1x10G interfaces. It can assign ip addresses to the interfaces, add an ARP entry and assumes the netmask to be 255.255.255.0. Check section Possible configuration scenario for IPFWD on page 1706 for more details. Now traffic can be run as per the routes created.

9.9.6.10.4 Running IPv4 forwarding on T4240 board

The instructions below describe how to run IPFWD on T4240. Traffic should only be directed to T4240 once the application is running and configuration via the ipfwd_config application is completed. · On linux prompt, assign IP address to eth0

$ ifconfig eth0 <IPADD> up

Running IPFWD

· Configure FMan PCD using fmc with the XML files in /usr/etc:

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c usdpaa_config_t4_serdes_1_1_6_6.xml -p usdpaa_policy_hash_ipv4.xml -a

· Run IPFWD application

$ipfwd_app m..n -c usdpaa_config_t4_serdes_1_1_6_6.xml -p usdpaa_policy_hash_ipv4.xml -d 0x10000000

For T4240, m..n can be 0..23.

SSH to t4240 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipfwd_20G.sh "pid"

$ ipfwd_20G.sh 2536

There is an example shell script available named as ipfwd_20G.sh creates routes for only the 2x10G interfaces. It can assign ip addresses to the interfaces, add an ARP entry and assumes the netmask to be 255.255.255.0. Now traffic can be run as per the routes created.

9.9.6.10.5 Running IPv4 forwarding on B4860 board

The instructions below describe how to run IPFWD on B4860. Traffic should only be directed to B4860 once the application is running and configuration via the ipfwd_config application is completed. · On linux prompt, assign IP address to eth0

$ ifconfig eth0 <IPADD> up

Running IPFWD

· Configure FMan PCD using fmc with the XML files in /usr/etc:

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c usdpaa_config_b4_serdes_0x2a_0x98.xml -p usdpaa_policy_hash_ipv4.xml -a

· Run IPFWD application

$ipfwd_app m..n -c usdpaa_config_b4_serdes_0x2a_0x98.xml -p usdpaa_policy_hash_ipv4.xml

For B4860, m..n can be 0..7.

SSH to b4860 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipfwd_20G.sh "pid"

$ ipfwd_20G.sh 2536

There is an example shell script available named as ipfwd_20G.sh creates routes for only the 2x10G interfaces. It can assign ip addresses to the interfaces, add an ARP entry and assumes the netmask to be 255.255.255.0. Now traffic can be run as per the routes created.

9.9.6.10.6 USDPAA IP Fwd performance gap between 6 core and 8 core

USDPAA IPfwd performance for 8 core is less than 6 core on e6500 series. USDPAA IP Fwd application need to run using "-s" option to bridge the gap between two configuration.

9.9.6.10.7 PPAC (and IPFwd) CLI commands

The following commands are illustrated in the context of IPFwd, but the commands are common to all PPAC-based applications.

To add a thread on a single CPU (e.g. CPU 2):

> add 2

To add threads on a range of CPUs:

> add 3..6

To list the threads (this also queries each thread, verifying that they aren't blocked):

> list

Thread uid:0 alive (on cpu 1)

Thread uid:1 alive (on cpu 2)

Thread uid:2 alive (on cpu 3)

Thread uid:3 alive (on cpu 4)

Thread uid:4 alive (on cpu 5)

Thread uid:5 alive (on cpu 6)

Thread uid:6 alive (on cpu 7)

To remove a thread by its UID:

> rm uid:2

Thread uid:2 killed (cpu 3)

To remove a thread running on a given CPU:

> rm 5 Thread uid:4 killed (cpu 5)

To enable all interfaces:

> macs on

To disable all interfaces:

> macs off

To perform a controlled shutdown of ipfwd (this includes disabling the network ports):

> quit

To query cgr

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 0

9.9.6.11 IPv4 forward application Configuration command

9.9.6.11.1 Syntax

The syntax is as follows:

$ [root@p4080 bin]# ipfwd_config --help

Usage: ipfwd_config [OPTION...]

-B, --routeadd=TYPE adding a route

-C, --routedel=TYPE deleting a route

-E, --showintf=TYPE show interfaces

-F, --intfconf=TYPE change intf config

-G, --arpadd=TYPE adding a arp entry

-H, --arpdel=TYPE deleting a arp entry

-O, --Start/ Go=TYPE Start the processing of packets

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

9.9.6.11.1.1 Command to show all enabled interfaces and their interface numbers

The command to show all the enabled interfaces while running IPv4 forward is as follows:

Ipfwd_config -P pid -E -a true

Table 272. Field Description (show all enabled interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	Show all the interfaces	Yes	true

Command to show all enabled interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# Ipfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces [root@p4080 bin]#

9.9.6.11.1.2 Help for show all enabled interfaces command

The command to obtain help for show all enabled interfaces command is as follows:

ipfwd_config -E -help

Help for show all enabled interfaces

[root@p4080 etc]# ipfwd_config -E --help

Usage: -E [OPTION...]

-a, --a=ALL All interfaces

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.6.11.1.3 Assign IP address to interfaces

The command to assign IP address while running IPv4 forward is as follows:

ipfwd_config -P pid -F -a 192.168.60.1 -i <Interface number>

NOTE

Note: The interface number to be used here must be one of the numbers that got displayed as the output of "show all enabled interfaces command" in section Command to show all enabled interfaces and their interface numbers on page 1721.

Table 273. Field description (assign IP address to interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	IP Address	Yes	a.b.c.d
-i	Interface number	Yes	0-11 (Choose this number from "show all enabled interfaces" command output)

Assign IP address to interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

ipfwd_config -P 2536 -F -a 192.168.60.1 -i 5

IPADDR assigned = 0xc0a83c01 to interface num 5

Intf Configuration Changed successfully

9.9.6.11.1.4 Help for assign IP address to interfaces

The command to obtain help for assign IP address to interfaces command is as follows:

ipfwd_config -F --help

Help for assign IP address to interfaces

[root@p4080 etc]# ipfwd_config -F --help

Usage: -F [OPTION...]

-a, --a=IPADDR IP Address

-i, --i=IFNAME If Name

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.6.11.1.5 Adding a Route Entry

The command to add a route while running IPv4 forward is as follows:

ipfwd_config -P pid -B -s a.b.c.d -d b.c.d.e -g c.d.e.f

Table 274. Field Description (Adding a Route Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d
-g	Gateway IP Address	Yes	a.b.c.d

Adding a Route Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# ipfwd_config -P 2536 -B -s 192.168.29.2 -d 192.168.24.2 -g 192.168.24.2

Route Entry Added successfully

[root@p4080 bin]#

9.9.6.11.1.6 Help for Route Entry Addition

The command to obtain help for route entry addition is as follows:

ipfwd_config -B --help

Help for Adding a Route Entry

[root@p4080 bin]# ipfwd_config -B --help

Usage: -B [OPTION]

-d, --d=DESTIP Destination IP

-f, --f=FLOWID Flow ID - (0 - 1024) {Default: 0}

-g, --g=GWIP Gateway IP

-s, --s=SRCIP Source IP

-t, --t=TOS Type of Service - (0 - 256) {Default: 0}

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.6.11.1.7 Deleting a Route Entry

The command to delete a route while running IPv4 forward is as follows:

ipfwd_config -P pid -C -s a.b.c.d -d b.c.d.e

Table 275. Field Description (Deleting a Route Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d

Deleting a Route Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# ipfwd_config -p 2536 -C -s 192.168.29.2 -d 192.168.24.2 Route Entry Deleted successfully

9.9.6.11.1.8 Help for Deleting a Route Entry

The command to obtain help for route entry deletion is as follows:

ipfwd_config -C --help

Help for Deleting a Route Entry

[root@p4080 bin]# ipfwd_config -C --help

Usage: -C [OPTION...]

-d, --d=DESTIP Destination IP

-s, --s=SRCIP Source IP

-t, --t=TOS Type of Service - (0 - 256) {Default: 0}

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.6.11.1.9 Starting the Application Processing

The command to start the application processing phase is as follows:

ipfwd_config -O

Starting the Application Processing

[root@p4080 bin]# ipfwd_config -O

Application Started successfully

9.9.6.11.1.10 Adding an ARP Entry

The command to add an ARP entry while running IPv4 forward is as follows:

ipfwd_config -P pid -G -s a.b.c.d -m aa:bb:cc:dd:ee [-r true]

Table 276. Field Description (Adding an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d
-m	Mac Address	Yes	aa:bb:cc:dd:ee
-r	Replace existing entry	No	true/ false {Default: false}

Adding an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# ipfwd_config -P 2536 -G -s 192.168.24.2 -m 02:00:c0:a8:33:fd -r true

ARP Entry Added successfully

9.9.6.11.1.11 Help for ARP Entry Addition

The command to obtain help for ARP entry addition is as follows:

ipfwd_config -G --help

Help for Adding an ARP Entry

[root@p4080 etc]# ipfwd_config -G --help

Usage: -G [OPTION...]

-m, --m=MACADDR MAC Address

-r, --r=Replace Replace Exiting Entry - true/ false {Default:

false}

-s, --s=IPADDR IP Address

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.6.11.1.12 Deleting an ARP Entry

The command to delete an ARP while running the IPv4 forward is as follows:

ipfwd_config -P pid -H -s a.b.c.d

Table 277. Field Description (Deleting an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d

Deleting an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# ipfwd_config -P 2536 -H -s 192.168.24.2

Arp Entry Deleted successfully

[root@p4080 bin]#

9.9.6.11.1.13 Help for Deleting an ARP Entry

The command to obtain help for ARP entry deletion is as follows:

ipfwd_config -H --help

Help for Deleting an ARP Entry

[root@p4080 etc]# ipfwd_config -H --help

Usage: -H [OPTION...]

-s, --s=IPADDR IP Address

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7 NXP USDPAA IPSecfwd User Manual

9.9.7.1 Introduction

The User Space Data Path Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document provides the following:

- A summary of the USDPAA IPSecfwd application.
- Execution steps for the IPSecfwd application.

9.9.7.1.1 Purpose

This document describes the USDPAA IPSec forwarding application. This application documents the USDPAA IPSecfwd demonstration applications forwarding flow.

9.9.7.1.2 Change History

Table 278. Change History

Version	Updates
1.1	Creation of IPSecfwd UG for phase v1.0 release. - PPAC/PPAM overview - Basic application flow - Commands to use - Testing IPSecfwd application
1.2	Addition of t4/b4 sections

9.9.7.2 USDPAA IPSecfwd application

The USDPAA IPSec forwarding (IPSecfwd) application is a multi-threaded application that routes IPv4 packets from one Ethernet interface to another after performing encryption/decryption if required on P4080/P3041/P5020/T4240/B4860 systems. The configuration done for the system and the type of the packet is used to determine the type of operation to be performed on the packet. The routing is done based on the source IP address and destination IP address in the frame.

Any combination of the 8 cores on the P4080 can run a USDPAA IPSec Forwarding application thread in USDPAA SDK v1.0.

9.9.7.2.1 Application Overview

The IPSecfwd application can route IPv4 traffic directly over interfaces as well as over the IPSec tunnel between two network nodes connected over different subnets with the assistance of the IPSec protocol security provided by SEC4.0 block. The application works as an extension of the IPv4 forwarding application with encryption/decryption in addition to route lookup and packet forwarding. The IPSec processing tunnel table contains information on frame queues toward SEC4.0 for the IPSec protocol processing of the packet before it is sent out on the egress interface. IPsec can use an extended sequence number (ESN) optionally that is authenticated but not transmitted. If an ESN is found in the PDB, it is given to the authentication CHA in the last. The ESN is incremented whenever the Seq Num rolls over.

The IPSecfwd application has two main phases. There is an initial configuration phase and a subsequent packet processing phase.

The configuration phase executes when the application starts. Application threads are created and global initialization of resources is done which is the part of PPAC (see USDPAA PPAC User Guide for more details). The configuration phase also includes PPAM (i.e. IPSecfwd) related initialization. Once the configuration phase is completed the IPSecfwd application moves to the packet processing phase.

The application provides a command-line interface to enable users to add and remove routing table, ARP cache entries and SA entries at any given time. For each user input, the appropriate information is communicated to the IPSecfwd application via standard Posix IPC. Messages are placed onto the message queue till they are received by the IPSecfwd application. Note that the IPSecfwd application does not dynamically resolve ARP - missing ARP entries will result in the application dropping the packet.

In the packet processing phase, the loop migrates from polling mode to a blocking ìIRQ modeî whenever IPSecfwd has looped a certain number of times without any forward progress. For more information on IRQ mode please refer to ìUSDPAA PPAC User Guideî. In polling mode - the application constantly looks for data to process on its dedicated QMan portal. Network traffic is classified and distributed by the FMan to frame queues based on source and destination IP address in the packet. There is an associated handler that processes the packets arriving on each frame queue.

9.9.7.2.2 Packet Flow

The IPSecfwd application is capable of routing packets with the security processing support from the P4080's SEC4.0 engine. After all the initialization and configurations, each core enters the polling loop and polls for packets from FMan(PPAC), or SEC4.0 (PPAM). The loop dequeues packets from the frame queue associated to pool channels shared by the application cores.

Once a frame is dequeued, it is sent for processing based on callback handler in contextB of the frame queue response ring entry. When the frame is ingressed from FMAN, then the callback handler is called which performs the route lookup and tunnel lookup; and then sends the packet to SEC4.0 block/FMan. For the frame returning from SEC4.0, the encap callback handler is called for a frame coming after encryption or decap callback handler is called for a frame coming after decryption.

The steps for the packet flow for ingress from FMan are as follows:

1. Once the packet is dequeued from FMan, DQRR callback handler associated with Fman is called.
2. After a basic sanity check of the packet (packet header is correct, packet checksum is correct etc.), the packet is checked for the ESP protocol.
    a. If the packet is ESP, a direct tunnel lookup happens based on FMan's PCD hash value and the frame is sent to SEC4.0 engine

b. If the packet is non-ESP, a route lookup based on FMan's PCD happens. If there is an SA entry, it is sent to SEC4.0 block after updating annotations in frame with next level route destination.

c. If the packet is non-ESP and the route is normal, the packet is sent to FMan interface.

d. If no route is found, the packet is discarded.

3. When the packet is dequeued from SEC4.0 Engine, the DQRR callback handler associated with SEC4.0 frame queues is called. Encap callback handler or Decap callback handler will be called from based on the callback handler in contextB of DQRR ring entry.

4. The packet is now taken directly to the FMan interface as the destination field was already filled while sending the packet to the SEC4.0 Engine.

A typical packet flow in a simulated P4080 environment is shown below.

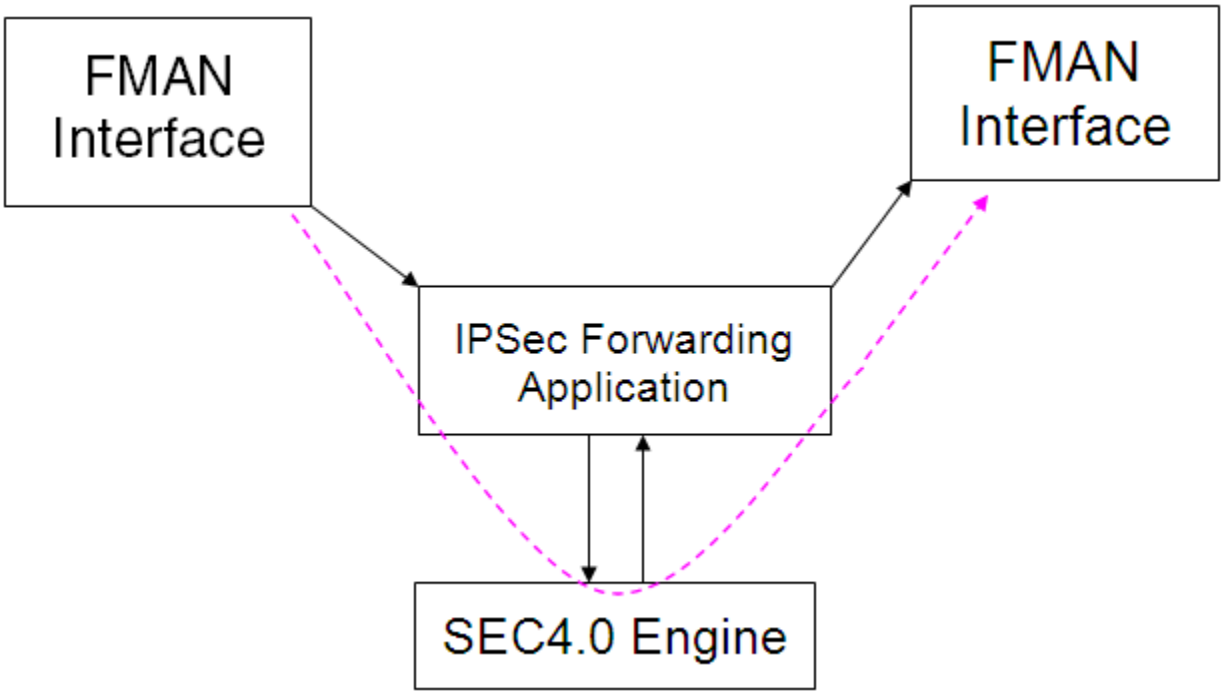

Figure 262. IPSecfwd Application basic packet flow

9.9.7.2.3 Overview of IPSecfwd packet processing

IPSecfwd Steady state processing or Forwarding consists of two parts

- Outbound processing: when un-encrypted packets are received by the system and tunneled using IPSecfwd application.
- Inbound processing: when encrypted packets are received by the systems and are decrypted by the system.

9.9.7.2.3.1 Outbound processing:

1. *Pre-processing:*

   a. Packet is received by the FM which uses 2-tuple (Src IP, Dest IP) to hash the packets to different Core Rx Queues.

   b. This packet is picked up by the core and first subjected to IPv4 Forwarding lookup.

   c. If the action is to do IPSec processing, then it looks up for a corresponding entry in the SADB, which has the SA information and Queue-ids for the SA used by SEC4.0.

2. *Crypto-processing:*

   a. SEC4.0 dequeues the job from egress Queue toward SEC4.0.

b. The SEC4.0 encrypts, authenticates and adds the ESP header and outer IP header to the packet. It then enqueues the processed packet to the Ingress Queue from SEC4.0.

3. *Post-processing*:

a. The core now dequeues the processed packet from the SEC4.0 on Out FQ and sends it to the IPv4 Forwarding module (since there is a new Outer-IP header).

b. IPv4 Forwarding module does a lookup and transmits the packet from the egress interface.

c. If the SEC4.0 result indicates an error in the Crypto processing of the packet, it is discarded and statistics (packet, octets, and errors - per SA / Interface) are updated.

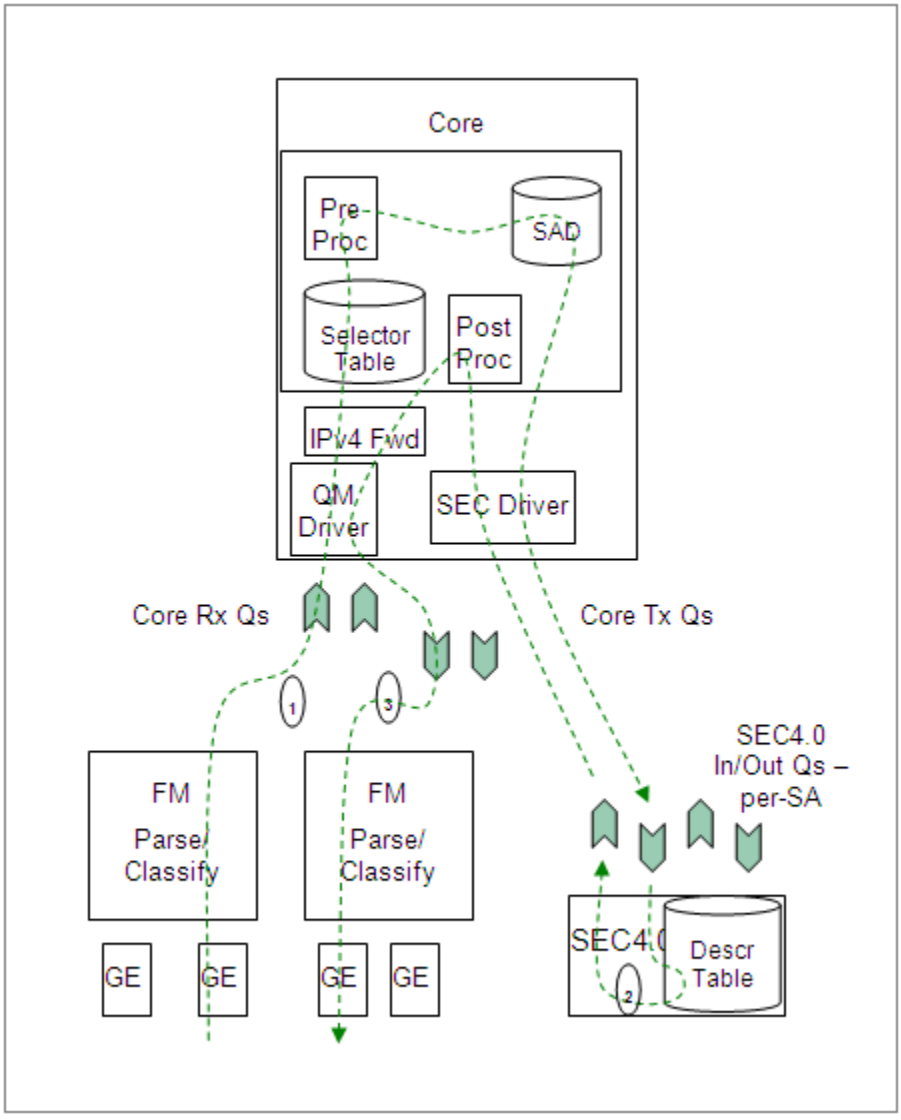

Figure 263. IPSecfwd Outbound processing

9.9.7.2.3.2 Inbound Processing:

1. Pre-processing:

a. The IPSec tunneled packet is received by the FM, which uses a 3-tuple (Dest-IP, Src-IP, SPI) to hash the packet to different Core Rx Queues.

b. The packet is picked up and undergoes IPv4 Forwarding lookup. If packet is self-destined, and protocol is ESP, it is sent to IPSec Forwarding module for processing.

c. The SA info in SADB yields a SEC4.0-In Queue for the SA. The packet is sent to that SEC4.0 on its ingress FQ.

2. Crypto-processing:

a. The SEC4.0 decrypts, authenticates and enqueues the processed packet to the SEC4.0-Out Queue found in its input FQs contextB.

3. Post-processing:

a. The core de-queues the processed packet from the SEC4.0-Out Queue, and subjects the packet to a Selector-table lookup.

b. The packet is handed over to IPv4 Forwarding module, which does a route cache lookup and transmits the packet from the egress interface.

c. If the SEC4.0 result indicates an error in the Crypto processing of the packet, it is discarded and statistics are updated.

sep text

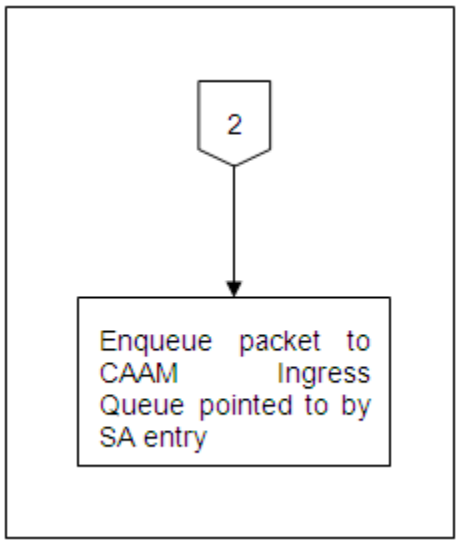

Figure 266. IPSecfwd packet processing

9.9.7.3 Overview of PPAC

The source code to IPSecfwd has been reorganized into two parts; the "PPAC" (Packet-Processing Application Core) and a "PPAM" (Packet-Processing Application Module). The PPAM portion implements the IPSecfwd application specific logic of processing the packet and forwarding it. On the other hand, the PPAC component represents the common infrastructure to support PPAM; initializing devices, handling flow-control, implementing a CLI (Command-Line Interface), managing threads and buffers. PPAC details can be found in the document "USDPAA PPAC User Guide".

9.9.7.4 IPSecfwd related PPAM Details

9.9.7.4.1 In-Place Encryption/Decryption

IPSecfwd application uses in-place Encryption/Decryption when packet is sent to SEC4.0 block. In-place Encryption/ Decryption is supported in IPSecfwd application by using the same output buffer as the input buffer.

In case of Encryption the size of the output packet is more than the size of input packet due to addition of tunnel header, padding of extra bytes etc. The FMam is configured to acquire the buffer from BMan which is large enough to accommodate the output packet after encryption.

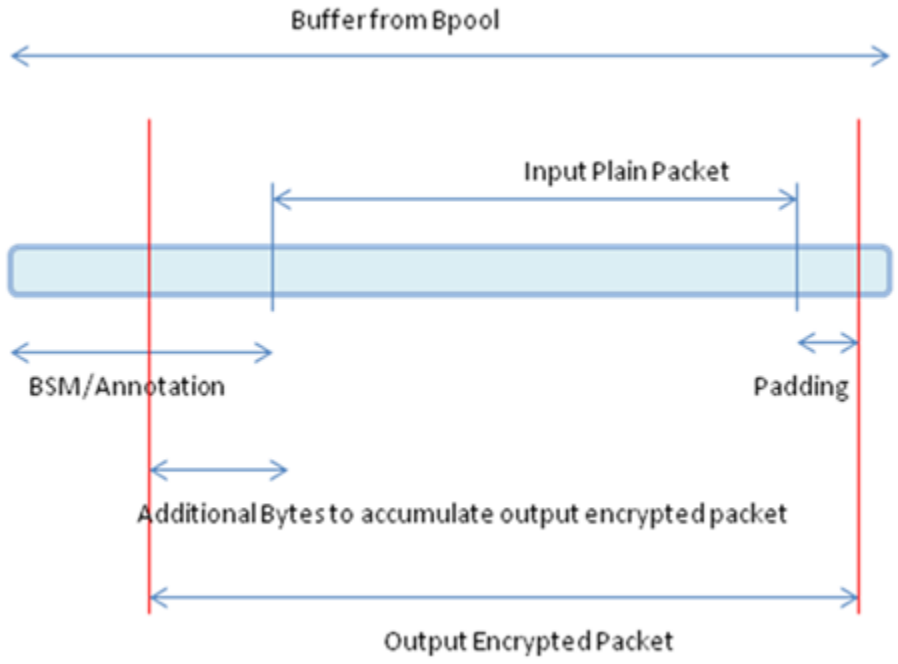

Figure 267. IPSecfwd In-place Encryption

In case of Decryption the output packet size is smaller than the Input packet size. So the output plain packet in case of Decryption can easily be accommodated in the buffer acquired by FMan for storing the Input packet.

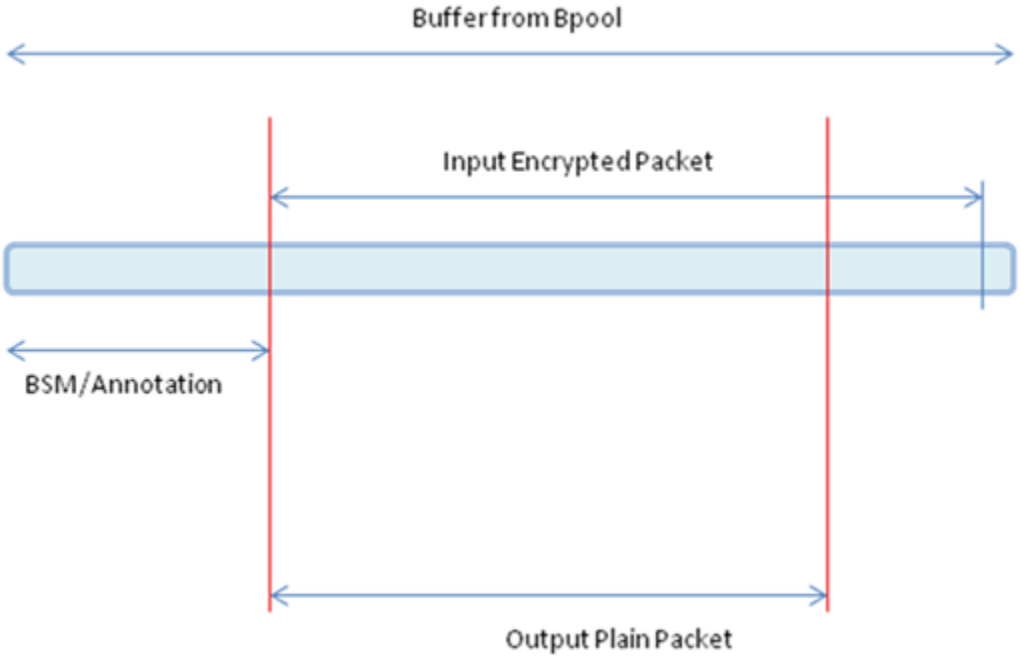

Figure 6: IPSecfwd In-place Decryption

Figure 268. IPSecfwd In-place Decryption

9.9.7.5 Secfwd application suite

The figure below shows the structure of the IPSecfwd USDPAA application suite. Its purpose is to encrypt/decrypt and forward IPv4 packets between the interfaces shown. No IP address is assigned to any of the interfaces by default. Using ipsecfwd_config command as mentioned in section 5.3.1.3 IP address can be assigned to all these interfaces. Each interface has a fixed netmask shown in the figure. The notation "/24" refers to a netmask of 255.255.255.0. The MAC addresses of these interfaces are determined by u-boot environment variables ethaddr, eth1addr, eth2addr, etc.

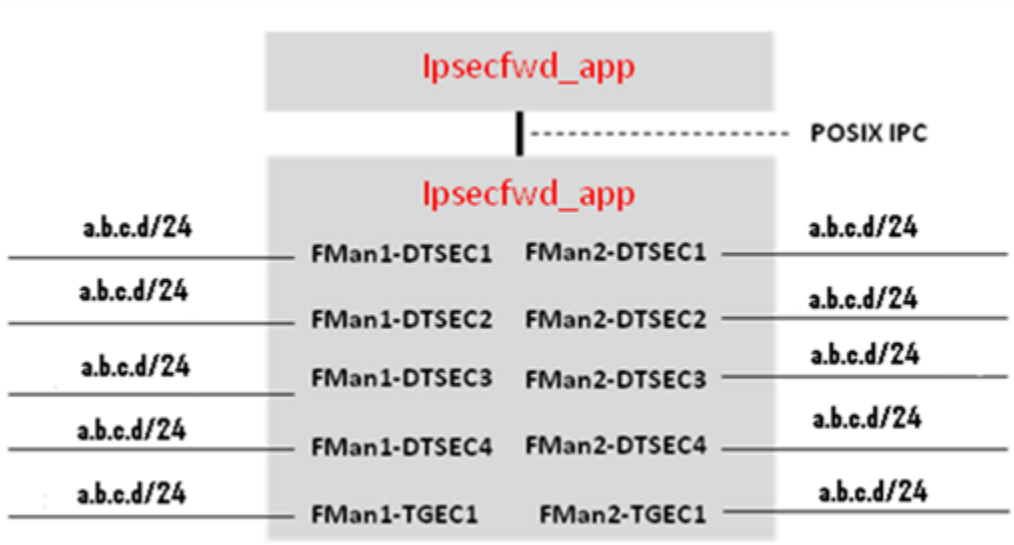

Figure 269. IPSecfwd application suite

The ipsecfwd application will respond to ARP requests on these interfaces. However, the application will not generate ARP requests to determine the destination MAC address of forwarded packets. An ipsecfwd_config command should be used to set these MAC addresses.

It is important to understand that the application can use only a subset of these interfaces at any one time. This is due to pin multiplexing rules on the P4080 SoC. The set of available interfaces is determined by a number of factors:

1. The interface set made available by the selected SerDes Protocol and u-boot variable "hwconfig". See the SDK document "NXP DPAA SDK X.Y: Selecting Ethernet Interfaces". This document is distributed with the DPAA SDK.
2. The Linux device tree determines which subset of the available interfaces is for use by USDPAA applications. See the USDPAA User Guide for more information.
3. Finally, the fmc configuration file passed by command line argument to ipsecfwd_app determines the subset of these interfaces that the application will attempt to initialize.

In the default SerDes 0xe example, the interfaces used by ipsecfwd_app are:

- FMan1-TGEC1
- FMan2-DTSEC3
- FMan2-DTSEC4
- FMan2-TGEC1

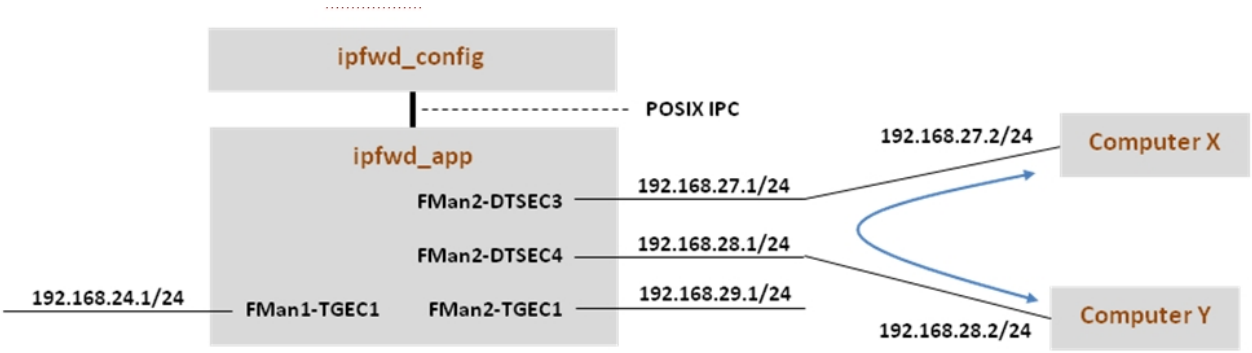
Running the ipsecfwd application suite involves four steps:

1. Run the fmc application to configure the FMan hardware instances.
2. Run ipsecfwd_app
3. Run ipsecfwd_config repeatedly to add SA Entries/routes.

Specific examples showing these steps are provided in other sections of this document.

9.9.7.5.1 Using Two Computers to Test the IPFWD Application Suite

This section describes how to configure the IPFWD application suite to forward packets between two ordinary computers as shown in the following figure. It is assumed that the two 1 Gbps Ethernet interfaces provided by SerDes 0xe are used.



Assign IP addresses to all the interfaces. The IP addresses used here for Computer X and Computer Y are examples. Their MAC addresses must be known as they will be needed in the commands below.

Keep in mind that ipfwd_app has no default IP address assigned to the interfaces. This means that you must first assign IP addresses to the interfaces and then use IP addresses for Computer X and Computer Y that are on the subnets shown in the figure. Please be careful with the network parameters. Any mistake will prevent packets from flowing from end to end.

Follow these steps on Computer X:

1. Set the ip address for eth0 interface

ifconfig eth0 192.168.27.2 up

Set the default gateway for subnet 192.168.27.1

route add default gw 192.168.27.1 eth0

2. Add arp for gw

arp –s 192.168.27.1 “MAC address for 192.168.27.1 on P4080”

Follow these steps on Computer Y:

1. Set the ip address for eth0 interface

ifconfig eth0 192.168.28.2 up

Set the default gateway for subnet 192.168.28.1

route add default gw 192.168.28.1 eth0

2. Add arp for gw

arp –s 192.168.28.1 “MAC address for 192.168.28.1 on P4080”

The commands to perform on P4080 are:

Boot the P4080 and login as root.

Assign IP address to fm1-gb1

ifconfig fm1-gb1 <IPADD> up

cd /usr/etc

fmc -c us_config_serdes_0xe.xml -p us_policy_hash_ipv4_src_dst_32_fq.xml -a

Assume use of cores 1 - 7 ipfwd_app 1..7

Now ssh to P4080 linux on other terminal

ssh root@<IPADD>

give IP address as assigned to fm1-gb1 in the beginning

Now assign ip address to the interfaces

First run command to check what all enabled interfaces are available

Note: check pid from application print "Message queue to send: /mq_snd_2536"

ipfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

PortID=1:3 is FMan interface node

with MAC Address

02:00:c0:a8:5b:fe

Interface number: 8

PortID=1:2 is FMan interface node

with MAC Address

02:00:c0:a8:51:fe

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces

Assign IP address to the interfaces.Use the same interface number displayed as an ouput on giving the above command

ipfwd_config -P 2536 -F -a 192.168.24.1 -i 5

ipfwd_config -P 2536 -F -a 192.168.28.1 -i 9

ipfwd_config -P 2536 -F -a 192.168.27.1 -i 8

ipfwd_config -P 2536 -F -a 192.168.29.1 -i 11

Now enter routes and MAC addresses. Format of a MAC address is

aa:bb:cc:dd:ee:ff where the letters are hexadecimal digits.

ipfwd_config -P 2536 -B -s 192.168.27.2 -d 192.168.28.2 -g 192.168.28.2

ipfwd_config -P 2536 -G -s 192.168.28.2 -m COMPUTER_Y_MAC_ADDRESS -r true

ipfwd_config -P 2536 -B -s 192.168.28.2 -d 192.168.27.2 -g 192.168.27.2

ipfwd_config -P 2536 -G -s 192.168.27.2 -m COMPUTER_X_MAC_ADDRESS -r true

Computer X and Computer Y need to be told to route via the P4080.

On Computer X (assuming it runs Linux), enter this command as root:

route add -net 192.168.28.0 netmask 255.255.255.0 gw 192.168.27.1

On Computer Y (assuming it runs Linux), enter this command as root:

route add -net 192.168.27.0 netmask 255.255.255.0 gw 192.168.28.1

Now, traffic can pass between Computer X and Computer Y. For example, on Computer X

enter:

ping 192.168.28.2

9.9.7.5.2 Running IPSecfwd on P4080DS board

The instructions below describe how to run IPSecfwd. Traffic should only be directed to the P4080DS once the application is running and configuration via the ipfsecwd_config application is completed.

•On linux prompt, assign IP address to fm1-gb1

```
$ ifconfig fm1-gb1 <IPADD> up
```

•Configure FMan PCD using fmc with the XML files in /usr/etc:

```
    $ cd /usr/etc
```

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

```
    $ fmc -c usdpaa_config_serdes_0xe.xml -p usdpaa_policy_hash_ipv4.xml -a
```

•Run IPSecfwd application

The main IPSecfwd application binary is called **ipsecfwd_app**. The application can run on multiple cores as specified by the first parameter to the application. To run it to handle traffic distributed over 32 ingress frame queues per port:

```
$ ipsecfwd_app <m..n>
```

By default ipsecfwd_app uses usdpaa_config_serdes_0xe.xml and usdpaa_policy_hash_ipv4.xml files.

IPSECFWD application command syntax:

```
[root@p4080 etc]# ipsecfwd_app --usage
Usage: ipsecfwd_app [-n?V] [-c FILE] [-p FILE] [--fm-config=FILE]
            [--non-interactive] [--fm-pcd=FILE] [--cpu-range] [--help]
            [--usage] [--version] [cpu-range]
```

IPSECFWD application run command:

```
[root@p4080 root]# cd /usr/etc
<_config_serdes_0xe.xml -p usdpaa_policy_hash_ipv4.xml -a
[root@p4080 etc]# ipsecfwd_app 1..7
[1] 5363
ipsecfwd_app starting
Message queue to send: /mq_snd_2536
Message queue to receive: /mq_rcv_2536
```

If in the run application command, cpu-range is given i.e. ìipsecfwd_app <m..n>î IPSecfwd application starts threads on cpu-range m..n. The main thread (by default on CPU1), then does global initialization needed by the application, including starting other application threads.

If on the other hand run application command is given without any cpu-range i.e. ìipsecfwd_appî IPSecfwd application starts up with a single thread running on CPU 1 by default, which does global initialization needed by the application and enables all the network interfaces.

•Once the application starts it can receive the configuration commands. Run application configuration script

For creating SA entries, the binary **ipsecfwd_config** is run. This binary processes the configuration request from the user (using the command line) and populates the configuration via Linux standard posix IPC messages to the IPSecfwd application.

The shell script mentioned below contains sample commands to add SA entries.

SSH to p4080 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to fm1-gb1 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipsecfwd_20G.sh "pid"

```
$ ipsecfwd_enc_20G.sh 2536 or
$ ipsecfwd_dec_20G.sh 2536
```

One of the example shell scripts available is ìipsecfwd_enc_20G.shî which creates SA Entries for encryption for only the 2 x 10G interfaces. They can assign IP addresses to the interfaces, add SA and ARP entries and assumes the netmask to be 255.255.255.0. The following table summarizes the settings done by this script.

Table 279. ipsecfwd_enc_20G.sh

Port ID	Source IP Address	Destination IP Address (for each src IP addr)	Source tunnel address	Destination tunnel address	Default Gateway IP Address
4	192.168.60.2 to 192.168.60.24	192.168.160.2 .. 24	192.168.60.2	192.168.60.1	192.168.160.2
9	192.168.160.2 to 192.168.160.24	192.168.60.2 .. 24	192.168.160.2	192.168.160.1	192.168.60.2

For the IPSecfwd application to send out traffic successfully, traffic destined for the P4080DS ports must have the appropriate source and destination addresses.

Console messages are printed for each entry added to the SA/routing table. Once all configuration is completed, the application moves to the packet processing phase - the message "Application Started successfully" is printed on the console. At this point, traffic can be sent to the IPSecfwd application which would do its processing on the cpu-range specified by the user on the application command-line.

9.9.7.5.3 Running IPSec forwarding on P3041/P5020 board

The instructions below describe how to run *IPSecfwd* on P3041/P5020. Traffic should only be directed to P3041/P5020 once the application is running and configuration via the *ipsecfwd_config* application is completed.

•On linux prompt, assign IP address to eth0

```
$ ifconfig eth0 <IPADD> up
```

•Configure FMan PCD *using fmc* with the XML files in /usr/etc:

```
    $ cd /usr/etc
```

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

```
    $ fmc -c usdpaa_config_p3_p5_serdes_0x36.xml -p usdpaa_policy_hash_ipv4.xml -a
```

•Run IPSecfwd application

```
    $ ipsecfwd_app <m..n> -c usdpaa_config_p3_p5_serdes_0x36.xml -p usdpaa_policy_hash_ipv4.xml
```

For P3041, m..n can be 0..3. For P5020, m..n can be 0..1.

SSH to p3041/p5020 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipsecfwd_mix_15G.sh "pid"

```
    $  ipsecfwd_mix_15G.sh 2536
```

This is an example shell script available which creates SA Entries for the 5 x 1G and 1x10G interfaces for back to back configuration.

9.9.7.5.4 Running IPSec forwarding on T4240 board

The instructions below describe how to run *IPSecfwd* on T4240. Traffic should only be directed to T4240 once the application is running and configuration via the *ipsecfwd_config* application is completed.

•On linux prompt, assign IP address to eth0

```
$ ifconfig eth0 <IPADD> up
```

•Configure FMan PCD *using fmc* with the XML files in /usr/etc:

```
    $ cd /usr/etc
```

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

```
    $ fmc -c usdpaa_config_t4_serdes_1_1_6_6.xml -p usdpaa_policy_hash_ipv4.xml -a
```

•Run IPSecfwd application

```
    $ ipsecfwd_app <m..n> -c usdpaa_config_t4_serdes_1_1_6_6.xml -p usdpaa_policy_hash_ipv4.xml -
d 0x10000000 -b 0:0:1024
```

For T4240, m..n can be 0..23.

SSH to t4240 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipsecfwd_mix_20G.sh "pid"

```
$  ipsecfwd_mix_20G.sh 2536
```

This is an example shell script available which creates SA Entries for the 2x10G interfaces for back to back configuration.

9.9.7.5.5 Running IPSec forwarding on B4860 board

The instructions below describe how to run *IPSecfwd* on B4860. Traffic should only be directed to B4860 once the application is running and configuration via the *ipsecfwd_config* application is completed.

•On linux prompt, assign IP address to eth0

```
$ ifconfig eth0 <IPADD> up
```

•Configure FMan PCD *using fmc* with the XML files in /usr/etc:

```
$ cd /usr/etc
```

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

```
$ fmc -c usdpaa_config_b4_serdes_0x2a_0x98.xml -p usdpaa_policy_hash_ipv4.xml -a
```

•Run IPSecfwd application

```
$ ipsecfwd_app <m..n> -c usdpaa_config_b4_serdes_0x2a_0x98.xml -p usdpaa_policy_hash_ipv4.xml
```

For B4860, m..n can be 0..7.

SSH to b4860 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

ipsecfwd_mix_20G.sh "pid"

```
$  ipsecfwd_mix_20G.sh 2536
```

This is an example shell script available which creates SA Entries for the 2x10G interfaces for back to back configuration.

9.9.7.5.6 PPAC (and IPSecfwd) CLI commands

The following commands are illustrated in the context of IPSecfwd, but the commands are common to all PPAC-based applications.

The CLI (Command-Line Interface) allows you to add and remove additional threads to enable the use of multiple CPUs, with the only restriction being that the primary thread on CPU 1 cannot be removed (except by shutting down the application).

To add a thread on a single CPU (e.g. CPU 2):

> add 2

To add threads on a range of CPUs:

> add 3..6

To list the threads (this also queries each thread, verifying that they aren't blocked):

> list

Thread alive on cpu 1

Thread alive on cpu 2

Thread alive on cpu 3

Thread alive on cpu 4

Thread alive on cpu 5

Thread alive on cpu 6

To enable all interfaces

> macs on

To disable all interfaces

> macs off

To perform a controlled shutdown of ipsecfwd (this includes disabling the network ports):

> quit

9.9.7.5.7 IPSecfwd application Configuration command

9.9.7.5.7.1 Syntax

The syntax is as follows:

```
$ [root@p4080 bin]# ipsecfwd_config --help
Usage: ipsecfwd_config [OPTION...]
  -A  --SAadd=TYPE           adding an SA entry
  -B, --routeadd=TYPE        adding a route
  -C, --routedel=TYPE        deleting a route
  -D  --SAdel=TYPE           deleting an SA entry
  -E, --showintf=TYPE        show interfaces
  -F, --intfconf=TYPE        change intf config
  -G, --arpadd=TYPE          adding a arp entry
  -H, --arpdel=TYPE          deleting a arp entry
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

9.9.7.5.7.1.1 Command to show all enabled interfaces and their interface numbers

The command to show all the enabled interfaces while running IPv4 forward is as follows:

Ipfwd_config -P pid -E -a true

Table 280. Field Description (show all enabled interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	Show all the interfaces	Yes	true

Command to show all enabled interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# Ipfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

PortID=1:3 is FMan interface node

with MAC Address

02:00:c0:a8:5b:fe

Interface number: 8

PortID=1:2 is FMan interface node

with MAC Address

02:00:c0:a8:51:fe

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces [root@p4080 bin]#

9.9.7.5.7.1.2 Help for show all enabled interfaces command

The command to obtain help for show all enabled interfaces command is as follows:

```
ipsecfwd_config -E -help
Example 2. Help for show all enabled interfaces
 [root@p4080 etc]# ipsecfwd_config -E --help
Usage: -E [OPTION...]
  -a, --a=ALL               All interfaces
  -?, --help                Give this help list
      --usage               Give a short usage message
  -V, --version             Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.3 Assign IP address to interfaces

The command to assign IP address while running IPSecfwd is as follows:

```
ipsecfwd_config -P pid  -F -a 192.168.60.1 -i <Interface number>
```

Note: The interface number to be used here must be one of the numbers that got displayed as the output of "show all enabled interfaces command" in section 2.8.1.1.

Table 281. Field description (assign IP address to interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	IP Address	Yes	a.b.c.d

Table continues on the next page...

Table 281. Field description (assign IP address to interfaces) (continued)

-i	Interface number	Yes	0-11 (Choose this number from "show all enabled interfaces" command output)

Example 3. Assign IP address to interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
ipsecfwd_config -P 2536 -F -a 192.168.60.1 -i 5
IPADDR assigned = 0xc0a83c01 to interface num 5
Intf Configuration Changed successfully
```

9.9.7.5.7.1.4 Help for assign IP address to interfaces

The command to obtain help for assign IP address to interfaces command is as follows:

```
ipsecfwd_config -F --help
```

Example 4. Help for assign IP address to interfaces

```
[root@p4080 etc]# ipsecfwd_config -F --help
Usage: -F [OPTION...]
  -a, --a=IPADDR             IP Address
  -i, --i=IFNAME             If Name
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.5 Adding an SA Entry

The command to add a SA while running IPSecfwd application is as follows:

```
ipsecfwd_config  -P pid  -A -a "AH SA configuration!" -e "encryption key" -s a.b.c.d -d b.c.d.e -
g
c.d.e.f -G a.d.d.a -i 0 -r dir
```

Example 5. Adding an SA Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
[root@p4080 bin]# ipsecfwd_config  -P 2536  -A -a "AH SA configuration!" -e "This is 128 bits" -s
192.168.10.2 -d 192.168.60.2 -g 192.168.61.254 -G 192.168.60.99 -i 0 -r in
```

SA Entry Added successfully

```
[root@p4080 bin]#
```

For the purpose of using ESN (Extended Sequence Number) feature, user is provided two optional parameters. One is -x, which is intended to tell if user wants to use ESN option or not. Other is -v, which the user can configure with some starting sequence number for the packets. For example :

```
[root@p4080 bin]# ipsecfwd_config  -P 2536  -A -a "AH SA configuration!" -e "This is 128 bits" -s
192.168.10.2 -d 192.168.60.2 -g 192.168.61.254 -G 192.168.60.99 -i 0 -r in -x 1 -v 4294967294
```

Table 282. Field Description (Adding an SA Entry)

Parameter	Description	Mandatory	Format/Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d
-g	Left tunnel IP Address	Yes	a.b.c.d
-G	Right Tunnel IP Address	Yes	a.b.c.d
-D	Default Gateway	No	a.b.c.d
-a	Authentication Key for HMAC-SHA1	No (Default key is taken if not supplied)	"string" of length 20 bytes (default = 0x2122_2324_2526_2728_292a_2b2c_2d2e_2f30_3132_3334;
-e	Encryption Key for AES-CBC	No (Default key is taken if not supplied)	"string" of length 16 bytes. (default = 0x0102_0304_0506_0708_090a_0b0c_0d0e_0f10
-i	SPI	Yes	Unsigned int
-r	Direction (encryption/ decryption)	Yes	in (decryption) or out (encryption)
-x	ESN option	No	Unsigned int
-v	Sequence number	No	Unsigned int

9.9.7.5.7.1.6 Help for SA Entry Addition

The command to help add a SA while running IPSecfwd application is as follows:

```
ipsecfwd_config -A --help
```

Example 6. Help for Adding an SA Entry

```
[root@p4080 bin]#]# ipsecfwd_config -A --help
Usage: -A [OPTION...]
  -a, --a=AKEY               Authentication Key
  -d, --d=DESTIP             Destination IP
  -D, --dg=DEFGW             Default Gateway
  -e, --e=EKEY               Encryption Key
  -g, --ss=SRCGW             Source Gateway IP
  -G, --sd=SRCGW             Destination Gateway IP
  -i, --spi=SPI              SPI - 32 bit unsigned int
  -p, --p=PROTO              IPsec Proto type - ESP(0) {Default: 0}
  -r, --dir=DIR              DIR- in/ out
  -s, --s=SRCIP              Source IP
  -t, --t=ETYPE              Encryption Type - AES-CBC(0), 3DES-CBC(1)
                             {Default: 0}
  -v, --seq_num=SEQNUM       Sequence Number
  -x, --is_esn=ESN           Extended Sequence Number support
  -y, --y=ATYPE              Authentication Type - HMAC-SHA1(0) {Default: 0}
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

```
[root@p4080 bin]#
```

9.9.7.5.7.1.7 Deleting an SA Entry

The command to delete an SA while running IPSecfwd is as follows:

```
ipsecfwd_config  -P pid  -D -s 192.168.10.2 -d 192.168.60.2 -g 192.168.61.254 -G 192.168.60.99 -i
0
```

Example 7. Deleting an SA Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
root@p4080 bin]# ipsecfwd_config -P 2536 -D -s 192.168.10.2 -d 192.168.60.2 -g 192.168.61.254 -G
192.168.60.99 -i 0
```

SA Entry Deleted successfully

```
[root@p4080 bin]#
```

Table 283. Field Description (Deleting an SA Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d
-g	Left tunnel IP Address	Yes	a.b.c.d

Table continues on the next page...

Table 283. Field Description (Deleting an SA Entry) (continued)

-G	Right Tunnel IP Address	Yes	a.b.c.d
-i	SPI	Yes	Unsigned int

9.9.7.5.7.1.8 1.4.1.8 Help for Deleting an SA Entry

The command to obtain help for SA entry deletion is as follows:

```
ipsecfwd_config -D --help
```

Example 8. Help for Deleting an SA Entry

```
[root@p4080 bin]# ipsecfwd_config -D --help
Usage: -D [OPTION...]
  -d, --d=DESTIP             Destination IP
  -g, --ss=SRCGW             Source gateway IP
  -G, --sd=DESTGW            Destination gateway IP
  -i, --spi=SPI              SPI
  -s, --s=SRCIP              Source IP
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

```
[root@p4080 bin]#
```

9.9.7.5.7.1.9 Adding a Route Entry

The command to add a route while running IPSecfwd is as follows:

```
ipsecfwd_config -P pid -B -s a.b.c.d -d b.c.d.e -g c.d.e.f
```

Table 284. Field Description (Adding a Route Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d
-g	Gateway IP Address	Yes	a.b.c.d

Example 9. Adding a Route Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
[root@p4080 bin]# ipsecfwd_config  -P 2536 -B -s  192.168.29.2 -d  192.168.24.2 -g  192.168.24.2
```

Route Entry Added successfully

```
[root@p4080 bin]#
```

9.9.7.5.7.1.10 Help for Route Entry Addition

The command to obtain help for route entry addition is as follows:

```
ipsecfwd_config -B --help
```

Example 10. Help for Adding a Route Entry

```
[root@p4080 bin]# ipsecfwd_config -B --help
Usage: -B [OPTION]
  -d, --d=DESTIP             Destination IP
  -f, --f=FLOWID             Flow ID - (0 - 1024) {Default: 0}
  -g, --g=GWIP               Gateway IP
  -s, --s=SRCIP              Source IP
  -t, --t=TOS                Type of Service - (0 - 256) {Default: 0}
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.11 Deleting a Route Entry

The command to delete a route while running IPSecfwd is as follows:

```
ipsecfwd_config  -P pid  -C -s a.b.c.d -d b.c.d.e
```

Table 285. Field Description (Deleting a Route Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Source IP Address	Yes	a.b.c.d
-d	Destination IP Address	Yes	a.b.c.d

Example 11. Deleting a Route Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
[root@p4080 bin]# ipsecfwd_config -P 2536 -C -s  192.168.29.2 -d  192.168.24.2 Route Entry
Deleted
successfully
```

9.9.7.5.7.1.12 Help for Deleting a Route Entry

The command to obtain help for route entry deletion is as follows:

```
ipsecfwd_config -C --help
```

Example 12. Help for Deleting a Route Entry

```
[root@p4080 bin]# ipsecfwd_config -C --help
Usage: -C [OPTION...]
  -d, --d=DESTIP             Destination IP
  -s, --s=SRCIP              Source IP
  -t, --t=TOS                Type of Service - (0 - 256) {Default: 0}
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.13 Adding an ARP Entry

The command to add an ARP entry while running IPSecfwd is as follows:

```
ipsecfwd_config  -P pid  -G -s a.b.c.d -m aa:bb:cc:dd:ee [-r true]
```

Table 286. Field Description (Adding an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d
-m	Mac Address	Yes	aa:bb:cc:dd:ee
-r	Replace existing entry	No	true/ false {Default: false}

Example 14. Adding an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
[root@p4080 bin]# ipsecfwd_config -P 2536  -G -s  192.168.24.2 -m 02:00:c0:a8:33:fd -r true
```

ARP Entry Added successfully

9.9.7.5.7.1.14 Help for ARP Entry Addition

The command to obtain help for ARP entry addition is as follows:

```
ipsecfwd_config -G --help
```

Example 15. Help for Adding an ARP Entry

```
[root@p4080 etc]# ipsecfwd_config -G --help
Usage: -G [OPTION...]
  -m, --m=MACADDR            MAC Address
  -r, --r=Replace            Replace Exiting Entry - true/ false {Default:
                             false}
  -s, --s=IPADDR             IP Address
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.15 Deleting an ARP Entry

The command to delete an ARP while running the IPSecfwd is as follows:

```
ipsecfwd_config   -P pid   -H -s a.b.c.d
```

Table 287. Field Description (Deleting an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d

Example 16. Deleting an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

```
[root@p4080 bin]# ipsecfwd_config -P 2536 -H -s  192.168.24.2
Arp Entry Deleted successfully
[root@p4080 bin]#
```

9.9.7.5.7.1.16 Help for Deleting an ARP Entry

The command to obtain help for ARP entry deletion is as follows:

```
ipsecfwd_config -H --help
```

Example 17. Help for Deleting an ARP Entry

```
[root@p4080 etc]# ipsecfwd_config -H --help
Usage: -H [OPTION...]
-s, --s=IPADDR             IP Address
  -?, --help                 Give this help list
      --usage                Give a short usage message
  -V, --version              Print program version
```

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.7.5.7.1.17 Adding a high bandwidth tunnel

A high bandwidth tunnel is same as normal tunnel except that it has capability to carry high volume of traffic. The purpose of this feature is to provide high throughput when only single IPSec tunnel is created. For non-high bandwidth tunnel only a single core can process a tunnel's packet at any point of time. High bandwidth tunnel option allows multiple cores to process in parallel the packets of a single tunnel.

To create a high bandwidth tunnel "-b 1" should be appended to command for creating a new security association as shown below:

```
ipsecfwd_config  -P pid  -b 1
```

Table 288. Field Description (Create a high bandwidth tunnel)

Parameter	Description	Mandatory	Format/ Value
-b	High bandwidth tunnel enable	No	1/0 [enable/ disable (default: false)]

When a tunnel is in high bandwidth mode, it should show a higher throughput

9.9.8.2 Introduction

About this Document

The User Space Data Path Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document provides the following:

- A summary of the USDPAA "simple crypto" application.
- Execution steps for the "simple crypto" application.

Conventions

This document uses the following conventions:

`Courier` is used to identify commands, explicit command parameters, code examples, expressions, data types, and directives.

9.9.8.3 USDPAA Simple Crypto Application

9.9.8.3.1 Overview

USDPAA Crypto Application is a multi-threaded Linux User space process. This application exercises the interface to the SEC4.0 engine for raw mode encryption, decryption, and authentication of data. Using the P4080 DPAA, the application generates traffic for the SEC4.0 engine and also processes the output from the SEC4.0 engine. The application also generates performance data for its SEC4.0 interactions.

The applications' threads are created using the standard pthreads library. In Linux User Space, any of the 8 cores can be configured to run a USDPAA Crypto application thread. A dedicated QMan software portal is assigned to a USDPAA application thread and each thread is affined to a core. Each core has its own dedicated Frame Queues to interact with the SEC4.0 block. Traffic is directed to the SEC4.0 via frame descriptor enqueues onto QMan frame queues, which are configured to deliver the frames to SEC4.0 engine for processing.

The SEC4.0 engine processes packets on the basis of commands passed in the form of a shared descriptor. A pointer to the shared descriptor is passed to the SEC4.0 in the ingress (towards the security engine) frame queue descriptors' *contextA* field. The egress FQID is used by SEC4.0 to return output to the application - this is passed in the *contextB* field of the ingress frame queue descriptor. Different SEC4.0 shared descriptors are created for different operation like encryption and decryption.

9.9.8.3.2 Parameters to the application

The crypto application supports various runtime parameters. These configurable parameters are passed to the crypto application from the command line while running the application.

1. Mode: Mode can be PERF or CIPHER
   a. **PERF** Mode: In PERF or Performance mode the application calculates the throughput of SEC4.0 processing of data (including enqueue and dequeue operations to and from SEC4.0 block).
   b. **CIPHER** mode: CIPHER mode allows a test run to demonstrate the SEC4.0 throughput and also compares ciphertext generated by SEC4.0 with ciphertext of a standard test vector.
2. Algorithm: This argument specifies the Algorithm to perform on the data. It is passed to SEC4.0 block using a Shared Descriptor. The algorithm choices are documented in Section Simple Crypto command syntax on page 1754.
3. Number of Iterations: This parameter specifies the number of iterations of data to be looped through the SEC4.0 engine in a test run.
4. Number of buffers: It specifies the total number of buffers to send to SEC4.0 block from each core in one encryption/ decryption or authentication iteration. These buffers are distributed among each core.
5. Size of the buffer: This argument is used only with PERF mode. It specifies the size of the each input buffers sent to SEC4.0.
6. Test set number: This argument is used only with CIPHER mode. It specifies the predefined test set to be used as the data set to send to SEC4.0. There are various test sets (with varying size and data) hardcoded in the application. These are documented in the Section Simple Crypto command syntax on page 1754.
7. Number of cores: This is an optional parameter. By default the application uses all the active cores for the processing of the data sets. By specifying the number of cores, the user can limit the application threads to a specific number of cores.

9.9.8.3.3 Packet Flow

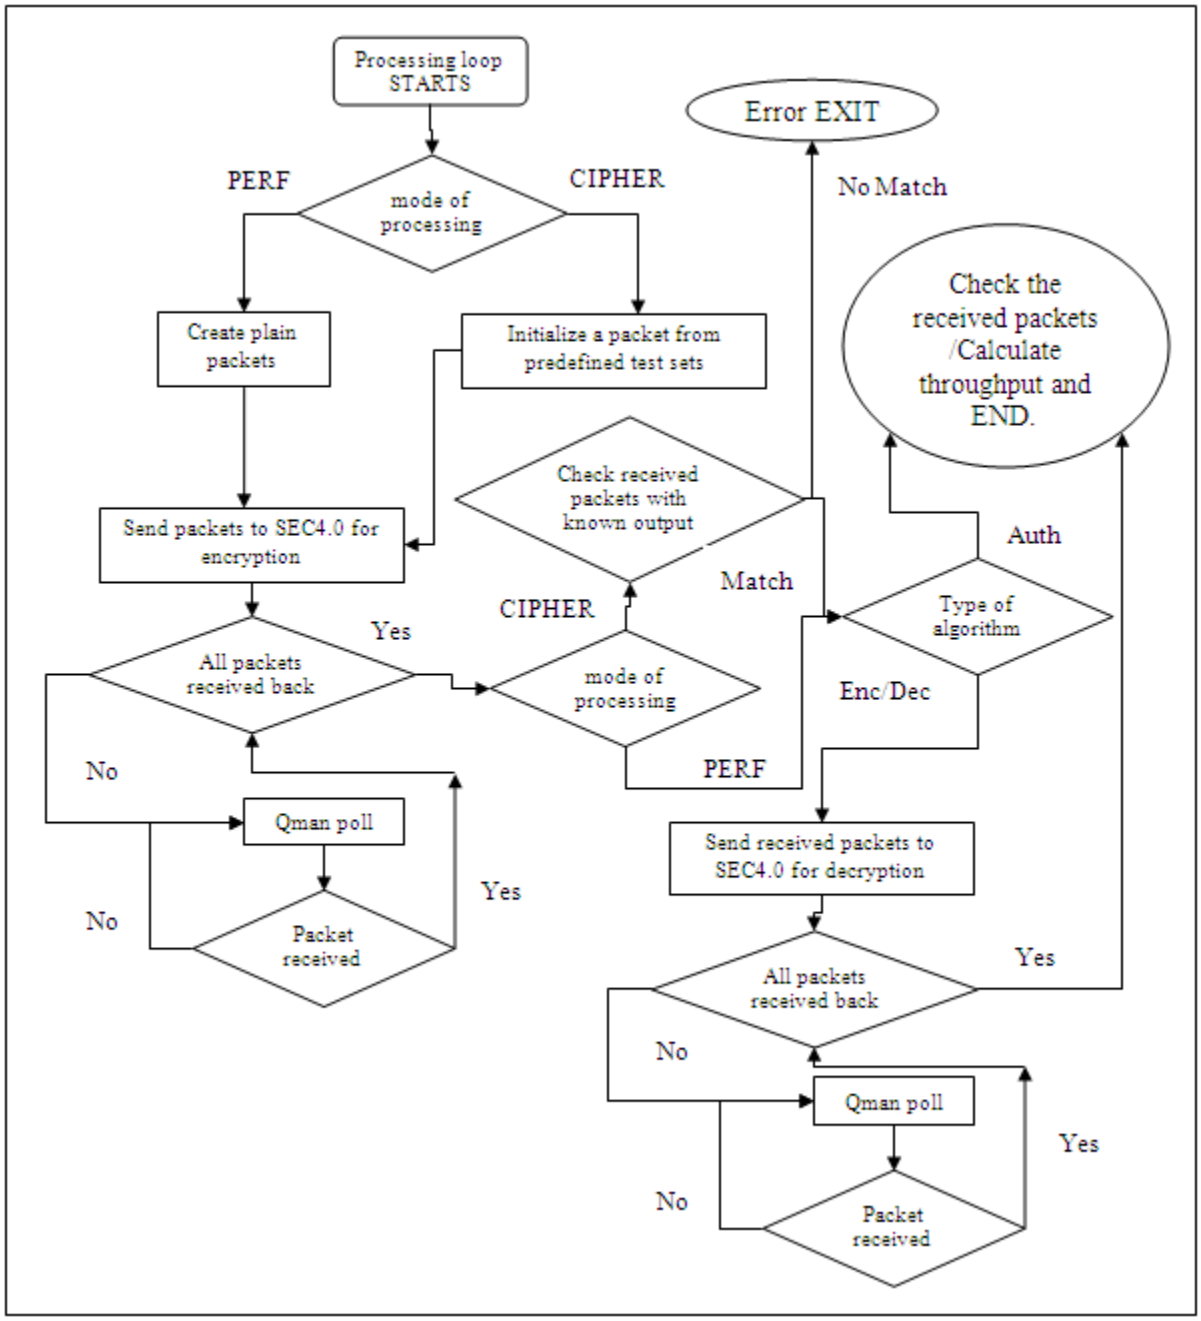

Figure 270. Packet Flow

After initializing the dedicated ingress and egress frame queues for a SEC4.0 operation, the application creates compound frame descriptors (FD's) and fills plain text or pre-defined "cipher" text in input buffers for SEC processing on the basis of the specified mode of operation. For PERF mode, this is plain text; and in the case of CIPHER mode it is pre-defined "cipher" text. The number of FD's equals to the total number of buffers. The FD's, which contain input and output buffer pointers, are first distributed amon the cores and then enqueued to the ingress FQ's. The application thread then polls for output packets from the SEC4.0 egress frame queue until all the packets are received back after being encrypted. As the application uses dedicated Frame Queues between cores and SEC4.0, each core receives the packets which it has enqueued.

In case of CIPHER mode the application checks the received encrypted packets with the already known result.

Lastly, the application checks for the algorithm type. If the algorithm is authentication, then it calculates the throughput in millions of bits per second (Mbps) and exits. If the algorithm type is encryption/decryption, the application sends the same packet (which it received from SEC4.0 after encryption) back to SEC4.0 block for decryption. It does this by changing the pointers of output buffers to point to input buffers and vice-versa in FD's and enqueues these to the SEC4.0's ingress FQ's. It then polls the packet from the SEC4.0 egress frame queue until all the encrypted packets are received back after decryption. The application checks if the packet received after decryption is same as the original plain/cipher text (as a packet after encryption followed by decryption should be the same as the original packet). It then calculates the throughput in Mbps and exits.

9.9.8.3.4 Throughput calculation

The application measures the CPU cycles just before enqueuing the first packet on the FQ and just after receiving the last packet after processing from SEC4.0 for each iteration. The difference between these is the 'delta_cycles' which is accumulated over all the iterations.

Throughput of the application is reported in millions of bits per second (Mbps).

Throughput calculation involves the following parameters.

- 'l' is the number of iterations the application runs for in a test run
- 'n' is the total number of buffers
- 's' is the size of buffer
- 'cpu_freq' is the CPU frequency in MHz

The cycles per frame equals:

cycles_per_frame = (delta_cycles) /(l*n);

Throughput in Mbps equals:

Throughput = (cpu_freq * bits_per_byte *s) / (cycles_per_frame);

= (cpu_freq * 8 *s) / (cycles_per_frame);

9.9.8.3.5 Running Simple Crypto Application on board

1. On the Linux prompt on USDPAA, run the application by typing the following command:

   ```
   simple_crypto -m <mode> -s <size> -n <num_buffer> -o <algo> -l <num_iterations> -t <test_set> [-c
   <num_cores>]
   ```

   Refer to section Simple Crypto command syntax on page 1754 for command syntax.

2. Upon successful completion, the application shows the following message on the USDPAA boot core's console. In case of a failure, a failure message is displayed

   ```
   INFO: SEC4.0 test PASSED
   ```

   Also upon successful completion, the application reports SEC4.0 raw algorithm's throughput on boot core's console.

9.9.8.3.6 Simple Crypto command syntax

The command syntax is as follows:

[root@p4080 root]# simple_crypto --help

Usage: simple_crypto [OPTION...]

-c, --ncpus=CPUS

OPTIONAL PARAMETER

Number of cpus to work for the Application (1-8)(OPTIONAL)

-l, --itrnum=ITERATIONS

Number of iteration to repeat

-m, --mode=TEST MODE

test mode: specify one of the following

1 for perf

2 for cipher

Only the following two combinations are valid. All options are mandatory:

-m 1 -s <buf_size> -n <buf_num_per_core>

-o <algo> -l <itr_num>

or

-m 2 -t <test_set> -n <buf_num_per_core>

-o <algo> -l <itr_num>

-n, --bufnum=TOTAL BUFFERS

Number of buffers per core (1-6400)

-o, --algo=ALGORITHM

Cryptographic operation to be performed by SEC4.0

Specify one of the following:

1 for AES_CBC

2 for TDES_CBC

3 for SNOW_F8

4 for SNOW_F9

5 for KASUMI_F8

6 for KASUMI_F9

7 for CRC

8 for HMAC_SHA1

9 for SNOW_F8_F9(only with PERF mode)

-s, --bufsize=BUFFER SIZE

OPTION IS VALID ONLY IN PERF MODE

Buffer size (64, 128 ...upto 6400)

-t, --testset=TEST SET

OPTION IS VALID ONLY IN CIPHER MODE

provide following test set number:

AES_CBC: 1-4

TDES_CBC: 1-2

SNOW_F8: 1-5

SNOW_F9: 1-5

KASUMI_F8: 1-5

KASUMI_F9: 1-5

CRC: 1-5

HMAC_SHA1: 1-2

SNOW_F8_F9: 1

-?, --help Give this help list

--usage Give a short usage message

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

Note: For For p3041 the ncpus(-c) varies from 1-4 and for p5020 it varies from 1-2.

9.9.8.3.7 Snapshot of Simple Crypto output

The figure below shows a snapshot of simple crypto application output.

9.9.9.2 Introduction

About this Document

The USDPAA Simple Proto application demonstrates the usage of security coprocessor's capabilities in handling traffic in security protocols context

This document provides the following:

- A summary of the USDPAA "simple proto" application.
- Execution steps for running "simple proto" application.

Conventions

This document uses the following conventions:

`Courier` is used to identify commands, explicit command parameters, code examples, expressions, data types, and directives.

9.9.9.3 USDPAA Simple Proto Application

9.9.9.4 Overview

USDPAA Simple Proto application demonstrates usage of SEC engine protocols' integrity and confidentiality algorithms. Using the DPAA framework, the application generates traffic and enqueues it to SEC engine, process the ouput and generate performance data for its SEC interactions.

This is a multi-threaded Linux User Space application. Threads are created using pthreads library, each application thread has an assigned QMan software portal and is affined to a core. Each core has its own dedicated Frame Queues to interact with SEC. Traffic is injected to SEC via frame descriptors enqueued onto QMan frame queues.

The SEC engine processes packets on the basis of commands passed in the form of a shared descriptor. A pointer to the shared descriptor is passed to the SEC in the ingress frame queue descriptors'*contextA* field. The egress FQID is used by SEC to return output to the application - this is passed in the *contextB* field of the ingress frame queue descriptor. Different SEC shared descriptors are created for different protocols' operation.

9.9.9.5 Parameters to the application

The simple_proto application supports various runtime parameters. These configurable parameters are passed to the application from the command line when running the application.

1. Mode: Mode can be PERF or CIPHER
   a. **PERF** Mode: In PERF or Performance mode the application calculates the throughput of SEC processing of data (including enqueue and dequeue operations to and from SEC block). Also, output frames from decapsulation are compared against input frames to encapsulation.

   b. **CIPHER** mode: CIPHER mode allows a test run to demonstrate the SEC throughput and also compares ciphertext generated by SEC with ciphertext of a standard test vector.

2. Protocol: This argument specifies the protocol to be tested. It is passed to SEC block using a Shared Descriptor. The protocol choices are documented in Section Simple Proto command syntax on page 1760. Each protocol has its own set of mandatory and/or optional parameters, which are explained in MACSec protocol options on page 1762, WiMAX protocol options on page 1762, PDCP protocol options on page 1762 and MBMS Protocol Options on page 1765
3. Number of Iterations: This parameter specifies the number of iterations of data to be looped through the SEC engine in a test run.
4. Number of buffers: This specifies the total number of buffers to send to SEC block from each core in one encryption/ decryption or authentication iteration. These buffers are distributed among each core.
5. Size of the buffer: This argument is used only with PERF mode. It specifies the size of the each input buffers sent to SEC.
6. Test set number: This argument is used only with CIPHER mode. It specifies the predefined test set to be used as the data set to send to SEC. There are various test sets (with varying size and data) hardcoded in the application. These are documented in the Section Simple Proto command syntax on page 1760.
7. Number of cores: This is an optional parameter. By default the application uses all the active cores for the processing of the data sets. By specifying the number of cores, the user can limit the application threads to a specific number of cores.
8. SEC Era: This is an optional parameter. This specifies the SEC era hardware block revision for which SEC descriptors will be generated. **By default, the application runs with default era set to value 2**. By specifying the SEC era, the user can set the right value for the targeted platform to test. For example, SEC era on the following platforms is:
   - 2 for P4080 TO2
   - 3 for P3041, P5020
   - 4 for P4080 TO3
   - 5 for P5040, B4860
   - 6 for T4240, T2080 and T1040
   - 7 for LS1021

9.9.9.6 Packet Flow

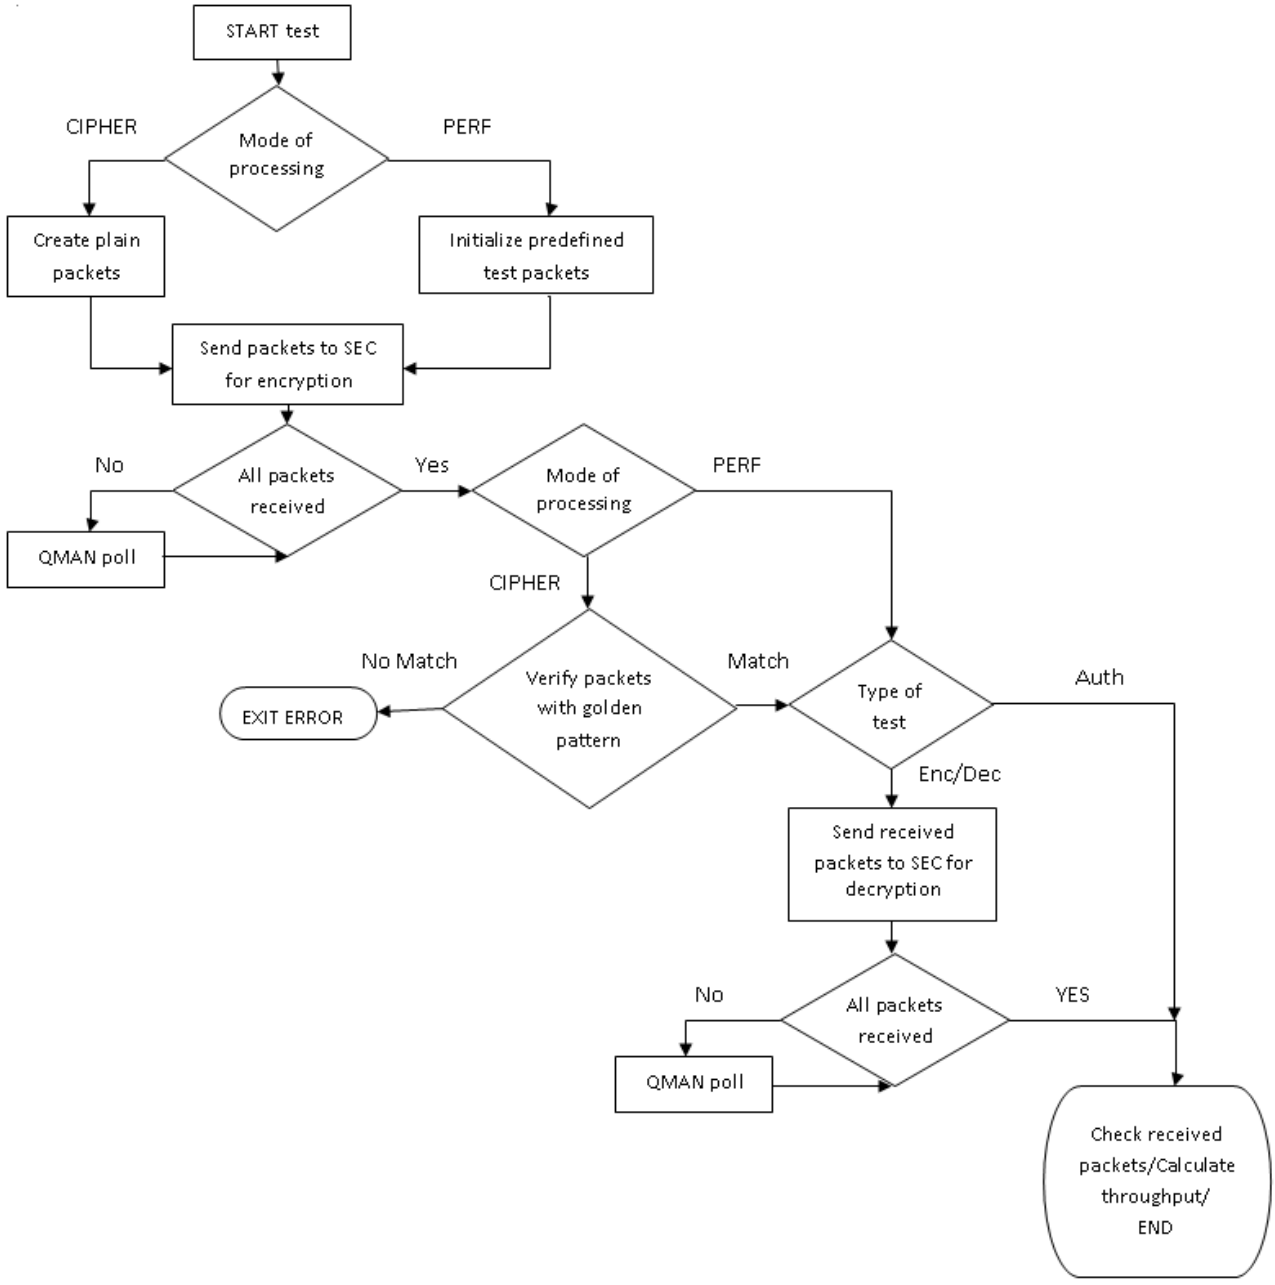

Figure 272. Packet Flow

After initializing the dedicated ingress and egress frame queues for a SEC operation, the application creates compound frame descriptors (FD's) and prepare input buffers for SEC processing based on specified mode of operation; for PERF mode, buffers are filled in with incrementing pattern plain text (for WiMAX encapsulation, SEC expects GMH aware input frames: GMH Header Type bit set to zero, the CRC indicatr bit set to one if CRC is included in the PDU, and the GMH LEN field updated accordingly to the input plain data length), and in the case of CIPHER mode, with golden pattern data. The number of FD's equals to the total number of buffers and are first distributed among the cores and then enqueued to the ingress FQ's. The application thread then polls for output packets from the SEC egress frame queue until all the packets are received back after being encapsulated. As the application uses dedicated Frame Queues between cores and SEC, each core receives the

packets which it has enqueued. In CIPHER test mode, the application checks the received encapsulated packets against a golden pattern.

The next step is the application to verify the type of test. If the test set is unidirectional , then it calculates the throughput in millions of bits per second (Mbps) and exits. If the test verifies both encapsulation/decapsulation, the application sends the packet which it received from SEC after encapsulation back to SEC block for decapsulation. It does this by interchanging the pointers to output and input buffers in FD's and enqueues these to the SEC's ingress FQ's. It then polls the packet from the SEC egress frame queue until all the encapsulated packets are received back after decapsulation. The application checks if the packet received after decapsulation is the same as the original plain/cipher text (as a packet after encapsulation followed by decapsulation should be the same as the original packet). It then calculates the throughput in Mbps and exits.

9.9.9.7 Throughput calculation

The application measures the CPU cycles just before enqueuing the first packet on the FQ and just after receiving the last packet after processing from SEC for each iteration. The difference between these is the 'delta_cycles' which is accumulated over all the iterations.

Throughput of the application is reported in millions of bits per second (Mbps).

Throughput calculation involves the following parameters.

- 'l' is the number of iterations the application runs for in a test run
- 'n' is the total number of buffers
- 's' is the size of buffer
- 'cpu_freq' is the CPU frequency in MHz

The cycles per frame equals:

cycles_per_frame = (delta_cycles) /(l*n);

Throughput in Mbps equals:

Throughput = (cpu_freq * bits_per_byte *s) / (cycles_per_frame);

= (cpu_freq * 8 *s) / (cycles_per_frame);

9.9.9.8 Running Simple Proto Application on board

1. On the Linux prompt on USDPAA, run the application by typing the following command:

   ```
   simple_proto -m <mode> -s <size> -n <num_buffer> -p <protocol> -l <num_iterations> -t <test_set> [-c <num_cores> -e <sec_era>]
   ```

   Refer to section Simple Proto command syntax on page 1760 for command syntax.

2. Upon successful completion, the application shows the following message on the USDPAA boot core's console:

   ```
   INFO: SEC4.0 test PASSED
   ```

   Also upon successful completion, the application reports SEC4.0 raw algorithm's throughput on boot core's console.

   In case of failure, a failure message is displayed on console.

9.9.9.9 Simple Proto command syntax

The command syntax is as follows:

```
root@p4080ds:~# simple_proto --help
Usage: simple_proto [OPTION...]

  -c, --ncpus=CPUS           OPTIONAL PARAMETER
```

```
                              Number of cpus to work for the application(1-8)

  -e, --sec_era=ERA           OPTIONAL PARAMETER

                              SEC Era version on the targeted platform(2-5)

  -l, --itrnum=ITERATIONS     Number of iterations to repeat

  -m, --mode=TEST MODE        Test mode:
                                 1 for perf
                                 2 for cipher

                              Following two combinations are valid only and all
                              options are mandatory:
                              -m 1 -s <buf_size> -n <buf_num_per_core> -p
                              <proto> -l <itr_num>
                              -m 2 -t <test_set> -n <buf_num_per_core> -p
                              <proto> -l <itr_num>

  -n, --bufnum=TOTAL BUFFERS Total number of buffers (1-6400). Both of Buffer
                              size and buffer number cannot be greater than 3200
                              at the same time.

  -p, --proto=PROTOCOL        Cryptographic operation to perform by SEC:
                               1 for MACsec
                               2 for WiMAX
                               3 for PDCP
                               4 for SRTP
                               5 for WiFi
                               6 for RSA
                               7 for TLS
                               8 for IPsec
                               9 for MBMS

  -s, --bufsize=BUFSIZE       OPTION IS VALID ONLY IN PERF MODE

                              Buffer size (64, 128 ... up to 6400). Note: Both
                              of Buffer size and buffer number cannot be greater
                              than 3200 at the same time.
                              The WiMAX frame size, including the FCS if
                              present, must be shorter than 2048 bytes.

  -t, --testset=TEST SET      OPTION IS VALID ONLY IN CIPHER MODE

  -?, --help                  Give this help list
      --usage                 Give a short usage message

Mandatory or optional arguments to long options are also mandatory or optional
for any corresponding short options.
```

NOTE

Depending on the hardware platform, the ncpus(-c) varies as follows: for p3041 between 1-4, for p5020 between 1-2, for B4860 between 1-8 and for T4240 between 1-24.

NOTE

The valid test set numbers are the following, per each protocol:

1. MACSec - 1 .. 5
2. WiMAX - 1 .. 4
3. PDCP - 1
4. SRTP - 1
5. WiFi - 1 .. 2
6. RSA - 1 .. 2
7. TLS - 1
8. IPsec - 1
9. MBMS:
    a. MBMS PDU Type 0 - 1 .. 2
    b. MBMS PDU Type 1 - 1 .. 3
    c. MBMS PDU Type 3 - 1 .. 3

9.9.9.10 MACSec protocol options

For MACSec processing, the simple_proto application understands the following parameters (apart from the mandatory & optional ones specified in Simple Proto command syntax on page 1760):

- -o, --algo : this is an optional parameter that, when set, allows the user to choose the cipher type. The cipher type can be GCM or GMAC; by default, the MACSec protocol will use GCM processing.

9.9.9.11 WiMAX protocol options

WiMAX processing is available only if SEC Era if equal or grater than 4.

For WiMAX processing, the simple_proto application understands the following parameters (apart from the mandatory & optional ones specified in Simple Proto command syntax on page 1760):

- -a, --ofdma : this is an optional parameter that, when set, it enables OFDMA processing for WiMAX. By default, the WiMAX protocol offload does OFDM processing;
- -f, --fcs : this is an optional parameter that, when set, instructs the WiMAX protocol offload to compute the FCS over the input frame, making it longer by 4 bytes;
- -w, --ar_len=ARWIN : another optional parameter that enables the anti-replay mechanism in WiMAX protocol processing. This parameter also sets the anti-replay window length, which cannot exceed 64 frames.

9.9.9.12 PDCP protocol options

Packet Data Convergence Protocol (abbrev. PDCP) is one of the layers of the Radio Traffic Stack in UMTS and performs IP header compression and decompression, transfer of user data and maintenance of sequence numbers for Radio Bearers which are configured for lossless serving radio network subsystem (SRNS) relocation.

In simple_proto application, the following protocol sub-sets are tested & supported:

1. PDCP Control Plane;
2. PDCP User Plane;
3. PDCP Short MAC.

The PDCP ciphering & integrity algorithm combinations supported by simple_proto application are the following:

1. PDCP Control Plane:
   a. NULL encryption & NULL integrity (EEA0/EIA0)
   b. NULL encryption & SNOW f9 integrity (EEA0/EIA1)
   c. NULL encryption & AES CMAC integrity (EEA0/EIA2)
   d. NULL encryption & ZUC integrity (EEA0/EIA3)*
   e. SNOW f8 encryption & NULL integrity (EEA1/EIA0)
   f. SNOW f8 encryption & SNOW f9 integrity (EEA1/EIA1)
   g. SNOW f8 encryption & AES CMAC integrity (EEA1/EIA2)
   h. SNOW f8 encryption & ZUC integrity (EEA1/EIA3)*
   i. AES CTR encryption & NULL integrity (EEA2/EIA0)
   j. AES CTR encryption & SNOW f9 integrity (EEA2/EIA1)
   k. AES CTR encryption & AES CMAC integrity (EEA2/EIA2)
   l. AES CTR encryption & ZUC integrity (EEA2/EIA3)*
   m. ZUC encryption & NULL integrity (EEA3/EIA0)
   n. ZUC encryption & SNOW f9 integrity (EEA3/EIA1)
   o. ZUC encryption & AES CMAC integrity (EEA3/EIA2)
   p. ZUC encryption & ZUC integrity (EEA3/EIA3)*
2. PDCP User Plane:
   a. NULL encryption (EEA0)
   b. SNOW f8 encryption (EEA1)
   c. AES CTR encryption (EEA2)
   d. ZUC encryption (EEA3)*
3. PDCP Short MAC:
   a. NULL integrity (EIA0)
   b. SNOW f9 integrity (EIA1)
   c. AES CMAC integrity (EIA2)
   d. ZUC integrity (EIA3)*

NOTE

Starred combinations above are available only for platforms with SEC ERA greater than 4 (for instance P5040/B4860R1&R2/T4240/etc.). Attempting to run these combinations on platforms without the proper SEC ERA version will result in a SEC error.

NOTE

For the following combinations used for decapsulating PDCP PDUs, the SEC will return an error code similar to 0x3000XX0a if the last 4 bytes of the decapsulated frame (the ICV) are not set to the value of {0x00, 0x00, 0x00, 0x00}

1. EEA1/EIA0
2. EEA2/EIA0
3. EEA3/EIA0

The following parameters can be provided to the simple_proto application (besides the optional & mandatory parameters specified in Simple Proto command syntax on page 1760):

Parameter	Explanation	Valid for Control Plane?	Valid for User Plane?	Valid for Short MAC?
-d, --direction	Selects the downlink direction for the inserted PDU; by default, the direction of thePDU is assumed to be uplink.	Yes, optional	Yes, optional	No
-i, --integrity	Selects the integrity algorithm to be used for processing the PDU	Yes, mandatory	No	Yes, mandatory
-r, --cipher	Selects the ciphering algorithm to be used for processing the PDU	Yes, mandatory	Yes, mandatory	No
-v, --hfn_ov	Enables the HFN value used for processing the PDU to be specified by the user.	Yes, optional	Yes, optional	No
-x, --snlen	Select the User Plane PDUs sequence number length. Three values are permitted: 0 = 12 bit Sequence Number PDU 1 = 7 bit Sequence Number PDU 2 = 15 bit Sequence Number PDU	No	Yes, optional	No
-y, --type	Selects the way the input PDU is to be treated: 0 = Control Plane 1 = User Plane 2 = Short MAC	Yes, mandatory	Yes, mandatory	Yes, mandatory

9.9.9.13 RSA operations options

For RSA processing, the simple_proto application understands the following parameter (apart from the mandatory & optional ones specified in Simple Proto command syntax on page 1760):

- -b, --form : this is an optional parameter that, when set, allows the user to choose one of the three RSA Decrypt Private Key formats:

  1 = Form 1 (default)

  2 = Form 2

  3 = Form 3

9.9.9.14 TLS protocol options

Transport Layer Security (TLS) and its predecessor, Secure Sockets Layer (SSL), are cryptographic protocols designed to provide communication security over the Internet.

simple_proto application tests and supports the TLS10 security protocol.

The following parameters can be provided to the simple_proto application (besides the optional & mandatory parameters specified in Simple Proto command syntax on page 1760):

Parameter	Explanation	Optional / Mandatory
-j, --cipher	Selects the ciphering algorithm to be used for processing the PDU: 0 = AES-CBC	mandatory
-k, --integrity	Selects the integrity algorithm to be used for processing the PDU: 0 = HMAC-SHA1	mandatory
-g, --version	Select the SSL protocol version to run: 0 = SSL30 (not supported) 1 = TLS10 2 = TLS11 (not supported) 3 = TLS12 (not supported) 4 = DTLS10 (not supported)	mandatory

9.9.9.15 IPsec protocol options

Internet Protocol Security (IPsec) is a protocol suite for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet of a communication session.

simple_proto application tests and supports 3des & hmac-md5-96 IPsec ESP Tunnel mode.

The following parameters can be provided to the simple_proto application (besides the optional & mandatory parameters specified in Simple Proto command syntax on page 1760):

Parameter	Explanation	Optional / Mandatory
-h, --cipher	Selects the ciphering algorithm to be used for processing the PDU: 0 = 3DES	mandatory
-q, --integrity	Selects the integrity algorithm to be used for processing the PDU: 0 = HMAC_MD5_96	mandatory

9.9.9.16 MBMS Protocol Options

MBMS SYNC protocol is defined in 3GPP TS 25.446 - MBMS synchronisation protocol (SYNC)

The MBMS Synchronisation protocol (SYNC) is located in the User plane of the Radio Network layer over the Iu interface: the Iu UP protocol layer.

The SYNC protocol for UTRAN is used to convey userdata associated to MBMS Radio Access Bearers.

The simple_proto application supports checking for the CRC validity of the following MBMS PDU Types:

1. MBMS PDU Type 0
2. MBMS PDU Type 1
3. MBMS PDU Type 3

The following table summarizes the behavior of the MBMS SYNC processing:

MBMS SYNC PDU	Default action	Header CRC fail action	Payload CRC fail action(s)
Type 0	Copy PDU	Drop PDU	N/A
Type 1	Copy PDU	Drop PDU	1. Update Payload CRC in PDU's header 2. Copy Header only
Type 3	Copy PDU	Drop PDU	1. Update Payload CRC in PDU's header 2. Copy Header only

The following table lists SEC return codes used for signaling the different actions the SEC takes in order to process the MBMS SYNC PDUs:

Processing result	SEC status/command
PDU Header & Payload CRC OK	0x0000_0000
Wrong PDU Header CRC	0x3000_XXAA
Wrong PDU Payload CRC	0x3000_XXAB

NOTE

The "XX" in the above rows is an internal offset used by SEC and can be safely masked out when checking the SEC status.

The following parameters can be provided to the simple_proto application (besides the optional & mandatory parameters specified in Simple Proto command syntax on page 1760

Parameter	Explanation	Valid values
-z, --type	Selects the MBMS PDU Type to be processed	• 0 - MBMS PDU Type 0 • 1 - MBMS PDU Type 1 • 3 - MBMS PDU Type 2

9.9.10 SEC Descriptor construction library (DCL)

9.9.10.1 SEC Descriptor Construction Library (DCL)

A description of the SEC descriptor construction library (DCL) as a library within USDPAA.

The following is a description of the SEC descriptor construction library (DCL) as a library within USDPAA:

- DCL Description on page 1767, provides a brief overview of the DCL
- DCL Packaging on page 1767, describes how the DCL is packaged
- DCL Files on page 1767, lists the supported files
- DCL Functional Description on page 1767, describes the three layers of the DCL:
  - Lower layers-Command Generator on page 1767, and Descriptor Disassembler on page 1767
  - Upper layer Upper-Tier DCL Functions - Descriptor Constructors on page 1781

9.9.10.2 DCL Description

The Descriptor Construction Library (DCL) provides a collection of simple functions capable of building SEC4.x descriptors for a wide range of purposes, either as a standalone library or integrated within a driver subsystem. Applications may use all, part, or none of the DCL's functions, or they may use DCL as a simple reference for their own construction functions.

The DCL package will evolve over time. Additional protocol support and descriptor utilities will be added in future software (SW) releases, as new applications for SEC 4.x are developed.

9.9.10.3 DCL Packaging

DCL is packaged with and used only by USDPAA sample applications.

Types in DCL are defined using POSIX conventions for the sake of external portability.

9.9.10.4 DCL Files

The following files are supported

- `cmdgen.c`-Descriptor command generator.
- `disasm.c`-Descriptor disassembler.
- `jobdesc.c`-Job descriptor constructors.
- `protoshared.c`-Shared/protocol descriptor constructors.
- `dcl.h`-Definitions for all published DCL functions.

9.9.10.5 DCL Functional Description

DCL consists of two layers, decomposed into three subsystems:

- A lower tier, comprising the following:
  - Command generator (described in Command Generator on page 1767), colloquially referred to as "cmdgen".
  - Descriptor disassembler (described in Descriptor Disassembler on page 1767)
- An upper tier, composed of descriptor constructors (described in Upper-Tier DCL Descriptor Constructors on page 1768). This is dependent on the command generator in the lower tier.

9.9.10.6 Command Generator

The Command Generator is the lowest level of DCL functionality. Each function within it is capable of generating a single command/instruction in a SEC4.x descriptor and increments a "next in" pointer to the next descriptor word following the generated command.

Applications may use the command generator independently of any other DCL functionality.

In general, creation of any application needing to generate a descriptor on an individual command basis like this starts by building the first commands (or PDB data) past the header, until the body of the descriptor is complete. At this point, the full size of the descriptor in known; the application can then fill in the header using this size.

9.9.10.7 Descriptor Disassembler

The Descriptor Disassembler is meant to be a simple debug tool that can display the content of a constructed descriptor for the user to see in a simple "disassembled" representation. It is intended for developers to use as a visualization aid during development, or as a debug tool, in which descriptor content can be displayed on-the-fly in a human-decipherable form. It does not perform consistency checking, or otherwise identify problem areas in poorly formed descriptors.

The disassembler is a simple C function, and can be packaged in the library with the balance of DCL functions so that it may be linked into a higher-level application.

An example of a disassembled IPSec CBC decapsulation shared descriptor:

```
shrdesc: stidx=8 len=20 share-always
     (pdb): [00] 0x00340001 0x00000000 0x00000000 0x00000000
     (pdb): [04] 0x00000000 0x00000000 0x00000000
       key: len=20 class2->keyreg inline
            [00] 0x000e0f00 0x0d0f0a00 0x0d0f0a00 0x0d0f0a00
            [04] 0x0d0f0a00
       key: len=16 class1->keyreg inline
            [00] 0x00e0f0a0 0x00d0f0a0 0x00e0f0a0 0x00d0f0a0
 operation: type=decap-pcl ipsec aes-cbc hmac-sha1-96
```

An example of a disassembled IPSec CBC encapsulation shared descriptor:

```
shrdesc: stidx=23 len=35 share-always
     (pdb): [00] 0x0000000d 0x00000000 0x00000000 0x00000000
     (pdb): [04] 0x00000000 0x00000000 0x00000000 0x00000000
     (pdb): [08] 0x00000034 0x34001045 0x00402512 0xd2860640
     (pdb): [12] 0x7746430a 0xc046430a 0x160022d0 0x5d891888
     (pdb): [16] 0x9cee1912 0xbc211080 0x00000898 0x0a080101
     (pdb): [20] 0x22759aa6 0xdb143f08
       key: len=20 class2->keyreg inline
            [00] 0x000e0f00 0x0d0f0a00 0x0d0f0a00 0x0d0f0a00
            [04] 0x0d0f0a00
       key: len=16 class1->keyreg inline
            [00] 0x00e0f0a0 0x00d0f0a0 0x00e0f0a0 0x00d0f0a0
 operation: type=encap-pcl ipsec aes-cbc hmac-sha1-96
```

9.9.10.8 Upper-Tier DCL Descriptor Constructors

A higher level of functionality is provided through complex descriptor constructors. These constructors are single-purpose functions capable of generating complete descriptors from user specifications. These constructors fit into two categories, one for job descriptors and another for shared descriptors generally targeted to protocol processing.

These constructors are by no means the "definitive" reference to all possible descriptor permutations, nor are they meant to work with any specific application. Instead, they are meant to be general-purpose examples of descriptor construction. It is expected that, over time, this library will grow to accommodate a wide range of examples.

All constructor functions are dependent on the underlying command generator.

9.9.10.9 API reference

9.9.10.9.1 API reference command generator

9.9.10.9.1.1 cmd_insert_shared_hdr()

`cmd_insert_shared_hdr()`: Insert a shared descriptor header into a descriptor

```
  u_int32_t *cmd_insert_shared_hdr(u_int32_t *descwd,
                                   u_int8_t startidx,
                                   u_int8_t desclen,
                                   enum ctxsave ctxsave,
                                   enum shrst share);
```

Inputs:

- descwd-pointer to target descriptor word to hold this command. Note that this should always be the first word of a descriptor.
- startidx-index to continuation of descriptor data, normally the first descriptor word past a PDB. This tells DECO what to skip over.
- desclen-length of descriptor in words, including header.
- ctxsave-Saved or erases context when a descriptor is self-shared
  - CTX_SAVE = context saved between iterations
  - CTX_ERASE = context is erased
- share-Share state of this descriptor:
  - SHR_NEVER = Never share. Fetching is repeated for each processing pass.
  - SHR_WAIT = Share once processing starts.
  - SHR_SERIAL = Share once completed.
  - SHR_ALWAYS = Always share (except keys)

Returns:

Pointer to next incremental descriptor word past the header just constructed. If an error occurred, returns 0.

NOTE

Headers should normally be constructed as the final operation in the descriptor construction, because the start index and overall descriptor length will likely not be known until construction is complete. For this reason, there is little use to the "incremental pointer" convention. The exception is probably in the construction of simple descriptors where the size is easily known early in the construction process.

9.9.10.9.1.2 cmd_insert_hdr()

cmd_insert_hdr(): Insert a standard descriptor header into a descriptor

```
u_int32_t *cmd_insert_hdr(u_int32_t *descwd,
                          u_int8_t startidx,
                          u_int8_t desclen,
                          enum shrst share,
                          enum shrnext sharenext,
                          enum execorder reverse,
                          enum mktrust mktrusted);
```

Inputs:

- descwd-pointer to target descriptor word to hold this command. Note that this should always be the first word of a descriptor.
- startidx-index to continuation of descriptor data, or if sharenext = SHRNXT_SHARED, then specifies the size of the associated shared descriptor referenced in the following instruction.
- desclen-length of descriptor in words, including header.
- share-Share state for this descriptor:
  - SHR_NEVER-Never share. Fetching is repeated for each processing pass.
  - SHR_WAIT-Share once processing starts.
  - SHR_SERIAL-Share once completed.

- SHR_ALWAYS-Always share (except keys)
- SHR_DEFER-Use the referenced sharedesc to determine sharing intent

- sharenext-Control state of shared descriptor processing
  - SHRNXT_SHARED-This is a job descriptor consisting of a header and a pointer to a shared descriptor only.
  - SHRNXT_LENGTH-This is a detailed job descriptor, thus desclen refers to the full length of this descriptor.
- reverse-Reverse execution order between this job descriptor, and an associated shared descriptor:
  - ORDER_REVERSE-execute this descriptor before the shared descriptor referenced.
  - ORDER_FORWARD-execute the shared descriptor, then this descriptor.
- mktrusted-DESC_SIGN-sign this descriptor prior to execution
  - DESC_STD -leave descriptor non-trusted

9.9.10.9.1.3 cmd_insert_key()

cmd_insert_key(): Insert a key command into a descriptor

```
u_int32_t *cmd_insert_key(u_int32_t           *descwd,
              u_int8_t                        *key,
              u_int32_t                       keylen,
              enum ref_type                   sgref,
              enum key_dest                   dest,
              enum key_cover                  cover,
              enum item_inline                imm,
              enum item_purpose purpose);
```

Inputs:

- descwd-pointer to target descriptor word to hold this command
- key-pointer to key data as an array of bytes.
- keylen-pointer to key size, expressed in bits.
- sgref-pointer is actual data, or a scatter-gather list representing the key:
  - PTR_DIRECT-points to data
  - PTR_SGLIST-points to SEC4.x-specific scatter gather table. Cannot use if imm = ITEM_INLINE.
- dest-target destination in SEC4.x to receive the key. This may be:
  - KEYDST_KEYREG-Key register in the CHA selected by an OPERATION command.
  - KEYDST_PK_E-The 'e' register in the public key block
  - KEYDST_MD_SPLIT-Message digest IPAD/OPAD direct load.
- cover-Key was encrypted, and must be decrypted during the load. If trusted descriptor, use TDEK, else use JDEK to decrypt.
  - KEY_CLEAR-key is cleartext, no decryption needed
  - KEY_COVERED-key is ciphertext, decrypt.
- imm-Key can either be referenced, or loaded into the descriptor immediately following the command for improved performance.
  - ITEM_REFERENCE-a pointer follows the command.

- ITEM_INLINE-key data follows the command, padded out to a descriptor word boundary.

- purpose-Sends the key to the class 1 or 2 CHA as selected by an OPERATION command. If dest is KEYDST_PK_E, this must be ITEM_CLASS1.

Returns:

If successful, returns a pointer to the target word incremented past the newly-inserted command (including item pointer or inlined data). Effectively, this becomes a pointer to the next word to receive a new command in this descriptor. If error, returns 0

9.9.10.9.1.4 cmd_insert_seq_key()

cmd_insert_key(): Insert a key command into a descriptor using a sequence

```
u_int32_t *cmd_insert_key(u_int32_t           *descwd,
                  u_int32_t                   keylen,
                  enum ref_type               sgref,
                  enum key_dest               dest,
                  enum key_cover              cover,
                  enum item_inline            imm,
                  enum item_purpose purpose);
```

Inputs:

- descwd-pointer to target descriptor word to hold this command

- keylen-pointer to key size, expressed in bits.

- sgref-pointer is actual data, or a scatter-gather list representing the key:

  - PTR_DIRECT-points to data

  - PTR_SGLIST-points to SEC4.x-specific scatter gather table. Cannot use if imm = ITEM_INLINE.

- dest-target destination in SEC4.x to receive the key. This may be:

  - KEYDST_KEYREG-Key register in the CHA selected by an OPERATION command.

  - KEYDST_PK_E-The 'e' register in the public key block

  - KEYDST_MD_SPLIT-Message digest IPAD/OPAD direct load.

- cover-Key was encrypted, and must be decrypted during the load. If trusted descriptor, use TDEK, else use JDEK to decrypt.

  - KEY_CLEAR-key is cleartext, no decryption needed

  - KEY_COVERED-key is ciphertext, decrypt.

- imm-Key can either be referenced, or loaded into the descriptor immediately following the command for improved performance.

  - ITEM_REFERENCE-a pointer follows the command.

  - ITEM_INLINE-key data follows the command, padded out to a descriptor word boundary.

- purpose-Sends the key to the class 1 or 2 CHA as selected by an OPERATION command. If dest is KEYDST_PK_E, this must be ITEM_CLASS1.

Returns:

If successful, returns a pointer to the target word incremented past the newly-inserted command (including item pointer or inlined data). Effectively, this becomes a pointer to the next word to receive a new command in this descriptor. If error, returns 0

9.9.10.9.1.5 cmd_insert_proto_op_ipsec()

`cmd_insert_proto_op_ipsec()`-Insert an IPSec protocol operation command into a descriptor.

```
u_int32_t *cmd_insert_proto_op_ipsec(u_int32_t     *descwd,
                           u_int8_t                cipheralg,
                           u_int8_t                authalg,
                           enum protdir            dir);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instrction. For an `OPERATION` instruction, this is normally the final word of a single descriptor.
- `cipheralg`-blockcipher selection for this protocol descriptor. This should be one of `CIPHER_TYPE_IPSEC_`.
- `authalg`-authentication selection for this protocol descriptor. This should be one of `AUTH_TYPE_IPSEC_`.
- `dir`-Select `DIR_ENCAP` for encapsulation, or `DIR_DECAP` for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.6 cmd_insert_proto_op_wimax()

`cmd_insert_proto_op_wimax()`-Insert an 802.16 WiMAX protocol OPERATION instruction into a descriptor. These can only operate as AES-CCM.

```
u_int32_t *cmd_insert_proto_op_wimax(u_int32_t     *descwd,
                           u_int8_t                mode,
                           enum protdir            dir);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction. For an `OPERATION` instruction within the scope of a protocol descriptor, this is normally the final word of a single descriptor.
- `mode`-a nonzero value selects OFDMa, else assume OFDM operation.
- `dir`-Select `DIR_ENCAP` for encapsulation, or `DIR_DECAP` for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.7 cmd_insert_proto_op_wifi()

`cmd_insert_proto_op_wifi()`-Insert an 802.11 WiFi protocol OPERATION command into a descriptor.

```
u_int32_t *cmd_insert_proto_op_wifi(u_int32_t  *descwd,
                        enum protdir           dir);
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction. For an OPERATION instruction within the scope of a protocol descriptor, this is normally the final word of a single descriptor.
- dir-Select DIR_ENCAP for encapsulation, or DIR_DECAP for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.8 cmd_insert_proto_op_macsec()

cmd_insert_proto_op_macsec()-Insert an MacSec protocol OPERATION instruction into a descriptor.

```
u_int32_t *cmd_insert_proto_op_macsec(u_int32_t    *descwd,
                        enum protdir               dir);
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction. For an OPERATION instruction within the scope of a protocol descriptor, this is normally the final word of a single descriptor.
- dir-Select DIR_ENCAP for encapsulation, or DIR_DECAP for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.9 cmd_insert_proto_op_unidir()

cmd_insert_proto_op_unidir()-Insert a unidirectional protocol OPERATION instruction into a descriptor.

```
u_int32_t *cmd_insert_proto_op_unidir(u_int32_t *descwd, u_int32_t protid,
                                                  u_int32_t protinfo);
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction. For an OPERATION instruction within the scope of a protocol descriptor, this is normally the final word of a single descriptor.
- protid -Select any PROTID field needed for a unidirectional protocol descriptor from OP_PCLID_.
- dir-Select DIR_ENCAP for encapsulation, or DIR_DECAP for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.10 cmd_insert_alg_op()

cmd_insert_alg_op()-Insert a simple algorithm OPERATION instruction into a descriptor.

```
u_int32_t *cmd_insert_alg_op(u_int32_t *descwd, u_int32_t optype,
                                    u_int32_t algtype, u_int32_t algmode,
                                    enum mdstatesel mdstate, enum icvsel icv,
                                    enum algdir dir);
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction.
- optype-specify as class 1 or 2 using OP_TYPE_CLASSx_ALG.

- `algtype`-cipher selection, specify one of `ALG_TYPE_`.
- `algmode`-cipher mode selection, specify one of `ALG_MODE_`. Some combinations are ORable depending on application.
- `mdstate`-if a message digest is being processed, selects the processing state. May be one of `MDSTATE_UPDATE`, `MDSTATE_INIT`, `MDSTATE_FINAL`, or `MDSTATE_COMPLETE`.
- `icv`-if processing a message digest, or a cipher with an inclusing authentication function, then `ICV_CHECK_ON` selects an inline signature comparison on the computed result.
- `protid` -Select any PROTID field needed for a unidirectional protocol descriptor from `OP_PCLID_`.
- `dir`-Select `DIR_ENCAP` for encapsulation, or `DIR_DECAP` for decapsulation operations.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.11 cmd_insert_pkha_op()

`cmd_insert_pkha_op()`-Insert a PKHA-algorithm OPERATION instruction into a descriptor.

```
u_int32_t *cmd_insert_pkha_op(u_int32_t *descwd, u_int32_t pkmode);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `pkmode`-mode selection bits, an OR of `OP_ALG_PKMODE_` from one of the 3 possible PKHA sets (clear memory, modular arithmetic, copy memory).

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.12 cmd_insert_seq_in_ptr()

`cmd_insert_seq_in_ptr()`: Insert an `SEQ IN PTR` command into a descriptor

```
int *cmd_insert_seq_in_ptr(u_int32_t  *descwd,
                           u_int32_t  *ptr,
                           u_int32_t  len,
                           enum ref_type sgref);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this command. For an `OPERATION` command, this is normally the final word of a single descriptor.
- `ptr`-bus address pointing to the input data buffer
- `len`-input length
- `sgref`-pointer is actual data, or a scatter-gather list representing the key:
  - `PTR_DIRECT`-points to data
  - `PTR_SGLIST`-points to SEC4.x-specific scatter gather table.

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.13 cmd_insert_seq_out_ptr()

`cmd_insert_seq_out_ptr()`: Insert an `SEQ OUT PTR` command into a descriptor

```
int *cmd_insert_seq_out_ptr(u_int32_t *descwd,
                            u_int32_t *ptr,
                            u_int32_t len,
                            enum ref_type sgref);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this command. For an `OPERATION` command, this is normally the final word of a single descriptor.
- `ptr`-bus address pointing to the output data buffer
- `len`-output length
- `sgref-`pointer is actual data, or a scatter-gather list representing the key:
  - `PTR_DIRECT`-points to data
  - `PTR_SGLIST`-points to SEC4.x-specific scatter gather table.

Returns:

Pointer to next incremental descriptor word past the instruction just insertted. If an error occurred, returns 0.

9.9.10.9.1.14 cmd_insert_load()

`cmd_insert_load()`: Insert a `LOAD` instruction into a descriptor:

```
u_int32_t *cmd_insert_load(u_int32_t *descwd, void *data,
                                  u_int32_t class_access, u_int32_t sgflag,
                                  u_int32_t dest, u_int8_t offset,
                                  u_int8_t len, enum item_inline imm)
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `data`-pointer to data to be loaded.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB
  - `LDST_CLASS_1_CCB` -access class 1 objects in CCB
  - `LDST_CLASS_2_CCB` -access class 2 objects in CCB
  - `LDST_CLASS_DECO` -access DECO objects
- `sgflag`-specify `LDST_SGF` if data reference points to a scatter/gather list representing the data.
- `dest` - internal destination for the LOAD. Should be one of `LDST_SRCDST_`.
- `offset` - starting point for writing in the destination.
- `len` - length of data in bytes.
- `imm` - if specified as `ITEM_INLINE`, data is inlined into the descriptor immediately following the LOAD instruction.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.15 cmd_insert_seq_load()

`cmd_insert_seq_load()`: Insert a `SEQ LOAD` instruction into a descriptor:

```
        int *cmd_insert_seq_load(u_int32_t *descwd,
 unsigned int class_access,
 int variable_len_flag,
 unsigned char dest,
 unsigned char offset,
 unsigned char len);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB
  - `LDST_CLASS_1_CCB` -access class 1 objects in CCB
  - `LDST_CLASS_2_CCB` -access class 2 objects in CCB
  - `LDST_CLASS_DECO` -access DECO objects
- `variable_len_flag`-use the variable input sequence length
  - `dest`-destination
  - `offset`-the start point for writing in the destination
  - `len`-length of data in bytes

Returns:

Pointer to next incremental descriptor word past the command just constructed. If an error occurred, returns 0.

9.9.10.9.1.16 cmd_insert_fifo_load()

`cmd_insert_fifo_load()`: Insert a FIFO LOAD instruction into a descriptor

```
u_int32_t *cmd_insert_fifo_load(u_int32_t *descwd, void *data, u_int32_t len,
                                u_int32_t class_access, u_int32_t sgflag,
                                u_int32_t imm, u_int32_t ext, u_int32_t type)
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `data` - pointer to data to be loaded.
- `len` - length of load data in bytes.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB
  - `LDST_CLASS_1_CCB`-access class 1 objects in CCB
  - `LDST_CLASS_2_CCB`-access class 2 objects in CCB
  - `LDST_CLASS_DECO`-access DECO objects

- `sgflag`-data points to a scatter/gather list representing the data to be loaded.
- `imm` - specify `FIFOLDST_IMM` if fdata is to be included immediately following this instruction.
- `ext` - if length needs to be >16 bits, specify `FIFOLDST_EXT` to inlclude the extended length in a word following the instruction.
- `type`-FIFO input data type specified as `FIFOLD_TYPE_`.r

Returns:

Pointer to next incremental descriptor word past the instruction just constructed. If an error occurred, returns 0.

9.9.10.9.1.17 cmd_insert_seq_fifo_load()

`cmd_insert_seq_fifo_load()`: Insert a SEQ FIFO LOAD instruction into a descriptor

```
u_int32_t *cmd_insert_seq_fifo_load(u_int32_t *descwd, u_int32_t class_access,
                                                    u_int32_t variable_len_flag,
                                                    u_int32_t data_type, u_int32_t len)
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB
  - `LDST_CLASS_1_CCB`-access class 1 objects in CCB
  - `LDST_CLASS_2_CCB`-access class 2 objects in CCB
  - `LDST_CLASS_DECO`-access DECO objects
- `variable_len_flag`-use the variable input sequence length
- `data_type`-FIFO input data type (`FIFOLD_TYPE_*` in `desc.h`)
- `len`-input data length

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.18 cmd_insert_store()

cmd_insert_store(): Insert a STORE instruction into a descriptor

```
u_int32_t *cmd_insert_store(u_int32_t *descwd, void *data,
                                    u_int32_t class_access, u_int32_t sg_flag,
                                    u_int32_t src, u_int8_t offset,
                                    u_int8_t len, enum item_inline imm)
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction.
- data - pointer to the data store location.
- class_access
- LDST_CLASS_IND_CCB-access class-independent objects in CCB
- LDST_CLASS_1_CCB-access class 1 objects in CCB
- LDST_CLASS_2_CCB-access class 2 objects in CCB

- LDST_CLASS_DECO-access DECO objects
- sgflag-if LDST_SGF, the data pointer references a scatter/gather list describing the buffer to receive the stored data.
- src - data souce specification, one of LDST_SRCDST_
- offset-offset into source to begin store operation.
- len-store length in bytes.
- imm - if LDST_IMM, then the data to be stored follows the instruction in the descriptor.

Returns:

1. Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.19 cmd_insert_seq_store()

`cmd_insert_seq_store()`: Insert a SEQ STORE instruction into a descriptor

```
u_int32_t *cmd_insert_seq_store(u_int32_t *descwd, u_int32_t class_access,
                                        u_int32_t variable_len_flag, u_int32_t src,
                                        u_int8_t offset, u_int8_t len);
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB
  - `LDST_CLASS_1_CCB`-access class 1 objects in CCB
  - `LDST_CLASS_2_CCB`-access class 2 objects in CCB
  - `LDST_CLASS_DECO`-access DECO objects
- `variable_len_flag`-if `LDST_VLF`, uses the variable sequence output length.
- `src` - data souce specification, one of `LDST_SRCDST_`
- `offset`-offset into source to begin store operation.
- `len`-store length in bytes.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.20 cmd_insert_fifo_store()

`cmd_insert_fifo_store()`: Insert a FIFO STORE instruction into a descriptor

```
u_int32_t *cmd_insert_fifo_store(u_int32_t *descwd, void *data, u_int32_t len,
                                         u_int32_t class_access, u_int32_t sgflag,
                                         u_int32_t imm, u_int32_t ext, u_int32_t type)
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `data` - pointer to data to be stored from FIFO.
- `len` - length of data to store.
- `class_access`
  - `LDST_CLASS_IND_CCB`-access class-independent objects in CCB

  - LDST_CLASS_1_CCB-access class 1 objects in CCB
  - LDST_CLASS_2_CCB-access class 2 objects in CCB
  - LDST_CLASS_DECO-access DECO objects
- sgflag-if FIFOLDST_SGF, data points to a scatter/gather list describing the buffer to be used for the store.
- imm - if FIFOLDST_IMM, store data is to be inlined into the descriptor itself, immediately following the generated instructuion.
- ext-if FIFOLDST_EXT, length exceeds 16 bits, and therefore cannot be included in the instruction itself. Write the extended length out to a word following the instruction.
- type-FIFO input type, an OR combination of FIFOST_TYPE_ type and last/flush bits for class1 and 2.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.21 cmd_insert_seq_fifo_store()

cmd_insert_seq_fifo_store(): Insert a SEQ FIFO STORE instruction into a descriptor

```
u_int32_t *cmd_insert_seq_fifo_store(u_int32_t *descwd, u_int32_t class_access,
                                                u_int32_t variable_len_flag,
                                                u_int32_t out_type, u_int32_t len)
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction.
- len - length of data to store.
- class_access
  - LDST_CLASS_IND_CCB-access class-independent objects in CCB
  - LDST_CLASS_1_CCB-access class 1 objects in CCB
  - LDST_CLASS_2_CCB-access class 2 objects in CCB
  - LDST_CLASS_DECO-access DECO objects
- sgflag-if FIFOLDST_SGF, data points to a scatter/gather list describing the buffer to be used for the store.
- imm - if FIFOLDST_IMM, store data is to be inlined into the descriptor itself, immediately following the generated instructuion.
- ext-if FIFOLDST_EXT, length exceeds 16 bits, and therefore cannot be included in the instruction itself. Write the extended length out to a word following the instruction.
- type-FIFO input type, an OR combination of FIFOST_TYPE_ type and last/flush bits for class1 and 2.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.22 cmd_insert_jump()

cmd_insert_jump(): Insert a JUMP instruction into a descriptor

```
u_int32_t *cmd_insert_jump(u_int32_t *descwd, u_int32_t jtype,
                                    u_int32_t class, u_int32_t test, u_int32_t cond,
                                    int8_t offset, u_int32_t *jmpdesc)
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction.
- jtype - type of jump to perform, one of JUMP_TYPE_
- class
  - CLASS_NONE -jump is not a checkpoint
  - CLASS_1 -jump is a checkpoing for a class 1 operation
  - CLASS_1 -jump is a checkpoint for a class 2 operation
  - CLASS_BOTH -jump is a checkpoint for both classes
- test -selects how to assess the conditional test, one of JUMP_TEST_
- cond - OR combination of conditions to test, based on the test type selected in test. May be a combination of JUMP_COND_. Note that the JSL bit is factored into the definitions for JUMP_COND_, and therefore there are two possible combinational sets.
- offset -relative offset of descriptor words to jump to if JUMP_TYPE_LOCAL is selected. May be a positive or negative offset.
- jmpdesc -address of descriptor to jump to is JUMP_TYPE_NONLOCAL is selected.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.23 cmd_insert_math()

cmd_insert_math(): Insert a MATH instruction into a descriptor

```
u_int32_t *cmd_insert_math(u_int32_t *descwd, u_int32_t func,
                                  u_int32_t src0, u_int32_t src1,
                                  u_int32_t dest, u_int32_t len,
                                  u_int32_t flagupd, u_int32_t stall,
                                  u_int32_t immediate, u_int32_t *data)
```

Inputs:

- descwd-pointer to target descriptor word intended to hold this instruction.
- func - math functuon to perform, one of MATH_FUN_.
- src0 -first source operand, one of MATH_SRC0_.
- src1 - second source operand, one of MATH_SRC1_. Note differences between what can be selected between SRC0 and SRC1.
- dest - destination operand for the result, one of MATH_DEST_.
- flagupd - specify MATH_NFU if the flags should not be updated.
- stall -specify MATH_STL to cause the instruction to consume an extra clock cycle.
- immediate -specify MATH_IFB to use 4 bytes of immediate data when the length needs to remain as 8.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.1.24 cmd_insert_move()

`cmd_insert_move()`: Insert a MOVE instruction into a descriptor

```
u_int32_t *cmd_insert_move(u_int32_t *descwd, u_int32_t waitcomp,
                                u_int32_t src, u_int32_t dst, u_int8_t offset,
                                u_int8_t length)
```

Inputs:

- `descwd`-pointer to target descriptor word intended to hold this instruction.
- `waitcomp` - specify `MOVE_WAITCOMP` if intending to stall execution until the move completes.
- `src` -data source, one of `MOVE_SRC_`.
- `dest` - destination, one of `MOVE_DEST_`.
- `offset` - offset into source for move.
- `length` -length of data to move.

Returns:

Pointer to next incremental descriptor word past the instruction just inserted. If an error occurred, returns 0.

9.9.10.9.2 Upper-Tier DCL Functions - Descriptor Constructors

A higher level of functionality is provided through complex descriptor constructors. These constructors are single-purpose functions capable of generating complete descriptors from user specifications. These constructors fit into two categories, one for job descriptors and another for shared descriptors generally targeted to protocol processing.

These constructors are by no means the “definitive” reference to all possible descriptor permutations, nor are they meant to work with any specific application. Instead, they are meant to be general-purpose examples of descriptor construction. It is expected that, over time, this library will grow to accommodate a wide range of examples.

All constructor functions are dependent on the underlying command generator.

9.9.10.9.2.1 Job descriptor constructors

9.9.10.9.2.1.1 cnstr_seq_jobdesc()

`cnstr_seq_jobdesc()`: Construct simple sequence job descriptor

```
          int cnstr_seq_jobdesc(u_int32_t *jobdesc, unsigned short *jobdescsz,

       u_int32_t *shrdesc, unsigned short shrdescsize,

       unsigned char *inbuf, unsigned long insize,

       unsigned char *outbuf, unsigned long outsize);
```

Inputs:

- `jobdesc`-pointer to buffer in which to build descriptor in
- `jobdescsz`-max size of descriptor build buffer
- `shrdesc`-pointer to associated shared descriptor holding session contex
- `shrdescsz`-size of associated shared descriptor
- `inbuf`-pointer to input frame

- `insize`-size of input frame
- `outbuf`-pointer to output frame
- `outsize`-size of output frame

Constructs a simple job descriptor, emulating QI-level frame processing behavior useful at the job queue level. Besides a target descriptor output, this constructor depends on three references.

1. A pointer to a shared descriptor to do the work. This is normally assumed to be some sort of a protocol-level shared descriptor.
2. A pointer to a packet/frame for input data
3. A pointer to a packet/frame for output data

The constructed descriptor is a simple reverse-order-execution descriptor, and has no provisions for other content specifications.

9.9.10.9.2.1.2 cnstr_jobdesc_blkcipher_cbc()

Construct a job descriptor capable of performing a CBC blockcipher operation:

```
int cnstr_jobdesc_blkcipher_cbc(u_int32_t *descbuf, u_int16_t *bufsz,
                                        u_int8_t *data_in, u_int8_t *data_out,
                                        u_int32_t datasz,
                                        u_int8_t *key, u_int32_t keylen,
                                        u_int8_t *iv, u_int32_t ivlen,
                                        enum algdir dir, u_int32_t cipher,
                                        u_int8_t clear);
```

Inputs:

- `descbuf` - Pointer to DMA-able buffer for descriptor construction.
- `bufsz` - Size of constructed descriptor (as output)
- `data_in` - Pointer to input message
- `data_out` - Pointer to output message
- `datasz` - Size of input/output messages
- `key` - Pointer to cipher key
- `keylen` - Size of cipher key
- `iv` - Pointer to cipher IV
- `ivlen` - Size of cipher IV
- `dir` - Direction of cipher operation, select DIR_ENCRYPT or DIR_DECRYPT
- `cipher` - Blockcipher algorithmselection chosen from OP_ALG_ALGSEL_.
- `clear` - Clear descriptor buffer before construction

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.3 cnstr_jobdesc_hmac()

Construct a job descriptor capable of performing an HMAC operation:

```
int32_t cnstr_jobdesc_hmac(u_int32_t *descbuf, u_int16_t *bufsize,
                                    u_int8_t *msg, u_int32_t msgsz, u_int8_t *digest,
                                    u_int8_t *key, u_int32_t cipher, u_int8_t *icv,
                                    u_int8_t clear);
```

Inputs:

- `descbuf` - descriptor buffer
- `bufsize` - limit/returned descriptor buffer size
- `msg` - pointer to message being processed
- `msgsz` - size of message in bytes
- `digest` - output buffer for digest (size derived from cipher)
- `key` - key data (size derived from cipher)
- `cipher` - OP_ALG_ALGSEL_MD5/SHA1-512
- `icv` - HMAC comparison for ICV, NULL if no check desired
- `clear` - clear buffer before writing

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.4 cnstr_jobdesc_mdsplitkey()

Generate an MDHA "split key" from HMAC key content. A split key is a precomputed IPAD/OPAD pair; MDHA can save cycles during sequential packet processing on a flow by using the precomputed pair directly, and thus saving the pad generation step for each packet.

Generally, the split key is generated at flow setup time as a control-plane activity, thus, this step is performed as a job descriptor.

```
int cnstr_jobdesc_mdsplitkey(u_int32_t *descbuf, u_int16_t *bufsize,
                             u_int8_t *key, u_int32_t cipher,
                             u_int8_t *padbuf);
```

Inputs:

- `descbuf` - pointer to buffer to hold constructed descriptor
- `bufsize` - pointer to size of descriptor once constructed
- `key` - pointer to HMAC key to generate pad pair from. Key size is determined by cipher selection. Note that SHA224/384 pairs are not truncated to the digest size:

Table 292.

	Key size	Split key size	Buffer size
OP_ALG_ALGSEL_MD5	16	32	32
OP_ALG_ALGSEL_SHA1	20	40	48
OP_ALG_ALGSEL_SHA224	28	64	64
OP_ALG_ALGSEL_SHA256	32	64	64
OP_ALG_ALGSEL_SHA384	48	128	128
OP_ALG_ALGSEL_SHA512	64	128	128

- `cipher` - HMAC algorithm selection, one of OP_ALG_ALGSEL_
- `padbuf` - buffer to store generated ipad/opad. Should be 2x the untruncated HMAC keysize for the chosen cipher rounded up to the nearest 16-byte boundary (where 16 bytes = an AES blocksize). See table under "`key`" above.

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.5 cnstr_jobdesc_aes_gcm()

Construct a job descriptor capable of performing an AES-GCM operation:

```
int cnstr_jobdesc_aes_gcm(u_int32_t *descbuf, u_int16_t *bufsize,
                              u_int8_t *key, u_int32_t keylen, u_int8_t *ctx,
                              enum mdstatesel mdstate, enum icvsel icv, enum algdir dir,
                              u_int8_t *in, u_int8_t *out, u_int16_t size, u_int8_t *mac);
```

Inputs:

- `descbuf` - pointer to buffer that will hold constructed descriptor
- `bufsiz` - pointer to size of descriptor once constructed
- `key` - pointer to AES key
- `keylen` - AES key length
- `ctx` - points to GCM context block. This is a concatenation of: MAC (128 bits), Yi (128 bits), Y0 (128 bits), IV (64 bits), and text bitsize (64 bits). See the AESA section of the blockguide for more information.
- `mdstate` - select `MDSTATE_UPDATE`, `MDSTATE_INIT`, or `MDSTATE_FINAL` if a partial MAC operation is desired, else select `MDSTATE_COMPLETE`.
- `icv` - select `ICV_CHECK_ON` if a MAC compare is requested.
- `dir` - select `DIR_ENCRYPT` or `DIR_DECRYPT` as needed for cipher operation
- `in` - Pointer to input text buffer
- `out` - Pointer to output data text
- `size` - Size of data to be processed
- `mac` - Pointer to output MAC. This can point to the head of context if an updated MAC is required for subsequent operations.

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.6 cnstr_jobdesc_kasumi_f8()

Construct a job descriptor capable of performing a Kasumi f8 (confidentiality) operation:

```
int cnstr_jobdesc_kasumi_f8(u_int32_t *descbuf, u_int16_t *bufsz,
                              u_int8_t *key, u_int32_t keylen,
                              enum algdir dir, u_int32_t *ctx,
                              u_int8_t *in, u_int8_t *out, u_int16_t size);
```

Inputs:

- `descbuf` - pointer to buffer that will hold constructed descriptor
- `bufsiz` - pointer to size of descriptor once constructed
- `key` - pointer to KFHA cipher key
- `keylen` - cipher key length
- `dir` - select `DIR_ENCRYPT` or `DIR_DECRYPT` as needed
- `ctx` - points to preformatted f8 context block, containing the 32-bit count (word 0), bearer (word 1 bits 7:16), and cb (word 1 bits 17:31). Refer to the KFHA section of the block guide for more detail.
- `in` - Pointer to input data text

- `out` - Pointer to output data text
- `size` - Size of the data to be processed

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.7 cnstr_jobdesc_kasumi_f9()

Construct a job descriptor capable of performing a Kasumi f9 (authentication) operation:

```
int cnstr_jobdesc_kasumi_f9(u_int32_t *descbuf, u_int16_t *bufsz,
                            u_int8_t *key, u_int32_t keylen,
                            enum algdir dir, u_int32_t *ctx,
                            u_int8_t *in, u_int16_t size, u_int_t *mac);
```

Inputs:

- `descbuf` - pointer to buffer that will hold constructed descriptor
- `bufsiz` - pointer to size of descriptor once constructed
- `key` - pointer to cipher key
- `keylen` - size of cipher key
- `dir` - select `DIR_ENCRYPT` or `DIR_DECRYPT` as required
- `ctx` - points to preformatted f8 context block, containing 32-bit count (word 0), bearer (word 1 bits 0:5), direction (word 1 bit 6), ca (word 1 bits 7:16), cb (word 1 bits 17:31), fresh (word 2), and the ICV input (word 3). Refer to the KFHA section of the block guide for more detail
- `out` - pointer to input data
- `out_siz` - size of input data
- `mac` - pointer to output MAC

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.8 cnstr_jobdesc_pkha_rsaexp()

Construct a job descriptor capable of performing an RSA exponentiation operation:

```
int cnstr_jobdesc_pkha_rsaexp(u_int32_t *descbuf, u_int16_t *bufsz,
                                  struct pk_in_params *pkin,
                                  u_int8_t *out, u_int32_t out_siz,
                                  u_int8_t clear);
```

Inputs:

- `descbuf` - pointer to buffer to hold descriptor
- `bufsiz` - pointer to size of written descriptor
- `pkin` - Values of A, B, E, and N
- `out` - Encrypted output
- `out_siz` - size of buffer for encrypted output
- `clear` - nonzero if descriptor buffer space is to be cleared before construction

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.1.9 cnstr_jobdesc_dsaverify()

Construct a job descriptor capable of performing DSA signature verification:

```
int cnstr_jobdesc_dsaverify(u_int32_t *descbuf, u_int16_t *bufsz,
                                  struct dsa_pdb *dsadata, u_int8_t *msg,
                                  u_int32_t msg_sz, u_int8_t clear);
```

Inputs:

- `descbuf` - pointer to descriptor buffer for construction
- `bufsz` - pointer to size of descriptor constructed (output)
- `dsadata` - pointer to DSA parameters
- `msg` - pointer to input message for verfication
- `msg_sz` - size of message to verify
- `clear` - clear buffer before writing descriptor

Returns: -1 on construction error, 0 if construction succeeded.

9.9.10.9.2.2 Protocol/shared descriptor constructors

These constructors build a full protocol-level shared descriptor used for semi-autonomous processing of secured traffic through SEC4.x. Such descriptors function as single-pass processors (integrating cipher and authentication functions into a single logical step) with the added factor of performing protocol-level packet manipulation in the same step in the packet-handling process, by maintaining protocol-level connection state information within the descriptor itself.

9.9.10.9.2.2.1 cnstr_pcl_shdesc_ipsec_cbc_decap()

Note: this function is deprecated in 2.0, and will be removed in a future release. Use `cnstr_shdsc_ipsec_decap()` instead.

`cnstr_pcl_shdesc_ipsec_cbc_decap()`: Shared protocol-level descriptor for IPSec CBC decapsulation. This function can create a descriptor capable of either tunnel or transport mode processing.

```
        int32_t cnstr_pcl_shdsc_ipsec_cbc_decap(u_int32_t           *descbuf,
                                                u_int16_t           *bufsize,
                                                struct pdbcont      *pdb,
                                                struct cipherparams *cipherdata,
                                                struct authparams   *authdata,
                                                u_int8_t             clear);
```

Inputs:

- `descbuf`-Points to a buffer to construct the descriptor in. All SEC4.x descriptors are built of an array of up to sixty-three 32-bit words. If the caller wishes to construct a descriptor directly in the executable buffer, then that buffer must be hardware DMA-able, and physically contiguous.
- `bufsize`-Points to an unsigned 16-bit word with the maximum length of the buffer to hold the descriptor. This will be written back to with the actual size of the descriptor once constructed. (Note: bounds checking not yet implemented).
- `pdb`-Points to a block of data (struct pdbcont) used to describe the content if the Protocol Data Block to be maintained inside the descriptor. PDB content is protocol and mode specific:
  - `pdb.opthdrlen` = Size of inbound header to skip over.
  - `pdb.transmode` = `PDB_TUNNEL/PDB_TRANSPORT` for tunnel or transport handling for the next header.
  - `pdb.pclvers` = `PDB_IPV4/PDB_IPV6` as appropriate for this connection.
  - `pdb.seq.esn` = `PDB_NO_ESN` unless extended sequence numbers are to be supported, then `PDB_INCLUDE_ESN`.

- pdb.seq/antirplysz = PDB_ANTIRPLY_NONE if no antireplay window is to be maintained in the PDB. Otherwise may be PDB_ANTIRPLY_32 for a 32-entry window, or PDB_ANTIRPLY_64 for a 64-entry window.

- cipherdata-Points to a block of data used to describe the cipher information for encryption/decryption of packet content:
  - algtype-one of CIPHER_TYPE_IPSEC_xxx
  - key-pointer to the cipher key data
  - keydata-size of the key data in bits
- authdata-Points to a block of data used to describe the authentication information for validating the authenticity of the packet source.
  - algtype-one of AUTH_TYPE_IPSEC_xxx
  - key-pointer to the HMAC key data
  - keydata-size of the key data in bits
- clear-If nonzero, buffer is cleared before writing

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.2 cnstr_pcl_shdesc_ipsec_cbc_encap()

Note: this function is deprecated in 2.0, and will be removed in a future release. Use cnstr_shdsc_ipsec_encap() instead.

cnstr_pcl_shdesc_ipsec_cbc_encap(): Shared protocol-level descriptor for IPSec CBC encapsulation. This function can construct a descriptor for either transport or tunnel mode operation.

```
int32_t cnstr_pcl_shdsc_ipsec_cbc_encap(u_int32_t  *descbuf,
                                        u_int16_t            *bufsize,
                                        struct pdbcont       *pdb,
                                        struct cipherparams  *cipherdata,
                                        struct authparams    *authdata,
                                        u_int8_t clear);
```

Inputs:

- descbuf-Points to a buffer to construct the descriptor in. All SEC4.x descriptors are built of an array of up to sixty-three 32-bit words. If the caller wishes to construct a descriptor directly in the executable buffer, then that buffer must be hardware DMA-able, and physically contiguous.
- bufsize-Points to an unsigned 16-bit word with the maximum length of the buffer to hold the descriptor. This will be written back to with the actual size of the descriptor once constructed. (Note: bounds checking not yet implemented).
- pdb-Points to a block of data (struct pdbcont) used to describe the content if the Protocol Data Block to be maintained inside the descriptor. PDB content is protocol and mode specific:
  - pdbinfo.opthdrlen = Size of outbound IP header to be prepended to output.
  - pdbinfo.opthdr = Pointer to the IP header to be prepended to the output, of size opthdrlen.
  - pdbinfo.transmode = PDB_TUNNEL/PDB_TRANSPORT for tunnel/transport handling for the next header.
  - pdbinfo.pclvers = PDB_IPV4/PDB_IPV6 as appropriate for this connection.
  - pdbinfo.seq.esn = PDB_NO_ESN unless extended sequence numbers are to be supported, then PDB_INCLUDE_ESN.

- pdbinfo.ivsrc = PDB_IV_FROM_PDB if the IV is to be maintained in the PDB, else PDB_IV_FROM_RNG if the IV is to be generated internally by SEC4.x's random number generator.

- cipherdata-Points to a block of data used to describe the cipher information for encryption/decryption of packet content:
  - algtype-one of CIPHER_TYPE_IPSEC_xxx
  - key-pointer to the cipher key data
  - keydata-size of the key data in bits
- authdata-Points to a block of data used to describe the authentication information for validating the authenticity of the packet source.
  - algtype-one of AUTH_TYPE_IPSEC_xxx
  - key-pointer to the HMAC key data
  - keydata-size of the key data in bits
- clear-If nonzero, buffer is cleared before writing

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.3 cnstr_shdsc_ipsec_encap()

Construct a shared protocol-level descriptor capable of performing IPSec ESP packet encapsulation:

```
int32_t cnstr_shdsc_ipsec_encap(u_int32_t *descbuf, u_int16_t *bufsize,
                                struct ipsec_encap_pdb *pdb, u_int8_t *opthdr,
                                struct cipherparams *cipherdata,
                                struct authparams *authdata);
```

Inputs:

- descbuf - Pointer to buffer used for descriptor construction
- bufsize - Pointer to size to be written back upon completion
- pdb - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the encapsulation PDB, and it's cipher-dependent unioned substructure.
- opthdr - Pointer to the optional header meant to be prepended to an encapsulated frame. Size of the optional header is defined in pdb.opt_hdr_len.
- cipherdata - Pointer to blockcipher transform definitions
- authdata - Pointer to authentication transform definitions. Note that an MDHA split key is to be used with this descriptor (potentially constructed using cnstr_jobdesc_mdsplitkey()), and so the size of the uncovered split key is to be specified here, not the size of the encrypted split key buffer. See the description of cnstr_jobdesc_mdsplitkey() for a detailed discussion of split key lengths versus buffer sizes

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.4 cnstr_shdsc_ipsec_decap()

Construct a shared protocol-level descriptor capable of performing IPSec ESP packet decapsulation:

```
int32_t cnstr_shdsc_ipsec_decap(u_int32_t *descbuf, u_int16_t *bufsize,
                                struct ipsec_encap_pdb *pdb,
```

```
                                struct cipherparams *cipherdata,
                                struct authparams *authdata);
```

Inputs:

- `descbuf`

  - Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the decapsulation PDB, and it's cipher-dependent unioned substructure.

- `cipherdata`

  - Pointer to blockcipher transform definitions

- `authdata`

  - Pointer to authentication transform definitions. Note that an MDHA split key is to be used with this descriptor (potentially constructed using

    `cnstr_jobdesc_mdsplitkey()`

    ), and so the size of the uncovered split key is to be specified here, not the size of the encrypted split key buffer. See the description of

    `cnstr_jobdesc_mdsplitkey()`

    for a detailed discussion of split key lengths versus buffer sizes

Returns:

1. -1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.5 cnstr_shdsc_wifi_encap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.11i WiFi packet encapsulation:

```
int32_t cnstr_shdsc_wifi_encap(u_int32_t *descbuf, u_int16_t *bufsize,
                               struct wifi_encap_pdb *pdb,
                               struct cipherparams *cipherdata);
```

Inputs:

- `descbuf`

  - Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the encapsulation PDB.

- `cipherdata`

  - Pointer to blockcipher transform definitions

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.6 cnstr_shdsc_wifi_decap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.11i WiFi packet decapsulation:

```
int32_t cnstr_shdsc_wifi_decap(u_int32_t *descbuf, u_int16_t *bufsize,
                               struct wifi_decap_pdb *pdb,
                               struct cipherparams *cipherdata);
```

Inputs:

- `descbuf`

  - Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the decapsulation PDB.

- `cipherdata`

  - Pointer to blockcipher transform definitions

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.7 cnstr_shdsc_wimax_encap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.16 WiMAX message encapsulation:

```
int32_t cnstr_shdsc_wimax_encap(u_int32_t *descbuf, u_int16_t *bufsize,
                                        struct wimax_encap_pdb *pdb,
                                        struct cipherparams *cipherdata,
                                        u_int8_t mode);
```

Inputs:

- `descbuf`

- Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size value to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the encapsulation PDB.

- `cipherdata`

  - Pointer to cipher parameters. Only

  `key`

  and

  `keylen`

  are used for this descriptor.

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.8 cnstr_shdsc_wimax_decap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.16 WiMAX message decapsulation:

```
int32_t cnstr_shdsc_wimax_decap(u_int32_t *descbuf, u_int16_t *bufsize,
                                        struct wimax_decap_pdb *pdb,
                                        struct cipherparams *cipherdata,
                                        u_int8_t mode);
```

Inputs:

- `descbuf`

  - Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size value to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the decapsulation PDB.

- `cipherdata`

  - Pointer to cipher parameters. Only

  `key`

and

```
keylen
```

are used for this descriptor.

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.9 cnstr_shdsc_macsec_encap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.1AE MACsec message encapsulation:

```
int32_t cnstr_shdsc_macsec_encap(u_int32_t *descbuf, u_int16_t *bufsize,
                                         struct macsec_encap_pdb *pdb,
                                         struct cipherparams *cipherdata);
```

- `descbuf`

  - Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size value to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the encapsulation PDB.

- `cipherdata`

  - Pointer to cipher parameters. Only

  `key`

  and

  `keylen`

  are used for this descriptor.

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.10 cnstr_shdsc_macsec_decap()

Construct a shared protocol-level descriptor capable of performing IEEE 802.1AE MACsec message decapsulation:

```
int32_t cnstr_shdsc_macsec_decap(u_int32_t *descbuf, u_int16_t *bufsize,
                                         struct macsec_decap_pdb *pdb,
                                         struct cipherparams *cipherdata);
```

Inputs:

- `descbuf`

- Pointer to buffer used for descriptor construction

- `bufsize`

  - Pointer to size value to be written back upon completion

- `pdb`

  - Pointer to the PDB to be used with this descriptor. This structure will be copied inline to the descriptor under construction. No error checking of the PDB content shall be made. Refer to the block guide for a detailed discussion of the content of the encapsulation PDB.

- `cipherdata`

  - Pointer to cipher parameters. Only

  `key`

  and

  `keylen`

  are used for this descriptor.

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.11 cnstr_shdsc_snow_f8()

Construct a shared descriptor capable of performing SNOW UEA2 confidentiality message processing:

```
int32_t cnstr_shdsc_snow_f8(u_int32_t *descbuf, u_int16_t *bufsize,
                                u_int8_t *key, u_int32_t keylen,
                                enum algdir dir, u_int32_t count,
                                u_int8_t bearer, u_int8_t direction);
```

Inputs:

- `descbuf`

  - pointer to descriptor-under-construction buffer

- `bufsize`

  - points to size to be updated at completion

- `key`

  - cipher key

- `keylen`

  - size of key in bits

- `dir`

  - cipher direction (DIR_ENCRYPT/DIR_DECRYPT)

- `count`

  - UEA2 count value (32 bits)

- `bearer`

  - UEA2 bearer ID (5 bits)

- `direction`

  - UEA2 direction (1 bit)

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.12 cnstr_shdsc_snow_f9()

Construct a shared descriptor capable of performing SNOW UIA2 message authentication:

```
int32_t cnstr_shdsc_snow_f9(u_int32_t *descbuf, u_int16_t *bufsize,
                                    u_int8_t *key, u_int32_t keylen,
                                    enum algdir dir, u_int32_t count,
                                    u_int32_t fresh, u_int8_t direction);
```

Inputs:

- `descbuf`

  - Pointer to buffer for descriptor construction

- `bufsize`

  - Pointer to descriptor size to be updated upon completion

- `key`

  - Cipher key

- `keylen`

  - Size of cipher key

- `dir`

  - Cipher direction (

  `DIR_ENCRYPT/DIR_DECRYPT`

)

- `count`

  - UEA2 count value (32 bits)

- `fresh`

  - UEA2 fresh value ID (32 bits)

- `direction`

  - UEA2 direction (1 bit)

- `clear`

  - Nonzero if descriptor buffer clear requested

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.13 cnstr_shdsc_kasumi_f8()

Construct a shared descriptor capable of performing Kasumi f8 confidentiality message processing:

```
int32_t cnstr_shdsc_snow_f8(u_int32_t *descbuf, u_int16_t *bufsize,
                                    u_int8_t *key, u_int32_t keylen,
                                    enum algdir dir, u_int32_t count,
                                    u_int8_t bearer, u_int8_t direction);
```

Inputs:

- `descbuf`

  - pointer to descriptor-under-construction buffer

- `bufsize`

  - points to size to be updated at completion

- `key`

  - cipher key

- `keylen`

  - size of key in bits

- `dir`

  - cipher direction (

  `DIR_ENCRYPT/DIR_DECRYPT`

)

- `count`

  -f8count value (32 bits)

- `bearer`

  - f8 bearer ID (5 bits)

- `direction`

  - f8 direction (1 bit)

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.14 cnstr_shdsc_kasumi_f9()

Construct a shared descriptor capable of performing Kasumi f9 message authentication:

```
int32_t cnstr_shdsc_snow_f9(u_int32_t *descbuf, u_int16_t *bufsize,
                                    u_int8_t *key, u_int32_t keylen,
                                    enum algdir dir, u_int32_t count,
                                    u_int32_t fresh, u_int8_t direction);
```

Inputs:

- descbuf - Pointer to buffer for descriptor construction
- bufsize - Pointer to descriptor size to be updated upon completion
- key - cipher key
- keylen - size of cipher key
- dir - cipher direction (DIR_ENCRYPT/DIR_DECRYPT)
- count - f9 count value (32 bits)
- fresh - f9 fresh value ID (32 bits)
- direction - f9 direction (1 bit)

Returns:

1. -1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.15 cnstr_shdsc_cbc_blkcipher()

Construct a shared descriptor capable of performing CBC blockcipher confidentiality processing:

```
int32_t cnstr_shdsc_cbc_blkcipher(u_int32_t *descbuf, u_int16_t *bufsize,
                                          u_int8_t *key, u_int32_t keylen,
                                          u_int8_t *iv, u_int32_t ivlen,
                                          enum algdir dir, u_int32_t cipher,
                                          u_int8_t clear);
```

Inputs:

- `descbuf`

  - Pointer to buffer for descriptor construction

- `bufsize`

  - Pointer to descriptor size to be updated upon completion

- `key`

  - Pointer to cipher key

- `keylen`

  - Size of cipher key

- `iv`

  - Pointer to IV data

- `ivsize`

  - Size of IV

- `dir`

  - Cipher direction (

  `DIR_ENCRYPT/DIR_DECRYPT)`

- `cipher`

  - Cipher selection (

  `OP_ALG_ALGSEL_AES/DES/3DES)`

- `clear`

  - Nonzero if descriptor buffer clear is requested

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.16 cnstr_shdsc_hmac()

Construct a shared descriptor capable of performing hashed message authentication processing:

```
int32_t cnstr_shdsc_hmac(u_int32_t *descbuf, u_int16_t *bufsize,
                                u_int8_t *key, u_int32_t cipher, u_int8_t *icv,
                                u_int8_t clear);
```

Inputs:

- `descbuf`

  - Pointer to buffer for descriptor construction

- `bufsize`

  - Pointer to size of descriptor to be updated upon

- `key`

  - Pointer to key data. Note that key length will be automatically selected based on the HMAC cipher chosen.

- `cipher`

  - HMAC cipher selection, one of

  `OP_ALG_ALGSEL_MD5/SHA1/SHA224/SHA256/SHA384/SHA512`

- `icv`

  - HMAC comparison for ICV, NULL if no check desired

- `clear`

  - Nonzero if descriptor buffer clear is requested

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.17 cnstr_pcl_shdsc_3gpp_rlc_decap()

Note: this is a P4080 tapeout #1 operation, to be replaced in a future release.

Construct a shared descriptor capable of performing 3GPP RLC message decapsulation operations:

```
int32_t cnstr_pcl_shdsc_3gpp_rlc_decap(u_int32_t *descbuf, u_int16_t *bufsize,
                                       u_int8_t *key, u_int32_t keysz,
                                       u_int32_t count, u_int32_t bearer,
                                       u_int32_t direction,
                                       u_int16_t payload_sz, u_int8_t clear);
```

Inputs:

- `descbuf`

  - Pointer to buffer for descriptor construction

- `bufsize`

  - Pointer to size of descriptor to be updated upon completion

- `key`

  - Pointer to f8 cipher key

- `keysz`

  - Size of cipher key

- `count`

  - f8 count value

- `bearer`

  - f8 bearer value

- `direction`

  - f8 direction value

- `payload_sz`

  - Size of payload to be processed (descriptor generated does not use VLF).

- `clear`

- clear descriptor buffer before construction

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.2.2.18 cnstr_pcl_shdsc_3gpp_rlc_encap()

Note: this is a P4080 tapeout #1 operation, to be replaced in a future release.

Construct a shared descriptor capable of performing 3GPP RLC message encapsulation operations:

```
int32_t cnstr_pcl_shdsc_3gpp_rlc_encap(u_int32_t *descbuf, u_int16_t *bufsize,
                                       u_int8_t *key, u_int32_t keysz,
                                       u_int32_t count, u_int32_t bearer,
                                       u_int32_t direction,
                                       u_int16_t payload_sz);
```

Inputs:

- `descbuf`

  - Pointer to buffer for descriptor construction

- `bufsize`

  - Pointer to size of descriptor to be updated upon completion

- `key`

  - Pointer to f8 cipher key

- `keysz`

  - Size of cipher key

- `count`

  - f8 count value

- `bearer`

  - f8 bearer value

- `direction`

  - f8 direction value

- `payload_sz`

  - Size of payload to be processed (descriptor generated does not use VLF).

Returns:

-1 if the descriptor creation failed for any reason, zero if creation succeeded.

9.9.10.9.3 Disassembler

9.9.10.9.3.1 caam_desc_disasm()

```
caam_desc_disasm()
```

-Top-level descriptor disassembler

```
        void caam_desc_disasm(u_int32_t *desc, u_int32_t opts);
```

Inputs:

- `desc`

  -points to the descriptor to disassemble. First command must be a header, or shared header, and the overall size to disassemble is determined by the header. Does not handle a QI preheader as its first command, and cannot yet follow links in a list of descriptors.

- `opts`

  - selects options to add to the disassembled output:

  `DISASM_SHOW_OFFSETS`

  - shows the index/offset of each instruction in the descriptor preceding the textual disassembly. This is useful for visualizing flow control changes in a descriptor, since any offset to a specific instruction in the disassembly will be displayed both as a relative number of instructions, and as the offset of the specific instruction.

  `DISASM_SHOW_RAW`

  - shows the hexadecimal value of each instruction before the displayed value of the instruction itself.

9.9.11 Runtime Assembler Library Reference

Use the Runtime Assembler Library to write SEC descriptors.

9.9.11.1 Runtime Assembler Library Reference

Use the Runtime Assembler Library to write SEC descriptors. This reference describes the structure, concept, functionality, and high level API.

9.9.12 USDPAA PME Loopback User Guide

9.9.12.1 Introduction

The User Space Datapath Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document describes the "pme_loopback" application. This application serves as an example for working with the PME USDPAA interface, as well as providing a benchmark for PME USDPAA system performance.

9.9.12.1.1 Purpose

This document describes the USDPAA pme_loopback application.

The material is technical in nature. The reader is assumed to be familiar with:

- General Linux software development, operation, and configuration for Power architecture devices in particular.
- Familiarity with the concept of device drivers and their role in operating systems.
- Linux network administration and use.
- The NXP Linux SDK for DPAA-based SoCs.
- At least broadly, the DPAA hardware blocks.
- The USDPAA User Guide document

9.9.12.1.2 Change history

Table 293. Change History

Version	Updates
1.0	Initial creation of pme_loopback UG.

9.9.12.2 Overview of pme_loopback

The pme_loopback is an interactive command line driven USDPAA application which generates and consumes frames to/from the PME hardware accelerator via the PME USDPAA APIs. The pme_loopback application focuses on demonstrating I/O performance through the PME from applications running on multiple cores. The application creates up to one core affine thread per core which sends a pre-generated frame to PME for scanning and processes the resulting scan result. The application does very little processing of the scan responses. it only does enough to determine if a match was found and updates state information.

When instructed via the CLI, each application thread does the following:

- initializes a pme_ctx object
- prepares an FD and associated payload data for PME scanning
- commences sending pme scan requests and processing the scan results
- terminates sending scan request and process all expected scan result
- displays performance results
- disables and frees pme_ctx object

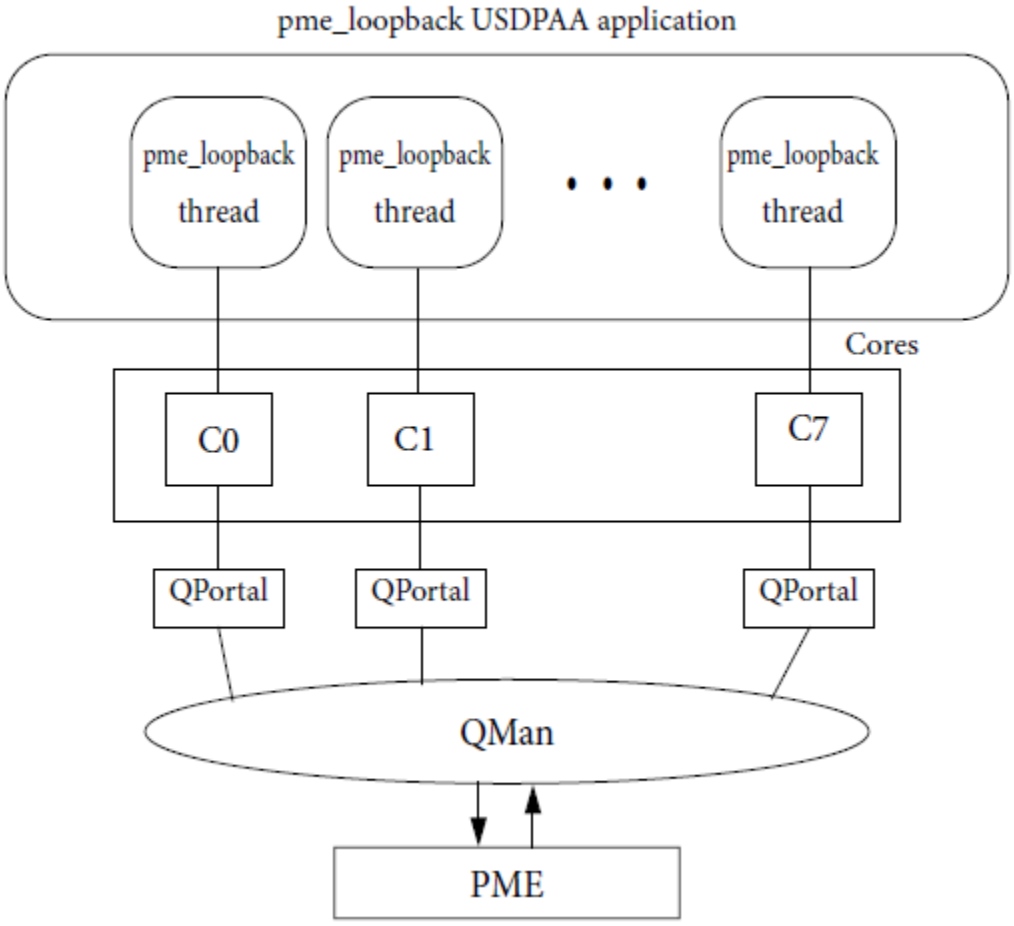

Figure 273. pme_loopback block diagram

9.9.12.2.1 pme_loopback application flow

The pme_loopback application transitions into various states as instructed by the CLI commands sent.

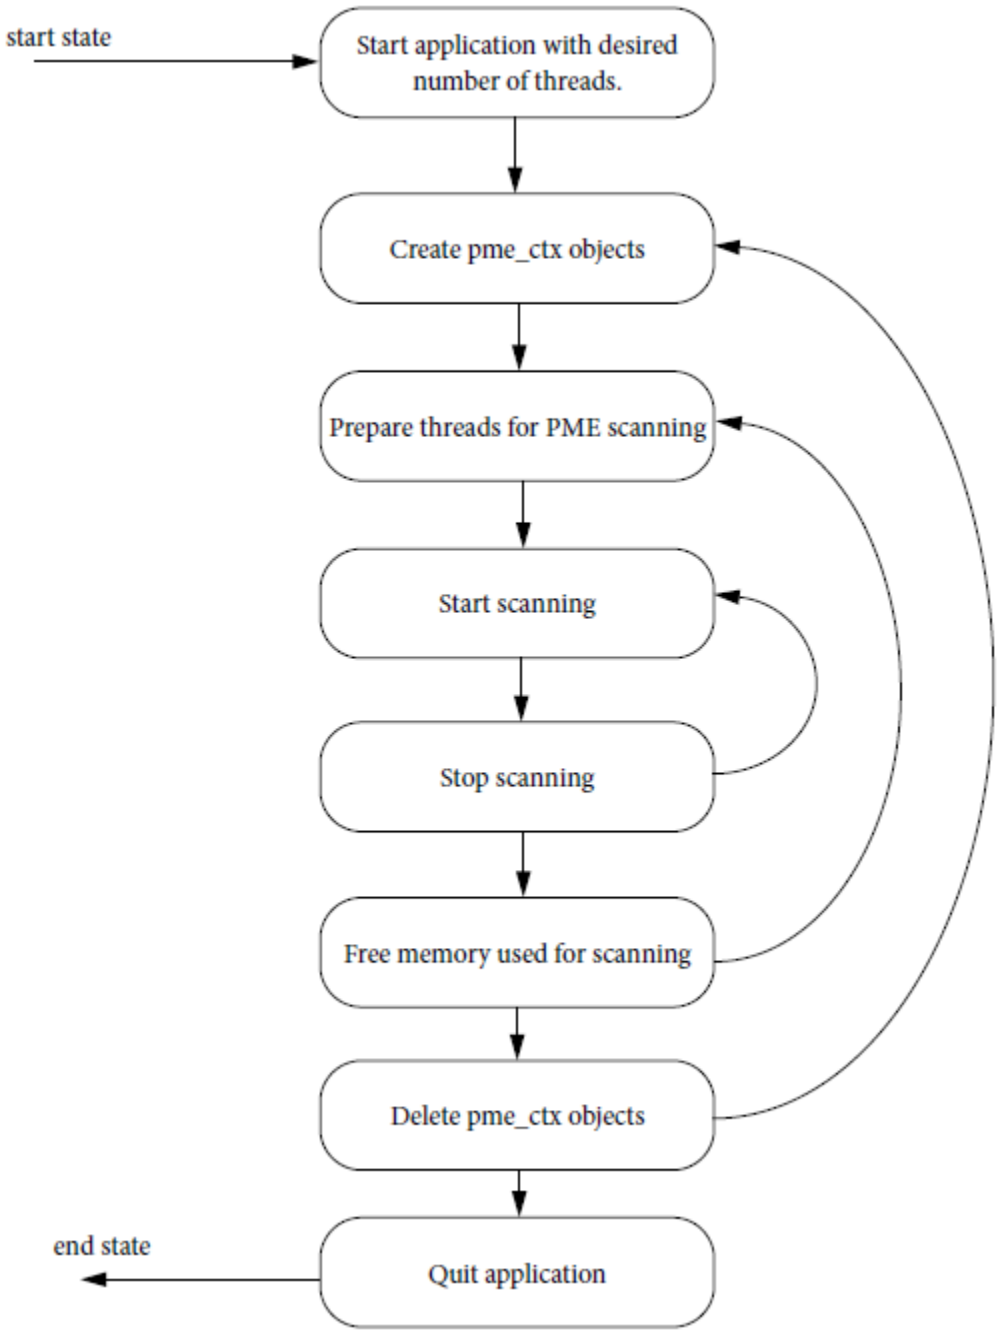

Figure 274. pme_loopback state transition diagram

Not all commands are valid depending on the current state. Unexpected behaviour may occur if an invalid command is sent. At this time the application does not validate if the request should not be performed. Below is the suggested method of running the pme_loopback application. Detailed description of pme_loopback cli commands can be found in pme_loopback application syntax on page 1804.

1. start the pme_loopback application with the desired number of threads
2. Create the pme_ctx objects associated with each thread via create_ctx_direct_mode or create_ctx_flow_mode commands.
3. prepare the threads FD data for scanning via the prep_scan or prep_scan_2 commands

4. start the scanning loop via start_scan command
5. after letting the application scan data through PME for a desired amount of time (e.g. 30 seconds), stop the scanning process via the stop_scan command.
6. collect the performance results displayed by the application
7. free the memory used by the threads for scanning via the free_mem command
8. return to step 3 if there is a desire to scan data with different characteristics (e.g. SUI size, SUI pattern, etc) as defined by the prep_scan and prep_scan_2 commands. Otherwise proceed to the next step.
9. Delete the pme_ctx objects associated with each thread via the delete_ctx command.
10. To re-initialize the pme_ctx objects associated with each thread return to step 2 or continue to next step
11. remove the threads and quit the application. The quit command will do both of these steps.

9.9.12.3 pme_loopback application syntax

The pme_loopback USDPAA application is a command line driven application. Each command instructs the application to perform a task which is usually tightly co-related to a specific PME USDPAA API.

Summary of commands:

```
        pme_loopback_test [core_ids]
        create_ctx_direct_mode [thread_ids]
        create_ctx_flow_mode sesson_id ren [thread_ids]
        prep_scan sui_size_in_bytes pattern_width low_threshold high_threshold use_compound_frame
[thread_ids]
        prep_scan_2 sui_size_in_bytes pattern_data low_threshold high_threshold
use_compound_frame [thread_ids]
        start_scan [thread_ids]
        stop_scan [thread_ids]
        display_stats [thread_ids]
        clear_stats [thread_ids]
        free_mem [thread_ids]
        delete_ctx [thread_ids]
        rm [core_ids]
        add [core_ids]
        list
        help
        quit
```

9.9.12.3.1 pme_loopback_test

USDPAA pme_loopback test application

Synopsis

```
pme_loopback_test [core_ids]
```

Description

Start the pme_loopback USDPAA application on the specified cores. This is an interactive command line driven application. A prompt ">" is displayed awaiting instructions. If no option is specified a single USDPAA thread is running on core 0.

OPTIONS

```
core_ids
```

Identifies which cores shall have a USDPAA thread created on. It identifies either a single core or a list of cores. The format is as follows:

```
single_core | first_core..last_core
single core = minimum core id up to maximum core id
first_core < last_core
```

EXAMPLES

To start pme_loopback on cores 0,1,2,3,4,5,6 and 7

```
pme_loopback_test 0..7
```

To start pme_loopback on core 2

```
pme_loopback_test 2
```

9.9.12.3.2 create_ctx_direct_mode

Initialize a pme_ctx object on the specified threads.

Synopsis

```
create_ctx_direct_mode [thread_ids]
```

Description

Each specified thread will invoke the pme_ctx_init() API. This API initializes the pme_ctx object which is associated to the thread and will specify the DIRECT pme_ctx flag. If no option is specified the command is sent to all the threads.

OPTIONS

```
thread_ids
```

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
where: first_thread < last_thread
```

EXAMPLES

To initialize pme_ctx object in direct mode on all pme_loopback USDPAA threads:

```
>create_ctx_direct_mode
```

To initialize a pme_ctx object in direct mode on the USDPAA threads which are on cores 0 to 7:

```
>create_ctx_direct_mode 0..7
```

To initialize a pme_ctx object in direct mode on the USDPAA thread which is on core 5:

```
>create_ctx_direct_mode 5
```

9.9.12.3.3 create_ctx_flow_mode

Initialize a pme_ctx object in flow mode on the specified threads.

Synopsis

```
create_ctx_flow_mode session_id ren [thread_ids]
```

Description

Each specified thread will invoke the pme_ctx_init() API. This API initializes the pme_ctx object which is associated to the thread. The pme_ctx will be initialized in flow mode and will have the specified session_id and whether its residue is on or off is determined by the ren parameter. If no thread_ids option is specified the command is sent to all the threads.

`session_id`

Index where the per-session context for this Flow will be accessed by SRE in the Session Context Table. The minimum session_id is 0. The maximum session_id is equal to /dev/fsl-pme-dev/sre_session_ctx_num - 1.

ex: `# cat /dev/fsl-pme-dev/sre_session_ctx_num 80`

Therefore the maximum session_id is 79.

`ren`

Indicates is residue is enabled or not. zero (0) indicates residue is disabled. One (1) indicated residue is enabled.

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

`single_thread | first_thread..last_thread`

where: `first_thread < last_thread`

EXAMPLES

To initialize pme_ctx object in flow mode on all pme_loopback USDPAA threads with session_id zero and residue disabled:

```
>create_ctx_flow_mode 0 0
```

To initialize a pme_ctx object in flow mode with session_id zero and residue enabled on the USDPAA threads which are on cores 0 to 7:

```
>create_ctx_flow_mode 0 1 0..7
```

To initialize a pme_ctx object in flow mode with session_id 1 and residue enabled on the USDPAA thread which is on core 5:

```
>create_ctx_direct_mode 1 1 5
```

9.9.12.3.4 prep_scan

Prepare the specified threads for pme scanning.

Synopsis

```
prep_scan sui_size_in_byte pattern_width low_threshold high_threshold use_compound_frame [thread_ids]
```

Description

Prepares the specified threads for pme scanning. This command will allocate memory for the SUI and will construct an appropriate FD: a compound frame is used if specified. The resulting FD will be used to repeatedly send pme scans. The thread will send scan requests until the high_threshold is reached. It will then switch to processing scan results until the low_threshold is reached at which point it will return to sending scans. The thread remains in this loop until the "stop_scan" command is received.

The content of the SUI is determined as follows:

There is an internal 50 character alphabet

```
1 2 3 4 5 6 7 8 9 0 a b c d e f g h i j k l m n o p q r s t u v w x y z ! @ # $ % ^ & * ( ) [ ] { } ?
" ;
```

The SUI which is of sui_size_in_byte byte long is filled with the above alphabet in an alternating pattern. Any remaining bytes are filled with the period "." symbol. The pattern is as follows:

- first character in the alphabet is repeated every 1 x pattern_width bytes

- second character in the alphabet is repeated every 2 x pattern_width bytes

- etc...

For example if a sui_size of 65 and a pattern_width of 5 is chosen the resulting pattern will emerge:

"1" is repeated every 5 bytes.

"2" is repeated every 10 bytes.

"3" is repeated every 15 bytes.

...etc

```
        1XXXX
        12XXX
        1X3XX
        12X4X
        1XXX5
        123XX
        1XXXX
        12X4X
        1X3XX
        12XX5
        1XXXX
        1234X
        1XXXX
```

Then the pme database can be populated with the pmm tool with appropriate signatures. For instance if the signature /4/ is set in the database and the above SUI is sent then there will be a match frequency of every 20 bytes.

If no thread_ids option is specified the command is sent to all the threads.

`sui_size_in_bytes`

This number of bytes will be allocated for the SUI which will be used to construct a frame descriptor. Initially the entire SUI is filled with the period character "."

`pattern_width`

The SUI is filled with an alternating pattern which is of this width. If zero, no alternating pattern will be used, the default all period "." pattern is used. The maximum value is 50.

`low_threshold`

The specified threads process scan results until the number of outstanding scans reduces to this amount.

`high_threshold`

The specified threads generate scan requests until the number of outstanding requests reaches this count: at which point the thread starts to process scan results.

`use_compound_frame`

A frame descriptor can be either be contiguous or a compound frame. If use_compound_frame is 0 then a contiguous frame format is used, otherwise a compound frame format is used. The compound frame output frame is of zero size bytes.

OPTIONS

`thread_ids`

Identifies which core affined thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

`single_thread | first_thread..last_thread`

```
where: first_thread < last_thread
```

EXAMPLES

The following example does the following:

- prepare the SUI in all threads with SUI size of 65 bytes
- no pattern width will be used (default all period)
- a low_threshold in flight SUI count of 15and a high_threshold in flight SUI count of 30
- compound_frame is not used (i.e. contiguous is used

```
>prep_scan 65 0 15 30 0
```

9.9.12.3.5 prep_scan_2

Prepare the specified threads for pme scanning.

Synopsis

```
prep_scan_2 sui_size_in_bytes pattern_data low_threshold high_threshold use_compound_frame
[thread_ids]
```

Description

This is a second version of the prep_scan command. The command is similar to prep_scan except that this version has the pattern_data parameter instead of pattern_width. The pattern_data is the literal string of characters that will copied into the SUI. If the pattern_data is larger than the SUI size than the pattern_data will be truncated. If the pattern_data is shorter than the SUI, the SUI is filled with the period "." character. This command will allocate memory for the SUI and will construct an appropriate frame descriptor (FD): a compound frame is used if specified. The resulting FD will be used to repeatedly send pme scans. The thread will send scan requests until the high_threshold is reached. It will then switch to processing scan results until the low_threshold is reached at which point it will return to sending scans. The thread remains in this loop until the "stop_scan" command is received.

If no thread_ids option is specified the command is sent to all the threads.

`sui_size_in_bytes`

This number of bytes will be allocated for the SUI which will be used to construct a frame descriptor. Initially the entire SUI is filled with the period character "."

`pattern_data`

A literal string of characters that will be copied in the SUI.

`low_threshold`

The specified threads process scan results until the number of outstanding scans reduces to this amount.

`high_threshold`

The specified threads generate scan requests until the number of outstanding requests reaches this count: at which point the thread starts to process scan results.

`use_compound_frame`

A frame descriptor can be either be contiguous or a compound frame. If use_compound_frame is 0 then a contiguous frame format is used, otherwise a compound frame format is used. The compound frame output frame is of zero size bytes.

OPTIONS

`thread_ids`

Identifies which core affined thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

The following example does the following:

- prepare the SUI in all threads with SUI size of 10 bytes
- the SUI pattern being sent is abcdefghij
- a low_threshold in flight SUI count of 15and a high_threshold in flight SUI count of 30
- compound_frame is not used (i.e. contiguous is used

```
>prep_scan_2 10 abcdefghij 15 30 0
```

9.9.12.3.6 start_scan

Instruct the specified threads to commence sending pme scan requests and processing the results.

Synopsis

```
start_scan [thread_ids]
```

Description

Each specified thread will enter the following loop:

```
        sending scan loop
        do
        invoke the pme_ctx_scan
        increment in_flight_scans by one
        while (in flight scans < high_threshold)
        processing scan response loop
        do
        qman_poll_dqrr(16)
        while (in_flight_scans >= low_threshold)
```

The qman_poll_dqrr() api will invoke the function callback specified in the pme_ctx object. This callback will decrement the in_flight_scans counter and also update some statistics such as number of notifications and truncations received.

The threads will remain in this loop until the stop_scan command is received.

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct all threads to start their scanning loop:

```
>start_scan
```

To instruct threads 0 to 4 to start its scanning loop:

```
>start_scan 0..4
```

To instruct thread 2 to start its scanning loop:

```
>start_scan 2
```

9.9.12.3.7 stop_scan

Instruct the specified threads to stop sending pme scan requests and complete processing all remaining scan results.

Synopsis

```
stop_scan [thread_ids]
```

Description

Each specified thread will stop sending scan requests and will process all scan results until the in_flight_scan counter reaches zero. The following performance statistics are displayed:

- Total units scanned
- Total number of SUIs sent to the PME device.
- Total time
- The time in seconds from the moment the first scan unit is sent until the last scan response is processed.
- Scan Units per second
- Total units scanned / Total time
- Bandwidth

The number of SUIs send and corresponding responses processed measured in Mbps.

i.e. 9512 Mbps

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct all threads to stop their scanning loop:

```
>stop_scan Total units scanned: 24622356 Total time: 31.007910 sec Scan Units per second: 794066
Bandwidth: 9528 Mbps
```

9.9.12.3.8 free_mem

Instruct the specified threads to free the memory previously allocated via the prep_scan or prep_scan_2 command.

Synopsis

```
free_mem [thread_ids]
```

Description

Each specified thread will free their memory previously allocated during the prep_scan and prep_scan_2 command. This command needs to be run to undo any previous prep_scan or prep_scan_2 commands.

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where:

```
first_thread < last_thread
```

EXAMPLES

To instruct all threads to free their allocated memory:

```
>free_mem
```

9.9.12.3.9 delete_ctx

Instruct the specified threads to disable and "finish" their previously initialized pme_ctx object.

Synopsis

```
delete_ctx [thread_ids]
```

Description

Each specified thread will invoked the pme_ctx_disabled() API on their pme_ctx object. Once completed they will invoked the pme_ctx_finish() API. These APIs free any internal resources used (such as frame queues) and render the pme_ctx object in an un-initialized state once again.

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct all threads to disable and finish their pme_ctx object:

```
>delete_ctx
```

9.9.12.3.10 rm

Remove a pme USDPAA core affined thread

Synopsis

```
rm thread_ids
```

Description

Each specified thread will be destroyed by the application. The application will display that the thread on a specific cpu has been killed.

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct threads 0 to 7 to be removed:

```
>rm 0..7 Thread killed on cpu 0 Thread killed on cpu 1 Thread killed on cpu 2 Thread killed on cpu 3
Thread killed on cpu 4 Thread killed on cpu 5 Thread killed on cpu 6 Thread killed on cpu 7
```

9.9.12.3.11 add

Add a pme USDPAA core affined thread

Synopsis

add core_ids

Description

Each specified core will have a pme USDPAA thread created by the application.

core _ids

Identifies which cores shall have an affine USDPAA thread created. The format is as follows:

single_thread | first_thread..last_thread

where: first_thread < last_thread

EXAMPLES

To instruct the application to create threads on cores 1 to 2:

>add 1..2 Thread alive on cpu 1 Thread alive on cpu 2

9.9.12.3.12 list

Display a list of pme USDPAA core affine threads.

Synopsis

```
list
```

Description

A command is sent to each thread. In response the thread will display on which core it is running on.

EXAMPLES

```
>list Thread alive on cpu 0 Thread alive on cpu 1 Thread alive on cpu 2 Thread alive on cpu 3 Thread
alive on cpu 4 Thread alive on cpu 5 Thread alive on cpu 6 Thread alive on cpu 7
```

9.9.12.3.13 display_stats

Instruct the specified threads to display their internal statistics

Synopsis

```
display_stats [thread_ids]
```

Description

Each specified thread will display their internal statistics.

OPTIONS

```
thread_ids
```

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct thread 0 to display its internal statistics:

```
>display_stats 0 in_flight = 0 rx_packets = 0 total_notifs = 0 num_queue_empty = 0 num_erns = 0
num_truncates = 0 full_fifo = 0 Time: 0.000000 secs
```

9.9.12.3.14 clear_stats

Instruct the specified threads to clear their internal statistics

Synopsis

```
clear_stats [thread_ids]
```

Description

Each specified thread will clear their internal statistics.

OPTIONS

`thread_ids`

Identifies which core affine thread shall receive this command. The thread_id has the same value as the core_ids indicated in pme_loopback_test on page 1804. If not specified, all threads receive this command. The format is as follows:

```
single_thread | first_thread..last_thread
```

where: `first_thread < last_thread`

EXAMPLES

To instruct all threads to clear their internal statistics:

```
>clear_stats
```

9.9.12.3.15 help

Display the list of pme_loopback commands

Synopsis

```
help
```

Description

Prints out all pme_loopback commands

OPTIONS

EXAMPLES

To display the list of command:

```
>help
```

Available commands:

```
help add list rm create_ctx_flow_mode create_ctx_direct_mode delete_ctx prep_scan prep_scan_2
start_scan stop_scan free_mem display_stats clear_stats
```

9.9.12.3.16 quit

Quit the pme_loopback application

Synopsis

```
quit
```

Description

This will shutdown the pme_loopback application. All threads will first be removed and then the application will exit.

9.9.12.4 Running pme_loopback

Log in to the p4080 DS environment as "root".

```
          login: root
          Password:
          [root@p4080 root]#
```

Clear the pme database via pmm application:

```
          [root@p4080 root]#pmm
Successfully created the PMM DB.
pmm> commit
Successfully committed changes made to the data base of expressions.
Command execution time: 00:00:00 [hour:min:sec].
pmm> quit
Terminating the PMM application.
[root@p4080 root]#
```

Start the pme_loopback application with threads on cores 0 to 7:

```
          /usr/bin/pme_loopback_test 0..7
          Qman: FQID allocator includes range 512:128
          Bman: BPID allocator includes range 56:8
          FSL dma_mem device mapped (phys=0xf8000000,virt=0x70000000,sz=0x4000000)
          Thread alive on cpu 0
          Thread alive on cpu 1
          Thread alive on cpu 2
          Thread alive on cpu 3
          Thread alive on cpu 4
          Thread alive on cpu 5
          Thread alive on cpu 6
          Thread alive on cpu 7
          >
```

A CLI (Command-Line Interface) is presented in order to allow you to enter the next pme_loopback commands.

Create a pme context in direct mode on each pme USDPAA thread.

```
          > create_ctx_direct_mode
```

Prepare the data for scanning.

```
          > prep_scan 1024 0 15 30 0
```

Start the scanning

Once the command to start scanning is executed it will stay in this mode scanning data until the stop_scan command is entered.

```
          > start_scan
```

[... wait 30 seconds (though as low as 10 seconds can also be used) before typing in stop command below. To allow enough data to be processed by the PME to make the initial command generation overhead amortized over adequate scans. (i.e. the result is a steady state performance result)]

Command to stop Scan

```
          > stop_scan
          Total units scanned: 34608812
```

```
Total time: 29.804104 sec
Scan Units per second: 1161209
Bandwidth: 9512 Mbps
```

Need to free scan memory which was allocated

```
> free_mem
```

Tear down application, need to delete contexts

```
> delete_ctx
```

Quit application

```
> quit
```

9.9.13 USDPAA IPFwd Longest Prefix Match User Manual

9.9.13.1 NXP P4080/P5020/P3041 USDPAA IPFwd Longest Prefix Match User Manual

9.9.13.1.1 Introduction

This user manual describes USDPAA IPFwd based upon Longest Prefix Match methodology. This IPFwd application is different from the other route cache based IPFwd. The User Space Datapath Acceleration Architecture (USDPAA) is a software framework that permits Linux user space applications to directly access DPAA queue and buffer manager portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as the security coprocessor and the frame manager.

This document provides the following:

- A summary of the USDPAA LPM IPFwd application
- A summary of usage of Shared MAC
- A summary of usage of MAC-less interface
- Execution steps for USDPAA LPM IPFwd application from the NXP SDK package on the P4080 DS/P3041DS/P5020DS

This document describes the USDPAA application which demonstrates:

1. IP Forwarding application using Longest prefix match as route decision algorithm
2. MAC less communication between USDPAA application and kernel
3. Sharing of same physical Ethernet port using shared-mac mode

9.9.13.1.2 Overview

The USDPAA LPM based IPv4 forwarding application is a multi-threaded application that routes IPv4 packets from one ethernet interface to another on all QorIQ platforms. The LPM routing algorithm uses the prefix for destination ip address to do the route look up. Any combination of the cores can run a LPM based USDPAA IPv4 Forwarding application thread. The packets that reach the USDPAA application can be forwarded to destination IP address using LPM route algorithm.

LPM IPFwd packet-processing:

· Receives ethernet frames on ethernet interfaces.

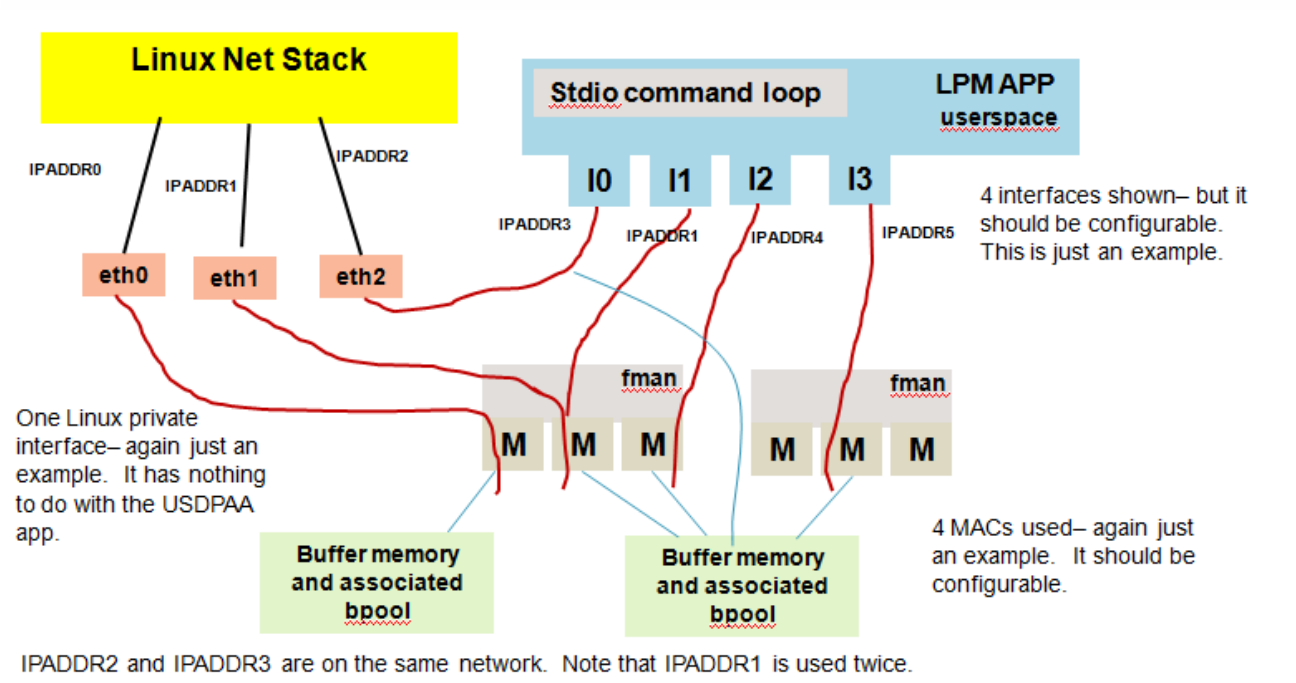
· On the basis of defined PCD rules in FMAN's PCD table, IPv4 traffic would be sent to USDPAA application through PCD Frame queue range.

· For IPv4 frames, processing takes place as defined in section Overview of packet flow: on page 1822

This application also demonstrates the following features:

. how the traffic coming from a common MAC port can be split in between kernel and USDPAA application on the basis of defined PCD rules. The packets that reach the USDPAA application can be forwarded to destination IP address using LPM route algorithm.

. ping between linux and USDPAA using MAC-less interface.



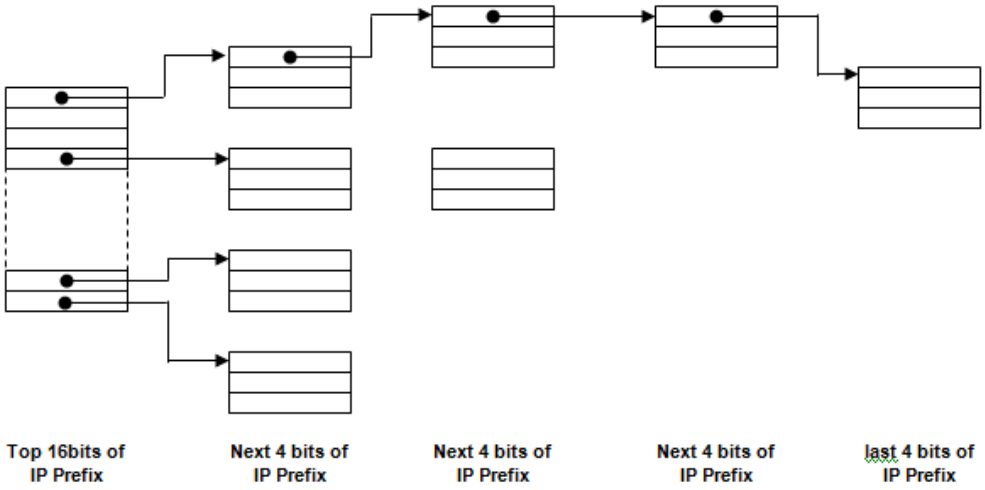
9.9.13.1.3 How is it different from existing Route cache based IPFwd?

This USDPAA application uses Longest Prefix Match algorithm for doing route lookup by using prefix for destination IP address in contrast to the existing route cache based IPFwd which takes route decision based upon hash results calculated by FMAN using source IP address and destination IP address in the frame.

The user will have to use new commands for route addition in LPM table (check the command section)

9.9.13.1.4 Longest Prefix Match algorithm

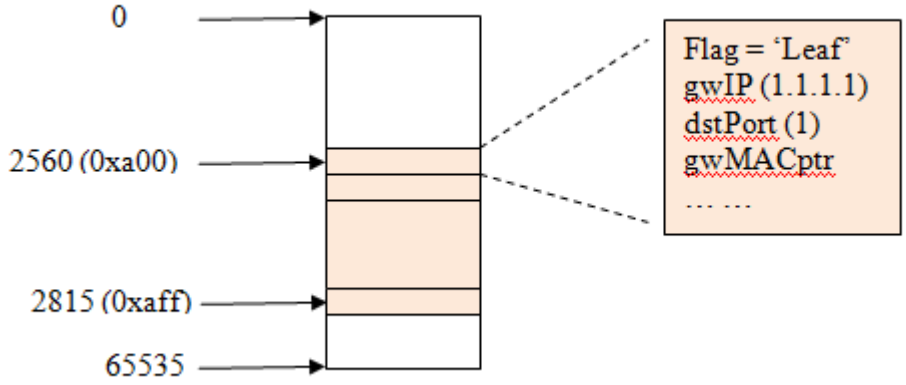
Instead of using traditional Radix-Trie algorithm, here we choose to use one simpler LPM algorithm. It uses 5 level tables: First level table – 65536 entries array, indexed by the top 16 bits of IP address. Second level table – 32 entries array, indexed by bit12~15 of IP address. Third level table – 32 entries array, indexed by bit8~11 of IP address. Fourth level table – 32 entries array, indexed by bit4~7 of IP address. Fifth level table – 32 entries array, indexed by bit0~3 of IP address. The 2nd level to 5th level tables are only created when its first level table entry has valid value. See below figure:



At init time, only the first level (i.e. top16 bits) array is created which contains 65536 null entries. While adding route entries to the FIB table, the 2nd level to 5th level arrays will be created accordingly. This is a typical ASIC design algorithm of LPM which is fast and simple to search while costs far more memory. The worst case is to index and compare 5 times when searching an IP address, but it's still fast enough.

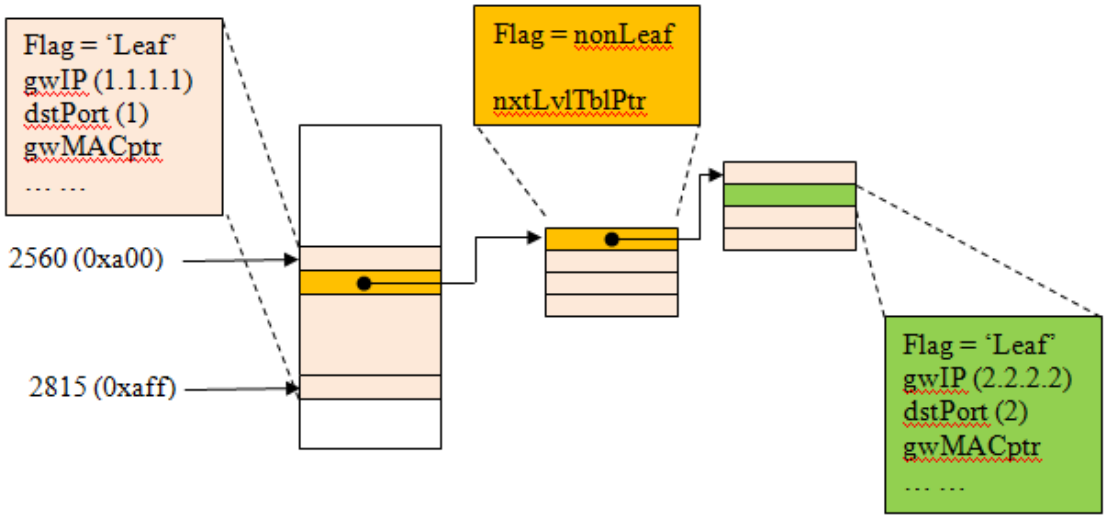
Examples:

1) Add one ClassA route 10.0.0.0/8 to the route table. (gateway is 1.1.1.1, destination port is 1) The first 16bit of 10.0.0.0 (0x0a000000) is 0x0a00 (2560). And the mask is 8 bit which is smaller than the 1st level bit-length (16b), so below entries (from 0x0a00 to 0x0aff) will be created in the FIB table:



From entry No.2560 to No.2815 (total 255 entries) are filled with same content (flag, gwIP, dstPort, ptr …). Now if a packet with DIP of 10.1.1.1 comes in, its first 16 bit value is 0x0a01 (2561). So, the No.2561 entry of the 1st level table will be checked. If it's a 'leaf' node (now it is), then the best-match is found. And the packet will be forwarded to the 'dstPort' after replacing the SMAC and DMAC. And, any DIP of 10.x.x.x will all be forwarded to port 1 with gwIP 1.1.1.1 based on above table.

2) Now, a new route 10.1.1.0/24 is added to the FIB table. The table will be like this:



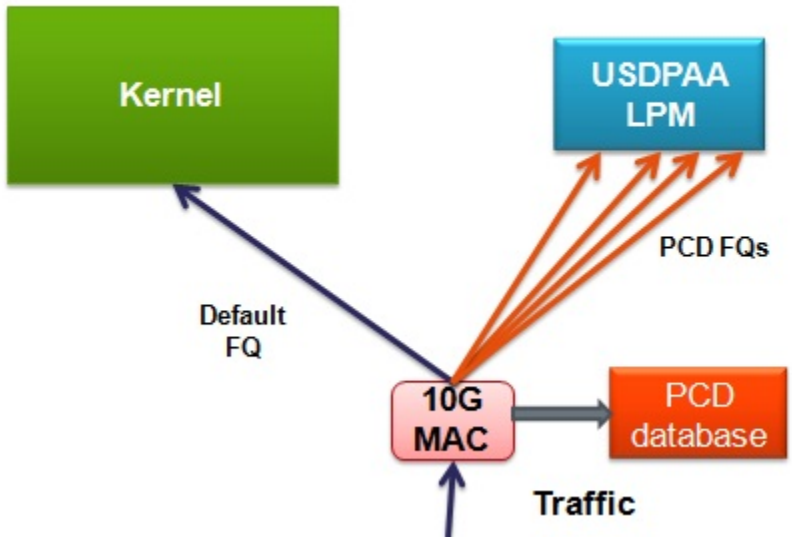
The new route will overwrite the No.2561 (0x0a01) entry with 'flag' of 'nonLeaf' and a pointer to 'next-level-table'. Now a 16-entry-block memory will be allocated as the 'next-level-table' because the 2nd level is 4bit indexed. And the base address of this new block will be set to the 'nxtLvlTblPtr' of No.2561. Because the next 4 bit of the new route is 0 (bit16 to bit19 of 0x0a010100), so the 1st entry in the 2nd level table is used as another 'nonLeaf' entry. While all the other entries in the 2nd level table should be filled with the same value of its 'parent' route (10.0.0.0/8). The netmask is 24bit which is larger than 16+4, so the 3rd level table should also be allocated (16 entries). And the next 4bit of the new route is 1 (bit20 to bit23 of 0x0a010100), so the 2nd entry will be used for the new route. And because the netmask (24bit) is no-larger-than 16+4+4, so this entry will be the 'Leaf' entry of this new route (see above figure in green). And the according values (gwIP, dstPort, etc.) will be filled in that entry. Now a frame with DIP of 10.1.1.100 comes. There will have 3 lookups to get the final result:

- Index with first 16bit of DIP, whose value is 0x0a01. 'Non-leaf' means to continue the next-level lookup.
- Index with the next 4bit of DIP, whose value is 0. Then 'Non-leaf' again.
- Index with the next 4bit of DIP, whose value is 1. Then the 'leaf' node is found and the lookup reaches an end.

Now a frame with DIP of 10.1.192.10 comes. You can see it will find the 'leaf' node in the 2nd level table and get the route of net-address 10.0.0.0/8. And a frame with DIP of 10.1.10.10 will find its 'leaf' node in the 3rd level table and also get the route of net-address 10.0.0.0/8 as we expected. The multi-branch trie algorithm provides a very fast way of route-lookup but a relatively complicated way of route-add/deletion.

9.9.13.1.5 Shared MAC Overview

The kernel and USDPAA should be able to receive traffic of their interest from a shared Ethernet port. On the basis of defined PCD rules in FMAN's PCD table, IPv4 traffic (for non-owned IP addresses) would be sent to USDPAA application through PCD Frame queue range and rest of the traffic (i.e. ICMP etc) would be sent to kernel through default Frame queue.



9.9.13.1.6 How to run shared MAC interface ?

1. Make sure to use the corresponding dtb to "p4080ds-usdpaa-shared-interfaces.dts" file from kernel source. In this example dts file ethernet@9 depicts shared MAC node.

   NOTE

   For p3-p5, use p3041ds-usdpaa-shared-interfaces.dts and p5020ds-usdpaa-shared-interfaces.dts respectively. ethernet@5 depicts shared MAC node.

   NOTE

   For B4, use b4860qds-usdpaa-shared-interfaces.dts where ethernet@9 depicts shared MAC node. And for T4, use t4240qds-usdpaa-shared-interfaces.dts where ethernet@15 depicts shared MAC node.

2. When linux comes up, check the output of "ifconfig -a".

   root@p4080ds:~# ifconfig -a

   fm2-10g Link encap:Ethernet HWaddr 00:e0:0c:00:96:09

   inet6 addr: fe80::2e0:cff:fe00:9609/64 Scope:Link

   UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1

   RX packets:0 errors:0 dropped:0 overruns:0 frame:0

   TX packets:5 errors:1 dropped:0 overruns:0 carrier:0

   collisions:0 txqueuelen:1000

   RX bytes:0 (0.0 B) TX bytes:378 (378.0 B)

   Memory:fe5f0000-fe5f0fff

3. Run fmc

   $cd /usr/etc

   fmc -c usdpaa_config_p4_serdes_0xe.xml -p usdpaa_policy_hash_shared_mac_ipv4.xml -a

   For p3-p5 use this command:

fmc -c usdpaa_config_p3_p5_serdes_0x36_shared_mac.xml -p usdpaa_policy_hash_shared_mac_ipv4.xml -a

For B4 use this command:

fmc -c usdpaa_config_b4_serdes_0x2a_0x98.xml –p usdpaa_policy_hash_shared_mac_ipv4.xml –a

For T4 use this command:

fmc -c usdpaa_config_t4_serdes_1_1_6_6.xml –p usdpaa_policy_hash_shared_mac_ipv4.xml –a

4. Run lpm-ipfwd application

   $lpm_ipfwd_app -d 0x10000000 -b 1600:1600:1600 -i fm2-10g

   For p3-p5

   $lpm_ipfwd_app -d 0x10000000 -b 1600:1600:1600 -i fm1-10g

   For B4

   $lpm_ipfwd_app -d 0x10000000 -b 1600:1600:1600 –c usdpaa_config_b4_serdes_0x2a_0x98.xml –p usdpaa_policy_hash_shared_mac_ipv4.xml -i fm1-mac10

   For T4

   $lpm_ipfwd_app -d 0x10000000 -b 1600:1600:1600 –c usdpaa_config_t4_serdes_1_1_6_6.xml –p usdpaa_policy_hash_shared_mac_ipv4.xml -i fm2-mac10

5. Assign ip address to USDPAA side as well as kernel side as per script "usdpaa_policy_hash_shared_mac_ipv4.xml".

   In this script, the coarse classification "ip_dest_clsf" corresponding to this port uses "192.168.44.3" for USDPAA and "192.168.44.4" for kernel.

   NOTE

   Check ip address for p3-p5 as per scripts usdpaa_config_p3_p5_serdes_0x36_shared_mac.xml and usdpaa_policy_hash_shared_mac_ipv4.xml.

   NOTE

   For B4/T4, use “192.168.44.3” for USDPAA and “192.168.44.4” for kernel as defined in usdpaa_policy_hash_shared_mac_ipv4.xml.

   ssh to p4080 and give these commands:

   $lpm_ipfwd_config -E -a true

   output:

   FMAN Interface number: 11

   , PortID=1:5 is FMan interface node with MAC Address 00:e0:0c:00:96:09

   NOTE

   Check pid from application print "Message queue to send: /mq_snd_2536"

   $ lpm_ipfwd_config -P 2536 -F -a 192.168.44.1 -i 11

   $ lpm_ipfwd_config -P 2536 -G -s 192.168.44.3 -m 02:00:c0:a8:a0:02 -r true

   $ lpm_ipfwd_config -P 2536 -B -c 1 -d 192.168.44.3 -n 16 -g 192.168.44.3

   $ifconfig fm2-10g 192.168.44.4

6. Now run traffic on fm2-10g using the above ip addresses and can see traffic splitting amongst kernel and USDPAA.

9.9.13.1.7 MAC-less use case

This section describes how MAC-less interface is being used in this application. The user space configuration commands and USDPAA application can communicate with each other through the management interface which can be a MAC interface (SGMII, RGMII etc) or MAC-less interface. In this application we are just using MAC-less interface. The user can do such a communication with USDPAA LPM application by using lpm_ipfwd_config binary. For command reference, please check section IPv4 forward application Configuration command on page 1720.

9.9.13.1.8 How to ping MAC-less interface ?

. Make sure to use the corresponding dtb to "p4080ds-usdpaa-shared-interfaces.dts" file from kernel source. In this example dts file ethernet@10 depicts MAC-less node.

. NOTE: For B4, use b4860qds-usdpaa-shared-interfaces.dts and for T4, use t4240qds-usdpaa-shared-interfaces.dts. In both cases, ethernet@16 is the macless node.

. When linux comes up, check the output of "ifconfig -a". The interface containing similar mac address as given under ethernet@10 node in device tree, is the MAC-less interface.

root@p4080ds:~# ifconfig -a

eth0 Link encap:Ethernet HWaddr 00:15:17:1e:22:9e

UP BROADCAST MULTICAST MTU:1500 Metric:1

RX packets:0 errors:0 dropped:0 overruns:0 frame:0

TX packets:0 errors:0 dropped:0 overruns:0 carrier:0

collisions:0 txqueuelen:1000

RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

Interrupt:42 Memory:40000000-40020000

eth3 Link encap:Ethernet HWaddr 00:11:22:33:44:55

BROADCAST MULTICAST MTU:1500 Metric:1

RX packets:0 errors:0 dropped:0 overruns:0 frame:0

TX packets:0 errors:0 dropped:0 overruns:0 carrier:0

collisions:0 txqueuelen:1000

RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

The above output shows that "eth3" is the MAC-less node.

. Run lpm-ipfwd application

$cd /usr/etc

$lpm_ipfwd_app -d 0x10000000 -b 1600:1600:1600 -i eth3:[66-22-33-44-55-66]

The mac address "66-22-33-44-55-66" is the mac that will be assigned as source mac address to USDPAA side of MAC-less interface

. Assign ip address to USDPAA side as well as kernel side.

ssh to p4080 and give these commands:

$lpm_ipfwd_config -E -a true

Output:

MACLESS Interface:

name : eth3

$lpm_ipfwd_config -F -a 192.168.55.6 -n eth3

$ifconfig eth3 192.168.55.2

$ping 192.168.55.6

PING 192.168.55.6 (192.168.55.6): 56 data bytes

64 bytes from 192.168.55.6: icmp_seq=0 ttl=64 time=12.413 ms

64 bytes from 192.168.55.6: icmp_seq=1 ttl=64 time=12.431 ms

9.9.13.1.9 USDPAA LPM based IPv4 forwarding application flow

The LPM based IPFwd application has two main phases. There is an initial configuration phase and a subsequent packet processing phase.

The configuration phase executes when the application starts. Application threads are created and global initialization of resources is done which is the part of PPAC (see USDPAA PPAC User Guide for more details). The configuration phase also includes PPAM (i.e. IPFwd) related initialization. Once the configuration phase is completed the IPFwd application moves to the packet processing phase. This application provides a command-line interface to enable users to add and remove routing table and ARP cache entries. For each user input, the appropriate information is communicated to the IPFwd application via standard Posix IPC. Messages are placed onto the message queue till they are received by the IPfwd application. Note that this application does not dynamically resolve ARP – missing ARP entries will result in the application dropping the packet.

In the packet processing phase, the loop migrates from polling mode to a blocking “IRQ mode” whenever LPM IPFwd has looped a certain number of times without any forward progress. For more information on IRQ mode please refer to “USDPAA PPAC User Guide”. In polling mode – the application constantly looks for data to process on its dedicated QMan portal . Network traffic is classified and distributed by the FMan to frame queues based on source and destination IP address in the packet. There is an associated handler that processes the packets arriving on each frame queue.

9.9.13.1.10 Overview of packet flow:

1. Static Route table entries are populated using the user space configuration commands.
2. If a packet received by the FMan is an IPv4 packet it uses 2-tuple (Src IP & Dest IP) to hash the packet to a Rx frame queue. Otherwise if packet is ICMP etc it would be sent through default Frame queue where the buffer is freed.
3. The packet enqueued to PCD FQ to reach USDPAA LPM based IPFwd application thread running on one of the cores is subjected to LPM based route lookup.
4. All of the threads enter the processing loop where they call Qman_poll till a frame is received.
5. If a frame is received, the application checks whether the destination IP address exist in the FIB table. For this it calls ip_route_lookup(), which does the route look up using LPM algorithm. The LPM IPFWD application does not change its FIB table in response to seeing the first packet in a flow. Instead the FIB table is set only by commands, as mentioned in section Syntax on page 1720.
6. If the route entry for this frame is not present in the FIB table, the frame is dropped. It then continues with Qman_poll.
7. If the route entry for this frame exists in the FIB table, the frame is sent for forwarding.
8. If the frame is to be forwarded, it is checked if ARP entry exists in ARP table for destination IP address. LPM IPFWD application will not dynamically resolve the ARP. So if sending packets to forward using a regular computer, the user will have to create static ARP entries. On host computer, ARP table can be updated by sending the ARP request. LPM IPFWD will respond to external ARP requests
9. If ARP entry exists, TTL is decremented in L3 header.
10. Finally, the L2 header is updated, which includes changing the dst MAC address in L2 header. The frame is then enqueued to the TX FQ.

9.9.13.1.11 Overview of PPAC

The source code to LPM-IPFwd has been reorganized into two parts; the “PPAC” (Packet-Processing Application Core) and a “PPAM” (Packet-Processing Application Module). The PPAM portion implements the LPM-IPFWD application specific logic of processing the packet using longest prefix match and forward it. On the other hand, the PPAC component represents the common infrastructure to support PPAM; initializing devices, handling flow-control, implementing a CLI (Command-Line Interface), managing threads and buffers. PPAC details can be found in the document “USDPAA PPAC User Guide”.

9.9.13.1.12 Compile-time configuration

PPAC-based application are compiled using a certain set of options that are currently defined in the header located at apps/include/ppac.h. The following describes the most useful options for modification if alternative application behaviour is desired.

9.9.13.1.13 Order Preservation in LPM-IPFWD

This section describes how user can enable Order Preservation in LPM-IPFWD application. By default Order Preservation is disabled in LPM-IPFWD application and in order to enable it the user will have to re-compile the binary by making following changes to the source code.

In file, usdpaa/apps/include/ppac.h you can find these two lines.

```
/* Application options */
#undef PPAC_HOLDACTIVE /* Process each FQ on one portal at a time */
#undef PPAC_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */
```

Change the above to

```
#define PPAC_HOLDACTIVE /* Process each FQ on one portal at a time */
#define PPAC_ORDER_PRESERVATION /* HOLDACTIVE + enqueue-DCAs */
```

And then compile usdpaa once again. Now run the LPM-IPFWD application with Order Preservation.

9.9.13.1.14 Order Restoration in LPM IPFWD

Order restoration is the functionality of QMan software portal interface which restores the relative temporal order of a flow of frames (sequence of frames) to that observed before transmitting to the destination Frame Queue and Order Definition Point (ODP) takes note of the correct order of packets before start processing by using the sequence number. Use of “HOLDACTIVE” is mutually exclusive with another QMan option “AVOIDBLOCK”, which is selected by default in PPAC. To enable order-restoration, the user will have to re-compile the binary by making following changes to the source code.

```
/* Application options */
#undef PPAC_HOLDACTIVE          /* Process each FQ on one portal at a time */
#undef PPAC_ORDER_PRESERVATION    /* HOLDACTIVE + enqueue-DCAs */
#undef PPAC_2FWD_ORDER_RESTORATION    /* Use ORP */
#define PPAC_AVOIDBLOCK          /* No full-DQRR blocking of FQs */
```

Change the above to

```
#undef PPAC_HOLDACTIVE          /* Process each FQ on one portal at a time */
#undef PPAC_ORDER_PRESERVATION    /* HOLDACTIVE + enqueue-DCAs */
#define PPAC_ORDER_RESTORATION    /* Use ORP */
#define PPAC_AVOIDBLOCK          /* No full-DQRR blocking of FQs */
```

And then compile usdpaa once again. Now run the LPM-IPFWD application with Order Restoration. Implementation note: Order restoration has been implemented such that each PCD Frame queue has a corresponding ORP (order restoration point) frame queue associated with it. Each ORP is configured with default window settings as seen below

#define PPAC_ORP_WINDOW_SIZE 7 /* 0->32, 1->64, 2->128, ... 7->4096 */

#define PPAC_ORP_AUTO_ADVANCE 1 /* boolean */

#define PPAC_ORP_ACCEPT_LATE 3 /* 0->no, 3->yes (for 1 & 2->see RM) */

Here the ORP window size is set to be 4K, auto advance window size as 4K and accept late arrival window size as 8K. This ensures that no traffic is getting dropped but are always accepted below and at Zero loss throughput. Beyond zero loss throughput, as usual packets would be dropped and thus you can see mis-ordering.

ORP FQ descriptor attributes settings:

- Prefer in cache
- No “ HOLDACTIVE ”
- No “ AVOIDBLOC K”
- ORP enabled

Assumption: To see the effect of Order Restoration in LPM-IPFwd application the user must use separate streamblocks as a source of traffic. If not done so, mis-ordering would be seen.

Key observation: It has been observed in LPM-IPFwd application that use of “HOLDACTIVE” with traffic generated using separate streamblocks, all the packets are IN sequence. Therefore, it is recommended that if user wants to see the real effect of Order restoration in LPM-IPFwd application he should use “AVOIDBLOCK” with “RESTORATION” and not “HOLDACTIVE” with “RESTORATION”

9.9.13.1.15 Monitoring Rx/Tx fill-levels and flow-control via CGR

If CGR-based monitoring is enabled, then two Congestion Group Records will be configured, with all Rx FQs for all interfaces being subscribed to one, and all Tx FQs being subscribed to the other. This simply allows the user to monitor the overall fill-level of frame queues in the system, in particular to determine whether build-up is occuring before or after the software-processing phase. Refer to section “ Monitoring Rx/Tx fill-levels via CGR ” of USDPAA PPAC User Guide for more details. To enable this feature, in ppac.h change;

#undef PPAC_CGR

to;

#define PPAC_CGR

The CGRs can also be configured to perform flow-control using Congestion state tail drop by setting CSTD_EN bits . Each congestion group record can be configured to track either byte counts or frame counts in all frame queues in the Congestion Group. When the threshold set for each CGR is exceeded, the CS bit is set in the CGR, and the congestion group is said to have entered congestion. At this point the incoming frames are marked for discard and QMAN will generate enqueue rejections to the producer. When the group’s I_BCNT returns below the threshold (minus approximately 1/8 of the threshold to provide hysteresis), the CS bit is cleared, and the congestion group’s state exits congestion. To enable tail drop, in ppac.h change;

#undef PPAC_CGR /* Track rx and tx fill-levels via CGR */

#undef PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

to

#define PPAC_CGR /* Track rx and tx fill-levels via CGR */

#define PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

And then compile usdpaa once again. Now run the IPFWD application with CGR tail drop enabled. To test this feature PPAC CLI provides a command “cgr” which will query and display all the fields of both CGRs. On pumping the traffic to IPFWD application at full line rate, t he instantaneous group byte count value I_BCNT(Instantaneous frame/byte count) must be maintained lesser than the CGR threshold set for each congestion group. Here is one such cgr command output:

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 0

cscn_targ: 0x00800000

cstd_en: 1

cs: 0

cs_thresh: 0x00_0000_1000

mode: 1

i_bcnt: 0x00_0000_0e1e

a_bcnt: 0x00_0000_0e1e

Tx CGR ID: 11, selected fields;

cscn_en: 0

cscn_targ: 0x00800000

cstd_en: 1

cs: 0

cs_thresh: 0x00_0000_0200

mode: 1

i_bcnt: 0x00_0000_0002

a_bcnt: 0x00_0000_0004

On the other hand if this feature of Congestion Group tail drop is disabled in IPFWD application I_BCNT is never maintained below CGR threshold value with traffic at full line-rate. This can be checked by compiling the IPFWD application with;

#define PPAC_CGR /* Track rx and tx fill-levels via CGR */

#undef PPAC_CSTD /* CGR tail-drop */

#undef PPAC_CSCN /* Log CGR state-change notifications */

Now on pumping traffic at full line-rate, atleast one of the CGRs must go into congestion state and its I_BCNT should be above CGR threshold value. Here is the sample output:

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 1

cscn_targ: 0x00800000

cstd_en: 0

cs: 0

cs_thresh: 0x00_0000_1000

mode: 1

i_bcnt: 0x00_0000_0006

a_bcnt: 0x00_0000_0004

Tx CGR ID: 11, selected fields;

cscn_en: 1

cscn_targ: 0x00800000

cstd_en: 0

cs: 1

cs_thresh: 0x00_0000_0200

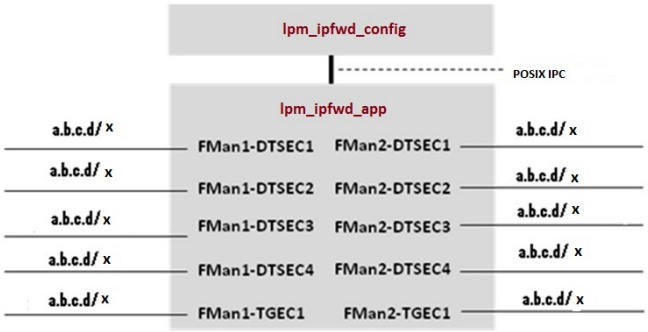
mode: 1

i_bcnt: 0x00_0000_5fb7

a_bcnt: 0x00_0000_5fb8

Thus, the above test showcases the flow control achieved by enabling congestion group tail drop in IPFWD application.

9.9.13.1.16 LPM IPFWD Application Suite



The figure above shows the structure of the LPM IPFWD USDPAA application suite. Its purpose is to forward IPv4 packets between the interfaces shown. No IP address is assigned to any of the interfaces by default. Using ipfwd_config command as mentioned in section Assign IP address to interfaces on page 1840 IP address can be assigned to all these interfaces. Each interface can have a variable netmask. The MAC addresses of these interfaces are determined by u-boot environment variables ethaddr, eth1addr, eth2addr, etc.

The ipfwd application will respond to ARP requests on these interfaces. However, the application will not generate ARP requests to determine the destination MAC address of forwarded packets. An ipfwd_config command should be used to set these MAC addresses. On host side, ARP table can be updated by sending ARP requests to this application.

It is important to understand that the application can use only a subset of these interfaces at any one time. This is due to pin multiplexing rules on the P4080 SoC. The set of available interfaces is determined by a number of factors:

1. The interface set made available by the selected SerDes Protocol and u-boot variable "hwconfig". See the SDK document "NXP DPAA SDK X.Y: Selecting Ethernet Interfaces". This document is distributed with the DPAA SDK.
2. The Linux device tree determines which subset of the available interfaces is for use by USDPAA applications. See the USDPAA User Guide for more information.
3. Finally, the fmc configuration file passed by command line argument to lpm_ipfwd_app determines the subset of these interfaces that the application will attempt to initialize.

In the default SerDes 0xe example, the interfaces used by lpm_ipfwd_app are:

- FMan1-TGEC1
- FMan2-DTSEC3

- FMan2-DTSEC4
- FMan2-TGEC1

Running the lpm ipfwd application suite involves four steps:

1. Run lpm_ipfwd_app
2. Run lpm_ipfwd_config repeatedly to add routes to LPM FIB table.
3. Run the fmc application to configure the FMan hardware instances.

Specific examples showing these steps are provided in other sections of this document.

9.9.13.1.17 Possible configuration scenario for LPM based IPFWD

LPM based IPfwd application can run in different configuration scenario. The table below shows the configuration files and corresponding sample shell script existing in the repository.

xml file	Sample shell script	Number of routes (as per sample shell script)	Netmask (as per sample shell script)
usdpaa_config_p4_serdes_0xe.xml (2x10G+2x1G)	lpm_ipfwd_20G.sh	1024 routes (2x10G)	16
	lpm_ipfwd_22G.sh	1024 routes (2x10G+2x1G)	16
	lpm_ipfwd_20G_1Mroutes.sh	1M/256 (4K) routes	24
usdpaa_config_p2_p3_p5_14g.xml(4x1G+10G)	lpm_ipfwd_14G.sh	1020 routes (4x1G+10G)	16

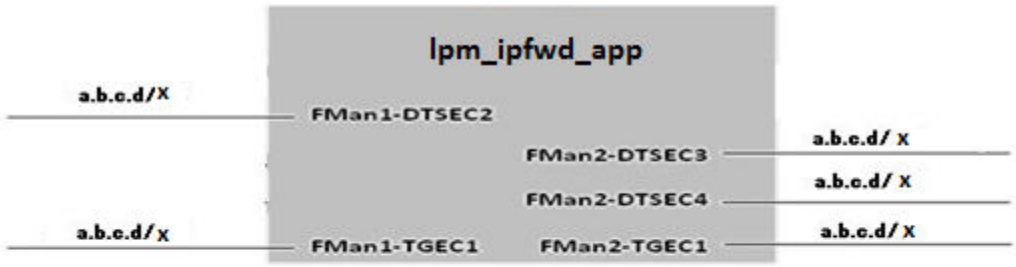


Figure 1: usdpaa_config_p4_serdes_0xe.xml

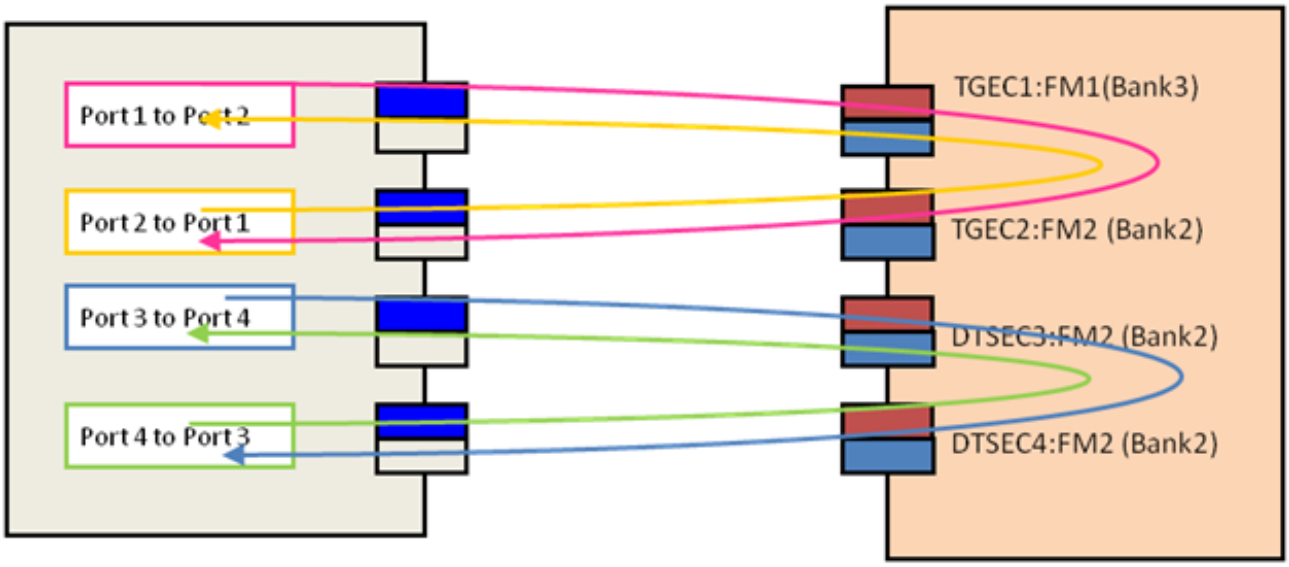
The figure above shows the ethernet interfaces available as per configuration file " usdpaa_config_p4_serdes_0xe.xml". It contains the 1 RGMII port (FMAN1, DTSEC 2), 2 SGMII ports (FMan2, DTSECs 3- 4) and 2 XAUI ports (FMAN1, TGEC1 and FMAN2-TGEC2). It is the user's wish to use any combination of ports available with the configuration file. The above table shows the sample shell scripts that user can use for this configuration. If user uses 2x10G, following is the flow configuration.

Test Center <-> P4080

Port 2 to Port 1 (512 flows) :
Dst : 190.0.24.2 - 190.255.24.2
Dst : 191.0.24.2 - 191.255.24.2
Gw : 192.168.60.2

Port 1 to Port 2 (512 flows) :
Dst : 192.0.24.2 - 192.255.24.2
Dst : 193.0.24.2 - 193.255.24.2
Gw : 192.168.160.2

Figure 2 : Flow Configuration for 2x10G on P4080DS



Port 2 to Port 1 (256 flows):
Dst : 190.0.24.2 - 190.255.24.2
Gw : 192.168.60.2

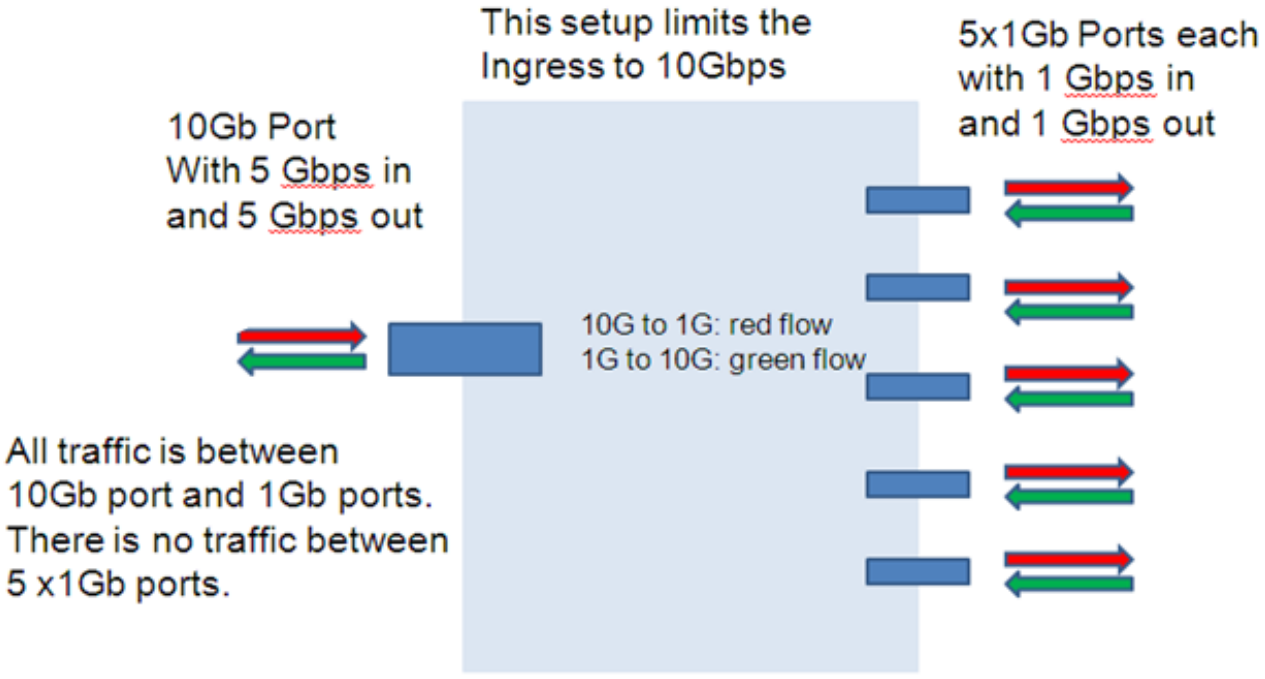
Port 1 to Port 2 (256 flows):
Dst : 193.0.24.2 - 193.255.24.2
Gw : 192.168.160.2

Port 4 to Port 3 (256 flows):
Dst : 191.0.24.2 - 191.255.24.2
Gw : 192.168.130.2

Port 3 to Port 4 (256 flows):
Dst : 192.0.24.2 - 192.255.24.2
Gw : 192.168.140.2

Figure 3 : configuration for 2x10G and 2x1G on P4080

For running LPM IPFwd on P3041DS/P5020DS, the user can use " usdpaa_config_p2_p3_p5_14g.xml". Following is the flow configuration.



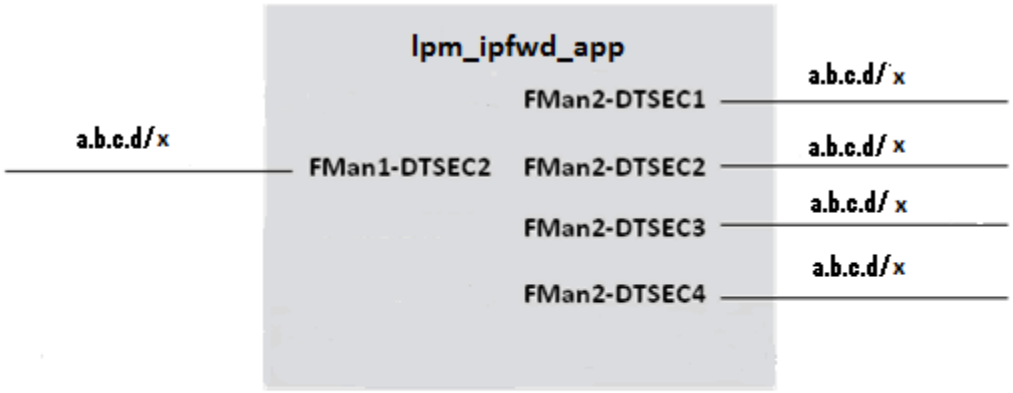
Left: 10G port (port6: fm1-10g)
Right: top-to-bottom: 1G port (port1-port6)

Figure 4 : Flow Configuration for 10G on P5020DS and P3041DS

Port 1 to Port 6 (100 flows): Dst: 195.0.24.2 – 195.99.24.2 Gw: 192.168.60.2	Port 6 to Port 1 (100 flows): Dst: 190.0.24.2 – 190.99.24.2 Gw: 192.168.10.2
Port 2 to Port 6 (100 flows): Dst: 196.0.24.2 – 196.99.24.2 Gw: 192.168.60.2	Port 6 to Port 2 (100 flows): Dst: 191.0.24.2 – 191.99.24.2 Gw: 192.168.20.2
Port 3 to Port 6 (100 flows): Dst: 197.0.24.2 – 197.99.24.2 Gw: 192.168.60.2	Port 6 to Port 3 (100 flows): Dst: 192.0.24.2 – 192.99.24.2 Gw: 192.168.30.2
Port 4 to Port 6 (100 flows): Dst: 198.0.24.2 – 198.99.24.2 Gw: 192.168.60.2	Port 6 to Port 4 (100 flows): Dst: 193.0.24.2 – 193.99.24.2 Gw: 192.168.40.2
Port 5 to Port 6 (100 flows): Dst: 199.0.24.2 – 199.99.24.2 Gw: 192.168.60.2	Port 6 to Port 5 (100 flows): Dst: 194.0.24.2 – 194.99.24.2 Gw: 192.168.50.2

How to run if user has no XAUI but only SGMII riser card?

Assume user does not have a XAUI riser card and wants to run LPM IPFwd using only the SGMII ports as shown below.



This configuration contains the 1 RGMII port (FMAN1, DTSEC 2), 4 SGMII ports (FMan2, DTSECs 1- 4). The user can modify the configuration file and sample shell scripts as per requirement. The configuration file would contain the following

```
<cfgdata>
<config>
<engine name="fm1">
<port type="1G" number="0" policy="hash_ipsec_src_dst_spi_policy6"/>
<port type="1G" number="1" policy="hash_ipsec_src_dst_spi_policy7"/>
<port type="1G" number="2" policy="hash_ipsec_src_dst_spi_policy8"/>
<port type="1G" number="3" policy="hash_ipsec_src_dst_spi_policy9"/>
</engine>
</config>
</cfgdata>
```

User can create a new shell script which would make routes between the 4x1G. Here is the content of the script.

```
net_pair_routes()
{
net=0
while [ "$net" -le $5 ]
do
lpm_ipfwd_config -P $pid -B -c $2 -d $1.$net.24.2 -n $3 -g \
192.168.$4.2
net=`expr $net + 1`
done
}
lpm_ipfwd_config -P $pid -F -a 192.168.110.1 -i 6
lpm_ipfwd_config -P $pid -F -a 192.168.120.1 -i 7
```

lpm_ipfwd_config -P $pid -F -a 192.168.130.1 -i 8

lpm_ipfwd_config -P $pid -F -a 192.168.140.1 -i 9

lpm_ipfwd_config -P $pid -G -s 192.168.110.2 -m 02:00:c0:a8:6e:02 -r true

lpm_ipfwd_config -P $pid -G -s 192.168.120.2 -m 02:00:c0:a8:78:02 -r true

lpm_ipfwd_config -P $pid -G -s 192.168.130.2 -m 02:00:c0:a8:82:02 -r true

lpm_ipfwd_config -P $pid -G -s 192.168.140.2 -m 02:00:c0:a8:8c:02 -r true

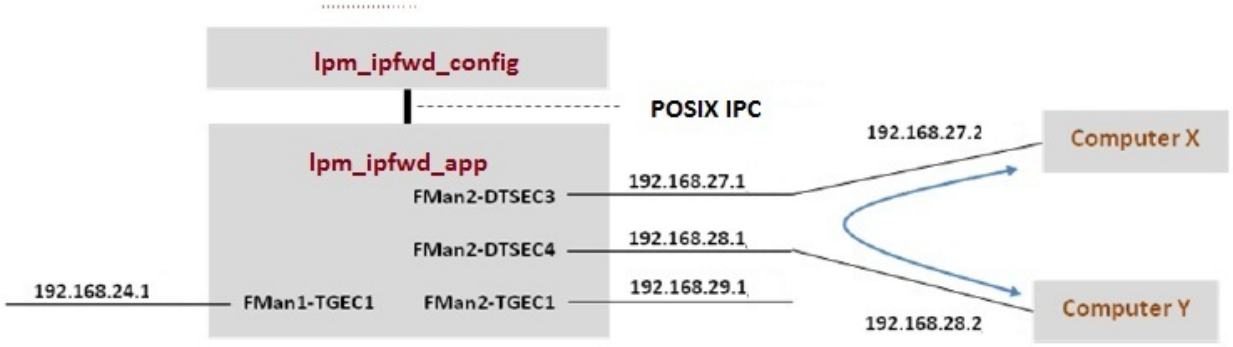
9.9.13.1.18 Using Two Computers to Test the IPFWD Application Suite

This section describes how to configure the IPFWD application suite to forward packets between two ordinary computers as shown in the following figure. It is assumed that the two 1 Gbps Ethernet interfaces provided by SerDes 0xe are used.



Assign IP addresses to all the interfaces. The IP addresses used here for Computer X and Computer Y are examples. Their MAC addresses must be known as they will be needed in the commands below.

Keep in mind that ipfwd_app has no default IP address assigned to the interfaces. This means that you must first assign IP addresses to the interfaces and then use IP addresses for Computer X and Computer Y that are on the subnets shown in the figure. Please be careful with the network parameters. Any mistake will prevent packets from flowing from end to end.

Follow these steps on Computer X:

1. Set the ip address for eth0 interface

ifconfig eth0 192.168.27.2 up

Set the default gateway for subnet 192.168.27.1

route add default gw 192.168.27.1 eth0

2. No need to add arp on host side. The application can handle external arp requests

Follow these steps on Computer Y:

1. Set the ip address for eth0 interface

ifconfig eth0 192.168.28.2 up

Set the default gateway for subnet 192.168.28.1

route add default gw 192.168.28.1 eth0

2. No need to add arp on host side. The application can handle external arp requests

The commands to perform on P4080 are:

Boot the P4080 and login as root.

Assign IP address to fm1-gb1

ifconfig fm1-gb1 <IPADD> up

Assume use of cores 1 - 7 lpm_ipfwd_app 1..7 -d 0x10000000 -b 0:0:1728 -i fm1-10g,fm2-gb2,fm2-gb3,fm2-10g

Now ssh to P4080 linux on other terminal

ssh root@<IPADD>

give IP address as assigned to fm1-gb1 in the beginning

Now assign ip address to the interfaces

First run command to check what all enabled interfaces are available

Note: check pid from application print "Message queue to send: /mq_snd_2536"

lpm_ipfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

PortID=1:3 is FMan interface node

with MAC Address

02:00:c0:a8:5b:fe

Interface number: 8

PortID=1:2 is FMan interface node

with MAC Address

02:00:c0:a8:51:fe

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces

Assign IP address to the interfaces.Use the same interface number displayed as an ouput on giving the above command

lpm_ipfwd_config -P 2536 -F -a 192.168.24.1 -i 5

lpm_ipfwd_config -P 2536 -F -a 192.168.28.1 -i 9

lpm_ipfwd_config -P 2536 -F -a 192.168.27.1 -i 8

lpm_ipfwd_config -P 2536 -F -a 192.168.29.1 -i 11

Now enter routes and MAC addresses. Format of a MAC address is

aa:bb:cc:dd:ee:ff where the letters are hexadecimal digits.

lpm_ipfwd_config -P 2536 -B -d 192.168.28.2 -g 192.168.28.2 -n 24 -c 1

lpm_ipfwd_config -P 2536 -G -s 192.168.28.2 -m COMPUTER_Y_MAC_ADDRESS -r true

lpm_ipfwd_config -P 2536 -B -d 192.168.27.2 -g 192.168.27.2 -n 24 -c 1

lpm_ipfwd_config -P 2536 -G -s 192.168.27.2 -m COMPUTER_X_MAC_ADDRESS -r true

Run fmc command cd /usr/etc

fmc -c usdpaa_config_p4_serdes_0xe.xml -p usdpaa_policy_hash_lpm_ipv4.xml -a

Now, traffic can pass between Computer X and Computer Y. For example, on Computer X

enter:

ping 192.168.28.2

9.9.13.1.19 Running LPM IPv4 forwarding on P4080DS board

The instructions below describe how to run LPM-IPFWD. Traffic should only be directed to the P4080DS once the application is running and configuration via the ipfwd_config application is completed.

- On linux prompt, assign IP address to fm1-gb1

$ ifconfig fm1-gb1 <IPADD> up

Now run the FMC command

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c usdpaa_config_p4_serdes_0xe.xml -p usdpaa_policy_hash_lpm_ipv4.xml -a

- Run LPM-IPFWD application

The main LPM-IPFwd application binary is called **lpm_ipfwd_app** *. The application can run on multiple cores as specified by the first parameter to the application. To run it to handle traffic distributed over 32 ingress frame queues per port:*

$ lpm_ipfwd_app <m..n>

By default lpm_ipfwd_app uses usdpaa_config_p4_serdes_0xe.xml and usdpaa_policy_hash_lpm_ipv4.xml files.

LPM-IPFWD application command syntax:

[root@p4080 etc]# lpm_ipfwd_app --usage

Usage: lpm_ipfwd_app [-n?V] [-b x:y:z] [-c FILE] [-d SIZE] [-i FILE] [-p FILE]

[--buffers=x:y:z] [--fm-config=FILE] [--dma-mem=SIZE]

[--fm-interfaces=FILE] [--non-interactive] [--fm-pcd=FILE]

[--cpu-range] [--help] [--usage] [--version] [cpu-range]

LPM-IPFWD application run command:

[root@p4080 root]# cd /usr/etc

[root@p4080 etc]# lpm_ipfwd_app 1..7 -d 0x4000000 -b 0:0:1728 -i fm1-10g,fm2-gb2,fm2-gb3,fm2-10g

To use dma region size as 64M in USDPAA for lpm-ipfwd application, make sure to set the same or greater size in bootargs. E.g. usdpaa_mem=256M

[1] 5363

[root@p4080 etc]# Found /fsl,dpaa/dpa-fman0-oh@1, Tx Channel = 46, FMAN = 0, Port ID = 1

Found /fsl,dpaa/ethernet@4, Tx Channel = 40, FMAN = 0, Port ID = 0

Found /fsl,dpaa/ethernet@7, Tx Channel = 63, FMAN = 1, Port ID = 2

Found /fsl,dpaa/ethernet@8, Tx Channel = 64, FMAN = 1, Port ID = 3

Found /fsl,dpaa/ethernet@9, Tx Channel = 60, FMAN = 1, Port ID = 0

Configuring for 4 network interfaces

Allocated DMA region size 0x10000000

lpm_ipfwd_app starting

IPv4 FIB table init now... Done!

Message queue to send: /mq_snd_2536

Message queue to receive: /mq_rcv_2536

Thread uid:0 alive (on cpu 1)

Release 0 bufs to BPID 7

Release 0 bufs to BPID 8

Release 1600 bufs to BPID 9

Thread uid:1 alive (on cpu 2)

Thread uid:2 alive (on cpu 3)

Thread uid:3 alive (on cpu 4)

Thread uid:4 alive (on cpu 5)

Thread uid:5 alive (on cpu 6)

Thread uid:6 alive (on cpu 7)

If, in the run application command, cpu-range is given i.e. "lpm_ipfwd_app <*m..n*>" LPM-IPFWD application starts threads on cpu-range m..n. The main thread (by default on CPU 1) then does global initialization needed by the application, including starting other application threads.

If, on the other hand, run application command is given without any cpu-range i.e. "lpm_ipfwd_app" LPM-IPFWD application starts up with a single thread running on CPU 1 by default, which does global initialization needed by the application and enables all the network interfaces.

The CLI (Command-Line Interface) allows you to add and remove additional threads to enable the use of multiple CPUs, with the only restriction being that the primary thread on CPU 1 cannot be removed (except by shutting down the application).

To add a thread on a single CPU (e.g. CPU 2):

> add 2

To add threads on a range of CPUs:

> add 3..6

To list the threads (this also queries each thread, verifying that they aren't blocked):

> list

Thread alive on cpu 1

Thread alive on cpu 2

Thread alive on cpu 3

Thread alive on cpu 4

Thread alive on cpu 5

Thread alive on cpu 6

To enable all interfaces

> macs on

To disable all interfaces

> macs off

To perform a controlled shutdown of ipfwd (this includes disabling the network ports):

> quit

- Once the application starts, it can receive the configuration commands. Run application configuration script.

For creating route entries, the binary *lpm_ipfwd_config* is run. This binary processes the configuration request from the user (using the command line) and populates the configuration via Linux standard posix IPC messages to the LPM-IPFwd application.

The shell script mentioned below contains sample commands to add route entries. Detailed description of all lpm_ipfwd_config commands is provided in section Syntax on page 1720.

SSH to p4080 linux on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to fm1-gb1 in the beginning)

Run the shell script:

The shell script needs pid as input (process id of the application to hook up with)

pid can be read from the application prints "Message queue to send: /mq_snd_2536 "

lpm_ipfwd_20G.sh "pid"

$ lpm_ipfwd_ 20G.sh 2536

There are example shell scripts available. They can assign IP addresses to the interfaces, add an ARP entry and can use variable netmask while creating route entries. The following table summarizes the settings done by these scripts. Check sectionPossible configuration scenario for LPM based IPFWD on page 1827 for more details.

For the LPM-IPFwd application to forward traffic successfully, traffic destined for the P4080DS ports must have the appropriate destination IP addresses.

Console messages are printed for each entry added to the routing table. Once all configuration is completed, the application moves to the packet processing phase - the message "LPM-IPFwd Route Creation completed" is printed on the console.

At this point, traffic can be sent to the ethernet interfaces, IPv4 packets would be processed by the LPM application on the cpu-range specified by the user on the application command-line.

9.9.13.1.20 Running LPM IPv4 forwarding on P3041/P5020 board

The instructions below describe how to run LPM-IPFWD on P3041/P5020. Traffic should only be directed to P3041/P5020 once the application is running and configuration via the lpm_ipfwd_config application is completed. On linux prompt, assign IP address to eth0

$ ifconfig eth0 <IPADD> up

Configure FMan PCD using fmc with the XML files in /usr/etc:

$ cd /usr/etc

To setup the FMan to distribute traffic to 32 ingress frame queues per port:

$ fmc -c usdpaa_config_p2_p3_p5_14g.xml -p usdpaa_policy_hash_lpm_ipv4.xml -a

Run lpm-IPFWD

$ lpm_ipfwd_app <m..n> -c usdpaa_config_p2_p3_p5_14g.xml -p usdpaa_policy_hash_lpm_ipv4.xml -d 0x4000000 -b 0:0:1728 -i fm1-gb0, fm1-gb1,fm1-gb3,fm1-gb4,fm1-10g

For P3041, m..n can be 0..3. For P5020, m..n can be 0..1.

SSH to board (linux) on another terminal:

$ ssh root@<IPADD> (give the IP address as assigned to eth0 in the beginning)

Run the shell script:

$ lpm_ipfwd_14G.sh

There is an example shell script available named as lpm_ipfwd_14G.sh creates routes for only the 4 x 1G and 1x10G interfaces. It can assign ip addresses to the interfaces, add an ARP entry . Check section Possible configuration scenario for LPM based IPFWD on page 1827 for more details. Now traffic can be run as per the routes created.

9.9.13.1.21 USDPAA LPM IP Fwd performance gap between 6 core and 8 core

USDPAA LPM IPfwd performance for 8 core is less than 6 core on e6500 series. USDPAA LPM IP Fwd application need to run using "-s" option to bridge the gap between two configuration.

9.9.13.1.22 PPAC (and IPFwd) CLI commands

The following commands are illustrated in the context of IPFwd, but the commands are common to all PPAC-based applications.

To add a thread on a single CPU (e.g. CPU 2):

> add 2

To add threads on a range of CPUs:

> add 3..6

To list the threads (this also queries each thread, verifying that they aren't blocked):

> list

Thread uid:0 alive (on cpu 1)

Thread uid:1 alive (on cpu 2)

Thread uid:2 alive (on cpu 3)

Thread uid:3 alive (on cpu 4)

Thread uid:4 alive (on cpu 5)

Thread uid:5 alive (on cpu 6)

Thread uid:6 alive (on cpu 7)

To remove a thread by its UID:

> rm uid:2

Thread uid:2 killed (cpu 3)

To remove a thread running on a given CPU:

> rm 5 Thread uid:4 killed (cpu 5)

To enable all interfaces:

> macs on

To disable all interfaces:

> macs off

To perform a controlled shutdown of ipfwd (this includes disabling the network ports):

> quit

To query cgr

> cgr

Rx CGR ID: 10, selected fields;

cscn_en: 0

cscn_targ: 0x00800000

9.9.13.1.23 Syntax

The syntax is as follows:

$ [root@p4080 bin]# ipfwd_config --help

Usage: ipfwd_config [OPTION...]

-B, --routeadd=TYPE adding a route

-C, --routedel=TYPE deleting a route

-E, --showintf=TYPE show interfaces

-F, --intfconf=TYPE change intf config

-G, --arpadd=TYPE adding a arp entry

-H, --arpdel=TYPE deleting a arp entry

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

9.9.13.1.24 Command to show all enabled interfaces and their interface numbers

The command to show all the enabled interfaces while running IPv4 forward is as follows:

lpfwd_config -P pid -E -a true

Table 294. Field Description (show all enabled interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	Show all the interfaces	Yes	true

Command to show all enabled interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# lpfwd_config -P 2536 -E -a true

Interface number: 11

PortID=1:5 is FMan interface node

with MAC Address

02:00:c0:a8:65:fe

Interface number: 9

PortID=1:3 is FMan interface node

with MAC Address

02:00:c0:a8:5b:fe

Interface number: 8

PortID=1:2 is FMan interface node

with MAC Address

02:00:c0:a8:51:fe

Interface number: 5

PortID=0:5 is FMan interface node

with MAC Address

02:00:c0:a8:33:fe

Are all the Enabled Interfaces [root@p4080 bin]#

9.9.13.1.25 Help for show all enabled interfaces command

The command to obtain help for show all enabled interfaces command is as follows:

lpm_ipfwd_config -E -help

Help for show all enabled interfaces

[root@p4080 etc]# lpm_ipfwd_config -E --help

Usage: -E [OPTION...]

-a, --a=ALL All interfaces

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.13.1.26 Assign IP address to interfaces

The command to assign IP address to shared or private interfaces while running IPv4 forward is as follows:

lpm_ipfwd_config -P pid -F -a 192.168.60.1 -i <Interface number>

The command to assign IP address to MAC-less interfaces while running IPv4 forward is as follows:

lpm_ipfwd_config -P pid -F -a 192.168.60.1 -n <MAC-less interface name>

NOTE

Note: The interface name(MAC-less) or interface number to be used here must be one of the names/numbers that got displayed as the output of "show all enabled interfaces command" in section Command to show all enabled interfaces and their interface numbers on page 1721.

Table 295. Field description (assign IP address to shared or private MAC interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	IP Address	Yes	a.b.c.d
-i	Interface number	Yes	0-11 (Choose this number from "show all enabled interfaces" command output)

Table 296. Field description (assign IP address to MAC-less interfaces)

Parameter	Description	Mandatory	Format/ Value
-a	IP Address	Yes	a.b.c.d
-n	MAC-less Interface name	Yes	eth3 (Choose this name in case of MAC-less from "show all enabled interfaces" command output)

Assign IP address to interfaces

Note: check pid from application print "Message queue to send: /mq_snd_2536"

. Command to assign IP address to private or shared MAC interfaces

lpm_ipfwd_config -P 2536 -F -a 192.168.60.1 -i 5

IPADDR assigned = 0xc0a83c01 to interface num 5

Intf Configuration Changed successfully

. Command to assign IP address to MAC-less interface

lpm_ipfwd_config -P 2536 -F -a 192.168.55.6 -n eth3

IPADDR assigned = 0xc0a88506 to MACLESS intf eth3

Intf Configuration Changed successfully

9.9.13.1.27 Help for assign IP address to interfaces

The command to obtain help for assign IP address to interfaces command is as follows:

lpm_ipfwd_config -F --help

Help for assign IP address to interfaces

[root@p4080 etc]# lpm_ipfwd_config -F --help

Usage: -F [OPTION...]

-a, --a=IPADDR IP Address

-i, --i=IFNUM If Number

-n, --n=IFNAME MACLESS Interface Name

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.13.1.28 Adding a Route Entry

The command to add a route while running IPv4 forward is as follows:

lpm_ipfwd_config -P pid -B -d b.c.d.e -g c.d.e.f -n maskbits -c numentry

Table 297. Field Description (Adding a Route Entry)

Parameter	Description	Mandatory	Format/ Value
-d	Destination IP Address	Yes	a.b.c.d
-g	Gateway IP Address	Yes	a.b.c.d
-n	netmask length to be used by LPM	Yes	upto 32 bits
-c	number of fib entries	Yes	1- valid count

Adding a Route Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# lpm_ipfwd_config -P 2536 -B -d 192.168.24.2 -g 192.168.24.2 -n 24 -c 1024

Route Entry Added successfully

[root@p4080 bin]#

9.9.13.1.29 Help for Route Entry Addition

The command to obtain help for route entry addition is as follows:

lpm_ipfwd_config -B --help

Help for Adding a Route Entry

[root@p4080 bin]# lpm_ipfwd_config -B --help

Usage: -B [OPTION]

-d, --d=DESTIP Destination IP

-g, --g=GWIP Gateway IP

-n, --n=MASKBITS Netmask length

-c, --c=NUMENTRY Number of fib entries

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.13.1.30 Deleting a Route Entry

NOT IMPLEMENTED

9.9.13.1.31 Help for Deleting a Route Entry

Delete route command is not implemented

9.9.13.1.32 Adding an ARP Entry

The command to add an ARP entry while running IPv4 forward is as follows:

lpm_ipfwd_config -P pid -G -s a.b.c.d -m aa:bb:cc:dd:ee [-r true]

Table 298. Field Description (Adding an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d
-m	Mac Address	Yes	aa:bb:cc:dd:ee
-r	Replace existing entry	No	true/ false {Default: false}

Adding an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# lpm_ipfwd_config -P 2536 -G -s 192.168.24.2 -m 02:00:c0:a8:33:fd -r true

ARP Entry Added successfully

9.9.13.1.33 Help for ARP Entry Addition

The command to obtain help for ARP entry addition is as follows:

lpm-ipfwd_config -G --help

Help for Adding an ARP Entry

[root@p4080 etc]# lpm_ipfwd_config -G --help

Usage: -G [OPTION...]

-m, --m=MACADDR MAC Address

-r, --r=Replace Replace Exiting Entry - true/ false {Default:

false}

-s, --s=IPADDR IP Address

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

9.9.13.1.34 Deleting an ARP Entry

The command to delete an ARP while running the IPv4 forward is as follows:

lpm_ipfwd_config -P pid -H -s a.b.c.d

Table 299. Field Description (Deleting an ARP Entry)

Parameter	Description	Mandatory	Format/ Value
-s	Gateway IP Address	Yes	a.b.c.d

Deleting an ARP Entry

Note: check pid from application print "Message queue to send: /mq_snd_2536"

[root@p4080 bin]# lpm_ipfwd_config -P 2536 -H -s 192.168.24.2

Arp Entry Deleted successfully

[root@p4080 bin]#

9.9.13.1.35 Help for Deleting an ARP Entry

The command to obtain help for ARP entry deletion is as follows:

lpm_ipfwd_config -H --help

Help for Deleting an ARP Entry

[root@p4080 etc]# lpm_ipfwd_config -H --help

Usage: -H [OPTION...]

-s, --s=IPADDR IP Address

-?, --help Give this help list

--usage Give a short usage message

-V, --version Print program version

Mandatory or optional arguments to long options are also mandatory or optional for any corresponding short options.

2. QMan/BMan API Guide

9.9.14 NXP USDPAA FRA Configuration User Manual

9.9.14.1 Introduction

9.9.14.1.1 Purpose

This document is intended to introduce how to configure the NXP RMan Application (FRA).

9.9.14.2 FRA Configuration

The NXP RMan Application is a multi-thread USDPAA application based on RMan driver. The RapidIO message manager (RMan) supports a message passing programming model for inter-processor and inter-device communication. The FRA configuration file is to configure the behavior of passing messages. This file follows standard XML rules and is composed of several elements. Each element begins with a start tag and can contain attributes and/or child elements. If the element contains child elements, it must have a corresponding end-tag after them. An element without child elements must end with a slash (/).

Note that element and attribute names are always case sensitive.

The FRA configuration file always begins with the <fra_cfg> root element. As such, the end-tag of the fra_cfg element must appear at the end of the file.

Attributes: No required attributes

For example:

```
<fra_cfg>
    <rman_cfg>
         <defcfg file="/usr/etc/rman_config.xml"/>
    </rman_cfg>

    <network_cfg>
        <defcfg file="/usr/etc/network_config.xml"/>
    </network_cfg>

    <trans_cfg>
        <defcfg file="/usr/etc/transactions_config.xml"/>
    </trans_cfg>

    <dists_cfg>
        <defcfg file="/usr/etc/distributions_config.xml"/>
    </dists_cfg>

    <policies_cfg>
        <defcfg file="/usr/etc/policies_config.xml"/>
        <policy name="processing2" enable="yes"/>
```

```
    </policies_cfg>
</fra_cfg>
```

This configuration file contains the following top elements:

- rman_cfg
- network_cfg
- trans_cfg
- dists_cfg
- policies_cfg

Each top element mentioned above may includes 'defcfg' element to include the default configuration file. Following 'defcfg', the different settings can be included to change the default value.

For example, in order to use sRIO port 2 to send messages, sRIO port number should be changed from default value 0 to 1. The configuration is as follows:

```
<dists_cfg>
    <defcfg file="/usr/etc/distributions_config.xml"/>

    <distribution name="fman_to_rman_dtsec0">
        <rio_port number="1"/>
    </distribution>
</dists_cfg>
```

9.9.14.2.1 Rman_cfg Element

This element is responsible for RMan general settings. It contains some child elements: fqbits, md_create, osid, bpid and sgfqid.

For example:

```
<rman_cfg>
        <fqbits type="Data-streaming" value="2"/>
        <fqbits type="Mailbox" value="2"/>
        <md_create mode="yes"/>

        <osid value="no"/>
        <bpid type="Data-streaming" value="11"/>
        <bpid type="Doorbell" value="10"/>
        <bpid type="Mailbox" value="11"/>
        <sgbpid value="12"/>
</rman_cfg>
```

OSID Element

Outbound Segmentation Interleaving Disable. Segmentation interleaving allows the message manager to interleave segments from two or more transactions with the same destination device ID (regardless of type). This may increase performance for transmission but may also consume additional reassembly resources at the destination.

A non-NXP target device may not complete Type 9 reassembly correctly when segmentation interleaving is performed on two PDUs with the same flow but different CoS. Workaround: disable segmentation interleaving by setting <osid value="yes">

Attributes:

value - (required) string, the valid value is "yes" or "no". "yes" means disable interleaving, "no" means enable interleaving.

EFQ Element

EFQ element is used to define error frame queue status. If enable EFQ, all the error information will be enqueued to a error frame queue.

Attributes:

value - (required) string, the valid value is "yes" or "no".

9.9.14.2.1.1 Fqbits Element

RMan supports algorithmic frame queue generation mode. This mode allows for steering transaction to a frame queue ID based on the RapidIO header attributes when wildcards are used with a classification rule. For The detailed information please refer to relevant manual. The current version of FRA application only support using ltr attribute of mailbox or stream ID attribute of data streaming transaction to dynamically generate the frame queue ID. The fqbits element indicates the number of rule mask bits to include in the frame queue ID.

Attributes:

value - (required) string; Defines the number of rule mask bits to include in the frame queue ID. For mailbox type 10 the valid value is 1 or 2. For data streaming is 1, 2, 3 or 4.

type - (required) string; Defines the transaction type, the valid value are 9 or 11.

9.9.14.2.1.2 Md_create Element

Md_create element is used to enable or disable RMan to write the inbound message descriptor. A performance improvement may be achieved by not writing the message descriptor.

Attributes:

mode - (required) string, the valid value is "yes" or "no". "yes" means do write the message descriptor, "no" means do not write the message descriptor.

9.9.14.2.1.3 BPID Element

BPID element is used to specify the buffer pool ID which RMan uses to store received transaction messages.

Attributes:

value - (required) string; Defines the buffer pool ID.

type - (required) string; Defines the transaction type, the valid value are 9-11.

9.9.14.2.1.4 SGBPID Element

SGBPID element is used to define the buffer pool ID which RMan uses to store the scatter/gather frame header.

Attributes:

value - (required) string; Defines the buffer pool ID.

9.9.14.2.2 Network_cfg Element

This element describes FMan ports that FRA will use. It has one child element: port

9.9.14.2.2.1 Port Element

Port Element is used to represent a FMan port.

Attributes:

name - (required) string: Defines the port name

type - (required) string: must be "MAC"

fm - (required) string: Define the FMan engine name, valid value is "0" or "1"

number - (required) string: Define the MAC index

9.9.14.2.3 Transaction Element

This element describes the RapidIO type 9/10/11 transaction information. Each transaction must be defined separately within its own elements. Each transaction is used for outbound and inbound operations.

Attributes:

name - (required) string; Defines a unique name for each transaction.

type - (required) string; Defines the transaction type, the valid value are Doorbell, Mailbox,Data-streaming.

9.9.14.2.3.1 Doorbell (type10) Transaction

A type10 outbound doorbell operation enables a producer to send a small amount of software-defined information across the interconnect fabric to a consumer's doorbell unit. It is the responsibility of the processor receiving the doorbell to determine the action to undertake. A small data payload of 2 bytes is used for doorbells.

This transaction has 1 child element: flowlvl

9.9.14.2.3.1.1 Flowlvl Element (type 10)

This element defines transaction flow level.

Attributes:

value - (required) string; Defines transaction flow level. 0: lowest flow level, 5: highest flow level

mask - (required) string; Defines flow conditional match.

0 Exact match on flow level

1 Match on less than or equal to flow level value

2 Match on greater than or equal to flow level value

3 Reserved

For example:

```
<transaction name="dbell-peer" type="Doorbell">
        <flowlvl value="5" mask="1"/>
</transaction>
```

9.9.14.2.3.2 Mailbox (type11) Transaction

A Type11 outbound RMan enables a producer to send a message across the interconnect fabric to a consumer's message hardware, called a mailbox. The receiving mailbox hardware places a message descriptor onto an inbound frame queue. A message may consist of one to sixteen segments. Messages can be queued for transmission in the producer's memory and the message hardware then processes them sequentially. Messages can also be queued in the consumer's memory while software processes them sequentially. The depths of the queues at the producer and consumer are configurable by software.

This transaction has 3 child elements: flowlvl, mbox, ltr, msglen.

9.9.14.2.3.2.1 Flowlvl Element (type 11)

This element defines transaction flow level.

Attributes:

value - (required) string; Defines transaction flow level. 0: lowest flow level, 5: highest flow level

mask - (required) string; Defines flow conditional match.

0 Exact match on flow level

1 Match on less than or equal to flow level value

2 Match on greater than or equal to flow level value

3 Reserved

9.9.14.2.3.2.2 Mbox Element (type 11)

This element defines mailbox field from packet header of mailbox transaction.

Attributes:

value - (required) string; Defines mailbox field, the valid value are 0,1,2,3

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

9.9.14.2.3.2.3 Ltr Element (type 11)

This element defines letter field from packet header of mailbox transaction. This field allows a sending processing element to concurrently send up to four messages to the same mailbox on the same processing element.

Attributes:

value - (required) string; Defines letter field. The valid value is 0-3.

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

9.9.14.2.3.2.4 Msglen Element (type 11)

This element defines message length field from packet header of mailbox transaction.

Attributes:

value - (required) string; Defines message length, and represents total number of packets comprising this message operation. The valid value is 0-15. A value of 0 indicates a single-packet message. A value of 15 (0xF) indicates a 16-packet message, etc.

mask - (required) string; Defines message length conditional match. Each bit set indicates don't care value for the inbound port-write header attribute.

0 Exact match on message length

1 Match on less than or equal to message length

2 Match on greater than or equal to message length

3 Reserved

For example:

```
<transaction name="mbox-10gec" type="Mailbox">
        <flowlvl value="0" mask="2"/>
        <mbox value="1" mask="0"/>
        <ltr value="0" mask="0" />
        <msglen value="6" mask="1"/>
</transaction>
```

9.9.14.2.3.3 Data streaming (type9) Transaction

A Type9 outbound segmentation operation enables a producer to send a packetized data unit (PDU) across the interconnect fabric to a consumer's reassembly hardware. The receiving reassembly hardware places the PDU descriptor onto an inbound frame queue. A PDU may consist of multiple segments supporting a total size of 64 Kbytes.

This transaction has 3 child elements: flowlvl, cos, streamid

9.9.14.2.3.3.1 Flowlvl Element (type 9)

This element defines transaction flow level.

Attributes:

value - (required) string; Defines transaction flow level. 0: lowest flow level, 5: highest flow level

mask - (required) string; Defines flow conditional match.

0 Exact match on flow level

1 Match on less than or equal to flow level value

2 Match on greater than or equal to flow level value

3 Reserved

9.9.14.2.3.3.2 CoS Element (type 9):

This element defines class-of-service field from the start or single packet header of data streaming transaction.

Attributes:

value - (required) string; Defines cos field, the valid value are 0-0xff

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

9.9.14.2.3.3.3 Streamid Element (type 9):

This element defines traffic stream identifier field from packet header of data streaming transaction. This is an end to end (producer to consumer) traffic stream identifier.

Attributes:

value - (required) string; Defines streamid field, the valid values is 0-0xffff

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

For example:

```
<transaction name="dstr-10gec" type="Data-streaming">
        <flowlvl value="0" mask="2"/>
        <cos value="15" mask="0"/>
        <streamid value="0" mask="0x1f"/>
</transaction>
```

9.9.14.2.4 Distribution Element

This element describes the approach of RMan/FMan processing message, it includes six ypes of distribution: RMAN_RX, RMAN_TX, FMAN_RX, FMAN_TX, RMAN_TO_FMAN, FMAN_TO_RMAN.

Attributes:

name - (required) string; Defines a unique name for each distribution.

type - (required) string; Defines the distribution type.

9.9.14.2.4.1 RMAN_RX Distribution

The RMAN_RX distribution describes RMan how to process the received message from RapidIO end point. Each enabled RMAN_RX distribution will be configured to a IBCU (Inbound Block Classification Unit). RMan has a total of 32 IBCU. If a

message matches an IBCU setting, it will be put to the corresponding queue. This type element contains four child elements: rio_port, sid, queue, transactionref

For example:

```
<distribution name="rman_to_dtsec0" type="RMAN_RX">
        <rio_port number="0" mask="1"/>
        <sid value="0" mask="0xff"/>
        <queue base="0x2500" mode="algorithmic" wq="0"/>
        <transactionref name="dstr-dtsec0"/>
</distribution>
```

9.9.14.2.4.1.1 RX Rio_port Element

This element defines the inbound messages come from which RapidIO port.

Attributes:

number - (required) string; Defines port number. The valid value is 1 or 2.

mask - (required) string; Defines bit mask for this field. If this value is 1, RMAN_RX/RMAN_TO_FMAN distribution will accepted messages from port 1 and port 2. This setting may be used for port 1 and port 2 loop-back mode.

9.9.14.2.4.1.2 RX Sid Element

This element defines the accepted messages sent by which device.

Attributes:

value - (required) string; Defines source device id,

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

9.9.14.2.4.1.3 RX Queue Element

This element defines the frame queue which the accepted messages will be put to. A frame queue is enqueued onto a Work Queue, and a work queue is grouped into a Channel. RMan supports direct mode and algorithmic mode to generate frame queue ID.

Attributes:

base - (required) string; Defines the basic queue id.

mode - (required) string; Defines the frame queue mode the valid value is "direct" or "algorithmic".

wq - (required) string; Defines the work queue

Transactionref element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.1.4 Transactionref Element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.2 RMAN_TX Distribution

This distribution describes RMan how to transmit a message. It contains four child elements: rio_port, did, queue, transactionref.

For example:

```
<distribution name="rman_to_peer_dtsec0" type="RMAN_TX">
        <rio_port number="0"/>
        <did value="1"/>
        <queue base="0x6000" count="4" wq="0"/>
        <transactionref name="dstr-dtsec0"/>
</distribution>
```

9.9.14.2.4.2.1 TX Rio_port Element:

This element defines RapidIO port number which will be used to send the messages.

Attributes:

number - (required) string; Defines RapidIO port number.

9.9.14.2.4.2.2 TX Did Element

This element defines device id that the message will send to.

Attributes:

value - (required) string; Defines destination device id.

9.9.14.2.4.2.3 TX Queue Element

This element defines the frame queue which the messages will be put to. The frame queue is enqueued onto a Work Queue. FRA supports up to 4 transmission frame queue.

Attributes:

base - (required) string; Defines the basic queue id.

count - (required) string; Defines the number of frame queue.

wq - (required) string; Defines the work queue

9.9.14.2.4.2.4 Transactionref Element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.3 FMAN_RX Distribution

FMAN_RX distribution describes FMan how to process the inbound message. This distribution contains two child elements: fman_port and queue.

For example:

```
<distribution name="dtsec0_to_rman" type="FMAN_RX">
        <fman_port name="dtsec0"/>
        <queue wq="4"/>
</distribution>
```

9.9.14.2.4.3.1 Fman_port Element

This element define the accepted messages come from which Fman port.

Attributes:

name - (required) string: Defines FMan port name. This is a reference to FMan port which defined in network_cfg element.

9.9.14.2.4.3.2 FMAN_RX Queue Element

This element defines the frame queue which the inbound messages will be put to. The FQID is defined in FMan policy file.

Attributes:
wq - (required) string; Defines the work queue.

9.9.14.2.4.4 FMAN_TX Distribution

FMAN_TX distribution describes FMan how to transmit the message.
This distribution contains two child elements: fman_port and queue.

For example:

```
<distribution name="dtsec0_to_network" type="FMAN_TX">
        <fman_port name="dtsec0"/>
        <queue count="2" wq="4"/>
</distribution>
```

9.9.14.2.4.4.1 Fman_port Element

This element define the accepted messages come from which Fman port.

Attributes:

name - (required) string: Defines FMan port name. This is a reference to FMan port which defined in network_cfg element.

9.9.14.2.4.4.2 [FMAN_TX Queue Element]

This element defines the frame queue which the messages will be put to. The frame queue is enqueued to a Work Queue. FRA supports up to 4 transmission frame queue.

Attributes:

count - (required) string; Defines the number of frame queue.

wq - (required) string; Defines the work queue

9.9.14.2.4.5 RMAN_TO_FMAN Distribution

The RMAN_TO_FMAN distribution describes RMan how to transfer the inbound message from RapidIO port to FMan port. It contains five child elements: rio_port, sid, queue, transactionref and fman_port

For example:

```
<distribution name="rman_to_fman0_dtsec0" type="RMAN_TO_FMAN">
       <rio_port number="0" mask="1"/>
       <sid value="0" mask="0xff"/>
       <queue base="0x1000" mode="algorithmic" wq="0"/>
       <transactionref name="mbox-dtsec0"/>
```

```
        <fman_port name="dtsec0"/>
</distribution>
```

9.9.14.2.4.5.1 RX Rio_port Element

This element defines the inbound messages come from which RapidIO port.

Attributes:

number - (required) string; Defines port number. The valid value is 1 or 2.

mask - (required) string; Defines bit mask for this field. If this value is 1, RMAN_RX/RMAN_TO_FMAN distribution will accepted messages from port 1 and port 2. This setting may be used for port 1 and port 2 loop-back mode.

9.9.14.2.4.5.2 RX Sid Element

This element defines the accepted messages sent by which device.

Attributes:

value - (required) string; Defines source device id,

mask - (required) string; Defines bit mask for this field. Each bit set indicates don't care value for the inbound port-write header attribute.

9.9.14.2.4.5.3 RX Queue Element

This element defines the frame queue which the accepted messages will be put to. A frame queue is enqueued onto a Work Queue, and a work queue is grouped into a Channel. RMan supports direct mode and algorithmic mode to generate frame queue ID.

Attributes:

base - (required) string; Defines the basic queue id.

mode - (required) string; Defines the frame queue mode the valid value is "direct" or "algorithmic".

wq - (required) string; Defines the work queue

Transactionref element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.5.4 Transactionref Element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.5.5 Fman_port Element

This element define the accepted messages come from which Fman port.

Attributes:

name - (required) string: Defines FMan port name. This is a reference to FMan port which defined in network_cfg element.

9.9.14.2.4.6 FMAN_TO_RMAN Distribution

The FMAN_TO_RMAN distribution describes FMan how to transfer the inbound message from network port to RMan and RpiadIO port. It contains five child elements: rio_port, did, queue, transactionref and fman_port

For example:

```
<distribution name="fman_to_rman_dtsec0" type="FMAN_TO_RMAN">
        <fman_port name="dtsec0"/>
        <queue wq="0"/>
        <rio_port number="0"/>
        <did value="1"/>
        <transactionref name="mbox-dtsec0"/>
</distribution>
```

9.9.14.2.4.6.1 TX Rio_port Element:

This element defines RapidIO port number which will be used to send the messages.

Attributes:

number - (required) string; Defines RapidIO port number.

9.9.14.2.4.6.2 TX Did Element

This element defines device id that the message will send to.

Attributes:

value - (required) string; Defines destination device id.

9.9.14.2.4.6.3 TX Queue Element

This element defines the frame queue which the messages will be put to. The frame queue is enqueued onto a Work Queue. FRA supports up to 4 transmission frame queue.

Attributes:

base - (required) string; Defines the basic queue id.

count - (required) string; Defines the number of frame queue.

wq - (required) string; Defines the work queue

9.9.14.2.4.6.4 Transactionref Element

This element refers to a transaction element by its name.

Attributes:

name - (required) string; Defines name of the transaction referred

9.9.14.2.4.6.5 Fman_port Element

This element define the accepted messages come from which Fman port.

Attributes:

name - (required) string: Defines FMan port name. This is a reference to FMan port which defined in network_cfg element.

9.9.14.2.5 Policy Element

This element describes the FRA's behavior. It was composed by one or more distribution order elements.

Attributes:

name - (required) string; Defines a unique name for each policy configuration.

enable - (required) string; Defines the policy status. The valide values are "yes" or "no"

9.9.14.2.5.1 Distribution Order Element

The dist_order element is a container for a list of distribution references. The distribution reference list contained within dist_order element is looked up sequentially and the first conforming record is the record to follow to. Thus, the order of distribution references is important.

9.9.14.2.5.1.1 Distributionref Element

The distributionref element refers to a distribution element by its name.

Attributes:

name - (required) string; Defines name of a distribution referred.

For example:

```
<policy name="processing1" enable="no">
        <!-- 10gec packets processing -->
        <dist_order>
                <distributionref name="10gec_to_rman"/>
                <distributionref name="rman_to_peer_10gec"/>
        </dist_order>
        <dist_order>
                <distributionref name="rman_to_10gec"/>
                <distributionref name="10gec_to_network"/>
        </dist_order>
</policy>
```

9.9.14.3 Revision History

Table 300. Revision History

Version	Updates
1.1	- Change distribution rx, tx, fwd to RMAN_RX, RMAN_TX, FMAN_RX, FMAN_TX respectively - Add network element to describe the FMan ports - Add FMAN_TO_RMAN and RMAN_TO_FMAN distribution to describe the messages transmission between FMan and RMan without core involvement.
1.0	Creation of FRA Configuration UM for SDK 1.1 release - RMan configuration introduction - RapidIO transaction configuration introduction - FRA distribution configuration introduction - FRA policy configuration introduction

9.9.15 NXP USDPAA FRA User Manual

9.9.15.1 Overview

This User Manual describes the NXP RMan Application (FRA) and explains how to install and configure and run FRA.

This Manual provides the following:

- A summary of the FRA application.
- Installing FRA based on SDK.
- Running and testing FRA steps

9.9.15.2 Introduction

9.9.15.2.1 Purpose

FRA NXP RMan Application is a Linux user space software to transfer packets from SRIO port to FMan port. This document describes the FRA installation, configuration, running and test.

9.9.15.2.2 Definitions and Acronyms

- FMan - Frame Manager
- BMan - Buffer Manager
- QMan - Queue Manager
- RMan - RapidIO Message Manager
- FRA - NXP RMan Application
- USDPAA - User Space Data Path Acceleration Architecture
- DPAA - Data path acceleration architecture

9.9.15.3 Overview of FRA

The USDPAA FRA application is a multi-thread USDPAA application that runs simultaneously on one or more boards which are connected with RapidIO cable. FRA application forwards IPv4 packets from one Ethernet interface to another boards using RapidIO transaction.

Overview of USDPAA

The NXP Data Path Acceleration Architecture comprises a set of hardware components which are integrated via a hardware queue manager and use a common hardware buffer manager. Software accesses the DPAA via hardware components called “software portals”. These directly provide queue and buffer manager operations such as enqueues, dequeues, buffer allocations, and buffer releases and indirectly provide access to all of the other DPAA hardware components via the queue manager. USDPAA is a software framework that permits Linux user space applications to directly access the DPAA queue and buffer manager software portals in a high performance manner. The applications can then use the portals to access other DPAA hardware components such as RMan and FMan

FRA Architecture

FRA is based on USDPAA. But comparing the normal USDPAA application, in order to reuse the frame queue and buffer pool codes between processing network packets and RapidIO packets, FRA’s architecture is adjusted.

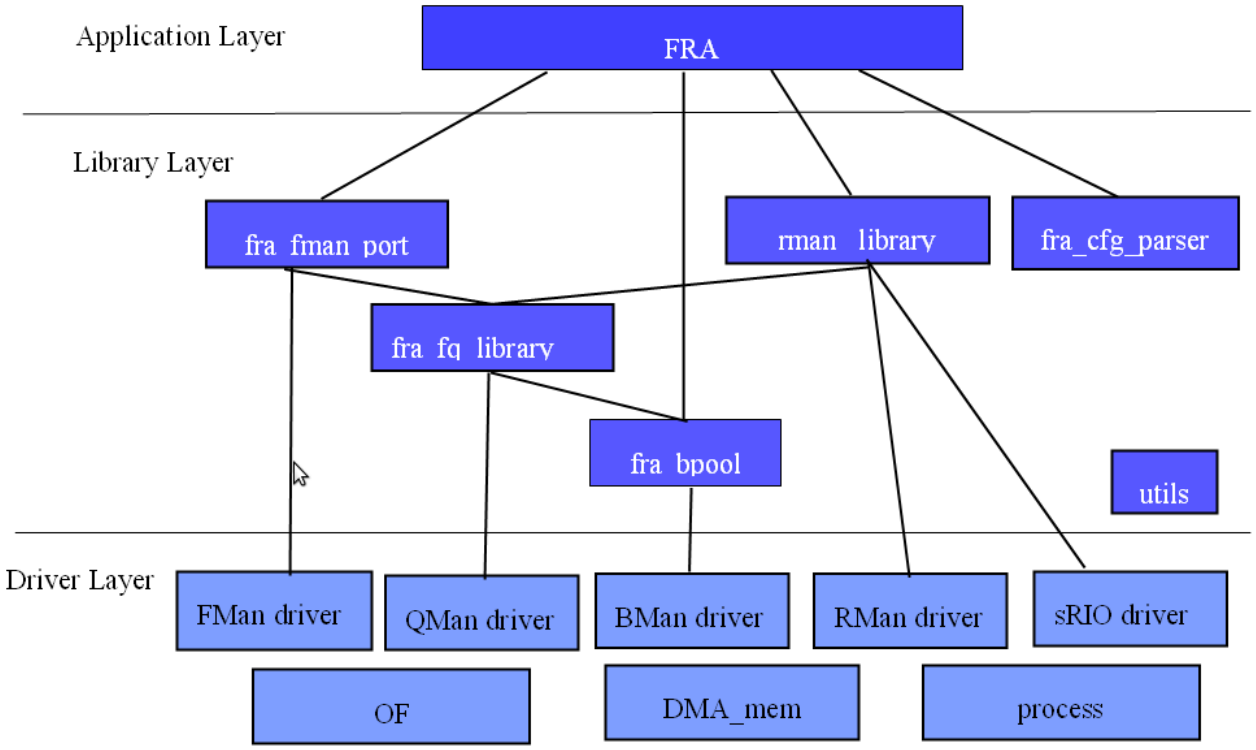

Figure 275. FRA Architeture

As Fig 1 shown, FRA is split to three layers, driver layer, library layer and application layer.

Driver Layer

Driver layer contains FMan, QMan, BMan, RMan, sRIO, DMA_mem, of, and process divers. All the driver code files are located in “usdpaa/drvier” folder, which are used by all the USDPAA applications. For FMan, QMan, BMan, DMA_mem, of, process driver information please refer to other USDPAA manuals.

sRIO driver

The serial RapidIO interface provides a RapidIO port to communicate with other RpaidIO devices. sRIO driver manages RapidIO ports hardware and provides some interfaces to configure port’s attributes and RapidIO protocol configuration such as “accept all”, “target id”, “traffic mode”. It also provides a few interface to handle interrupt events.

RMan driver

RapidIO message manager supports the message passing programming model for inter-processor and inter-device communication. RMan has a total of 32 inbound traffic classification units. A block is a group of eight classification units. The units are managed through a set of runtime registers. There are 4 outbound segmentation units. RMan driver is used to manage RMan global registers and inbound blocks. Users can call rman_dev_config() to configure global registers. This function supports setting inbound message descriptor write mode and the frame queue assembly rule of the doorbell mailbox and data-streaming transaction. RMan driver provides enable/disable/clear/status interfaces to handle interrupt and provides a few functions to request/release, enable/disable configure classification unit.

Library Layer

Library layer contains utils library, FMan port library, frame queue library, buffer pool library, RMan library, FRA configure parser library. All the libraries code files are located in “usdpaa/app/fra/lib” folder.

Utils Library

Utiles library is at the bottom of the layer. It provides the common interface for all the other libraries. At present, utils maily provides fra_dbg() function to print the debug information and cli_cmd() function to define a command.

Buffer Pool Library

Buffer pool library is intended to manage buffer pools. FRA supports up to 64 buffer pools. Each pool has buffer pool id, buffer number and buffer size three attributes which are grouped to a structure, as follows:

```
struct bpool_config {
       int bpid;
       uint32_t num;
       uint32_t sz;
};
```

Users can pass the array of the structure bpool_config to function bpools_init() to initialize a series of buffer pools. Buffer pool library will initialize the buffer pools and allocate DMA memory and release them to the pools. Buffer pool interface also provides acquire/free buffer functions to allocate and release buffers.

Frame queue Library

Frame queues that used by FMan and RMan can be separated into three types: nonpcd, pcd and tx.

Nonpcd frame queues are used to receive the error or complete status frame which are generally enqueued by FMan or RMan. Those frame queues normally has a higher priority and uses dynamically frame queue id, and only support QM_FQCTRL_CTXASTASHING option.

Pcd frame queues are used to store inbound data frame, such as network packets frame or RapidIO transaction message frames. Those frame queues support more control option such as QM_FQCTRL_AVOIDBLOCK, QM_FQCTRL_PREFERINCACHE and QM_FQCTRL_CTXASTASHING.

Tx frame queues are used to send outbound data frame which Fman or Rman dequeus and send out. These frame queues need to set contex A and B accroding hardware specifition.

This libary supports send/free frame via calling fra_send_frame() and fra_drop_frame() respectively.

FMan Port Library

Each FMan port is seperated into rx and tx functional modules. Rx module includes pcd rx sockets and nonpcd rx sockets. Pcd rx sockets is used to receive the Ipv4/Ipv6 real data frames. Nonpcd rx sockets is used to receive the frame that describe error status. The tx module is similar to rx module.

RMan Library

Rman library performs the iniliazation of the RMan and sRIO ports. There is a series of A interfaces provided to recieve and transmit messages.

The main interfaces as follows:
1. RMan rx API
RMan rx socket contains a set of frame queues to receive the RapidIO messages. Each RMan rx socket corresponds to a classification unit.
1.1 rman_rx_init
This function requests a RMan hardware resource-classification unit and then creates the rx frame queues. Returns the pointer of rman_rx on success or NULL on failure.
1.2 rman_rx_listen
Configure classification unit to receive the specific RapidIO messages which come from specified sid did and port.
1.3 rman_rx_enable
Enable rman_rx to receive messages.
1.4 rman_rx_disable

Stop rman_rx receiving messages, but don't release ibcu resource.
1.5 rman_rx_finish
Stop classification unit receiving, release rx frame queues ibcu resource and rman_rx socket.
1.6 rman_rx_get_fqs_num
RMan supports two mode direct and algorithmic to generate frame queue ID, if direct mode returns 1, if algorithmic mode, calculates and returns the number of frame queues according to algorithmic rule and transaction configuration.
1.7 rman_rx_get_ibcu
Return the classification unit index which is assigned to the specific RMan rx socket
1.8 rman_rx_get_opt
Structure hash_opt is used to describe which frame queue the received frame will be enqueued to Each RMan rx may include one or some rx frame queues, each rx frame queue has a hash opt attribute.
2. RMan tx API
RMan tx socket contains a set of frame queues to send the RapidIO messages using the same transaction.
2.1 rman_tx_init
Create tx frame queues and tx status frame queue
2.2 rman_tx_status_listen
Set rman_tx to receive the completed or/and error status frame
2.3 rman_tx_connect
Connect rman_tx socket to the destination device
2.4 rman_tx_finish
Release RMan tx and tx status frame queues.
2.5 opt_bindto_rman_tx
Bind the opt to the specific rman tx

FRA Configuration Parser Library

Fra configuration parser interface is to parse the fra configuration file which contains values of the RapidIO transaction header fields and distribution settings and policy setting.

Application Layer

FRA application is similar with normal USDPAA application. It also supports add/rm/list commands to manage thread, supports q or quit to exit. FRA adds status command to print the fra information including Rman configuration, RapidIO ports information and distributions information.
Fra application supports a few options defined by macro in fra_cfg.h file.
ENABLE_FRA_DEBUG - to print debug information
FRA_CORE_COPY_MD – to use processor to copy the RMan descriptor
FRA_MBOX_MULTICAST – to support multi-cast mode
FRA_VIRTUAL_MULTI_DID – to enable virtual multi-did.
The frame queue options are also defined in this files. For the detailed information please refer to USDPAA user manual.
This file also contains buffer pool settings.
bp 10 is used to store doorbell messages
bp 11 is used to store data-streaming/mailbox messages
bp 12 is used to store s/g tables.

```
#define DMA_MEM_BP4_BPID10
#define DMA_MEM_BP4_SIZE80
#define DMA_MEM_BP4_NUM0x100 /* 0x100*80==20480 (20KB) */
#define DMA_MEM_BP5_BPID11
#define DMA_MEM_BP5_SIZE1600
#define DMA_MEM_BP5_NUM0x2000 /* 0x2000*1600==13107200 (12.5M) */
#define DMA_MEM_BP6_BPID12
#define DMA_MEM_BP6_SIZE64
#define DMA_MEM_BP6_NUM0x2000 /* 0x2000*64==524288 (0.5MB) */
```

```
/* DMA memory size */
#define FRA_DMA_MAP_SIZE0x4000000 /* 64MB */
```

FRA Configuration

Fra configuration includes RMan global configuration, transaction settings distribution setting and policy setting. FRA Configuration User Manual detailedly describes each element

RMan Configuration

This element is responsible for RMan general settings. It contains a few child elements: fqbits and md_create and bpid settings.

For example:

```
<rman_cfg>
        <fqbits type="Data-streaming" value="2"/>
        <fqbits type="Mailbox" value="2"/>
        <md_create mode="yes"/>
        <bpid type="Data-streaming" value="11"/>
        <bpid type="Doorbell" value="10"/>
        <bpid type="Mailbox" value="11"/>
        <sgbpid value="12"/>
</rman_cfg>
```

Transaction Configuration

FRA configuration supports doorbell mailbox and data-streaming transaction. Almost all the values of the header fields of each transaction can be defined in this element.

For example:

```
<transaction name="dstr-10gec" type="Data-streaming">
        <flowlvl value="0" mask="2"/>
        <cos value="15" mask="0"/>
        <streamid value="0" mask="0x1f"/>
</transaction>
```

Distribution Configuration

This element describes the approach of processing message of RMan or FMan, it includes six types of distribution: rman_rx, rman_tx, fman_rx, fman_tx, fman_to_rman, rman_to_fman.

Policy Configuration

A distribution describes the one device module FMan or RMan how to process a series of specified packets. A distribution order element containing a sequence of distribution describes the board how to process specified packets. Policy element including one or more distribution order elements describes the one or two boards how to process all the packets. The typical dist order elements and the packets processing flows are as follows:

1. rman_rx and fman_tx distrubution forms a packets processing flow

```
<dist_order>
        <distributionref name=" rman_to_10gec "/>
        <distributionref name="10gec_to_network "/>
</dist_order>
```

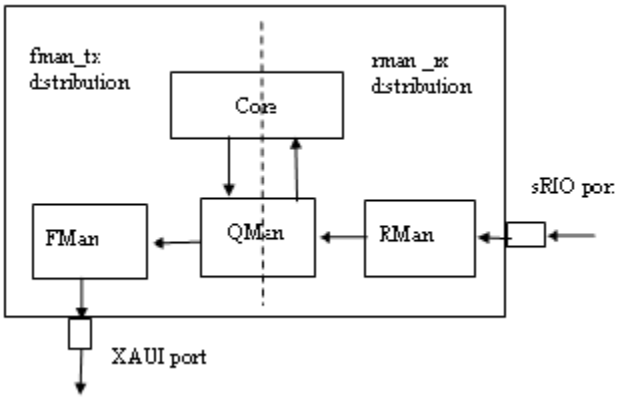

Figure 276. RMan-core-FMan Processing Packet Flow

2. rman_rx and rman_tx distributions forms a loopback processing flow

```
<dist_order>
        <distributionref name="rman_to_10gec"/>
        <distributionref name="rman_to_peer_10gec"/>
</dist_order>
```

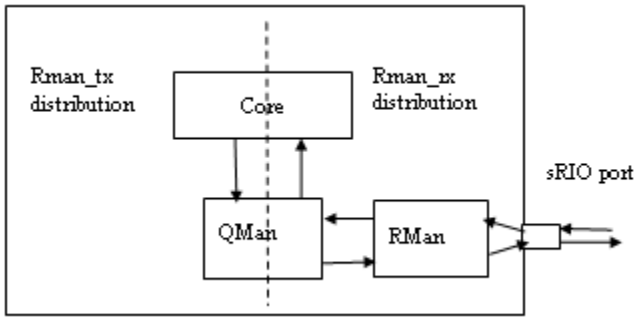

Figure 277. RMan-core-RMan Processing Packet Flow

3. rman_to_fman distrbution forms a packets processing flow without core involvement.

```
<dist_order>
        <distributionref name="rman_to_fman0_10gec"/>
</dist_order>
```

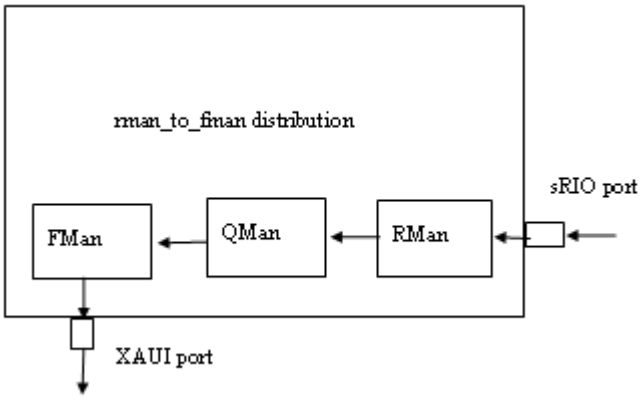

Figure 278. RMan-FMan Processing Packet Flow

4. fman_to_rman distrbution forms a packets processing flow without core involvement.

```
<dist_order>
        <distributionref name="fman_to_rman0_10gec"/>
</dist_order>
```

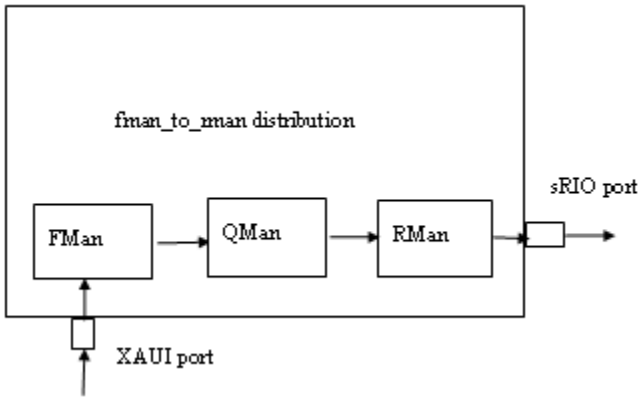

Figure 279. FMan-RMan Processing Packet Flow

Packet Flow

The FRA application can run on two boards at the same time, the two boards host and agent are connected with RapidIO cable. FRA first parses the configuration, and then creates threads to do packet processing. FRA provides two packets processing flows – processing1 and processing2.

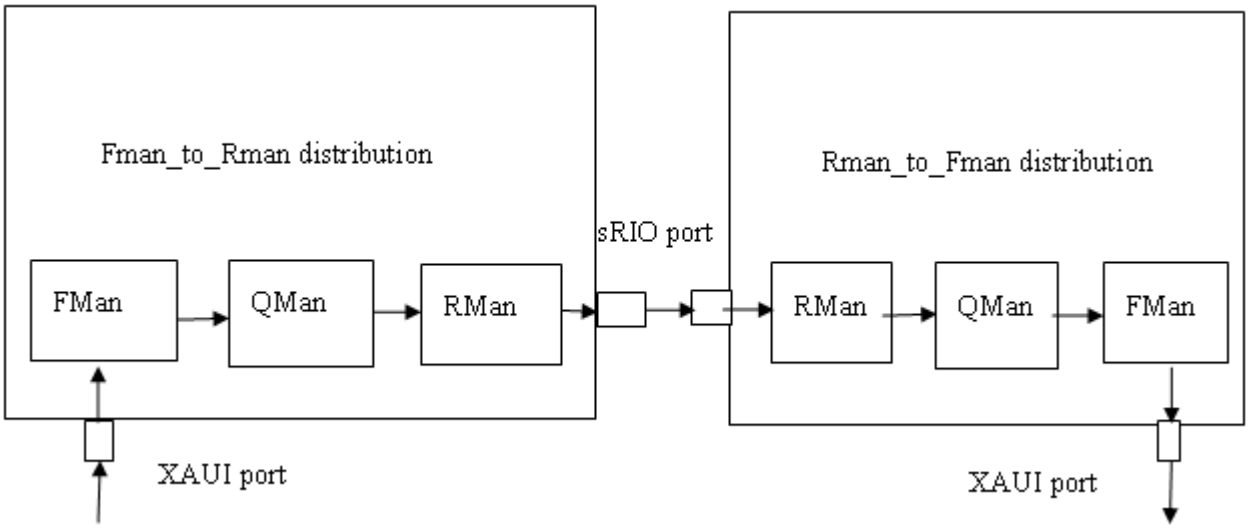

Figure 280. Processing1 Packet Flow

As the Fig6 shown, the processing1 is that RMan directly enqueues the packets to FMan dedicated transmission channel, FMan directly enqueues the packets to RMan dedicated transmission channel, and the core does not need to participate in the processing.

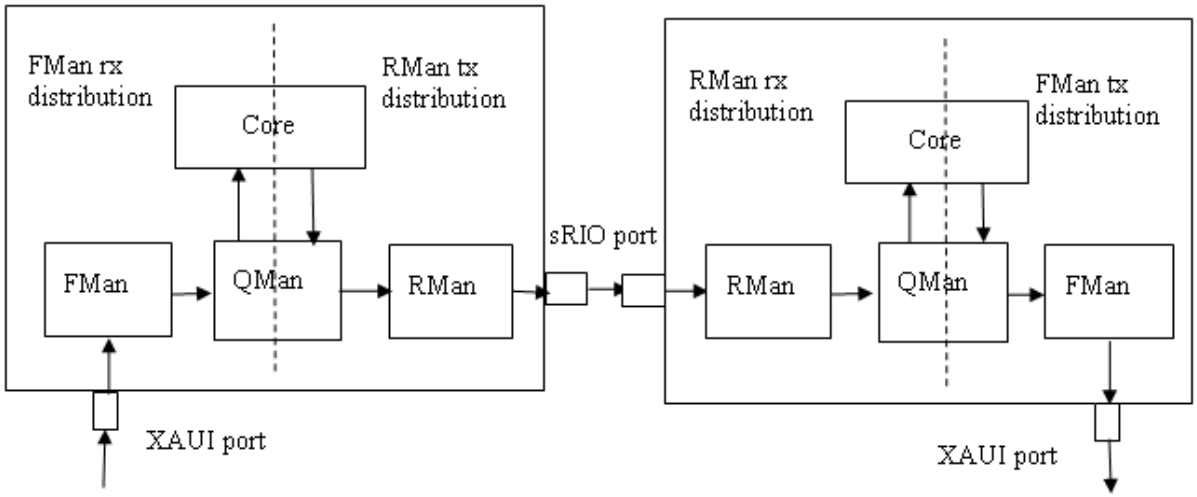

Figure 281. Processing2 Packet Flow

As the Fig7 shown, the processing 2 is that FMan and RMan enqueues the packets to a frame queue of pool channel, and the core will dequeue and process the packets, and then enqueue them to the FMan or RMan dedicated transmission channel to send out.

FRA Configuration Files

FRA configuration files are located in “usdpaa/app/fra/app_config” folder. There are five files.
fra_config_dstr_processing1.xml – do packets processing1 using data-streaming transaction
fra_config_dstr_processing2.xml - do packets processing2 using data-streaming transaction
fra_config_mbox_processing1.xml - do packets processing1 using mailbox transaction
fra_config_mbox_processing2.xml - do packets processing1 using mailbox transaction

fra_config_dstr_port1_port2_loopback.xml – do packets loopback processing using data-streaming transaction

fra_config_port_write_test.xml - do Port-Write testing

Features

The FRA features are as follows:
• Supports all the network interfaces settings.
• Supports sRIO ports and RMan error interrupt handler.
• Supports two sRIO ports loopback mode on one board.
• Supports setting RMan writing the inbound message descriptor mode
• Supports Doorbell transaction with the following features:
—Supports setting flow level using configuration file
• Supports Mailbox transaction with the following features:
— Supports setting flow level, mailbox, letter, message length fields using configuration file
—Supports setting the frame queue mode “direct” or “algorithmic”.
—Supports multi-cast mode
• Supports Data streaming transaction with the following features:
— Supports setting flow level, cos, streamid fields using configuration file
—Supports setting the frame queue mode “direct” or “algorithmic”.
• Supports setting the behavior of each network port.

• Supports Port-Write transaction

9.9.15.4 Running FRA on Two Boards

9.9.15.4.1 Installation

The DPAA SDK has included the FRA code. So just need to install SDK.

9.9.15.4.2 Compilation

Please follow the SDK build guide to build the software. This will perform a default build of all files needed to boot Linux and run the FRA software. These files include dtb, FMan ucode image, u-boot image, kernel image, and rootfs image.

When build kernel, make sure these options are selected.

```
Device Drivers  --->
          <*> Userspace I/O drivers  --->
                    <*>   Freescale Serial RapidIO support
          [*] Staging drivers  --->
                    [*]     Freescale RapidIO Message Manager support
```

9.9.15.4.3 Configuring FRA

The FRA application uses three configuration files. One is to configure how FRA to process packets, the default name is fra_config_dstr_processing1.xml. Currently, default packet flow is processing 1. If you want to test the processing 2, you should run FRA with fra_config_dstr_processing2.xml configuration file. Similarly, if we want to use mailbox transaction to transmit the IP packets, using fra_config_mbox_processing1.xml or fra_config_mbox_processing2.xml. All the FRA configuration files located in /usr/etc folder. More detailed configuration refers to NXP FRA Configuration User's Manual.

The other two files are to configure FMD action, default names are usdpaa_config_p3_p5_serdes_0x33.xml and usdpaa_policy_hash_ipv4.xml. these two file we can refer to frame manager configuration manual.

If we want to specify the configuration file, use the following command on the both boards:

```
# fra -c usdpaa_config_p3_p5_serdes_0x33.xml -p usdpaa_policy_hash_ipv4.xml -f
fra_config_dstr_processing1.xml
```

9.9.15.4.3.1 Selecting Ethernet interfaces for FRA

The following device tree snippet shows a Linux private interface and also an interface used privately by FRA.

```
ethernet@0 {
        compatible = "fsl,p3041-dpa-ethernet-init", "fsl,dpa-ethernet-init";
        fsl,bman-buffer-pools = <&bp7 &bp8 &bp9>;
        fsl,qman-frame-queues-rx = <0x50 1 0x51 1>;
        fsl,qman-frame-queues-tx = <0x70 1 0x71 1>;

};
thernet@1 {
        compatible = "fsl,p3041-dpa-ethernet", "fsl,dpa-ethernet";
        fsl,fman-mac = <&enet0>;

};
```

The first Ethernet is used by FRA. The second is used by the Linux Ethernet driver.

The following list shows the correspondence between Ethernets in the device tree and physical Ethernet MACs on FMan hardware instances on P3041.

Table 301. Correspondence between Ethernets in DTS and physical Ethernet

SW Interface #	FMAN1
0	DTSEC 0
1	DTSEC 1
2	DTSEC 2
3	DTSEC 3
4	DTSEC 4
5	10GEC

9.9.15.4.4 Prepare the Hardware

The FRA application needs two PC or one PC with multiple Ethernet interfaces, two p3041DS or P5020DS boards, when using 0x33 RCW each board should been inserted a RapidIO card to slot6. Check board's switch, sw2 is 0b00100001î(slot7->PEX1, slot6->SRIO, slot4->PEX3, slot2->XAUI), Sw5 is 0b00010100î (Serdes reference clock for bank1 is 100MHz, bank2 is 125MHz bank3 is 125MHz). For P5020DS board sw2 is also 0b00100001. For P2041RDB, using 0x02 RCW, RapidIO card should be inserted to slot1. and the following command should be run

```
cpld lane_mux 6 0;
cpld lane_mux a 0;
cpld lane_mux c 0;
cpld lane_mux d 0;
cpld reset altbank;
```

FRA supports 15G network interfaces. But 0x33 RCW only provides 12G network interfaces: RGMII1 (DTSEC3), RGMII2 (DTSEC4) and XAUI. As the Fig8 shown, we can use DTSEC3 to receive and transmit the IP packets. The host machine should connect to host board RGMII1 port, and agent machine should connect to agent board RGMII 1 port too.

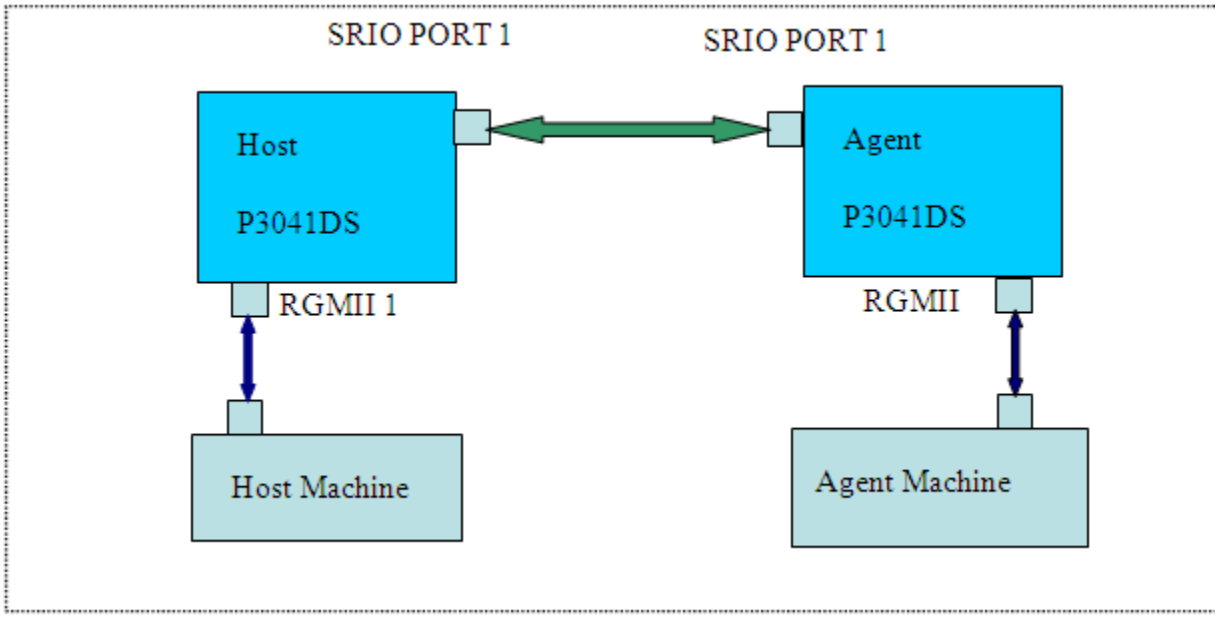

Figure 282. Serdes 0x33 protocol hardware setup

9.9.15.4.5 Managing RCW and U-boot Image

The RCW, FMan microcode, and u-boot binary files must be programmed into the P3041DS NOR-flash We can use Processor Expert (PEx) to create serdes 0x33 rcw file and then convert to rcw image.

```
serdes 0x33 RCW of P3041DS is :
00000000: AA55 AA55 010E 0100 1260 0000 0000 0000
00000010: 241C 0000 0000 0000 CC98 4A00 0300 2000
00000020: FE80 0000 4100 0000 0000 0000 0000 0000

```

Convert rcw xxd format to image

```
$ xxd -r rcw.xxd > rcw-0x33.bin
```

The P3041DS divides the flash into multiple banks. This permits multiple copies of RCW and u-boot files to be kept in flash. It is not required, but NXP suggests leaving a functional u-boot in bank0 (which is used when the board is powered on) and program new rcw and u-boot files into bank 4. This method ensures that a working u-boot (in bank 0) is retained in case of a mistake in programming bank 4. To program bank 4, first do a power-on reset to boot from bank 0. Use the u-boot in bank 0 to program the files into bank 4. Networking parameters need to be set for the u-boot in bank 0 so that it can tftp. U-boot uses environment variables to control network settings. Variables are given values with the ìsetenvî command. The choices for these settings must match your local network. Note in particular serverip. A machine with that IP address is assumed to be running a tftp server containing the files to be transferred via tftp. The major U-boot networking variables are:

```
 => setenv ethact <active Ethernet interface for u-boot use. Should be FM1@DTSEC5 if using the
recommended SerDes protocol number 0xe>
=> setenv ethaddr <MAC address 0>
=> setenv ethNaddr <MAC address N=1 to 5>
...
=> setenv ipaddr <your ip address>
=> setenv netmask <your netmask>
=> setenv gatewayip <your default gateway ip address>
=> setenv serverip <the address of your TFTP server>
=> sav
```

The following instructions show how to reprogram bank 4. Remember to do this only when booted from bank 0.

```
 # Be booted from bank 0!!!!
=> tftp 0x02000000 u-boot.bin
=> protect off 0xebf80000 +$filesize
=> erase 0xebf80000 +$filesize
=> cp.b 0x02000000 0xebf80000 $filesize
=> tftp 0x02000000 rcw_0x33.bin
=> protect off 0xec000000 +$filesize
=> erase 0xec000000 +$filesize
=> cp.b 0x02000000 0xec000000 $filesize
 => tftp 0x02000000 fsl_fman_ucode.bin
=> protect off 0xeb000000 +$filesize
 => erase 0xeb000000 +$filesize
=> cp.b 0x02000000 0xeb000000 $filesize
 # Reset to bank 4:
=>pix altbank
```

U-boot in bank 4 will then run and one can proceed to boot Linux and run the FRA software.

9.9.15.4.6 Booting Linux

Set following environment settings on board's bank4, Setup networking variables for tftp in bank4:

```
=> setenv ethact <active Ethernet interface for u-boot use>
=> setenv ethaddr <MAC address 0>
=> setenv ethNaddr <MAC address N=1 to 5>
...
=> setenv ipaddr <your ip address>
=> setenv netmask <your netmask>
=> setenv gatewayip <your default gateway ip address >
=> setenv serverip <the address of your TFTP server>
=> sav
```

Setup and save other uboot variables to tftp the USDPAA device tree, root file system and Linux image and boot Linux.

```
=>setenv bootargs "root=/dev/ram rw console=ttyS0,115200"
=>setenv fraboot "tftp 1000000 uImage-p3041ds.bin; tftp 2000000 fsl-image-core-p3041ds.ext2.gz.u-
```

```
boot;  tftp c00000 uImage-p3041ds-usdpaa.dtb; bootm 1000000 2000000 c00000"
=>run fraboot
```

Following are some booting information points:

u-boot boot log:

```
Flash: 128 MiB
L2:    128 KB enabled
Corenet Platform Cache: 1024 KB enabled

rio_tran:dstr-dtsec3 type:Data-streaming
fra>
```

• Enable or disable debug information output

Note: this function is effective only when compiling with ENABLE_FRA_DEBUG definition

```
fra> debug [on/off]
```

• If you want to quit FRA , should use the following command, FRA will release the related resource.

```
fra> q
```

9.9.15.4.8 Testing FRA

In order to test FRA, we need to send IP packets to host board's Ethernet interface, since FRA does not support ARP protocol, we should do IP and MAC binding on host PC. Following are the test FRA steps on P3041DS boards.

1. Setup the hardware as Fig9 and run the FRA application on both host and agent as described in previous section.
2. Find the host board's Ethernet interface Mac address

   This case, FRA will use the port 3 to receive the IP packets; on host board console Linux startup log has the MAC information:

   ```
   cpu0: fsl_mac: FSL FMan MAC API based driver ()
   cpu0: fsl_mac: ffe4e6000.ethernet: FMan dTSEC version: 0x08240101
   cpu0: fsl_mac: ffe4e6000.ethernet: FMan MAC address: 00:e0:0c:00:d7:03
   cpu0: fsl_mac: ffe4e8000.ethernet: FMan dTSEC version: 0x08240101
   cpu0: fsl_mac: ffe4e8000.ethernet: FMan MAC address: 00:e0:0c:00:d7:04
   cpu0/0: Applying 10G tx-ecc error workaround (10GMAC-A004) ...
   cpu0/0: done.
   cpu0: fsl_mac: ffe4f0000.ethernet: FMan XGEC version: 0x00010330
   cpu0: fsl_mac: ffe4f0000.ethernet: FMan MAC address: 00:e0:0c:00:d1:05
   ```

   So we find DTSEC3's Mac address is 00:e0:0c:00:d7:03.
3. If we has configure the Ethernet card IP address 192.168.2.1, so on host machine create a ARP entry in subnet range of the host pc network port connected to host board's DTSEC3, by using the following command:

   ```
   $ sudo arp -s 192.168.2.2 00:e0:0c:00:d7:03
   ```

4. On host machine ping host board's DTSEC3

```
$ ping 192.168.2.2
```

5. Run Wireshark on agent machine and to capture the network port connected to the agent board's DTSEC3 network port.

```
$ sudo wireshark
```

As the figure below shows, we should see the ping packets sent from host machine.

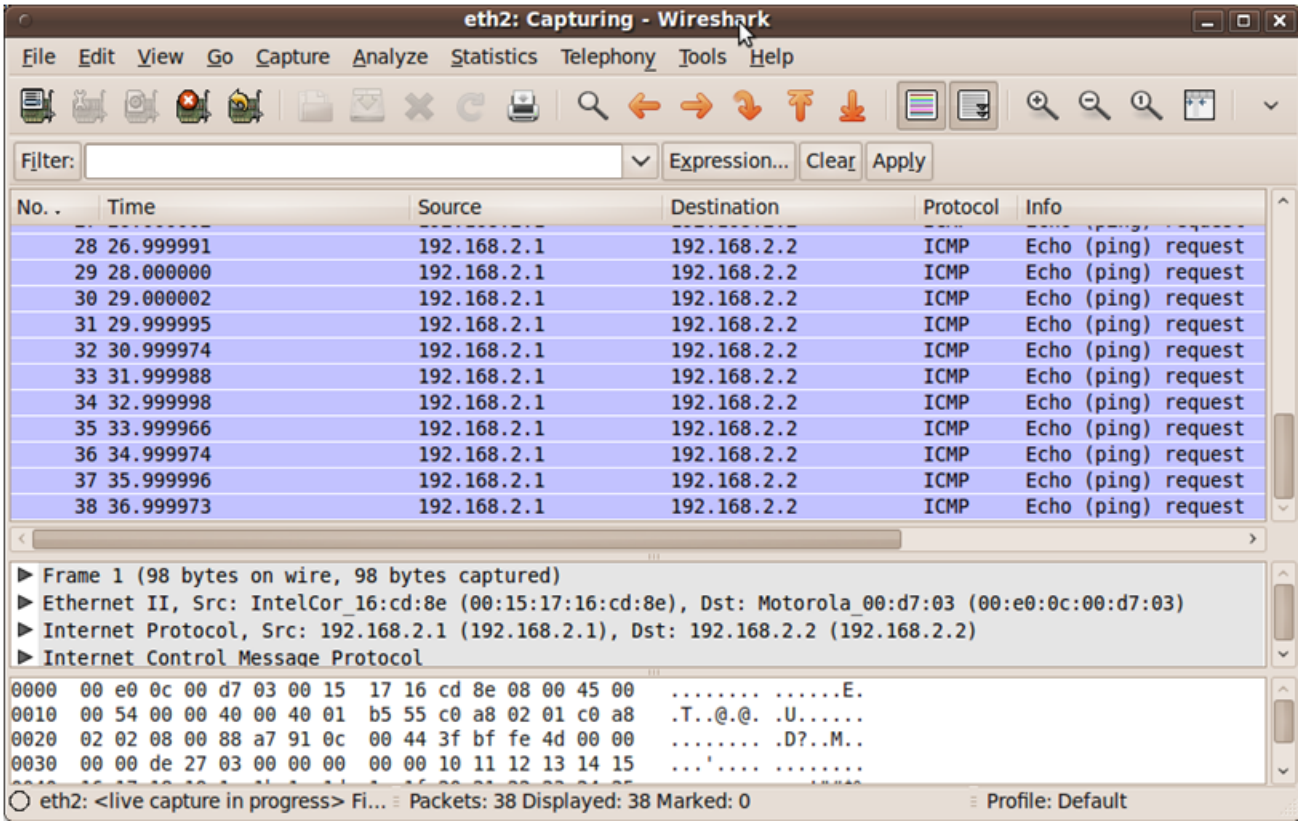

Figure 283. Wireshark Capturing Packets

9.9.15.4.9 Debugging FRA

We may need to debug FRA with detailed output log. FRA provides debug command to enable or disable those debug information output. In order to support debug mode, we should insert the following sentence to fra.h file line 46 and then re-compile.

```
#define ENABLE_FRA_DEBUG
```

Use the following command to enable or disable the debug information output.

```
fra> debug [on/off]
```

9.9.15.4.10 Testing Port Write

A Type8 port-write is intended as an error reporting mechanism from an end point-less device to a control processor or other system host. The RMan also supports generation of outbound port-writes for testability and debug. Inbound port-writes have dedicated hardware for guaranteed delivery.

Run the FRA application with Port-Write test configuration file

```
root@t4240qds:~# fra -r -f fra_config_port_write_test.xml
    fra: BPOOL: Release 8192 bufs to BPID 9
    fra: BPOOL: Release 256 bufs to BPID 10
    fra: BPOOL: Release 8192 bufs to BPID 11
    fra: BPOOL: Release 8192 bufs to BPID 12
    Start dist(pw_to_peer)
    fra: RMan inbound block0 is initialized
    Start dist(pw_from_peer)
    Thread uid:0 alive (on cpu 1)
    fra>
```

Send Port-Write message using "pw" command

```
fra> pw 1234
```

Receive the Port-Write message on the peer

```
 fra> Port Write: get 4 bytes data:1234
```

• Note: RapidIO supports a maintenance port-write type that contains a data payload 4 8 16 32 or 64 bytes.

9.9.15.5 Running FRA with flow control

The chapter is intended to introduce how to run FRA with flow control.

The operations of installation and testing are similar to Chapter 3, So those sections please refer to above description.

9.9.15.5.1 Booting Linux

Set following environment settings on board's bank4, Setup networking variables for tftp in bank4:

```
=> setenv ethact <active Ethernet interface for u-boot use>
=> setenv ethaddr <MAC address 0>
=> setenv ethNaddr <MAC address N=1 to 5>
...
=> setenv ipaddr <your ip address>
=> setenv netmask <your netmask>
=> setenv gatewayip <your default gateway ip address >
=> setenv serverip <the address of your TFTP server>
=> sav
```

Setup srio device ID on left board.

```
=> mm 0xffe0d0100
fe0d0100: 00000000 ? 808b0000
fe0d0104: 00000000 ? q
=>
```

Setup srio device ID on right board.

```
=> mm 0xffe0d0100
fe0d0100: 00000000 ? 808d0000
fe0d0104: 00000000 ? q
=>
```

Setup and save other uboot variables to tftp the USDPAA device tree, root file system and Linux image and boot Linux.

```
=>setenv bootargs "root=/dev/ram rw console=ttyS0,115200 usdpaa_mem=0x4000000"
=>setenv fraboot "tftp 1000000 uImage-t4240qds.bin; tftp 2000000 fsl-image-core-
t4240qds.ext2.gz.u-boot;  tftp c00000 uImage-t4240qds-usdpaa.dtb; bootm 1000000 2000000 c00000"
=>run fraboot
```

Following are some booting information points:

u-boot boot log:

```
Flash: 128 MiB
L2:    128 KB enabled
Corenet Platform Cache: 1024 KB enabled
SRIO1: enabled
SRIO2: disabled
NAND:  1024 MiB
MMC:  FSL_ESDHC: 0
```

Linux kernel boot log:

```
fsl-of-srio ffe0c0000.rapidio: Rapidio UIO driver initialized
...
fsl-of-rman ffe1e0000.rman: Of-device full name /soc@ffe000000/rman@1e0000 initialized
fsl-of-rman ffe1e0000.rman: RMan inbound block0 initialized.
fsl-of-rman ffe1e0000.rman: RMan inbound block1 initialized.
fsl-of-rman ffe1e0000.rman: RMan inbound block2 initialized.
fsl-of-rman ffe1e0000.rman: RMan inbound block3 initialized.
```

9.9.15.5.2 Compilation FRA with flow control

Please follow the SDK build guide to build the software. This will perform a default build of all files needed to boot Linux and run the FRA software. These files include dtb, FMan ucode image, u-boot image, kernel image, and rootfs image.

When build kernel, make sure these options are selected.

```
Device Drivers  --->
          <*> Userspace I/O drivers  --->
                    <*>   Freescale Serial RapidIO support
          [*] Staging drivers  --->
                    [*]     Freescale RapidIO Message Manager support
```

When build rootfs, make sure to define FRA_FC in fra_cfg.h.

```
#define FRA_FC
```

9.9.15.5.3 Running FRA

Logging into Linux

At the Linux prompt, login as "root".

```
Yocto (Built by Poky 6.0) 1.1 t4240qds ttyS0

t4240qds login: root
root@t4240qds:~#
```

Configure FMan PCD using fmc with the XML files in /usr/etc:

```
[root@t4240 root]# cd /usr/etc
[root@t4240 root]# fmc -c usdpaa_config_t4_serdes_1_1_6_6.xml -p fra_dstr_fc_policy.xml -a
```

Run the FRA application on left board:

```
root@t4240qds:~# fra -c usdpaa_config_t4_serdes_1_1_6_6.xml -p fra_dstr_fc_policy.xml -f
fra_config_dstr_fc_processing1_left.xml
```

Run the FRA application on right board:

```
root@t4240qds:~# fra -c usdpaa_config_t4_serdes_1_1_6_6.xml -p fra_dstr_fc_policy.xml -f
fra_config_dstr_fc_processing1_right.xml
```

Additional FRA threads can be started on other CPUs by entering commands at the FRA command prompt. Running threads can also be queried and the application can also be shutdown.

• add a FRA thread on a single cpu (e.g. cpu 2)

```
fra> add 2
```

• add FRA threads on a range of cpus

```
fra> add 2..3
```

• list the cpus currently enabled (by querying them, i.e. this also verifies that they aren't blocked)

```
fra> list
Thread alive on cpu 1
Thread alive on cpu 2
Thread alive on cpu 3
```

• display FRA congestion group status

```
fra> cgr
```

• display FRA configuration and status

```
fra> status

```
fra> q
```

9.9.15.6 Running FRA on One Board

The chapter is intended to introduce how to run FRA on one board. The operations of installation and compilation are similar to Chapter 3, So those sections please refer to above description.

9.9.15.6.1 Prepare the Hardware (one board)

FRA can run on one board P3041DS or P5020DS. As the Fig10 shown, when FRA application run on one board, needs two PC or one PC with two Ethernet interfaces. Two pc's Ethernet interfaces are connected with two RGMI interface of the board respectively. The board should been inserted two RapidIO card to slot6 and slot7. Check board's switch, sw2 is 0b10100101(slot7->SRIO2, slot6->SRIO1, slot3->PEX2, slot2->SGMI), Sw5 is 0b00010100(Serdes reference clock for bank1 is 100MHz, bank2 is 125MHz bank3 is 125MHz).

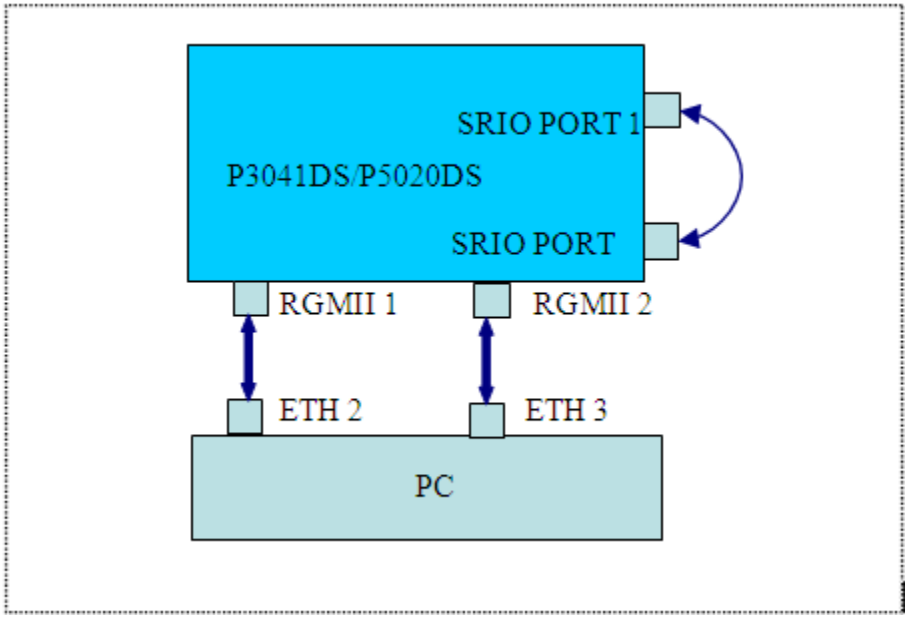

Figure 284. Serdes 0x04 protocol hardware setup

9.9.15.6.2 Configuring FRA (one board)

In this case FRA default configuration file is fra_config_dstr_port1_port2_loopback.xml. Under This configuration the packet flow is shown as Fig5. Board receives the IP packets from RGMII 1, adds RMan message descriptor to the headroom of each packet according to configuration, and then directly sends them from SRIO port 1; the packets are looped back to SRIO port2. RMan receives those packets, and transfers them to RGMI2. So PC can receive packets which it sends out.

The other configuration files are also valid. The difference with the default configuration is that board will use the same network port for receiving and sending.

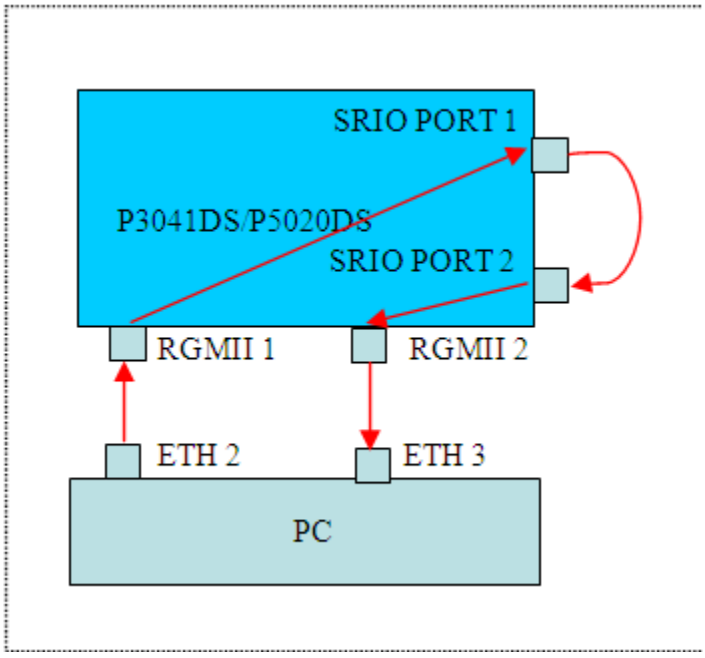

Figure 285. packet flow under port1-port2 loop back mode

When we run FRA on one board, may use the following command:

```
# fra -f /usr/etc/fra_config_dstr_port1_port2_loopback.xml
```

9.9.15.6.3 Managing RCW

In order to enable board's two SRIO ports, we should select the appropriate RCW setting, As the example this section provides a valid RCW of Serdes 0x04 type for P3041Ds and P5020DS .

RCW for P3041DS is :

```
00000000: AA55 AA55 010E 0100 1260 0000 0000 0000
00000010: 241C 0000 0000 0000 1081 6400 2400 2000
00000020: FE80 0000 4100 0000 0000 0000 0000 0000
00000030: 0000 0000 1007 0000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 2F4C A9FA
```

RCW for P5020DS is :

```
00000000: AA55 AA55 010E 0100 0C54 0000 0000 0000
00000010: 1E12 0000 0000 0000 1081 6400 2400 2000
00000020: FE80 0000 4100 0000 0000 0000 0000 0000
00000030: 0000 0000 1007 0000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 FA0A 674D
```

Save the above RCW data to rcw-0x04.xxd file and then convert to RCW image

```
$ xxd -r rcw-0x04.xxd > rcw-0x04.bin
```

9.9.15.6.4 Running FRA

According to Chapter 3 description, apply the related patches; build the software and burn images to board.

Following are some u-boot boot log:

```
Flash: 128 MiB
L2:    128 KB enabled
Corenet Platform Cache: 1024 KB enabled
SRIO1: enabled
SRIO2: enabled
NAND:  1024 MiB
MMC:  FSL_ESDHC: 0
```

The above log has printed out SRIO status, if SRIO1 or SRIO2 is not enabled, we should check RCW image and uboot image.

The other output log is same with Chapter 3.

Configure FMan PCD using fmc with the XML files located in /usr/etc:

```
[root@p3041 root]# cd /usr/etc
[root@p3041 root]# fmc -c usdpaa_config_p3_p5_serdes_0x04.xml -p
usdpaa_policy_hash_ipv4.xml -a
```

Run the FRA application:

```
[root@p3041 root]# fra -f /usr/etc/fra_config_dstr_port1_port2_loopback.xml
```

We can use status command to check the FRA configuration:

9.9.15.6.5 Testing FRA (one board)

We can configure ETH2's IP address is 192.168.2.1, ETH3's IP address is 192.168.3.1. In order to test FRA, we need to send IP packets to a RGMII Ethernet interface, since FRA does not support ARP protocol, we should do IP and MAC binding on PC. On board console Linux startup log has the MAC information.

```
cpu0: fsl_mac: FSL FMan MAC API based driver ()
cpu0: fsl_mac: ffe4e2000.ethernet: FMan dTSEC version: 0x08240101
cpu0: fsl_mac: ffe4e2000.ethernet: FMan MAC address: 00:e0:0c:00:d7:01
cpu0: fsl_mac: ffe4e4000.ethernet: FMan dTSEC version: 0x08240101
cpu0: fsl_mac: ffe4e4000.ethernet: FMan MAC address: 00:e0:0c:00:d7:02
cpu0: fsl_mac: ffe4e6000.ethernet: FMan dTSEC version: 0x08240101
cpu0: fsl_mac: ffe4e6000.ethernet: FMan MAC address: 00:e0:0c:00:d7:03
cpu0: fsl_mac: ffe4e8000.ethernet: FMan dTSEC version: 0x08240101
cpu0: fsl_mac: ffe4e8000.ethernet: FMan MAC address: 00:e0:0c:00:d7:04
cpu0/0: Applying 10G tx-ecc error workaround (10GMAC-A004) ...
cpu0/0: done.
cpu0: fsl_mac: ffe4f0000.ethernet: FMan XGEC version: 0x00010330
cpu0: fsl_mac: ffe4f0000.ethernet: FMan MAC address: 00:e0:0c:00:d7:05
```

For 0x04 RCW, RGMII1 corresponds to DTSEC3, RGMII2 corresponds to DTSEC4. So we find the RGMII1 port Mac address is 00:e0:0c:00:d7:03, RGMII2 port Mac address is 00:e0:0c:00:d7:04.

Create an ARP entry on pc by using the following command:

```
$ sudo arp -s 192.168.2.2 00:e0:0c:00:d7:03
$ sudo arp -s 192.168.3.2 00:e0:0c:00:d7:04
```

On PC ping host board's DTSEC3

```
$ ping 192.168.2.2
```

Run Wireshark on PC to capture the ETH3 which connected to the board's RGMII2 port.

```
$ sudo wireshark
```

As the figure below shows, we should see the ping packets sent from PC.

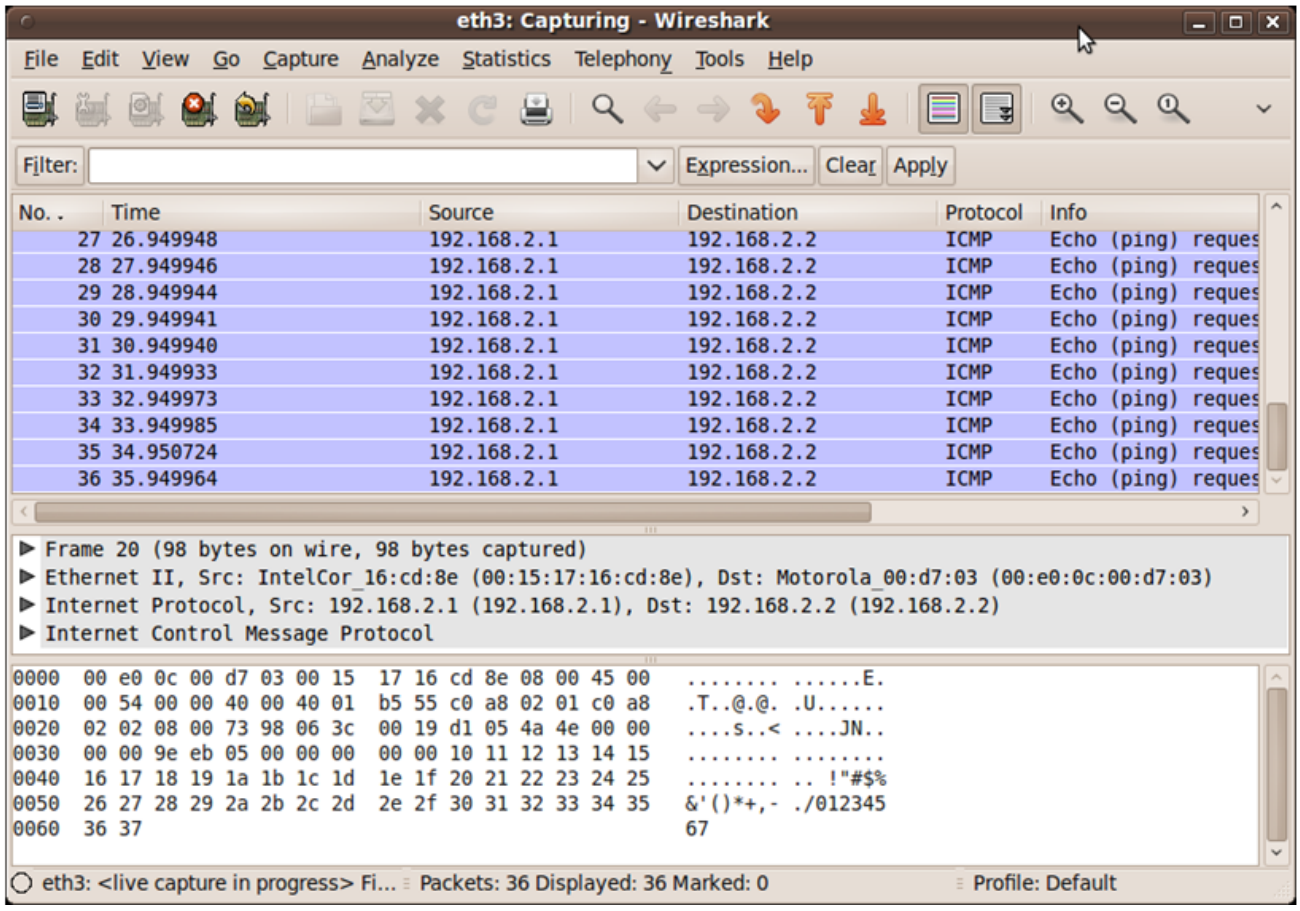

Figure 286. Wireshark Capturing Packets

9.9.15.7 Revision History

1.0	Creation of FRA UM for sdk 1.1 release. - Basic application flow - Commands to use - Testing FRA application

9.9.16 NXP USDPAA SRA User Manual

9.9.16.1 Serial RapidIO application

This User Manual describes the NXP P3041DS/P4080DS/P5020DS/T4240QDS/B4860QDS Serial RapidIO linux user space driver. This user manual provides you with instructions about how to use SRIO (Serial RapidIO) user space driver.

9.9.16.1.1 Overview

NXP Serial RapidIO user space driver is based on NXP Linux SDK. It is composed of Linux UIO driver in Linux kernel space and SRIO driver/application in Linux user space. There are dma and srio UIO drivers which map dma/srio registers and SRIO window to linux user space for user space driver usage. User space dma and srio driver provide driver interfaces for application, and timer driver provide means to measure the performance. Application can use driver interface to accomplish the final srio function. Currently, the srio driver support two rapidio ports, and the dma driver supports two controllers and eight channels based on basic direct mode and basic chain mode . The demo sra application can implement SRIO SWRITE, NWRITE, NWRITE_R, NREAD, ATOMIC_INC, ATOMIC_DEC, ATOMIC_CLR, ATOMIC_SET type protocols based on window/segment/subsegment, and give user srio performance data to evaluate NXP rapidio IP block. Currently, it can run on P3041DS/P4080DS/P5020DS/T4240QDS/B4860QDS board.

9.9.16.1.2 SRA environment setup

9.9.16.1.2.1 Hardware environment

To run SRIO application demo, have two P3041DS/P4080DS/P5020DS/T4240QDS/B4860QDS boards connected with each other via SRIO cable through their RapidIO ports, as shown in Figure 1 (SRIO riser card located in slot6 on P3041DS/ P5020DS, and located in slot3 on P4080DS, in slot6 on T4240QDS, in additional AMC2PEX-2S card on B4860QDS). Or using one board, connecting its port1 with port2 via SRIO cable, as shown in Figure 2 (SRIO riser card located in slot6 and slot7 on single P3041DS/ P5020DS). Then burn the updated rcw, u-boot, ucode for Fman to flash to setup board environment.

For a two SRIO port operation on single board, burn rcw-0x04 file (support 4 lanes for each rapidio port) on P3041DS/ P5020DS. For two board SRIO connection, burn rcw-0x33 file on P3041DS/ P5020DS (support 4 lanes for SRIO1), and rcw-0x16 on P4080DS (support 4 lanes for each rapidio port, but only SRIO1 can be connected between two P4080DS with 4 lanes). These RCW can be found in the SDK. P4080DS can also use rcw-0x1d to accomplish two board connection via two RapidIO ports with 1 lane for each port. Since this RCW is not included in SDK, generate it following the later RCW generation guide. For T4240QDS and B4860QDS platforms, you should create the new rcw files using QCS based on your specific environment.

For P3041DS/P5020DS, when using rcw-0x33 for two board connection via SRIO, check the board's switch: sw2 is "0b00100001"(slot7->PEX1, slot6->SRIO, slot4->PEX3, slot2->XAUI), sw5 is "0b00010100" (Serdes reference clock for bank1 is 100MHz, bank2 is 125MHz bank3 is 125MHz). For P3041DS/P5020DS, when using rcw-0x04 for two SRIO port connections on one board, board's switch should be: sw2 is "0b10101001"(slot7->SRIO2, slot6->SRIO1, slot3->PEX2, slot2->SGMI), Sw5 is "0b00010100" (Serdes reference clock for bank1 is 100MHz, bank2 is 125MHz bank3 is 125MHz). For P4080DS, when using rcw-0x16 for two SRIO port connections between two boards, board's switch should be: sw3 is "0b01001100" (Serdes reference clock for bank1 is 125MHz, bank2 is 125MHz, bank3 is 125MHz).

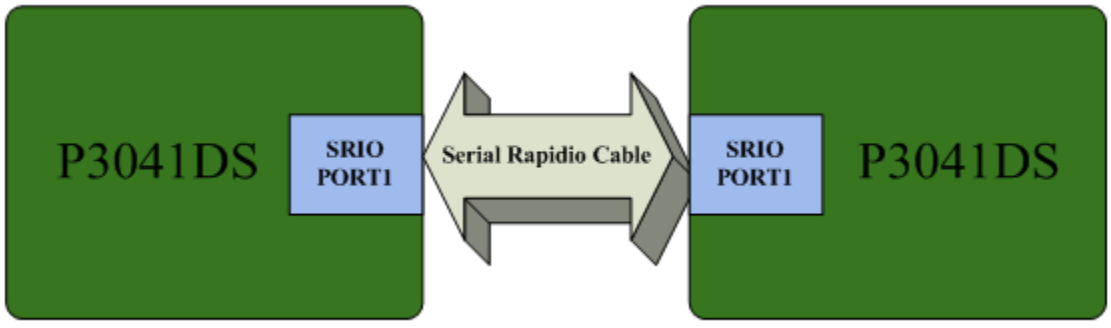

Figure 287. SRIO Hardware Connection between Two Boards

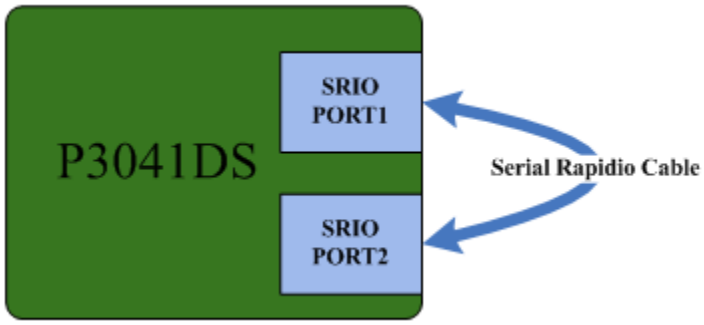

Figure 288. SRIO Hardware Connection between two Ports on One Board

9.9.16.1.2.2 SDK Installation

SRA is based on NXP Linux SDK. So to use SRA, make sure NXP Linux SDK is well installed.

9.9.16.1.2.3 RCW Generation

For P3041DS and P5020DS platforms, user can use NXP PBL tools to create SerDes 0x04 RCW file (support srio two ports) or SerDes 0x33 RCW file (support srio one port) and then convert to rcw image.

SerDes 0x33 RCW of P3041DS is :

```
0000000: aa55 aa55 010e 0100 1260 0000 0000 0000
0000010: 241c 0000 0000 0000 cc98 4a00 0300 2000
0000020: fe80 0000 4100 0000 0000 0000 0000 0000
0000030: 0000 0000 1007 0000 0000 0000 0000 0000
0000040: 0000 0000 0000 0000 0813 8040 cf8e 2f88
```

SerDes 0x33 RCW of P5020DS is :

```
0000000: aa55 aa55 010e 0100 0c54 0000 0000 0000
0000010: 1e12 0000 0000 0000 cc98 4a00 0300 2000
0000020: fe80 0000 4100 0000 0000 0000 0000 0000
0000030: 0000 0000 1007 0000 0000 0000 0000 0000
0000040: 0000 0000 0000 0000 0813 8040 1ac8 e13f
```

Save the above RCW data to rcw-0x33.xxd file and then convert to RCW image

```
$ xxd -r rcw-0x33.xxd  > rcw-0x33.bin
```

SerDes 0x04 RCW for P3041DS is :

```
00000000: aa55 aa55 010e 0100 1260 0000 0000 0000
00000010: 241c 0000 0000 0000 1081 6400 2400 2000
00000020: fe80 0000 4100 0000 0000 0000 0000 0000
00000030: 0000 0000 1007 0000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 2f4c a9fa
```

SerDes 0x04 RCW for P5020DS is :

```
00000000: aa55 aa55 010e 0100 0c54 0000 0000 0000
00000010: 1e12 0000 0000 0000 1081 6400 2400 2000
00000020: fe80 0000 4100 0000 0000 0000 0000 0000
```

```
00000030: 0000 0000 1007 0000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 fa0a 674d
```

Save the above RCW data to rcw-0x04.xxd file and then convert to RCW image

```
$ xxd -r rcw-0x04.xxd > rcw-0x04.bin
```

For P4080DS platform, SerDes 0x16 RCW file supports srio two X4 ports; SerDes 0x1d RCW file supports srio two X1 ports.

SerDes 0x16 RCW for P4080DS is :

```
00000000: aa55 aa55 010e 0100 105a 0000 0000 0000
00000010: 1e1e 181e 0000 cccc 5840 0000 3c3c 2000
00000020: fe80 0000 e100 0000 0000 0000 0000 0000
00000030: 0000 0000 008b 6000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 532a bb17
```

Save the above RCW data to rcw-0x16.xxd file and then convert to RCW image

```
$ xxd –r rcw-0x16.xxd > rcw-0x16.bin
```

SerDes 0x1d RCW for P4080DS is :

```
0000000: aa55 aa55 010e 0100 0c58 0000 0000 0000
0000010: 1818 1818 0000 8888 7440 4000 0000 2000
0000020: fe80 0000 0100 0000 0000 0000 0000 0000
0000030: 0000 0000 0083 0000 0000 0000 0000 0000
0000040: 0000 0000 0000 0000 0813 8040 0129 56be
```

Save the above RCW data to rcw-0x1d.xxd file and then convert to RCW image

```
$ xxd –r rcw-0x1d.xxd > rcw-0x1d.bin
```

For P2041RDB platform, SerDes 0x02 RCW file supports srio one X4 ports. RapidIO card should be inserted to slot1. and the following commands should be ran first:

```
cpld lane_mux 6 0;
cpld lane_mux a 0;
cpld lane_mux c 0;
cpld lane_mux d 0;
cpld reset altbank;
```

SerDes 0x02 RCW for P2041RDB is :

```
00000000: AA55 AA55 010E 0100 1260 0000 0000 0000
00000010: 241C 0000 0000 0000 0899 30C0 C7C0 2000
00000020: FE80 0000 4000 0000 0000 0000 0000 0000
00000030: 0000 0000 D003 0F07 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 57B0 F7D9
```

Save the above RCW data to rcw-0x02.xxd file and then convert to RCW image

```
$ xxd –r rcw-0x02.xxd > rcw-0x02.bin
```

For T4240QDS and B4860QDS platforms, please select the right RCW files from the released SDK.

u-boot/kernel/sra generation:

Please follow the SDK build guide.

9.9.16.1.2.4 Build Configuration

When build kernel, make sure these options are selected.

```
Device Drivers  --->
          <*> Userspace I/O drivers  --->
                    <*>     Freescale Serial RapidIO support
                    <*>     Freescale DMA support
```

9.9.16.1.3 Boot

To run the USDPAA software, one must first boot Linux with the correct files. These files are including u-boot.bin, uImage, p3041ds/p4080ds/p5020ds/t4240qds/b4860qds-usdpaa.dtb and initramfs.cpio.gz.uboot. Please use the ucode and rcw file in the SDK package.

Following are some booting information points:

u-boot boot log (rcw-0x04):

```
Flash: 128 MiB
L2:    128 KB enabled
Corenet Platform Cache: 1024 KB enabled
SRIO1: enabled
SRIO2: enabled
NAND:  1024 MiB
```

Linux kernel boot log:

```
cpu2: fsl_oh: FSL FMan Offline Parsing port driver ()
cpu2: fsl_oh: dpa-fman0-oh.32: Found OH node handle compatible with fsl,dpa-oh.
cpu2: fsl_oh: dpa-fman0-oh.32: OH port /soc@ffe000000/fman@400000/port@82000 enabled.
fsl-of-srio ffe0c0000.rapidio: Rapidio UIO driver initialized
fsl-of-dma ffe100300.dma: dma channel dma-uio0-0 initialized
fsl-of-dma ffe100300.dma: dma channel dma-uio0-1 initialized
fsl-of-dma ffe100300.dma: dma channel dma-uio0-2 initialized
fsl-of-dma ffe100300.dma: dma channel dma-uio0-3 initialized
fsl-of-dma ffe101300.dma: dma channel dma-uio1-0 initialized
fsl-of-dma ffe101300.dma: dma channel dma-uio1-1 initialized
fsl-of-dma ffe101300.dma: dma channel dma-uio1-2 initialized
fsl-of-dma ffe101300.dma: dma channel dma-uio1-3 initialized
ehci_hcd: USB 2.0 'Enhanced' Host Controller (EHCI) Driver
ohci_hcd: USB 1.1 'Open' Host Controller (OHCI) Driver
```

9.9.16.1.4 SRA Demo

SRA is a demo application to implement SRIO functions, via dma and srio driver interface. It supports SRIO SWRITE, NWRITE, NWRITE_R, NREAD, ATOMIC_INC, ATOMIC_DEC, ATOMIC_CLR, ATOMIC_SET type protocols based on window/segment/subsegment, using command input. It can read data from the other board memory, and write data to the other board memory, then display the memory. It can also evaluate the srio performance, and print out the performance result. These functions are done by dma direct mode operation or core. It also supports dma basic chain mode test and basic direct mode performance test. Currently, it supports two rapidio ports. And you can assign a port to implement rapidio performance test. It will measure the srio performance under different transmission protocol type, with different transmission data size, and with different dma BWC (bandwith control).

As shown in Figure 3, SRA defines two large areas for two rapidio ports in dma pool. Each large area is 8M bytes. And the large area is divided into four small areas, each of which is 2M bytes. They are:

map space - match data written from other rapidio ports come into this area.

read data space - when read data from other ports, the data is saved in this area.

writing preparing space - this area is preparing data for writing to other rapidio ports.

reserved space - unused.

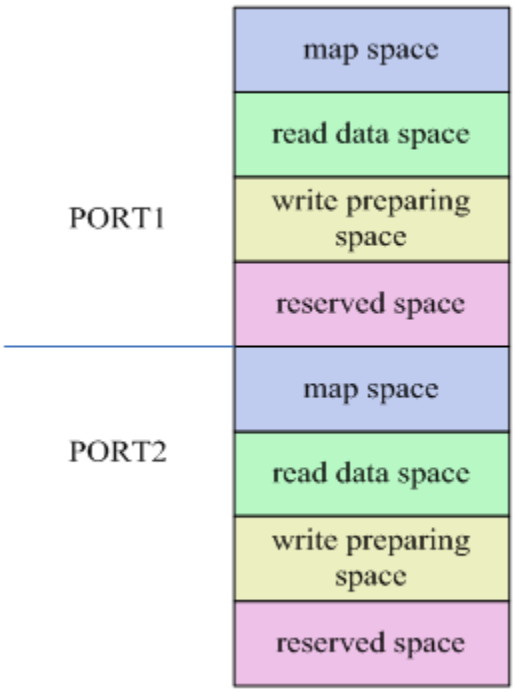

Figure 289. SRA DMA Pool Partition

9.9.16.1.5 SRA Command Description

There are sra command formats as followings:

```
sra -attr [port_id] [fun] [fun_id]([write_attr] [read_attr])

sra -attr port1/2 device_id [id]
sra -attr port1/2 target_id [id]
sra -attr port1/2 seg_num [num]
sra -attr port1/2 subseg_num [num]
sra -attr port1/2 subseg_tdid [seg_id] [tdid]
sra -attr port1/2 accept_all [id]
sra -attr port1/2 irq [id]
sra -attr port1/2 win_attr [id] [write_attr] [read_attr]
sra -attr port1/2 seg_attr [id] [write_attr] [read_attr]
```

Notes: This is sra attribute command serial, which set rapidio attribute.

-attr: It indicates this is an attribute setting command.

port_id: It indicates which port is set currently. It can be these characters: port1, port2.

fun: It indicates which function this command sets. The function names are listed above.

fun_id: It indicates which operation this function uses. In most case, it is a number.

write_attr: This is writing attribute when sra do writing operation. It can be these characters: swrite, nwrite, nwrite, nwrite_r which are consistent with rapidio standard protocol.

read_attr: This is reading attribute when sra do reading operation. It can be these characters: nread, atomic_inc, atomic_dec, atomic_clr, atomic_set, which are consistent with rapidio standard protocol.

```
sra -op [port_id] [win_id] [seg_id] [subseg_id] [operation] [data_len]

sra -op port1/2 [win_id] [seg_id] [subseg_id] w/r/s/p [data_len]
```

-op: It indicates this is an operation command.

port_id: It indicates which port is set currently. It can be these characters: port1, port2.

win_id: It indicates which window this operation works on. Currently, application uses window 1 as the only window for operation.

seg_id: It indicates which segment this operation works on.

subseg_id: It indicates which subsegment this operation works on.

operation: It indicates what operation should do.

s(set): It sets 0/1/2/3/4/5/6/7 in different area to local memory and ignore the data_len value.

p(print): It prints definite parts of local memory and ignore the data_len value.

w(write): It sends data in current port write preparing space to the other board map space in memory according to data_len.

r(read): It reads the other board port map space data, and saves them in its read data space in local memory according to data_len.

data_len: This is the data transmission length. It can be any number which is smaller than 2M. And for ATOMIC operation, the data_len should be 1/2/4. Other number using for ATOMIC reading operation will cause transmission fault. The data_len will be ignored for the s(set) and p(print) commands, but when run the s(set) and p(print) commands you also should give the data_len parameter, any value will be ok.

```
sra -test [case] [port] [task] [srio] [number]
 sra -test srio port1/2 dma/core [srio_type] payload_size
        [srio_type] should be swrite/nwrite/nwrite_r/nread
        payload_size should be less than 2M bytes
 sra -test dma_chain
 sra -test show_perf port1/2 times
 sra -test show_task
 sra -test free_task port1/2
```

-test: It indicates sra will do test or create a srio transmission task.

case: The type of the test, can be srio, dma_chain, show_perf, show_task, or free_task. There should be different following parameters for different test case. And also there are some dependent relationships between the cases.

port: Indicates which SRIO port will be used for the test, can be port1 or port2.

task: Determines the mode of the test, can be dma or core. If you select the core mode, the transmission will be implemented with memcpy function, so you'd better very clear about the effect of the cache. The testing memory space for the srio was configured to be cached by default, so the results of the core test may don't make any sense for the normal requirements.

srio: Indicates the type of the srio transmission, can be swrite, nwrite, nwrite_r, or nread.

number: The payload size of the srio transmission task or the times for a performance calculation.

9.9.16.1.6 SRA command Usage

- SRA Help

```
#sra
sra> sra
```

Then sra help will display. Error command will cause sra to print help information. Followings are the help information:

```
-----------------SRIO APP CMD FORMAT-----------------
Set window attribute
sra -attr [port_id] [fun] [fun_id]([write_attr] [read_attr])
sra -attr port1/2 device_id [id]
sra -attr port1/2 target_id [id]
sra -attr port1/2 seg_num [num]
sra -attr port1/2 subseg_num [num]
sra -attr port1/2 subseg_tdid [seg_id] [tdid]
sra -attr port1/2 accept_all [id]
sra -attr port1/2 irq [id]
sra -attr port1/2 win_attr [id] [write_attr] [read_attr]
sra -attr port1/2 seg_attr [id] [write_attr] [read_attr]

Notes:
        [id] for command accept_all: 0 - disable; 1 - enable
        [id] for irq: 0 - disable; 1 - enable
                [write_attr]    : swrite/nwrite/nwrite_r
        [read_attr]     :
 nread/atomic_inc/atomic_dec/atomic_set/atomic_clr

Do sra operation
sra -op [port_id] [win_id] [seg_id] [subseg_id] [operation] [data_len]
sra -op port1/2 [win_id] [seg_id] [subseg_id] w/r/s/p [data_len]
        [data_len]      : should be less than the window/segment/subsegment's size, max size is 2M
                        data_len should be 1/2/4 for ATOMIC operation

Do SRIO test and print performance result
sra -test [case] [port] [task] [srio] [number]
 sra -test srio port1/2 dma/core [srio_type] payload_size
        [srio_type] should be swrite/nwrite/nwrite_r/nread
       payload_size should be less than 2M bytes
 sra -test dma_chain
 sra -test show_perf port1/2 times
 sra -test show_task
 sra -test free_task port1/2
-----------------------------------------------------
```

- **SRA Set SRIO Port Device Id**

This command sets SRIO port device id. Any package from other srio device will be accepted only when the sender's target id matches the accepter's device id.(When "accept all" functions is closed)

```
sra> sra -attr port1 device_id 0x55
```

- **SRA Set SRIO Port Target Id**

This command sets SRIO port1 target id.

```
sra> sra -attr port1 target_id 0x33
```

- **SRA Set SRIO Port Segment Number**

This command sets the segment number in a window of a srio port. The number can be 1/2/4.

```
sra> sra -attr port1 seg_num 4
```

- **SRA Set SRIO Port Sub Segment Number**

This command sets the sub segment number in a segment of a srio port. The number can be 1/2/4/8. This command needs the segment to be set firstly.

```
sra> sra -attr port1 subseg_num 4
```

•SRA Set SRIO Port Sub Segment base target id

This command sets the sub segment base target id for subsegment serial of a srio port. This command needs srio segment/subsegment number be set firstly. [seg_id]: It indicates the segment which is used for subsegment setting. [tdid]: subsegment base target id. It should be aligned with the subsegment number.

```
sra> sra -attr port1 subseg_tdid 1 0x40
```

•SRA Set SRIO Port enable or disable accept all function

This command can enable or disable srio port accept all package feature. [id]: 0 - disable the feature; 1 - enable the feature.

```
sra> sra -attr port1 accept_all 1
```

•SRA Set SRIO enable or disable irq

This command can enable or disable srio irq. [id]: 0 - disable irq; 1 - enable irq.

```
sra> sra -attr port1 irq 1
```

•SRA Set SRIO Port Window Attributes

This command sets SRIO port outbound window attributes. The outbound window attribute for write can be nwrite, swrite, nwrite_r, and for read can be nread, atomic_inc, atomic_dec, atomic_set, atomic_clr. [id]: indicates window id. Currently, this parameter should 1, indicating sra setting window 1.

```
sra> sra -attr port1 1 nwrite nread
```

•SRA Set SRIO Port Window1 Segment Attributes

This command sets SRIO port1/2 window1 segment attribute. The outbound window segment attribute for write can be nwrite, swrite, nwrite_r, and for read can be nread, atomic_inc, atomic_dec, atomic_set, atomic_clr. [id]: indicates window1 segment id. Currently, this parameter should be compatible with segment number. Ex. if segment number is 4, the segment id can be 1/2/3/4.

•SRA Setting and Printing Operation

This command sets 0/1/2/3/4/5/6/7 to the eight areas in local memory. [win_id] indicates the window id. [seg_id] indicates the segment id. [subseg_id] indicates the subsegment id.

```
sra> sra -op port1 1 0 0 s 0x100000
```

This command prints parts of local memory data.

```
sra> sra -op port1 1 0 0 p 0x100000
```

•SRA Writing Operation

This command sends 1M bytes data in port writing preparing space to other board memory, using port attribute set in attribute command.

```
sra> sra -op port1 1 0 0 w 0x100000
```

•SRA Reading Operation

This command uses port attribute to read 1M byte data from other port, and stores the data in port read data space in local memory.

Notes: ATOMIC operation requires data length should be 1/2/4.

```
sra> sra -op port2 1 0 0 r 0x100000
```

•SRA Test Operation

This command uses srio port1 or port2 to implement rapidio performance test, or do dma basic chain mode test based on the [case] parameter input. In rapidio performance test, if you just give the parameters [case], [port], [task], it will measure the srio performance under different transmission protocol type, with different transmission data size, and with different dma BWC (bandwith control), and print out the performance result. If you give all the parameters [case], [port], [task], [srio], [number], it will create a task for the specific srio transmission performance test. When you want to get the performance result from the task, you can start the calculation by the other command. In dma basic chain mode test, sra will copy lower region data to the upper region.

•SRA Test under dma mode

It will measure the srio port1 performance using dma under different transmission protocol type with different transmission data size, and with different dma BWC (bandwith control). It will print out the performance result finally.

```
sra> sra -test srio port1 dma
```

•SRA Test under core mode

It will measure the srio port1 performance using core under different transmission protocol type with different transmission data size. It will print out the performance result finally.

Note: The cache will impact the results of the performance.

```
sra> sra -test srio port1 core
```

•SRA Test to create a transmission task with dma mode

It will create a srio transmission task with the port1, dma mode, the swrite protocol type, and the 4096 bytes payload size. It can print out the performance result for the specific transmission when start the performance calculation with the other command.

Note: The payload size should be less then 2M bytes.

```
sra> sra -test srio port1 dma swrite 4096
```

•SRA Test to create a transmission task with core mode

It will create a srio transmission task with the port2, core mode, the nread protocol type, and the 2048 bytes payload size. It can print out the performance result for the specific transmission when start the performance calculation with the other command.

Note: The payload size should be less then 2M bytes, and the cache will impact the results of the performance.

```
sra> sra -test srio port2 core nread 2048
```

•SRA Test for dma chain

The sra will implement the dma chain mode test.

```
sra> sra -test dma_chain
```

•SRA Test to start the task's performance calculation

When there is a srio task on port1, this command can start the performance calculation with the 10000 transmission times. And it will print out the performance result finally.

```
sra> sra -test show_perf port1 10000
```

•SRA Test to show the existing tasks

When there are srio tasks, this command can show the all tasks on port1 and port2, and print out the task's parameters.

```
sra> sra -test show_task
```

•SRA Test to free the task

When there is a srio task on port1, this command can free the task.

```
sra> sra -test free_task port1
```

9.9.16.1.7 Run SRA Demo

Example 1: Board A sends 1M byte data to board B memory via rapidio NWRITE protocol. Two boards are connected via board A port1 and board B port1.

The figure below describes the two board memory map. Board A copies data from its port1 write preparing space to outbound window via dma. And board A outbound window is mapped to board B port1 map space via rapidio system. So writing to board A outbound window just like writing to board B ddr. Following is the command operation steps.

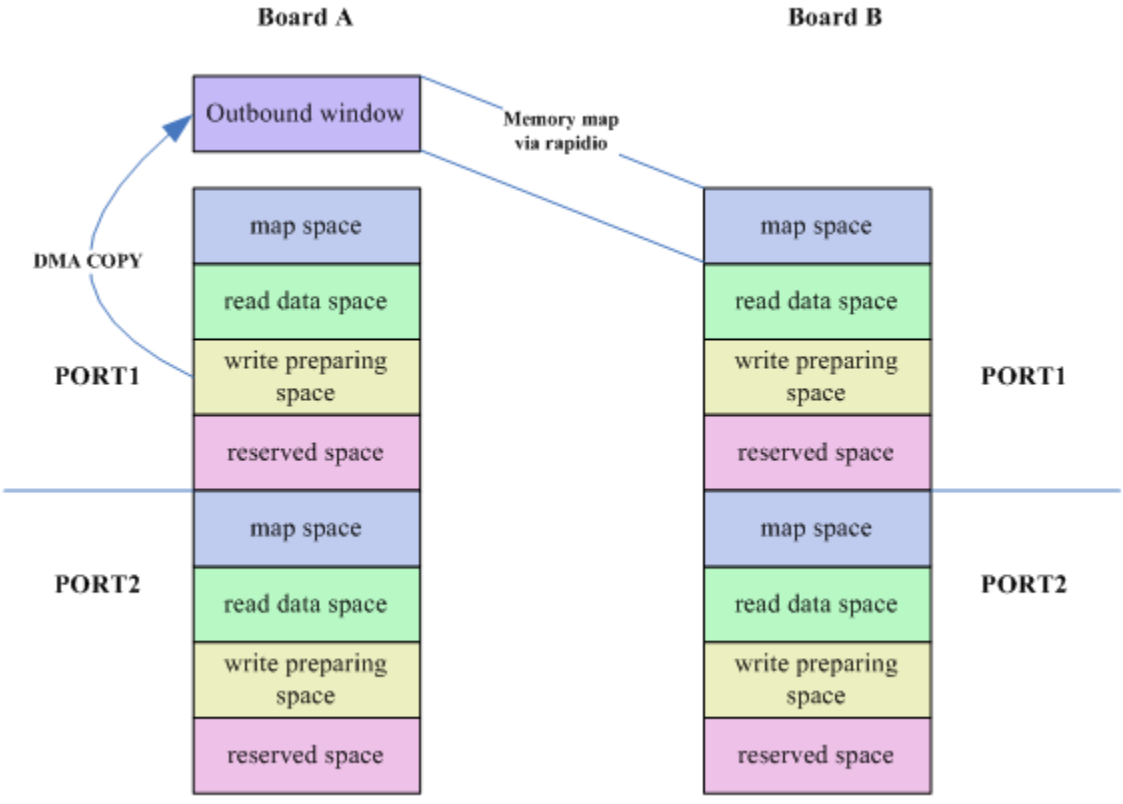

Figure 290. SRIO NWRITE Operation with Two Boards

```
Step1:      Boot up two boards.
Step2:
```

```
Board B:
sra> sra -attr port1 win_attr 1 nwrite nread (set board B port1 window 1 attribute to nwrite,
nread)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see the memory data)
Step3:
Board A:
sra> sra -attr port1 win_attr 1 nwrite nread (set board A port1 outbound window with nwrite,
nread attribute)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether memory is set)
sra> sra -op port1 1 0 0 w 0x100000 (send 1M data in writing preparing space to board B map space)
Step4:
Board B:
sra> sra -op port1 1 0 0 p 0x100000 (To see whether board A write preparing data are written to
board B map space)
```

Example 2: Board A NREAD 1M byte data from Board B memory. Two boards are connected via board A port1 and board B port2.

The figure below describes the two board memory maps. Board A copies data from its port1 outbound window to its read data space via dma. And board A port1 outbound window is mapped to board B port2 map space via rapidio system. So reading from board A outbound window just like reading from board B ddr. Following is the command operation steps.

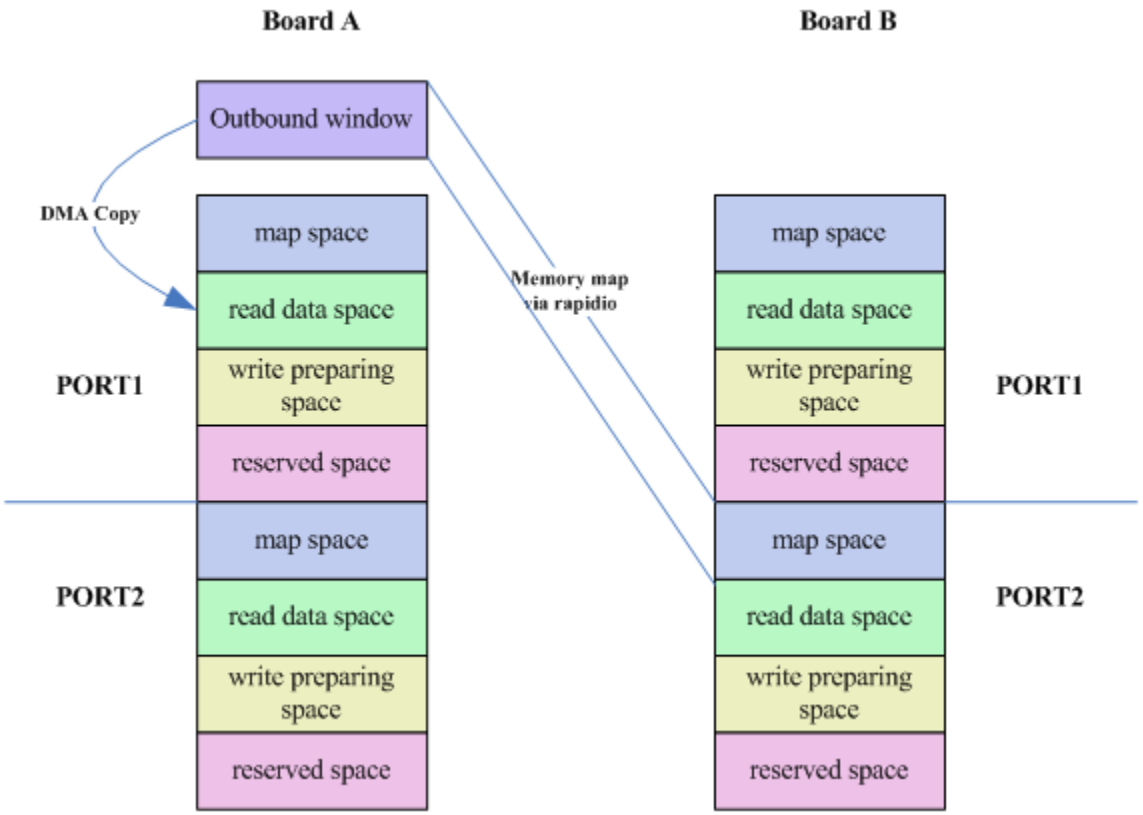

Figure 291. SRIO NREAD Operation with Two Boards

```
Step1:      Boot up the two boards.
Step2:
Board B:
sra> sra -attr port2 win_attr 1 nwrite nread (set board B port2 outbound window attribute to
```

```
nwrite, nread)
sra> sra -op port2 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port2 1 0 0 p 0x100000 (to see the memory data)
Step3:
Board A:
sra> sra -attr port1 win_attr 1 nwrite nread (set board A port1 outbound window attribute to
nwrite, nread)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether memory is set)
sra> sra -op port1 1 0 0 r 0x100000 (read 1M data from board B map space, and save them in its
read data space)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether board B map space data is saved in its port1
read data space)
```

Example 3: Board A ATOMIC_INC read 4 byte from Board B memory. Two boards are connected via board A port1 and board B port1.

```
Step1:      Boot up the two boards.
Step2:
Board B:
sra> sra -attr port1 win_attr 1 nwrite nread (set board B port1 outbound window attribute to
nwrite, nread)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see the memory data)
Step3:
Board A:
sra> sra -attr port1 win_attr 1 nwrite atomic_inc (set board A port1 outbound window attribute to
nwrite, atomic_inc)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether the data is set)
sra> sra -op port1 1 0 0 r 0x4 (read 4 byte data from board B map space, and save them in its
read data space)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether read data is correct)
Step4:
Board B:
sra> sra -op port1 1 0 0 p 0x100000 (to see whether Board B data is added by 1)
```

Example 4: As shown in the figure below, on one board, using NREAD protocol to read 1M byte data from its port2 map space, and then store data into its port1 read data space. In this scenario, user can test srio two port functions on one board. It needs connecting two srio ports on P3041 board via srio cable.

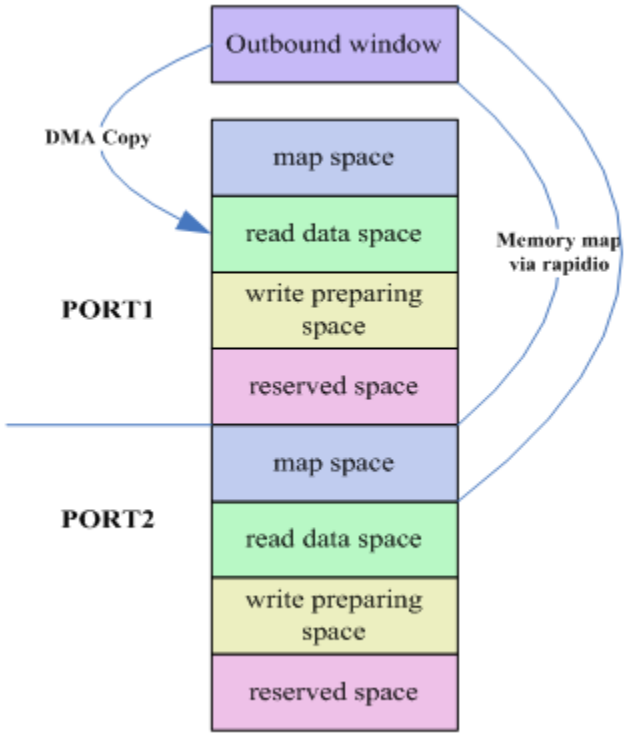

Figure 292. SRIO NREAD Operation with Two Ports on One Board

```
Step1:      Boot up the board.
Step2:
sra> sra -attr port1 win_attr 1 nwrite nread (set port1 outbound window attribute to nwrite,
nread)
sra> sra -attr port2 win_attr 1 nwrite nread (set port2 outbound window attribute to nwrite,
nread)
sra> sra -op port1 1 0 0 s 0x100000 (set local memory to predefined data)
sra> sra -op port1 1 0 0 p 0x100000 (to see the memory data)
sra> sra -op port1 1 0 0 r 0x100000 (port1 reads 1M byte data from port2 map space, and save them
in port1's read data space)
sra> sra -op port1 1 0 0 p 0x100000 (to see whether read data is correct)
```

NOTE

Currently, SRA is used to demonstrate IO related transaction functionalities, not include functionalities of Message unit and RMan, and not support Doorbell Mailbox Data-streaming transactions.

9.9.16.2 Revision History

Document revision history.

Table 303. Revision History

Version	Author	Description

9.9.17 USDPAA RMU User Manual

9.9.17.1 RapidIO Message Unit Application

This User Manual describes the NXP RapidIO Message Unit Linux user space driver, provides you with instructions about how to use RMU user space application.This user manual provides you with instructions about how to use RMU user space application.

9.9.17.2 Overview

NXP RapidIO Message Unit user space driver is implemented based on NXP Linux SDK. It is composed of Linux UIO driver in Linux kernel space and RMU driver/application in Linux user space. There is RMU UIO driver which maps RMU registers to Linux user space for user space driver. User space RMU driver provides interfaces for application, and application accomplishes the final RMU function. Currently, the RMU driver support two message units and one doorbell unit. The demo RMU application can implement RapidIO message and doorbell type protocols, and give performance data to evaluate NXP RMU IP block.

9.9.17.3 RMU Environment Setup

To run the RMU application, user needs to build an appropriate environment based on the requirements of hardware, software, RCW and other configurations.

9.9.17.3.1 Hardware Environment

To run RMU application demo, user needs two P4080DS boards connected with each other via SRIO cable as shown in Figure 1 (SRIO card locates in slot3 on P4080DS). Then update the RCW, U-Boot, Ucode to setup board environment.

For the RCW, user should burn RCW-0x16 on P4080DS (support 4 lanes for each RapidIO port, but only SRIO1 can be connected between two P4080DS boards with 4 lanes). The RCW can be found in SDK. P4080DS can also use RCW-0x1d to accomplish two boards connection via two rapidio 1x ports. This RCW is not included in SDK, user needs to generate it following the later RCW generation guide.

For P4080DS, when using RCW-0x16 for two SRIO ports connection between two boards, board's switch should be: sw3 is "0b01001100" (Serdes reference clock for bank1 is 125MHz, bank2 is 125MHz, bank3 is 125MHz).

Figure 293. SRIO Hardware Connection between Two Boards

9.9.17.3.2 SDK Installation

RMU is based on NXP Linux SDK. So to use RMU, make sure NXP Linux SDK is well installed.

9.9.17.3.3 RCW Generation

User can use the released RCW binaries in SDK or to create the specific RCW by NXP PBL tool.

serdes 0x16 RCW for P4080DS is :

```
00000000: aa55 aa55 010e 0100 105a 0000 0000 0000
00000010: 1e1e 181e 0000 cccc 5840 0000 3c3c 2000
00000020: fe80 0000 e100 0000 0000 0000 0000 0000
00000030: 0000 0000 008b 6000 0000 0000 0000 0000
00000040: 0000 0000 0000 0000 0813 8040 532a bb17
```

Save the above RCW data to rcw-0x16.xxd file and then convert to RCW image

```
$ xxd -r rcw-0x16.xxd > rcw-0x16.bin
```

serdes 0x1d RCW for P4080DS is :

```
0000000: aa55 aa55 010e 0100 0c58 0000 0000 0000
0000010: 1818 1818 0000 8888 7440 4000 0000 2000
0000020: fe80 0000 0100 0000 0000 0000 0000 0000
0000030: 0000 0000 0083 0000 0000 0000 0000 0000
0000040: 0000 0000 0000 0000 0813 8040 0129 56be
```

Save the above RCW data to rcw-0x1d.xxd file and then convert to RCW image

```
$ xxd -r rcw-0x1d.xxd > rcw-0x1d.bin
```

9.9.17.3.4 Kernel Building Configuration

When building kernel, make sure these options are selected.

```
Device Drivers  --->
          <*> Userspace I/O drivers  --->
                    <*> Freescale Rapidio Message Unit support
```

9.9.17.4 Boot

To run the RMU application, one must first boot Linux with the correct files. They include u-boot.bin, uImage, p4080ds-usdpaa.dtb and initramfs.cpio.gz.uboot. And please use the ucode and RCW file in the SDK package.

Following are some booting information points:

u-boot boot log:

```
POST memory PASSED
Flash: 128 MiB
L2:    128 KB enabled
Corenet Platform Cache: 2048 KB enabled
SRIO1: enabled
SRIO2: enabled
MMC:  FSL_SDHC: 0
```

Linux kernel boot log:

```
fsl-of-rmu ffe0d3000.rmu: rmu unit rmu-uio-msg0 initialized
fsl-of-rmu ffe0d3000.rmu: rmu unit rmu-uio-msg1 initialized
fsl-of-rmu ffe0d3000.rmu: rmu unit rmu-uio-doorbell initialized
```

9.9.17.5 RMU Demo

RMU is a demo application to implement NXP RapidIO message and doorbell functions. It can send message or doorbell package to the partner board, then the partner can display the received package. It can also evaluate the message and doorbell unit performance, and print out the result. Currently, it supports two message units and one doorbell unit, and uses message unit 0 and SRIO port 0 to implement performance tests. It will measure the message unit performance with different transmission data size.

As shown in Figure 1, RMU defines three areas for each message unit in DMA pool. They are:

Message Tx description map – all 32 entries for the message unit Tx description ring.

Message Tx buffer map – each buffer of the 32 entries loads the Tx data of message package.

Message Rx buffer map – every received message package will be saved to each of the 32 entries buffer.

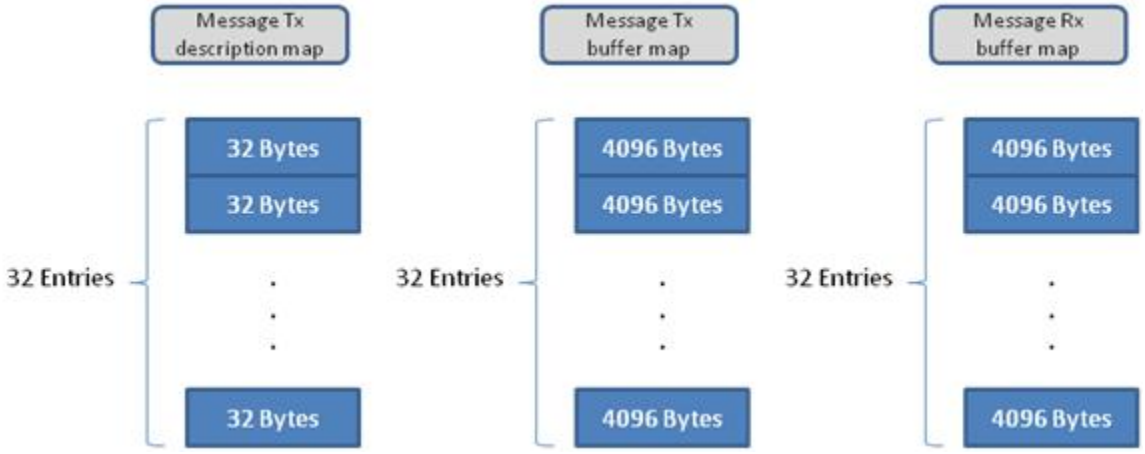

Figure 294. RMU each message unit DMA Pool Partition

The doorbell unit just needs one area in DMA pool for the received package, as shown in Figure 2.

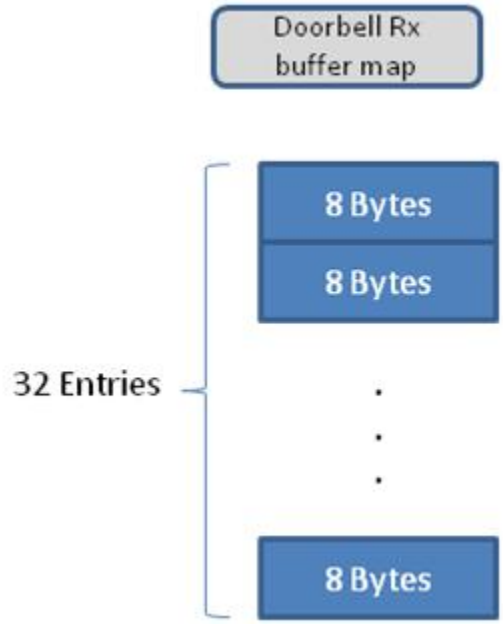

Figure 295. RMU doorbell unit DMA Pool Partition

9.9.17.6 RMU Commands

There are RMU command formats as followings. It will also display when you give the command " rmu help" or give a wrong command.

```
-----------------RMU APP CMD FORMAT-----------------
--Set Rmu Attribute--
rmu -attr [unit_name] [fun] [slot]
rmu -attr msg0/msg1/dbell  txdesc [slot]
rmu -attr msg0/msg1/dbell  txbuff [slot]
rmu -attr msg0/msg1/dbell  rxbuff [slot]
        -[unit_name]: msg0/msg1/dbell
        -[slot]: the slot of the buffer in the ring

--Do Rmu Operation--
rmu -op [unit_name] [operation] [port_id] [dest_id] [dest_mbox] [priority] [data] [data_len]
rmu -op msg0/msg1/dbell t/r/ar/s/p [port_id] [dest_id] [dest_mbox] [priority] [data] [data_len]
        -[operation]: t---tx a message or doorbell
                r---rx a message or doorbell and print
                ar---create a rx thread for the unit and print
                s---set next tx message buffer
                p---print next tx local buffer
        -[data]: for message should be u8 size
                for dbell should be u16 size
        -[data_len]: for message should be 8~4096 bytes
                for dbell should be equal 2 bytes

--Do Rmu Test and Print Performance Result--
rmu -test [case_name]
        -[case_name]: msg/dbell
----------------------------------------------------
```

As shown in the above print information, RMU commands consist of three formats:

-attr: Attribute printing serial. Print the buffers of the message or doorbell unit.

```
rmu -attr [unit_name] [fun] [slot]

    unit_name: which message or doorbell unit will be operated
               valid characters: msg0, msg1 or dbell

    fun: which buffer will be printed
         valid characters: txdesc, txbuff, rxbuff
         Note: The doorbell unit just has rxbuff.

    slot: which entry of the buffer in the 32 entries ring will be printed
          valid value: 0 ~ 31. Over 31 will print all the 32 entries

Example:

● Print the message unit 0 Tx description slot 0.

Command:
rmu> rmu -attr msg0 txdesc 0

Display:
ATTR: Msg0 Tx Desc ......
        cell size:32bytes; entries:32
        base virt addr:1000000; base phy addr:27000000
```

```
        desc 0; virt addr:1000000; phy addr:27000000
        01000000: 00000000 00000000 00000000 00000000
        01000010: 00000000 00000000 00000000 00000000
```

-op: Operate command serial. Accomplish sending, receiving, setting and other operations.

```
rmu -op [unit_name] [operation] [port_id] [dest_id] [dest_mbox] [priority] [data] [data_len]

    unit_name: which message or doorbell unit will be operated
               valid characters: msg0, msg1 or dbell

    operation: which operation will be implemented
               valid characters:
                     t – send a message or doorbell package
                     r – print the valid received package
                     ar – create a receive thread, it can receive and print the packages
continually
                     s – set next local Tx message buffer with a specific value
                     p – print next local Tx message buffer to verify the sending value
               Note: For each of the message units and doorbell unit, it has a 32
                     entries Rx buffer ring for all the received packages. Once
                     received a package, it will occupy a Rx buffer in the ring, the
                     buffer will be released and can be re-used after the reading
                     command. If no “r” or “ar” commands to release the used Rx
                     buffers, the message or doorbell unit can just receive 32
                     packages because of the 32 entries of the Rx buffer ring.

    port_id: which SRIO port the package will be sent through
             valid value: 0, 1
             Note: The used port must be enabled in RCW.

    dest_id: the device ID of the partner. Generally set it to 0

    dest_mbox: which mailbox of the partner will receive this package
               Valid value: 0, 1

    priority: the priority of the sending package
              valid value: 0, 1, 2
              Note: 0 is the lowest and the 2 is the highest.

    data: the value should be set or sent
          valid value: for message should be u8 size, for dbell should be u16 size

    data_len: how many bytes will be set or sent for the message package
              Note: Doorbell operations don't need this parameter.

Note: Different operation command needs different number of parameters! Followings
      are all the “-op” commands based on the msg0 and dbell.

Example:

● Send a message with msg0 to the partner’s mailbox.

Command:
rmu> rmu -op msg0 t 0 0 0 0 128

    -op: operation command
    msg0: [unit_name] - operate message unit 0
    t: [operation] - send a message package
```

```
    0: [port_id] - through the local SRIO port 0
    0: [dest_id] - the destination device ID is 0
    0: [dest_mbox] - send this package to the partner's mailbox 0
    0: [priority] - set the sending package's priority to 0
    128: [data_len] - The package payloads 128 bytes. It must be 8 ~ 4096 size.

Note: This command will send the data in the next msg0 Tx buffer. So if want to send
      a specific value, you need to accomplish "s" command first to set the Tx
      buffer.

● Print the next valid received message package for the msg0.

Command:
rmu> rmu -op msg0 r

    -op: operation command
    msg0: [unit_name] - operate message unit 0
    r: [operation] - Find the next available received message package and print

Note: If there is no available package in the Rx buffer ring, following information
      will display:

OP: next available rx message for msg0:
        message fetch failed!

● Create a receive thread for the msg0.

Command:
rmu> rmu -op msg0 ar 1

    -op: operation command
    msg0: [unit_name] - operate message unit 0
    ar: [operation] - Create a receive thread for the msg0
    1: [data] - 1: create the receive thread
                0: release the thread

Note: If create the receive thread successfully, you can see the following
      information:

OP: msg0 rx thread ...create success!

● Set next local Tx buffer for the msg0.

Command:
rmu> rmu -op msg0 s 0x5a 4096

    -op: operation command
    msg0: [unit_name] - operate message unit 0
    s: [operation] - Set a specific value to the next local Tx buffer of the msg0
    0x5a: [data] - the value to be set
    4096: [data_len] - set 4096 bytes

Note: For the message Tx buffer, [data] must be one byte size. The size of the Tx
      buffer is 4096 bytes, so the max length you can set is 4096. There will be the
      following information after the command:

OP: msg0 NEXT tx buffer SET, slot:0
        txbuff 0; virt addr:1020000; phy addr:27020000
        Slot 0 tx buff set down.
```

```
● Print the next local Tx buffer of the msg0 to verify the sending value.

Command:
rmu> rmu -op msg0 p 64

    -op: operation command
    msg0: [unit_name] - operate message unit 0
    p: [operation] - print the next local Tx buffer with specific printing size.
    64: [data_len] - just print 64 bytes of the Tx buffer.

Note: The max size of the Tx buffer is 4096, so the [data_len] should be equal or
      smaller than 4096. The following information will display after the command:

OP: msg0 NEXT tx buffer PRINT, slot:1
        txbuff 1; virt addr:1021000; phy addr:27021000
        01021000: 00000000 00000000 00000000 00000000
        01021010: 00000000 00000000 00000000 00000000
        01021020: 00000000 00000000 00000000 00000000
        01021030: 00000000 00000000 00000000 00000000

● Send a doorbell package to the partner.

Command:
rmu> rmu -op dbell t 0 0 0 0x5a5a

    -op: operation command
    dbell: [unit_name] - operate doorbell unit
    t: [operation] - send a doorbell package
    0: [port_id] - through the local SRIO port 0
    0: [dest_id] - the destination device ID is 0
    0: [priority] - set the sending package's priority to 0
    0x5a5a: [data] - the value to be doorbell package.

Note: The payload of the doorbell package must be 2 bytes.

● Print the next valid received doorbell package for the dbell.

Command:
rmu> rmu -op dbell r

● Create a receive thread for the dbell.

Command:
rmu> rmu -op dbell ar 1

Note: Dbell has no the "s" and "p" commands because it does not need the Tx buffers.
```

-test: Message unit or doorbell unit performance test commands.

```
rmu -test [case_name]

    case_name: which performance test will be done
               valid characters: msg, dbell

Note: It will use the msg0 for the message unit test. In order to avoid running out
      of the partner's Rx buffer, it's recommended to open the Rx thread in
      partner's board using the "ar" command.

Example:
```

```
● Message unit performance test.

Command:
rmu> rmu -test msg

The following information will display:

TEST: msg0 performance test ......
        txbuff 0; virt addr:1020000; phy addr:27020000
Slot 0 tx buff set down.
 length(byte): 8               time(us): 2.034187       avg Gb/s: 0.031462        max Gb/s:
0.032282

length(byte): 4096            time(us): 19.619639      avg Gb/s: 1.670163        max Gb/s:
1.670400

● Doorbell unit performance test.

Command:
rmu> rmu -test dbell

The following information will display:

TEST: dbell performance test ......
length(byte): 2               time(us): 1.361402       avg Gb/s: 0.011753        max Gb/s:
0.012175
```

9.9.17.7 Run RMU Demo

To run the RMU application, user needs to construct the environment based on the above information.

After the board get the RMU application binary, user should first run the RMU to initialize the two message units and one doorbell unit. If success, the following information will be printed:

```
root@p4080ds:~# ./rmu
RMU: msg0 uio initialized.
     -msg0desc ...
        cell size:32bytes; entries:32
        base virt addr:1000000; base phy addr:27000000
     -msg0txbuff ...
        cell size:4096bytes; entries:32
        base virt addr:1020000; base phy addr:27020000
     -msg0rxbuff ...
```

```
        cell size:4096bytes; entries:32
        base virt addr:1040000; base phy addr:27040000
RMU: msg1 uio initialized.
     -msg1desc ...
        cell size:32bytes; entries:32
        base virt addr:1000400; base phy addr:27000400
     -msg1txbuff ...
        cell size:4096bytes; entries:32
        base virt addr:1060000; base phy addr:27060000
     -msg1rxbuff ...
        cell size:4096bytes; entries:32
        base virt addr:1080000; base phy addr:27080000
RMU: doorbell uio initialized.
     -dbellrxbuff ...
        cell size:8bytes; entries:32
        base virt addr:1000800; base phy addr:27000800
rmu>
```

Then you can implement the RMU application commands under the “rmu>” prompt.

9.9.18 USDPAA SRIO IPSec Offload User Manual

9.9.18.1 Introduction

This document describes the usage of "srio_ipsec_offload" application which is built on USDPAA PPAC architecture. User can experience the functionality of using SRIO (Serial RapidIO) and RMAN with this application. In this application, it shows how to use DPAA technology to implement high performance autonomous ipsec with sRIO-Ethernet connection.

The concept of RMAN is beyond scope of this document. The user should refer to RMAN user manual for this part.

9.9.18.2 Overview of srio_ipsec_offlaod demo

This application is based on ipsec_offlaod(eth-eth) to support srio-eth connection. In this way, it shows how to use DPAA technology to implement high performance autonomous ipsec between srio and ethernet. It mainly supports below configuration:

•IPv4 autonomous /non-autonomous

•ESP tunnel mode

•Fragmentation & reassembly

•SRIO Msg Type9

9.9.18.2.1 Srio_IPSec_offload outbound flows

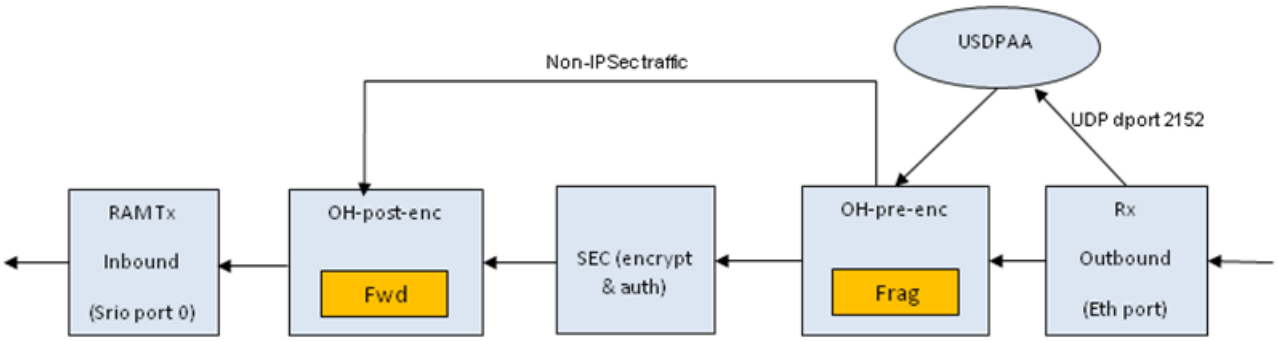

Figure 1 Outbound processing

Figure 296. Outbound processing

As srio_ipsec_offload application is based on ipsec_offlaod, regarding outbound processing, Please prefer to IPSec_offload outbound flows. The main difference in srio_ipsec_offload is that encrypted packets from post-encryption OH port will be directly sent to RMAN which adds RMan message descriptor to the headroom of each packet according to configuration (Message Type 9), and then directly sends them to SRIO port 0.

9.9.18.2.2 Srio_IPSec_offload inbound flows

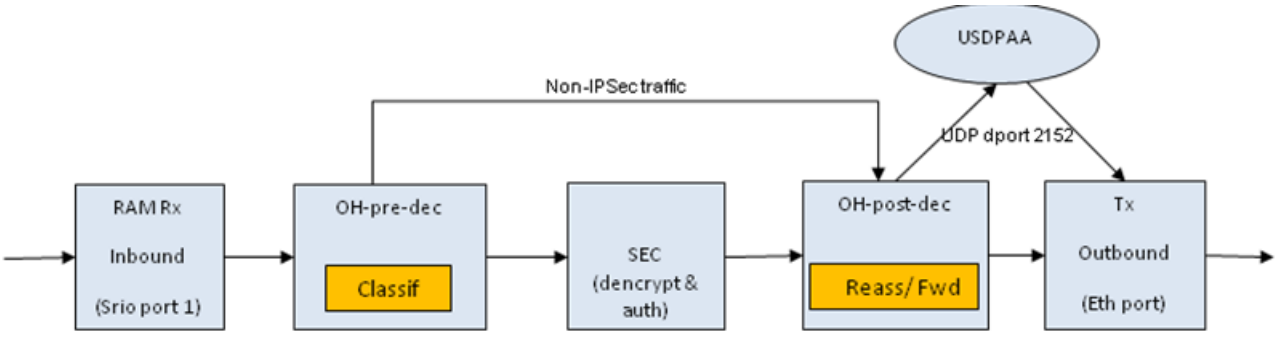

Figure 2 Inbound processing

Figure 297. Inbound processing

IPsec traffic (IPv4/IPv6 ESP and UDP-encap ESP) received on the inbound port srio 1 through RMAN is directly sent to pre-decryption OH port where the traffic is classified according to offloaded security associations. Frames for which a security association is found are sent to the appropriate SEC engine input queues for decryption/decapsulation; traffic for which a security association is not found is dropped. Non-IPsec traffic is directly sent to post-decryption OH port. Decrypted and non-IPsec traffic is reassembled if fragmented, and further a post IPsec classification which sends frames matching UDP destination port 2152 to USDPAA frame processing threads. Frames not matching UDP destination port 2152 have their Ethernet source and destination MAC addresses updated with Tx port MAC address and next hop MAC address respectively.

9.9.18.2.3 Limitations

The traffic load in outbound direction is not higher than 750Mbps.

This application doesn't support for restarting functionality.

9.9.18.3 Running srio_ipsec_offload

Before running this demo, please make sure some kernel options are enabled and the device tree used for this application is compiled. For more details, please refer to “Compiling the device tree and enabling kernel options”.

9.9.18.3.1 Application environment specifications

To simplify the test setup, it uses the similar environment as ipsec_offload, please refer to Application environment specifications in ipsec_offload. The application forwards traffic between one Ethernet port and two sRio ports. The one Ethernet is used for receiving clear packets, the other two srio ports process encrypted packets. Here two srio ports are connected with external line. So one srio port(srio 0) works as TX port, the other one(srio 1) as RX port. Like ipsec_offload , one port is configured as the protected interface-BP(eth port), the others as unprotected-BH(sRio port).Now it only supports on B4860QDS Platform.

9.9.18.3.2 Running srio_ipsec_offload

Srio_ipsec_offload only supports b4860qds platform at present. The rcw named N_RRSS_0x2A_0x7A is dedicated to using for this application. Before running this application, need to update this rcw in uboot. Use the steps described in Compiling the device tree for B4860 to generate a device tree binary file. Boot the board with the compiled kernel (arch/powerpc/boot/uImage) and the DTB file. To reserve memory for USDPAA and enable the scatter-gather support in the DPAA Ethernet driver add the following to the boot arguments: setenv othbootargs “fsl_fm_max_frm=9600" For setting up the USDPAA network configuration and PCD resources used by the application run the following commands:

```
export DEF_CFG_PATH="/usr/etc/srio_ipsec_offload_config_b4860.xml"
export DEF_PCD_PATH="/usr/etc/srio_ipsec_offload_pcd_b4.xml"
export DEF_SWP_PATH="/usr/etc/srio_ipsec_offload_swp.xml"
export DEF_PDL_PATH="/etc/fmc/config/hxs_pdl_v3.xml"
Start the application with the following commands:
/usr/bin/srio_ipsec_offload  \
-c /usr/etc/srio_ipsec_offload_config_b4860.xml\
-p /usr/etc/srio_ipsec_offload_policy.xml \
--vif macless0  --vof eth2   --vipsec eth3 -y -z --mtu-pre-enc 500
```

Notes: Interfaces vif, vof and vipsec may change due to different hardware configuration.

To disable ECN tunneling in outbound and inbound direction, following parameters are used:

```
-y Disable inbound ECN tunneling
```

```
-z Disable outbound ECN tunneling
```

The following arguments specify two Linux virtual interfaces associated with inbound and outbound Ethernet ports. These interfaces are used for adding neighboring entries used for Ethernet header update before transmission:

```
--vif virtual inbound interface index
```

```
--vof virtual outbound interface index
```

The following argument configures MTU for pre encryption fragmentation. Frames larger than this value will be fragmented prior encryption:

```
--mtu-pre-enc pre encryption MTU
```

9.9.18.3.3 Application configuration for IPsec

IPSec can be configured for offloading using setkey tool. To add an SA and two corresponding SPs add the following lines in a setkey.conf file:

```
flush;
spdflush;
add 192.168.100.1 192.168.200.1 esp 0x201
-E 3des-cbc "abcdefghipqrstuvwxyabcde"
-A hmac-sha1 "abcdefghipqrstuvwxya";
spdadd 172.16.0.1/32[any] 172.17.0.1/32[any] udp
-P out ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
spdadd 172.17.0.1/32[any] 172.16.0.1/32[any] udp
-P in ipsec esp/tunnel/192.168.100.1-192.168.200.1/require;
Now run the command:
setkey –f setkey.conf
```

These commands create an ESP tunnel with the following endpoints: IP src 192.168.100.1 – IP dst 192.168.200.1, SPI 0x201, 3DES-CBC encryption and HMAC-SHA1 authentication. The UDP traffic coming from 172.16.0.1 going to 172.17.0.1 will be tunneled using the defined tunnel.

To add neighboring entries for Ethernet header update run the following commands: ip neigh add 192.168.0.200 lladdr <inbound port MAC address> dev macless0 ip neigh add 172.17.0.1 lladdr <next hop MAC address> dev eth2

9.9.18.3.4 Running Traffic

Assuming that the traffic is generated with a directly connected Linux box, you need to configure the Linux box to output frames for 172.16.0.1 on the connected interface (ethX):ifconfig <ethX> 172.16.0.2 netmask 255.255.0.0 up

You can use the hping tool to generate UDP packets and tcpdump to capture traffic on interface ethX. Each sent frame should be returned by the application. hping -2 -s 2150 -p 2150 -c 1 172.17.0.1

At any point you can use the following commands to show packet and byte statistics

- sa_stats <sa-id>

This command shows the statistics for a particular SA

- ipsec_stats 0

This command shows the global IPSec statistics. This includes the miss counters for the inbound and outbound direction.

9.9.18.4 Compiling the device tree and enabling kernel options

9.9.18.4.1 Compiling the device tree for B4860

Go to your Linux kernel source code directory.

```
cp drivers/staging/fsl_dpa_offload/dts/b4860si-pre.dtsi
arch/powerpc/boot/dts/fsl
cp drivers/staging/fsl_dpa_offload/dts/b4860si-chosen-offld.dtsi
arch/powerpc/boot/dts/fsl/b4860si-chosen.dtsi
cp drivers/staging/fsl_dpa_offload/dts/b4860qds-usdpaa-srio-eth-shared-interfaces.dts
arch/powerpc/boot/dts
scripts/dtc/dtc –f –b 0 –p 1024 –I dts –O dtb –o b4860qds-usdpaa-srio_eth_shared-mac.dtb
arch/powerpc/boot/dts/b4860qds-usdpaa-srio-eth-shared-interfaces.dts
```

The DTB file b4860qds-usdpaa-srio_eth_shared-mac.dtb will be built in the current directory.

9.9.18.4.2 Enabling DPA Offloading and RMAN Drivers in the Linux Kernel

Regarding srio_ipsec_offload, it need two srio ports, some options related to them should be selected as below.

```
Device Drivers  --->
         <*> Userspace I/O drivers  --->
                    <*>   Freescale Serial RapidIO support
          [*] Staging drivers  --->
                    [*]   Freescale RapidIO Message Manager support
                    [*]   Freescale Datapath Offloading Driver
```

Chapter 10
Boot Loaders

10.1 Primary Protected Application (PPA) User's Guide

10.1.1 Introduction

10.1.1.1 Rationale and Scope

This document is the Specification and Users Guide for a loadable secure services firmware component running in TrustZone. This component, called the Primary Protected Application (PPA), has the following characteristics:

- Is loaded into the secure side of an ARM core early in the boot process
- Remains resident after boot
- Provides secure services for boot software and runtime software
- Contains a Secure Monitor, which controls access to/from the secure world
- Implements services behind a std abstract interface (published by ARM)
- Has the secure world exception vectors and handlers
- Is the focal point for implementing the Platform Security Policy

Each of these will be discussed in detail in the sections that follow. Although secure boot and other boot components such as bootloaders and bootrom will be mentioned here, this specification is not intended to exhaustively cover secure boot, bootloaders (such as UEFI and U-boot), or bootrom code.

The phrase “secure world’, used heavily in this doc, refers to ARM TrustZone, *and vice-versa*. The phrase “secure monitor” refers to the ARM v8 definition of a software entity that runs at EL3 and controls access to/from the secure world. Do not confuse “secure monitor” in this context with “security monitor”, which is a hardware component of the QorIq Trust Architecture.

There are a number of compelling reasons for having a resident secure services layer:

1. The secure services layer is first-and-foremost a focal point for implementation of a Platform Security Policy.
2. ARM cores come out of reset executing in the secure world.
3. The non-secure world needs an agent to perform tasks in the secure world
4. The PSCI interface, which is ARM’s abstract power mgmt interface, runs in the secure world.
5. A resident secure firmware can streamline bootloaders, making it easier to support multiple bootloaders.
6. The PPA is the foundation upon which a deeper TrustZone software stack can be built.

10.1.1.3 Definitions

AP – Application Processor, same as GPP

ATF – ARM Trusted Firmware

Bootloader – FW that loads the OS kernel (uboot, uefi)

ESBC – External Secure Boot Code, image validation code in the bootloader

GPP – General Purpose Processor

ISBC – Internal Secure Boot Code, image validation code in the bootrom

OCRAM – On-Chip RAM

PPA – Primary Protected Application, the secure monitor and associated functions that comprise the base EL3 sw foundation

Protected – Higher-privilege sw, such as a hypervisor

PSCI – Power State Coordination Interface, an ARM std interface

Secure – SW or components that are isolated by the TrustZone architecture

Secure Monitor – the SW running at EL3 that controls the gateway from the non-secure world to the secure world

Security Monitor – a HW feature of the QorIQ Trust Architecture

SCP

SMC – an ARM instruction which generates an exception, *and* an ARM std interface based on that excepton call

SP – Service Processor, an auxiliary core that performs initial boot functions on the SoC

TPM – Trusted Platform Module, a specification of the Trusted Computing Group

Trusted Architecture (TA) – a security architecture found in the QorIq family of SoCs, including the ARM-based QorIq products

TrustZone (TZ) – an isolation context provided as part of the ARM architecture; an infrastructure for building secure subsystems

10.1.2 Boot Flow Architecture

10.1.2.1 LS1043A PPA Boot Flow

Component Load Sequence

1. GPP Bootrom loads/validates* 1st stage bootloader
2. 1st stage bootloader loads/validates* 2nd stage bootloader
3. 1st stage bootloader loads/validates* PPA
4. 2nd stage bootloader loads/validates* kernel

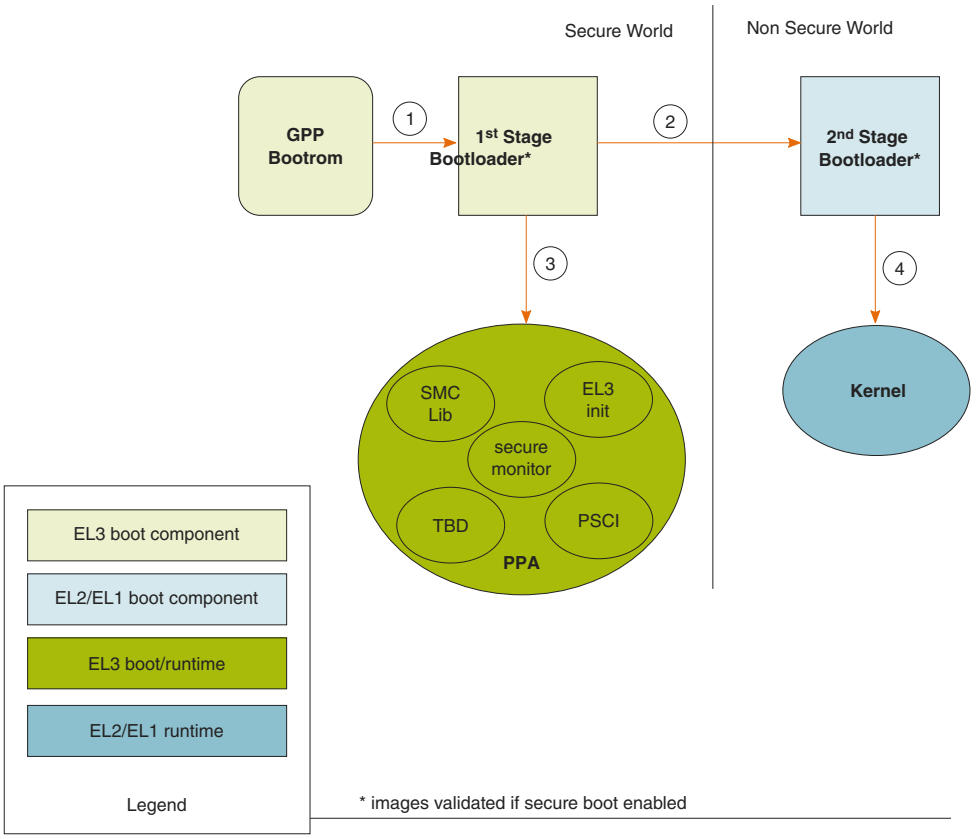

Figure 298. Component Load Sequence

Boot execution Order

1. Execution begins in the PBI State Machine when the SoC comes out of reset
2. After PBI, execution starts with bootcore in GPP bootrom
3. Bootcore branches to 1st stage bootloader running in EL3
4. Bootcore in 1st stage bootloader branches to EL3 init code in PPA
5. When bootcore completes EL3 init, it branches to 2nd stage bootloader in EL2
6. Bootcore in 2nd stage bootloader branches to Linux kernel in EL1
7. Kernel calls PSCI (cpu_on) to release secondary cores (LS1043A only)

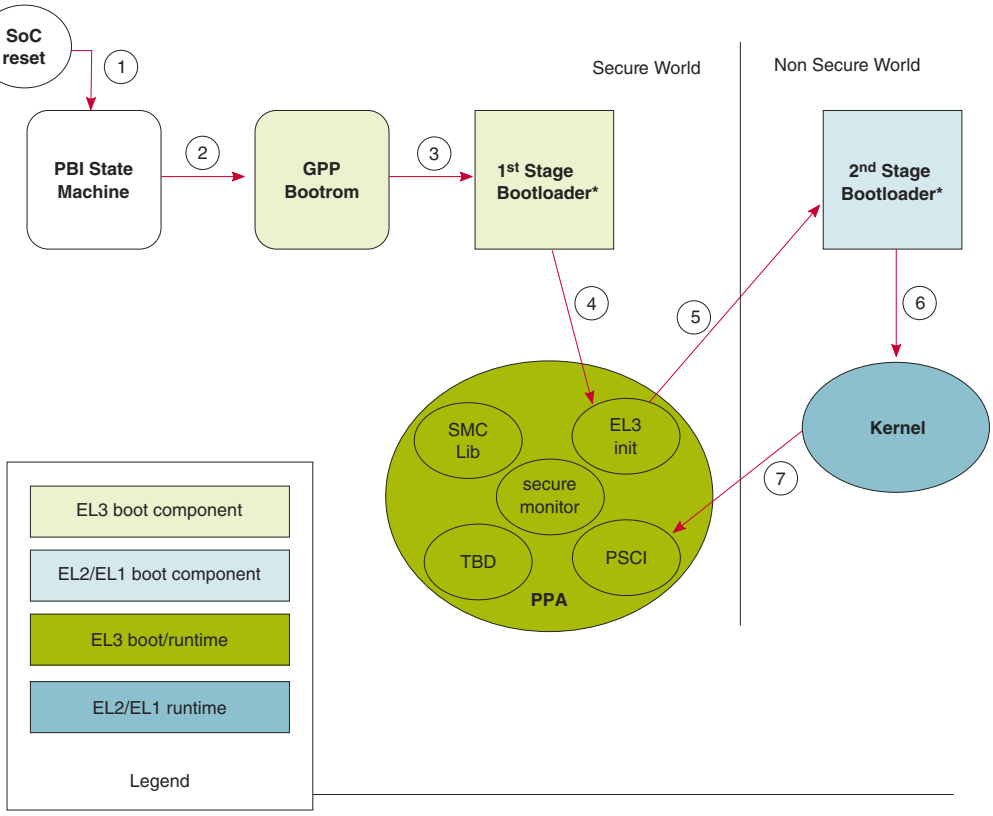

Figure 299. Boot Execution Order

Secondary core execution path

1. Execution starts in the GPP bootrom when secondary core released from reset
2. If core is marked to be disabled, core enters power-down sequence in bootrom
3. Cores not disabled branch to EL3 init code in PPA
4. Upon completion of EL3 init, cores branch to start address at EL2 in kernel

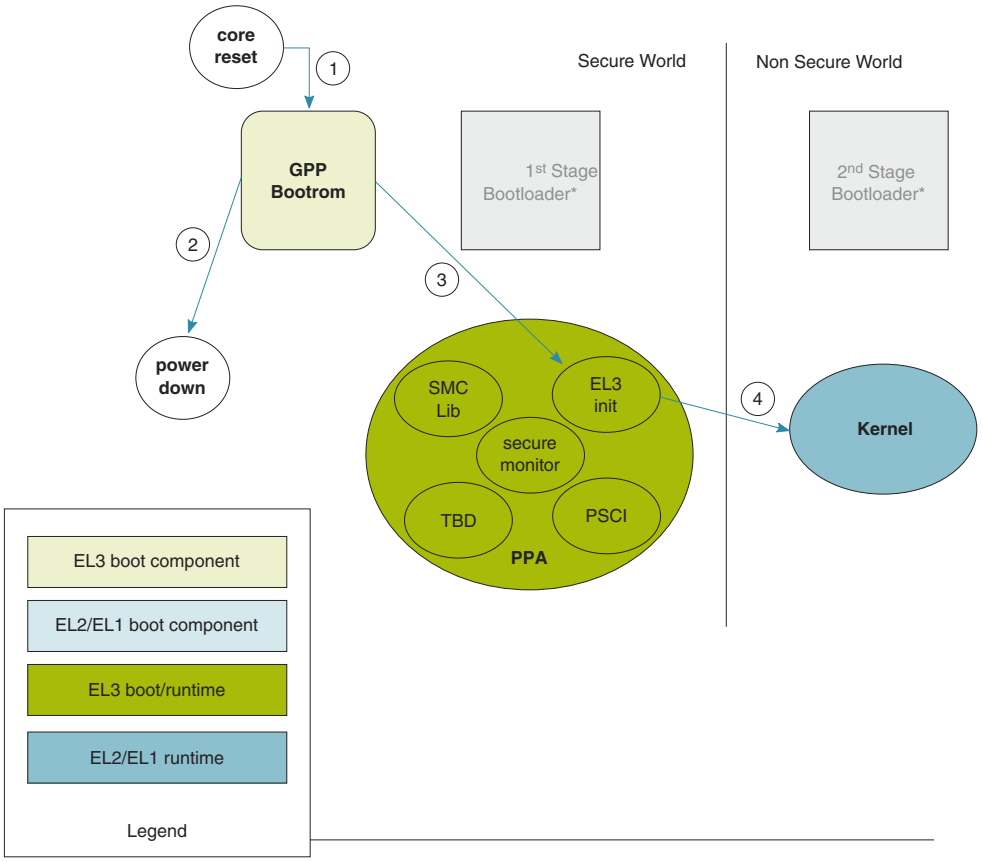

Figure 300. Secondary Core Execution Path

10.1.2.2 LS1043A/LS1012A Boot Flow

Component Load Sequence

1. GPP Bootrom loads/validates* 1st stage bootloader
2. 1st stage bootloader loads/validates* 2nd stage bootloader
3. 1st stage bootloader loads/validates* PPA
4. 2nd stage bootloader loads/validates* kernel

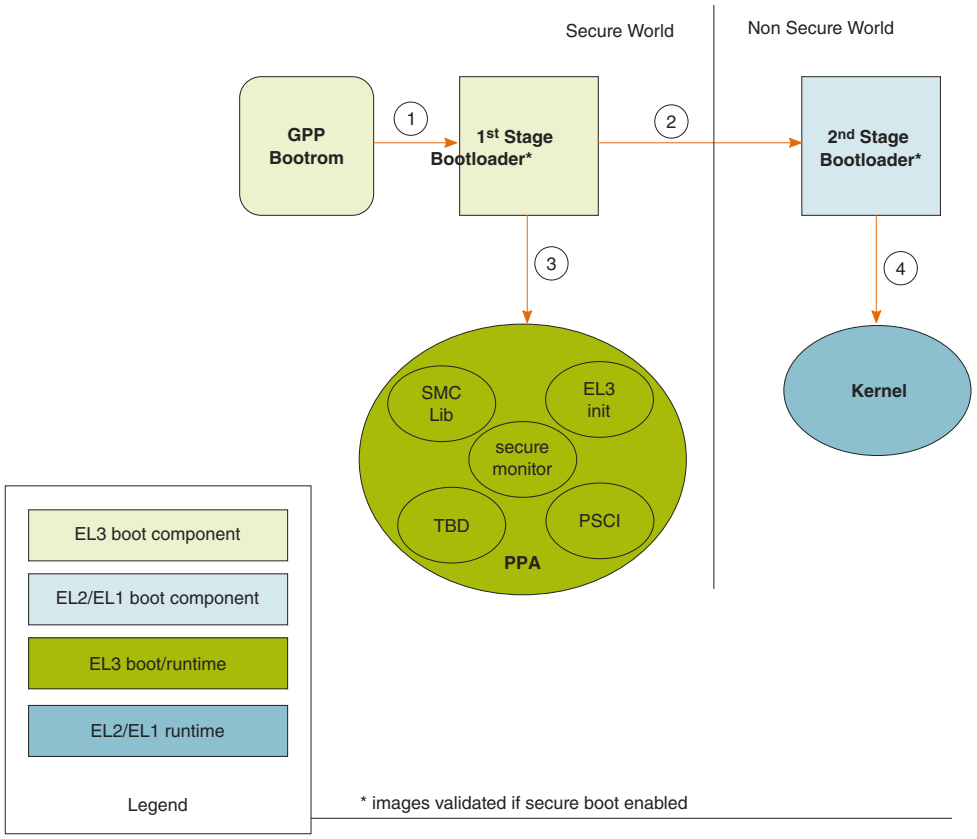

Figure 301. Component Load Sequence

Boot execution Order

1. Execution begins in the PBI State Machine when the SoC comes out of reset
2. After PBI, execution starts with bootcore in GPP bootrom
3. Bootcore branches to 1st stage bootloader running in EL3
4. Bootcore in 1st stage bootloader branches to EL3 init code in PPA
5. When bootcore completes EL3 init, it branches to 2nd stage bootloader in EL2
6. Bootcore in 2nd stage bootloader branches to Linux kernel in EL1
7. Kernel calls PSCI (cpu_on) to release secondary cores (LS1043A only)

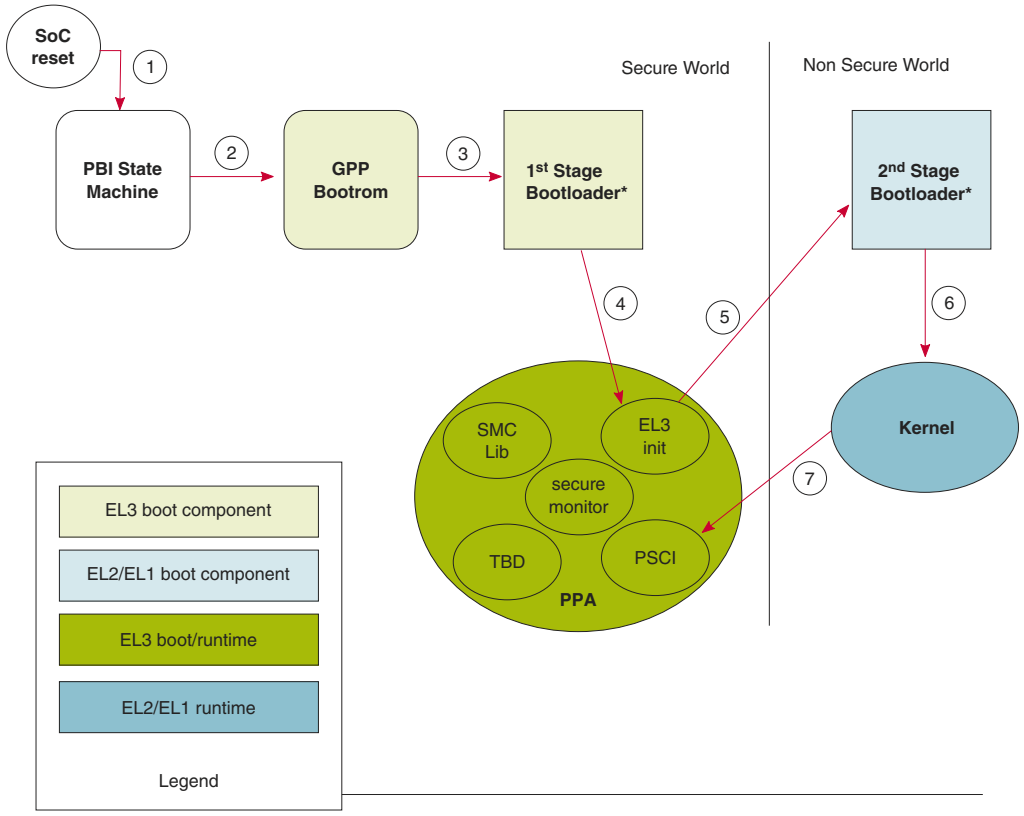

Figure 308. Boot Execution Order

Secondary core execution path

1. Execution starts in the GPP bootrom when secondary core released from reset
2. If core is marked to be disabled, core enters power-down sequence in bootrom
3. Cores not disabled branch to EL3 init code in PPA
4. Upon completion of EL3 init, cores branch to start address at EL2 in kernel

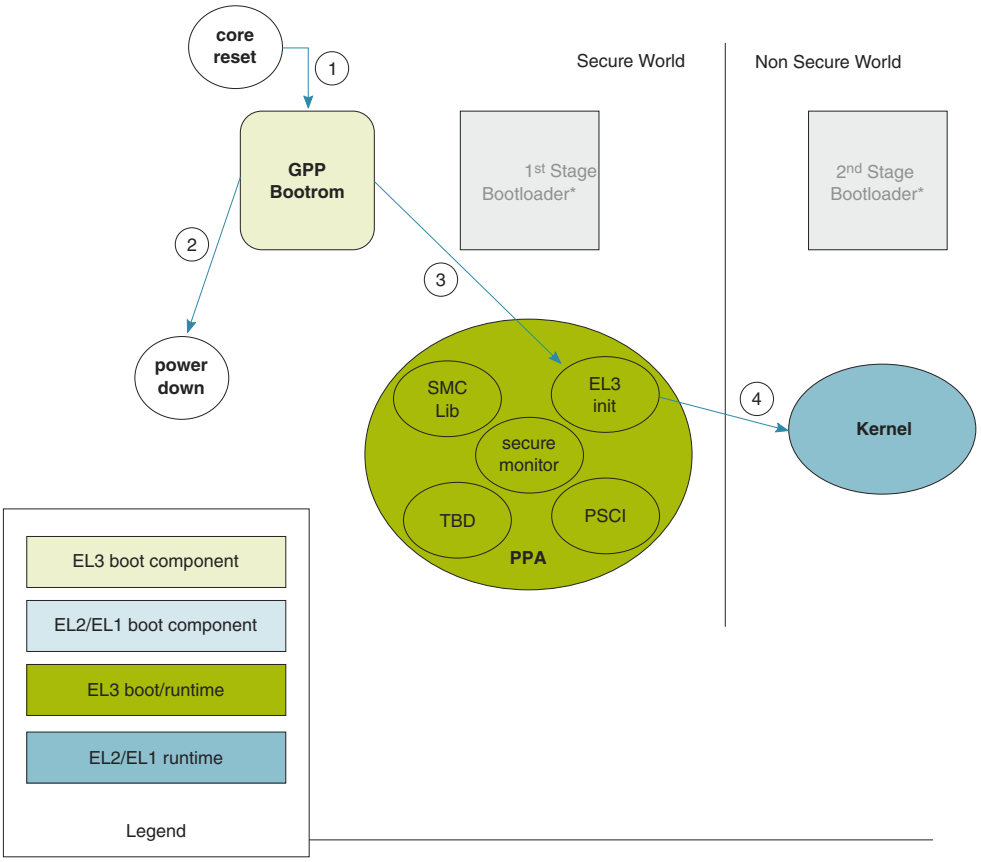

Figure 309. Secondary Core Execution Path

10.1.3 Loading and Initializing the PPA

- The PPA must be loaded to a 64Kb boundary
- Copy the binary image to the load address – the component installing the PPA MUST be executing at EL3
- PPA should be loaded to an address in secure memory - recommend a 2MB secure region in DDR (but PPA can be tested in non-secure DDR)
- After copying the image file to DDR, clean the data cache by VA (all virtual address ranges affected by PPA load) , and invalidate the instruction cache
- The PPA initialization runs at EL3 – but the PPA transfers control back to the address loaded in BOOTLOCPTR **at EL2** – you must write the start address of the EL2 portion of your bootloader into BOOTLOCPTR *before* initializing the PPA
- After writing the EL2 start address in BOOTLOCPTR, initialize the PPA by branching to its start address

10.1.4 How to Call SMC/PSCI functions

- SMC functions obey the ARM ABI
- SMC functions treat registers x0-x12 as volatile, all others are preserved
- To call an SMC/PSCI function, load the registers according to the table below, then execute an “SMC 0x0” instruction
- If the function specifies a return value, it will be found in register x0

- Return values, including error returns, are returned in x0
- The “SMC 0x0” instruction generates an exception – after the exception is processed in the secure monitor (when the SMC function has completed), control will return to the instruction following the “SMC 0x0”
- Please refer to [2] for more details of the SMC calling convention
- Note: currently, only SMC “fast calls” are implemented (including PSCI). This means that while the calling core is in the secure world, interrupts to the core are masked.

SMC input parameters:

Register	Meaning
X0	*Function ID* (see Section 5, 6)
X1	*First optional parameter*
X2	*Second optional parameter*
X3	*Third optional parameter*

SMC return values:

Register	Meaning
X0	*Return value, Error return code*

10.1.5 PSCI Function List

Please see [11] for details of the PSCI function interface. Keep in mind that the PSCI interface is a subset of the SMC Calling Convention [2].

10.1.5.1 PSCI_VERSION

Get the Version number of this PSCI implementation.

Function ID: 0x8400_0000

Input parameters:

Register	Meaning
X0	*Function ID*
No other inputs	

Return values:

Register	Meaning
X0 bits[31:16]	*Major Version Number*
X0 bits [15:0]	*Minor Version Number*

Currently, the PSCI v0.2 specification is implemented. Thus, the *Major Version Number* returned is 0x0, and the *Minor Version Number* returned is 0x2.

10.1.5.2 CPU_ON

Release a secondary core from reset, or from the CPU_OFF state.

Function ID: 0xC400_0000

Input Parameters:

Register	**Meaning**
X0	*Function ID*
X1	*Target CPU, in MPIDR format (see [11])*
X2	*Start address (Physical)*
X3	*Context ID*

Return Values:

Register	**Return Code** (see 5.8)
X0	SUCCESS
“	INVALID_PARAMETERS
“	ALREADY_ON
“	ON_PENDING
“	INTERNAL_FAILURE

NOTE

When cores are delivered to the *Start Address*, they will be executing at EL2.

10.1.5.3 CPU_OFF

Power down the calling core.

Function ID: 0x8400_0002

Input Parameters:

Register	**Meaning**
X0	*Function ID*

Return Values:

Register	**Return Code** (see 5.8)
Function does not return if successful	
X0	DENIED

Note that this function is called on the core that is to be powered down. There is no mechanism to power down one core from another core. By definition, a power-down state is a state without retention, so the caller must save whatever state is needed when the core resumes execution.

The only way to restart a core after a call to *CPU_OFF* is with a call to *CPU_ON*.

If successful, this function does not return.

10.1.5.4 CPU_SUSPEND

Put the calling core/cluster/system into a low-power state.

Function ID: 0xC400_0001

Input Parameters (see [11]):

Register	**Meaning**
X0	*Function ID*
X1	*Power_State*
X2	*Start_Address (Physical)*
X3	*Context_Id*

Return Values:

Register	**Return Code** (see 5.8)
X0	SUCCESS
“	INVALID_PARAMETERS

Note that this function is called on the core/cluster/system that is to be suspended. There is no mechanism to suspend one core from another core. There are two available power states, *Standby* and *Power-Down* (see [11]).

For cluster low-power states, all cores of the cluster except this final core must already be in the requested power state. The function checks to see if this is the “last core standing” of the cluster – if it is the last core, the core is suspended along with the cluster. If this function is called when there is more than one active core in the cluster, the function will return with the INVALID_PARAMETERS value in x0.

Likewise for system power-down, the function checks to see if this is the last active gpp core in the SoC. If it is the last active core, then the core is suspended along with the SoC. If it is not the last active core, then the function returns with the error value INVALID_PARAMETERS in x0.

The input parameters to this function describe a complex interface. Please see [11] for details of how to use this function call.

If successful, this function does not return.

10.1.5.5 AFFINITY_INFO

Get information about a specific affinity level.

Function ID: 0xC400_0004

Input Parameters (see [11]):

Register	**Meaning**
X0	*Function ID*
X1	*Target_Affinity*
X2	*Lowest_Affinity*

Return Values:

Register	Return Codes (see 5.8, 5.8.1)
X0	ON_PENDING
“	OFF
“	ON
“	INVALID_PARAMETERS
“	NOT_PRESENT
“	DISABLED

10.1.5.6 SYSTEM_OFF

Power down the entire system.

Function ID: 0x8400_0008

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

The function does not return.

10.1.5.7 SYSTEM_RESET

Perform a hard reset on the entire system.

Function ID: 0x8400_0009

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

The function does not return.

10.1.5.8 PSCI Return Code Values

Mnemonic	Value
SUCCESS	0
NOT_SUPPORTED	-1
INVALID_PARAMETERS	-2
DENIED	-3

Table continues on the next page...

Table continued from the previous page...

ALREADY_ON	-4
ON_PENDING	-5
INTERNAL_FAILURE	-6
NOT_PRESENT	-7
DISABLED	-8

PSCI Return Codes Specific to Affinity_Info

Mnemonic	Value
ON	0
OFF	1
ON_PENDING	2

10.1.5.9 PSCI Functions Implemented, by SoC

	LS1012A	LS1043A	LS1046A	LS2088A
CPU_ON	N/A	✓	✓	✓
CPU_OFF	N/A	✓	✓	WIP
AFFINITY_INFO	✓	✓	✓	✓
CPU_SUSPEND	WIP	✓	✓	WIP
PSCI_VERSION	✓	✓	✓	✓
SYSTEM_RESET	✓	✓	✓	WIP
SYSTEM_OFF	X	X	X	X

10.1.6 SMC Function List

Please see [2] for details of the SMC function interface.

10.1.6.1 Function Count - SMC64

Return the number of functions implemented by the smc64 interface, including this function and PSCI functions using this interface.

Uses smc64 interface.

Function ID: 0xC200_FF00

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

Register	Value
X0	*Smc64 function count*

10.1.6.2 Function Count - SMC32

Return the number of functions implemented by the smc32 interface, including *this* function and PSCI functions using this interface.

Uses smc32 interface.

Function ID: 0x8200_FF00

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

Register	Value
X0	*Smc32 function count*

10.1.6.3 Get UUID

Return the 128-bit UUID uniquely identifying this SMC implementation.

Uses the smc32 interface.

Function ID: 0x8200_FF01

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

Register	Value
X0	Bytes [3:0] of UUID
X1	Bytes [7:4] of UUID
X2	Bytes [11:8] of UUID
X3	Bytes [15:12] of UUID

10.1.6.4 Get Revision

Return the major and minor revision numbers of the SIP portion of this SMC implementation.

Uses smc32 interface.

Function ID: 0x8200_FF03

Input Parameters:

Register	Meaning
X0	*Function ID*

Return Values:

Register	Value
X0	Major revision number of sip-smc
X1	Minor revision number of sip-smc

10.1.7 Building the PPA

In the SDK, the PPA image will be built as part of the Yocto recipe.

10.1.8 System Considerations When Calling SMC & PSCI Functions

There is always the possibility that malware will attempt to execute an SMC. The affects of this may be mitigated with three methods:

1. Insure that calling an smc/psci function can *never* corrupt the machine
2. Insure that calling an smc/psci function can *never* lower the security stance of the machine
3. Provide *only* one place in the system, a kernel driver, from which *all* smc calls are made

Items (1) & (2) mean that even if malware successfully makes an smc call, the effects of that call will not open the system up to an attack. Take careful note of item (2) – this means that any EL3 configuration that lowers the security of the system must be set in **the PPA initialization phase**, and *not* as a dynamic smc function.

Item (3) allows the PPA to determine if an unauthorized access has been attempted. Since the smc call generates an exception, the register ELR_EL3 is loaded, by hw, with the return address of the caller. If there is only one place in the system where smc calls are made from, then the PPA can be configured to register the return address. Malware, attempting to make an smc call, will have a different return address. The secure monitor in the PPA can detect this different return address, and reject the request. In addition, the secure monitor can return to the authorized return address with a security violation error. To enable this capability in later revisions of the PPA, the kernel developer should implement a kernel driver where all smc calls are made from.

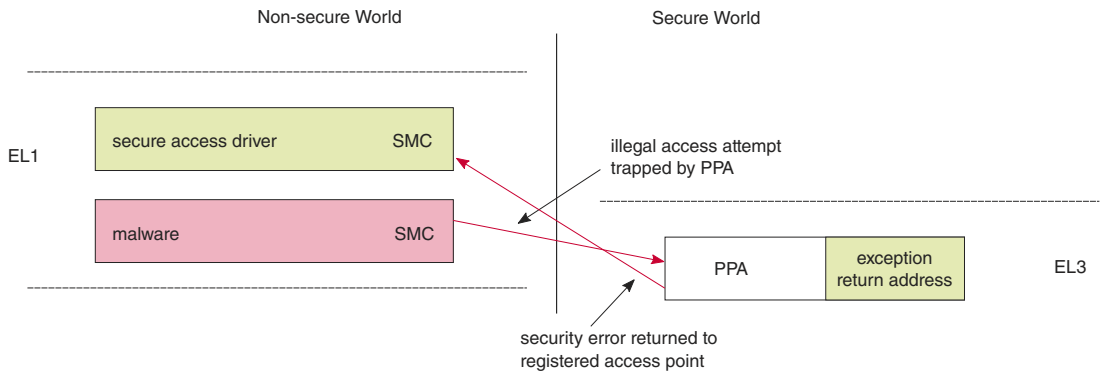

Figure 310. System Considerations When Calling SMC and PSCI Functions

10.2 U-Boot

10.2.1 eSPI/SD/NAND Boot

Description

The Corenet Soc integrates a pre-boot-loader(PBL) which performs configuration registers read and write to initialize external memory devices such as I2c, eLBC FCM (NAND flash), eSDHC, or SPI interface, loads RCW and/or pre-boot initialization commands from those devices before the local cores are permitted to boot.

Specifications

Target board:	NXP CoreNet board
CPU:	NXP P2041E/P3041E/P4080E/P5020E/P5040E/T1024/T1040/T4240/T2080/B4860
Software:	U-boot 2014.01+

Introduction

The QorIQ SoC is capable of booting from eSPI/SD/NAND besides NOR boot. The bootup process can be divided into two stages:

1. PBL loads boot Image from eSPI/SD/NAND, the boot Image contains three parts, the first is RCW, the second is PBI commands, the third is the u-boot image. During the load process, PBL will do:

```
load the RCW first;
```

```
load the PBI commands to write configuration registers, e.g. to initialize SPI interface, and
configure CPC as SRAM;
```

```
load U-boot image to the CPC.
```

2. U-boot will run in the CPC and then boot up to U-Boot prompt.

Note: for T4240/T2080(with 512KB CPC) and T1024/T1040(with 256KB CPC), CPC are not big enough to store the U-boot since the U-boot size is 768KB, a two-stage boot is introduced which produces two U-boot images, the first stage u-boot is loaded to CPC, and run in CPC, which will init DDR and load the second stage u-boot to DDR, then jump to DDR to boot up to U-boot command line.

Test Procedure

The creation of such a PBL image requires:

1. a known working RCW, taken from the QorIQ SDK release.
2. the QorIQ Configuration Suite (QCS) PBL tool.

```
QCS can be downloaded from  http://www.nxp.com/QCVS
```

```
Install QCS and review its documentation before proceeding
```

3. a U-boot image for booting from eSPI flash, SD Card or NAND flash, built from the QorIQ SDK release.

Building the U-boot images

In the following example procedure the SoC is a P2041 with the RCW taken from the QorIQ SDK release.

In the SDK installation folder, go to the build folder for the chosen target machine:

```
$ cd build_p241rdb_release
$ source ./SOURCE_THIS
$ bitbake -c cleansstate u-boot
$ bitbake -f u-boot
```

This will produce all supported U-boot images for the target machine in build_p2041rdb_release/tmp/work/p2041rdb-fsl-linux/u-boot-git-r<xx>/image/boot:

```
$ ls -gG | sort
lrwxrwxrwx 1 37 Mar 18 15:41 u-boot-nand.bin -> u-boot-nand-P2041RDB_NAND-git-r27.bin
lrwxrwxrwx 1 37 Mar 18 15:41 u-boot-sd.bin -> u-boot-sd-P2041RDB_SDCARD-git-r27.bin
lrwxrwxrwx 1 39 Mar 18 15:41 u-boot.bin -> u-boot-P2041RDB_SECURE_BOOT-git-r27.bin
lrwxrwxrwx 1 40 Mar 18 15:41 u-boot-spi.bin -> u-boot-spi-P2041RDB_SPIFLASH-git-r27.bin
-rwxr-xr-x 1 524288 Mar 18 15:41 u-boot-nand-P2041RDB_NAND-git-r27.bin
-rwxr-xr-x 1 524288 Mar 18 15:41 u-boot-P2041RDB-git-r27.bin
-rwxr-xr-x 1 524288 Mar 18 15:41 u-boot-P2041RDB_SECURE_BOOT-git-r27.bin
-rwxr-xr-x 1 524288 Mar 18 15:41 u-boot-sd-P2041RDB_SDCARD-git-r27.bin
-rwxr-xr-x 1 524288 Mar 18 15:41 u-boot-spi-P2041RDB_SPIFLASH-git-r27.bin
```

Note: for T4240/T2080/T1040/T1042, the two stage boot produces two U-boot images, one is u-boot.bin, another is u-boot-spl.bin under directory spl.

```
$ ls u-boot.bin spl/u-boot-spl.bin
spl/u-boot-spl.bin  u-boot.bin
```

Generating the PBL image

Create a new QorIQ Configuration Project for SoC. Example procedure the SoC is a P2041

- In the wizard choose:

```
P2041 SoC
```

```
Silicon revision 1.0
```

```
PBL - Preboot Loader RCW Configuration Component
```

```
select the proposed RCW Hard-coded configuration
```

- Once the project is created, open a Component Inspector window for the **PBL1:PBL** component
- In the **Import** tab:

```
Select the Binary input format
```

```
Hit the Browse button to choose a QorIQ SDK release pre-build RCW
```

```
Hit the Import button
```

```
The message "Successfully Imported" appears, if the RCW contains any PBI data, it will also be
imported.
```

- In the **Properties** tab change the following properties:

```
Reset Configuration Word (RCW)->RCW Source
```

```
Boot Configuration->PBI_SRC = 0b0110 - SD/MMC (change PBI_SRC are per requirmenet, For SPI 24-
bit it is 0b0101)
```

```
Boot Configuration->BOOT_LOC = 0b10000 - Memory Complex 1
```

Note:

For T208xRDB:

PBI_SRC need to set to 0b1110 - IFC.

BOOT_LOC need to set to 0b11000 - IFC.

IFC_MODE need to set to 0b100000100 - 8-bit NAND Flash.

SD/SPI/NAND boot use the same settings.

For T2080QDS:

PBI_SRC need to set to 0b1110 - IFC.

BOOT_LOC need to set to 0b10000 - Memory Complex.

IFC_MODE need to set to 0b100000100 - 8-bit NAND Flash.

SD/SPI/NAND boot use the same settings.

NOTE

Note: The RCW bits might need to be change as per requirement or SoC. Please refer to Hardware document for details.

- Putting together the PBI data

```
Go to the PBI Data input -> PBI Data input property
```

```
Click on the Value field then on the ellipsis dots [...] button on the right
```

```
The PBI Data Input panel is now shown, if the RCW imported above has any PBI commands, they
will be shown in the panel;
```

Append the common PBI commands below into the text panel:

```
PBI Commands (Lines started with '#' is a comment):

Below are common PBI commands for P-series SoCs which have 1MB CPC.
#Clear CPC1
09010000 00200400
09138000 00000000
091380c0 00000100
#Initialize CPC1 as 1MB SRAM
09010100 00000000
09010104 fff0000b
09010f00 08000000
09010000 80000000
#Configure LAW for CPC1
09000d00 00000000
09000d04 fff00000
09000d08 81000013
#Initialize eSPI controller
09110000 80000403
09110020 2d170008
09110024 00100008
09110028 00100008
0911002c 00100008
#Configure alternate space
09000010 00000000
09000014 ff000000
09000018 81000000
#Flush data
09138000 00000000
091380c0 00000000

For T-/B-series SoCs (with 512 KB CPC SRAM) :
#Initialize CPC1
09010000 00200400
09138000 00000000
091380c0 00000100
#512KB SRAM
09010100 00000000
09010104 fff80009
09010f00 08000000
#enable CPC1
09010000 80000000
#Configure LAW for CPC1
09000d00 00000000
09000d04 fff80000
09000d08 81000012
#Initialize eSPI controller
```

```
09110000 80000403
09110020 2d170008
09110024 00100008
09110028 00100008
0911002c 00100008
#Configure alternate space
09000010 00000000
09000014 ff000000
09000018 81000000
#Flush PBL data
09138000 00000000
091380c0 00000000

For T-series SoCs like T1040 (with 256 KB CPC SRAM)
#Initialize CPC1
09010000 00200400
09138000 00000000
091380c0 00000100
#Configure CPC1 as 256KB SRAM
09010100 00000000
09010104 fffc0007
09010f00 081e000d
09010000 80000000
#Configure LAW for CPC1
09000cd0 00000000
09000cd4 fffc0000
09000cd8 81000011
#Configure alternate space
09000010 00000000
09000014 ff000000
09000018 81000000
#Configure SPI controller
09110000 80000403
09110020 2d170008
09110024 00100008
09110028 00100008
0911002c 00100008
#Flush PBL data
091380c0 000FFFFF
```

Hit the **Apply** button

NOTE

The PBI commands stated above are for reference. Ensure to change only required register bits. The register settings might change as per SoC. Hardware document should be refer for details.

- Insert the u-boot image file:

```
Select ACS File (data from binary file) then file Browse appears.
```

```
For P-series SoCs:
```

```
Change Offset: 0xf40000
```

```
Browse to File: u-boot-sd.bin
```

```
For T4240/T2080/T1040 SoCs:
Change offset: 0xfd000 (will change to 0xfd8000 if U-boot version is 2014.04+)
Browse to File: u-boot-spl.bin

Hit the Add button, then the Apply button
```

- Select and click Add for these 2 PBI commands:

```
Flush
```

```
Wait
```

```
Hit the Apply button
```

NOTE

Note: Some devices like T1040, B4860 does not support FLUSH command for SD-boot, SPI-boot. In that cases FLUSH command should be replaced with WAIT command. Refer to hardware document for details

- In **Properties** tab goto **PBL data->Output Format** property, click value field and select **Binary**.

```
From the QCS menu, click on Project -> Generate Processor Expert Code  button.
```

```
The generated file can be found in the QCS project under : Generated Code -> PBL1.bin
```

Preparing the external memory for booting

Two images must be programmed in the external memory : the PBL image and the FMan microcode image. Copy both images to the TFTP server directory, so they are available for download by U-boot.

Procedure for eSPI flash:

-
```
All operations are done on the target board in the u-boot console.

For P-series SoCs:

1) write PBL1.bin to eSPI from offset 0x0

=>tftp 100000 PBL1.bin
=>sf probe 0
=>sf erase 0 100000
=>sf write 100000 0 $filesize

For T-series SoCs:
need to write two Images, the first is the PBL1.bin produced by QCS tool, the second is the u-
boot.bin.
```

```
1.1) write PBL1.bin at offset 0:

=>tftp 100000 PBL1.bin
=>sf probe 0
=>sf erase 0 100000
=>sf write 100000 0 $filesize

1.2) write u-boot.bin at offset 0x40000 (256KB):

=>tftp 100000 u-boot.bin
=>sf write 100000 40000 $filesize

2.1) write fman ucode to eSPI from offset 0x110000

=>tftp 100000 fsl_fman_ucode_xx.bin
=>sf erase 110000 10000
=>sf write 100000 110000 $filesize

2.2) write CS4315 PHY ucode.txt to eSPI from offset 0x120000 (only for T2080RDB/T4240RDB)

=>tftp 100000 cs4315-ucode.txt
=>sf erase 120000 40000
=>sf write 100000 120000 $filesize

3) power down board
4) Change board switch configuration.

P3041/P4080/P5020/P5040: SW1[1:5] = '00101'.
P2041:                   SW1[1:5] = '10100'.
T2080/T1040:                   SW1[1:8] = '00100010', SW2[1] ='1'.

5) power on board
```

Procedure for SD card:

-

```
All operations are done on the target in the U-boot console

For P-series SoCs:

1) write PBL1.bin to SD card from offset block 8

=>tftp 100000 PBL1.bin
=>mmcinfo
=>mmc write 100000 8 block_number

2) write fman ucode to SD card from offset 1680(0x690)

=>tftp 100000 fsl_fman_ucode_xx.bin
=>mmc write 100000 690 block_number

For T-series SoCs:

need to write two Images, the first is the PBL1.bin produced by QCS tool, the second is the u-
boot.bin.

1.1)write PBL1.bin at offset block 8:
```

```
=>tftp 100000 PBL1.bin
=>mmcinfo
=>mmc write 100000 8 block_number

1.2)write u-boot.bin at offset 0x41000 (260KB), e.g. 520(0x208) blockes (For T4240QDS, the
offset is 0x200, it's changed to 0x208 in 2014.04+).

=>tftp 100000 u-boot.bin
=>mmc write 100000 208 block_number

2.1) write fman ucode to SD card from block 0x820

=>tftp 100000 fsl_fman_ucode_xx.bin
=>mmc write 100000 820 block_number

2.2) write CS4315 ucode to SD from block 0x8a0 (only for T2080RDB/T4240RDB)

=>tftp 100000 CS4315-ucode.txt
=>mmc write 100000 8a0 200

3) power down board
4) Change board switch configuration

P3041/P4080/P5020/P5040: SW1[1:5] = '00110'.
P2041:                   SW1[1:5] = '01100'.
T4240(FPGA V3 or later): SW1[1:8] = '00100000'; SW2[1] = '0'; SW7[4] = '1'.
T2080/T1040:                   SW1[1:8] = '00100000', SW2[1] = '0'.

5) power on board

Note: the block_number is HEX of ($filesize - 1) /512 + 1.
```

Procedure for NAND flash:

- ```
  All operations are done on the target in the U-boot console

  For P-series SoCs:

  1) write PBL1.bin to NAND from offset 0x0.

  =>tftp 100000 PBL1.bin
  =>nand info
  =>nand erase 0 e0000
  =>nand write 100000 0 $filesize

  2) write fman ucode to NAND from offset 0x100000

  =>tftp 100000 fsl_fman_ucode_xx.bin
  =>nand erase 100000 20000
  =>nand write 100000 100000 $filesize

  For T4240QDS/T2080QDS(NAND block size is 128KB):

  1.1) write PBL1.bin to NAND from offset 0x0.

  =>tftp 100000 PBL1.bin
  =>nand info
  =>nand erase 0 40000
  =>nand write 100000 0 $filesize
  ```
  ```

```
1.2) write u-boot.bin to NAND from offset 0x40000 (256KB).
=>tftp 100000 u-boot.bin
=>nand info
=>nand erase 40000 c0000
=>nand write 100000 40000 $filesize

2) write ucode.bin to NAND from offset 0x160000.
=>nand info
=>tftp 100000 ucode.bin
=>nand erase 160000 20000
=>nand write 100000 160000 $filesize

For T2080RDB, T104xD4RDB(NAND block size is 512KB):

1.1) write PBL1.bin to NAND from offset 0x0.

=>tftp 100000 PBL1.bin
=>nand info
=>nand erase 0 100000
=>nand write 100000 0 $filesize

1.2) write u-boot.bin to NAND from offset 0x40000 (256KB).
=>tftp 100000 u-boot.bin
=>nand write 100000 40000 $filesize

2.1) write fman ucode to NAND from offset 0x180000.
=>nand info
=>tftp 100000 fsl_fman_ucode_xx.bin
=>nand erase 180000 80000
=>nand write 100000 180000 $filesize

2.2) write CS4315 PHY ucode to NAND from offset 0x200000 (only for T2080RDB/T4240RDB).
=>nand info
=>tftp 100000 CS4315-ucode.txt
=>nand erase 200000 80000
=>nand write 100000 200000 $filesize

3) power down board
4) Change board switch configuration

P3041/P5020/P5040: SW1[1:5] = '01001'.
                   SW7[1:4] = '1001'.
p2041:             SW1[1:5] = '10010'.
T4240QDS/T2080QDS: SW1[1:8] = '10000010', SW2[1.1] = '0', SW6[1:4] = '1001'.
T2080RDB:          SW1[1:8] = '10000010', SW2[1] = '1', SW3[4] = '1'.
T1040(or personality) RDB boards:         SW1[1:8] = '10001000', SW2[1] = '0', SW3[4] = '1'.

5) power on board
```

Known Bugs, Limitations, or Technical Issues

- Provided steps for building PBL images with some reference settings. Hardware document should be refer for exact setting for particular SoC, board

Supporting Documentation

10.2.2 Corenet DS Boards Boot up from SRIO/PCIE User Manual

Description

For some PowerPC processors with SRIO or PCIE interface, boot location can be configured to SRIO or PCIE by RCW. The processor booting from SRIO or PCIE can do without flash for u-boot image, UCode and ENV. All the images can be fetched from another processor's memory space by SRIO or PCIE link connected between them. This UM describes the processes based on an example implemented on P4080DS platforms and RCW examples with boot from SRIO or PCIE configuration.

Specifications

Target board:	NXP Corenet DS boards (P2041/P3041/P4080/P5020/T2080/T4240/B4860)
CPU:	NXP P2041/P3041E/P4080E/P5020E/T2080/T4240/B4860
Software:	U-boot 2012.10+

Environment

Two Corenet DS boards connected with SRIO/PCIE cable, one is Master and the other is Slave. Only Master has NorFlash for booting, and all the Master's and Slave's U-Boot images, UCodes will be stored in this flash. Slave's NorFlash has been programmed only for its RCW.

Make-Config Options

Option	Description
make P4080DS_config	Compile Master U-Boot image for SRIO or PCIE Boot
make P4080DS_SRIO_PCIE_BOOT_config	Compile Slave U-Boot image for SRIO or PCIE Boot

Slave's RCW for boot from SRIO or PCIE

All cores in holdoff and Slave will boot from SRIO port 1	All cores in holdoff and Slave will boot from PCIE port 1
00000000: aa55 aa55 010e 0100 0c58 0000 0000 0000 00000010: 1818 1818 0000 8888 7440 4000 0000 2000 00000020: f440 0000 0100 0000 0000 0000 0000 0000 00000030: 0000 0000 0083 0000 0000 0000 0000 0000 00000040: 0000 0000 0000 0000 0813 8040 063c 778f	00000000: aa55 aa55 010e 0100 0c58 0000 0000 0000 00000010: 1818 1818 0000 8888 1440 4000 0000 2000 00000020: f040 0000 0100 0000 0020 0000 0000 0000 00000030: 0000 0000 0083 0000 0000 0000 0000 0000 00000040: 0000 0000 0000 0000 0813 8040 547e ffc9

Test Procedure

- **Update RCW for Slave with boot from SRIO or PCIE port 1 and all cores in holdoff configurations.**

  We can update the RCW in Slave's NorFlash for the test, and should ensure the Slave can get RCW from its local NorFlash. For the boards can be booted up from vbank 0, vbank 2 or bank 4, we can update the RCW in the vbank 2 or vbank 4 and implement the SRIO/PCIE boot in vbank 2 or vbank 4.

  Note: Currently just B4860 platform should be implemented from vbank2, and all others should be implemented from vbank4.

- **Update Master's U-Boot image compiled normally.**

  Update this U-Boot image for Master's vbank 2 or vbank 4 boot space.

- **Program Slave's U-Boot image, UCode and ENV parameters into master's NorFlash.**

Slave's U-Boot image should be compiled with the "make P4080DS_SRIO_PCIE_BOOT_config". Based on the configurations in file "include/configs/corenet_ds.h" or "include/configs/B4860QDS.h" or other relative header files, we should write all the Slave's images from these addresses into Master's NorFlash:

Write Slave's U-Boot image from 0xeb240000 (P4080DS) or 0xed240000 (B4860QDS) in Master's NorFlash when Master has been started up in vbank 0 environment.

```
P4080DS:

tftp 1000000 tftpboot/u-boot.bin.slave;erase eb240000 eb2fffff;cp.b 1000000 eb240000 c0000

B4860QDS:

tftp 1000000 tftpboot/u-boot.bin.slave;erase ed240000 ed2fffff;cp.b 1000000 ed080000 c0000
```

Write Slave's UCode from 0xeb100000 (P4080DS) or 0xed100000 (B4860QDS) in Master's NorFlash when Master has been started up in vbank 0 environment.

```
The size of the UCode is 64k bytes.
```

Write Slave's ENV from 0xeb120000 (P4080DS) or 0xed120000 (B4860QDS) in Master's NorFlash when Master has been started up in vbank 0 environment.

```
The size of the ENV is 128k bytes.
```

- **Set environment variable "bootmaster" to "SRIO1" or "PCIE1" and save this variable for master's vbank 2 (B4860QDS) or vbank 4 (P4080DS) boot space.**

```
        setenv bootmaster SRIO1

      or

        setenv bootmaster PCIE1

        saveenv
```

- **Power down the Master and Slave boards after all the configurations described above.**

  When set all cores in holdoff by RCW, we should power on the Slave board first, and it will implement the configurations based on the RCW and then wait to be released by Master.

- **Power on the Slave board and switch to the vbank 4 (P4080DS) or vbank 2 (B4860QDS), the board will wait to be released because of all the cores in holdoff.**

- **Power on the Master board and switch to the vbank 4 (P4080DS) or vbank 2 (B4860QDS), it will finish some necessary configurations and then release Slave's core 0.**

  Master will boot up normally from its NorFlash. Then it will finish necessary configurations for slave's boot from SRIO or PCIE port 1 and release Slave's core 0 by SRIO or PCIE interface. When the core 0 is released, Slave will fetch U-Boot image, UCode and ENV from Master's NorFlash by SRIO or PCIE interface.

  If has opened the debug messages, Master will give some information about the SRIO or PCIE boot when starting up:

SRIOBOOT - MASTER: Port [ 1 ] is ready, now release slave's core ...

SRIOBOOT - MASTER: Release slave successfully! Now the slave should start up!

MMC:  FSL_ESDHC: 0

.........
```

Important Note

- For the Master board, do not need to rebuild an image when change the SRIO or PCIE port for boot from SRIO/PCIE, just using the same U-Boot image and set the corresponding value to "bootmaster" based on the SRIO or PCIE port used for the boot. For example, you can set and save the environment variable "bootmaster" with "SRIO1", "SRIO2" or "PCIE1", "PCIE2", "PCIE3". And in addition, do not forget to update the RCW for Master based on your selection.
- For the Slave board, do not need to rebuild an image when change the SRIO or PCIE port for boot from SRIO/PCIE, just using the same U-Boot image and rewrite the new RCW with selected port, then the code will get the port information by reading new RCW and configure the port automatically.

Known Bugs, Limitations, or Technical Issues

- Because the Slave cannot erase, write master's Norflash by SRIO or PCIE interface, so it also cannot modify the ENV parameters stored in Master's Norflash using "saveenv" or other commands.
- It is very important to ensure that all master and slave RapidIO or PCIE ports are correct. If the SRIO link has been initialized and worked well, then reboot master or slave will result in an error state of the partner's RapidIO port. This error is most likely caused by the mismatching of the AckIDs on the both sides of the link, and will result in a link failure.

  In order to make the SRIO link recover and work well:

  1. If master and slave are directly connected, when reboot one, the other must also be rebooted.

  2. If master and slave are indirectly connected, for example switch chip is used in the RapidIO system, when reboot one, another must be responsible for the link back to normal, or reboot the entire system.

  PCIE link has no this issue.
- For the P2041RDB board, the SRIO lanes should be reconfigured to right slot by CPLD commands; But when the slave is in hold-off mode, we cannot implement those reconfigurations. So the P2041RDB cannot support Boot from SRIO.

10.3.1 Hardware PreBoot Loader (PBL) Based Platforms

10.3.1.1 Introduction

This document is intended for end-users to demonstrate the image validation process. The image validation can be split into stages, where each stage performs a specific function and validates the subsequent stage before passing control to that stage. In the example, the ESBC is NXP* provided reference code referred to as ESBC uboot.

Chain of Trust

ESBC uboot performs minimal SoC configuration before validating the Next Executable using the same CSF header format as the ISBC used to validate ESBC Uboot. The CSF Header and signature are added to the Next Executable using the NXP Code Signing Tool.

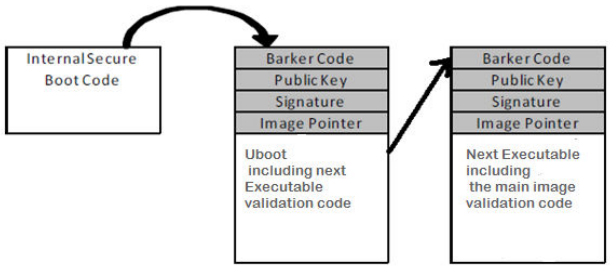

Figure 311. Chain of Trust

Chain of Trust with confidentiality

The validated ESBC uboot image is allowed to use the One Time Programmable Master Key to decrypt system secrets. Cryptographic blob mechanism is used to establish Chain of trust with confidentiality.

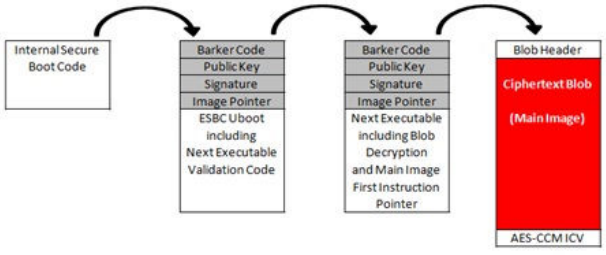

Figure 312. Chain of Trust with confidentiality

This document provides more details on the secure boot flow, ISBC, ESBC and NXP Code signing tool.

NOTE

NXP and Freescale may be used synonymously in this document. Registers, register file names, and Trust Architecture software may not be updated to NXP for an extended period of time.

10.3.1.2 Secure boot Process

Secure boot process uses a digital signature validation routine already present in INTERNAL BOOT ROM. This routine performs validation using HW bound RSA public key to decrypt the signed hash and compare it to a freshly calculated hash over the same system image. If the comparison passes, the image can be considered as authentic.

The complete process can be broken down into following phases:

- Pre Boot Phase
  1. PBL
  2. SFP
- ISBC
- ESBC

The Complete Secure boot Process is shown in the Figure below.

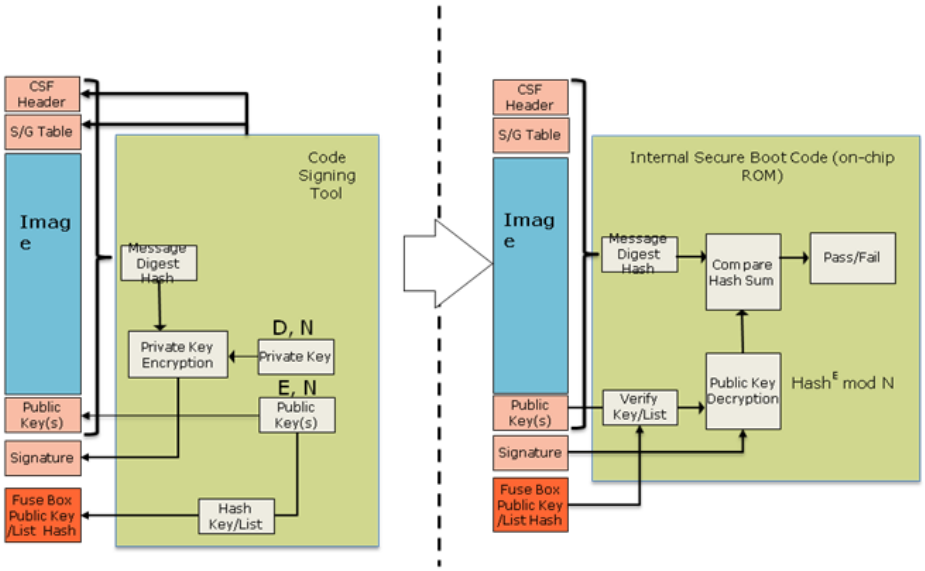

Figure 313. Secure Boot Process

10.3.1.3 Pre-Boot Phase

When the processor is powered on, reset control logic blocks all device activity (including scan and debug activity) until fuse values can be accurately sensed. The most important fuse value at this stage of operation is the 'Intent to Secure' (ITS) bit. When an OEM sets ITS, they intend for the system to operate in a secure and trusted manner.

The two main components involved during this process are :

The security fuse processor (SFP) has two roles. The first is to physically burn fuses during device provisioning. The second is to use these provisioned values to enforce security policy in the pre-boot phase, and to securely pass provisioned keys and other secret values to other hardware blocks when the system is in a trusted/secure state.

PreBoot Loader (PBL) is the micro-sequencer that can simplify system boot by configuring the DDR memory controllers to more optimal settings and copying code and data from low speed memory into DDR. This allows subsequent phases of boot to operate at higher speed. The setting of ITS determines where the PBL is allowed to read and write. The use of the PBL is mandatory when performing secure boot. At a minimum, the PBL must read a command file from a location determined by the Reset Configuration Word (RCW) and perform a store of a value to the ESBC Pointer Register within the SoC. If the PBL doesn't perform this operation (or sets the ESBC pointer to the wrong value), the ISBC will fail to validate the ESBC. Once the PBL has completed any operations defined by its command file, the PBL is disabled until the next Power on Reset and the Boot Phase begins.

Some example PBI commands used in the demo are given below. The commands are embedded in the RCW's mentioned in the SDK Images required for the demo

 */
```

The ISBC is capable of reading from NOR flash connected to the Local Bus, on-chip memory configured as SRAM, or main memory. Unless the ESBC is stored in NOR flash, the developer is required to create a PBL Image that copies the image to be validated from NVRAM to main memory or internal SRAM prior to writing the SCRATCHRW1 Register and executing the ISBC code.

To assist with the creation of PBL Images (for both normal and Trust systems), NXP offers a PBL Image Tool.

Note that it is possible for an attacker to modify the board to direct the PBL to the wrong non-volatile memory interface, or change the PBL Image and CSF Header pointer, however this will result in a secure boot failure and the system remaining in an idle loop indefinitely.

10.3.1.4 ISBC Phase

10.3.1.4.1 Flow in the ISBC Code

With the PBL disabled and all external masters blocked by the PAMUs, CPU 0 is released from boot hold-off and begins executing instructions from a hardwired location within the Internal BootROM. The instructions inside the Internal BootROM are NXP developed code known as the Internal Secure Boot Code (ISBC). The ISBC leads CPU 0 to perform the following actions:

1. **Who am I check?** - CPU 0 reads its Processor ID Register, and if it finds any value besides physical CPU 0, the CPU enters a loop. This insures that only CPU 0 executes the ISBC.
2. **Sec_Mon check** - CPU 0 confirms that the Sec_Mon is in the Check state. If not, it writes a ‘fail’ bit in a Sec_Mon control register, leading to a state transition.
3. **ESBC pointer read** - CPU 0 reads the ESBC Pointer Register, and then reads the word at the indicated address, which is the first word of the Command Sequence File Header which precedes the ESBC itself. If the contents of the word don’t match a hard coded preamble value, the ISBC takes this to mean it has not found a valid CSF and cannot proceed. This leads to a fail, as described in #2 above.

4. **CSF parsing and public key check** - If CPU 0 finds a valid CSF header, it parses the CSF header to locate the public key to be used to validate the code. There can be a single public key or a table of 4 public keys present in the header. The Secure Fuse Processor doesn't actually store a public key, it stores a SHA-256 hash of the public key/table of 4 keys. This is done to allow support for up to 4096b keys without an excessively large fuse block. If the hash of the public key fails to match the stored hash, secure boot fails.
5. **Signature validation** - With the validated public key, CPU 0 decrypts the digital signature stored with the CSF header. The ISBC then uses the ESBC lengths and pointer fields in the CSF header to calculate a hash over the code. The ISBC checks that the CSF header is included in the address range to be hashed. Option flags in the CSF header tell the ISBC whether the NXP Unique ID and the OEM Unique ID (in the Secure Fuse Processor) are included in the hash calculation. Including these IDs allows the image to be bound to a single platform. If the decrypted hash and generated hash don't match, secure boot fails.
6. **ESBC First Instruction Pointer check** - One final check is performed by the ISBC. This check confirms that the First Instruction Pointer in the CSF header falls within the range of the addresses included in the previous hash. If the pointer is valid, the ISBC writes a 'PASS' bit in a Sec_Mon command register, the state machine transitions to 'Trusted', and the OTPMK is made available to the SEC.
7. In case of failure , for Trust v2.0 devices , secondary flag is checked in the CSF header. If set, ISBC reads the CSF header pointer form SCRATCHRW3 location and repeats from step 4.

There are many reasons the ISBC could fail to validate the ESBC. Technicians with debug access can check the SCRATCHRW2 Register to obtain an error code. For a list of error codes refer ISBC Validation Error Codes.

10.3.1.4.2 Super Root keys (SRKs) and signing keys

These are RSA public and private key pairs. Private keys are used to sign the images and public keys are used to validate the image during ISBC and ESBC phase.

Public keys are embedded in the header and the hash of srk table is fused in SRKH register of SFP.

These are Hardware Bound Keys, once the hash is fused the public private key pair can't be modified.

Keys of sizes 1k, 2k and 4k are supported in FSL Secure Boot Process.

It is the OEM's responsibility to tightly control access to the RSA private signature key. If this key is ever exposed, attackers will be able to generate alternate images that will pass secure boot.

If this key is ever lost, the OEM will be unable to update the image.

10.3.1.4.3 Key Revocation

Trust Architecture 2.x introduces support for revoking the RSA public keys used by the ISBC to verify the ESBC. The RSA public keys used for this purpose are called super root keys.

OEM can use either a single key or a list of upto 4 super root keys in the Trust Arch v2.x devices.

In the NXP Code Signing Tool (CST), the OEM defines whether the device uses a single super root key, or offers a list of super root keys. If using a single super root key, a new flag bit in the CSF header will indicate "Key", otherwise the flag will indicate "Key List". Assuming key list, the OEM can populate a list of up to 4 super root keys for trust arch v2.x onwards platforms . And calculates a SHA-256 hash over the list. This hash is written to the SRKH registers in the SFP.

As part of code signing, the OEM defines which key in the key list is to be used for validating the image. This key number is included as a new field in the CSF header.

During secure boot, the ISBC determines whether a key list is in use. If the key list is valid, the ISBC checks the key number indicated in the CSF header against the revocation fuses in the SFP's OEM Security Policy Register (SFP_OSPR). If the key is revoked, the image validation fails.

NOTE

In order to prevent unauthorized revocation of keys, SFP provides a bit (Write Disable). If the bit is set, the Key revocation bits cannot be written to.

In regular operation, the ESBC (early Trusted S/W) needs to set the SFP Write Disable bit. When circumstances call for revoking a key, the OEM will use an ESBC image with “Write Disable” bit not set. So, the SFP will be in a state in which key revocation fuses can be set.

Logically after revoking the required key(s), the OEM would then load a new signed ESBC image with code to set the "Write Disable" bit, with new CSF header indicating which of the remaining non-revoked key to use.

So, only the possessor of a legitimate RSA private key can enable key revocation.

One possible motivation for an OEM to revoke a super root key is the loss of the associated RSA private key to an attacker. If the attacker has gained access to a legitimate RSA private key, and the attacker can turn on power to the fuse programming circuitry, then the attacker could maliciously revoke keys. To prevent this from being used to permanently disable the system, one super root key does not have an associated revocation fuse.

10.3.1.4.4 Alternate Image Support

Trust 2.0 onwards will support a primary and alternate image, where failure to find a valid image at the Primary location will cause the ISBC to check a configured alternate location.

To execute, the alternate image must be validated using a non-revoked public key as defined by its CSF Header. A valid alternate image has same rights and privileges as a valid primary image.

This feature helps to reduce risk of corrupting single valid image during firmware update or as a result of Flash block wear-out.

To enable this feature, create PBI with pointers for both Primary and Alternate Images (HW PBL uses SCRATCHRW1 & SCRATCHRW3).

10.3.1.4.5 ESBC with CSF Header

ESBC is the generic name for the code that the ISBC validates. A few ESBC scenarios are described in later sections.

The figure below provides an example of an ESBC with CSF (Command Sequence File) Header. The CSF Header includes lengths and offset which allow the ISBC to locate the operands used in ESBC image validation, as well as describe the size and location of the ESBC image itself.

Note: CSF Header and ESBC Header may be used synonymously in this and other NXP Trust Architecture documentation.

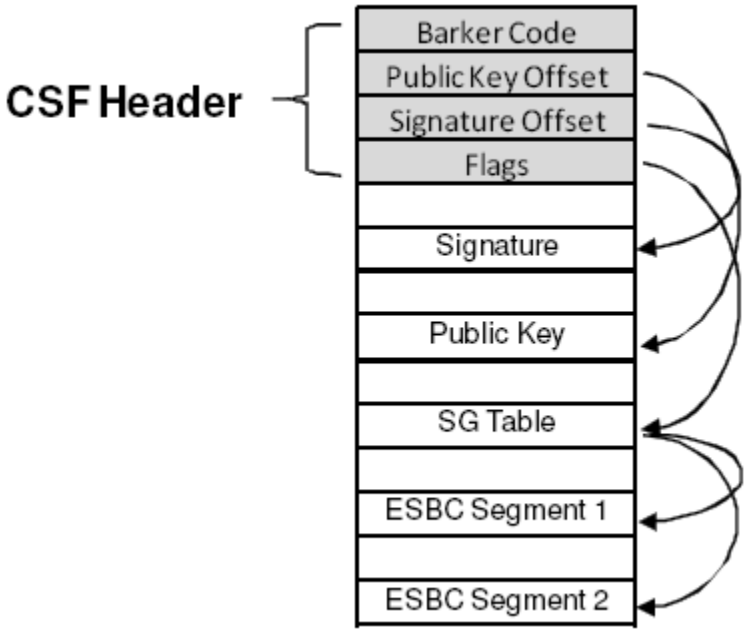

Figure 314. ESBC with CSF Header

10.3.1.5 ESBC Phase

Unlike the ISBC, which is in an internal ROM and therefore unchangeable, the ESBC is NXP-supplied reference code, and can be changed by OEMs. The remainder of this section is the description of a reasonable secure boot chain of trust based on NXP's reference software for secure boot. Depending on the requirement, ESBC can be a monolithic image - including uboot, device trees, boot firmware, drivers along with the OS and applications or can be mini-uboot.

NXP provided ESBC consists of standard u-boot which has been signed using a private key. U-boot reserves a small space for storing environment variables. This space is typically one sector above or below the u-boot and is stored on persistent storage devices like NOR flash if macro CONFIG_ENV_IS_IN_FLASH is used. In case of secure boot, macro CONFIG_ENV_IS_NOWHERE is used and so, environment is compiled in uboot image and is called default environment. This default environment can't be stored on flash devices. User won't be able to edit this environment also as he can't reach to uboot prompt in case of secure boot. There is default boot command for secure boot in this default environment which executes on autoboot.

ESBC validates a file called boot script and on successful validation execute the commands in the boot script.

There are many reasons ESBC could fail to validate Client images or boot script. The error status message along with the code is printed on the u-boot console. For a list of error codes refer ESBC Validation Error Codes.

Users are free to use NXP ESBC as it is provided or to use it as reference to modify their own secure boot system.

NOTE

On Soc's with ARMv8 core (eg:- LS1043, LS1046,LS1012), during ISBC phase in Internal Boot ROM, SMMU (which by default is in by-pass mode) is configured to allow only secure transactions from CAAM.

The security policy w.r.t. SMMU in ESBC phase must be decided by the user/customer. So, currently in ESBC (U-Boot), SMMU is configured back to by-pass mode allowing all transactions (secure as well as non-secure).

10.3.1.5.1 Boot script

Bootscript is a U-Boot script image which contains u-boot commands. ESBC would validate this boot script before executing commands in it.

NOTE

1. Boot script can have any commands which u-boot supports. No checking on the allowed commands in boot script. Since it is validated image, assumption is that commands in boot script would be correct.
2. If some basic scripting error done in boot script like unknown command, missing arguments, the required usage of that command and core is put in infinite loop.
3. After execution of commands in boot script, if control reaches back in u-boot, error message would be printed on u-boot console and core would be put in spin loop by command esbc_halt.
4. Scatter gather images not supported with validate command.
5. If ITS fuse is blown, any error in verification of the image would result in system reset. The error would be printed on console before system goes for a reset.

10.3.1.5.1.1 Where to place the boot script?

NXP's ESBC u-boot expects the boot script to be loaded in flash as specified in address map for different platforms under the topic 'Appendix <platform> Secure Boot Demo'. ESBC u-boot code assumes that the public/private key pair used to sign the boot script is same as that was used while signing the u-boot image. If user used different key pair to sign the image, hash of the N and E component of the key pair should be defined in macro:

CONFIG_BOOTSCRIPT_KEY_HASH.

Note - The hash defined should be hex value, 256 bits long.

Both the above macros can be defined or changed in the configuration file secure_boot.h at the following location in u-boot code:

`u-boot/arch/powerpc//include/asm/fsl_secure_boot.h`

Two new commands called esbc_validate and esbc_halt have been added in NXP ESBC u-boot.

Two more commands are present, 'blob enc' and 'blob dec' for running chain of trust with confideniality.

10.3.1.5.1.2 Chain of Trust

Boot script contains information about the next level of images, e.g. Linux, HV, etc. ESBC validates these images as per their public keys and then executes bootm command to pass-on the control to next image.

Users are free to use NXP ESBC as it is provided or to use it as reference to modify their own secure boot system.

Figure below shows the Chain of trust established for Validation with this ESBC u-boot.

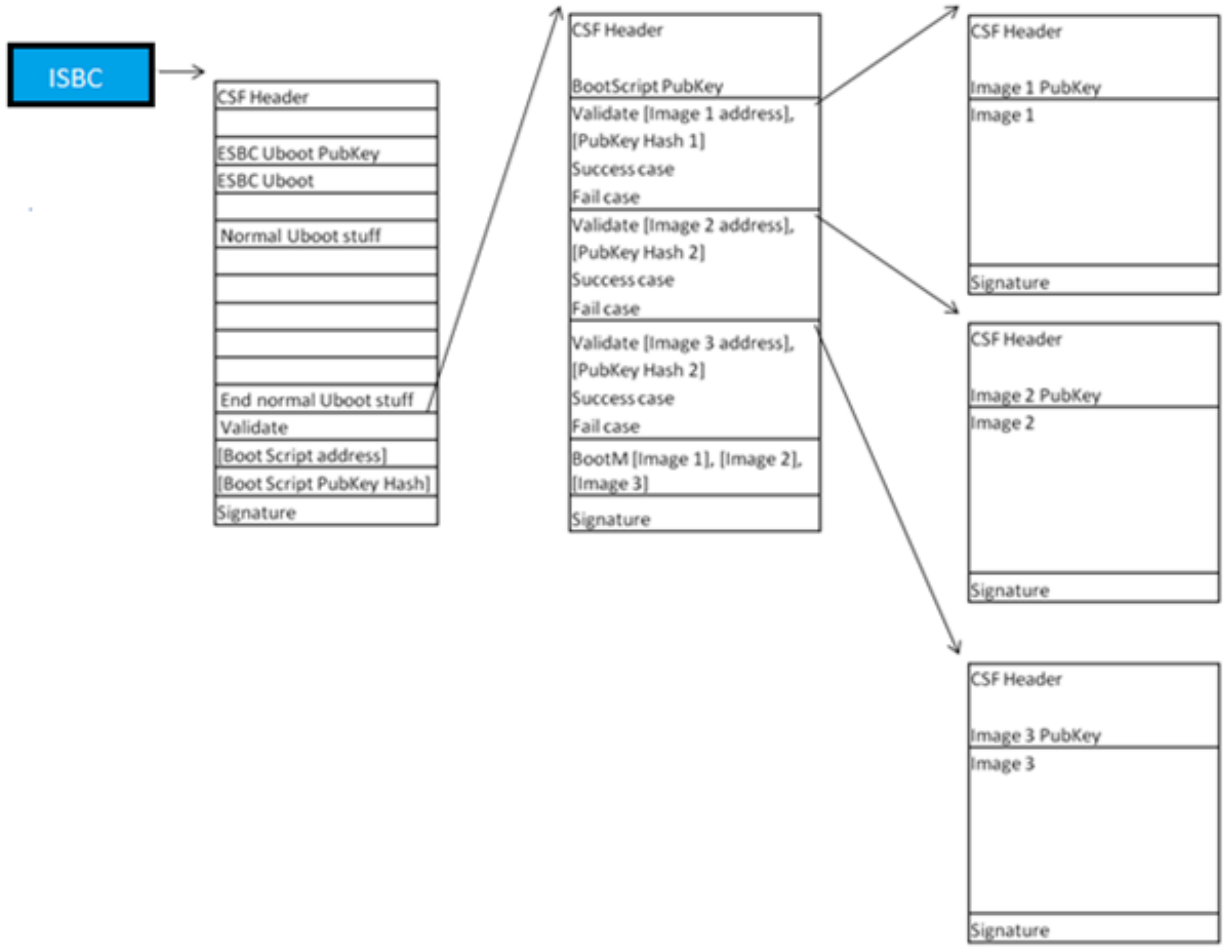

Figure 315. Secure boot flow (Chain of Trust)

10.3.1.5.1.2.1 Sample Boot Script

A sample boot script would look like:

```
...
esbc_validate <Img1 header addr> <pub_key hash>
esbc_validate <Img2 header addr> <pub_key hash>
esbc_validate <Img3 header addr> <pub_key hash>
...
bootm <img1 addr> <img2 addr> <img3 addr>
```

10.3.1.5.1.2.1.1 esbc_validate command

esbc_validate img_hdr [pub_key_hash]

Input arguments:

`img_hdr` - Location of CSF Header of the image to be validated

`pub_key_hash` - hash of the public key used to verify the image. This is optional parameter. If not provided, code makes the assumption that the key pair used to sign the image is same as that used with ISBC. So the hash of the key in the header is checked against the hash available in SRK fuse for verification.

Description:

The command would do the following:

- Perform CSF header validation on the address passed in the image header. During parsing of the header, image address in stored in an environment variable which is later used in source command in default secure boot command.
- Signature checks on the image

10.3.1.5.1.2.1.2 esbc_halt command

esbc_halt (no arguments)

Description:

The command would do the following:

This command puts core in spin loop.

After successful validation of images, bootm command in bootscript should execute and control should never reach back to uboot. If somehow, control reaches back to uboot (eg. bootm not present in bootscript), core should just spin.

10.3.1.5.1.3 Chain of Trust with Confidentiality

To establish chain of trust with confidentiality, cryptgraphic blob mechanism can be used. In this chain of trust, validated image is allowed to use the One Time Programmable Master Key to decrypt system secrets.

Two bootscripts are to be used. First encap bootscripts is used which creates a blob of the LINUX images and saves them. After this the system is booted after replacing the encap bootscript with decap bootscript which decapsulates the blobs and boot the LINUX with the images.

Figures below show the Chain of trust with confidentiality (Encapsulation and Decapsulation).

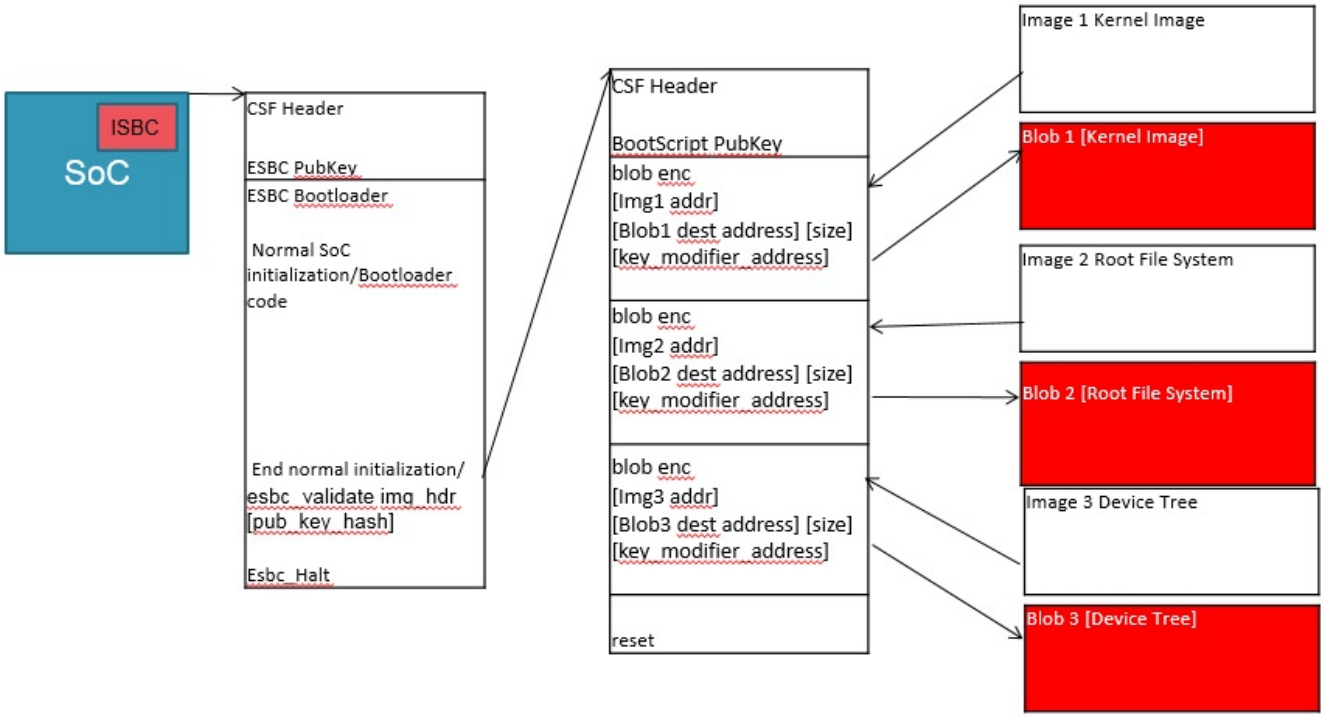

Figure 316. Chain of Trust with Confidentiality (Encapsulation)

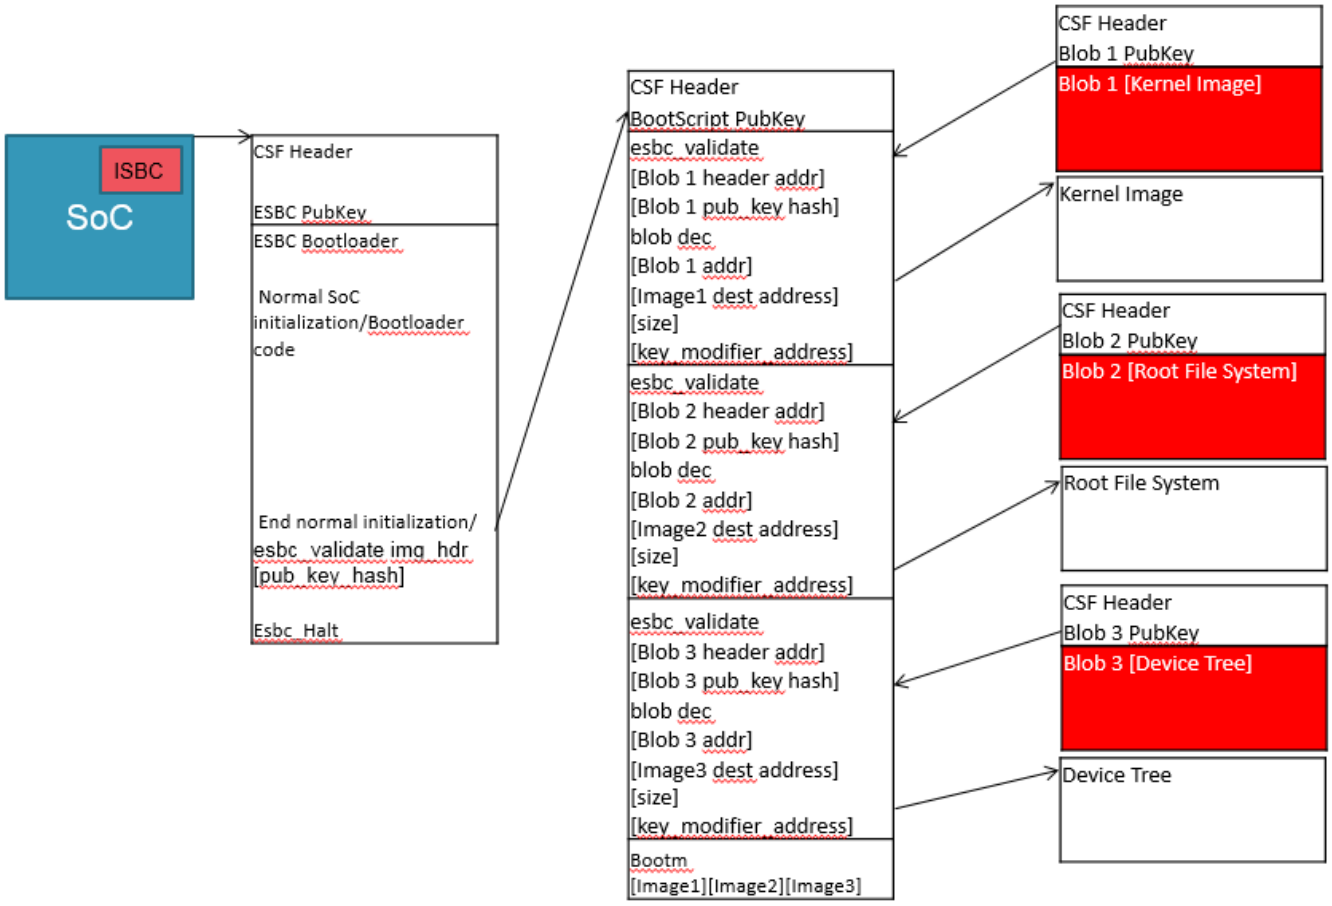

Figure 317. Chain of Trust with Confidentiality (Decapsulation)

10.3.1.5.1.3.1 Sample Encap Boot Script

A sample encap boot script would look like:

```
...
blob enc <Img1 addr> <Img1 dest addr> <Img1 size> <key_modifier address>
erase <encap Img1 addr> +<encap Imag1 size>
cp.b <Img1 dest addr> <encap Img1 addr> <encap Imag1 size>

blob enc <Img2 addr> <Img2 dest addr> <Img2 size> <key_modifier address>
erase <encap Img2 addr> +<encap Imag2 size>
cp.b <Img2 dest addr> <encap Img2 addr> <encap Imag2 size>

blob enc <Img3 addr> <Img3 dest addr> <Img3 size> <key_modifier address>
erase <encap Img3 addr> +<encap Imag3 size>
cp.b <Img3 dest addr> <encap Img3 addr> <encap Img3 size>

...
```

10.3.1.5.1.3.1.1 blob enc command

blob enc <src location> <dst location> <length> <key_modifier address>

Input arguments:

`src location` - Address of the image to be encapsulated

`dst location` - Address where the blob will be created

`length` - Size of the image to be encapsulated

`key_modifier address` - Address where a random number 16 bytes long(key modifier) is placed

Description:

The command would do the following:

- Create a cryptographic blob of the image placed at src location and place the blob at dst location.

10.3.1.5.1.3.2 Sample Decap Boot Script

A sample decap boot script would look like:

```
...
blob dec <Img1 blob addr> <Img1 dest addr> <expected Img1 size> <key_modifier address>
blob dec <Img2 blob addr> <Img2 dest addr> <expected Img2 size> <key_modifier address>
blob dec <Img3 blob addr> <Img3 dest addr> <expected Img3 size> <key_modifier address>
...
bootm <Img1 dest addr> <Img2 dest addr> <Img3 dest addr>
```

10.3.1.5.1.3.2.1 blob dec command

blob dec <src location> <dst location> <length> <key_modifier address>

Input arguments:

`src location` - Address of the image blob to be decapsulated

`dst location` - Address where the decapsulated image will be placed

`length` - Expected Size of the image after decapsulation.

`key_modifier address` - Address where key modifier (Same as that used for Encapsulation) is placed

Description:

The command would do the following:

- Decapsulate the blob placed at src location and place the decapsulated data of expected size at dst location.

10.3.1.6 Next Executable (Linux Phase)

The bootloader (ESBC) finishes the platform initialization and passed control to the Linux image. The boot-chain can be further extended to be able to sign application which would be running on Linux prompt. Further RTIC can be integrated to verify memory regions using Security Engine (SEC) during run time.

10.3.1.7 Product execution

This section presents the steps needed to be followed in order to properly run the software product according to its intended use and functionalities.

10.3.1.7.1 Getting started

The example below demonstrates the secure-boot flow with all the images loaded in NOR Flash.

Steps in the demo would be:

1. ISBC code would validate the ESBC code.
2. On successful validation, ESBC code would run, which would then validate the boot script.
3. On successful validation of boot script, commands in boot script would be executed.
4. The boot script contains commands to validate next level images, i.e rootfs, linux uImage and device tree.

5. Once all the images are validated, bootm command in boot script would be executed which would pass control to linux.

NOTE

For PowerPC SoC's, ISBC expects the code to be validated i.e. ESBC code to be within 0 - 3.5G address map. In the demo we map the flash to address 0xc0000000 for the ISBC code to validate ESBC in NOR Flash using PBI commands. Once the control reaches the ESBC code the earlier mapping of flash is removed and flash is mapped to address 0xe0000000.

For useful commands of U-Boot and CCS, refer to commands for different platforms under the topic 'Appendix <platform> Secure Boot Demo'

10.3.1.7.1.1 Environment for Secure Boot

There are 2 ways in which secure boot can be initiated:

- Set SB_EN bit in RCW to 1.
- Programming the ITS fuse.

In a manufacturing environment, it is recommended that all fuses be programmed at once, including the ITS and OEM Section Write Protect bits. In a prototyping environment, it may be preferable to leave ITS and Write Protect unprogrammed (relying on RCW to initiate secure boot) until the developer has confidence in the secure boot process.

Two different RCW's are provided for the demo purpose:

1. The RCW which has SB_EN bit set as 0 (sben0) and can be used when ITS = 1 i.e user wants to initiate secure boot flow using fuse.
2. The RCW which has the SB_EN bit set as 1 (sben1)and can be used when user wants to initiate secure boot using RCW.

10.3.1.7.1.2 SDK/ Images required for the demo

Given below are the images required for the demo which are built with Yocto as part of the SDK:

1. RCW with PBI commands
2. ESBC (U-Boot)
3. uImage (Linux Image) *
4. rootfs Image *
5. Device tree *

Please refer to User Manual QorIQ DPAA SDK for detailed description on how to run Yocto Build. Once the build process finishes, all the binaries would be present at the following location:

build_<platform>_release/tmp/deploy/images

The images will be created with the following names:

u-boot-<platform>.bin	U-Boot binary image for Secure Boot
uImage-<platform>.bin	kernel image that can be loaded with U-Boot
fsl-image-core-<platform>.ext2.gz.u-boot	ramdisk filesystem image that can be loaded with U-Boot
uImage-<platform>.dtb	device tree binary(dtb) for kernel bootup

RCW files will be present in the path ***build_<platform>_release/tmp/deploy/images/rcw***

NOTE

* Some platforms like LS1043 have support for LINUX boot using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB)

10.3.1.7.2 Chain of Trust

This section presents the steps needed to be followed in order to execute Chain of Trust.

Steps in the demo would be:

1. ISBC code would validate the ESBC code.
2. On successful validation, ESBC code would run, which would then validate the boot script.
3. On successful validation of boot script, commands in boot script would be executed.
4. The boot script contains commands to validate next level images, i.e rootfs, linux uImage and device tree.
5. Once all the images are validated, bootm command in boot script would be executed which would pass control to linux.

10.3.1.7.2.1 Other images required for the demo

Apart from SDK images described above, the following images are also required:

1. CSF Header of the ESBC u-boot image
2. CSF Header of the uImage *
3. CSF Header of the rootfs image *
4. CSF Header of the device tree *
5. Boot Script
6. CSF Header of the boot script

The following section describes how to create the CSF headers and boot script.

NOTE

* Some platforms like LS1043 have support for LINUX boot using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB). For these platforms a single CSF Header is required.

10.3.1.7.2.2 Boot Script and Signing the images

User can sign all the images with same public/private key pair or can use different key pairs to sign the images. Section below describes both the processes.

CST tool used for signing the images is provided as a package with yocto and is built for host. It can be run from your host machine.

Install path for CST binaries in yocto:

```
tmp/sysroots/x86_64-linux/usr/bin/cst/
```

CST uses openssl libraries, version 0.9.8.

In the Yocto environment, the user needs to use below commands to rebuild cst:

1. bitbake cst-native –c cleanall
2. bitbake cst-native
3. Modify the CST source code if needed.
4. bitbake cst-native –c cleanall
5. bitbake cst-native –c patch

Note: after step5, CST binary will be put to build_<platform_release/tmp/sysroots/x86_64-linux/usr/bin/cst/ directory.

Table 304. Platforms supported in SDK for Secure Boot

Soc	<platform> supported in SDK	<platform> supported in CST
B4860	b4860qds	b4860 [nor]
P2041	p2041rdb	p3_p4_p5 [nor]
P3041	p3041ds	p3_p4_p5 [nor/nand]
P4080	p4080ds	p3_p4_p5 [nor]
P5020	p5020ds	p3_p4_p5 [nor/nand]
P5040	p5040ds	p3_p4_p5 [nor/nand]
T1024	t1024rdb	t1_t2_t4 [nor]
T104x	t1040rdb, t1042rdb	t1_t2_t4 [nor/nand]
T2080	t2080qds, t2080rdb	t1_t2_t4 [nor]
T4240	t4240qds	t1_t2_t4 [nor]
LS1021	ls1021aqds	ls1 [nor]
LS1021	ls1021atwr	ls1 [nor/sd]
LS1043	ls1043ardb	ls1043 [nor/nand_sd]
LS1043	ls1043aqds	ls1043 [nor]
LS1046	ls1046aqds	ls1046 [nor]
LS1046	ls0146ardb	ls0146 [qspi/nand/sd]
LS1012	ls1012ardb	ls1012 [qspi]

NOTE

Some platforms with ARMv8 core have support for LINUX boot using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB).

For such platforms, in CST as well instead of 3 different input files for signing uImage, rootfs and dtb, there is a single input file named **input_kernel_secure** which can be used to sign the single kernel FIT image.

This applies to all subsequent sections below.

10.3.1.7.2.2.1 Signing the images using same key pair

CSF header needs to be generated for all the images. More details on the commands provided by CST can be found in Section .

1. Generate the key pair to be used for signing the image

   ```
   ./gen_keys 1024
   ```

   Key pair - public key file - srk.pub and private key in srk.priv would be generated.

2. Obtain hash string of the key pair generated to be programmed in SFP

   ```
   ./uni_sign --hash input_files/uni_sign/<platform>/input_uboot_secure
   ```

   This would provide you the 256 bit hash in form of string of the key pair generated in the previous step. The hash has to be programmed in the SRK hash Fuse.

3. Create CSF header for u-boot Image.

   ```
   ./uni_sign input_files/uni_sign/<platform>/input_uboot_secure
   ```

   The input fields are specified in input_uboot_secure file. Please ensure that the filename mentioned in the input_uboot_secure is same as copied in the cst directory.

4. Create CSF header for Linux uImage

   ./uni_sign input_files/uni_sign/<platform>/input_uimage_secure

   uImage.bin would be validated form u-boot. The flash address used here is according to the address map of u-boot. Please ensure that filename mentioned in the input_uimage_secure is same as copied in the cst directory.

5. Create CSF header for rootfs

   ```
   ./uni_sign input_files/uni_sign/<platform>/input_rootfs_secure
   ```

   ```
   Please make sure that filename mentioned in the input_rootfs_secure is same as copied in the cst directory
   ```

6. Create CSF Header for hardware device tree

   ```
   ./uni_sign input_files/uni_sign/<platform>/input_dtb_secure
   ```

   ```
   Please make sure that filename mentioned in the input_dtb_secure is same as copied in the cst directory
   ```

7. Create Boot script

   Bootscript is a U-Boot script image. Steps to create bootscript are given below :

   a. Create a text file bootscript.txt with following commands.

   ```
   esbc_validate <uImage CSF Header address>

   esbc_validate <dtb CSF Header address>

   esbc_validate <rootfs CSF Header address>

   bootm <uImage Address> <rootfs address> <dtb address>
   ```

   b. Then you will have to use the mkimage tool to convert this text file into a U-Boot image (using the image type script)

   powerpc arch:: `/tmp/sysroots/x86_64-linux/usr/bin/mkimage -A ppc -T script -a 0 -e 0x40 -d bootscript.txt bootscript`

   arm arch:: `/tmp/sysroots/x86_64-linux/usr/bin/mkimage -A arm -T script -a 0 -e 0x40 -d bootscript.txt bootscript`

8. Generate CSF hdr for the boot script

   ./uni_sign input_files/uni_sign/<platform>/input_bootscript_secure

   The fields can be changed in the input files for the images based on the requirement.

10.3.1.7.2.2.2 Signing the images using different key pair

If boot script is also signed with a different key, remember to define the macro "**CONFIG_BOOTSCRIPT_KEY_HASH**" with the hash of the key used to sign the boot script in file *arch/powerpc/asm/include/fsl_secure_boot.h*. *ESBC u-boot would have to be recompiled if any change in this file is made*.

1. Generate the key pair to be used for signing the image

   ```
   ./gen_keys 1024 -p u-boot.priv -k u-boot.pub
   ```

   Key pair - public key file - u-boot.pub and private key in u-boot.priv would be generated.

2. Obtain hash string of the key pair generated to be programmed in SFP

   ```
   ./uni_sign --hash input_files/uni_sign/<platform>/input_uboot_secure
   ```

   This would provide you the 256 bit hash in form of string of the key pair generated in the previous step. The hash has to be programmed in the SRK hash Fuse.

3. Create CSF header for u-boot Image.

   Open `input_files/uni_sign/<platform>/input_uboot_secure` and change PRI_KEY and PUB_KEY to u-noot.priv and u-boot.pub respectively and run the following command.

   ./uni_sign input_files/uni_sign/<platform>/input_uboot_secure

4. Create CSF header for Linux uImage using different key pair.

   Repeat step 1 to generate another key pair.

   ```
   ./gen_keys 1024 -p lnx.priv -k lnx.pub
   ```

   Open `input_files/uni_sign/<platform>/input_uimage_secure` and change PRI_KEY and PUB_KEY to lnx.priv and lnx.pub respectively and run the following command. **./uni_sign input_files/uni_sign/<platform>/input_uimage_secure**

   Remember the "Key Hash" printed as it would be required in esbc_validate command in boot script. Say the hash of the key is <lnx_key_hash>

5. Create CSF header for rootfs

   ```
   ./gen_keys 1024 -p rootfs.priv -k rootfs.pub
   ```

   Open `input_files/uni_sign/<platform>/input_rootfs_secure` and change PRI_KEY and PUB_KEY to rootfs.priv and rootfs.pub respectively and run the following command.

   ./uni_sign input_files/uni_sign/<platform>/input_rootfs_secure

   Remember the "Key Hash" printed as it would be required in esbc_validate command in boot script. Say the hash of the key is <rootfs_key_hash>

6. Create CSF Header for hardware device tree

   ```
   ./gen_keys 1024 -p dtb.priv -k dtb.pub
   ```

   Open `input_files/uni_sign/<platform>/input_dtb_secure` and change PRI_KEY and PUB_KEY to dtb.priv and dtb.pub respectively and run the following command. **./uni_sign input_files/uni_sign/<platform>/input_dtb_secure**

   Remember the "Key Hash" printed as it would be required in esbc_validate command in boot script. Say the hash of the key is <dtb_key_hash>

7. Write Boot script

   Bootscript is a U-Boot script image. Steps to create bootscript are given below :

   a. Create a text file bootscript.txt with following commands.

   ```
   esbc_validate <uImage CSF Header address>  <lnx_key_hash>
   esbc_validate <dtb CSF Header address>  <dtb_key_hash>
   esbc_validate <rootfs CSF Header address>  <rootfs_key_hahs>
   bootm <uImage Address> <rootfs address> <dtb address>
   ```

   NOTE

   Hashes would be the 256 bit string hash. These are the hashes of the key used to sign the respective images.

   b. Generate header over bootscript.txt which will be consumed by uboot command source

powerpc arch :: tmp/sysroots/x86_64-linux/usr/bin/mkimage -A ppc -T script -a 0 -e 0x40 -d bootscript.txt bootscript

arm arch :: tmp/sysroots/x86_64-linux/usr/bin/mkimage -A arm -T script -a 0 -e 0x40 -d bootscript.txt bootscript

8. Generate CSF hdr for the boot script

```
./gen_keys 1024 -p bs.priv -k bs.pub
```

Open `input_files/uni_sign/<platform>/input_dtb_secure` and change `PRI_KEY` and `PUB_KEY` to `bs.priv` and `bs.pub` respectively and run the following command.

```
./uni_sign input_files/uni_sign/<platform>/input_dtb_secure
```

10.3.1.7.2.3 Running secure boot (Chain of Trust)

1. Setup the board for secure boot flow. You can choose any if the flows mentioned below.
   a. **Flow A**

      Program the ITS fuse. Use RCW with SB_EN=0

      Or

   b. **Flow B**

      For protyping phase, don't blow the ITS fuse, but use rcw with SB_EN = 1.

      Note: For P3/P4/P5, if ITS fuse is blown, then ITF fuse must also be blown. (The value of ITS and ITF fuse must be identical.)

2. Blow other required fuses on the board. (OTPMK and SRK hash[17]) For more details regarding fuse blowing, CCS and Boot Hold Off, refer to Platform reference manual and Trust Architecture User Guide.

> **NOTE**
>
> SRK hash in the fuse should be same as the hash of the key pair being used to sign the ESBC u-boot. Step 2 of Signing the images using same key pair on page 1954
>
> For testing purpose, the SRK Hash can be written in the mirror registers.
>
> gen_otpmk_drbg utility in cst can be used to generate otpmk key.

3. Flash all the generated images at locations as described in the address map (specified for different platforms under the topic 'Appendix <platform> Secure Boot Demo').
   a. **Flow A** - All the images would have to be flashed at the current bank addresses. Once ITS fuse is blown, the control would automatically shift to ISBC on power on.
   b. If you are using **Flow B**, you can use alternate bank for demo purpose. This would mean flashing the images on alternate bank addresses from Bank0 and then switching to Bank4.
4. Give a power on cycle to the board.
   a. For **Flow A** and **Flow B** (*Secure boot Images flashed on default Bank*)
      - On power on, ISBC code would get control, validate the ESBC image.
      - ESBC image would further validate the signed linux, rootfs and dtb images
      - Linux would come up
   b. **Flow B** (*Secure boot Images flashed on alternate Bank*)

[17] Blowing of **OTPMK**is essential to run secure boot for both Production (Flow A) and Prototyping/Development (Flow B).

For **SRK Hash**,in Development Mode (Flow B), there is a workaround to avoid blowing fuses. For this use RCW with BOOT_HO = 1. This will put the core in Boot Hold off stage. Then a CCS can be connected via JTAG.

Write the SRK Hash value in SFP mirror registers and then release the core out of Boot Hold off by writing to Core Release Register in DCFG.

- On power on cycle, u-boot prompt on bank 0 would come up.
- On switching to alternate bank, the secure boot flow as mentioned above would execute.

10.3.1.7.3 Chain of Trust with Confidentiality

This section presents the steps needed to be followed in order to execute Chain of Trust with confidentiality.

The demo would be divided into two parts:

1. Creating /encrypting images in form of blobs.
2. Decrypting the images, and booting from decrypted images.

Steps in the demo would be:

Step 1: Creating blobs

1. ISBC code would validate the ESBC code.
2. On successful validation, ESBC code would run, which would then validate the boot script.
3. On successful validation of boot script, commands in boot script would be executed.
4. The boot script contains commands to encapsullate next level images, i.e rootfs, linux uImage and device tree.

blob encapsulation command::

blob enc src dst len km - Encapsulate and create blob of data

$len - Number of bytes to be encapsulated.

$src - The address where image to be encapsulated is present.

$dst - The address where encapsulated image will be stored.

$km - It is the address where the key modifier is stored. The modifier is required and used as key for cryptographic operation. Key modifier should be 16 bytes long.

Step 2: Decrypting blob and booting

1. ISBC code would validate the ESBC code.
2. On successful validation, ESBC code would run, which would then validate the boot script.
3. On successful validation of boot script, commands in boot script would be executed.
4. The boot script contains commands to decapsulate/decrypt next level images, i.e rootfs, linux uImage and device tree.
5. After decryption, bootm command would be executed in boot script to pass control to Linux.

blob decapsulation command::

blob dec src dst len km - Decapsulate the image and recover the data

$len - Number of bytes to be decapsulated.

$src - The address where encapsulated image is present.

$dst - The address where decapsulated image will be stored.

$km - It is the address where the key modifier is stored. The modifier is required and used as key for cryptographic operation. Key modifier should be 16 bytes long. It should be same as passed while encapsulating the image.

10.3.1.7.3.1 Other images required for the demo

Apart from SDK images described above, the following images are also required:

1. Encap Boot script
2. Decap Boot script
3. CSF header for ESBC u-boot Image

4. CSF Header of the encap boot script
5. CSF Header of the decap boot script

The following section describes how to create the CSF headers and boot script.

10.3.1.7.3.2 Encap Bootscript

1. Create a bootscript_en.txt file with following commands:

```
blob enc <uImage address> 0x10000000 <uImage size> <key_modifier address>

erase <encapsulated uImage address> +<encapsulated uImage size>
cp.b 0x10000000 <encapsulated uImage address> <encapsulated uImage size>

blob enc <rootfs address> 0x20000000 <rootfs size> <key_modifier address>

erase <encapsulated rootfs address> +<encapsulated rootfs size>
cp.b 0x20000000 <encapsulated rootfs address>  <encapsulated rootfs size>

blob enc <dtb address> 0x1000000 <dtb size> <key_modifier address>

erase <encapsulated dtb address> +<encapsulated dtb size>
cp.b 0x1000000 <encapsulated dtb address>  <encapsulated dtb size>
```

   For the addresses to load images refer Section for different platforms under the topic 'Appendix <platform> Secure Boot Demo'

2. Use the mkimage tool to convert this text file into a U-Boot image (using the image type script)

```
/tmp/sysroots/x86_64-linux/usr/bin/mkimage -A ppc -T script -a 0 -e 0x40 -d bootscript_en.txt
bootscript_encap
```

10.3.1.7.3.3 Decap Bootscript

1. Create a bootscript_de.txt file with following commands:

```
blob dec <encapsulated uImage address> 0x10000000 <uImage size + 0x30> <key_modifier address>

blob dec <encapsulated rootfs address> 0x20000000 <rootfs size + 0x30> <key_modifier address>

blob dec <encapsulated dtb address> 0x1000000 <dtb size + 0x30> <key_modifier address>

bootm 0x10000000 0x20000000 0x1000000
```

   For the addresses to load images refer section for different platforms under the topic 'Appendix <platform> Secure Boot Demo'

   The script decapsulates/decrypts the blob created by earlier boot script and boots using them.

> **NOTE**
>
> 0x30(48 bytes) should be added in the size of encapsulated images while decapsulating them. Always 48B are added at the end of the encapsulated image which needs to be added while providing the size of image to be decapsulated in blob dec command.

2. Use the mkimage tool to convert this text file into a U-Boot image (using the image type script)

```
/tmp/sysroots/x86_64-linux/usr/bin/mkimage -A ppc -T script -a 0 -e 0x40 -d bootscript_de.txt
bootscript_decap
```

10.3.1.7.3.4 Creating CSF Headers

- **CSF Header for ESBC**

  Use the command given below to generate the hdr for u-boot binary.

  ./uni_sign input_files/uni_sign/<platform>/<input file for uboot>

  Please change the binary name as per your uboot binary in “IMAGE_1”.

- **CSF Header for bootscript_encap and bootscript_decap**

  Use the command given below to generate the headers for bootscripts

  ./uni_sign input_files/uni_sign/<platform>/<input file for bootscript>

  Please change the binary name as per your bootscript in “IMAGE_1”.

10.3.1.7.3.5 Running secure boot (Chain of Trust with Confidentiality)

1. Setup the board for secure boot flow. You can choose any if the flows mentioned below.
   a. **Flow A**

      Program the ITS fuse. Use RCW with SB_EN=0

      Or

   b. **Flow B**

      For protyping phase, don't blow the ITS fuse, but use rcw with SB_EN = 1.

      Note: For P3/P4/P5, if ITS fuse is blown, then ITF fuse must also be blown. (The value of ITS and ITF fuse must be identical.)

2. Blow other required fuses on the board. (OTPMK and SRK hash[18]) For more details regarding fuse blowing, CCS and Boot Hold Off, refer to Platform reference manual and Trust Architecture User Guide.

   NOTE

   SRK hash in the fuse should be same as the hash of the key pair being used to sign the ESBC u-boot.

   For testing purpose, the SRK Hash can be written in the mirror registers.

   gen_otpmk_drbg utility in cst can be used to generate otpmk key.

3. Flash all the generated images at locations as described in the address map specified for different platforms under the topic 'Appendix <platform> Secure Boot Demo'
   - Uboot binary
   - CSF Header of uboot
   - Linux uImage
   - Rootfs
   - Device tree
   - bootscript_encap

[18] Blowing of **OTPMK**is essential to run secure boot for both Production (Flow A) and Prototyping/Development (Flow B).

For **SRK Hash**,in Development Mode (Flow B), there is a workaround to avoid blowing fuses. For this use RCW with BOOT_HO = 1. This will put the core in Boot Hold off stage. Then a CCS can be connected via JTAG.

Write the SRK Hash value in SFP mirror registers and then release the core out of Boot Hold off by writing to Core Release Register in DCFG.

- CSF Header for bootscript_encap

a. **Flow A** - All the images would have to be flashed at the current bank addresses. Once ITS fuse is blown, the control would automatically shift to ISBC on power on.

b. If you are using **Flow B**, you can use alternate bank for demo purpose. This would mean flashing the images on alternate bank addresses from Bank0 and then switching to Bank4.

4. Give a power on cycle to the board.
   a. For **Flow A** and **Flow B** (*Secure boot Images flashed on default Bank*)
      - On power on, ISBC code would get control, validate the ESBC image.
      - ESBC image would further validate the bootscript.
      - Bootscript would encapsulate the Linux, rootfs and device tree and store the blobs at the desired locations.
   b. **Flow B** (*Secure boot Images flashed on alternate Bank*)
      - On power on cycle, u-boot prompt on bank 0 would come up.
      - On switching to alternate bank, the secure boot flow as mentioned above would execute.
5. Give a power on cycle to the board.
6. Replace the encap bootscript and its CSF header with decap bootscript and the CSF header of the decap bootscript respectively.
7. Give a power on cycle to the board.
   a. For **Flow A** and **Flow B** (*Secure boot Images flashed on default Bank*)
      - On power on, ISBC code would get control, validate the ESBC image.
      - ESBC image would further validate the bootscript.
      - Bootscript would decapsulate the Linux, rootfs and device tree bloband store them on DDR
      - Bootm commnd in bootscript would execute on successful decapsulation
      - Linux prompt would come up. .
   b. **Flow B** (*Secure boot Images flashed on alternate Bank*)
      - On power on cycle, u-boot prompt on bank 0 would come up.
      - On switching to alternate bank, the secure boot flow as mentioned above would execute.

10.3.1.7.4 NAND Secure Boot (Chain of Trust)

This section presents the steps and images needed for running Secure Boot Chain of Trust from NAND on **P3/P5 and T1**.

The procedure for running Secure boot from NAND is same as Secure Boot from NOR. The only difference is that in case of NOR, image is not required to be copied from NOR while in case of NAND, images have to be copied from NAND to SRAM/ DDR before validation.

Images Required for Demo

- **For P3/P5 platform**
  1. PBL.bin : For P3/P5 platforms, the PBL.bin is generated using QCVS Tool. It creates the RCW along with PBI commands. ESBC (U-boot) and CSF Header for U-Boot are added using ACS_WRITE PBI commands. (For details/ screenshots refer Using QCVS Tool (Secure Boot From NAND) on page 1997)
  2. u-boot.bin
  3. uImage (Linux Image)
  4. rootfs
  5. dtb (Device Tree)

6. CSF Header of the uImage
7. CSF Header of the u-boot.bin
8. CSF Header of the rootfs image
9. CSF Header of the device tree
10. Boot Script
11. CSF Header of the Boot Script

- **For T1 and TA2.x based platforms**

1. u-boot image : The SRAM is of 256KB so, SPL image is loaded there and the main u-boot is loaded by the SPL to DDR. To add ACS commands to rcw file in this case, CST tool can be used.
2. u-boot-spl.bin
3. u-boot.bin
4. uImage (Linux Image) *
5. rootfs *
6. dtb (Device Tree) *
7. CSF Header of the u-boot-spl.bin
8. CSF Header of the u-boot.bin
9. CSF Header of the uImage *
10. CSF Header of the rootfs image *
11. CSF Header of the device tree *
12. Boot Script
13. CSF Header of the Boot Script

NOTE

Some platforms like LS1043 have support for LINUX boot using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB). For these platforms a single CSF Header is required.

Boot Script

The sample bootscript.txt would have the following commands:

```
# Read uImage & Header
nand read <uImage DDR> <uImage NAND> <uImage size>
nand read <uImage Header DDR> <uImage Header NAND> <uImage Header size>

# Read rootfs & Header
nand read <rootfs DDR> <rootfs NAND> <rootfs size>
nand read <rootfs Header DDR> <rootfs Header NAND> <rootfs Header size>

# Read dtb & Header
nand read <dtb DDR> <dtb NAND> <dtb size>
nand read <dtb Header DDR> <dtb Header NAND> <dtb Header size>

# Validate and Boot
esbc_validate <uImage Header DDR>
esbc_validate <DTB Header DDR>
esbc_validate <rootfs Header DDR>
bootm <uImage DDR> <rootfs DDR> <dtb DDR>
```

Image Signing

- The image signing process for P3/P5 will remain same as in case of NOR Boot Script and Signing the images on page 1953

<platform> will be p3_p4_p5/nand for P3/P5

- The image signing process for signing for T1 and TA2.x platforms in case of nand boot is as below

  The CSF headers of images are to be generated as follows

  1. Generate the key pair to be used for signing the image

     ```
     ./gen_keys 1024
     ```

     Key pair - public key file - srk.pub and private key in srk.priv would be generated

  2. Create CSF header for above mentioned images

     ```
     ./uni_sign input_files/uni_sign/<platform>/nand/input_uboot_secure
     ```

     The input fields are specified in input_uboot_secure file. Please ensure that the filename mentioned in the input_uboot_secure is same as copied in the cst directory

     Similarly for other images

     ```
     ./uni_sign input_files/uni_sign/<platform>/nand/input_uimage_secure
     ./uni_sign input_files/uni_sign/<platform>/nand/input_bootscript_secure
     ./uni_sign input_files/uni_sign/<platform>/nand/input_rootfs_secure
     ./uni_sign input_files/uni_sign/<platform>/nand/input_dtb_secure
     ./uni_sign input_files/uni_sign/<platform>/nand/input_spl_uboot_secure
     ```

     For platforms using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB), only one image used to be signed instead of three.

     ```
     ./uni_sign input_files/uni_sign/<platform>/nand/input_kernel_secure
     ```

  3. Generate new RCW (which will contain ACS command to copy u-boot-spl ad its header to OCRAM.

     Usage :: $**./uni_pbi [options] <input_file>**

     ```
     ./uni_pbi input_files/create_pbi/<platform>/input_pbi_nand_secure
     ```

NOTE

ISBC Key Extension Feature is not applicable for Secure Boot from NAND.

10.3.1.7.4.1 Running Secure Boot Chain of Trust (from NAND)

1. Setup the board for secure boot flow. You can choose any if the flows mentioned below.

   a. **Flow A**

      Program the ITS fuse. Use RCW with SB_EN=0

      Or

   b. **Flow B**

      For protyping phase, don't blow the ITS fuse, but use rcw with SB_EN = 1.

      Note: For P3/P5, if ITS fuse is blown, then ITF fuse must also be blown. (The value of ITS and ITF fuse must be identical.)

2. Blow other required fuses on the board. (OTPMK and SRK hash[19]) For more details regarding fuse blowing, CCS and Boot Hold Off, refer to Platform reference manual and Trust Architecture User Guide.

   NOTE

   SRK hash in the fuse should be same as the hash of the key pair being used to sign the ESBC u-boot. Step 2 of Signing the images using same key pair on page 1954

   For testing purpose, the SRK Hash can be written in the mirror registers.

   gen_otpmk_drbg utility in cst can be used to generate otpmk key.

3. Flash all the generated images on NAND Flash at locations as described in the address map (specified for different platforms under the topic 'Appendix <platform> Secure Boot Demo').
4. Switch to NAND Boot.
   a. **FLOW A (for P3/P5 platforms)**

      Change the Switch Settings to change the RCW_SRC to NAND and power on the board.

      OR

      Power on the board to bring up Non-Secure U-Boot on NOR and from U-Boot promt issue the following command in case of P3/P5 platforms

      ```
      mw.b 0xffdf0020 0x48;mw.b 0xffdf0021 0x78;mw.b 0xffdf002c 0x90;mw.b 0xffdf002d 0xf0;mw.b
      0xffdf0010 0; mw.b 0xffdf0010 1
      ```

      - The PBL would configure CPC as SRAM, update the SCRATCH register and copy the Header and U-boot (ESBC) on CPC configured as SRAM.
      - ISBC code would get control, validate the ESBC image
      - ESBC image would further copy the Boot Script Header and Boot Script from NAND to DDR, validate the boot script and execute it.
      - The Boot Script has commands to copy the linux images and their respective headers from NAND to DDR, validate the signed linux, rootfs and dtb images.
      - Linux would be booted.

   b. **FLOW B (for T1 and TA2.x platforms)**

   - PBL will load u-boot-spl and its header to OCRAM, u-boot and its header will be appended to rcw file that wil be copied to nand flash along with rcw.
   - ISBC will validate u-boot spl and then u-boot-spl will load the main u-boot to DDR and will validate main u-boot (ESBC).
   - ESBC image would further copy the Boot Script Header and Boot Script from NAND to DDR, validate the boot script and execute it.
   - The Boot Script has commands to copy the linux images and their respective headers from NAND to DDR, validate the signed linux, rootfs and dtb images.
   - Linux would be booted.

[19] Blowing of **OTPMK**is essential to run secure boot for both Production (Flow A) and Prototyping/Development (Flow B).

For **SRK Hash**,in Development Mode (Flow B), there is a workaround to avoid blowing fuses. For this use RCW with BOOT_HO = 1. This will put the core in Boot Hold off stage. Then a CCS can be connected via JTAG.

Write the SRK Hash value in SFP mirror registers and then release the core out of Boot Hold off by writing to Core Release Register in DCFG.

10.3.1.7.5 SD Secure Boot (Chain of Trust)

This section presents the steps and images needed for running Secure Boot Chain of Trust from SD

The procedure for booting from SD is similar to NOR, the only difference being, SD is a non XIP memory so the images are to be copied from SD to DDR before validation

The images needed to run SD secure boot

1. RCW with PBI commands (rcw.bin)
2. U-Boot ESBC images
   a. u-boot-spl.bin
   b. u-boot-dtb.bin
3. uImage (uImage.bin)*
4. rootfs Image (rootfs)*
5. Device tree (uImage.dtb)*

NOTE

Some platforms like LS1043 have support for LINUX boot using a single kernel FIT image instead of 3 separate images (uImage, rootfs and DTB). For these platforms a single CSF Header is required.

Sample BootScript

```
mmc rescan
setenv bootfile uImage.bin
setenv fdtfile uImage.dtb
setenv consoledev ttyS0
setenv loadaddr 0x83000000
setenv fdtaddr  0x83800000
setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,$baudrate;
mmcinfo;
ext2load mmc 0:2 82020000 /boot/hdr_dtb.out
ext2load mmc 0:2 82000000 /boot/hdr_linux.out
ext2load mmc 0:2 0x83000000 /boot/$bootfile;
ext2load mmc 0:2 0x83800000 /boot/$fdtfile;
esbc_validate 0x82000000
esbc_validate 0x82020000
bootm $loadaddr - $fdtaddr
```

Signing the images

The CSF headers of images are to be generated as follows

1. Generate the key pair to be used for signing the image

   ```
   ./gen_keys 1024
   ```

   Key pair - public key file - srk.pub and private key in srk.priv would be generated

2. Create CSF header for above mentioned images

   ```
   ./uni_sign input_files/uni_sign/<platform>/sdboot/input_uboot_secure
   ```

   The input fields are specified in input_uboot_secure file. Please ensure that the filename mentioned in the input_uboot_secure is same as copied in the cst directory

Similarly for other images

```
./uni_sign input_files/uni_sign/<platform>/sdboot/input_uimage_secure
./uni_sign input_files/uni_sign/<platform>/sdboot/input_bootscript_secure
./uni_sign input_files/uni_sign/<platform>/sdboot/input_rootfs_secure
./uni_sign input_files/uni_sign/<platform>/sdboot/input_dtb_secure
./uni_sign input_files/uni_sign/<platform>/sdboot/input_spl_uboot_secure
```

3. Generate new Rcw

   Usage :: $**./uni_pbi [options] <input_file>**

```
./uni_pbi input_files/create_pbi/<platform>/input_pbi_sd_secure
```

   The above command will add ACS Write command to the **rcw** to write u-boot SPL and its header from SD card to OCRAM, and also append bootscript, uboot and their header to it

Running Secure Boot Chain of Trust(from SD)

There are two porcedures to run secure boot

- In one flow, all images are flashed on SD in raw form. The images are then copied to OCRAM/DDR and then validated.

  To view commands for this flow refer Appendix LS1020 Secure Boot demo on page 2008 , for LS1021 specific SD boot

- Alternate method to boot from SD is by mounting the root file system on SD. In that case rootfs won't be validated. The procedure for alternate SD Secure boot is mentioned below.

1. Set up the board for secure boot flow
   a. Use rcw with SB_EN =1
   b. Blow required fuses on the board (OTPMK and SRK hash). For more details regarding fuse blowing, CCS and Boot Hold Off, refer to Platform reference manual and Trust Architecture User Guide

> **NOTE**
>
> Blowing of OTPMKis essential to run secure boot for both Production (Flow A) and Prototyping/ Development (Flow B).
>
> For SRK Hash,in Development Mode (Flow B), there is a workaround to avoid blowing fuses. For this use RCW with BOOT_HO = 1. This will put the core in Boot Hold off stage. Then a CCS can be connected via JTAG.
>
> Write the SRK Hash value in SFP mirror registers and then release the core out of Boot Hold off by writing to Core Release Register in DCFG.

2. Connect the card reader with SD card to the Linux Host PC.The partition on SD card can also be created by connecting it to the board used once the linux is up using any other boot source (eg nor)

   Make two partitions in SD card, both MS DOS partition.

```
fdisk /dev/mmcblk0
```

   p – to see the partitions already created

   n – to create new partitions

```
partition no 1
first sector default
sector +1G (to indicate the size of first partition
```

   L – the type of partition

   w -to write the partition

3. After creating partition, use mkfs.ext2 to create filesystems

```
mkfs.vfat /dev/mmcblk0p1
mkfs.ext2 /dev/mmcblk0p2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp

```
mkdir /mnt
mount /dev/mmcblk0p2 /mnt/
cd /mnt/
```

5. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs

```
tar -zxvf QorIQ_SDK_<Version>_<release date>_ROOTFS_Image.tar.gz
rm QorIQ_SDK_V2.0_CORTEXA7_20160527_ROOTFS_Image.tar.gz
```

6. Make sure the kernel image, dtb file and their headers are in /mnt/boot directory, then umount the /mnt

```
scp -r $path/uImage.* ./boot
scp -r $path/hdr_linux.out ./boot
scp -r $path/hdr_dtb.out ./boot
umount /mnt
```

7. Write the new RCW file created, to 1st partition of SD at 8th sector

   The below command can be used to write to SD

   The **default** switch settings is such that the **boot source is nor**

```
setenv path <path>
tftp 81000000 $path/u-boot-with-spl-pbl-sec.bin
mmc erase 8 0x940
mmc write 0x81000000 8 0x940
```

Execution FLOW

- PBL will load u-boot-spl and its header to OCRAM, u-boot and its header will be appended to RCW file that wil be copied to SD flash along with RCW.
- ISBC will validate u-boot spl and then u-boot-spl will load the main u-boot to DDR and will validate main u-boot (ESBC).
- ESBC image would further copy the Boot Script Header and Boot Script from SD to DDR, validate the boot script and execute it.
- The Boot Script has commands to copy the linux images and their respective headers from SD to DDR, validate the signed linux, rootfs and dtb images.
- Linux would be booted.

10.3.1.7.6 NAND Secure Boot (Chain of Trust with Confidentiality)

This section presents the steps and images needed for running Secure Boot Chain of Trust with Confidentiality from NAND on **P3/P5**

The procedure for running Secure boot from NAND is same as Secure Boot from NAND. The only difference is that in case of NOR, image is not required to be copied from NOR while in case of NAND, images have to be copied from NAND to SRAM/ DDR before validation.

Images Required for Demo

1. PBL.bin

The PBL.bin is generated using QCVS Tool. It creates the RCW along with PBI commands. ESBC (U-boot) and CSF Header for U-Boot are added using ACS_WRITE PBI commands. (For details/screenshots refer Using QCVS Tool (Secure Boot From NAND) on page 1997)

2. uImage (Linux Image)
3. rootfs
4. dtb (Device Tree)
5. Encap Boot Script
6. CSF Header of the Encap Boot Script
7. Decap Boot Script
8. CSH Header for Decap Boot Script

Encap Boot Script

```
# uImage
nand read <uImage DDR> <uImage NAND> <uImage size>

bootm 0x10000000 0x20000000 0x1000000
```

Image Signing

The image signing process will remain same as in case of NOR NAND Secure Boot (Chain of Trust with Confidentiality) on page 1967

<platform> will be p3_p4_p5/nand

10.3.1.7.6.1 Running Secure Boot Chain of Trust with Confidentiality (from NAND)

1. Setup the board for secure boot flow. You can choose any if the flows mentioned below.
   a. **Flow A**

      Program the ITS fuse. Use RCW with SB_EN=0

      Or

   b. **Flow B**

      For protyping phase, don't blow the ITS fuse, but use rcw with SB_EN = 1.

      Note: For P3/P5, if ITS fuse is blown, then ITF fuse must also be blown. (The value of ITS and ITF fuse must be identical.)
2. Blow other required fuses on the board. (OTPMK and SRK hash[20]) For more details regarding fuse blowing, CCS and Boot Hold Off, refer to Platform reference manual and Trust Architecture User Guide.

   NOTE

   SRK hash in the fuse should be same as the hash of the key pair being used to sign the ESBC u-boot. Step 2 of Signing the images using same key pair on page 1954

   For testing purpose, the SRK Hash can be written in the mirror registers.

   gen_otpmk_drbg utility in cst can be used to generate otpmk key.
3. Flash all the generated images on NAND Flash at locations as described in the address map (specified for different platforms under the topic 'Appendix <platform> Secure Boot Demo')
   a. PBL.bin
   b. LINUX Images (uImage, dtb, rootfs)
   c. CSF Header for bootscript_encap)
   d. bootscript_encap
4. Switch to NAND Boot.
   a. **FLOW A**

      Change the Switch Settings to change the RCW_SRC to NAND and power on the board.
   b. **FLOW B**

      Power on the board to bring up Non-Secure U-Boot on NOR and from U-Boot promt issue the following command.

```
mw.b 0xffdf0020 0x48;mw.b 0xffdf0021 0x78;mw.b 0xffdf002c 0x90;mw.b 0xffdf002d 0xf0;mw.b
0xffdf0010 0; mw.b 0xffdf0010 1
```

   - The PBL would configure CPC as SRAM, update the SCRATCH register and copy the Header and U-boot (ESBC) on CPC configured as SRAM.
   - ISBC code would get control, validate the ESBC image.
   - ESBC image would further copy the Boot Script Header and Boot Script from NAND to DDR, validate the boot script and execute it.

[20] Blowing of **OTPMK**is essential to run secure boot for both Production (Flow A) and Prototyping/Development (Flow B).

For **SRK Hash**,in Development Mode (Flow B), there is a workaround to avoid blowing fuses. For this use RCW with BOOT_HO = 1. This will put the core in Boot Hold off stage. Then a CCS can be connected via JTAG.

Write the SRK Hash value in SFP mirror registers and then release the core out of Boot Hold off by writing to Core Release Register in DCFG.

- Bootscript would encapsulate the Linux, rootfs and device tree and store the blobs at the desired locations.

5. Revert the switch settings to earlier RCW_SRC and power on the board. Replace the encap bootscript and its CSF header with decap bootscript and the CSF header of the decap bootscript respectively.
6. Switch to NAND Boot.
   a. **FLOW A**

      Change the Switch Settings to change the RCW_SRC to NAND and power on the board.

   b. **FLOW B**

      Power on the board to bring up Non-Secure U-Boot on NOR and from U-Boot promt issue the following command.

```
mw.b 0xffdf0020 0x48;mw.b 0xffdf0021 0x78;mw.b 0xffdf002c 0x90;mw.b 0xffdf002d 0xf0;mw.b
0xffdf0010 0; mw.b 0xffdf0010 1
```

- The PBL would configure CPC as SRAM, update the SCRATCH register and copy the Header and U-boot (ESBC) on CPC configured as SRAM.
- ISBC code would get control, validate the ESBC image.
- ESBC image would further copy the Boot Script Header and Boot Script from NAND to DDR, validate the boot script and execute it.
- Bootscript would copy the Linux, rootfs and device tree blobs on DDR and then decapsulate them on DDR.
- Bootm commnd in bootscript would execute on successful decapsulation.
- Linux prompt would come up.

10.3.1.8 Troubleshooting

Table 305. Troubleshooting

	Symptoms	Reasons and/or Recommended actions
1.	No print on UART console.	• Check the status register of sec mon block (location 0xfe314014). Refer to the details of the register from the Reference Manual. Bits OTPMK_ZERO, OTMPK_SYNDROME and PE should be 0 otherwise there is some error in the OTPMK fuse blown by you. • If OTMPK fuse is correct (see Step 1), check the SCRATCHRW2 register for errors. Refer to Section for error codes. • If **Error code = 0** then check the Security Monitor state in HPSR register of Sec Mon. **Sec Mon in Check State (0x9)** If ITS fuse = 1, then it means ISBC code has reset the board. This may be due to the following reasons: Hash of the public key used to sign the ESBC u-boot doesn't match with the value in SRK Hash Fuse Or Signature verification of the image failed **Sec Mon in Trusted State (0xd) or Non Secure State (0xb)** Check the entry point field in the ESBC header. It should be 0xcffffffc for the demo described in Section 4. If entry point is correct, ensure that u-boot image has been compiled with the required secure boot configuration.
2.	Instead of linux prompt, you get a u-boot command prompt instead of linux prompt.	You have not booted in secure boot mode. You never get a u-boot prompt in secure boot flow. Check Step 1 in Running secure boot (Chain of Trust) on page 1957. You would reach this stage if ITS = 0 and you are using rcw where sben0 is present in its name.
3	u-boot hangs or board resets	Some validation failure occurred in ESBC u-boot. Error code and description would be printed on u-boot console. Refer to for more details on errors.

10.3.1.9 CSF Header Data Structure

The CSF Header provides the ISBC with most of the information needed to validate the image.

P3/P4/P5 Platforms

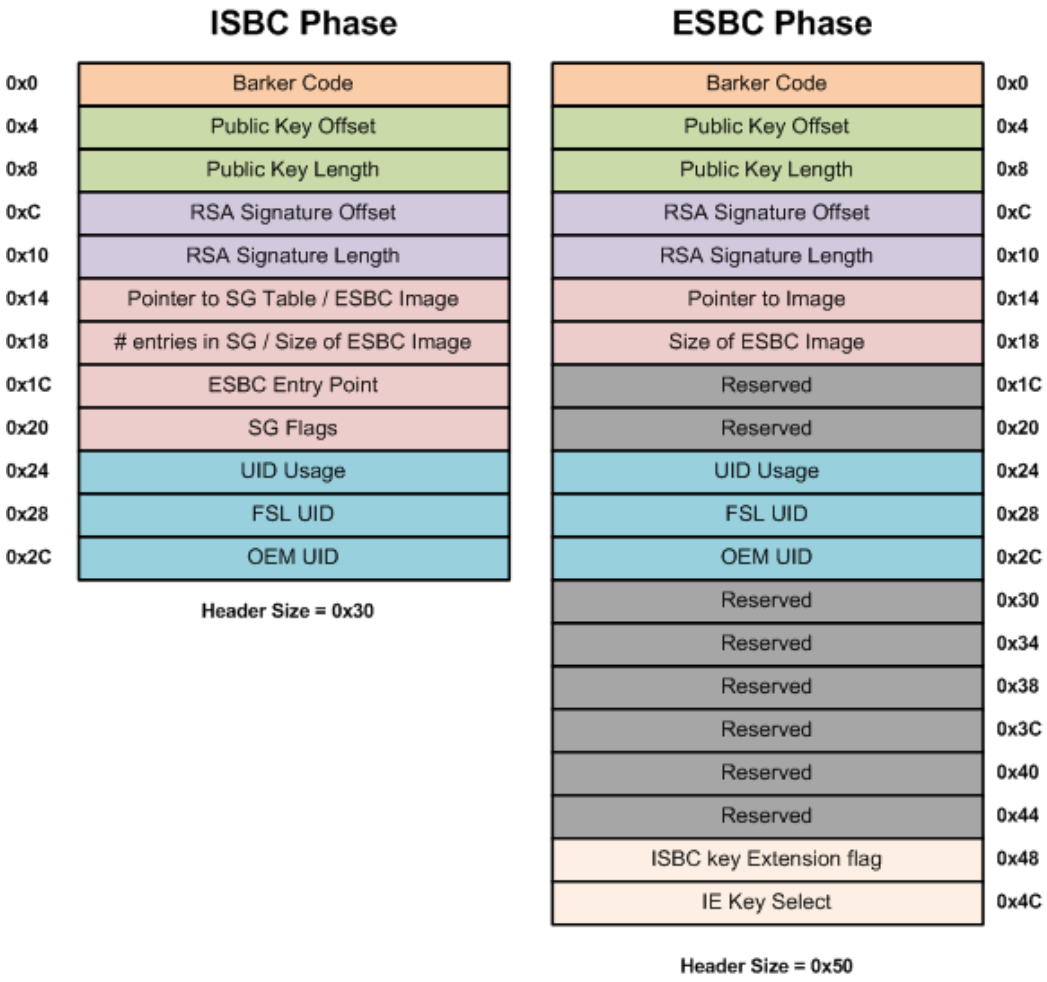

Figure 318. CSF Header for P3/P4/P5 (ISBC and ESBC Phase)

Table 306. CSF Header Format (P3/P4/P5 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	**Barker code**. This location should contain the value: 0x68392781. The ISBC code searches for this Barker code. If the value in this location does not match the Barker code, the ISBC stops execution and reports error.
0x04-0x07	**Public key offset**. This location contains an offset in bytes of the public key from the start of CSF header. Using this offset and the public key length, the public key is read.
0x08-0x0b	**Public key length** in bytes. (Value populated here should be twice of Modulus size). Supported sizes are 256, 512 or 1024 bytes (2 * 1024, 2 * 2048 , 2 * 4096 bits).

Table continues on the next page...

Table 306. CSF Header Format (P3/P4/P5 Platforms) (continued)

Offset	Data Bits [0:31]
0x0c-0x0f	**RSA Signature offset**. This location contains an offset(in bytes) of the RSA signature from the start of CSF header. Using this offset and the Signature length, the RSA signature is read. The RSA signature is calculated over CSF Header, Scatter Gather table and ESBC images.
0x10-0x13	**RSA Signature length** in bytes.
0x14-0x17	For ISBC Phase: Based on the Scatter Gather flag in CSF header, this location can either be treated as **Pointer to Scatter Gather table or the address of ESBC image**. For ESBC Phase: This location is treated as **address of image**(linux/bootscript/rootfs/dtb) to be validated.
0x18-0x1b	For ISBC Phase: Based on the Scatter gather flag in CSF Header, this location can either be treated as **number of entries in SG table or ESBC image size** in bytes. For ESBC Phase: Size of image to be validated
0x1c-0x1f	For ISBC Phase: **ESBC entry poin**t. ISBC transfers control to this location upon successful validation of ESBC image(s). For ESBC Phase: Reserved.
0x20-0x23	For ISBC Phase: **Scatter Gather flag**. 0x0000 - 0x14-0x17 is a pointer to the ESBC image 0x0001 - 0x14-0x17 is a pointer to a scatter/gather table. For ESBC Phase: Reserved
0x24-0x27	**Unique ID Usage**. UIDs present in the CSF Header are compared to the corresponding UIDs in the SFP, and are included in the ESBC validation. 0x0000 - No UIDs are present in CSF header 0x0001 - FSL_UID and OEM_UID are present in CSF header 0x0002 - Only OEM_UID present in CSF header 0x0004 - Only FSL_UID present in CSF header
0x28-0x2b	**NXP unique ID**. A unique 32 bit value, which is specific to NXP. This value is compared with the FSL ID in Secure Fuse Processor 's FSL-ID registers

Table continues on the next page...

Table 306. CSF Header Format (P3/P4/P5 Platforms) (continued)

Offset	Data Bits [0:31]
0x2c-0x2f	**OEM unique ID**. A unique 32 bit value, which is specific to OEM. This value is compared with the OEM ID in Secure Fuse Processor 's OEM-ID registers
0x30-0x47	For ISBC Phase: Not Applicable For ESBC Phase: Reserved
0x48-0x4b	For ISBC Phase: Not Applicable For ESBC Phase: **ISBC key Extension flag**. If this flag is set, key to be used for validation needs to be picked up from IE Key table.
0x4c-0x4f	For ISBC Phase: Not Applicable For ESBC Phase: **IE Key Select**. Key Number to be used from the IE Key Table if IE flag is set.

Table 307. Scatter Gather Table Format (P3/P4/P5 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	Length in bytes of the first segment of the ESBC image.
0x04-0x07	Pointer to first segment of ESBC image.
0x08-0x0b	Length in bytes of the second segment of the ESBC image.
0x0c-0x0f	Pointer to second segment of ESBC image.
0xww-0xxx	Length in bytes of the nth segment of the ESBC image.
0xyy-0xzz	Pointer to nth segment of ESBC image

Table 308. Signature (P3/P4/P5 Platforms)

Offset	Data Bits [0:31]
0x00-size	The RSA signature calculated over CSF Header, Scatter Gather table and ESBC image(s).

Table 309. Public key (P3/P4/P5 Platforms)

Offset	Data Bits [0:31]
0x00-size	Public Key Value. The hash of this public key is compared with the hash stored in Secure Fuse Processor SRKH registers.

B4/T1/T2/T4 Platforms

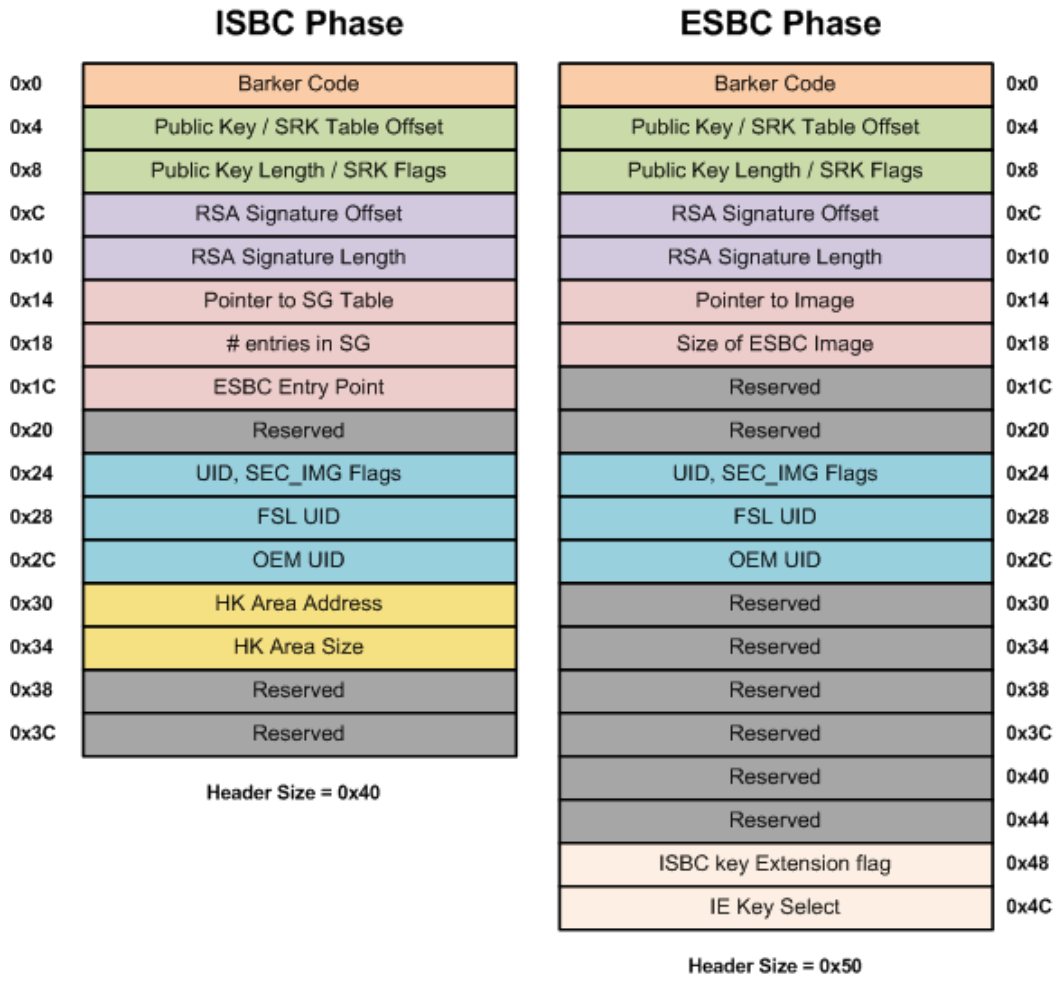

Figure 319. CSF Header for B4/T1/T2/T4 (ISBC and ESBC Phase)

Table 310. CSF Header Format (B4/T1/T2/T4 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	**Barker code**. This location should contain the value: 0x68392781. The ISBC code searches for this Barker code. If the value in this location does not match the Barker code, the ISBC stops execution and reports error.

Table continues on the next page...

Table 310. CSF Header Format (B4/T1/T2/T4 Platforms) (continued)

Offset	Data Bits [0:31]
0x04-0x07	If the srk_table_flag is not set : • **Public key offset**: This location contains an address which is the offset of the public key from the start of CSF header. Using this offset and the public key length, the public key is read. If srk_table_flag is set: • **Srk table offset**: This location contains an address which is the offset of the srk table from the start of CSF header. Using this offset and the number of entries is SRK Table, the SRK table is read.
0x08	**Srk table flag**. This flag indicates whether hash burnt in srk fuse is of a single key or of srk table.
0x09-0x0b	If the srk_table_flag is not set : • **Public key length**: This location contains the length of the public key in bytes. If srk_table_flag is set: • 0x09 – **Key Number from srk table** which is to be used for verification. • 0x0a-0x0b – **Number of entries in srk table**. Minimum number of entries in table = 1, Maximum = 4.
0x0c-0x0f	**RSA Signature offset**. This location contains an offset(in bytes) of the RSA signature from the start of CSF header. Using this offset and the Signature length, the RSA signature is read. The RSA signature is calculated over CSF Header, Scatter Gather table and ESBC images.
0x10-0x13	**RSA Signature length** in bytes.
0x14-0x17	For ISBC Phase: **SG Table offset** This location contains an address which is the offset of the SG table from the start of CSF header. Using this offset and the number of entries is SG Table, the SG table is read. For ESBC Phase: Address of the image to be validated.
0x18-0x1b	For ISBC Phase: **Number of entries in SG Table** (Earlier ,Based on the Scatter gather flag in CSF Header, this location can either be treated as number of entries in SG table or ESBC image size in bytes.). For ESBC Phase: **Size of Image** to be validated

Table continues on the next page...

Table 310. CSF Header Format (B4/T1/T2/T4 Platforms) (continued)

Offset	Data Bits [0:31]
0x1c-0x1f	For ISBC Phase: **ESBC entry point**. ISBC transfers control to this location upon successful validation of ESBC image(s). For ESBC Phase: Reserved
0x20-0x23	**Reserved** .(Earlier this field was SG Flag. SG flag is always assumed to be 1 in unified implementation.)
0x24	For ISBC Phase: Reserved For ESBC Phase: Reserved
0x25	For ISBC Phase: **Secondary Image flag** Indicates if user has a secondary image available in case of failures in validating primary iamge.Valid in case of primary Images's Header. For ESBC Phase:Reserved
0x26-0x27	**Unique ID Usage** This location contains a flag which specifies one of these possibilities • 0x00 - No UID's present • 0x01 - FSL UID and OEM UID are present • 0x02 - Only FSL UID is present • 0x04 - Only OEM UID is present
0x28-0x2b	**NXP unique ID**. A unique 32 bit value, which is specific to NXP. This value is compared with the FSL ID in Secure Fuse Processor 's FSL-ID registers
0x2c-0x2f	**OEM unique ID**. A unique 32 bit value, which is specific to OEM. This value is compared with the OEM ID in Secure Fuse Processor 's OEM-ID registers
0x30-0x33	For ISBC Phase: **Housekeeping area address** This is address of start of a memory which can be accessed by devices on SOC bus. (DDR, L3 cache configured as SRAM). The area should have been pre-configured by user through PBL commands or configuration header For ESBC Phase: Reserved

Table continues on the next page...

Table 310. CSF Header Format (B4/T1/T2/T4 Platforms) (continued)

Offset	Data Bits [0:31]
0x34-0x37	For ISBC Phase: **Size of the housekeeping area** Size of the pre-configured memory which can be used by Boot Rom Code. For ESBC Phase: Reserved
0x38-0x3f	Reserved
0x40-0x47	For ISBC Phase: Not Applicable For ESBC Phase: Reserved
0x48-0x4b	For ISBC Phase: Not Applicable For ESBC Phase: **ISBC key Extension flag** If this flag is set, key to be used for validation needs to be picked up from IE Key table.
0x4c-0x4f	For ISBC Phase: Not Applicable For ESBC Phase: **IE Key Select** Key Number to be used from the IE Key Table if IE flag is set.

Table 311. Scatter Gather Table Format (B4/T1/T2/T4 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	Length. This location specifies the length in bytes of the ESBC image 1.
0x04-0x07	Target where the ESBC Image 1 can be found. This field is ignored in case of PBL based SOC's.
0x08-0x0b	Source Address of ESBC Image 1
0x0c-0x0f	Destination Address of ESBC Image 1 If the target address is 0xffffffff, the image is not copied to the target. This field is ignored in case of PBL based SOC's.
0x10-0x13	Length. This location specifies the length in bytes of the ESBC image 2.
0x14-0x17	Target where the ESBC Image 2 can be found. This field is ignored in case of PBL based SOC's.
0x18-0x1b	Source Address of ESBC Image 2
0x1c-0x1f	Destination Address of ESBC Image 2 If the target address is 0xffffffff, the image is not copied to the target. This field is ignored in case of PBL based SOC's.

Table 312. Signature (B4/T1/T2/T4 Platforms)

Offset	Data Bits [0:31]
0x00-size	The RSA signature calculated over CSF Header, Scatter Gather table and ESBC image(s).

Table 313. Public key (B4/T1/T2/T4 Platforms)

Offset	Data Bits [0:31]
0x00-size	Public Key Value. The hash of this public key is compared with the hash stored in Secure Fuse Processor SRKH registers.

Table 314. SRK Table (B4/T1/T2/T4 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	Key 1 length
0x04-0x403	Key 1 value. (Remaining bytes will be padded with zero)
0x404-0x407	Key 2 length
0x408-0x807	Key 2 value. (Remaining bytes will be padded with zero)
0x808-0x80b	Key 3 length
0x80c-0xb0b	Key 3 value. (Remaining bytes will be padded with zero)
0xb0c-0xb0f	Key 4 length
0xb10-0xe10	Key 4 value. (Remaining bytes will be padded with zero)

LS1 Platform

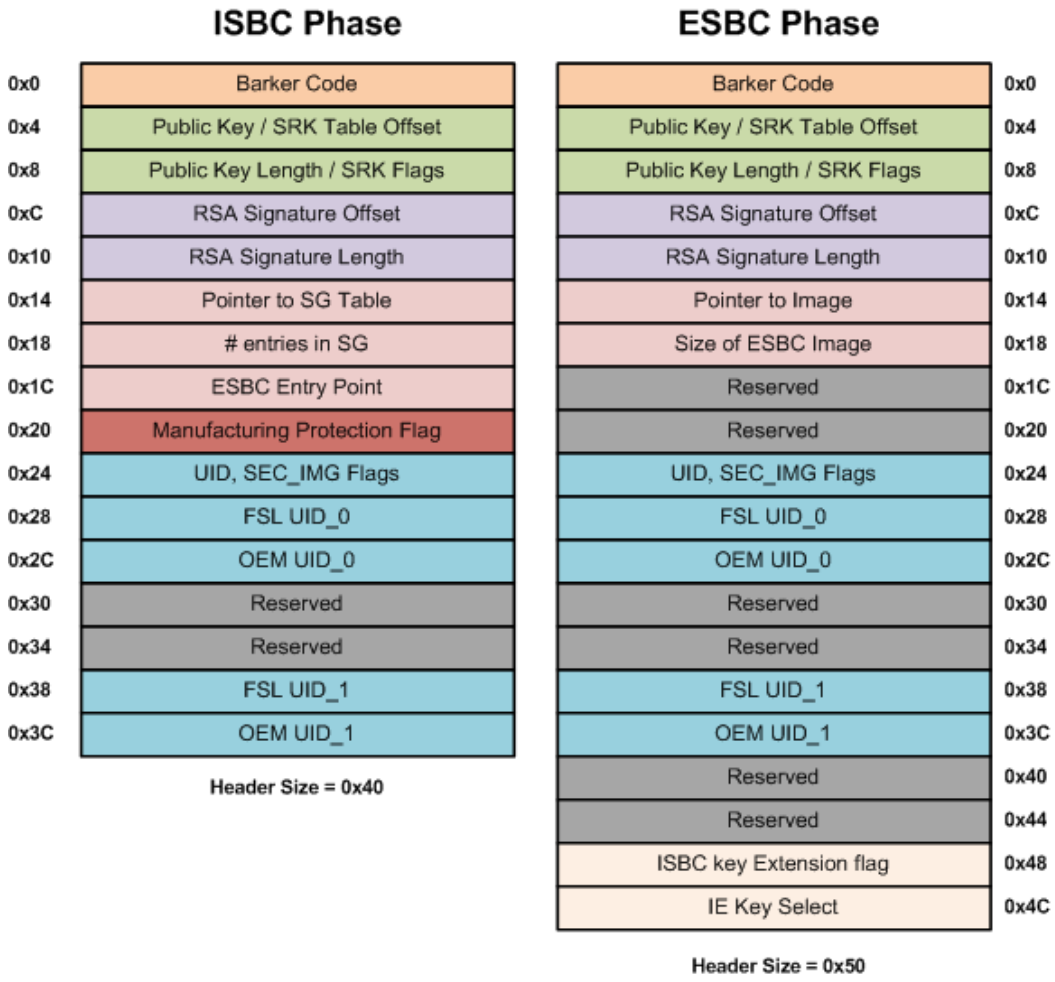

Figure 320. CSF Header for LS1 (ISBC and ESBC Phase)

Table 315. CSF Header Format (LS1 Platform)

Offset	Data Bits [0:31]
0x00-0x03	**Barker code**. This location should contain the value: 0x68392781. The ISBC code searches for this Barker code. If the value in this location does not match the Barker code, the ISBC stops execution and reports error.
0x07-0x04	If the srk_table_flag is not set : • **Public key offset**: This location contains an address which is the offset of the public key from the start of CSF header. Using this offset and the public key length, the public key is read. If srk_table_flag is set: • **Srk table offset**: This location contains an address which is the offset of the srk table from the start of CSF header. Using this offset and the number of entries is SRK Table, the SRK table is read.

Table continues on the next page...

Table 315. CSF Header Format (LS1 Platform) (continued)

Offset	Data Bits [0:31]
0x08	**Srk table flag**. This flag indicates whether hash burnt in srk fuse is of a single key or of srk table.
0x0b-0x09	If the srk_table_flag is not set : • **0x0b-0x9** -- **Public key length**: This location contains the length of the public key in bytes. If srk_table_flag is set: • **0x09** – **Key Number from srk table** which is to be used for verification. • **0x0b-0x0a** – **Number of entries in srk table**. Minimum number of entries in table = 1, Maximum = 4.
0x0f-0x0c	**RSA Signature offset**. This location contains an offset(in bytes) of the RSA signature from the start of CSF header. Using this offset and the Signature length, the RSA signature is read. The RSA signature is calculated over CSF Header, Scatter Gather table and ESBC images.
0x13-0x10	**RSA Signature length** in bytes.
0x17-0x14	**For ISBC Phase**: **SG Table offset** This location contains an address which is the offset of the SG table from the start of CSF header. Using this offset and the number of entries is SG Table, the SG table is read. **For ESBC Phase**: Address of the image to be validated.
0x1b-0x18	**For ISBC Phase**: **Number of entries in SG Table** (Earlier ,Based on the Scatter gather flag in CSF Header, this location can either be treated as number of entries in SG table or ESBC image size in bytes.). **For ESBC Phase** **Size of image** to be validated
0x1f-0x1c	**For ISBC Phase**: **ESBC entry point**. ISBC transfers control to this location upon successful validation of ESBC image(s). **For ESBC Phase**: Reserved
0x21-0x20	**Manufacturing Protection Flag** Indicates if manufacturing protection has to be enabled or not in ISBC.
0x23-0x22	**Reserved** .(Earlier this field was SG Flag. SG flag is always assumed to be 1 in unified implementation.)

Table continues on the next page...

Table 320. CSF Header Format (LS1043/LS1046/LS1012 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	**Barker code**. This location should contain the value: 0x68392781. The ISBC code searches for this Barker code. If the value in this location does not match the Barker code, the ISBC stops execution and reports error.
0x07-0x04	If the srk_table_flag is not set : • **Public key offset**: This location contains an address which is the offset of the public key from the start of CSF header. Using this offset and the public key length, the public key is read. If srk_table_flag is set: • **Srk table offset**: This location contains an address which is the offset of the srk table from the start of CSF header. Using this offset and the number of entries is SRK Table, the SRK table is read.

Table continues on the next page...

Table 320. CSF Header Format (LS1043/LS1046/LS1012 Platforms) (continued)

Offset	Data Bits [0:31]
0x08	**Srk table flag**. This flag indicates whether hash burnt in srk fuse is of a single key or of srk table.
0x0b-0x09	If the srk_table_flag is not set : • **0x0b-0x9** -- **Public key length**: This location contains the length of the public key in bytes. If srk_table_flag is set: • **0x09** – **Key Number from srk table** which is to be used for verification. • **0x0b-0x0a** – **Number of entries in srk table**. Minimum number of entries in table = 1, Maximum = 4.
0x0f-0x0c	**RSA Signature offset**. This location contains an offset(in bytes) of the RSA signature from the start of CSF header. Using this offset and the Signature length, the RSA signature is read. The RSA signature is calculated over CSF Header, Scatter Gather table and ESBC images.
0x13-0x10	**RSA Signature length** in bytes.
0x17-0x14	**For ISBC Phase**: **SG Table offset** This location contains an address which is the offset of the SG table from the start of CSF header. Using this offset and the number of entries is SG Table, the SG table is read. **For ESBC Phase**: Reserved
0x1b-0x18	**For ISBC Phase**: **Number of entries in SG Table** (Earlier ,Based on the Scatter gather flag in CSF Header, this location can either be treated as number of entries in SG table or ESBC image size in bytes.). **For ESBC Phase** **Size of image** to be validated
0x1f-0x1c	**For ISBC Phase**: **ESBC entry point**. ISBC transfers control to this location upon successful validation of ESBC image(s). **For ESBC Phase**: Reserved
0x21-0x20	**Manufacturing Protection Flag** Indicates if manufacturing protection has to be enabled or not in ISBC.
0x23-0x22	**Reserved** .(Earlier this field was SG Flag. SG flag is always assumed to be 1 in unified implementation.)

Table continues on the next page...

Table 320. CSF Header Format (LS1043/LS1046/LS1012 Platforms) (continued)

Offset	Data Bits [0:31]
0x24	For ISBC Phase: Reserved For ESBC Phase: Reserved
0x25	**For ISBC Phase** **Secondary Image flag** Indicates if user has a secondary image available in case of failures in validating primary iamge.Valid in case of primary Images's Header. **For ESBC Phase**:Reserved
0x27-0x26	**Unique ID Usage** This location contains a flag which specifies one of these possibilities • 0x00 - No UID's present • 0x01 - FSL UID and OEM UID are present • 0x02 - Only FSL UID is present • 0x04 - Only OEM UID is present
0x2b-0x28	**NXP unique ID 0** Upper 32 bits of a unique 64 bit value, which is specific to NXP. This value is compared with the FSL ID 1 in Secure Fuse Processor 's FSL-ID registers
0x2f-0x2c	**OEM unique ID 0** Upper 32 bits of a unique 64 bit value, which is specific to OEM. This value is compared with the OEM ID 0 in Secure Fuse Processor 's OEM-ID registers
0x37-0x30	Reserved
0x3b-0x38	**NXP unique ID 1** Lower 32 bits of a unique 64 bit value, which is specific to NXP. This value is compared with the FSL ID 1 in Secure Fuse Processor 's FSL-ID registers
0x3f-0x3c	**OEM unique ID 1** Lower 32 bits of a unique 32 bit value, which is specific to OEM. This value is compared with the OEM ID 1 in Secure Fuse Processor 's OEM-ID registers
0x40-0x47	**For ISBC Phase**: Not Applicable **For ESBC Phase**: 64 bit pointer to ESBC image
0x48-0x4b	**For ISBC Phase**: Not Applicable **For ESBC Phase**: **ISBC key Extension flag** If this flag is set, key to be used for validation needs to be picked up from IE Key table.

Table continues on the next page...

Table 320. CSF Header Format (LS1043/LS1046/LS1012 Platforms) (continued)

Offset	Data Bits [0:31]
0x4c-0x4f	**For ISBC Phase**: Not Applicable **For ESBC Phase**: **IE Key Select** Key Number to be used from the IE Key Table if IE flag is set.

Table 321. Scatter Gather Table Format (LS1043/LS1046/LS1012 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	Length. This location specifies the length in bytes of the ESBC image 1.
0x04-0x07	Target where the ESBC Image 1 can be found. This field is ignored in case of PBL based SOC's.
0x08-0x0b	Source Address of ESBC Image 1
0x0c-0x0f	Destination Address of ESBC Image 1 If the target address is 0xffffffff, the image is not copied to the target. This field is ignored in case of PBL based SOC's.
0x10-0x13	Length. This location specifies the length in bytes of the ESBC image 2.
0x14-0x17	Target where the ESBC Image 2 can be found. This field is ignored in case of PBL based SOC's.
0x18-0x1b	Source Address of ESBC Image 2
0x1c-0x1f	Destination Address of ESBC Image 2 If the target address is 0xffffffff, the image is not copied to the target. This field is ignored in case of PBL based SOC's.

Table 322. Signature (LS1043/LS1046/LS1012 Platforms)

Offset	Data Bits [0:31]
0x00-size	The RSA signature calculated over CSF Header, Scatter Gather table and ESBC image(s).

Table 323. Public key (LS1043/LS1046/LS1012 Platforms)

Offset	Data Bits [0:31]
0x00-size	Public Key Value. The hash of this public key is compared with the hash stored in Secure Fuse Processor SRKH registers.

Table 324. SRK Table (LS1043/LS1046/LS1012 Platforms)

Offset	Data Bits [0:31]
0x00-0x03	Key 1 length
0x04-0x403	Key 1 value. (Remaining bytes will be padded with zero)
0x404-0x407	Key 2 length
0x408-0x807	Key 2 value. (Remaining bytes will be padded with zero)
0x808-0x80b	Key 3 length
0x80c-0xb0b	Key 3 value. (Remaining bytes will be padded with zero)
0xb0c-0xb0f	Key 4 length
0xb10-0xe10	Key 4 value. (Remaining bytes will be padded with zero)

10.3.1.10 ISBC Validation Error Codes

P3/P4/P5 platforms

Table 325. ISBC Validation Failures (P3/P4/P5 platforms)

Value	Code	Definition
0x1	CPUID_NO_MATCH	ISBC is not running on CPU0
0x2	ESBC_HDR_LOC	ESBC header location is not in 3.5G space
0x4	ESBC_HEADER_BARKER	Barker code in the header is incorrect.
0x8	ESBC_HEADER_KEY_LEN	Length of public key in header is not one of the supported values.
0x10	ESBC_HEADER_SIGN_LEN	Length of RSA signature in header is not one of the supported values.
0x20	ESBC_HEADER_KEY_LEN_NOT_TWICE_SIG_LEN	Public key is not twice the length of the RSA signature
0x40	ESBC_HEADER_SG_TABLE_ADDR_NULL	SG table/ESBC image address (0x14-0x17 in CSF Header) is null
0x80	ESBC_HEADER_SG_TABLE_ADDR_NOT_IN_3_5G	SG table/ESBC image address (0x14-0x17 in CSF Header) is beyond 3.5G
0x100	ESBC_HEADER_KEY_MOD_1	Most significant bit of modulus in header is zero.

Table continues on the next page...

Table 325. ISBC Validation Failures (P3/P4/P5 platforms) (continued)

Value	Code	Definition
0x200	ESBC_HEADER_KEY_MOD_2	Modulus in header is even number
0x400	ESBC_HEADER_SIG_KEY_MOD	Signature value is greater than modulus in header
0x800	ESBC_HEADER_SG_ENTRIES_NUL	SG Table contains zero entries
0x1000	ESBC_HEADER_SG_ENTRIES_NOT_IN_3_5G	Address in SG entry in not in 3.5G
0x2000	ESBC_HEADER_SG_ESBC_EP	ESBC entry point in header not within ESBC address range
0x4000	HASH_COMPARE_KEY	Super Root Key Hash Comparison failure. Mismatch in the hash of the public key as present in the header with the value in the SRK HASH fuse.
0x8000	HASH_COMPARE_EM	RSA signature check failure. Signature provided by you in the header doesn't match with the signature of the ESBC image generated by ISBC. The ESBC image loaded by you may be different than the image used while generating the signature(using CST)
0x10000	SSM_CHECKSTS	SEC_MON State Machine not in CHECK state at start of ISBC. Some Security violation could have occurred. Details can be found in P4080 Reference Manual.
0x20000	SSM_TRUSTSTS	SEC_MON State Machine not in TRUSTED state at end of ISBC.
0x40000	FSL_UID	FSL_UID in ESBC Header did not match the FSL_UID in SFP
0x80000	OEM_UID	OEM_UID in ESBC Header did not match the OEM_UID in SFP
0x100000	BAD_ADDRESS	A Data / Instruction TLB Exception occurred during ISBC execution
0x200000	MISC	E500mc exception other than TLB
0x400000	ESBC_HEADER_SG_ENTIRES_BAD	SG Table too large (too many entries)

NOTE

For error codes 0x2 - 0x2000 i,e errors in the ESBC Header, check the value of that particular field by dumping the header.

B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms

Errors in the system can be of following types:

1. Core Exceptions
2. System State Failures

3. Header Checking Failures
    a. General Failures
    b. Key/Signature/UID related errors
4. Verification Failures
5. SEC/PAMU errors

Table 326. Core Exceptions (LS1 platform)

Value	Code	Definition
0x1	ERROR_UNDEFINED_INSTRUCTION	Occurs if neither the processor nor any attached co-processor recognizes the currently executing instruction.
0x2	ERROR_SWI	Software Interrupt is a user-defined interrupt instruction. It allows a program running in User mode, for example, to request privileged operations that run in Supervisor mode.
0x3	ERROR_PREFETCH_ABORT	Occurs when the processor attempts to execute an instruction that has been prefetched from an illegal address.
0x4	ERROR_DATA_ABORT	Occurs when a data transfer instruction attempts to load or store data at an illegal address.
0x5	ERROR_IRQ	Occurs when the processor external interrupt request pin is asserted (LOW) and IRQ interrupts are enabled.
0x6	ERROR_FIQ	Occurs when the processor external fast interrupt request pin is asserted (LOW) and FIQ interrupts are enabled.

Table 327. Core Exceptions (LS1043/LS1046/LS1012 platforms)

Error Code	Value
Current EL with SP0	
ERROR_EXCEPTION_SYNC_SP0	0x01
ERROR_EXCEPTION_IRQ_SP0	0x02
ERROR_EXCEPTION_FIQ_SP0	0x03
ERROR_EXCEPTION_SERROR_SP0	0x04
Current EL with SPx	
ERROR_EXCEPTION_SYNC_SPX	0x05
ERROR_EXCEPTION_IRQ_SPX	0x06
ERROR_EXCEPTION_FIQ_SPX	0x07
ERROR_EXCEPTION_SERROR_SPX	0x08
Lower EL using AArch64	
ERROR_EXCEPTION_SYNC_L64	0x11
ERROR_EXCEPTION_IRQ_L64	0x12

Table continues on the next page...

Table 327. Core Exceptions (LS1043/LS1046/LS1012 platforms) (continued)

ERROR_EXCEPTION_FIQ_L64	0x13
ERROR_EXCEPTION_SERROR_L64	0x14
Lower EL using AArch32	
ERROR_EXCEPTION_SYNC_L32	0x15
ERROR_EXCEPTION_IRQ_L32	0x16
ERROR_EXCEPTION_FIQ_L32	0x17
ERROR_EXCEPTION_SERROR_L32	0x18

Table 328. Core Exceptions (B4/T1/T2/T4 platforms)

Value	Code	Definition
0x1	ERROR_MACHINECHECK	Machine check Exception
0x2	ERROR_DSI	DSI Exception
0x3	ERROR_ISI	ISI Exception
0x4	ERROR_CRITICAL	Critical Exception
0x5	ERROR_ALIGN	Alignment Exception
0x6	ERROR_PROG	Program Exception
0x13	ERROR_DATA_TLB	Data TLB Miss
0x14	ERROR_INST_TLB	Instruction TLb Miss
0x20	ERROR_MISC	Any other exception

Table 329. System State Failures (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms)

Value	Code	Definition
0x100	ERROR_CORE_NON_ZERO	ISBC is not running on CPU0
0x101	ERROR_STATE_NOT_CHECK	SEC_MON State Machine not in CHECK state at start of ISBC. Some Security violation could have occurred.
0x102	ERROR2_STATE_NOT_CHECK	SEC_MON State Machine not in CHECK state, when trying to transition it to Trusted/Non Secure/Soft Fail state
0x103	ERROR_SSM_TRUSTSTS	SEC_MON State Machine not in TRUSTED state at end of ISBC.

Table 330. General Header Checking Failures (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms)

Value	Code	Definition
0x301	ERROR_ESBC_HDR_LOC	ESBC header location is not in 3.5G space
0x302	ERROR_ESBC_HEADER_BARKER	Barker code in the header is incorrect.
0x303	ERROR_ESBC_HEADER_SG_ENTRIES_NOT_IN_3_5G	SG table/ESBC image address (header address + image offset in sg table) is beyond 3.5G
0x303	ERROR_ESBC_HEADER_SG_ENTRIES_ON_OCRAM	One Entry in the SG table is on OCRAM
0x304	ERROR_ESBC_HEADER_SG_ESBC_EP	ESBC entry point in header not within ESBC address range
0x305	ERROR_SGL_ENTIRES_NOT_SUPPORTED	Number of entries in SG table exceeds maximum limit i.e 8
0x306	ERROR_ESBC_HEADER_HKAREA_LEN_ZERO	Houskeeping area not provided in header
0x307	ERROR_ESBC_HEADER_HKAREA_NOT_IN_3_5G	House keeping area not in 3.5G boundary
0x308	ERROR_ESBC_HEADER_HKAREA_LEN_INSUFFICIENT	Housekeeping area length provided is not sufficient.
0x309	ERROR_SG_TABLE_NOT_IN_3_5	SG Table is not in 3.5G boundary
0x309	ERROR_SG_TABLE_ON_OCRAM	SG table is on OCRAM
0x310	ERROR_ESBC_HEADER_HKAREA_NOT_4K_ALIGNED	House keeping area is not aligned to 4K boundary
0x311	ERROR_SGL_ENTRIES_SIZE_ZERO	SG table has entry with size zero.

Table 331. Key/Signature/UID related errors (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms)

Value	Code	Definition
0x320	ERROR_ESBC_HEADER_KEY_LEN	Length of public key in header is not one of the supported values.
0x321	ERROR_ESBC_HEADER_KEY_LEN_NOT_TWICE_SIG_LEN	Public key is not twice the length of the RSA signature
0x322	ERROR_ESBC_HEADER_KEY_MOD_1	Most significant bit of modulus in header is zero.
0x323	ERROR_ESBC_HEADER_KEY_MOD_2	Modulus in header is even number
0x324	ERROR_ESBC_HEADER_SIG_KEY_MOD	Signature value is greater than modulus in header
0x325	ERROR_FSL_UID	FSL_UID in ESBC Header did not match the FSL_UID in SFP if fsl uid flag Is 1
0x326	ERROR_OEM_UID	OEM_UID in ESBC Header did not match the OEM_UID in SFP if oem uid flag is 1.

Table continues on the next page...

Table 331. Key/Signature/UID related errors (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms) (continued)

Value	Code	Definition
0x327	ERROR_INVALID_SRK_NUM_ENTRY	Number of entries field in CSF Header is > 4(This is when srk_flag in header is 1)
0x328	ERROR_INVALID_KEY_NUM	Key number to be used from srk table is not present in table. (This is when srk_flag in header is 1)
0x329	ERROR_KEY_REVOKED	Key selected from srk table has been revoked(This is when srk_flag in header is 1)
0x32a	ERROR_INVALID_SRK_ENTRY_KEYLEN	Key length specified in one of the entries in srk table is not one of the supported values (This is when srk_flag in header is 1)
0x32b	ERROR_SRK_TBL_NOT_IN_3_5	SRK Table is not in 3.5G boundary (This is when srk_flag in header is 1)
0x32b	ERROR_SRK_TBL_ON_OCRAM	SRK Table is on OCRAM
0x32c	ERROR_KEY_NOT_IN_3_5G	Key is not in 3.5G boundary
0x32c	ERROR_KEY_ON_OCRAM	Key on OCRAM

Table 332. Verification Failures (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms)

Value	Code	Definition
0x340	ERROR_HASH_COMPARE_KEY	Super Root Key Hash Comparison failure. Mismatch in the hash of the public key/srk table as present in the header with the value in the SRK HASH fuse.
0x341	ERROR_HASH_COMPARE_EM	RSA signature check failure. Signature provided by you in the header doesn't match with the signature of the ESBC image generated by ISBC. The ESBC image loaded by you may be different than the image used while generating the signature(using CST)

Table 333. SEC/PAMU Failures (B4/T1/T2/T4/LS1/LS1043/LS1046/LS1012 platforms)

Value	Code	Definition
0x700	ERROR_SEC_ENQ	Error when enqueuing to SEC
0x701	ERROR_SEC_DEQ	Sec Block returned some error when dequeuing from it.
0x702	ERROR_SEC_DEQ_TO	Timeout when trying to deq from SEC
0x800	ERROR_PAMU	Error while programming PAACT/SPAACT tables in PAMU (For PowerPC platforms only)

10.3.1.11 ESBC Validation Error Codes

For trust arch version 1.x and 2.x.

Table 334. ESBC Validation Failures

Value	Code	Definition
0x0	ERROR_ESBC_CLIENT_MAX	NULL
0x4	ERROR_ESBC_CLIENT_HEADER_BARKER	Wrong barker code in header
0x8	ERROR_ESBC_CLIENT_HEADER_KEY_LEN	Wrong public key length in header
0x10	ERROR_ESBC_CLIENT_HEADER_SIG_LEN	Wrong signature length in header
0x11	ERROR_ESBC_CLIENT_HEADER_KEY_REVOKED	Key used to sign the image revoked
0x12	ERROR_ESBC_CLIENT_HEADER_INVALID_SRK_NUM_ENTRY	Wrong key entry
0x13	ERROR_ESBC_CLIENT_HEADER_INVALID_KEY_NUM	Selected key no. not in SRK table
0x14	ERROR_ESBC_CLIENT_HEADER_INV_SRK_ENTRY_KEYLEN	Unsupported key length of key in SRK table
0x15	ERROR_ESBC_CLIENT_HEADER_IE_KEY_REVOKED	Selected key in IE key table revoked
0x16	ERROR_ESBC_CLIENT_HEADER_INVALID_IE_NUM_ENTRY	Wrong IE Key entry
0x17	ERROR_ESBC_CLIENT_HEADER_INVALID_IE_KEY_NUM	Selected key no. not in IE Key table
0x18	ERROR_ESBC_CLIENT_HEADER_INV_IE_ENTRY_KEYLEN	Unsupported key length of key in IE Key table
0x19	ERROR_IE_TABLE_NOT_FOUND	information about IE table missing
0x20	ERROR_ESBC_CLIENT_HEADER_KEY_LEN_NOT_TWICE_SIG_LEN	Public key length not twice of signature length
0x21	ERROR_KEY_TABLE_NOT_FOUND	SRK Key/key table not found
0x40	ERROR_ESBC_CLIENT_HEADER_KEY_MOD_1	Public key Modulus most significant bit not set
0x80	ERROR_ESBC_CLIENT_HEADER_KEY_MOD_2	Public key Modulus in header not odd
0x100	ERROR_ESBC_CLIENT_HEADER_SIG_KEY_MOD	Signature not less than modulus
0x200	ERROR_ESBC_CLIENT_HEADER_SG_ESBC_EP	Entry Point error

Table continues on the next page...

Table 334. ESBC Validation Failures (continued)

Value	Code	Definition
0x400	ERROR_ESBC_CLIENT_HASH_COMPARE_KEY	Public key hash comparison failed
0x800	ERROR_ESBC_CLIENT_HASH_COMPARE_EM	RSA verification failed
0x1000	ERROR_ESBC_CLIENT_SSM_TRUSTSTS	SNVS not in TRUSTED state
0x2000	ERROR_ESBC_CLIENT_BAD_ADDRESS	Bad address error
0x4000	ERROR_ESBC_CLIENT_MISC	Miscallaneous error
0x8000	ERROR_ESBC_CLIENT_HEADER_SG_ENTIRES_BAD	Incorrect entries in SG table
0x10000	ERROR_ESBC_CLIENT_HEADER_SG	No SG support
0x20000	ERROR_ESBC_CLIENT_HEADER_IMG_SIZE	Invalid Image size
0x40000	ERROR_ESBC_WRONG_CMD	Failure in command/Unknown command/Wrong arguments of boot script.
0x80000	ERROR_ESBC_MISSING_BOOTM	Bootm command missing from boot script.

10.3.1.12 Trust Architecture and SFP Information

SoC	Trust Arch. Version	SFP Version	POVDD	DRVR		OTPMK		SNVS/SFP Register to check Hamming Error
				Algo (CST)	Register to check Hamming Error	Algo (CST)	Register to check Hamming Error
