Rev. 0, 03/2017

QorIQ SDK v2.0-1703 Documentation

For QorIQ Processors

Contents

Chapter 1
Welcome to the Linux SDK for QorIQ Processors Knowledge Center

QorIQ LS Series Communications Processors

The QorIQ communications processor portfolio is unmatched in depth and breadth. With the addition of the next-generation QorIQ LS1 and LS2 product families, the portfolio extends performance from the smallest form factor, power-constrained networking applications to software-defined networking applications requiring an advanced datapath and network peripheral interfaces. The LS1 and LS2 families based on ARM® technology offer optimized performance and power efficiency, plus pin compatibility, enabling customers to simply and smoothly migrate applications between these next-generation QorIQ devices.

QorIQ T Series Communications Processors

The QorIQ T series communications processors introduced 28nm to the portfolio in 2010 with scalable, pin-compatible 64-bit and multi-threaded Power Architecture cores, new and improved acceleration engines for fixed function processing as well as advanced power management technology. The T series products offer up to 4x performance improvements over the previous generation and reintroduces the highly-popular AltiVec vector processing unit for high-bandwidth data processing and algorithmic-intensive computations.

QorIQ P Series Communications Processors

The QorIQ P series communications processors launched in 2008 as an evolution of our leading PowerQUICC line. The devices are designed on 45 nm process technology to reduce power and increase integration – offering some of the industry's best performance to power ratios. The P series processors integrate enhanced Power Architecture cores, ranging from single to eight core devices, and include hallmark features such as CoreNet coherency fabric and acceleration engines for NXP's data path acceleration architecture (DPAA) including security and pattern matching. Today the P series is 25 products strong and powers solutions across every node of the network.

QorIQ Qonverge Series Baseband Processors

The QorIQ Qonverge portfolio of multimode solutions for femtocell, picocell, metrocell and macrocell base station applications support WCDMA, LTE and LTE-Advanced. The baseband SoC heterogeneous platform combines high-performance, market-proven 32-bit & 64-bit multi-threaded Power Architecture® CPU cores and performance leading StarCore DSP cores, featured with application acceleration platforms such as the MAPLE-B for baseband processing and DPAA for data path processing, security acceleration and more. The QorIQ Qonverge portfolio spans across world-class silicon process nodes of 45nm and 28nm already in production and beyond. NXP provides comprehensive solutions for the QorIQ Qonverge platform with ready-to-go software, ecosystem, software and hardware development tools to ease development and speed time to market for wireless base station applications.

See also the Linux SDK for QorIQ Processors summary page.

Chapter 2
SDK Overview

2.1 Introduction

This topic provides an introduction to the NXP Linux Software Development Kit, including intended audience, purpose and scope, and detailed sections on technical considerations.

Intended Audience

NXP SDK documentation is written for software developers and system engineers who have a technical background, and a working knowledge of Linux. The audience for the NXP QorIQ Linux SDK are users of QorIQ Communication, QorIQ Qonverge, and select PowerQUICC Communications Processors.

Overview of the SDK: Purpose and Scope

The NXP SDK is a Linux-oriented development kit. It allows users to

1. Evaluate and explore NXP SoC processors' features; experience how they are supported in Linux by working "out of the box" on NXP development boards.
2. Develop Linux-based solutions; the NXP SDK is thoroughly tested and backed by NXP software and services support from development to production.

One question might be why is this called a Software Development Kit (SDK) rather than a board support package (BSP)? The reason is that the SDK contains more than a single BSP; it supports numerous NXP processors and contains all the tools, accelerators, and unique features supported in the particular release. Many customers never need additional tools to get into production.

Normally a complete Linux environment is called a Linux "distribution" and contains a boot loader, the Linux kernel and user space components, a tool chain, a build system, and a package manager. All of these building blocks are included in the SDK, and can be used across many products.

The SDK is based on a widely-supported and open source community-oriented Linux Foundation effort called the Yocto Project and its' Poky software; for more information see http://www.yoctoproject.org. The SDK is a Linux-distribution created using Yocto Project/Poky that provides integrated SoC software support. The SDK includes support for the NXP Power™ architecture and ARM cores, and drivers for NXP-specific peripheral hardware.

Yocto Project/Poky distributions are embedded-oriented, and Yocto Project/Poky uses the OpenEmbedded-core package set. Embedded distributions use cross-compilation, and are capable of producing focused target images that are efficiently sized. Yocto Project/Poky is flexible, and its build system can also produce larger images with features such as target-resident (native) tool chains; the NXP SDK leverages this flexibility, and supports a wide range of pre-defined configurations.

The NXP SDK strategy is to use Yocto Project/Poky, and enhance it with NXP-specific SoC support; this way the basic SDK framework is familiar to anyone who has used Yocto Project/Poky on another architecture. Yocto Project resources, such as documentation, now become useful and relevant for development with the NXP SDK. The use of Yocto Project/Poky provides a straight-forward way to achieve a minimum footprint and maximum performance for your project.

Boot Loader

The SDK includes a popular and widely-used open source community boot loader called U-Boot. NXP, along with community developers, add support for NXP SoCs and peripherals. See www.denx.de/wiki/U-Boot.

NXP recommends and provides support services when using the CodeWarrior embedded software development studio and a CodeWarrior TAP to program U-Boot into flash memories for the first time.

Linux Kernel

The SDK is based upon the standard Linux kernel from http://www.kernel.org, but with patches added by the Yocto Project, NXP, and other community members to support NXP SoCs. Much of the NXP-supplied Linux software is within the kernel; NXP is one of the top 20 global kernel.org contributors.

One or more times per year NXP will upgrade to the latest long-term supported kernel version; then throughout the year, the team will accumulate changes for that kernel version. Occasionally, NXP will produce an “off cycle” SDK release that adds specific support for a new IC using patches. NXP is experienced with porting code to the latest kernels, across several product lines and architectures, when it is needed by our customer base.

Standard User Space

Many user space components, such as applications, initialization scripts, shells, etc., are architecture-independent so that the same software is built for the needed target architecture. For the most part, the NXP SDK provides these components unchanged from Yocto Project/Poky, and the build system compiles them for cores based on Power Architecture© or ARM technology.

The SDK includes upwards of 2,500 packages that add up to 15+ million lines of code, and NXP offers reference designs in our test benches. For example, we provide a storage area networking reference design to demonstrate how NXP processors and the SDK can work for those applications.

NXP User Space

NXP also supplies its own user space software as part of the SDK. QorIQ Communications Processes have extensive support for direct userspace access to NXP's DPAA and DPAA2 hardware blocks. Opensource packages like OpenDataPlane (ODP) and Data Plane Development Kit (DPDK) coupled with NXP enablement, and NXP's USDPAA package, provide a large set of userspace drivers and sample applications to enable this functionality. ODP, DPDK and USDPAA are packaged in SDK as Yocto Project/Poky packages with standard open-embedded recipes.

Virtualization

Virtualization provides an environment that enables multiple virtual machines (or partitions) on a single system. NXP offers two virtualization solutions as part of the SDK: a Linux-based KVM and the NXP Embedded Hypervisor. NXP tests these configurations to ensure quality. We have customers who use these configurations to keep from rewriting software to amalgamate separate boards together into a single board. The support also includes running OVS in kernel or userspace along with Virtual Machine running kernel or DPDK based user space networking.

Tool Chain

The SDK uses the GNU tool chain, but with additional patches supplied by the Yocto Project, other community members, and NXP. The SDK tool chain supports C and C++, and cross and native compiling; patches that provide the latest optimization for cores based on Power Architecture© or ARM technology are included. The standard gdb debugger, and other tools such as binutils , are also supported. To speed development time, NXP also has a commercial software development system called CodeWarrior Development Studio that compliments the SDK. Find that software here .

Build System

The SDK uses the Poky build system that uses the OpenEmbedded-core. The SDK strategy is to use this component in the same fashion across all architectures. To reduce build times, Yocto Project/Poky supports caching binaries.

Package Management

The SDK supports package management and selection using standard Yocto Project/Poky methods. The distribution is source based, and source code is provided for most packages and all packages are provided under the GNU Public License.

SDK System Images

As mentioned above, the SDK can generate several different user space system images that range in size from large to small. Users who are new to the SDK may wish to start by booting a system using" fsl-image-full." In fact, this image is pre-installed on many NXP development boards.

2.2 What's New

NXP Digital Networking is pleased to announce the release of QorIQ Linux SDK V2.0 supporting our QorIQ family of processors. All processors and boards supported in QorIQ SDK V2.0 utilize a common source base.

What's New in SDK V2.0-1703

Highlights

- Integrates off-train release for LS2088A BSP v0.3
- Integrates off-train release for LS1012A BSP v0.5
- Removal of LS2080A and LS2085A-RDB
- MC 10.1.2 update
- Added DPDK support for DPAA2 platforms (LS2088A)
- Integrates Open Data Plane (ODP) for LS2088A
- Includes several software fixes. See Fixed, Open, and Closed Issues on page 64 section which has a list of all fixed issues
- Includes additional workarounds for Chip Errata: A-009241, A-009942, A-010554, A-010635, A-010812

See list of changes in below

Processor and Board Support

- LS2088A r1.0 and Rev.D RDB, Rev. F RDB
- Removal of LS2080A and LS2085A-RDB
- LS1012A RDB revC and FRDM revD

Linux Kernel Core, Virtualization

- LS2088A: libvirt, LXC, docker engine

Linux Kernel Drivers

- LS2088A: DUART, DDR4, I2C, PCIe, SATA, USB, SD, MMC, NOR, NAND flash, Networking support, SEC
- LS1012A: 2.5G SGMII, Checksum offload to PFE hardware
- CPU Frequency on LS1012A
- DPAA2 ethernet: socket busy poll, IEEE802.3x flow control, tx congestion management
- eMMC HS200 and SD UHS-I on LS1012A and LS1046A
- PFE driver: Checksum offload to PFE hardware

Data Plane Development Kit (DPDK)

- DPDK v16.07.2 Support with Stable patches from Upstream
- DPAA2 support for DPDK
- Various performance optimization and bug fixes
- Features supported:
  - Fragmentation and Re-assembly
  - RX Queue Tail drop for performance improvement at high traffic rates
  - DPAA2 now supports Flow Control (Pause Frame)

- DPAA1 now supports Multicast address filtering

Virtualization - OVS-DPDK

- DPAA2 support enabled in OVS-DPDK
- DPDK working in Virtual Machine on DPAA2 and DPAA1

Open Data Plane (ODP)

- Supported on LS2088A
- Supports ODP API v1.11
- Following Applications are supported:
  - ODP generator sample application
  - ODP pktio sample application
  - ODP ipsec transport and tunnel sample applications
  - ODP packet classify sample application
  - ODP timer sample application
  - ODP LPM IP Forwarding sample application
  - ODP Traffic Manager sample application
  - ODP OpenFastPath Applications (FPM & FPM_BURSTMODE)

U-Boot Boot Loader

- LS2088A: DUART, DDR4, I2C, PCIe, SATA, USB, SD, MMC, NOR, NAND flash, Networking support, Boot from NOR flash
- NAND secure boot on LS1043A
- SD secure boot on LS1043A and LS1046A

Other Tools and Utilities

- LS2088A: Primary Protected Application (PPA) firmware
- MC 10.1.2 updates
- Restool: DPNI configuration support for Order Restoration, Debug Configration, Loopback Option
- Benchmark: power management benchmark on LS1046A

What's New in SDK V2.0-1701

Highlights

- Kernel 4.1.35 upgrade
- Integrates off-train releases for LS1012A BSP v0.4
- DPDK on LS1043A, LS1046A and LS2080A
- Real-time support recovery on B4860, LS1012A and P4080
- PSCI and sleep 32-bit kernel on LS1012A, LS1043A and LS1046A
- Includes several software fixes. See Fixed, Open, and Closed Issues on page 64 section which has a list of all fixed issues
- Includes additional workarounds for Chip Errata: A-010284, A-010150, A-008975

See list of changes in below

Processor and Board Support

- LS1012A r1.0 and RDB, Freedom
- LS1046A r1.0: upgrading platform and fman frequency to 700MHz and 800MHz, adding 0.9v part support, adding core/platform/fman 1.2GHz/400MHz/600MHz
- LS1021A default core frequency 1.2GHz upgrade

Linux Kernel Core, Virtualization

- Kernel 4.1.35 upgrade
- QEMU 2.6 upgrade

Linux Kernel Drivers

- LS1012A: Crypto driver supporting SEC 5 (CAAM), DDR, DUART, DSPI, eSDHC, I2C, PCIe RC, PFE Ethernet (Packet Rx/Tx), PHY support: RGMII & SGMII, Power management, QSPI, SAI/I2S, SATA, UART, USB 2/3 mass storage, Watchdog
- LS1046A: Thermal monitor
- PSCI and sleep 32-bit kernel on LS1012A, LS1043A and LS1046A
- Real-time support
- User space IO

Data Plane Development Kit (DPDK)

- DPDK v16.07 API Support
- Following DPDK Applications have been verified
  - l2fwd
  - l3fwd
  - l2fwd_crypto
  - ipsecgateway

Virtualization - OVS-DPDK

- OVS-DPDK working with vhost-virtio interfaces
- DPDK working in Virtual Machine

U-Boot Boot Loader

- Enable CONFIG_PARTITION_UUIDS, CONFIG_EFI_PARTITION, CONFIG_CMD_GPT
- LS1012A: Non-secure boot, Secure Boot, Clock, CPLD, DDR4, DSPI, eSDHC, I2C, Generic Timers, PCIe, Primary Protected Application (PPA) firmware integration, QSPI, SATA, UART, USB
- Loading 32-bit kernel for ARMv8 with PSCI and PPA enabled

Other Tools and Utilities

- LS1012A: Primary Protected Application (PPA) firmware

What's New in SDK V2.0-1611

NOTE

The list of highlights below are incremental changes relative to functionality available in previous releases

Highlights

- U-Boot 2016.09 upgrade
- Integrates off-train releases for LS1046A r1.0 and LS1043A r1.1

- 32-bit kernel on LS1043A and LS1046A (Note: no 32-bit kernel on LS2080, no 32-bit USDPAA)
- Includes several software fixes. See Fixed, Open, and Closed Issues on page 64 section which has a list of all fixed issues
- Includes additional workarounds for Chip Errata: A-010539, A-007273, A-008975

See list of changes in below

Processor and Board Support

- LS1046A and LS1046A-RDB, adding core frequency 1.8GHz support
- LS1043A r1.1
- LS1021A default core frequency 1.2GHz upgrade

Linux Kernel Core, Virtualization

- ARM A72 (AARCH64), Little Endian (default)
- ARM A72 32-bit effective kernel addressing
- ARM A72 64-bit effective addressing

Linux Kernel Drivers

- LS1046A: CEETM, Crypto via SEC 5, DSPI, DPAA Networking, eDMA, eSDHC, Flextimer, GIC-400, I2C, IEEE1588, IFC NOR & NAND, MDIO, PCIe RC & Endpoint, PCIe MSI, Power Management: CPU Idle, Device Frequency Scaling (DFS), CPU Hotplug (LPM20), Thermal Monitor (TMU), QDMA, SATA, SMMU, USB 2.0 & 3.0, UART, Watchdog timer
- LS1043A: CPU Hotplug (LPM20), PCIe MSI

User Space Datapath Acceleration Architecture (USDPAA) and Reference Applications

- LS1046A: Base and DPAA drivers, USDPAA Applications: Hello Reflector, PPAC Reflector, RC IPFWD, LPM IPFWD, IPSecFwd, Simple Proto, Simple Crypto

U-Boot Boot Loader

- U-Boot 2016.09
- LS1046A: Non-secure boot, Secure Boot, Clock, CPLD, DDR4, DSPI, eSDHC, FMan IM, GIC-400, I2C, IFC NOR & NAND, MDIO, OCRAM, PCIe, Primary Protected Application (PPA) firmware integration, QSPI, SATA, UART, USB

Other Tools and Utilities

- Primary Protected Application (PPA) firmware [LS1046A, LS1043A] - Hotplug (LPM20), System Reset

What's New in SDK V2.0-1609

Highlights

- Updated to Linux kernel 4.1.30 which includes several fixes from the community
- Includes several software fixes. See Fixed, Open, and Closed Issues on page 64 section which has a list of all fixed issues
- Includes additional workarounds for Chip Errata: A-009942, A-007728, A-010240, A-007728, A-008822

See list of changes in SDK V2.0 below

What's New in SDK V2.0

Highlights

- Linux 4.1 Long-Term Support (LTS) kernel upgrade
- Yocto 2.0 (jethro) upgrade
- U-Boot 2016.01 upgrade

- Integrates off-train releases for LS1043A and LS2080A
- Continued support for QorIQ ARM and Power Architecture processors in a common source base
- Support for QorIQ LS1012A SoC (32-bit and 64-bit kernel)

See full list of features and changes below:

Processor and Board Support

- LS1043A and LS1043A-RDB
- LS2080A and LS2085A-RDB
- P1010, P1021/2/3/4/5, P2020/10, and BSC9131/2 no longer supported. Please see prior SDK releases and support in upstream repositories

Yocto and Toolchain

- Yocto/Poky 2.0 "jethro"
- power: gcc-4.9.2, glibc-2.20, binutils-2.25, gdb-7.10.1
- arm: gcc-linaro-4.9.3-r2015.03, glibc-linaro-2.20--r2014.11, binutils-linaro-2.25-r2015.01, gdb-7.10.1

Linux Kernel Core, Virtualization

- Linux kernel 4.1.8
- ARMv8: AARCH64, 64-bit effective addressing, Little Endian (default), Multicore SMP, Huge Pages (hugetlbfs), Kernel-based Virtual Machine (KVM), Libvirt, Linux Containers (LXC), Docker Engine

Linux Kernel Drivers

- LS1043A: CEETM, Crypto via SEC 5, DSPI, DPAA Networking, eDMA, eSDHC, Flextimer, GIC-400, I2C, IEEE1588, IFC NOR & NAND, MDIO, PCIE, Power Management: CPU Idle, Device Frequency Scaling (DFS), CPU Hotplug (PW15), Thermal Monitor (TMU), QDMA, QE TDM, SATA, SMMU, USB 2.0 & 3.0, UART, Watchdog timer
- LS2080A: Crypto via SEC6, DCE, Datapath I/O services (DPIO), DPAA2: MC Bus, Ethernet, Edge Virtual Bridge (EVB), DSPI, DUART, GIC-500, I2C, IFC NOR & NAND, PCIE, Power Management: Device Frequency Scaling (DFS), Thermal Monitor (TMU), PHYs: RGMII, SGMII, XFI, Quad-SPI, Real-Time Clock, SATA, SMMU, USB, VFIO, Watchdog timer
- IEEE1588 PTPd support on LS1021A

OpenDataPlane

- v16.05 release (available separately)
- Conforms to ODP 1.4
- Open source APIs for networking data plane
- ODP application support including pktio, l2/l3forwarding, ipsec, classifier, timer

User Space Datapath Acceleration Architecture (USDPAA) and Reference Applications

- LS1043A: Base and DPAA drivers, USDPAA Applications: Hello Reflector, PPAC Reflector, RC IPFWD, LPM IPFWD, IPSecFwd, Simple Proto, Simple Crypto
- CAPWAP no longer supported

U-Boot Boot Loader

- NOTE: FLASH MAP CHANGE FOR SDK 1.6 AND LATER
- U-Boot 2016.01
- ARMv8 core
- LS1043A: Non-secure boot, Secure Boot, Clock, CPLD, DDR3L, DDR4, DSPI, eSDHC, FMan IM, GIC-400, I2C, IFC NOR & NAND, MDIO, OCRAM, PCIe, Primary Protected Application (PPA) firmware integration, SATA, UART

- LS2080A: LS2040A personality, Non-secure boot, Secure Boot, DUART, DDR3, DPAA2 networking, DSPI, GIC-500, I2C, IFC NOR & NAND, Boot from NOR, MC boot, MDIO, PCIE, SATA, USB 2 & 3
- Voltage ID on T4240RDB

Other Tools and Utilities

- Primary Protected Application (PPA) firmware [LS1043A] - Hotplug (PW15), System Reset
- Management Complex (MC) Firmware version 9.0.5 – binary only, supporting DPAA2 resource containers and network objects, Resource Manager and Link Manager
- DPAA2 resource container and object management tool (RESTOOL)
- Convenience scripts to create and manage common objects like network interfaces. There scripts are packaged in ls2-scripts tarball.

For a list of Fixed, Open and Closed Issues, see “Fixed, Open, and Closed Issues on page 64”.

2.3 Components

Top-level components in the QorIQ SDK

Overall

- Yocto
- GNU Toolchain
- Linux Kernel and Virtualization
- Linux Kernel Drivers
- Application Specific Fastpath (ASF)
- Data Plane Development Kit (DPDK)
- Virtulization - OVS-DPDK
- Open Data Plan (ODP)
- U-Boot Boot Loader
- User Space Datapath Acceleration Architecture (USDPAA) and Applications
- Embedded Hypervisor (Topaz)
- Other Tools and Utilities

Yocto

- Yocto/Poky 2.0 "jethro"
- Open source collaboration project that provides templates, tools and methods for building custom Linux-based systems for embedded products
- 32-bit or 64-bit user space

GNU Toolchain

- power: gcc-4.9.2, glibc-2.20, binutils-2.25, gdb-7.10.1
- arm: gcc-linaro-4.9.3-r2015.03, glibc-linaro-2.20--r2014.11, binutils-linaro-2.25-r2015.01, gdb-7.10.1
- Based on sources from Free Software Foundation
- Includes additional updates from NXP

Linux Kernel Core and Virtualization

- Linux kernel 4.1.35
- ARM A7 (AARCH32), A53, A57 and A72 (AARCH64), Little Endian (default)
- Power Architecture e500mc, e5500, e6500
- Multicore SMP support and multithread (e6500)
- 32-bit effective kernel addressing [e500mc, e5500, A57, A72]
- 64-bit effective addressing [e6500, A53, A57, A72]
- Huge Pages (hugetlbfs)
- Kernel-based Virtual Machine (KVM)
- Libvirt 1.2.19
- Linux Containers (LXC) 1.1.4 function support
- QEMU 2.6

Linux Kernel Drivers

- Customer Edge Egress Traffic Management (CEETM)
- Crypto driver via SEC 3, 4, 5 & 6 (CAAM)
- Display Control Unit (DCU) and HDMI [LS1021A]
- Display Interface Unit (DIU) [T1042 and P1022]
- DPAA Offloading Driver [T4240, T2080, P4080, P2041, B4860, B4420]
- DUART, eSPI, I2C
- Edge Virtual Bridge (EVB) [DPAA2 processors]
- Ethernet DPAA [DPAA1 processors]
- Ethernet DPAA2 [DPAA2 processors]
- Ethernet eTSEC (gianfar) [LS1012A, C29x]
- Frame Manager (FMan) [DPAA1 processors]
- GIC-400, GIC-500 [ARM processors]
- IEEE1588
- Integrated Flash Controller (IFC) NOR and NAND flash
- Local Bus Controller (eLBC) NOR and NAND flash
- LPUART [LS1021A, LS1043A], LS1046A]
- Management Complex Bus [DPAA2 processors]
- MDIO
- Multiprocessor Interrupt Controller (MPIC)
- PCIe Root Complex and Endpoint, MSI
- PFE Ethernet (Packet Rx/Tx) [LS1012A]
- Platform DMA
- Pattern Matching Engine (PME)
- Peripheral Access Management Unit (PAMU) [Power Architecture]
- PHY support: RGMII, SGMII, XFI and XAUI

- Power Management (PM) – CPU hotplug (PH20), CPU idle (PW15/20), Sleep (LPM20), Deep sleep (LPM35), Auto-Response, Dynamic Frequency Scaling (DFS), Thermal Monitor, Power Monitor (board specific)
- Power Monitor using on-board sensors [T4240QDS, P5020DS, P1022DS]; direct access or through FPGA-OCM
- Queue Manager (QMan) and Buffer Manager (BMan) [DPAA1 processors]
- QUICC Engine UART, Ethernet, TDM
- RAID Engine & support for hardware-assist [P5020]
- Real-Time Linux [B4860, T4240, LS1021A, LS2088A]
- SATA
- Secured Digital Host Controller (eSDHC) and SD/MMC support [all except for TF on T2080]
- Serial RapidIO (SRIO)
- System Memory Management Unit (SMMU) [ARM processors]
- Universal Serial Bus (USB) 2.0 and 3.0 [LS1021A, LS1043A, LS1046A, LS2088A]
- User space IO
- Virtual Function I/O (VFIO) - PCIe pass-through [Power Architecture Processors]
- Virtual Function I/O (VFIO) - mmap PCI sources [LS1043A, LS1046A, LS2088A]
- Watchdog Timers

Application Specific Fastpath (ASF)

- Loadable kernel module based fastpath solution
- IP Forward, IPSec Forward, QoS
- IPv4 and IPv6
- 32-bit and 64-bit effect addressing
- Supported platforms are LS1021A, T1040D4RDB, P4080

Data Plane Development Kit (DPDK) [LS1043A, LS1046A, LS2088A]

- DPDK v16.07 API Support
- Following DPDK Applications have been verified
  - l2fwd
  - l3fwd
  - l2fwd_crypto
  - ipsecgateway

Virtualization - OVS-DPDK

- OVS-DPDK working with vhost-virtio interfaces
- DPDK working in Virtual Machine

Open Data Plane (ODP) [LS2088A]

- ODP API v1.11
- ODP generator sample application
- ODP pktio sample application
- ODP ipsec transport and tunnel sample applications
- ODP packet classify sample application

- ODP timer sample application
- ODP LPM IP Forwarding sample application
- ODP Traffic Manager sample application
- ODP OpenFastPath Applications (FPM & FPM_BURSTMODE)

User Space Data Path Acceleration Architecture (USDPAA)

- Device-tree handling
- QMan and BMan drivers and C API
- DMA Memory Management
- Network Configuration
- CPU Isolation
- Drivers - BMan, QMan, RMan, SRIO, PME, Offloading

USDPAA Reference Applications

- PPAC Reflector
- Hello Reflector
- IP Forward (route cache)
- IP Forward (longest prefix match)
- IPSec Forward
- PME Loopback
- RMan application
- RMU (RapidIO Message Unit) application
- Simple Crypto
- Simple Proto
- SRIO Applicaton
- DPAA Offload: Classifier [LS1043A], IPSec Offload Fragmentation, Reassembly [T4240, T2080, B4860, P4080, P2041]

U-Boot Boot Loader

- **NOTE: FLASH MAP CHANGE FOR SDK 1.6 AND LATER (on Power Architecture processors)**
- U-Boot: 2016.09
- On ARM platforms, the U-Boot image includes the device tree
- Non-secure and Secure Boot (ESBC)
- Primary Protected Application (PPA) firmware integration. See PPA features in “Other Tools …” below
- Clock, CPLD, DUART, DDR3, DDR4, DSPI, eSDHC, GIC-400, GIC-500, I2C, OCRAM, PCIe, USB 2 & 3, SATA, UART
- Networking support using eTSEC, FMAN Independent Mode or DPAA2 networking, PFE based Ethernet support
- DCU, eMMC 4.5, I2C3, LPUART, QSPI [LS1021A, LS1043A, LS1046A]
- eLBC and IFC access to NOR and NAND flash
- Boot from NOR, NAND flash, eSPI, SDHC
- Boot from SRIO [B4860, P5020, P4080]
- Voltage ID (board specific)
- CodeWarrior debug patch for U-Boot

Embedded Hypervisor (Topaz)

- Partitioning of CPUs, memory and I/O devices
- Protection and isolation of resources from other partitions
- Sharing of hardware resources between partitions
- Virtualization of devices
- [all Power Architecture processors]

Other Tools and Utilities

- Primary Protected Application (PPA) firmware [LS1012A, LS1043A, LS1046A, LS2088A]
- Management Complex (MC) Firmware version 10.1.2 – binary only, supporting DPAA2 resource containers and network objects, Resource Manager and Link Manager
- Manager, Link Manager, DPDMUX basic configurations
- DPAA2 resource container and object management tool (RESTOOL)
- Convenience scripts to create and manage common objects like network interfaces. There scripts are packaged in ls2-scripts tarball
- FLIB/RTA - SEC descriptor creation library [all processors with SEC 4 or 5]
- OpenSSL 1.0.2h - includes heartbleed patch
- OpenSSL offload - includes TLS Record Layer and Public Key offload
- DSP Boot [B4860/4420]
- Frame Manager Configuration Tool (FMC) [DPAA1 processors]
- Frame Manager Ucode [DPAA1 processors]
- PME Tools [DPAA1 processors]
- Inter-process Communication (IPC) between Power and DSP cores [B4860/4420]
- L1 Defense [B4860/4420]
- L2 Switch User Space Driver and Demo Application [T1040]

2.4 Supported Targets

Processors, development boards, and cards supported all releases.

NOTE

In the following tables, in the rows corresponding to the processors, the silicon revision is indicated. In the rows corresponding to the development boards, the board is marked with a checkmark if it is supported. "N" means that a processor or development board is not supported.

Table 1. QorIQ Value-Performance Processors Supported

2.6 Acronyms and Abbreviations

Term	Definition
AH	Authentication Header (RFC 4302) – a network protocol designed to provide authentication services in IPv4 and IPv6.
AMP	Asynchronous Multi-Processing, running multiple operating system images on different processors of the same machine without virtualization.
API	Application Programming Interface
ARP	Address Resolution Protocol
ASF	Application Specific Fast Path – a software abstraction layer providing different network services (e.g. firewall, IPSec, IP reassembly, forwarding, etc.) to top level applications implemented in various environments (such as Linux kernel, Linux user space, etc.). These services may be hardware accelerated or not depending on the hardware the ASF is running on. The hardware offloading is provided transparently to the top level applications.
BMan	Buffer Manager – a DPAA hardware block performing buffer and buffer pool management.
BPID	(BMan) Buffer Pool ID
CAAM	Cryptographic Acceleration and Assurance Module
CCSR	Configuration and Control Status Register
CEETM	Customer Edge Egress Traffic Management
CPU	Central Processing Unit, also known more generally as "Processor"
DCD	Device Configuration Data
DMA	Direct Memory Access

Table continues on the next page...

Table continued from the previous page...

Term	Definition
DPAA	Data Path Acceleration Architecture
DPAA2	Data Path Acceleration Architecture (Second Generation)
DSK	Device Secret Key
DTB	Device Tree Blob—the binary representation of device trees
DTS	Device Tree Syntax—the textual representation of device trees
ePAPR	Embedded Power Architecture Platform Requirements
ESBC	External Secure Boot Code
ESP	Encapsulating Security Payload (RFC 4303) – a network protocol designed to provide a mix of security services in IPv4 and IPv6.
FDB	Forwarding Data Base
FMan	Frame Manager – a DPAA hardware block performing frame processing management.
FMC	Frame Manager Configuration application
FRA	Freescale RMan Application
FUID	Freescale Unique ID
HAL	Hardware Abstraction Library
IBR	Internal Boot ROM
IPC	Inter-Process Communication, can be interpreted as being communication between distinct application execution flows or between distinct hardware processing units.
inbound (traffic)	Encrypted traffic which is coming from an unprotected interface. This traffic will be terminated on the CPU.
IPFwd	IPv4 Forward
IPSec	IP Security – a communication standard defined and refined by several public RFCs (such as RFC-2401 and RFC-4301) where hosts exchange encrypted IP data packets.
IPSec Tunnel	A communication convention between two network gateways to IPSec process certain network traffic in a particular way. An IPSec tunnel has two endpoints (which are the gateways), a clearly delimited set of encryption and authentication methods, keys, encapsulation headers and security policies, which define the traffic that is sent through the tunnel.
ISBC	Internal Secure Boot Code
ISR	Interrupt Status Register

Table continues on the next page...

Table continued from the previous page...

Term	Definition
ITF	Intent to Fail
ITS	Intent to Secure
KVM	Kernel-based Virtual Machine - A Linux kernel module that allows a user space program access to the hardware virtualization features of NXP processors.
LIODN	Logical I/O Device Number
OEM	Original Equipment Manufacturer
oNIC	Offload Network Interface Controller - a virtual Ethernet driver, similar to Macless.
OS	Operating System
OUID	OEM Unique ID
outbound (traffic)	Clear traffic which is coming from a software application which generates traffic that must be encrypted and forwarded via an unprotected interface.
PAMU	Peripheral Access Management Unit
PBL	Pre-Boot Loader
PCD	Parse, Classify, Distribute – a software architecture concept in NXP DPAA drivers which allows the user to configure the DPAA hardware (FMan) to do frame parsing, classification or distribution on a series of frame queues.
PDCP	Packet Data Convergence Protocol – It is one of the layers of the Radio Traffic Stack in UMTS/LTE and performs IP header compression and decompression, transfer of user data and maintenance of sequence numbers for Radio Bearers which are configured for lossless serving radio network subsystem (SRNS) relocation.
PME	Pattern Matcher Engine
PPAM	Packet Processing Application Module
QEMU	Quick EMUlator - A hosted hypervisor that performs hardware virtualization.
QMan	Queue Manager – a DPAA hardware block performing frame queue management.
RC	Route Cache
RFC	Request for Comments – a public document which describes a software standard.
RCW	Reset Configuration Word - hardware boot-time parameters for the P4080
RMan	RapidIO Message Manager – a DPAA hardware block performing message passing for inter-processor and inter-devices communication.

Table continues on the next page...

Table continued from the previous page...

Term	Definition
SA	Security Association – a data record, defined by RFC 4301, which stores the information related to the IPSec processing needed for a specific network traffic type (such as encryption/decryption keys and algorithms, traffic endpoints description, authentication algorithms, and so on).
SAD	Security Association Database – the database holding all the valid SAs in a system.
SDK	Software Development Kit
SEC	Security Engine Coprocessor – a DPAA hardware block performing cryptographic acceleration and offloading hardware.
SFP	Secure Fuse Processor
SKMM	Secure Key Management Module
SMP	Symmetric Multi-Processing, running an operating system image on multiple CPUs simultaneously.
SNVS	Secure Non-Volatile Storage
SoC	System on a Chip, a chip integrating one or more processors and on-chip peripherals.
SP	Security Policy – a set of rules that network traffic must comply with in order to be eligible for IPSec processing.
SPD	Security Policy Database – the database storing all the SPs in a system.
SRE	Stateful Rule Engine
SRK	Super Root Key
SRKH	Super Root Key Hash
SUI	String Under Inspection
TLB	Translation Lookaside Buffer
TTL	Time To Live
UID	Unique Device ID
UIO	User space I/O
USDPAA	User Space Data Path Acceleration Architecture
VID	Voltage IDentifier

2.7 Fixed, Open, and Closed Issues

Known issues for this and previous releases of the QorIQ SDK

This section contains 3 tables: Fixed, Open and Closed issues. Fixed issues have a software fix that has been integrated into the 'Fixed In' Release. Open issues do not currently have a resolution. Workaround suggestions are provided where possible. Closed issues are issues where the root cause and fix are outside the scope of the QorIQ SDK.

Table 12. SDK V2.0-1703 Fixed Issues

ID	Description	Disposition	Opened In	Fixed in
QUBOOT-2338	The data read from the address of 32M in QSPI flash is incorrect on LS1012AFDRM and LS1012ARDB.	Fixed	SDK v2.0-1701	SDK v2.0-1703
QLINUX-6048	Out of memory (OOM) might be reported at high traffic rates, when running IPSec in tunnel mode with 3DES-CBC-HMAC-SHA1 cipher. The SEC cryptographic engine will be oversubscribed, backlog will increase, buffers will not be released, and in the end the system memory will be depleted. Affected SoCs: P2041, P3041, P4080, P5020.	Fixed	SDK v1.9	SDK v2.0-1703
QLINUX-5996	The behaviour ("Error enqueuing frame" with EBUSY error code) is expected when there is oversubscription. It results in traffic getting dropped due to congestion. It does not affect the result of performance tests like RFC2544.	Fixed	SDK v2.0-1609	SDK v2.0-1703
QSDK-2420	When testing Linux_IEEE1588_ptpd_unicast, the synchronization got more than 300000. This is the bug of PTPd 2.3.1-rc2 version.	Fixed	SDK v1.9	SDK v2.0-1703
QLINUX-6130	Realtime support is not available in SDK 2.0-1611 as 4.1.30 is not the official version supported by Realtime kernel.	Fixed	SDK v2.0-1611	SDK v2.0-1701
QUBOOT-1998	The system cannotenter sleep whenenabling Qman.	Fixed	LS1046A BSP v0.4	SDK v2.0-1611
QLINUX-5988	There is kernel calltrace while doingbridgeperformance testover PCIe and 10Gports in MSI mode	Fixed	LS1046A BSP v0.4	SDK v2.0-1611
QLINUX-5898	PCIe end pointmode can't bedetected with x86PC host.	Fixed	LS1046A BSP v0.2	SDK v2.0-1611
QSDK-3006	C293 - SKMM host driver - Host kernel recompile IOMMU disable dependency removed.	Fixed	SDK v2.0	SDK v2.0-1609

Table continues on the next page...

Table 12. SDK V2.0-1703 Fixed Issues (continued)

QSDK-3005	C29x - fix instability issue observed while loading PKC firmware T4240 based systems	Fixed	SDK v2.0	SDK v2.0-1609
QLINUX-5794	The SDK2.0 is based on the vanilla kernel release v4.1.8. The networking stack in this kernel version has an issue that results in RCU stalls in certain conditions. Two patches addressing the RCU stall issue were backported from kernel version v4.6.	Fixed	SDK v2.0	SDK v2.0-1609
QLINUX-5764	CAAM - JR Driver - fix for public key offload reported post SDK 2.0	Fixed	SDK v2.0	SDK v2.0-1609
QUBOOT-1640	On LS1043A RDB board, when running Secure Boot, U-boot must be executed with a valid PPA binary and CSF Header of PPA loaded on NOR Flash.	Fixed	SDK v2.0	SDK v2.0-1609
QLINUX-5416	DPAA2 Ethernet cannot be compiled as a module.	Fixed	LS2085A EAR6	SDK v2.0
QLINUX-5333	dpaa2-evb: port state is not updated as expected.	Fixed	LS2085A EAR6	SDK v2.0
QUBOOT-1522	The USB controller will work with specific clock settings (multiple of 100 MHz), so 533MHz is believed to render USB non-functional. Usb controller derives its clock from the system bus clock itself (PFA). When SoC operates at 533 Mhz sys clock, disable the USB.	Fixed	LS2085A EAR6	SDK v2.0
QLINUX-4941	The "cat" output of MC console displays a junk line as first line	Fixed	LS2085A EAR6	SDK v2.0
QLINUX-4624	Messages like "Error enqueuing frame: -16" may be observed when running IPsec performance tests. The behaviour ("error enqueuing frame" with EBUSY error code) is expected when there is oversubscription. It results in traffic getting dropped due to congestion. It does not affect the result of performance tests like RFC2544.	Fixed	SDK v2.0	SDK v2.0-1609
QSDK-2235	C293 - PKC host driver - Host kernel recompile IOMMU disable dependency removed.	Fixed	SDK v2.0	SDK_V2-0_1609
QSDK-1793	On LS1021A, some USB3.0 flash drives do not work with USB xHCI controller. These devices suddenly stop responding to commands from xHCI controller (there is no bus/system error).	Fixed	SDK v1.8	SDK_V2-0_1609

Table 13. SDK V2.0-1703 Open Issues

ID	Description	Disposition	Opened In	Workarounds
QUBOOT-20333	For the PCIe card with multiple switch, it fails when needing more stream IDs to support mutilple switch.	Open	LS2088A BSP v0.3	Increase the stream IDs in u-boot code.
QLINUX-69611	In 32-bit kernel, jumboframe floodping causes call trace on LS1012A RDB and LS1012A FRDM board.	Open	LS1012A BSP v0.5	
QLINUX-67119	KVM VFIO test fails and call trace occurs on guest on T1023 and T1024.	Open	SDK v2.0-1701	
QLINUX-65995	Sleep causes the hardware interrupt timeout issue for SD CMD18 on LS1046ARDB.	Open	SDK v2.0-1701	

Table continues on the next page...

Table 13. SDK V2.0-1703 Open Issues (continued)

DPDK-3033	There is "IPSEC: Unsupported packet type" when running dpdk_ipsec_secgw_armce-4c4g test on LS1043ARDB.	Open	SDK v2.0-1701	
QLINUX-6507	In the current release the IPSec performance tests will be affected by the missing congestion group support from MC firmware. The DPAA2_CAAM Driver has been updated to support congestion group management, ut in order to validate the IPSec peformance, a new MC binary with DPSECI version >= 5.1 will have to be deployed on the board. The new versions MC binaries will be available on https://github.com/qoriq-open-source/mc-binary	Open	LS2088A BSP v0.3	
QLINUX-61700	IFC NAND on LS2088A RDB does not work in Linux.	Open	LS2088A BSP v0.3	
QLINUX-60644	PPFE on LS1012A doesn't support real-time feature.	Open	LS1012A BSP v0.4	

Table continues on the next page...

Table 13. SDK V2.0-1703 Open Issues (continued)

QLINUX-58833	The PPFE port does not work after power management being entered and exited repeatedly.	Open	LS1012A BSP v0.4	
QLINUX-58411	Linux IPfwd for small frame size has more degradation compared with LS1012A BSP v0.3 on LS1012ARDB.	Open	LS1012A BSP v0.3	
QLINUX-57768	rmmod of PFE modules crashes the kernel on LS1012A.	Open	LS1012A BSP v0.2	
QLINUX-57738	USB HDD (Oyen Digital) cannot be detected in Linux properly on LS1012AFRDM and LS1012ARDB	Open	LS1012A BSP v0.1	

Table continues on the next page...

Table 13. SDK V2.0-1703 Open Issues (continued)

QLINUX-6089	Traffic stops after running two netperf sessions (TCP_STREAM and TCP_MAERTS) per interface/core on LS1043A	Open	SDK v2.0-1611	
QLINUX-6082	Macless devices are not supported (neither in the Linux kernel nor in usdpaa) on LS1043A and LS1046A.	Open	SDK v2.0	
QLINUX-6049	On T1023/T1024/P5040 platforms KVM USB pass-through feature causes a call trace in guest.	Open	SDK 2.0-1611	
QLINUX-5981	The USB do not work properly after system resumes from deep sleep. Enabling USB with deep sleep leads to unidentified behavior of kernel.	Open	SDK v2.0-1609	Disable USB when using deep sleep

Table continues on the next page...

Table 13. SDK V2.0-1703 Open Issues (continued)

QSDK-28889	The vulnerability is indexed as CVE-2015-7547. Multiple stack-based buffer overflows in the (1) send_dg and (2) send_vc functions in the libresolv library in the GNU C Library (aka glibc or libc6) before 2.23 allow remote attackers to cause a denial of service (crash) or possibly execute arbitrary code via a crafted DNS response that triggers a call to the getaddrinfo function with the AF_UNSPEC or AF_INET6 address family, related to performing "dual A/AAAA DNS queries" and the libnss_dns.so.2 NSS module.	Open	SDK v2.0	The fix is available on https://sourceware.org/git/?p=glibc.git;a=commitdiff;h=d5a4840c6b4025302f485b9271e4c72d315221f5
QLINUX-56016	On LS1043A, KVM support on host machines with 64KB pages is not functional. Limitation exists because the memory range associated with the GIC CPU interface, in the GIC400 memory map, is not aligned to 64KB.	Open	SDK v2.0	Use only host machines with 4KB pages in order to support KVM virtualization.
QLINUX-56022	Please make sure to enable "CONFIG_MTD_CFI_BE_BYTE_SWAP" for LS1043A. It is required because IFC is big-endian in LS1043A. SDK2.0 by-default does not enable CONFIG_MTD_CFI_BE_BYTE_SWAP for ARMV8 defconfig to support LS2080A which has IFC as little endian.	Open	SDK v2.0	

Table 14. SDK V2.0-1701 Closed Issues

ID	Description	Disposition	Found In	Workarounds
DPDK-327	In DPDK test, OVS setup fails on LS1043ARDB.	Not an Issue in the latest release	SDK v2.0-1701	

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QLINUX-6529	For ARMv8 platforms LS1012ARDB, LS1043ARDB and LS1046ARDB compiled in ARMv7 compatibility mode, the ARMv8 Crypto functionalities are not available.	Won't Fix	SDK v2.0-1701	
QUSDPA-878	USDPAA IPSec High Bandwidth is not available on LS1046.	Won't Fix	SDK v2.0-1611	
QUBOOT-2161	The LS1021ATWR board and CPLD could not provide clock frequency information to the software. So the u-boot software can only support static frequency settings (100M DDR clock and 100M system clock). If different clock settings are selected through the switch configurations. User needs to change the settings in software manually(include/ configs/ls1021atwr.h). Change the following settings to the frequency actually selected by the switches. #define CONFIG_SYS_CLK_FREQ 100000000 #define CONFIG_DDR_CLK_FREQ 100000000	Won't Fix	DK v2.0-1701	
QUBOOT-2055	The parameter of fdt_high set to 0xffffffff causes the failure of booting images from nor flash directly.	Won't Fix	SDK v2.0-1611	Set fdt_high in uboot environment variable to 0xa0000000 by using the command in uboot: =>setenv fdt_high 0xa0000000
ODP-417	Per CoS, pool configuration is not supported.	Won't Fix	ODPv16.08	
QUBOOT-1737	If Code Warrior is used to program u-boot or RCW on QSPI Flash, the flash gets into invalid state.	Won't Fix		Use Code-Warrior to program the 64 MB SDK image (LS1012) thereby programming the entire flash. After power recycle the board will start functioning.

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QLINUX-5717	USB 3.0 sticks (Kingston 3.0 16 gb and HP 3.0 8 GB) are not getting detected in Linux on LS2080RDB board. 1)When devices are connected through USB2.0 cable, then those are getting detected in high speed mode. [expected] When CATC is in path (without CATC device is not getting detected) : 2)USB3.0 :: When connected through CATC with Sniffing disabled, devices are getting detected as USB2.0 devices. [wrong behavior :: expected speed is USB3.0] 3)When connected through CATC but with CATC sniffing enabled, devices are getting connected as USB3.0 devices. (experiment is same as in item-2 but capturing traces via CATC)	Hardware Issue	NA	
QLINUX-5661/ QUBOOT-1320	HP 2.0 pen drive not enumerated in Standard A port on LS2080ARDB and LS1043ARDB board. It is concluded as USB connector (Standard A port) issue. However, it is properly enumerated in micro port.	Hardware Issue	NA	
QLINUX-5671	On LS1021A TWR board, when doing deep sleep with all three Ethernet ports on, there may be the error message "PM: Device mdio@2d24000:02 failed to suspend: error -16".	Hardware Issue	NA	Upgrade the on-board CPLD to version 3.2.
QLINUX-5637	On LS1021A TWR board, after resuming from deep sleep, the kerenl can't initialize SD card and occurs call trace because the card never leaves busy state.	Hardware Issue	NA	Upgrade the on-board CPLD to version 3.2.
QLINUX-5504	Performance measurements in different IPv6 forwarding and IPv6 SEC forwarding scenarios revealed that a small performance degradation was introduced by the kernel upgrade from version 3.12 to 4.1. The actual amount of this reduction in performance varies with the use case, some showing a certain depreciation, others no degradation. Tests performed in isolation showed no or insignificant performance impact for the changes made in NXP owned components.	Upstream Issue	SDK v2.0	
QLINUX-5417	Cortina PHY LEDs are permanently off.	Hardware Issue	NA	
QLINUX-5325	AQR PHY LED remains off if link is at 1Gbps.	Hardware Issue	NA	

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QSDK-2478	On LS1021A, boot dtb, kernel and filesystem directly from QSPI flash could not be supported.	Won't Fix	SDK v1.9	1.Program the general dtb, Linux kernel and ramdisk to the QSPI flash by 'sf write' command(under sdboot or qspiboot). 2.Boot the dtb, kernel and ramdisk from QSPI flash. Avoid booting from QSPI flash directly. Read the dtb, kernel and ramdisk from the QSPI flash to RAM by 'sf read' u-boot command and then boot from RAM. By default, the QSPI flash on the TWR-LS1021A includes: rcw, uboot, kernel, dtb, and ramdisk. Note: This workaround only applies to QSPI flash.
QUSDPA-797	On LS1043A RDB board, USDPAA IPFwd performance does not scale up from 2 cores to 4 cores.	Hardware Issue	NA	
QLINUX-3645	When using T4240QDS or RDB, PCL10 and CPU frequency scaling may not always work reliably.	Hardware Issue	NA	Please check with your sales representative for a board replacement.

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QUSDPA-749	On e6500 processors, Linux application performance may be impacted due to the upgrade of eglibc from 2.15 to 2.19 as compared to SDK 1.7. These changes were introduced by the upstream community. Some of these changes address a security concern discovered in eglibc 2.15. In the SDK, this can be observed when executing USDPAA IPFwd LPM and comparing results against SDK 1.7.	Hardware Issue	NA	None. Recommend to use eglibc 2.19 or later to avoid the security concern in previous versions.
QLINUX-3357	With TWR-LS1021A, some resolutions (e.g. 1920x1080) may not work well with some monitors. The software will not downgrade to another resolution automatically.	Hardware Issue	NA	Manually set another resolution such as: 1024x768@60 : fbset -fb /dev/fb0 -g 1024 768 1024 768 24 -t 15384 168 8 29 3 144 6
QSDK-1841	With TWR-LS1021A, copy from NOR flash to NOR flash fails. It is a known limitation with Micron flash.	Hardware Issue	NA	
QSDK-1716	The read performance using PCIe SATA 3132 card on T4240QDS/T4240RDB/T2081QDS is about 93MB/s which is lower than the read performance (~133MB/s) on other platforms. Using LS2 PCIe card (LSI SAS 9211-8i) can get the similar read performance between different platforms.	Won't Fix	SDK v1.6	Use GEN2 PCIe card (LSI SAS 9211-8i) to get better read performance.
QSDK-1677	When telneting to board console from Linux server connected to on LS1021A TWR, the board will power reset due to wrong signal sent.	Hardware Issue	NA	Remove R214 from the board.
QSDK-1616	To bring up UP (uni-processor), only disabling the SMP in kernel configuration will result in the warning information.	Functions as designed	SDK v1.7	Delete the node for another processor and change the reg of the left one to 00.

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QLINUX-2924	Linux IPv6 network stack exhibits exponential degradation for large number of cores, this affects performance for IPv6 forwarding, which degrades from 16 to 24 cores. Degradation is caused by atomic operations being used in IPv6 routing code from upstream kernel: # Overhead Command Shared Object Symbol # with 16 cores 17.26% ksoftirqd/1 [kernel.kallsyms] [k] .atomic_dec_return_noinline 13.45% ksoftirqd/1 [kernel.kallsyms] [k] .atomic_inc_noinline 5.53% ksoftirqd/1 [kernel.kallsyms] [k] .ip6_pol_route # with 24 cores 32.45% ksoftirqd/1 [kernel.kallsyms] [k] .atomic_dec_return_noinline 30.56% ksoftirqd/1 [kernel.kallsyms] [k] .atomic_inc_noinline 4.71% ksoftirqd/1 [kernel.kallsyms] [k] .ip6_pol_route	Upstream Issue	SDK v1.6	One workaround is to use a PCD policy that distributes IPv6 traffic only on 16 cores e.g. <distribution name="ipv6eth14" > <queue count="16" base="0x7c00" / > <key > <fieldref name="ipv6.src"/ > <fieldref name="ipv6.dst"/ > <fieldref name="ipv6.tos"/ > </key > </distribution > This distribution can be added to a standard IPv4 PCD policy that distributes IPv4 traffic on core-affine FQs <policy name="linux_fman_tester_policy_14" > <dist_order > <distributionref name="ipv6eth14"/ > <distributionref name="udpeth14"/ >

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

				<distributionref name="tcpeth14"/ > <distributionref name="ipv4eth14"/ > <distributionref name="garbage_dist_14"/ > </dist_order > </policy > If you want to use the pool channel for IPv4 traffic, as if no policy was applied, it will not work. The FMan will drop all traffic that is not matched by the policy. You can read the RX default FQID of the interface from sysfs and create a distribution that sends all IPv4 traffic on the default RX FQ. root@t4240rdb:~# cat /sys/devices/fsl,dpaa.19/ethernet.30/net/fm2-mac9/fqids Rx error: 32782 Rx default: 32783 # which means in hexa 0x800f Rx PCD: 31744 - 31871

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

				Edit the policy file: <distribution name="ipv4eth14" > <queue count="1" base="0x800f"/ > </distribution > <policy name="linux_fman_tester_policy_14" > <dist_order > <distributionref name="ipv6eth14"/ > <distributionref name="ipv4eth14"/ > </dist_order > </policy >
QUBOOT-799	When using the T4240QDS, the system may hang after reset of the board. This is due to an erratum for the eMMC device (MTFC4GGQDQ) in which it fails to reset.	Resolved	QUBOOT_2014_SDK_V1-6	Cycle power to the board.
QUBOOT-749	A compatibility issue has been found on some PCIe Gen 1 cards when used with a PCIe Gen2 controller. A common symptom is that U-Boot hangs during PCIe initialization with such a card inserted.	Closed	QUBOOT_T1040_V0-3	Use PCI Gen2 cards. Or set the following RCW: RCW[SRDS_DIV_PEX]=2 for T1024 and T1040 RCW[SRDS_DIV_PEX_S1]=2 and RCW[SRDS_DIV_PEX_S2]=1 for T2080

Table continues on the next page...

Table 14. SDK V2.0-1701 Closed Issues (continued)

QLINUX-2504	On e6500 core, if hardware threads are disabled, such as by the use of CONFIG_PPC_DISABLE_THREADS, tracebacks will appear roughly two minutes after boot, indicating that certain threads have hung. This is due to Linux creating per-cpu software threads for the hardware threads that are disabled. There should be no harmful effect of this beyond the error output.	Won't Fix	SDK v1.5	Enable hardware threads, or ignore the error output.
QLINUX-2240	When running 8C20G Linux IPv4 forward using two XFI ports on B4860QDS, 'non-zero error counters in fman statistics' is found	Hardware Issue	NA	
QLINUX-1816	On B4860QDS and B4420QDS, a hang may be observed when performing the reboot command at the kernel prompt. The system won't be able to reach the U-Boot prompt. This is when RCW is at NOR Flash. This is a issue of NOR flash(S29GL01GS11TFI010) and It is reported to "Spansion".	Hardware Issue	NA	Options: 1) Re-configure the board to read the RCW from I2C EEPROM. 2) Boot from NAND Flash such that the RCW, U-Boot, etc. are in NAND flash.
QSDK-610	On B4860QDS and B4420QDS even though the NOR Flash size is 128M, only 64M can be accessed due to a board issue. Standard CFI commands will return the NOR Flash size to be 128M; however, only 64M can be accessed. The address range for NOR Flash is limited to 0xec000000 to 0xffffffff instead of 0xe8000000 to 0xffffffff. When attempting to read the NOR Flash at addresses 0xe8000000 to 0xebffffff, the data shown corresponds to 0xec000000 to 0xffffffff. As a result only 4 vbanks are supported. Please refer to the SDK documentation for more details of the NOR Flash memory map.	Hardware Issue	NA	None

Chapter 3
Getting Started

Yocto Project is an open-source collaboration project for embedded Linux developers. Yocto Project uses the Poky build system to make Linux images. For complete information about Yocto Project, see https://www.yoctoproject.org/.

3.1 SDK File System Images

This section describes the file system images that can be built using standard Yocto Project recipes included with the NXP SDK.

The file system images contain the programs, scripts, and other files that make up Linux user space. There are five standard images. They are described in the following sections.

In the SDK installation directory, look in `meta-freescale/recipes-fsl/images` for files that define these images.

Where to start: "`fsl-image-full`" contains a rich set of standard Linux features and all special NXP SDK-specific features. It is the best starting point for exploration and evaluation.

3.1.1 fsl-image-minimal: A Barebones Starting Point for Products

Contents:

This is a barebones image. It contains a small file set that allows Linux to boot and little else.

Purpose:

This image is intended as a starting point for product development. Users may add packages to it to form an image that targets their particular project or purpose. Packages may be added by editing conf/local.conf and adding new packages to be built and installed via

```
IMAGE_INSTALL_append = " package1 package2 etc"
```

Then, rebuild the image using bitbake. The result will be an image that is small enough for simple flash devices and is narrowly focused on a specific goal.

Users must add packages to "fsl-image-minimal" to make it useful. Thus it is not intended for "out-of-the-box" evaluation. Instead, use it as the basis for targeted images for your specific product.

3.1.2 fsl-image-mfgtool: A Small Flash Image for Managing Disks and Larger Images

Contents:

This is a small image that NXP preprograms into the flash on development boards. On many boards, the image is stored in a NOR flash and is loaded into a RAM disk when Linux boots. It contains disk management functions as described in the next section.

Purpose:

This image is intended to help users to load much larger images onto disks or disk-like devices such as SDHC cards or USB thumb drives. Thus, this image contains networking support to transfer images and also standard Linux disk and file system manipulation commands.

NXP preloads "fsl-image-full" (see below) onto disks on development boards that have them. For these boards, "fsl-image-mfgtool" can be used to restore the larger disk image if it becomes corrupted.

Users will find that it is often convenient to work with larger images and may wish to install “fsl-image-full” onto a disk-type device and use it with NXP development boards that do not come with a disk drive.

The networking and disk management commands that NXP supplies are standard Linux commands. They are, in fact, identical on all architectures and thus are not unique to NXP. Users with Linux experience will find them familiar. They include:

- ifconfig, ip, route, etc. (configure networking)
- ftp (transfer files via the network)
- scp (another way to transfer files via the network)
- date and rdate (set date and time)
- fdisk (partition disks and disk-type devices)
- mkfs (make file systems)
- tar (extract file system images, and more)
- fsck (check file systems)
- mount/umount (mount and umount file systems)

3.1.3 fsl-image-full: A Full-Featured Image, Useful Out-of-Box

Contents:

This is a large image that contains many standard Linux commands and features including native (target-resident) versions of the GNU tools including gcc and gdb.

If you boot this image, the resulting Linux environment will be much like a command-line on a full desktop-type Linux system rather than an embedded system.

Purpose:

While this type of image may not be appropriate for a final embedded product, it can be very helpful for many development and evaluation tasks. The reason is the full set of standard Linux facilities that are already present in the image. In fact, users may find that they can use this image instead of installing the Yocto Project-based NXP SDK onto a development system, at least initially.

For this reason, “fsl-image-full” is preinstalled on the disk drives of NXP development boards that have disks.

For example, the image is complete enough that the standard Linux open source command sequence “configure; make” stands a decent chance of working for arbitrary open source packages that do not happen to be on the image already.

To be clear, the NXP SDK is a Yocto Project/Poky-derived embedded distribution. However, the Yocto Project standard Linux package set is large enough that if one enables a lot of the available packages, the result begins to have the feel of desk top Linux. NXP added the special NXP-specific packages, and the result is “fsl-image-full.” It is intended for “out-of-the-box” evaluation because it is rather complete.

3.1.4 fsl-image-core: A Small Image with NXP-Specific Packages Present

Contents:

This is a small image somewhat like “fsl-image-minimal” except it contains all of the NXP-specific SDK packages.

Purpose:

This image is useful for evaluating the NXP-specific software packages in the context of a file system image that is much more embedded-oriented than “fsl-image-full”.

Embedded file system images contain fewer helpful tools and utilities by definition. They are intended to support an embedded product's functionality rather than a developer's tasks. Thus, it can be convenient to begin with "fsl-image-core" for evaluation and planning and then later narrowly extend "fsl-image-minimal" to support your embedded product.

3.1.5 fsl-image-virt: An image for KVM deployment

Contents:

This is an image which contains the specific packages needed to enable virtualization.

Purpose:

This image is useful for virtualization scenarios (KVM, libvirt, lxc). It contains:

- the guest root filesystem
- the guest image (uImage format for Power based architectures and zImage for ARM based architectures)
- QEMU
- all necessary libraries and tools for libvirt and lxc support

3.2 Essential Build Instructions

The following sections are essential to the build process and must be performed when using Yocto Project to build the SDK. In order to install the SDK, download the necessary ISO's and follow steps for installing SDK 2.0, install SDK v2.0-1703. When those steps are completed, prepare the host environment, setup Poky, perform builds, and follow the instructions in the subsequent sections. When these steps are completed, the build process will be complete. Linux images that have been built will be found in the following directory: `build_<machine>/tmp/deploy/images/<machine>`

See Additional Instructions for Developers for more information on using Yocto Project.

3.2.1 Install SDK V2.0-1703

SDK-V2.0-1703 is an incremental update to SDK 2.0. Prior to installing SDK-V2.0-1703, install SDK 2.0. Both SDK 2.0 and SDK V2.0-1703 can be downloaded from www.nxp.com/sdk. SDK 2.0 documentation and installation instructions can be found on Install SDK 2.0 on page 81 section.

SDK-V2.0-1703 includes all the changes of previous incremental/NPI releases, such as SDK-V2.0-1701/SDK-V2.0-1611/SDK-V2.0-1609/LS1046A-SDK-V0.4. They can't be installed at the same time. The install script will detect conflict releases and prompt the steps to deal with them.

How to install SDK-V2.0-1703 on a host machine.

1. Extract the SDK-V2.0-1703.tar.bz2, and run the 'install' script to install the incremental updates:

```
$ tar -xjf SDK-V2.0-1703.tar.bz2
$ ./SDK-V2.0-1703/install
```

2. During the install process, the user will be prompted to input the SDK 2.0 ISO installed location, i.e., `<ISO_INSTALL_PATH>/QorIQ-SDK-V2.0-20160527-yocto.`

3.2.2 Install SDK 2.0

How to install Yocto Project on the host machine.

1. Mount the ISO on your machine:

```
$ sudo mount -o loop QorIQ-SDK-<version>-<target>-<yyyymmdd>-yocto.iso /mnt/cdrom
```

2. As a non-root user, install Yocto Project:

```
$ /mnt/cdrom/install
```

3. When you are prompted to input the install path, ensure that the current user has the correct permission for the install path.

There is no uninstall script. To uninstall Yocto Project, you can remove the <yocto_install_path>/QorIQ-SDK-<version>-<yyyymmdd>-yocto directory manually.

NOTE

* The *source* ISO contains the package source tarballs and Yocto Project recipes. It can be installed and used to do non-cache build.

* The *cache* ISO contains the pre-built cache binaries. To avoid a long time build, you can install the source ISO and the cache ISO in the same installation folder.

* The *image* ISO includes all prebuilt images: flash images, standalone toolchain installer, HD rootfs images and small images.

* The source ISO can be used separately. The cache ISO and the source ISO should work together.

3.2.3 Set Up Host Environment

Yocto Project requires some packages to be installed on the host.

Use the following steps to prepare the Yocto Project environment.

In general, Yocto Project can work on most recent Linux distributions with Python-2.7.3 or greater (excluding python3 which is not supported), git-1.7.8 or greater, tar-1.24 or greater and required packages installed. The default Python is not 2.7.x on some Linux distros, e.g. CentOS 6.5 installs python 2.6.6. Follow the instructions below to install the Python 2.7.x in custom path instead of override the system default python, the override may cause system utilities breaking.

```
$ wget https://www.python.org/ftp/python/2.7.6/Python-2.7.6.tar.xz
[NOTE: Python 2.7.3 and python 2.7.5 can be used as well.]
$ tar -xf Python-2.7.6.tar.xz
$ cd Python-2.7.6
$ ./configure --prefix=/opt/python-2.7.6
$ make
$ sudo make install
```

Run the export command below to ensure python 2.7.x is used for Yocto build.

```
$ export PATH=/opt/python-2.7.6/bin:$PATH
```

Yocto Project supports typical Linux distributions: Ubuntu, Fedora, CentOS, Debian, OpenSUSE, etc. More Linux distributions are continually being verified. This SDK has been verified on following Linux distributions: Ubuntu 14.04, CentOS-7.1.1503, Debian 8.2, Fedora 22 and OpenSUSE 13.2

For a list of the Linux distributions tested by the Yocto Project community see `SANITY_TESTED_DISTROS` in `poky/meta-yocto/conf/distro/poky.conf`.

To ensrure Yocto can run on host machine with different Linux distribution, the following packages should be installled on the host.

For CentOS hosts:

```
$ sudo yum install gawk make wget tar bzip2 gzip python unzip perl patch \
     diffutils diffstat git cpp gcc gcc-c++ glibc-devel texinfo chrpath socat SDL-devel xterm
```

For the Fedora hosts:

```
$ sudo yum install gawk make wget tar bzip2 gzip python unzip perl patch \
     diffutils diffstat git cpp gcc gcc-c++ glibc-devel texinfo chrpath \
     ccache perl-Data-Dumper perl-Text-ParseWords perl-Thread-Queue socat \
     findutils which SDL-devel xterm
```

For Ubuntu and Debian hosts:

```
$ sudo apt-get install gawk wget git-core diffstat unzip texinfo gcc-multilib \
     build-essential chrpath socat libsdl1.2-dev xterm
```

Extra packages are needed for Ubuntu-64b:

```
$ sudo apt-get install lib32z1 lib32ncurses5 lib32bz2-1.0 ia32-libs lib32ncurses5-dev
```

For OpenSUSE host:

```
$ sudo zypper install python gcc gcc-c++ libtool subversion git chrpath automake make wget
diffstat makeinfo freeglut-devel libSDL-devel
```

3.2.4 Set Up Poky

Source the following poky script to set up your environment for your particular NXP platform. This script needs to be run once for each terminal, before you begin building source code. Make sure that you are currently in the <install_path> when running the commands below.

```
$ . ./fsl-setup-env -m <machine>
```

For example:

```
$ . ./fsl-setup-env -m b4860qds-64b
```

The following shows the usage text for the `fsl-setup-env` command:

Usage:

```
$ . ./fsl-setup-env -h
Usage: . fsl-setup-env -m <machine>

    Supported machines
    QorIQ: b4420qds-64b b4420qds b4860qds-64b b4860qds c293pcie ls1021atwr ls1043ardb p2041rdb
p3041ds p4080ds p5020ds-64b p5020ds p5040ds-64b p5040ds t1023rdb-64b t1023rdb t1024rdb-64b t1024rdb
t1040d4rdb-64b t1040d4rdb t1042d4rdb-64b t1042d4rdb t2080qds-64b t2080qds t2080rdb-64b t2080rdb
t4160qds-64b t4160qds t4240qds-64b t4240qds t4240rdb-64b t4240rdb ls1012afrdm-32b ls1012afrdm
ls1012ardb-32b ls1012ardb ls1043ardb-32b ls1046ardb-32b ls1046ardb ls2088ardb

  Op  tional parameters:
    * [-m machine]: the target machine to be built.
    * [-b path]:    non-default path of project build folder.
    * [-j jobs]:    number of jobs for make to spawn during the compilation stage.
    * [-t tasks]:   number of BitBake tasks that can be issued in parallel.
    * [-d path]:    non-default path of DL_DIR (downloaded source)
    * [-c path]:    non-default path of SSTATE_DIR (shared state Cache)
    * [-g]:         enable Carrier Grade Linux
    * [-l]:         lite mode. To help conserve disk space, deletes the building
```

```
                    directory once the package is built.
    * [-h]:         help
```

3.2.5 Perform Builds

How to Set Up a Cross Compile Environment and Perform Builds

Follow these steps to do builds using Yocto Project. Be sure to set up the host environment before doing these steps.

1. `$ cd <sdk-install-dir>/build_<machine>`
2. `$ bitbake <image-target>`

   Where `<image-target>` is one of the following:

   - `fsl-image-minimal`: contains basic packages to boot up a board
   - `fsl-image-core`: contains common open source packages and NXP specific packages.
   - `fsl-image-full`: contains all packages in the full package list.
   - `fsl-image-kernelitb`: A FIT image comprising the Linux image, dtb and rootfs image.
   - `fsl-image-mfgtool`: contains all the user space apps needed to deploy the fsl-image-mfgtool image to a USB stick, hard drive, or other large physical media.
   - `fsl-image-virt`: contains toolkit to interact with the virtualization capabilities of Linux
   - `core-image-x11`: NXP image with a very basic X11 image with a terminal
   - `fsl-toolchain`: the cross compiler binary package
   - `package-name(usdpaa)`: build a specific package

Contents of the Built Images Directory:

A Yocto Project build produces images that will be located in the following directory:

```
<sdk-install-dir>/build_<machine>/tmp/deploy/images/<machine>/
```

The following list shows the typical directory/image files (exact contents depend on the setting of the `<IMAGE_FSTYPES>` variable):

- `fsl-image-<machine>.ext2.gz.u-boot` - ramdisk image that can be loaded with U-Boot
- `fsl-image-<machine>.ext2.gz` - gzipped ramdisk image
- `fsl-image-<machine>.tar.gz` - gzipped tar archive of the image
- `uImage-<machine>.bin` - kernel binary of the image
- `u-boot-<machine>.bin` - U-Boot binary image that can be programmed into board Flash
- `uImage-<machine>.dtb` - device tree binary (dtb).
- `fsl_fman_ucode_<machine>_<version>.bin` - fman ucode for <machine> board
- `hv/hv.uImage` - uImage for hypervisor
- `hv-cfg/*/*/hv.dtb` - dtb for hypervisor
- `rcw/*/rcw_*.bin` - rcw

NOTE

For additional Yocto Project usage information, please refer to the https://www.yoctoproject.org/.

3.3 Additional Instructions for Developers

This section describes additional "How To" instructions for getting started with Yocto Project.

Each set of instructions is aimed towards developers that are interested in modifying and configuring the source beyond the default build. Each section will describe instructions on how to use Yocto Project to achieve a specific development task.

3.3.1 Customize U-Boot

How to Configure, Modify, or Rebuild U-Boot

To Modify U-Boot Configuration:

Modify `UBOOT_CONFIG`. Values for `UBOOT_CONFIG` are listed in `<sdk-install-dir>/sources/meta-freescale/conf/machine/<machine>.conf`

e.g. UBOOT_CONFIG ??= "nor"

To Modify U-Boot Source Code:

If source code has already been installed, please skip steps 1 & 2 and proceed modifying source code.

1. `$ bitbake -c cleansstate u-boot`

   NOTE

   Other helpful bitbake cleaning commands:

   `bitbake -c clean <target>`

   - Removes work directory in `build_<machine>/tmp/work`

   `bitbake -c cleansstate <target>`

   - Removes work directory in `build_<machine>/tmp/work`
   - Removes cache files in `<sdk-install-dir>/sstate-cache/` directory.

2. `$ bitbake -c patch u-boot`
3. `$ cd <S>` and modify the source code. Follow instructions to "Rebuild U-Boot Image" when you are finished modifying source code.

   NOTE

   Use `bitbake -e <package-name> | grep ^S=` to get value of <S>, the package source code directory.

To Rebuild U-Boot Image:

1. `$ cd build_<machine>`
2. `$ bitbake -c compile -f u-boot`
3. `$ bitbake u-boot`

   NOTE

   U-Boot image can be found in `build_<machine>/tmp/deploy/images/<machine>/`

3.3.2 Customize Linux Kernel

How to Configure, Modify, or Rebuild the Linux Kernel

To Modify Kernel Source Code:

If source code has already been installed, please skip steps 1 & 2 and proceed modifying source code.

1. `$ bitbake -c cleansstate virtual/kernel`
2. `$ bitbake -c patch virtual/kernel`
3. `$ cd <S>` and change the source code. Follow instructions to "Rebuild Kernel Image" when you are finished modifying source code.

NOTE

Use `bitbake -e <package-name> | grep ^S=` get the value of `<S>` (package source code directory).

To Change the Kernel defconfig:

1. Update `KERNEL_DEFCONFIG` variable in <sdk-install-dir>/sources/meta-freescale/conf/machine/<machine>.conf

To Change dts:

1. Update `KERNEL_DEVICETREE` variable in <sdk-install-dir>/sources/meta-freescale/conf/machine/<machine>.conf

To Do menuconfig:

1. `$ bitbake -c menuconfig virtual/kernel`

NOTE

If you are going to reuse this new kernel configuration for future builds, tell menuconfig to "Save Configuration to Alternate File" and give it an absolute path of `/tmp/my-defconfig`. If you do not do this, the new `defconfig` file will be removed when doing a `clean/cleansstate` for kernel.

NOTE

This runs the normal kernel `menuconfig` within the Yocto Project environment. If the kernel configure UI cannot open, edit `/<yocto_install_path>/build_<machine>/conf/local.conf` and add the following based on your environment (prior to issuing the bitbake command).

For a non-X11 environment:

- `OE_TERMINAL = "screen"`

The following commands can be used for the other environments:

For a GNOME environment (default):

- `OE_TERMINAL = "gnome"`

For a KDE environment:

- `OE_TERMINAL = "konsole"`

For non-GNOME and non-KDE environments:

- `OE_TERMINAL = "auto"`

To Rebuild Kernel Image:

1. `$ cd build_<machine>`
2. `$ bitbake -c compile -f virtual/kernel`
3. `$ bitbake virtual/kernel`
4. `$ bitbake fsl-image-kernelitb`

NOTE

Kernel images can be found in `<sdk-install-dir>/build_<machine>/tmp/deploy/images/<machine>/`

3.3.3 Patch Packages

How to Patch and Rebuild a Package

1. `$ cd <sdk-install-dir>/build_<machine>`
2. `$ bitbake -c cleansstate <package-name>`
3. `$ cd <RECIPE_FOLDER>`

> **NOTE**
> Use bitbake `<package-name> -e | grep ^FILE_DIR` to get the value of `<RECIPE_FOLDER>`

4. `$ mkdir -p <RECIPE_FOLDER>/files`
5. Copy patch into `<RECIPE_FOLDER>/files`
6. Modify `<BB_FILE>` and add follow content in `package-name-<version>.bb` file

```
SRC_URI += "file://<name-of-patch1> \
                  file://<name-of-patch2> \
                                ... \
                  file://<name-of-patchn>"
```

7. Rebuild this package:

```
$ bitbake <package-name>
```

3.3.4 Extract Source Code

How to Extract the Source Code for a Package

To extract the source code of a package, do the following:

1. `$ bitbake -c cleansstate <package-name>`
2. `$ bitbake -c patch <package-name>`
3. `$ cd <S>`

> **NOTE**
> Use `bitbake -e <package-name> | grep ^S=` to get the value of `<S>`.

For example, to do a U-boot of a T2080RDB processor.

1. `$ bitbake -c cleansstate u-boot`
2. `$ bitbake -c patch u-boot`

> **NOTE**
> U-boot source code is installed in the folder: `build_t2080rdb/tmp/work/t2080rdb-fsl-linux/u-boot-qoriq/2016.01+fslgit-r0/git/`

3.3.5 Customize Root Filesystem

How to Customize a Root Filesystem

Packages included in a rootfs can be customized by editing the corresponding recipe:

```
fsl-image-mfgtool:sources/meta-freescale/recipes-fsl/images/fsl-image-mfgtool.bb
```

```
fsl-image-core:sources/meta-freescale/recipes-fsl/images/fsl-image-core.bb
fsl-image-full:sources/meta-freescale/recipes-fsl/images/fsl-image-full.bb
fsl-image-virt: sources/meta-freescale/recipes-fsl/images/fsl-image-virt.bb
fsl-image-minimal:sources/meta-freescale/recipes-fsl/images/fsl-image-minimal.bb
fsl-image-kernelitb:sources/meta-freescale/recipes-fsl/images/fsl-image-kernelitb.bb
fsl-toolchain:sources/meta-freescale/recipes-fsl/images/fsl-tooichain.bb
```

The rootfs type can be customized by setting the IMAGE_FSTYPES variable in the above recipes.

Supported rootfs types include the following:

```
cpio
cpio.gz cpio.xz
cpio.lzma
cramfs
ext2
ext2.gz
ext2.gz.u-boot
ext2.bz2.u-boot
ext3
ext3.gz.u-boot
ext2.lzma
jffs2
live
squashfs
squashfs-lzma
ubi
tar
tar.gz
tar.bz2
tar.xz
```

Path of source tarballs and patches:

- Package source tarballs are in the folder named `sources`, which is in the same folder level as `build_<machine>`.
- Patches are in the corresponding recipe folder

Specify the preferred version of package:

`<PREFERRED_VERSION_pkgname>` is used to configure the required version of a package.

If `<PREFERRED_VERSION>` is not defined, Yocto Project will pick up the recent version. For example, to downgrade Samba from 3.4.0 to 3.1.0: add `PREFERRED_VERSION_samba = "3.1.0"` in `<sdk-install-dir>/sources/meta-freescale/conf/machine/<machine>.conf`

Rebuild rootfs:

```
$ bitbake <image-target>
```

3.3.6 Build Native Packages

How to Build Native Packages for the Host

Native packages such as cst-native are supported in Yocto Project. To build a native package, do the following:

```
$ bitbake cst-native
```

NOTE

The binaries can be found in `build_<machine>/tmp/sysroot/`

3.3.7 Install the Standalone Toolchain

Build and install the standalone toolchain with Yocto Project:

1.
```
$ . ./fsl-setup-env -m <machine>
```

2.
```
$ bitbake fsl-toolchain
```

3.
```
$ cd build_<machine>/tmp/deploy/sdk
```

4.
```
$ ./fsl-qoriq-glibc-<host_arch>-<core>-toolchain-<release>.sh
```

NOTE

The default installation path for standalone toolchain is `/opt/fsl-qoriq/2.0/`. The install folder can be specified during the installation procedure.

To use the installed toolchain, go the the location where the toolchain is installed and source the `environment-setup-<core>` file. This will set up the correct path to the build tools and also export some environment variables relevant for development (eg. `$CC`, `$ARCH`, `$CROSS_COMPILE`, `$LDFLAGS` etc).

To invoke the compiler, use the $CC variable (eg. `$CC <source files>`).

NOTE

This is a sysrooted toolchain. GCC needs option `--sysroot=<path-to-target-sysroot>` to find target fragments and libraries (eg. crt*, libgcc.a) as the default sysroot is poisoned to /not/exist. However, when invoking the compiler through the $CC variable, there is no need to pass the --sysroot parameter as it is already included in the variable (check by running echo $CC).

3.3.8 How to Use Multilib

Build an rootfs image with multilib libraries (e.g. ppc64 rootfs with lib32).

1. Use the following setting in local.conf (this example is for e6500 targets)

```
require conf/multilib.conf
MULTILIBS = "multilib:lib32"
DEFAULTTUNE_virtclass-multilib-lib32 = "ppce6500"
```

2. Add `IMAGE_INSTALL += "lib32-<pkg>"` in `<image_target>.bb`
3. `$ bitbake <rootfs_image>`

3.3.9 Mixture Build Mode for e6500 Targets

Both "64bit kernel + 32bit userspace" and "64bit kernel + 64bit userspace" are supported by e6500 targets.

Below introduces how to built 64bit rootfs for e6500 targets.

1. Install both source ISO and e6500-64b cache ISO in the same folder
2. `$ cd <sdk-install-dir>`
3. `$ . ./fsl-setup-env -m <machine> # e.g. . ./fsl-setup-env -m t2080rdb-64b`
4. `$ bitbake <rootfs-target>`

The standalone toolchain generated by Yocto Project doesn't support multilib, 32bit and 64bit build should be done by different toolchain. This SDK supports to build 32-bit and 64-bit standalone toolchains. Both prebuilt toolchains are provided in the image ISO. The kernel image should be built using `fsl-qoriq-glibc-*-ppc64e6500-.toolchain-<sdk_version>+*.sh`.

- `fsl-qoriq-glibc-i686-ppce6500-toolchain-<sdk_version>.sh`: toolchain for building 32-bit images on i686 machine.
- `fsl-qoriq-glibc-i686-ppc64e6500-toolchain-<sdk_version>.sh`: toolchain for building 64-bit images on i686 machine.
- `fsl-qoriq-glibc-x86_64-ppce6500-toolchain-<sdk_version>.sh`: toolchain for building 32-bit images on x86_64 machine.
- `fsl-qoriq-glibc-x86_64-ppc64e6500-toolchain-<sdk_version>.sh`: toolchain for building 64-bit images on x86_64 machine.

3.3.10 Build rootfs which Supports OpenJDK

How to build the rootfs which supports openjdk.

The SDK supports openjdk-7 on 32b targets and 64b targets, Jtreg has been used to verify the openjdk.

Following describes how to build the rootfs image of java support.

1. `$ . ./fsl-setup-env -m <machine>`
2. `$ bitbake java-test-image`

NOTE

The rootfs image with openjdk support can be found in `build_<machine>/tmp/deploy/images/<machine>/`

3.3.11 Deploy Openstack

How to deploy OpenStack on QorIQ platform

Setup Diagram

Host Machine based on QorIQ platform can be used for Openstack Multiple Node demo in the following way:

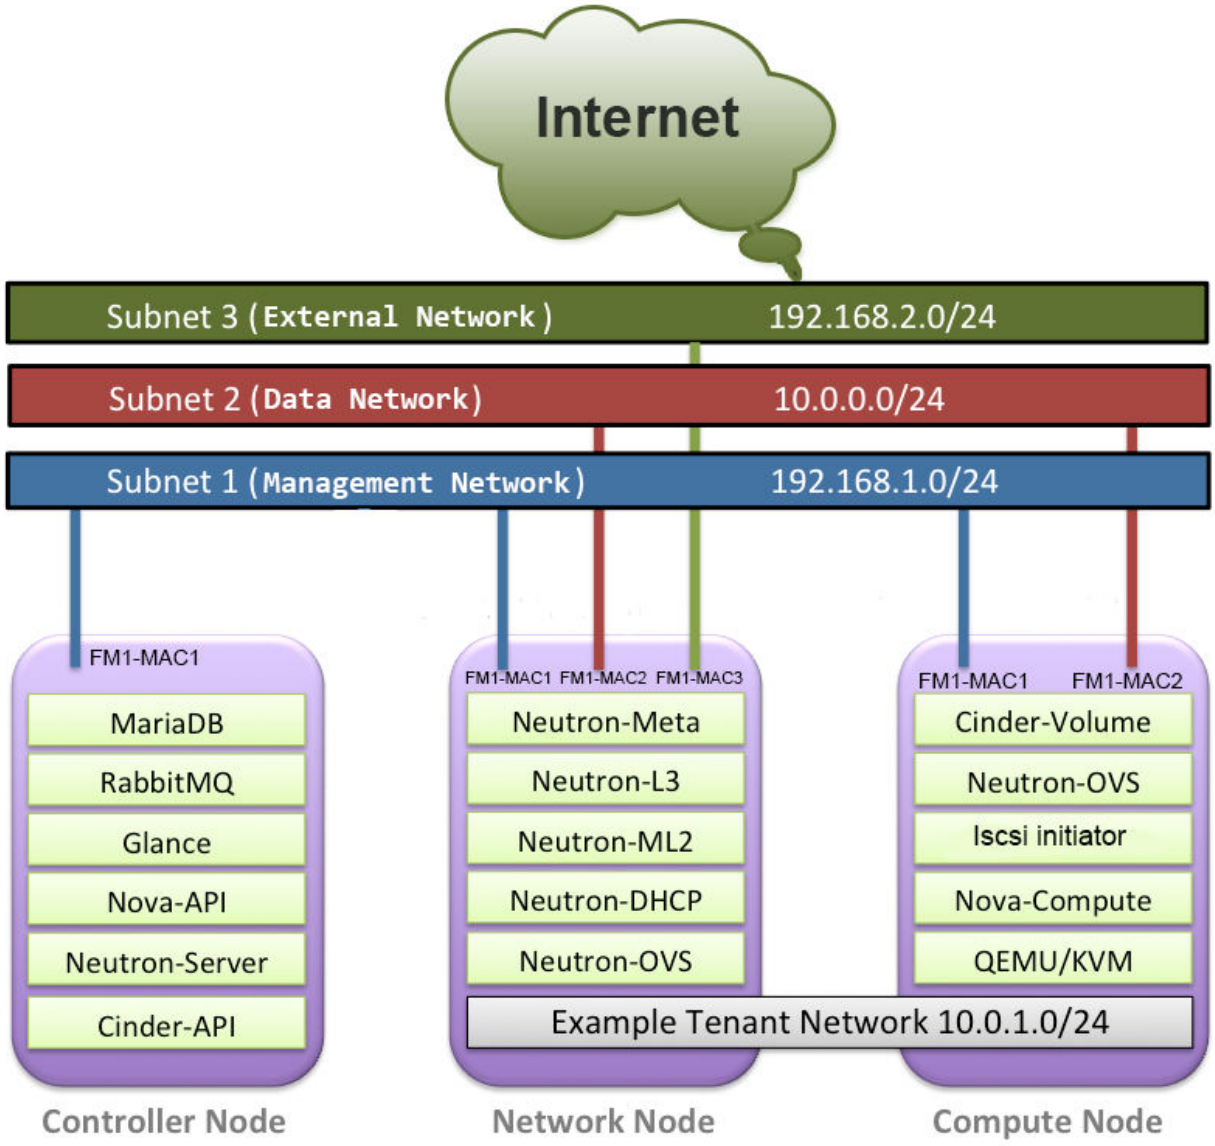

Figure 1. Host Machine based on QorIQ Platform Setup Diagram

Build Openstack images for QorIQ Platform

To build Openstack images for QorIQ Platform, X86 Laptop/Host machine for Yocto Project build should be available. After build environment is ready, refer to following steps to build images:

1. Install QorIQ SDK ISO on X86 host
   a. Install cache ISO(`QorIQ-SDK-<version>-<target>-CACHE-<yyyymmdd>-yocto.iso`)
   b. Then install source(`QorIQ-SDK-<version>-SOURCE-<yyyymmdd>-yocto.iso ) ISO`
2. After those two ISOs install successfully, create project for target platform

```
$ . ./fsl-setup-poky -m <targer_platform>
```

Or

```
$ . ./fsl-setup-poky -m <targer_platform>
```

3. Add following line into conf/local.conf

```
sources/meta-DELTA_KERNEL_DEFCONFIG_append = " <ISO Install folder>/meta-fsl-networking/recipes-kernel/linux/files/openstack_config "
```

4. Build images for Openstack

```
Openstack Controller
$ bitbake openstack-image-controller
Openstack Network Node
$ bitbake openstack-image-network
Openstack Compute Node
$ bitbake openstack-image-compute
```

5. After the image builds successfully, you will see following images under directory

```
cd tmp/deploy/images/<target_platform>
Controller Rootfs:
        openstack-image-controller-<target_platfrom>.tar.gz
Network Node Rootfs:
        openstack-image-network-<target_platform>.tar.gz
Compute Node Rootfs:
       openstack-image-compute-<target_platform>.tar.gz
```

6. Transfer those images to tftpserver for SATA Boot Deployment

Deploy Openstack images(controller/compute/network) on Target platform

1. Bootup target platform by referring target platform deployment guide
2. After booting, login using username `'root'`
3. Unmount the Hard drive if it's already mounted
4. Create the partition in the Hard drive using the following commands:
   a. Run the following command to enter into partitioning system

```
$ fdisk /dev/sda
```

   b. Enter `'n'` and press enter to create new partition

```
Command (m for help): n
```

   c. Enter `'p'` and press enter to create a primary partition

```
Command action
      e   extended
      p   primary partition (1-4)
      p
```

   d. Enter `'1'` and press enter to create partition number 1

```
Partition number (1-4):1
```

   e. Press enter to select first cylinder as `'1'`

```
First cylinder (1-1018, default 1):
```

f. Press enter to select complete disk size

```
Last cylinder or +size or +sizeM or +sizeK (1-1018, default 1018):
```

g. Enter 'w' and press enter to write the changes to Hard drive

```
Command (m for help): w
```

5. Format the partition as ext3 file system using following command

```
$ mkfs.ext2 /dev/sda1
```

6. Mount the formatted partition to local folder. Run the following command to execute it

```
$ mkdir /media/sda1
$ mount /dev/sda1 /media/sda1
```

7. Download the openstack rootfs to SATA HDD Drirve

```
$ scp <username>@<tftp_server>:<Openstack_image_dir>/openstack-image-controller-
<target_platform>.tar.gz /media/sda1
```

8. Uncompress the tarball to SATA HDD Drive.

```
$ cd /media/sda1
$ tar -zxf openstack-image-controller-<target_platform>.tar.gz
```

9. Umount the SATA HDD Drive and reboot system

```
$ umount /media/sda1; reboot
```

10. Boot the board with Hard drive

```
For PPC platform:
=> setenv sataboot 'setenv bootargs root=/dev/sda1 rootfstype=ext2 rootdelay=10 rw console=
$consoledev,$baudrate $othbootargs;tftp $loadaddr $bootfile;tftp $fdtaddr $fdtfile;bootm
$loadaddr - $fdtaddr'
Note: assume the SATA HDD drive is sda1
=> run sataboot
For LS2085ARDB/LS2088AARDB platform:
=> tftp a0000000 <ls2085ardb_kernel_itb>.itb
=> setenv bootargs 'root=/dev/sda1 rw rootdelay=10 console=ttyS1,115200 earlycon=uart8250,mmio,
0x21c0600 default_hugepagesz=2m hugepagesz=2m hugepages=256
=> bootm a0000000:kernel@1 - a0000000:fdt@1
For LS1043ARDB platform:
=> tftp a0000000 <ls1043ardb_kernel_itb>.itb
=> setenv bootargs 'root=/dev/sda1 rw rootdelay=10 console=ttyS0,115200
earlyprintk=uart8250-8bit,0x21c0600,115200 default_hugepagesz=2m hugepagesz=2m hugepages=256
=> bootm a0000000:kernel@1 - a0000000:fdt@1
```

NOTE

Make sure at least two ethernet ports on target platform are available. One port is for management interface, another one is for data interface.

Configuration for Openstack

1. Please refer to Openstak Kilo configuration as following link:

```
http://docs.openstack.org/kilo/install-guide/install/apt/content/index.html
```

References

OpenStack Installation Guide:

```
*http://docs.openstack.org/kilo/config-reference/content/list-of-compute-config-options.html
*hhttp://docs.openstack.org/kilo/install-guide/install/apt/openstack-install-guide-apt-kilo.pdf
```

3.3.12 Shared State (sstate) Cache

BitBake has the capability to accelerate builds based on previously built output. This is done using "shared state" files which can be thought of as cache objects and this option determines where those files are placed. The shared state cache (sstate-cache), as pointed to by SSTATE_DIR.

1. Use the following setting in local.conf:

```
SSTATE_DIR="<absolute_path_of_cache_folder>"
e.g. SSTATE_DIR = "/home/yocto/sdk/sstate-cache/"
```

NOTE

Some packages have no caches because the ISO uses 4GB of space. Thus, cache size is limited by ISO size. Some packages (e.g. u-boot, kernel, rcw, hv-cfg, fmc, depmodwrapper-cross, keymaps, base-files, merge-files, shadow-securetty, etc.) have no caches and building them requires about 20 minutes.

3.3.13 FAQ

Frequently Asked Questions about Yocto Project

Q: How do I install source code, modify source code and rebuild u-boot/kernel?

A: Use the following steps:

1. `$ cd <sdk-install-dir>/build_<machine>`
2. If the source code has been installed, please skip this step.
   - `$ bitbake -c patch <package-name>`
   - `$ cd <S>` and do change

NOTE

Use `bitbake -e <package-name> | grep ^S =` to get the value of `<S>`.

3. Modify configure (dts can also be modified):
   - Modify the `UBOOT_CONFIG` variable in `sources/meta-freescale/conf/machine/<machine>.conf` or update the `KERNEL_DEFCONFIG` variable in `sources/meta-freescale/conf/machine/<machine>.conf`
4. Rebuild images:
   - `$ cd <sdk-install-dir>/build_<machine>`
   - `$ bitbake -c compile -f <package-name>`
   - `$ bitbake <package-name>`

NOTE

u-boot.bin, Image and dtb files can be found in build_<machine>/tmp/deploy/images/<machine>.

Or set <ARCH> and <CROSS_COMPILE> and build the u-boot/kernel manually

Q: How do I build u-boot/kernel with debugger (CodeWarrior support)?

A: *For u-boot:*

1. $ cd <sdk-install-dir/build_<machine>
2. $ bitbake -c cleansstate u-boot
3. Modify the u-boot-qoriq_<version>.bb file and add following content:
   - $ cd sources/meta-freescale/recipes-bsp/u-boot
   - $ add 'EXTRA_OEMAKE += "CONFIG_CW=1"' in u-boot-qoriq_<version>.bb file
4. Rebuild u-boot:
   - $ bitbake u-boot

For kernel:

1. $ cd <sdk-install-dir>/build_<machine>.
2. If kernel source code is not installed, install the kernel source code first.
   - $ bitbake -c cleansstate virtual/kernel
   - $ bitbake -c patch virtual/kernel
3. Configure kernel to enable CW support:
   - $ bitbake -c menuconfig virtual/kernel
   - Enable Kernel hacking -> Include CodeWarrior kernel debugging in kernel configuration UI.
4. Rebuild kernel:
   - $ bitbake virtual/kernel

Q: How do I view the content of rootfs?

A: The expanded rootfs is in <IMAGE_ROOTFS>

NOTE

Use bitbake -e <rootfs-name> | grep ^IMAGE_ROOTFS= to get the value of <IMAGE_ROOTFS>.

Q: How do I add a pre-built binary into the rootfs?

A: Do the following:

1. $ cd <sdk-install-dir>.
2. Add the files:
   - $ cd sources/meta-freescale/recipes-extended/merge-files
   - Put the files into files/merge, e.g. put bash into files/merge/, bash will be included in /home/root/ of the new rootfs.
3. Build new rootfs image:
   - $ bitbake <rootfs-target>

Q: What's an example of using dtc to reverse to a dts from a dtb?

A: Do the following

1. ```
   $ export PATH=<path-of-dtc>:$PATH
   ```
2. ```
   $ dtc -I dtb -O dts -o name-of-dts name-of-dtb
   ```

Q: How do I build fsl-toolchain?

A: Do the following

1. ```
   $bitbake fsl-toolchain
   ```

NOTE

fsl-qoriq-glibc-x86_64-<target>-toolchain-<VERSION>.sh can be found in `build_<machine>/tmp/deploy/sdk/`

NOTE

fsl-qoriq-glibc-x86_64-<target>-toolchain-<VERSION>.sh runs and the toolchain can be installed in special path

Q: I failed to get source tarball of a packages with wget. What should I do?

A: Use the `--no-check-certificates` optionwhen Yocto Project uses `wget` to fetch source tarball from internet, the option is only available when `wget` was configured at build time with SSH support. Ensure that `wget` on your host is built with SSH support.

Q: How do I include toolchain in rootfs?

A: The toolchain runs on target board, which is the same exact version as the cross tools in this SDK, is only included in `fsl-image-full` rootfs, if you want to add toolchain into other rootfs images, do the following:

1. Edit `fsl-image-minimal.bb/fsl-image-core.bb` to add `packagegroup-core-buildessential` in the `IMAGE_INSTALL` variable.
2. `$ bitbake <rootfs-target>.`

Q: How do I use standalone toolchain to build kernel?

A: If you want to build the linux kernel using toolchain, you can do the following:

1. ```
   cd <toolchain-install-dir>
   ```
2. ```
   source environment-setup-<core>-fsl-linux
   ```
3. ```
   export LDFLAGS=""
   ```
4. ```
   cd <linux-src-dir>
   ```
5. ```
   make mrproper
   ```
6. ```
   ./scripts/kconfig/merge_config.sh
   arch/arm64/configs/defconfig
   arch/arm64/configs/freescale.config
   ```
7. ```
   make CC="$CC" LD="$LD"
   ```

Chapter 4
Deploy U-Boot, Linux Kernel, and Root Filesystem to a Reference Design Board (RDB)

4.1 Introduction

This chapter describes how to deploy U-Boot, Linux kernel and root file system to the NXP Reference Design Board (RDB) . The guide starts with generic host and target board pre-requisites. This is followed by board-specifc configuration:

- Switch Settings
- U-Boot environment Variables
- Device Microcodes
- Management Complex (MC), DPC, DPL
- Reset Configuration Word (RCW) and Ethernet Interfaces (if applicable)
- System Memory Map
- Flash Bank Usage

The "Switch Settings" section within each guide shows the default switch settings for the reference design board. If more information is needed beyond the scope of the default configuration, refer to the reference design board's Quick Start Guide and Reference Manual/ User Manual.

For reference design boards with more than one QSPI flash, the "Programming a New U-Boot, RCW, Management Complex" section describes how the user can individually or simultaneously update U-Boot, RCW, and Management Complex, DPC, DPL by flashing them to the board's second QSPI flash prior to deployment.

Once the board is set-up and configured appropriately, select one of the following deployment methods:

- Ramdisk deployment from TFTP
- Ramdisk deployment from Flash
- NFS deployment
- Harddisk deployment (if applicable)
- SD deployment (if applicable)
- Hypervisor deployment (if applicable)

Each of these guides will step you through the deployment method of your choice.

4.2 Basic Host Set-up

Since TFTP will be used to download files onto the target board, a TFTP server must be running on your host system. If you are going to use NFS deployment then an NFS server must also be running on your host system.

Once TFTP and NFS servers are installed, use the following generic instructions to complete the host set-up:

1. Create the tftboot directory.

```
mkdir /tftpboot
```

2. Copy over kernel, bootloader, and flash filesystem images for your deployment to the /tftpboot directory:

```
cp <yocto_work_dir>/build_<platform>_release/tmp/deploy/images/* /tftpboot
```

3. Use Yocto Project to generate a tar.gz type file system, and uncompress it in <nfs_root_path>.
4. Edit /etc/exports and add the following line:

```
<nfs_root_path> <target_board_IP> (rw,no_root_squash, async)
```

5. Edit /etc/xinetd.d/tftp to enable TFTP server:

```
service tftp
{
disable= no
socket_type= dgram
protocol= udp
wait= yes
user= root
server= /usr/sbin/in.tftpd
server_args= /tftpboot
}
```

6. Restart the nfs and tftp servers on your host:

```
/etc/init.d/xinetd restart
/etc/init.d/nfs restart
```

7. Connect the board to the network.
8. Connect the target to the host via a cross cable serial connection.
9. Open a serial console tool on the host system and set it up to talk to the target board:
   - Select appropriate serial device.
   - Configure the serial port with the following settings: Baud rate = 115,200; Data = 8 bit; Parity = none; Stop = 1 bit; Flow control = none.
   - Power on board and see the console prompt.

NOTE

(i) The Linux distribution running on your host will determine the specific instructions to use.

(ii) Steps 3 and 4 are only necessary when using NFS deployment.

4.3 Target Board Set-up

Once the host set-up is complete, follow these steps to set-up and power on the target board:

1. Power off the Target board system if the power is already on.

2. Connect the Target board to the network via an Ethernet port on the board.
3. Connect the Target board to the host machine via the serial port with an RS-232 cable and the joined NXP adaptor cable, if needed.
4. Start the serial console tool on the host system.
5. Verify that all switches and jumpers are setup correctly as described in the board's Reference Manual/User Guide.
6. Power on the board.

Below is an example of a typical U-Boot log:

```
U-Boot 2016.012.0+g2ea81ad (Apr 10 2016 - 14:30:36 +0800)

CPU0:  T1023E, Version: 1.0, (0x85490010)
Core:  e5500, Version: 2.1, (0x80241021)
Single Source Clock Configuration
Clock Configuration:
       CPU0:1200 MHz, CPU1:1200 MHz,
       CCB:400  MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), IFC:100  MHz

```

NOTE

If the target board does not have a working U-Boot, see System Recovery on page 406.

4.4 Supported Boards

4.4.1 B4420QDS

4.4.1.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.1.2 Switch Settings

The development system has user selectable switches for evaluating different boot options for the B4420 device. The table below lists the default switch settings. For a description of these settings, see B4420 Reference Manual, B4860QDS User's Guide and B4860QDSHGS.

Table 15. Default DIP Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]
SW2	ON	OFF	ON	OFF	ON	ON	OFF	OFF
SW3	OFF	OFF	OFF	ON	OFF	OFF	ON	OFF
SW5	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON

Table 16. Frequency Settings in MHz

SysClk	CPU Core (e6500)	CCB	DDR	FMan	DDRCLK	StarCore (SC3900)	CPRI (Maple)	eTVPE (Maple)	ULB (Maple)
66.67 MHz	1600	667	800	667	133.33 MHz	1200	600	1000	800

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 17. Boot Device Scenarios

Alternate Boot Device	Change these DIP switch settings (0=OFF/1=ON)
a) NAND boot with ECC disabled	• SW1 [1] = 1 • SW2 [1] = 0 • SW3 [1:4] = 1000
b) NAND boot with ECC enabled	• SW1 [1] = 1 • SW2 [1] = 1 • SW3 [1:4] = 1000
c) NOR boot	• SW1 [1] = 0 • SW2 [1] = 1 • SW3 [1:4] = 0001
d) Hard Code setting	• SW2 [1] = 0 • SW2 [5] = 0 • SW3 [1:8] = 01000011
e) I2C EEPROM setting	• SW2 [1] = 1 • SW3 [1:8] = 00100100

4.4.1.3 U-Boot Environment Variables

4.4.1.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig=fsl_ddr:ctlr_intlv=null,bank_intlv=cs0_cs1;en_cpc:cpc1,usb1:dr_mode=host,phy_type=ulpi;fs
l_fm1_xaui_phy:xfi
```

NOTE

For USB gadget set "dr_mode=peripheral"

VID Support for B4420

The fuse status register provides the values from on-chip voltage ID efuses programmed at the factory. These values define the voltage requirements for the chip, specifically VDD (core voltage). U-Boot reads FUSESR and translates the values into the appropriate commands to set the voltage output value of an external voltage regulator. B4420QDS has a PowerOne ZM7300 programmable digital Power Manager, which is programmed as per the value read from the fuses.

There is an environment variable also provided to override the fuse specified voltage.

```
"b4qds_vdd_mv"
```

For example:

```
=> setenv b4qds_vdd_mv 950
=> save
=> reset
```

The commands above will override the Voltage with 0.95V.

```
=> setenv b4qds_vdd_mv 1100
=> save
=> reset
```

The commands above will override the Voltage with 1.1V.

NOTE

The time of Power on the board boots at 1.0V default and then the Voltage adjustment happens in the U-Boot flow.

Changing Board Personalities

Use the following steps to change from a B4860QDS to a B4420QDS:

1. Boot from vbank0
2. Flash vbank2 with B4420 RCW binary and U-Boot
3. Type the following commands on the U-Boot prompt:

```
mw.b ffdf0040 0x30;
mw.b ffdf0010 0x00;
mw.b ffdf0062 0x02;
mw.b ffdf0050 0x02;
mw.b ffdf0010 0x30;
```

4. Reset

4.4.1.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
```

```
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.1.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for B4420 version information (e.g., B4420E version 2.2) and also for the version of FMan microcode currently flashed on the B4420QDS (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, the following FMan microcode binary should be used:

- For silicon revision 2.2:

```
fsl_fman_ucode_b4860_r2.2_106_4_18.bin (*)
fsl_fman_ucode_b4860_r2.2_108_4_5.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.1.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains the following RCW binary for use on the B4420QDS:

- N_PNSS_0x18_0x9E/rcw_2sgmii_1600mhz_rev2.bin (default)

The RCW directories' names for the B4420QDS conform to the following naming convention:

```
a_bcde_f_g
```

Table 18. B4420QDS Naming Convention Legend

Slot	Convention
a	'N' if not available/not supported
b [What is available in Slot 1] c [What is available in Slot 2]	'N' if not available/not used 'P' if PCIe 'R' if SRIO 'S' if SGMII 'A' is AURORA
d	'S' if RGMII is there on phy1 of dual SGMII phy VSC8662 'N' if not available /not used
e	'S' if RGMII is there on phy2 of dual SGMII phy VSC8662 'N' if not available /not used
f	Hex value of serdes1 protocol value
g	Hex value of serdes2 protocol value

For example,

```
N_PNSS_0x9_0xa
```

means:

- RGMII is unsupported
- PCIE on Slot 1
- Nothing on Slot 2
- SGMII on phy1
- SGMII on phy2
- SERDES1 protocol is 0x9
- SERDES2 protocol os 0xa

Below is a table that maps the different ports available on B4420 and their names in different environments.

Table 19. Port Map

Port in U-boot	Port in Linux	FMAN Address
FM1@dTSEC3	fm1-mac3	0xffe4e4000
FM1@dTSEC4	fm1-mac4	Oxffe4e6000

4.4.1.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Discription	Size
0xF_FFDF_1000	0xF_FFFF_FFFF	Free	2 MB
0xF_FFDF_0000	0xF_FFDF_0FFF	IFC - FPGA	4 KB
0xF_FF81_0000	0xF_FFDE_FFFF	Free	5 MB
0xF_FF80_0000	0xF_FF80_FFFF	IFC - NAND Flash	64 KB
0xF_FF00_0000	0xF_FF7F_FFFF	Free	8 MB
0xF_FE00_0000	0xF_FEFF_FFFF	CCSRBAR	16 MB
0xF_F801_0000	0xF_FDFF_FFFF	Free	95 MB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64 KB
0xF_F600_0000	0xF_F7FF_FFFF	Queue manager software portal	32 MB
0xF_F400_0000	0xF_F5FF_FFFF	Buffer manager software portal	32 MB
0xF_F000_0000	0xF_F3FF_FFFF	Free	64 MB
0xF_E800_0000	0xF_EFFF_FFFF	IFC - NOR Flash	128 MB
0xF_E000_0000	0xF_E7FF_FFFF	Promjet	128 MB
0xF_A100_0000	0xF_DFFF_FFFF	Free	1008 MB
0xF_A000_0000	0xF_A0FF_FFFF	MAPLE0, MAPLE1, MAPLE2	16 MB
0xF_0040_0000	0xF_9FFF_FFFF	Free	12 GB
0xF_0000_0000	0xF_003F_FFFF	DCSR	4 MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Discription	Size
0xC_4000_0000	0xE_FFFF_FFFF	Free	11 GB
0xC_2000_0000	0xC_3FFF_FFFF	Free (Since no sRIO)	512 MB
0xC_0000_0000	0xC_1FFF_FFFF	PCI Express 1 Mem Space	512 MB
0x1_0000_0000	0xB_FFFF_FFFF	Free	44 GB
0x0_8000_0000	0x0_FFFF_FFFF	SC DDR (DDRC1-CS1)	2 GB
0x0_0000_0000	0x0_7FFF_FFFF	PA DDR (DDRC1-CS0)	2 GB

4.4.1.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration B4420QDS preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, please refer to the U-Boot log.

```
CPU0:  B4420E, Version: 2.2, (0x86890222)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1600 MHz, CPU1:1600 MHz,
       CCB:666.667 MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), IFC:166.667 MHz
       FMAN1: 666.667 MHz
       QMAN:  333.333 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 14000c18 0f001218 00000000 00000000
       00000010: 2e9d0000 80002400 ec025000 a9000000
       00000020: 00000000 00000000 00000000 0003b000
       00000030: 00000000 14000020 00000000 00000011
Board: B4420QDS, Sys ID: 0x21, Sys Ver: 0x13, vBank: 2
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>qixis_reset
```

- Switch to alternate bank:

```
=>qixis_reset altbank
```

Known Bugs, Limitations, or Technical Issues

Sometime "qixis_reset altbank" hang.

Workaround:- Please use below commands intesad of "qixis_reset" commands for NOR vbank selection.

Moving from vbank0 --> vbank2 :

mw.b ffdf0010 0x00; mw.b 0xffdf0040 0x30; mw.b 0xffdf0050 0x2;mw.b 0xffdf0010 0x30; reset

Moving from vbank2 --> vbank0 :

mw.b ffdf0010 0x00; mw.b 0xffdf0040 0x30; mw.b 0xffdf0050 0x0;mw.b 0xffdf0010 0x30; reset

The table below shows the B4420QDS NOR flash memory map.

Table 20. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xEFF40000	0xEFFFFFFF	U-Boot (current bank)	768 KB
0xEFF20000	0xEFF3FFFF	U-Boot env (current bank)	128 KB
0xEFF00000	0xEFF1FFFF	FMAN Ucode (current bank)	128 KB
0xEF300000	0xEFEFFFFF	rootfs (alternate bank)	12 MB
0xEE900000	0xEE9FFFFF	HV config device tree (alternate bank)	1 MB
0xEE800000	0xEE8FFFFF	Hardware device tree (alternate bank)	1 MB

0xEC000000	0xEC01FFFF	RCW (current bank)	128 KB

4.4.1.8 Programming a New U-Boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *qixis_reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *qixis_reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>qixis_reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *qixis_reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location

of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>qixis_reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *qixis_reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>qixis_reset altbank
```

Writing SPD

DDRC takes its configuration parameters from EEPROM that are on I2C bus. To provide configuration to DDRC, its respective EEPROM needs to be programmed with the desired configuration.

EEPROM for DDRC1 is at address 0x51

B4420QDS has only one DDRC, so only one SPD needs to be programmed for this DDR controller.

By default, EEPROMs are write protected. Use the following commands to make them writable:

```
mw.b 0xffdf0055 0x8
```

In order to write SPD, TFTP SPD binaries and write them on EEPROMs using the following commands:

```
tftp 1000000 spd_1866_dual_rank_4GB_DDRC1.bin
i2c write 0x1000000 0x51 0 0x80
reset
```

After configuring EEPROM, reset board to let DDRC settings take effect.

4.4.1.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.1.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
=>saveenv
```

NOTE

ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.1.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
```

```
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.1.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
```

```
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.1.9.4 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

   ```
   =>tftp 1000000 <platform_name>-usdpaa.dtb
   =>erase e8800000 +$filesize
   =>cp.b 1000000 e8800000 $filesize
   ```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

4.4.2 B4860QDS

4.4.2.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.2.2 Switch Settings

The Development System has user selectable switches for evaluating different boot options for the B4860QDS device. The table below lists the default switch settings. For a description of these settings, see B4860QDS Reference Manual.

Table 21. B4860QDS Default DIP Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]	OFF [0]
SW2	ON	ON	ON	ON	ON	ON	OFF	OFF
SW3	OFF	OFF	OFF	ON	OFF	OFF	ON	OFF
SW5	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 22. Boot Device Scenarios

Alternate Boot Device	Change these DIP switch settings (0=OFF/1=ON)
a) NAND boot with ECC disabled	• SW1 [1] = 1 • SW2 [1] = 0 • SW3 [1:4] = 1000
b) NAND boot with ECC enabled	• SW1 [1] = 1 • SW2 [1] = 1 • SW3 [1:4] = 1000
c) NOR boot	• SW1 [1] = 0 • SW2 [1] = 1 • SW3 [1:4] = 0001
d) Hard Code setting	• SW2 [1] = 0 • SW2 [5] = 0 • SW3 [1:8] = 01000011
e) I2C EEPROM setting	• SW2 [1] = 1 • SW3 [1:8] = 00100100

4.4.2.3 U-Boot Environment Variables

4.4.2.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;fsl_fm1_xaui_phy:xfi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm1_xaui_phy:xfi
```

To use *hwconfig en_cpc*, append the following:

```
en_cpc:cpc2;
```

or

```
en_cpc=cpc1
```

By default, CPC1 is not enabled since only CPC2 should be used. However, by editing the *hwconfig en_cpc* option, CPC1 can also be enabled.

To use 10G PHY, append the following:

```
fsl_fm1_xaui_phy:xfi
```

To use USB gadget, set the following:

```
dr_mode=peripheral
```

NOTE

To use XFI, these changes are needed:

1. "fsl_b4860_serdes2:sfp_amc=sfp" must be in hwconfig
2. Make sure the B4860QDS board has extra heat sinks on VSC3308 devices. They are labeled U45 and U96 near the AMC connector, located at the two sides of the board
3. Use Source Photonics optical modules SPP-10E-SR-CDFD. Then the XFI ports can be used as normal 10G ports.
4. U-Boot configures matrix for CPRI modes according to SerDes protocol number.

VID Support for B4860

The fuse status register provides the values from on-chip voltage ID efuses programmed at the factory. These values define the voltage requirements for the chip, specifically VDD (core voltage). U-Boot reads FUSESR and translates the values into the appropriate commands to set the voltage output value of an external voltage regulator. B4860QDS has a PowerOne ZM7300 programmable digital Power Manager, which is programmed as per the value read from the fuses.

There is an environment variable also provided to override the fuse specified voltage.

```
"b4qds_vdd_mv"
```

For example:

```
=> setenv b4qds_vdd_mv 950
=> save
=> reset
```

The commands above will override the Voltage with 0.95V.

```
=> setenv b4qds_vdd_mv 1100
=> save
=> reset
```

The commands above will override the Voltage with 1.1V.

NOTE

The time of Power on the board boots at 1.0V default and then the Voltage adjustment happens in the U-Boot flow.

Known Bugs, Limitations, or Technical Issues

Sometime "qixis_reset altbank" hang.

Workaround:- Please use below commands intesad of "qixis_reset" commands for NOR vbank selection.

Moving from vbank0 --> vbank2 :

mw.b ffdf0010 0x00; mw.b 0xffdf0040 0x30; mw.b 0xffdf0050 0x2;mw.b 0xffdf0010 0x30; reset

Moving from vbank2 --> vbank0 :

mw.b ffdf0010 0x00; mw.b 0xffdf0040 0x30; mw.b 0xffdf0050 0x0;mw.b 0xffdf0010 0x30; reset

4.4.2.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.2.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for B4860 version information (e.g., B4860E version 2.2) and also for the version of FMan microcode currently flashed on the B4860QDS (e.g., microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1

```
fsl_fman_ucode_b4860_r1.0_106_3_15.bin
```

- For silicon revision 2

```
fsl_fman_ucode_b4860_r2.0_106_4_15.bin
```

- For silicon revision 2.2

```
fsl_fman_ucode_b4860_r2.2_106_4_18.bin (*)
fsl_fman_ucode_b4860_r2.2_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a New U-boot, RCW, FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.2.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains RCW binaries for use on the B4860QDS:

- N_RSSS_0x2A_0x8D/rcw_4sgmii_4srio_2xfi_1600mhz_1866ddr_rev2.bin (default)

The RCW directories' names for the B4860QDS conform to the following naming convention:

```
a_bcde_f_g
```

Table 23. B4860QDS Naming Convention Legend

Slot	Convention
a	'R' if RGMII is supported 'N' if not available/not used
b [What is available in Slot 1] c [What is available in Slot 2]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'A' is AURORA
d	'S' if SGMII is there on phy1 of dual SGMII phy VSC8662 'N' if not available /not used
e	'S' if SGMII is there on phy2 of dual SGMII phy VSC8662 'N' if not available /not used
f	'hex value of serdes1 protocol value'
g	'hex value of serdes2 protocol value'

For example,

```
N_PNSS_0x9_0xa
```

means:

- RGMII is unsupported
- PCIE on Slot 1
- Nothing on Slot 2
- SGMII on phy1
- SGMII on phy2
- SERDES1 Protocol is 0x9 and the SERDES2 Protocol is 0xa

Below is a table that maps the different ports available on B4860QDS and their names in different environments.

Table 24. B4860QDS Port Map

Port in U-boot	Port in Linux
FM1@DTSEC3	fm1-mac3
FM1@DTSEC4	fm1-mac4
FM1@DTSEC5	fm1-mac5
FM1@DTSEC6	fm1-mac6
FM1@TGEC1	fm1-mac9
FM1@TGEC2	fm1-mac10

4.4.2.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Discription	Size
0xF_FFDF_1000	0xF_FFFF_FFFF	Free	2 MB
0xF_FFDF_0000	0xF_FFDF_0FFF	IFC - FPGA	4 KB
0xF_FF81_0000	0xF_FFDE_FFFF	Free	5 MB
0xF_FF80_0000	0xF_FF80_FFFF	IFC - NAND Flash	64 KB
0xF_FF00_0000	0xF_FF7F_FFFF	Free	8 MB
0xF_FE00_0000	0xF_FEFF_FFFF	CCSRBAR	16 MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Discription	Size
0xF_F801_0000	0xF_FDFF_FFFF	Free	95 MB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64 KB
0xF_F600_0000	0xF_F7FF_FFFF	Queue manager software portal	32 MB
0xF_F400_0000	0xF_F5FF_FFFF	Buffer manager software portal	32 MB
0xF_F000_0000	0xF_F3FF_FFFF	Free	64 MB
0xF_E800_0000	0xF_EFFF_FFFF	IFC - NOR Flash	128 MB
0xF_E000_0000	0xF_E7FF_FFFF	Promjet	128 MB
0xF_A100_0000	0xF_DFFF_FFFF	Free	1008 MB
0xF_A000_0000	0xF_A0FF_FFFF	MAPLE0, MAPLE1, MAPLE2	16 MB
0xF_0200_0000	0xF_9FFF_FFFF	Free	2528 MB
0xF_0000_0000	0xF_01FF_FFFF	DCSR	32 MB
0xC_4008_0000	0xE_FFFF_FFFF	Free	11263 MB
0xC_4000_0000	0xC_4007_FFFF	SC CPC1 as SRAM	512KB
0xC_3000_0000	0xC_3FFF_FFFF	Serial Rapid I/O 2	256 MB
0xC_2000_0000	0xC_2FFF_FFFF	Serial Rapid I/O 1	256 MB
0xC_0000_0000	0xC_1FFF_FFFF	PCI Express 1 Mem Space	512 MB
0x1_0000_0000	0xB_FFFF_FFFF	Free	44 GB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Discription	Size
0x0_8000_0000	0x0_FFFF_FFFF	SC DDR (DDRC1)	2 GB
0x0_0000_0000	0x0_7FFF_FFFF	PA DDR (DDRC2)	2 GB

4.4.2.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration B4860QDS preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, please refer to the U-Boot log:

```
CPU0:  B4860E, Version: 2.2, (0x86880022)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1600 MHz, CPU1:1600 MHz, CPU2:1600 MHz, CPU3:1600 MHz,
       CCB:666.667 MHz,
       DDR:933.333 MHz (1866.667 MT/s data rate) (Asynchronous), IFC:166.667 MHz
       FMAN1: 666.667 MHz
       QMAN:  333.333 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 14000e18 0f001218 00000000 00000000
       00000010: 52b10000 8000a400 dc025000 a9000000
       00000020: 01000000 00000000 00000000 0001b1f8
       00000030: 00000000 14000020 00000000 00000011
Board: B4860QDS, Sys ID: 0x21, Sys Ver: 0x13, vBank: 0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>qix
```

- Switch to alternate bank:

```
=>qix altbank
```

The table below shows the B4860QDS NOR flash memory map.

Table 25. NOR Flash Memory Map

Range Start	Range End	Definition	Size

Table continues on the next page...

4.4.2.8 Programming a New U-Boot, RCW, FMan Microcode, and Writing SPD

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *qix altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters on page 102 to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *qix*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>qix altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *qix*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>qix altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *qix*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of microcode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the microcode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>qix altbank
```

Writing SPD

DDRC's take their configuration parameters from EEPROM that are on I2C bus. To provide configuration to both DDRC, their respective EEPROMs need to be programmed with the desired configuration.

EEPROM for DDRC1 is at address 0x51

EEPROM for DDRC2 is at address 0x53

By default, EEPROMs are write protected. Use the following commands to make them writable:

```
mw.b 0xffdf0055 0x8
```

In order to write SPD, TFTP SPD binaries and write them on EEPROMs using the following commands:

```
tftp 1000000 spd_1866_dual_rank_4GB_DDRC1.bin
i2c write 0x1000000 0x51 0 0x80
reset

tftp 2000000 spd_1866_single_rank.bin
i2c write 0x2000000 0x53 0 0x80
reset
```

After configuring both EEPROMs, reset board to let the DDRC1 and DDRC2 settings take effect.

4.4.2.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.2.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.2.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

   ```
   =>tftp 1000000 <uImage name>
   =>protect off <kernel_start_addr> +$filesize
   =>erase <kernel_start_addr> +$filesize
   =>cp.b 1000000 <kernel_start_addr> $filesize
   =>protect on <kernel_start_addr> +$filesize
   ```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

   ```
   =>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>protect off <ramdisk_start_addr> +$filesize
   =>erase <ramdisk_start_addr> +$filesize
   =>cp.b 2000000 <ramdisk_start_addr> $filesize
   =>protect on <ramdisk_start_addr> +$filesize
   ```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

   ```
   =>tftp c00000 <platform dtb name>
   =>protect off <dtb_start_addr> +$filesize
   =>erase <dtb_start_addr> +$filesize
   =>cp.b c00000 <dtb_start_addr> $filesize
   =>protect on <dtb_start_addr> +$filesize
   ```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.2.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 1000000 <uImage name>
   =>tftp c00000 <platform dtb name>
   =>bootm 1000000 - c00000
   ```

   Now the board will boot up with NFS filesystem.

4.4.2.9.4 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

```
=>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>erase e9300000 +$filesize
=>cp.b 1000000 e9300000 $filesize
```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

```
=>tftp 1000000 hv.uImage
=>erase e8700000 +$filesize
=>cp.b 1000000 e8700000 $filesize
```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.3 C29XPCIe

4.4.3.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.3.2 Switch Settings

The C29xPCIe has user selectable switches for evaluating different boot options. The tables below list the default switch settings. For a description of these settings, see C29xPCIe User Guide.

Table 26. NOR Boot Default Switch Settings

Switch	1	2	3	4	5	6	7	8
SW4	ON	OFF	ON	OFF	OFF	ON	ON	ON
SW5	OFF	OFF	OFF	OFF	ON	ON	OFF	OFF
SW6	ON	ON	ON	ON	OFF	OFF	OFF	OFF
SW7	OFF	ON	ON	OFF	ON	OFF	OFF	OFF
SW8	ON	ON	ON	ON	OFF	OFF	OFF	OFF

Table 27. SPI Boot Default Switch Settings

Switch	1	2	3	4	5	6	7	8
SW4	ON	OFF	ON	OFF	OFF	ON	ON	ON
SW5	ON	OFF	OFF	ON	ON	ON	OFF	OFF
SW6	ON	ON	ON	ON	OFF	OFF	OFF	OFF
SW7	OFF	ON	ON	OFF	ON	OFF	OFF	OFF
SW8	ON	ON	ON	ON	OFF	OFF	OFF	OFF

Table 28. NAND Boot Default Switch Settings

Switch	1	2	3	4	5	6	7	8
SW4	ON	OFF	ON	OFF	OFF	ON	ON	ON
SW5	ON	ON	OFF	ON	ON	OFF	OFF	OFF
SW6	ON	ON	ON	ON	OFF	OFF	OFF	OFF
SW7	OFF	ON	ON	OFF	ON	OFF	OFF	OFF
SW8	ON	ON	ON	ON	OFF	OFF	OFF	OFF

NOTE

1 means 'OFF', 0 means 'ON' for all SW settings in this document.

C29XPCIE DIP-switch Settings for Boot Mode:

```
SW5[1:4]= 1111 and SW5[6]= 0 for NOR boot
SW5[1:4]= 0110 and SW5[6]= 0 for SPI boot
SW5[1:4]= 0010 and SW5[6]= 1 for NAND boot
```

C29XPCIE DIP-switch Settings for DDR Speed:

```
SW6[1:5]= 00001 for 400MHz(800MT/s data rate)
SW5[1:5]= 00110 for 500MHz(1000MT/s data rate)
SW5[1:5]= 01011 for 600MHz(1200MT/s data rate)
```

PCIe EP Scenario

Configure PCIe RC or EP mode with the switch settings:

Table 29. PCIe EP Scenario Switch Settings

PCIe Port	Host/Agent	Switch Settings
PCIE 1	Host (RC mode)	SW7[5] = OFF(1)
PCIE 1	Agent (EP mode)	SW7[5] = ON(0)

4.4.3.3 U-Boot Environment Variables

4.4.3.3.1 Boot Settings

Secure Boot Settings

- Make sure the hardware pins PO1VDD_EN(1), PO2VDD_EN(2) to be at 1.5V;
- Check the hardware pin VDD_LP whether it was provide the 1.0v power when board is powered on. This requires J15 to be linked ON and J16 pin 1 and pin 2 to be linked ON in the standalone board;
- SW7[6] is used to set secure boot to Disable; when it is ON(0), secure boot is set to Enable;
- Switch settings

  NOR secure boot mode:

```
SW5[1:4]= 1111, SW5[6]= 0, SW7[1]= 0, SW7[6]= 0
```

  SPI secure boot mode:

```
SW5[1:4]= 0110, SW5[6]= 0, SW7[1]= 0, SW7[6]= 0
```

2. Building an Image for Different Boot Modes on C29xPCIe

NOTE

0 stands for ON, 1 stands for OFF

After setting cross-compiler for PowerPC

```
1) For NOR boot
   If SW5[7:8] = 00, bank description as:
      - bank 1 on the flash 0x0000000~0x0ffffff
      - bank 2 on the flash 0x1000000~0x1ffffff
      - bank 3 on the flash 0x2000000~0x2ffffff
      - bank 4 on the flash 0x3000000~0x3ffffff

   make distclean
   make C29XPCIE

   To make sure the SW5[6] set to ON in order to route the CS0 chip select to NOR flash before
power up.
```

```
   => tftp 1000000 u-boot.bin
   For bank4
     => pro off all;era eff40000 effffffff;cp.b 1000000 eff40000 $filesize
   set SW5[1:4]= 1111, SW5[6]=0 then power on the board
   For bank3
     => pro off all;era eef40000 eeffffff;cp.b 1000000 eef40000 $filesize
   set SW5[1:4]= 1111, SW5[6]=0 then power on the board
   For bank2
     => pro off all;era edf40000 edffffff;cp.b 1000000 edf40000 $filesize
   set SW5[1:4]= 1111, SW5[6]=0 then power on the board
   For bank1
     => pro off all;era ecf40000 ecffffff;cp.b 1000000 ecf40000 $filesize
   set SW5[1:4]= 1111, SW5[6]=0 then power on the board

2) For SPI boot
   make distclean
   make C29XPCIE_SPIFLASH

   Need the boot_format tool to generate u-boot-spi.bin from the u-boot.bin.

   =>  tftp 1000000 u-boot-spi.bin
   =>  sf probe 0; sf erase 0 100000; sf write 1000000 0 100000
   set SW5[1:4]= 0110 and SW5[6]= 0(make sure the SW5[6] set to be ON in order to route the CS0
chip select to NOR flash), then power on the board

3) For NAND boot
__ make distclean
   make C29XPCIE_NAND

   => tftp 1000000 u-boot-with-spl.bin
   => nand erase.chip
   => nand write 1000000 0 $filesize
   set SW5[1:4]= 0010, SW5[6]=1, then power on the board.
```

4.4.3.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.3.4 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Address Start	Address End	Memory Type	Size
0x0_0000_0000	0x0_1fff_ffff	DDR	512 MB
0xc_0000_0000	0xc_8fff_ffff	PCI Express MEM	256 MB
0xf_ec00_0000	0xf_efff_ffff	NOR Flash	64 MB
0xf_ffb0_0000	0xf_ffb7_ffff	SRAM	512 KB
0xf_ffc0_0000	0xf_ffc0_ffff	PCI Express IO	64 KB
0xf_ffdf_0000	0xf_ffdf_0fff	CPLD	4 KB
0xf_ffe0_0000	0xf_ffef_ffff	CCSR	1 MB

4.4.3.5 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>cpld reset
```

- Switch to alternate bank:

```
=>cpld reset altbank
```

The tables below show the C29XPCIe memory maps.

Flash Memory Map

Table 30. NOR Flash Memory Map Address

Start Offset	End Offset	Description	Size
0xec00_0000	0xec3f_ffff	Linux kernel image	4 MB
0xec40_0000	0xec4f_ffff	dtb file	1 MB
0xecf2_0000	0xecf3_ffff	U-Boot ENV (alter bank)	128 KB
0xecf4_0000	0xecff_ffff	U-Boot (alter bank)	768 KB
0xed00_0000	0xeeff_ffff	rootfs	32 MB
0xeff2_0000	0xeff3_ffff	U-Boot ENV	128 KB
0xeff4_0000	0xefff_ffff	U-Boot	768 KB

Table 31. SPI Flash Memory Map Address

Start Offset	End Offset	Description	Size
0x0000_0000	0x000f_ffff	U-Boot	1 MB
0x0010_0000	0x0017_ffff	DTB file	512 KB
0x0018_0000	0x0057_ffff	Linux kernel image	4 MB
0x0058_0000	0x0098_ffff	Compressed RFS image	4 MB
0x0098_0000	0x00ff_ffff	JFFS2 RFS image	6.5 MB

Table 32. NAND Flash Memory Map Address

Start Offset	End Offset	Description	Size
0x0000_0000	0x000f_ffff	U-Boot	1 MB
0x0010_0000	0x001f_ffff	NAND DTB file	1 MB
0x0020_0000	0x005f_ffff	Linux kernel image	4 MB
0x0060_0000	0x009f_ffff	Compressed RFS image	4 MB
0x00a0_0000	0x018f_ffff	NAND JFFS2 RFS	15 MB
0x0190_0000	0x01ff_ffff	User area	7 MB

4.4.3.6 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.3.6.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
=>saveenv
```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.3.6.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

   ```
   =>tftp 1000000 <uImage name>
   =>protect off <kernel_start_addr> +$filesize
   =>erase <kernel_start_addr> +$filesize
   =>cp.b 1000000 <kernel_start_addr> $filesize
   =>protect on <kernel_start_addr> +$filesize
   ```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

   ```
   =>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>protect off <ramdisk_start_addr> +$filesize
   =>erase <ramdisk_start_addr> +$filesize
   =>cp.b 2000000 <ramdisk_start_addr> $filesize
   =>protect on <ramdisk_start_addr> +$filesize
   ```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

   ```
   =>tftp c00000 <platform dtb name>
   =>protect off <dtb_start_addr> +$filesize
   =>erase <dtb_start_addr> +$filesize
   =>cp.b c00000 <dtb_start_addr> $filesize
   =>protect on <dtb_start_addr> +$filesize
   ```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.3.6.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 1000000 <uImage name>
   =>tftp c00000 <platform dtb name>
   =>bootm 1000000 - c00000
   ```

   Now the board will boot up with NFS filesystem.

4.4.4 LS1021ATWR

4.4.4.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.4.2 Switch Settings

The TWR has user selectable switches for evaluating different boot options for the LS1021A device. Table below lists the default switch settings and the description of these settings.

Table 33. Default Clock Frequency

ARM CPU Core	Platform	DDR rate
1200 MHZ	300 MHZ	1600 MT/S

Table 34. Default LS1021A TWR-PB Switch Setting

Switch	1	2	3	4	5	6	7	8
SW2	ON [1]	OFF [0]	OFF [0]	OFF [0]	ON [1]	ON [1]	ON [1]	ON [1]
SW3	OFF	ON	ON	OFF	OFF	ON	OFF	ON

4.4.4.3 U-Boot Environment Variables

4.4.4.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set in the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified in the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which should disable interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=null,bank_intlv=null
```

4.4.4.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
```

```
=>setenv eth3addr <mac addr3>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

* <ethx> is the Ethernet port on the board connected to the Linux boot server. "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to approriate MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9f:ef:00:00
=>setenv eth1addr 00:04:9f:ef:01:01
=>setenv eth2addr 00:04:9f:ef:02:02
=>setenv eth3addr 00:04:9f:ef:03:03
=>saveenv
```

NOTE

1. For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).
2. In the overwhelming majority of cases, eth<*>addr can be autoset.

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.4.4 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains the following RCW binary for use on the LS1021ATWR:

- RSR_PPS_70/rcw_1200.bin (default for bank0)
- SSR_PNS_30/rcw_1200.bin
- SSR_PNS_30/rcw_1200_usb2.bin
- SSR_PNS_30/rcw_1200_lpuart.bin (default for bank1)

The RCW directories' names for the LS1021ATWR conform to the following naming convention:

```
abc_def_g
```

Table 35. LS1021ATWR Directories Naming Convention Legend

Slot	Convention
a[What is available for eTSEC1]	'R' indicates RGMII@eTSEC1 is supported 'S' indicates SGMII@eTSEC1 is supported 'N' if not available/not used
b[What is available for eTSEC2]	'R' indicates RGMII@eTSEC2 is supported 'S' indicates SGMII@eTSEC3 is supported 'N' if not available/not used

Table continues on the next page...

Table 35. LS1021ATWR Directories Naming Convention Legend (continued)

c[What is available for eTSEC3]	'R' indicates RGMII@eTSEC3 is supported 'S' indicates SGMII@eTSEC3 is supported 'N' if not available/not used
d	'P' indicates PCIe@slot1 is supported 'N' if not available/not used
e	'P' indicates PCIe@slot2 is supported 'N' if not available/not used
f	'S' indicates sata is supported 'N' if not available/not used
g	Hex value of serdes protocol value

For example,

```
SSR_PNS_30
```

means:

- SGMII@eTSEC1
- SGMII@eTSEC2
- RGMII@eTSEC3
- PCIE [Slot 1]
- SATA [Support]
- SERDES Protocol is 0x30

The RCW file names for the LS1021ATWR conform to the following naming convention:

```
rcw_<frequency>_<specialsetting>.rcw
```

Table 36. LS1021TWR Files Naming Convention Legend

Code		Convention
frequency		Core frequency(MHZ)
specialsetting	bootmode	sdboot (default is nor boot)
	special support	lpuart:used for lpuart sben:Secure boot support usb2:USB 2.0 support

For example,

```
rcw_1200_sd.rcw means rcw for core frequency of 1200MHz with sd boot.
rcw_1200_lpuart.rcw means rcw for core frequency of 1200MHz with nor boot special for enable lpuart.
```

Default rcw:

- SSR_PNS_30/rcw_1200_lpuart.bin[1 SGMII, 1 RGMII, 2D-ACE, lpuart1, 2PCIE, SATA, CAN, SAI]
- RSR_PPS_70/rcw_1200.bin[2 SGMII, 1 RGMII, 1SATA, 1PCIE, CAN]

4.4.4.5 System Memory Map

In 32-bit u-boot, there is a 1:1 mapping of physical address and effective address. After system startup, the boot loader maps physical address and effective address as shown in the following table:

Start Physical Address	End Physical Address	Memory Type	Size
0x0100_0000	0x0FFF_FFFF	CCSR	240MB
0x1000_0000	0x1000_FFFF	OCRAM0	64KB
0x1001_0000	0x1001_FFFF	OCRAM1	64 KB
0x2000_0000	0x20FF_FFFF	DCSR	16MB
0x4000_0000	0x5FFF_FFFF	QSPI	512MB
0x6000_0000	0x67FF_FFFF	NOR Flash	128MB
0x7FB0_0000	0x7FB0_0FFF	Board CPLD	4KB
0x8000_0000	0xFFFF_FFFF	DDR	2GB

4.4.4.6 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for LS1021ATWR, SW3[5]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU:   Freescale LayerScape LS1021E, Version: 2.0, (0x87081120)
Clock Configuration:
       CPU0(ARMV7):1200 MHz,
       Bus:300  MHz, DDR:800  MHz (1600 MT/s data rate),
```

```
Reset Configuration Word (RCW):
       00000000: 0608000c 00000000 00000000 00000000
       00000010: 70000000 00007900 e0025a00 21046000
       00000020: 00000000 00000000 00000000 20000000
       00000030: 00080000 881b7340 00000000 00000000
Board: LS1021ATWR
CPLD:  V2.0
PCBA:  V1.0
VBank: 0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>reset
```

- Switch to alternate bank:

```
=>boot_bank 1
```

The table below shows a memory map for LS1021A TWR:

Table 37. NOR Flash Memory Map

Start	End Offset	Description	Size
0x60000000	0x6001ffff	bank0 rcw image	128 K
0x600c0000	0x600dffff	bank0 qe	128 K
0x600e0000	0x600fffff	bank0 u-boot env	128 K
0x60100000	0x601fffff	bank0 u-boot Image	1 M
0x60200000	0x602fffff	bank0 DTB	1 M
0x60300000	0x609fffff	bank0 Linux Kernel Image	7 M
0x60a00000	0x63ffffff	bank0 Ramdisk Root File System	54 M
0x64000000	0x6401ffff	bank1 rcw image	128 K
0x640c0000	0x640dffff	bank1 qe	128 K
0x640e0000	0x640fffff	bank1 u-boot env	128 K
0x64100000	0x641fffff	bank1 u-boot Image	1 M
0x64200000	0x642fffff	bank1 DTB	1 M
0x64300000	0x649fffff	bank1 Linux Kernel Image	7 M
0x64a00000	0x67ffffff	bank1 Ramdisk Root File System	54 M

4.4.4.7 Programming a New U-Boot and RCW

The following three sections will discuss how to individually update U-Boot, RCW. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash both two at once, there is no need to switch into the

alternate bank after each configuration, i.e. type the command "boot_bank 1" after U-Boot and RCW have both been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 82000000 <u-boot_file_name>.bin
=>protect off 64100000 +$filesize
=>erase 64100000 +$filesize
=>cp.b 82000000 64100000 $filesize
=>protect on 64100000 +$filesize
=>boot_bank 1
```

The commands above will only program a new U-Boot. Programming a new RCW will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address 0x64000000. 0x64000000 is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 82000000 <rcw_file_name>.bin
=>protect off 64000000 +$filesize
=>erase 64000000 +$filesize
=>cp.b 82000000 64000000 $filesize
=>protect on 64000000 +$filesize
=>boot_bank 1
```

Programming U-boot to SD card

To program U-boot, first boot the board to u-boot. Next, load the new u-boot SD boot image(u-boot-with-spl-pbl.bin) to RAM by downloading it via TFTP and then copying it to SD card with blk offset 0x8. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 81000000 u-boot-with-spl-pbl.bin
=>mmc erase 8 0x800
=>mmc write 0x81000000 8 0x800
```

Program the image to SD card in Linux.

```
dd if=u-boot-with-spl-pbl-sd.bin of=/dev/sdb bs=512 seek=8
```

Programming U-boot and RCW to QSPI

To program a new RCW and u-boot, first switch to QSPI boot mode by performing a hard reset or by typing *reset*. Next, load the new RCW and U-Boot image for QSPI boot to RAM by downloading it via TFTP and then copying it to flash. Execute the following commands at the U-Boot prompt to program the RCW and U-Boot to flash.

```
=> sf probe 0:0
=> tftp 81000000 rcw_qspiboot_1000_swap.bin
=> sf erase 0 0x90000
=> sf write 81000000 0 0x100
=> tftp 82000000 u-boot-qspiboot-swap.bin
=> sf write 82000000 0x10000 0x80000
```

If the original QSPI boot image on board is broken, you can recover it by SD boot image in the BSP release ISO, which supports QSPI.

1. Bring up the board by SD boot mode, you should use the SD boot image in the BSP release ISO;
2. Execute the above commands at the U-Boot prompt to program the RCW and U-Boot to QSPI flash;
3. Switch to QSPI boot mode, then bring up the board.

4.4.4.8 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the NOR Flash Memory Map within Flash Bank Usage as reference for the specific addresses.

4.4.4.8.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters on page 137 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw ramdisk_size=40000000 console=ttyS0,115200'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 83000000 < uImage_name>
   =>tftp 88000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 8f000000 <platform_dtb_name>
   =>bootm 83000000 88000000 8f000000
   ```

   Now the board will boot into Linux using the images generated by Yocto.

4.4.4.8.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_start_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

   ```
   =>tftp 82000000 <uImage name>
   =>protect off <kernel_start_addr> +$filesize
   =>erase <kernel_start_addr> +$filesize
   =>cp.b 82000000 <kernel_start_addr> $filesize
   =>protect on <kernel_start_addr> +$filesize
   ```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

   ```
   =>tftp 88000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>protect off <ramdisk_start_addr> +$filesize
   =>erase <ramdisk_start_addr> +$filesize
   =>cp.b 88000000 <ramdisk_start_addr> $filesize
   =>protect on <ramdisk_start_addr> +$filesize
   ```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

   ```
   =>tftp 8f000000 <platform dtb name>
   =>protect off <dtb_start_addr> +$filesize
   =>erase <dtb_start_addr> +$filesize
   =>cp.b 8f000000 <dtb_start_addr> $filesize
   =>protect on <dtb_start_addr> +$filesize
   ```

5. **Booting Up the System**

   The U-Boot environment variables `fdt_high` and `initrd_high` need to be set to `0xa0000000`.

   ```
   fdt_high=0xa0000000
   initrd_high=0xa0000000
   ```

The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.4.8.3 NFS Deployment

1. **Generating File System with Yocto**

   Use Yocto to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   nfs_root_path board_ipaddress(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 137 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 83000000 <uImage name>
   =>tftp 8f000000 <platform dtb name>
   =>bootm 83000000 - 8f000000
   ```

   Now the board will boot up with NFS filesystem.

4.4.4.8.4 SD Deployment

The ext2 file system generated by Yocto could be stored in a SD card.

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

   ```
   #fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to create the filesystems.

   ```
   # mkfs.vfat /dev/sdb1
   # mkfs.ext2 /dev/sdb2
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdb2 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

   ```
   # cp uImage and uImage.dtb to /temp/boot folder
   # umount /temp
   ```

8. Plug in the SD card to the target board and power on.

4.4.4.8.5 QSPI Deployment

Prepare SD boot to program QSPI flash

1. Build U-Boot image for SD boot(enables QSPI):

```
$make distclean ARCH=aarch64 CROSS_COMPILE=${toolchain_path}/gcc-linaro-arm-linux-
gnueabihf-4.8-2014.04_linux/bin/arm-linux-gnueabihf-
$make ARCH=arm ${board_name}_sdcard_qspi_defconfig
$make CROSS_COMPILE=${toolchain_path}/gcc-linaro-arm-linux-gnueabihf-4.8-2014.04_linux/bin/arm-
linux-gnueabihf- -j4
```

2. Write the U-Boot image to SD card:

```
=>tftp 0x81000000 u-boot-with-spl-pbl.bin
=>mmc write 0x81000000 8 0x800
```

3. Switch to SD boot(enables QSPI):set switches referring to board configuration document and power on the board from SD boot.

Build U-Boot image for QSPI boot

1. Compile QSPI boot image(enable QSPI):

```
$make distclean ARCH=arm CROSS_COMPILE=${toolchain_path}/gcc-linaro-arm-linux-
gnueabihf-4.8-2014.04_linux/bin/arm-linux-gnueabihf-
$make ARCH=arm  ${board_name}_qspi_defconfig
$make CROSS_COMPILE=${toolchain_path}/gcc-linaro-arm-linux-gnueabihf-4.8-2014.04_linux/bin/arm-
linux-gnueabihf- -j4
```

2. Swap the bytes for RCW:

```
$tclsh byte_swap.tcl rcw_1200_qspiboot.bin rcw_1200_qspiboot_swap.bin 8
```

   The byte_swap.tcl script is a shareable tool and can be found under `rcw/tool/` directory.

3. Write RCW and U-Boot images to QSPI flash under SD boot (enables QSPI) mode:

```
=>sf probe 0:0
```

   SF: Detected N25Q128 with page size 256 Bytes, erase size 64 KiB, total 16 MiB

```
=>tftp 81000000 rcw_1200_qspiboot_swap.bin;sf erase 0 +$filesize;sf write 81000000 0 $filesize
=>tftp 82000000 u-boot-dtb.bin;sf erase 10000 +$filesize;sf write 82000000 10000 $filesize
```

4. Switch to QSPI boot: Set switches referring to board configuration document and power on the board from QSPI boot.

4.4.4.9 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
0 - AR8031/AR8033 <--> eTSEC2
1 - AR8031/AR8033 <--> eTSEC3
2 - AR8031/AR8033 <--> eTSEC1
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 3 eTSEC interfaces and on the 10GEC interface. If you see “Generic” reported, it is an indication that something is there but the LS1021ATWR can’t communicate with the device/port.

Check Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read eTSEC1 1
Reading from bus FSL_MDIO0
PHY at address 2:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

4.4.4.10 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 brd + dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

4.4.4.11 Hardware Setting for Special Purposes

The TWR has user selectable switches for evaluating different pin mux and boot options for the LS1021A device. Information below lists the hardware setting for those special purposes.

General UART port setting for TWR board:

1. J19 and J20 short 2-3.
2. Power on the board first and then connect J5 with USB serial port to host.
3. Wait for auto-install the USB serial port driver on the host.
4. Decompress "Serial_driver.tar".
5. Install "2_mbedWinSerial_16466.exe"(for windows host).

LPUART console setting.

1. J19 and J20 short 1-2.
2. Use rcw: rcw_1200_lpuart.bin.
3. Follow the general UART port setting steps above to install the drivers.

NOR boot setting

1. X2 board: Set SW2[1:8]+SW3[1]=0b'0001_0010_1,X3 board: SW2[1:8]=0b’1000_1111;
2. Bank0: SW3[5]=0b'0; Bank1: SW3[5]=0b'1

SD boot setting

1. image:u-boot-with-spl-pbl.bin
2. Program the image to SD card in u-boot.

```
=>tftp 82000000 u-boot-with-spl-pbl.bin
=>mmc write 82000000 8 800
```

3. Program the image to SD card in Linux.

```
dd if=u-boot-with-spl-pbl-sd.bin of=/dev/sdb bs=512 seek=8
```

4. Insert SD card in adaptor;
5. X2 board: Set SW2[1:8]+SW3[1]=0b'0010_0000_0,X3 board: Set SW2[1:8]=0b’0010’1111.

QSPI boot setting

1. X2 board don't support QSPI boot.
2. X3 board: Set SW2[1:8]=0b’0001’0111.

GPIO test setting

1. GPIO pins 4 to 9 of GPIO controller 2 are tested on board : GPIO2[4:9]
2. Use rcw: rcw_1200_misc.bin
3. eTSEC1 will be disabled under GPIO testing.

2D-ACE test setting

1. Select LPUART0 as the console;
2. Use rcw: rcw_1200_lpuart.bin;

USB 2.0 test setting

1. Select LS1021ATWR X3 board and TWR-SER2;
2. Plug USB device on USB OTG poart;
3. Use rcw: rcw_1000_usb2.bin;
4. Set SW2[6]=0b’0;
5. Set in u-boot: hwconfig=usb1:dr_mode=host,phy_type=ulpi;usb2;

SATA test setting

1. Plug SATA disk on J4 SATA port
2. Use rcw: RSR_PPS_70/rcw_1200.bin;

Secure boot execution setting

1. Short J11.

NOTE

For more information about specific settings for the console (i.e. baud rate, ports used etc.), please refer to the LS1021ATWR Quick Start Guide.

4.4.5 LS1012ARDB

4.4.5.1 Overview

The LS1012A reference design board (RDB) is the high-performance computing, evaluation, and development platform that supports the QorIQ LS1012A processor. This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.5.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options i.e. QSPI Flash 1 for the LS1012A device. Table below lists the default switch settings and the description of these settings.

Table 38. Switch configuration

	1	2	3	4	5	6	7	8
SW1	1	0	1	0	0	1	1	0
SW2	0	0	0	0	0	0	0	0

Below are additional switch settings for alternate boot option i.e QSPI Flash2.

Table 39. Switch configuration

	1	2	3	4	5	6	7	8
SW1	1	0	1	0	0	1	1	0
SW2	0	0	0	0	0	0	1	0

4.4.5.3 U-Boot Environment Variables

The following sections will guide the users on how to set the U-Boot environment and configure the U-Boot network parameters.

4.4.5.3.1 U-Boot Environment Variable "hwconfig"

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set in the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified in the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.The default setting for for "hwconfig" on LS1012ARDB is as follows:

```
hwconfig = fsl_ddr:bank_intlv=auto
```

4.4.5.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD

=>saveenv
```

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

Possible <ethx> value

- pfe_eth0
- pfe_eth1

4.4.5.4 RCW (Reset Configuration Word) and Ethernet Interfaces

The following RCW binary is used on the LS1012ARDB board

`RR_SPNH_3508/PBL_0x35_0x08_800_250_1000_default.bin`

This RCW enables

- Boot from QSPI
- 800MHz Core, 250MHz Platfrom, 1000MT/s DDR
- SDHC1, SDHC2, I2C1,
- SerDes Protocol 0x3508
- PCIe, SATA,
- RGMII, SGMII
- USB 3.0

4.4.5.5 System Memory Map

In 64-bit u-boot, there is a 1:1 mapping of physical address and effective address. After system startup, the boot loader maps physical address and effective address as shown in the following table:

Start Physical Address	End Physical Address	Memory Type	Size
0x00_0000_0000	0x00_00FF_FFFF	Secure Boot ROM	1MB
0x00_0100_0000	0x00_0FFF_FFFF	CCSR	240MB
0x00_1000_0000	0x00_1000_FFFF	OCRAM1	64KB
0x00_1001_0000	0x00_1001_FFFF	OCRAM2	64 KB
0x00_4000_0000	0x00_5FFF_FFFF	QSPI	512MB
0x00_8000_0000	0x00_FFFF_FFFF	DRAM	2GB
0x08_8000_0000	0x0F_FFFF_FFFF	DRAM2	30G
0x40_0000_0000	0x47_FFFF_FFFF	PCI Express1	32G

4.4.5.6 Flash Bank Usage

LS1012ARDB has 2 QSPI flash connected over QSPI contoller.

Only one QSPI flash is available at a time depending upon the board switch settings. These switch settings can also be overriden by I2C commands.

To protect the default U-Boot in flash1 (aka bank1), it is a convention employed by NXP to deploy work images into the flash2 (aka bank2), and then switch to the flash2 (aka bank2) for testing. Switching to the flash2 (aka bank2) can be done in software using I2C commands and effectively swaps the flash1 (aka bank1) with the flash2 (aka bank2). This protects flash1 and keeps the board bootable under all circumstances.

```
U-Boot 2016.01-g5ab5bba (Jun 14 2016 - 12:56:17 +0530)

SoC:  LS1012AE (0x87040010)

How to boot from flash 2 (aka bank2)

1. To check which bank booted, refer to "**Board: LS1012ARDB Version: RevB, boot from QSPI: bank1"** in the U-Boot logs.
2. I2C commands to flash2 bank2 switch **" i2c mw 0x24 0x7 0xfc; i2c mw 0x24 0x3 0xf5 "**
3. Program QSPI flash as per flash layout
4. To boot from bank2 give "**reset"** command.
5. To move back to bank 1 from bank 2, power on/off the board or use **"i2c mw 0x24 0x3 0xf4 "** and then give "**reset**" command.

QSPI flash Layout

Image	Size	Start Address
RCW + PBI	1MB	0x4000_0000
U-boot boot loader + PFE binary	1MB	0x4010_0000
U-boot Env	1MB	0x4020_0000
PPA FIT image	2MB	0x4050_0000
Kernel ITB	59MB	0x40A0_0000

4.4.5.7 Programming a New U-Boot, RCW, and PPA Firmware

The following sections will discuss how to individually update U-Boot and RCW. For specific addresses, please refer to the QSPI Flash Memory Map as a reference.

Please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot. By default, an existing U-Boot is run in flash1 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate flash/bank, first switch to flash 1 (bank 0) by performing a hard reset or by typing `reset`. Then use the following commands to change flash2/bank1 and program a new U-Boot and then switch to that flash2 or alternate bank where the new U-Boot is flashed:

```
=>i2c mw 0x24 0x7 0xfc; i2c mw 0x24 0x3 0xf5
=>tftp 0x80000000 <u-boot_file_name>.bin
=>sf probe 0:0
=>sf erase 0x100000 +$filesize
=>sf write 0x80000000 0x100000 $filesize
=> reset
```

Programming a New RCW: To program a new RCW, first switch to flash1 (bank 0) by performing a hard reset or by typing `reset`. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash2 at offset 0x000000. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>i2c mw 0x24 0x7 0xfc; i2c mw 0x24 0x3 0xf5
=>tftp 0x80000000 <rcw_file_name>.bin
=>sf probe 0:0
=>sf erase 0x0 +$filesize
=>sf write 0x80000000 0x0 $filesize
=> reset
```

NOTE

RCW and U-Boot binary must be byte swapped using command (tclsh ./byte_swap.tcl u-boot-dtb.bin u-boot-dtb_swap.bin 8)

Programming a New Primary Protected Application (PPA) Firmware: To program a new PPA firmware, first switch to bank 0 by performing a hard reset or by typing *reset*. Next, load the new PPA firmware to RAM by downloading it via TFTP and then copying it to flash at address `0x500000`. `0x500000` is the location of PPA firmware in the alternate bank. Then execute the following commands at the U-Boot prompt to program the PPA firmware to flash and reset to alternate bank.

```
=> tftp 0x80000000 <ppa_file_name>.itb
=> sf probe 0:0
=> sf erase 0x500000 +$filesize
=> sf write 0x80000000 0x500000 $filesize
=> reset
```

NOTE

All the files which are to be flashed need to be byte-swapped.

4.4.5.8 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.5.8.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'ttyS0,115200 root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500'
=>saveenv
```

NOTE

ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 0xa0000000 <kernel_itb_name>
=>bootm 0xa0000000
```

   Now the board will boot into Linux using the images generated by Yocto.

4.4.5.8.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv bootcmd 'run ramargs; pfe stop; sf probe 0:0; sf read 0x96000000 0xa00000 0x2800000;
bootm 0x96000000
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to QSPI Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 0x96000000 <kernel ITB>
=>sf probe 0:0;
=>sf erase <kernel_itb_addr> +$filesize
=>sf write 0x96000000 <kernel_itb_addr> $filesize
```

3. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> run ramargs; pfe stop; sf probe 0:0; sf read 0x96000000 0xa00000 0x2800000; bootm 0x96000000
```

4.4.5.8.3 NFS Deployment

1. **Generating File System with Yocto**

   Use Yocto to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 164 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

NOTE

<ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 96000000  kernel.itb;
   =>bootm 96000000:kernel@1 - 96000000:fdt@1
   ```

   Now the board will boot up with NFS filesystem.

4.4.5.8.4 SD Deployment

Partition SD Card

1. Insert SD card into the Linux Host PC.
2. Use the "fdisk" command to repartition the SD card.

   ```
   # fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to creat the filesystem.

   ```
   #mkfs.ext2 /dev/sdb1
   ```

NOTE

When connecting the SD card on Linux host, look for the log messages on the Linux console and accordingly, only format that device (which represents SD card).

1. Insert SD card into the Linux Host PC.
2. Create temp director in host PC and mount the ext2 partition to the temp

```
#mkdir temp
#mount /dev/sdb1 temp
```

3. Copy the FIT Kernel Image to the SD card partition.

```
#cp  kernel.itb temp/
```

4. Copy the Root File System to the SD card partition.

```
#cp fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/
#tar xvfz fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz
#rm  fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/
```

5. Umount the temp director

```
#umount temp
```

Setting U-Boot Environment

- Execute the following commands at the U-Boot prompt

```
=> setenv bootcmd "ext2load mmc 0 a0000000 kernel.itb && bootm a0000000"
```

- Using the Ramdisk as the Root File Systemp

```
=> setenv bootargs  "root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500
console=ttyS0,115200"
```

- Using the Ext2 Partition of SD card as the Root File Systemp

```
=> setenv bootargs  "root=/dev/mmcblk0p1 rw earlycon=uart8250,0x21c0500
console=ttyS0,115200"
```

- Saving the environment

```
=>saveenv
```

Note: The `kernel.itb` is the name of your FIT Image, you can use the `ext2ls` command to list it at the U-Boot prompt

4.4.5.9 Check 'Link Up' for Serial Ethernet Interfaces

This section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors when experiencing problems with Ethernet interfaces.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command `mdio list`. The U-Boot command mdio list will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
PFE_MDIO:
1 - RealTek RTL8211F <--> pfe_eth1
2 - RealTek RTL8211F <--> pfe_eth0
```

The results from the `mdio list` command above show that U-Boot was able to see PHYs on each of the RGMII/SGMII interfaces.

Check Link Status for External PHY

In order to check the status of a RGMII/SGMII link, use the mdio read command. Since this is a Clause 22 device, we pass two arguments to the `mdio read` command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read pfe_eth0 1
Reading from bus PFE_MDIO
PHY at address 2:
1 - 0x79ad
=> mdio read pfe_eth1 1
Reading from bus PFE_MDIO
PHY at address 1:
1 - 0x79ad
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the example above, the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7989.

4.4.5.10 Basic Networking Ping Test

U-BOOT

The LS1012ARDB has one SGMII and one RGMII. The log below shows how to ping from those 2 interfaces.

```
U-Boot 2016.01-gc423721 (Jun 27 2016 - 13:06:22 +0530)

NOTE

Yocto users do not need to install the pfe.ko module. However, developers who are building the kernel need to install the pfe.ko module. Once the pfe.ko module is installed, the pfe interfaces will function like normal ethernet interfaces e.g. eth0, eth1.

4.4.6 FRDM-LS1012A

4.4.6.1 Switch Settings

No On-Board Switch setting available

4.4.6.2 U-Boot Environment Variables

The following sections will guide the users on how to set the U-Boot environment and configure the U-Boot network parameters.

4.4.6.2.1 U-Boot Environment Variable "hwconfig"

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set in the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified in the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.The default setting for for "hwconfig" on LS1012ARDB is as follows:

```
hwconfig = fsl_ddr:bank_intlv=auto
```

4.4.6.2.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD

=>saveenv
```

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

Possible <ethx> value

- pfe_eth0
- pfe_eth1

4.4.6.3 RCW (Reset Configuration Word) and Ethernet Interfaces

The following RCW binary is used on the FRDM-LS1012A board:

```
S_SPNN_3305/PBL_0x33_0x05_800_250_1000_default.bin
```

This RCW enables:

- Boot from QSPI
- 800MHz Core, 250MHz Platfrom, 1000MT/s DDR
- I2C1,
- SerDes Protocol 0x3505

- SGMII, SGMII
- USB 3.0

4.4.6.4 System Memory Map

In 64-bit u-boot, there is a 1:1 mapping of physical address and effective address. After system startup, the boot loader maps physical address and effective address as shown in the following table:

Start Physical Address	End Physical Address	Memory Type	Size
0x00_0000_0000	0x00_00FF_FFFF	Secure Boot ROM	1MB
0x00_0100_0000	0x00_0FFF_FFFF	CCSR	240MB
0x00_1000_0000	0x00_1000_FFFF	OCRAM1	64KB
0x00_1001_0000	0x00_1001_FFFF	OCRAM2	64 KB
0x00_4000_0000	0x00_5FFF_FFFF	QSPI	512MB
0x00_8000_0000	0x00_FFFF_FFFF	DRAM	2GB
0x08_8000_0000	0x0F_FFFF_FFFF	DRAM2	30G
0x40_0000_0000	0x47_FFFF_FFFF	PCI Express1	32G

4.4.6.5 Flash Bank Usage

The FRDM-LS1012A only has one QSPI flash connected over QSPI contoller.

```

QSPI flash Layout

Image	Size	Start Address
RCW + PBI	1MB	0x4000_0000
U-boot boot loader + PPFE binary	1MB	0x4010_0000
U-boot Env	1MB	0x4020_0000
PPA FIT image	2MB	0x4050_0000
Kernel ITB	59MB	0x40A0_0000

4.4.6.6 Programming a New U-Boot and RCW

The following sections will discuss how to individually update U-Boot and RCW. For specific addresses, please refer to the QSPI Flash Memory Map as a reference.

Please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot. Use the commands below to update images:

```
=>tftp 0x80000000 <u-boot_file_name>.bin
=>sf probe 0:0
=>sf erase 0x100000 0xa0000
=>sf write 0x80000000 0x100000 $filesize
=> reset
```

The commands above will only program a new U-Boot. Programming a new RCW will be discussed in the next section.

Programming a New RCW: Use the commands below to update images:

```
=>tftp 0x80000000 <rcw_file_name>.bin
=>sf probe 0:0
=>sf erase 0x0 40000
=>sf write 0x80000000 0x0 $filesize
=> reset
```

Note: RCW and U-Boot binaries must be byte swapped using command (tclsh ./byte_swap.tcl u-boot-dtb.bin u-boot-dtb_swap.bin 8). The ./byte_swap.tcl script is included as a part od the RCW source code.

4.4.6.7 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.6.7.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'ttyS0,115200 root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 0x96000000 <kernel_itb_name>
   =>bootm 0x96000000
   ```

   NOTE

   The DDR load address for LS1012ARDB is different from FRDM-LS1012A. Using the wrong address could crash Linux.

   Now the board will boot into Linux using the images generated by Yocto.

4.4.6.7.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv bootcmd 'run ramargs; pfe stop; sf probe 0:0; sf read 0x96000000 0xa00000 0x2800000;
   bootm 0x96000000
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to QSPI Flash**

The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 0x96000000 <kernel ITB>
=>sf probe 0:0;
=>sf erase <kernel_itb_addr> +$filesize
=>sf write 0x96000000 <kernel_itb_addr> $filesize
```

3. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

   or

   ```
   => run ramargs; pfe stop; sf probe 0:0; sf read 0x96000000 0xa00000 0x2800000; bootm 0x96000000
   ```

4.4.6.7.3 NFS Deployment

1. **Generating File System with Yocto**

   Use Yocto to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 164 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 96000000  kernel.itb;
=>bootm 96000000:kernel@1 - 96000000:fdt@1
```

   Now the board will boot up with NFS filesystem.

4.4.6.8 Check 'Link Up' for Serial Ethernet Interfaces

This section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors when experiencing problems with Ethernet interfaces.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command `mdio list`. The U-Boot command `mdio list` will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
PFE_MDIO:
1 - RealTek RTL8211F <--> pfe_eth1
2 - RealTek RTL8211F <--> pfe_eth0
```

The results from the `mdio list` command above show that U-Boot was able to see PHYs on each of the SGMII interfaces.

Check Link Status for External PHY

In order to check the status of a SGMII link, use the `mdio read` command. Since this is a Clause 22 device, we pass two arguments to the `mdio read` command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read pfe_eth0 1
Reading from bus PFE_MDIO
PHY at address 2:
1 - 0x79ad
=> mdio read pfe_eth1 1
Reading from bus PFE_MDIO
PHY at address 1:
1 - 0x79ad
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7989.

4.4.6.9 Basic Networking Ping Test

U-BOOT

The LS1012FRDM has 2 SGMII interfaces. The log below shows how to ping from those 2 interfaces.

```
U-Boot 2016.01-g1c18d6a (Jun 17 2016 - 15:15:39 +0530)

```

NOTE

Yocto users do not need to install the pfe.ko module. However, developers who are building the kernel need to install the pfe.ko module. Once the pfe.ko module is installed, the pfe interfaces will function like normal ethernet interfaces e.g. eth0, eth1.

4.4.7 LS1043ARDB

4.4.7.1 Overview

The LS1043A reference design board (RDB) is the high-performance computing, evaluation, and development platform that supports the QorIQ LS1043A processor.

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.7.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options and different configurations for the LS1043A device. Table 40. Default Switch Settings on page 174 lists the default switch settings. See the QorIQ LS1043A Reference Design Board Reference Manual for a description of the switch settings.

Table 40. Default Switch Settings

	1	2	3	4	5	6	7	8
SW3	ON [1]	OFF [0]	ON [1]	ON [1]	OFF [0]	OFF [0]	ON [1]	ON [1]
SW4	OFF	OFF	OFF	ON	OFF	OFF	ON	OFF
SW5	ON	OFF	ON	OFF	OFF	OFF	OFF	OFF

The default switch settings select NOR Flash as the boot device. Table 41. LS1043ARDB Switch Settings on page 174 lists additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 41. LS1043ARDB Switch Settings

Boot Source	Switch
NOR (bank0)	SW4[1-8] +SW5[1] = 0b'00010010_1 SW5[4-6]= 0b'000
NOR (bank4)	SW4[1-8] +SW5[1] = 0b'00010010_1 SW5[4-6]= 0b'001
NAND	SW4[1-8] +SW5[1] = 0b'10000011_0
SD	SW4[1-8] +SW5[1] = 0b'00100000_0

4.4.7.3 U-Boot Environment Variables

4.4.7.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set in the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified in the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for for "hwconfig" on LS1043ARDB is as follows:

```
hwconfig = fsl_ddr:bank_intlv=auto
```

4.4.7.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

* <ethx> is the Ethernet port on the board connected to the Linux boot server. "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to approriate MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9f:ef:00:00
=>setenv eth1addr 00:04:9f:ef:01:01
=>setenv eth2addr 00:04:9f:ef:02:02
=>setenv eth3addr 00:04:9f:ef:03:03
=>saveenv
```

NOTE

1. For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).
2. In the overwhelming majority of cases, eth<*>addr can be autoset.

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.7.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for LS1043A version information and also for the version of FMan microcode currently flashed on the LS1043A (e.g., microcode version 106.4.18). For QorIQ SDK 2.0, the following FMan microcode binaries should be used:

```
fsl_fman_ucode_ls1043_r1.1_106_4_18.bin (*)
fsl_fman_ucode_ls1043_r1.1_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a New U-boot, RCW, FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.7.5 RCW (Reset Configuration Word)

The RCW directories' names conform to the following naming convention:

```
ab_cdef_g
```

Table 42. RCW directories Naming Convention Legend

Slot	Convention
a	'R' indicates RGMII1@DTSEC3 is supported 'N' if not available/not used
b	'R' indicates RGMII2@DTSEC4 is supported 'N' if not available/not used
c	What is available in lane A
d	What is available in lane B
e	What is available in lane C
f	What is available in lane D
g	Hex value of serdes1 protocol value

Table 43. For Lanes (C through F)

Flag	Convention
'N'	NULL, not available/not used
'P'	PCIe
'X'	XAUI
'S'	SGMII
'Q'	QSGMII
'F'	XFI

Table continues on the next page...

Table 43. For Lanes (C through F) (continued)

'H'	SATA
'A'	AURORA

For example,

```
RR_FQPP_1455
```

means:

- RGMII1@DTSEC3 on board
- RGMII2@DTSEC4 on board
- XFI
- QSGMII
- PCIe2 on Mini-PCIe slot
- PCIe3 on PCIe Slot
- SERDES1 Protocol is 0x1455

The RCW file names for the ls1043ardb conform to the following naming convention:

```
rcw_<frequency>_<specialsetting>.rcw
```

Table 44. RCW Files Naming Convention Legend

Code		**Convention**
frequency		Core frequency(MHZ)
specialsetting	bootmode	SD/NAND/NOR and so on
	special support	nand: Nand boot sben: Secure boot lpuart: lpuart1 qspiboot: qspi boot

For example,

```
rcw_1500_sd.rcw means rcw for core frequency of 1500MHz with sd boot.
```

```
ls1043ardb/RR_FQPP_1455/rcw_1500.rcw means rcw for core frequency 0f 1500MHz with NOR boot.
```

The following RCW binaries are used on the ls1043ardb

```
RR_FQPP_1455/rcw_1500.bin
```

```
RR_FQPP_1455/rcw_1500_qetdm.bin
```

```
RR_FQPP_1455/rcw_1500_sben.bin
```

```
RR_FQPP_1455/rcw_1600.bin
```

```
RR_FQPP_1455/rcw_1600_qetdm.bin
```

```
RR_FQPP_1455/rcw_1600_sben.bin
```

4.4.7.6 System Memory Map

In 64-bit u-boot, there is a 1:1 mapping of physical address and effective address. After system startup, the boot loader maps physical address and effective address as shown in the following table:

Start Physical Address	End Physical Address	Memory Type	Size
0x00_0000_0000	0x00_00FF_FFFF	Secure Boot ROM	1MB
0x00_0100_0000	0x00_0FFF_FFFF	CCSR	240MB
0x00_1000_0000	0x00_1000_FFFF	OCRAM0	64KB
0x00_1001_0000	0x00_1001_FFFF	OCRAM1	64 KB
0x00_2000_0000	0x00_23FF_FFFF	DCSR	64MB
0x00_4000_0000	0x00_5FFF_FFFF	QSPI	512MB
0x00_6000_0000	0x00_7FFF_FFFF	IFC region	512MB
0x00_8000_0000	0x00_FFFF_FFFF	DRAM	2GB
0x05_0000_0000	0x05_07FF_FFFF	QMAN S/W Portal	128M
0x05_0800_0000	0x05_0FFF_FFFF	BMAN S/W Portal	128M
0x40_0000_0000	0x47_FFFF_FFFF	PCI Express1	32G

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Memory Type	Size
0x48_0000_0000	0x4F_FFFF_FFFF	PCI Express2	32G
0x50_0000_0000	0x57_FFFF_FFFF	PCI Express1	32G

4.4.7.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
U-Boot 2016.012.0+g2ea81ad

Clock Configuration:
       CPU0(A53):1600 MHz  CPU1(A53):1600 MHz  CPU2(A53):1600 MHz
       CPU3(A53):1600 MHz
       Bus:      400  MHz  DDR:      1600 MT/s  FMAN:     500  MHz
Reset Configuration Word (RCW):

=>
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0 for RDB:

```
=>cpld reset
```

- Switch to alternate bank for RDB:

```
=>cpld reset altbank
```

The table below shows the memory map for LS1043A:

Table 45. NOR Flash Memory Map for LS1043ARDB

Start	End Offset	Description	Size
0x60000000	0x600FFFFF	bank0 rcw + pbi	1M
0x60100000	0x601FFFFF	bank0 U-Boot image	1 M
0x60200000	0x602FFFFF	bank0 U-Boot Env	1 M
0x60300000	0x603FFFFF	bank0 Fman ucode	1 M

4.4.7.8 Programming a New U-Boot, RCW, FMan Microcode, PPA firmware

The following three sections will discuss how to individually update U-Boot, RCW, FMan Microcode, and PPA firmware. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to update mutliple images, there is no need to switch into the alternate bank after each configuration, i.e. there is no need to type the command "cpld reset altbank" after flashing each individual image.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 82000000 <u-boot_file_name>.bin
=>protect off 64100000 +$filesize
=>erase 64100000 +$filesize
=>cp.b 82000000 64100000 $filesize
=>protect on 64100000 +$filesize
=>cpld reset altbank
```

The commands above will only program a new U-Boot.

Programming U-Boot to SD card

For instructions on how to program U-Boot to SD card refer to SD Deployment on page 184.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address 0x64000000. 0x64000000 is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 82000000 <rcw_file_name>.bin
=>protect off 64000000 +$filesize
=>erase 64000000 +$filesize
```

```
=>cp.b 82000000 64000000 $filesize
=>protect on 64000000 +$filesize
=>cpld reset altbank
```

Programming a New FMan Microcode

Program a new microcode to NOR flash:

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address 0x64300000. 0x64300000 is the location of microcode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the microcode to flash and reset to alternate bank.

```
=>tftp 83000000 <ucode_file_name>.bin
=>protect off 64300000 +$filesize
=>erase 64300000 +$filesize
=>cp.b 83000000 64300000 $filesize
=>protect on 64300000 +$filesize
=>cpld reset altbank
```

Program a new microcode to NAND flash:

```
=>tftp 83000000 <ucode_file_name>.bin
=>nand erase 160000 +$filesize;nand write 83000000 160000 $filesize
=>cpld reset nand
```

Program a new microcode to SD Card:

```
=>tftp 83000000 <ucode_file_name>.bin
=>mmc write 83000000 820 50
=>cpld reset sd
```

Programming a New Primary Protected Application (PPA) firmware

Program a new PPA firmware to NOR flash:

To program a new PPA firmware, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new PPA firmware to RAM by downloading it via TFTP and then copying it to flash at address 0x64500000. 0x64500000 is the location of PPA firmware in the alternate bank. Then execute the following commands at the U-Boot prompt to program the PPA firmware to flash and reset to alternate bank.

```
=>tftp 83000000 <ppa_file_name>.itb
=>protect off 64500000 +$filesize
=>erase 64500000 +$filesize
=>cp.b 83000000 64500000 $filesize
=>protect on 64500000 +$filesize
=>cpld reset altbank
```

4.4.7.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the NOR Flash Memory Map within Flash Bank Usage as reference for the specific addresses.

4.4.7.9.1 FIT Image Deployment from TFTP

1. **Setting U-Boot Environment**

   Before performing FIT image deployment, the U-Boot environment variables need to be configured.

Refer to Configuring U-Boot Network Parameters on page 175 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for FIT image deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200'
=>saveenv
```

2. **Booting Up the System**

   Execute the following commands to TFTP the image to the board, then boot into Linux.

```
=>tftp a0000000 < FIT_image_name>
=>bootm a0000000
```

   Now the board will boot into Linux .

4.4.7.9.2 FIT Image Deployment from Flash

1. **Setting U-Boot Environment**

   Before performing FIT image from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for deployment from flash:

```
=>setenv  bootargs root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200
=>setenv bootcmd   bootm <FIT_image_addr>
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming FIT image to NOR Flash**

   The image should be downloaded to the RAM using TFTP then copied to the flash address <FIT_image_addr>. At the U-Boot prompt, use the following commands to program the image to flash:

```
=>tftp 82000000 <FIT Image name>
=>protect off <FIT_image_addr> +$filesize
=>erase <FIT_image_addr> +$filesize
=>cp.b 82000000 <FIT_image_addr> $filesize
=>protect on <FIT_image_addr> +$filesize
```

3. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <FIT_image_addr>
```

4. **FIT Image address on Flash Memory Map**

```
> Bank0: FIT_image_addr = 0x0_6110_0000
```

```
> Bank4: FIT_image_addr = 0x0_6510_0000
```

4.4.7.9.3 NFS Deployment

1. **Generating File System**

   Use Yocto to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   nfs_root_path board_ipaddress(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/portmap restart
   ```

   ```
   /etc/init.d/nfs-kernel-server  restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 175 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>: <your_gatewayip>:<your_netmask>:<board_name>:<ethx>:off
   console=ttyS0,115200 earlycon=uart8250,mmio,0x21c0500
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel FIT image to the board, then boot it up.

   ```
   =>tftp a0000000  kernel.itb;
   =>bootm a0000000:kernel@1 - a0000000:fdt@1
   ```

   Now the board will boot up with NFS filesystem.

4.4.7.9.4 SD Deployment

This section shows steps to load the U-Boot image, kernel image and rootfs into a SD card and boot from it. The first step is to partition a SD card. No less than 2M space should be reserved for RCW, PBI, and U-Boot images.

The second step is to put U-Boot image into SDcard:

There are two ways to deploy U-Boot image into SDcard: * Use "dd" command under a linux host. * Use "mmc write" command under U-Boot prompt. The last step is to put the kernel image and rootfs into SDcard: There are two types of rootfs to select. * Use SDcard partition as the rootfs. * Use Ramdisk as the rootfs.

Create a new partition on SD Card

1. Insert SD card into the Linux Host PC. After inserting it, use the `dmesg` command to determine the name of sd card.

```
$ dmesg | tail -20
...
[84626.337992] sd 5:0:0:0: [sdc] 499712 512-byte logical blocks: (255 MB/244 MiB)
[84626.339229] sd 5:0:0:0: [sdc] Write Protect is off
[84626.339234] sd 5:0:0:0: [sdc] Mode Sense: 0b 00 00 08
[84626.340482] sd 5:0:0:0: [sdc] No Caching mode page found
[84626.340488] sd 5:0:0:0: [sdc] Assuming drive cache: write through
```

   From the above log, we could know the name of sd card. In this instance, it is "`sdc`". If you couldn't see the log as above, please use `dmesg | tail - 30(or greater)` to show more.

2. Use the `fdisk` command to repartition the SD card.

   a. Use the "df" to check whether partitions of sd card has being mounted or not by host automatically .

```
$ df
Filesystem     1K-blocks      Used Available Use% Mounted on
/dev/sda2       38317716  29660848   6687360  82% /
udev              927520         4    927516   1% /dev
tmpfs             201372      1064    200308   1% /run
/dev/sdc1         236876      2062    218277   1% /media/songwb/
5e36404d-9c18-44ba-9bec-6525862dfdb7
```

   From the log above, if any partition of SD card has been mounted, umount it. For this instance, `sdc1` has been mounted, so umount the `/dev/sdc1` using the `unmount` commmand.

```
$ umount /media/songwb/5e36404d-9c18-44ba-9bec-6525862dfdb7
```

   b. Use the `fdisk` command to create a new partition.

```
#fdisk /dev/sdc
Command (m for help): p

Disk /dev/sdc: 255 MB, 255852544 bytes
4 heads, 16 sectors/track, 7808 cylinders, total 499712 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
Disk identifier: 0x354419bd

Device Boot      Start         End      Blocks   Id  System
/dev/sdc1            2048      499711      248832    6  FAT16
```

NOTE

`sdc` is your SD device name from step1.

NOTE

note: "p" means printing all partitions on SD card.

```
Command (m for help): d
Selected partition 1
```

NOTE

if there has been a partition, delete it using `d`.

```
Command (m for help): n
Partition type:
            p   primary (0 primary, 0 extended, 4 free)
            e   extended
```

NOTE

`n` means creating a new partition.

```
Select (default p):
Using default response p
```

NOTE

select a default.

```
Partition number (1-4, default 1): note: select a default.
Using default value 1
First sector (2048-499711, default 2048): 4096
```

NOTE

Skip the first `4096` blocks reserved for deploying U-Boot image.

```
Last sector, +sectors or +size{K,M,G} (4096-499711, default 499711):
Using default value 499711
```

NOTE

select a default.

```
Command (m for help): w
The partition table has been altered!
```

NOTE

`w` means writing the new partition table to sd card.

```
Calling ioctl() to re-read partition table.
Syncing disks.
```

3. Use the `mkfs.ext2` command to format the filesystem.

```
# mkfs.ext2 /dev/sdc1

mke2fs 1.42.9 (4-Feb-2014)
Filesystem label=
OS type: Linux
Block size=1024 (log=0)
Fragment size=1024 (log=0)
Stride=0 blocks, Stripe width=0 blocks
62000 inodes, 247808 blocks
12390 blocks (5.00%) reserved for the super user
First data block=1
Maximum filesystem blocks=67371008
31 block groups
```

```
8192 blocks per group, 8192 fragments per group
2000 inodes per group
Superblock backups stored on blocks:
       8193, 24577, 40961, 57345, 73729, 204801, 221185

Allocating group tables: done
Writing inode tables: done
Writing superblocks and filesystem accounting information: done
```

NOTE

The first 4096 sectors of SD card must be reserved for deploying U-Boot image.

Deploy the kernel image and rootfs

1. Mount this new partition to a temporary directory

```
#mkdir temp
#mount /dev/sdc1 temp
```

2. Deploy the linux fit iamge.

```
#cp  kernel.itb temp/
```

3. Deploy the rootfs. If you want to use this new partition as rootfs, follow the below steps, if not, skip this step.

```
#cp fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/
#tar xvfz fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz
#rm  fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/.
```

4. Umount the temporary directory

```
#umount temp
```

Deploy the U-Boot image

There are two ways to deploy the U-Boot image to SD card. And note that PreBoot loader (PBL) will load the U-Boot image at the offset of `0x1000`, So we should skip 8 blocks(if the block size of sd card is 512B).

- Under the linux host, use `dd` command to deploy it
  1. Insert SD card into Host.
  2. Use the `dd` command

```
# dd if=u-boot-with-spl-pbl.bin of=/dev/sdb  seek=8 bs=512
```

- Under U-Boot prompt, use `mmc write` to deploy it
  1. Insert SD card into target board and power on.
  2. Setup the network connection if necessary
  3. Program U-Boot image to SD Card

```
=> tftpboot 82000000 u-boot-with-spl-pbl.bin
=> mmc write 82000000 8 800
=> cpld reset sd
```

If the SD card is already in the slot before powering on the board, the card will be initialized when U-Boot boots. If the SD card is inserted after U-Boot has booted, use `mmc rescan` to scan and initialize the sd card, and use `mmc info` to make sure the sd card is ok:

```
=> mmc rescan
=> mmcinfo
```

Bootup kernel

If you want to use SD card partition as rootfs, make sure the rootfs image has been delopyed in it, and use the following steps.

```
=> setenv bootargs  "root=/dev/mmcblk0p1 rw earlycon=uart8250,0x21c0500 console=ttyS0,115200"
=> ext2load mmc 0 a0000000 kernel.itb && bootm a0000000
```

If you want to use RAMDISK as rootfs, use the following steps.

```
=> setenv bootargs  "root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200"
=> ext2load mmc 0 a0000000 kernel.itb && bootm a0000000
```

NOTE

The `kernel.itb` is the name of your FIT Image, you can use the `ext2ls` command to list it at the U-Boot prompt

4.4.7.9.5 QSPI Deployment

Insert an X-nor card

1. X-nor card hardware configuration:

```
SW1[1:4]=1000
SW4[1:4]=1111
SW3[1:4]=0001
```

2. Insert the X-nor card into the IFC Card slot to enable QSPI flash on it.

Prepare SD boot to program QSPI flash

1. Build U-Boot image for SD boot (enables QSPI):

```
$make distclean ARCH=aarch64 CROSS_COMPILE=${toolchain_path}/gcc-linaro-aarch64-linux-
gnu-4.9-2014.07_linux/bin/aarch64-linux-gnu-
$make ARCH=aarch64 ${board_name}_sdcard_qspi_defconfig
$make CROSS_COMPILE=${toolchain_path}/gcc-linaro-aarch64-linux-gnu-4.9-2014.07_linux/bin/
aarch64-linux-gnu- -j4
```

2. Write the U-Boot image to SD card:

```
=>tftp 0x81000000 u-boot-with-spl-pbl.bin
=>mmc write 0x81000000 8 0x800
```

3. Switch to SD boot(enables QSPI):

```
=>qixis_reset sd_qspi
```

Or set switches referring to board configuration document and power on the board from SD boot.

Build U-Boot image for QSPI boot

1. Compile QSPI boot image(enable QSPI):

```
$make distclean ARCH=aarch64 CROSS_COMPILE=${toolchain_path}/gcc-linaro-aarch64-linux-
gnu-4.9-2014.07_linux/bin/aarch64-linux-gnu-
$make ARCH=aarch64  ${board_name}_qspi_defconfig
$make CROSS_COMPILE=${toolchain_path}/gcc-linaro-aarch64-linux-gnu-4.9-2014.07_linux/bin/
aarch64-linux-gnu- -j4
```

2. Swap the bytes for RCW:

```
$tclsh byte_swap.tcl rcw_1600_qspiboot.bin rcw_1600_qspiboot_swap.bin 8
```

   The byte_swap.tcl script is a shareable tool and can be found under `rcw/tool/` directory.

3. Write RCW and U-Boot images to QSPI flash under SD boot (enables QSPI) mode:

```
=>sf probe 0:0
```

   SF: Detected S25FL128S_64K with page size 256 Bytes, erase size 64 KiB, total 16 MiB

```
=>tftp 81000000 rcw_1600_qspiboot_swap.bin;sf erase 0 +$filesize;sf write 81000000 0 $filesize
=>tftp 82000000 u-boot-dtb.bin;sf erase 10000 +$filesize;sf write 82000000 10000 $filesize
```

4. Switch to QSPI boot:

```
=>qixis_reset qspi
```

   Or set switches referring to board configuration document and power on the board from QSPI boot.

Write FMan ucode to QSPI flash to use FMan
Do it under SD boot(enbles QSPI) or QSPI boot:

```
=>sf probe 0:0
```

SF: Detected S25FL128S_64K with page size 256 Bytes, erase size 64 KiB, total 16 MiB

```
=>tftp 83000000 <ucode_file_name>.bin
=>sf probe 0:0;sf erase d0000 +$filesize;sf write 83000000 d0000 $filesize
```

4.4.7.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
FSL_MDIO0:
1 - RealTek RTL8211F <--> FM1@DTSEC3
2 - RealTek RTL8211F <--> FM1@DTSEC4
4 - Vitesse VSC8514 <--> FM1@DTSEC1
```

```
5 - Vitesse VSC8514  <--> FM1@DTSEC2
6 - Vitesse VSC8514  <-->  FM1@DTSEC5
7 - Vitesse VSC8514 <--> FM1@DTSEC6
FM_TGEC_MDIO:
1 - Aquantia AQR105  <-->  FM1@TGEC1
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 6 DTSEC interfaces and on the 10GEC interface. If you see “Generic” reported, it is an indication that something is there but the ls1043ardb can’t communicate with the device/port.

Check Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC1 1
Reading from bus FSL_MDIO0
PHY at address 2:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

4.4.7.11 Hardware Setting for Special Purposes

The RDB has user selectable switches for evaluating different pin mux and boot options for the LS1043A device. Information below lists the hardware setting for those special purposes.

For RDB:

General UART port :

1. UART1(J4 bottom)
2. UART2(J4 top).

NOR boot setting

1. Set SW4[1:8]+SW5[1]=0b'0001_0010_1;
2. Bank0: SW5[4:6]=0b'000;
3. Bank1: SW5[4:6]=0b'001

SD boot setting

1. image:u-boot-with-spl-pbl.bin
2. Program the image to SD card in u-boot.

```
=>tftp 82000000 u-boot-with-spl-pbl.bin
=>=>mmc erase 8 0x800; mmc write 82000000 8 0x800
```

3. Program the image to SD card in Linux.

```
dd if=u-boot-with-spl-pbl-sd.bin of=/dev/sdb bs=512 seek=8
```

4. Insert SD card in adaptor;
5. Set SW4[1:8]+SW5[1]=0b'0010_0000_0

NAND boot setting

1. image:u-boot-with-spl-pbl.bin
2. Program the image to SD card in u-boot.

```
=>tftp 82000000 u-boot-with-spl-pbl.bin
=>=>nand erase.chip; nand write 82000000 0 100000
```

3. Set SW4[1:8]+SW5[1]=0b'1000_0011_0

NOTE

For more information about specific settings for the console (i.e. baud rate, ports used etc.), please refer to the ls1043ardb Quick Start Guide.

For customized board

General UART port:

Refer to board configuration document

Lpuart

1. RCW - support for lpuart
   a. Program the RCW image

```
=>tftp 82000000 <rcw_lpuart_image.bin>;
```

```
=>protect off <rcw_image_addr> +$filesize;
```

```
=>erase <rcw_image_addr> +$filesize
```

```
=>cp.b 0x82000000 <rcw_image_addr> $filesize
```

```
=>protect on <rcw_image_addr> +$filesize
```

2. U-boot - with lpuat console
   a. Program the uboot image

```
=>tftp 82000000 u-boot-dtb.bin
```

```
=>protect off <uboot_image_addr> +$filesize
```

```
=>erase <uboot_image_addr> +$filesize
```

```
=>cp.b 0x82000000 <uboot_iamge_addr> $filesize
```

```
=>protect on <uboot_iamge_addr> +$filesize
```

3. Boot using lpuart console
   a. Set uboot environment variable.

```
=>setenv bootargs "console=ttyLP0,115200 root=/dev/ram0 earlycon=lpuart32,0x2950000"
```

   b. Bootup kernel

```
=>tftp a0000000 kernel.itb
```

```
=>bootm a0000000
```

SATA

1. RCW - support for SATA
   a. Program the RCW image

```
tftp 82000000 <rcw_sata_image.bin>
```

```
protect off <rcw_image_addr> +$filesize
```

```
erase <rcw_image_addr> +$filesize
```

```
cp.b 0x82000000 <rcw_image_addr> $filesize
```

```
protect on <rcw_image_addr> +$filesize
```

2. U-boot
   a. Program the uboot image

```
=>tftp 82000000 u-boot-dtb.bin
```

```
=>protect off <uboot_image_addr> +$filesize
```

```
=>erase <uboot_image_addr> +$filesize
```

```
=>cp.b 0x82000000 <uboot_image_addr> $filesize
```

```
=>protect on <uboot_image_addr> +$filesize
```

3. Boot & Test
   a. Program the RCW and U-Boot image.
   b. Enable SATA support

```
Refer to board configuration document
```

   c. Boot using the new image
   d. Test SATA on uboot

```
=>scsi info
```

e. Bootup kernel

```
=>tftp a0000000 kernel.itb && bootm a0000000
```

f. Test SATA on kernel

```
#hdparm -i /dev/sda
```

4.4.8 LS1046ARDB

4.4.8.1 Overview

The LS1046A reference design board (RDB) is the high-performance computing, evaluation, and development platform that supports the QorIQ LS1046A processor. This guide provides board-specific configurations and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.8.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options for the LS1046A device. Table below lists the default switch settings and the description of these settings.('0' is OFF, '1' is ON.)

Table 46. Default Switch Settings

	1	2	3	4	5	6	7	8
SW3	0	1	0	0	0	1	1	0
SW4	0	0	1	1	1	0	1	1
SW5	0	0	1	0	0	0	1	0

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 47. LS1046ARDB Switch Settings

Boot Source	Switch
QSPI flash 0 (bank0)	SW5[1-8] +SW4[1] = 0b'00100010_0 SW3[3-5]= 0b'000
QSPI flash 1 (bank4)	SW5[1-8] +SW4[1] = 0b'00100010_0 SW3[3-5]= 0b'001
SD	SW5[1-8] +SW4[1] = 0b'00100000_0

4.4.8.3 U-Boot Environment Variables

The following sections will guide the users on how to set the U-Boot environment and configure the U-Boot network parameters.

4.4.8.3.1 U-Boot Environment Variable "hwconfig"

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set in the U-Boot prompt using the "*setenv*" command.

- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified in the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for for "hwconfig" on LS1046ARDB is as follows:

```
hwconfig = fsl_ddr:bank_intlv=auto
```

4.4.8.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

* <ethx> is the Ethernet port on the board connected to the Linux boot server. "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to approriate MAC addresses for your board.

```
=>setenv ethaddr 00:e0:0c:00:89:00
=>setenv eth1addr 00:e0:0c:00:89:01
=>setenv eth2addr 00:e0:0c:00:89:02
=>setenv eth3addr 00:e0:0c:00:89:03
=>saveenv
```

NOTE

1. For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).
2. In the overwhelming majority of cases, eth<*>addr can be autoset.

The flashed version of U-Boot is now ready for TFTP based deployments.

4.4.8.4 Frame Manager Microcode (FMan Ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See

the U-Boot log for LS1046A version information and also for the version of FMan microcode currently flashed on the LS1046A (e.g., microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

```
fsl_fman_ucode_ls1046_r1.0_106_4_18.bin(*)
fsl_fman_ucode_ls1046_r1.0_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(i) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a New U-boot, RCW, FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.8.5 RCW (Reset Configuration Word) and Ethernet Interfaces

The RCW directories' names conform to the following naming convention:

```
ab_cdef_ghij
```

Table 48. RCW directories Naming Convention Legend

Slot	Convention
a	'R' indicates RGMII1@DTSEC3 is supported
b	'R' indicates RGMII2@DTSEC4 is supported 'N' indicates not available/not used
c	What is available in SerDes1 Lane 0
d	What is available in SerDes1 Lane 1
e	What is available in SerDes1 Lane 2
f	What is available in SerDes1 Lane 3
g	What is available in SerDes2 Lane 0
h	What is available in SerDes2 Lane 1
i	What is available in SerDes2 Lane 2
j	What is available in SerDes2 Lane 3

Table 49. For Lanes (c through j)

Flag	Convention
'N'	NULL, not available/not used

Table continues on the next page...

Table 49. For Lanes (c through j) (continued)

'P'	PCIe
'X'	XAUI
'S'	SGMII
'Q'	QSGMII
'F'	XFI
'H'	SATA
'A'	AURORA

For example,

```
RR_FFPPPN_1133_5559
```

means:

- RGMII1@DTSEC3 on board
- RGMII2@DTSEC4 on board
- XFI9 on SFP cage
- XFI10 on SFP cage
- SGMII5 on Slot 2
- SGMII6 on Slot 1
- PCIe1 on Slot 3
- PCIe2 on Slot 4
- PCIe3 on Slot 5
- SATA
- SERDES1 Protocol is 0x1133
- SERDES2 Protocol is 0x5559

The RCW file names for the ls1046ardb conform to the following naming convention:

```
rcw_<frequency>_<specialsetting>.rcw
```

Table 50. RCW Files Naming Convention Legend

Code		Convention
frequency		Core frequency(MHZ)
specialsetting	bootmode	QSPI/SD/EMMC

Table continues on the next page...

Table 50. RCW Files Naming Convention Legend (continued)

	special support	emmc: eMMC boot sdboot: SD boot sben: Secure boot qspiboot: QSPI boot

For example,

```
rcw_1600_sdboot.rcw means rcw for core frequency of 1600MHz with sd boot.
```

```
ls1046ardb/RR_FFPPPN_1133_5559/rcw_1600_qspiboot.rcw means rcw for core frequency 0f 1600MHz with
QSPI boot.
```

The following RCW binaries are used on the ls1046ardb:

```
RR_FFPPPN_1133_5559/rcw_1600_qspiboot.bin
```

```
RR_FFPPPN_1133_5559/rcw_1600_qspiboot_sben.bin
```

4.4.8.6 System Memory Map

In 64-bit u-boot, there is a 1:1 mapping of physical address and effective address. After system startup, the boot loader maps physical address and effective address as shown in the following table:

Start Physical Address	End Physical Address	Memory Type	Size
0x00_0000_0000	0x00_00FF_FFFF	Secure Boot ROM	1MB
0x00_0100_0000	0x00_0FFF_FFFF	CCSR	240MB
0x00_1000_0000	0x00_1000_FFFF	OCRAM0	64KB
0x00_1001_0000	0x00_1001_FFFF	OCRAM1	64KB
0x00_2000_0000	0x00_23FF_FFFF	DCSR	64MB
0x00_4000_0000	0x00_5FFF_FFFF	QSPI	512MB
0x00_6000_0000	0x00_7FFF_FFFF	IFC region	512MB
0x00_8000_0000	0x00_FFFF_FFFF	DRAM	2GB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Memory Type	Size
0x05_0000_0000	0x05_07FF_FFFF	QMAN S/W Portal	128M
0x05_0800_0000	0x05_0FFF_FFFF	BMAN S/W Portal	128M
0x08_8000_0000	0x0F_FFFF_FFFF	DRAM	30GB
0x40_0000_0000	0x47_FFFF_FFFF	PCI Express1	32G
0x48_0000_0000	0x4F_FFFF_FFFF	PCI Express2	32G
0x50_0000_0000	0x57_FFFF_FFFF	PCI Express3	32G

4.4.8.7 Flash Bank Usage

LS1046ARDB has 2 QSPI flash connected over QSPI contoller.

Only one QSPI flash is available at a time depending upon the board switch settings. These switch settings can also be overriden by CPLD commands.

To protect the default U-Boot in flash0 (aka bank0), it is a convention employed by NXP to deploy work images into the flash1 (aka bank4), and then switch to the flash1 (aka bank4) for testing. Switching to the flash1 (aka bank4) can be done in software using CPLD commands and effectively swaps the flash0 (aka bank0) with the flash1 (aka bank4). This protects flash1 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
U-Boot 2016.01 (Aug 19 2016 - 16:59:27 +0800)

SoC:  LS1046E (0x87070010)
Clock Configuration:
       CPU0(A72):1600 MHz  CPU1(A72):1600 MHz  CPU2(A72):1600 MHz
       CPU3(A72):1600 MHz
       Bus:      600  MHz  DDR:      2100 MT/s  FMAN:     700  MHz
Reset Configuration Word (RCW):
       00000000: 0c150010 0e000000 00000000 00000000
       00000010: 11335559 40005012 40025000 c1000000
       00000020: 00000000 00000000 00000000 00238800

```

Bank switching can be done in U-Boot using the following statements:

- Switch to QSPI bank 0(default) for RDB:

```
=>cpld reset
```

- Switch to QSPI bank 4 for RDB:

```
=>cpld reset altbank
```

The table below shows the QSPI flash memory map for LS1046ARDB:

Table 51. QSPI Flash Memory Map for LS1046ARDB

Start	End Offset	Description	Size
0x40000000	0x400FFFFF	bank0 rcw + pbi	1 M

4.4.8.8 Programming a New U-Boot, RCW and FMan Ucode

The following three sections will discuss how to individually update U-Boot, RCW. For specific addresses, please refer to the QSPI Flash Memory Map as a reference.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Here are U-Boot commands to switch between the three different boot sources:

1. `cpld reset`: reset to boot from current bank
2. `cpld reset altbank`: reset to boot from alternate bank
3. `cpld reset sd`: reset to boot from SD card

Programming a New U-Boot to QSPI flash

By default, an existing U-Boot is run in QSPI bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp <uboot_image_addr> <uboot_file_name>.bin
=>sf probe 0:1
=>sf erase 100000 +$filesize
=>sf write <uboot_image_addr> 100000 $filesize
=>cpld reset altbank
```

NOTE

Using "sf probe 0:0" could program U-Boot to the current bank.

Programming a New RCW to QSPI flash

To program a new RCW, first switch to QSPI bank 0 by performing a hard reset or by typing *reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash offset 0x0. 0x0 is the offset address of RCW in the QSPI flash. Execute the following commands at the U-Boot prompt to program the RCW to QSPI flash and reset to alternate bank.

```
=>tftp <rcw_image_addr> <rcw_file_name>.bin
=>sf probe 0:1
=>sf erase 0 +$filesize
=>sf write <rcw_image_addr> 0 $filesize;
=>cpld reset altbank
```

NOTE

1. Using "sf probe 0:0" could program RCW to the current bank.
2. The RCW image needs to be swapped. Yocto Project generates the swapped RCW image, which is programmed into QSPI flash. For steps to generate RCW and U-Boot without using Yocto Project, refer to QSPI Deployment.

Programming a New U-Boot to SD card

To program U-boot, first boot the board to u-boot. Next, load the new U-Boot SD boot image(u-boot-with-spl-pbl.bin) to RAM by downloading it via TFTP and then copying it to SD card with blk offset 0x8. Execute the following commands at the U-Boot prompt to program the U-Boot to SD card and reset to sd boot.

```
=>tftp <uboot_image_addr> u-boot-with-spl-pbl.bin
=>mmc erase 8 0x800
=>mmc write <uboot_image_addr> 8 0x800
=>cpld reset sd
```

Program the image to SD card in Linux.

```
dd if=u-boot-with-spl-pbl-sd.bin of=/dev/sdb bs=512 seek=8
```

Programming a New FMan Microcode

Program a new microcode to QSPI flash 1(bank 4):

To program a new microcode, first switch to QSPI bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then writing it to flash offset 0x300000. 0x300000 is the offset of ucode in the QSPI flash. Then execute the following commands at the U-Boot prompt to program the ucode to the boot device.

```
=>tftp <ucode_image_addr> <ucode_file_name>.bin
=>sf probe 0:1
=>sf erase 300000 +$filesize
=>sf write <ucode_image_addr> 300000 $filesize

NOTE: Using "sf probe 0:0" could program microcode to the current bank.
```

Program a new microcode to SD Card:

```
=>tftp <ucode_image_addr> <ucode_file_name>.bin
=>mmc write <ucode_image_addr> 820 50
```

4.4.8.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.8.9.1 FIT Image Deployment from TFTP

1. **Setting U-Boot Environment**

   Before performing FIT image deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters on page 194 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for FIT image deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200'
   =>saveenv
   ```

2. **Booting Up the System**

   Execute the following commands to TFTP the image to the board, then boot into Linux.

```
=>tftp a0000000 <fit_image_name>
=>bootm a0000000
```

   Now the board will boot into Linux .

4.4.8.9.2 FIT Image Deployment from Flash

1. **Setting U-Boot Environment**

   Before performing FIT image from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for deployment from flash:

```
=>setenv bootargs root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200
=>setenv bootcmd sf probe 0:0;sf read <fit_image_addr> 1000000 2800000;bootm <fit_image_addr>
=>saveenv
```

2. **Programming FIT image to QSPI Flash**

   The FIT image should be downloaded to the RAM address using TFTP then copied to flash offset 0x1000000 as per "QSPI memory map" in Flash Bank Usage. At the U-Boot prompt, use the following commands to program the image to QSPI current bank:

```
=>tftp <fit_image_addr> <fit_image_name>
=>sf probe 0:0
=>sf erase 0x1000000 +$filesize
=>sf write <fit_image_addr> 0x1000000 $filesize
```

3. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <fit_image_addr>
```

4.4.8.9.3 NFS Deployment

1. **Generating File System**

   Use Yocto to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
nfs_root_path board_ipaddress(rw,no_root_squash,async)
```

b. Restart the NFS service:

```
/etc/init.d/portmap restart
```

```
/etc/init.d/nfs-kernel-server  restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 194 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>: <your_gatewayip>:<your_netmask>:<board_name>:<ethx>:off
console=ttyS0,115200 earlycon=uart8250,mmio,0x21c0500
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel FIT image to the board, then boot it up.

```
=>tftp a0000000  kernel.itb;
=>bootm a0000000:kernel@1 - a0000000:fdt@1
```

   Now the board will boot up with NFS filesystem.

4.4.8.9.4 SD Deployment

Partition SD Card

1. Insert SD card into the Linux Host PC.
2. Use the "fdisk" command to repartition the SD card.

```
# fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to creat the filesystem.

```
#mkfs.ext2 /dev/sdb1
```

NOTE

The first 2056 sectors of SD card must be remained for u-boot image

FIT Kernel Image and Root File System Deployment from SD Card

1. Insert SD card into the Linux Host PC.

2. Create temp director in host PC and mount the ext2 partition to the temp

```
#mkdir temp
#mount /dev/sdb1 temp
```

3. Copy the FIT Kernel Image to the SD card partition.

```
#cp  kernel.itb temp/
```

4. Copy the Root File System to the SD card partition.

```
#cp fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/
#tar xvfz fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz
#rm  fsl-image-core-ls1043ardb_<release date>.rootfs.tar.gz  temp/
```

5. Umount the temp director

```
#umount temp
```

U-Boot Image Deployment from SD Card

- Form Linux Host PC
  1. Insert SD card into Host.
  2. Use the "dd" command

```
# dd if=u-boot-with-spl-pbl.bin of=/dev/sdb  seek=8 bs=512
```

- Form ls1043ardb Board
  1. Insert SD card into target board and power on.
  2. Programming U-boot image to SD Card

```
=> tftpboot 82000000 u-boot-with-spl-pbl.bin
=> mmc write 82000000 8 800
=> cpld reset sd
```

Setting U-Boot Environment

- Execute the following commands at the U-Boot prompt

```
=> setenv bootcmd "ext2load mmc 0 a0000000 kernel.itb && bootm a0000000"
```

- Using the Ramdisk as the Root File Systemp

```
=> setenv bootargs  "root=/dev/ram0 earlycon=uart8250,mmio,0x21c0500 console=ttyS0,115200"
```

- Using the Ext2 Partition of SD card as the Root File Systemp

```
=> setenv bootargs  "root=/dev/mmcblk0p1 rw earlycon=uart8250,0x21c0500 console=ttyS0,115200"
```

- Saving the environment

```
=>saveenv
```

NOTE

The `kernel.itb` is the name of your FIT Image, you can use the `ext2ls` command to list it at the U-Boot prompt

4.4.8.9.5 QSPI Deployment

Build U-Boot image for QSPI without Yocto Project

The U-Boot image generated from code needs to be swapped for QSPI boot. Yocto generates the swapped U-Boot image, which is programmed into QSPI flash. Below are steps to build U-Boot without Yocto:

1. Compile QSPI boot image(enable QSPI):

```
$make distclean ARCH=aarch64 CROSS_COMPILE=${toolchain_path}/bin/aarch64-linux-gnu-
```

```
$make ARCH=aarch64 ls1046ardb_qspi_defconfig
```

```
$make CROSS_COMPILE=${toolchain_path}/bin/aarch64-linux-gnu- -j4
```

2. Swap the bytes for QSPI boot:

```
$tclsh byte_swap.tcl rcw_1600_qspiboot.bin rcw_1600_qspiboot_swap.bin 8
```

   The byte_swap.tcl script is a shareable tool and can be found under rcw/tool/ directory.

3. Switch to QSPI altbank:

```
=>cpld reset altbank
```

   Or set switches referring to board configurations Switch Settings and power on the board from QSPI boot.

Build Linux image and FIT image for QSPI boot

1. Compile Linux kernel image:

```
$make distclean ARCH=aarch64 CROSS_COMPILE=${toolchain_path}/bin/aarch64-linux-gnu-
```

```
$make ARCH=arm64  $make defconfig freescale.config
```

```
$make CROSS_COMPILE=${toolchain_path}/bin/aarch64-linux-gnu- -j4
```

2. Make it into kernel.itb:

```
$mkimage -f kernel-ls1046a-rdb.its kernel.itb
```

To boot kernel, please refer to FIT Image Deployment from TFTP and FIT Image Deployment from Flash.

4.4.8.10 Check 'Link Up' for Serial Ethernet Interfaces

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
1 - RealTek RTL8211F <--> FM1@DTSEC3
2 - RealTek RTL8211F <--> FM1@DTSEC4
3 - RealTek RTL8211F <--> FM1@DTSEC5
4 - RealTek RTL8211F <--> FM1@DTSEC6
FM_TGEC_MDIO:
0 - Aquantia AQR107 <--> FM1@TGEC1
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 4 DTSEC interfaces and on the 10GEC interface. If you see “Generic” reported, it is an indication that something is there but the ls1046ardb can’t communicate with the device/port.

Check Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC3 1
Reading from bus FSL_MDIO0
PHY at address 1:
1 - 0x79ad
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x79a9.

4.4.8.11 Basic Networking Ping Test

U-BOOT

The LS1046ARDB has two RGMII ports and two SGMII ports. The log below shows how to ping from FM1@DTSEC3 and FM1@DTSEC4 interfaces.

```
U-Boot 2016.01 (Aug 19 2016 - 16:59:27 +0800)

SoC:  LS1046E (0x87070010)

4.4.9 LS2085ARDB/LS2088ARDB

4.4.9.1 Introduction

This guide describes how to deploy software images onto the LS2085ARDB/LS2088ARDB board. This board supports multiple SoCs within a family of pin-compatible SoCs. These include:

- LS2080A (not supported in this release)
- LS2085A (a non-production SoC)
- LS2088A
- LS2084A
- Future planned SoCs

The images to be deployed are produced by the SDK's built process (bitbake). They are also available in pre-built form on the "images" ISO supplied with the SDK.

U-Boot is a very flexible boot loader and supports many possible boot devices that can contain images. This guide's main focus is NOR flash and using U-Boot's Ethernet to program it.

4.4.9.2 LS2085ARDB/LS2088ARDB Board Introduction

The LS2085ARDB/LS2088ARDB (reference design board) with a LS2088A SoC is a high-performance computing, evaluation, and development platform.

Most are configured with a socket for the SoC .

4.4.9.2.1 Overview

The figure below shows the LS2085ARDB/LS2088ARDB without a case:

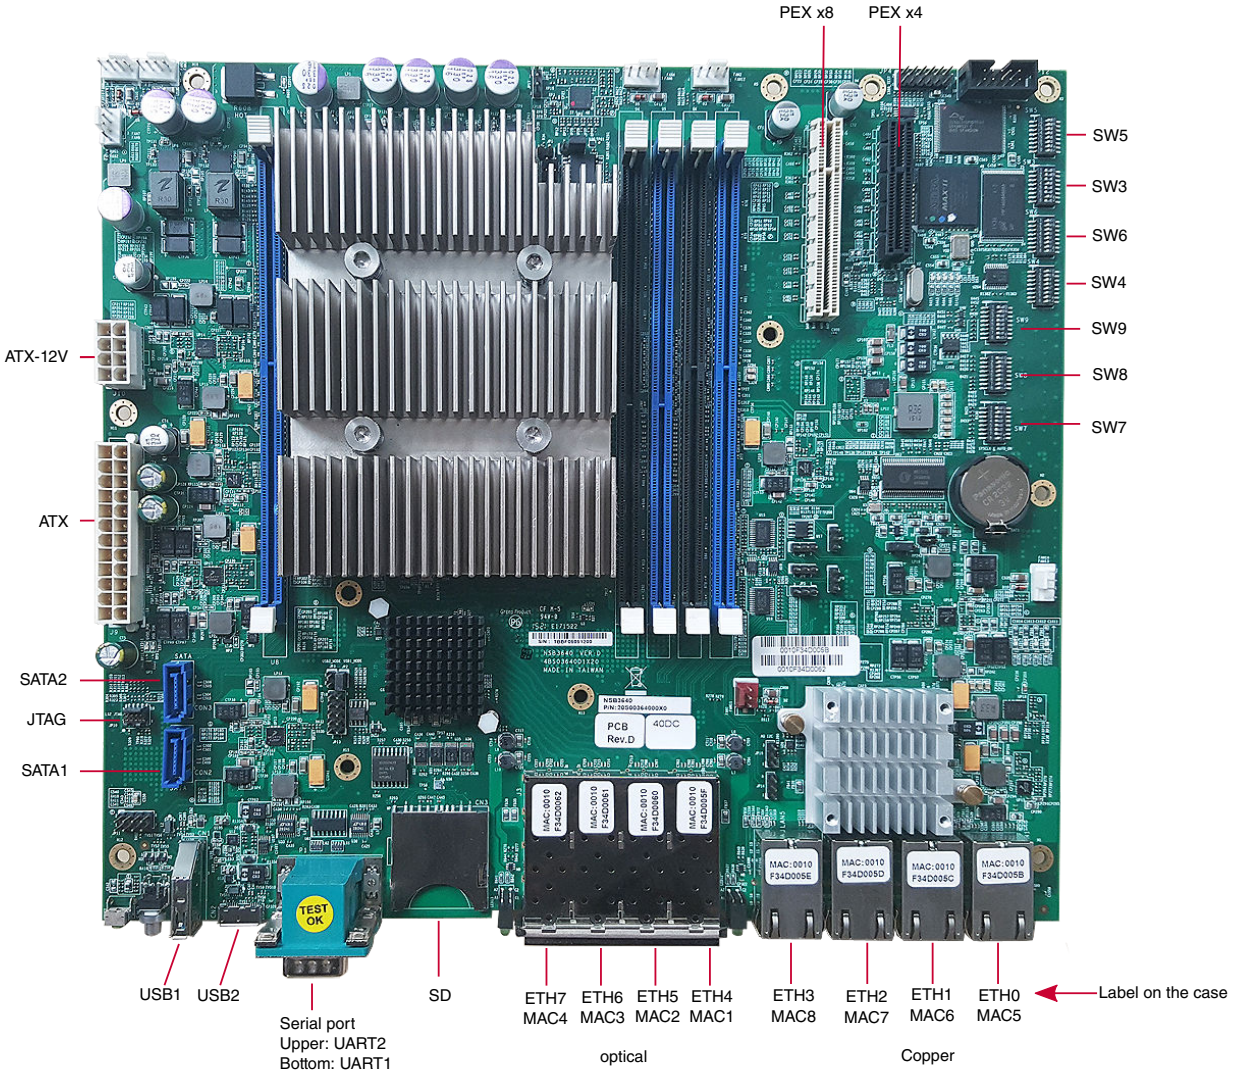

Figure 2. LS2085ARDB/LS2088ARDB

4.4.9.2.1.1 On-board front panel connection for 10G Ethernet

The RDB provides eight 10G interfaces using XFI SerDes protocols; four 10G interfaces are optical and the other four interfaces use copper connections.

The following figure shows the optical and copper interfaces available on the RDB. The optical ports are fitted with SFP modules and require fiber cables for connecting the interfaces. The copper interfaces take standard CAT6A/7 cables with RJ45 connectors.

The figure below labels the interfaces with their various identifiers. The DPMAC is the DPAA2 object that identifies the physical interface. As such, DPMAC1 to DPMAC8 represent the specific physical RDB interfaces shown below.

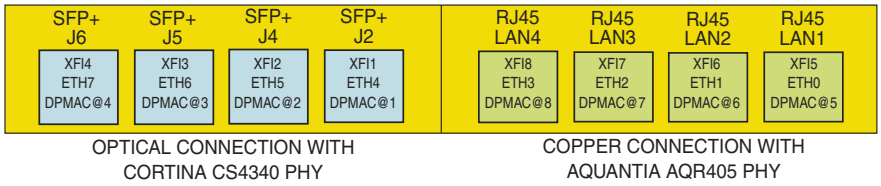

Figure 3. RDB optical and copper interfaces

When U-Boot starts, it prints the names of available interfaces using a syntax like "DPMAC5@xgmii" and "e1000#0" for the PCIe e1000 card. For example, suppose you plug a copper cable into the port labelled "DPMAC@5" in the figure. As described layer, you will set ethact in U-Boot to DPMAC5@xgmii. Note that the ETHX labels in the figure above are the physical labels on the chassis and are not the names of the interfaces in Linux. The interfaces in Linux are called niX.

The LS2088A SoC supports 80 Gbps total Ethernet bandwidth so all 8 ports can be used at the same time.

4.4.9.2.1.2 PCIe interface

The RDB board is normally provided with an e1000 PCIe Ethernet card fitted into a PCIe slot. This provides a demonstration of PCIe functionality and also provides a general purpose 1 Gbps copper Ethernet port that both Linux and U-Boot can use.

The PCIe NIC Ethernet card is connected to the board via an L-shaped adapter.

4.4.9.2.2 Board preparation

Use the serial port labeled UART2 for the console. It is the upper port. Connect the 10G interfaces according to your use case needs as described below.

Figure 4. LS2085ARDB/LS2088ARDB front panel

The following picture shows the rear of the board: the PCIe Ethernet card connector and power socket on the RDB.

Figure 5. LS2085ARDB/LS2088ARDB rear panel

Use the following steps to prepare the RDB for use:

1. Connect Ethernet cables to whichever Ethernet ports you want to use. If you are doing software development related to DPAA2, using the PCIe Ethernet can be convenient because it operates completely independently of the SoC's DPAA2 subsystem.
2. Attach a UART cable between the RDB top port and host computer.

3. Open a serial console tool on the host computer to communicate with the RDB.
4. Configure the host computer's serial port with the following settings:
   - Data rate: 115200 bps
   - Number of data bits: 8
   - Parity: None
   - Number of stop bits: 1
   - Flow control: Hardware/None
5. Connect the power supply to the board.

4.4.9.2.3 Default boot of the RDB

The RDB comes pre-loaded with software. The software is loaded in NOR flash on the RDB. Power on the RDB by pressing the power button on the front of the chassis and the U-Boot boot loader will automatically run and then load and start Linux using images located in vbank0 of the RDB's NOR flash. You can press a key while U-Boot is counting down to stop the Linux boot and get a U-Boot command prompt.

An example boot log is available in Detailed deployment steps on page 226.

4.4.9.3 LS2085ARDB/LS2088ARDB Details

4.4.9.3.1 On-board switch settings

The figure below shows default configuration switch settings for rev D - F boards. Earlier boards are not supported.

The bits on the switches are numbered from 1 to 8. In the figure, bit 1 is on the left.

Switch	Settings (1: ON, 0: OFF)
SW5	1111 1111
SW3	0001 0010
SW4	1111 1111
SW6	1111 1111
SW7	0100 0010 (100 MHz SYSCLOCK)
SW9	0100 0000
SW8	0101 1111

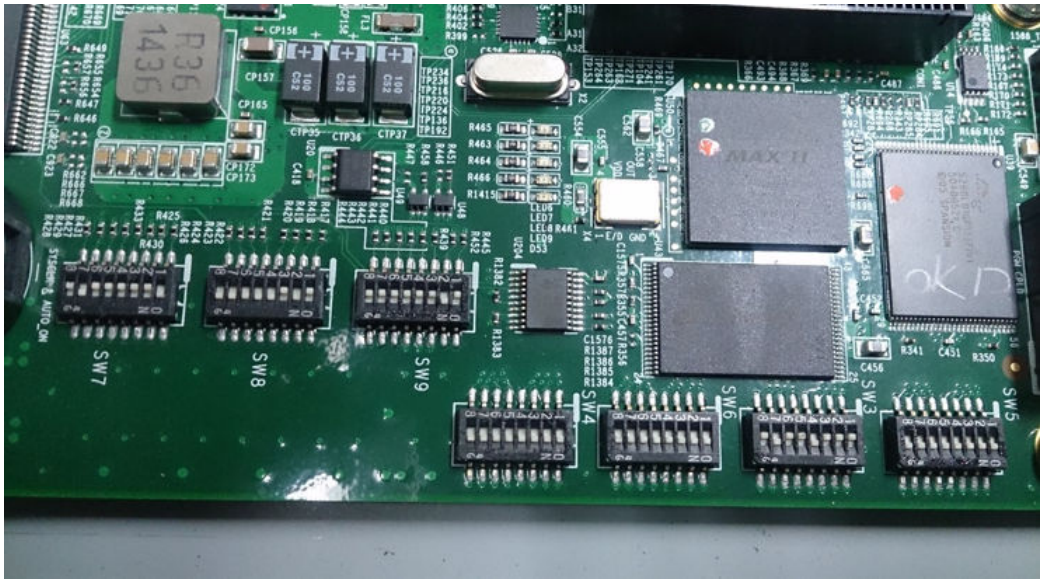

Figure 6. Switches on Rev D - F Boards

Refer to the *QorIQ LS2085A/LS2088A Reference Design Board Reference Manual* for detailed switch descriptions.

4.4.9.3.2 PBL, clocks, NOR Flash banks, and switches

This section describes features of the LS2085ARDB/LS2088ARDB that are relevant to deploying images. Understanding these features will help you to understand the deployment steps. The section concludes by outlining a deployment strategy.

This section explains:

- The connection between SYSCLK and PBL file changes.
- What a NOR flash bank is and why they are useful.
- The overall strategy of NOR flash deployments.

4.4.9.3.2.1 PBL files and SYSCLK

Pre-boot loader (PBL) files are automatically read by SoCs when they reset. The PBL file specifies important hardware configuration parameters including multipliers and dividers that are used to create the frequencies of the various clocks that the SoC requires. These clocks are formed by applying multipliers and dividers to a clock called SYSCLCK that is an input signal to the SoC.

For example, the clocks driving the ARM cores and the clock driving general SoC platform logic are derived from SYSCLK using multipliers and dividers specified in the PBL file. This means that a given PBL file is designed to be used with a particular SYSCLK frequency. The RDB must be configured to provide the SYSCLK that the PBL file you deploy requires.

4.4.9.3.2.2 RDB switch settings and SYSCLK frequency selection

The SYSCLK frequency is controlled by switch settings on the RDB. For revisions D – E of the LS2085ARDB/LS2088A RDB, SYSCLK is controlled by bits 1:3 of SW7. The available SYSCLK frequencies are:

Table 52. Available SYSCLK frequencies

Switch Setting	Frequency
off off off	66.666 MHz

Table continues on the next page...

Table 52. Available SYSCLK frequencies (continued)

Switch Setting	Frequency
off off on	83.333 MHz
off on off	100.000 MHz
off on on	125.000 MHz
on off off	133.333 MHz

You must set the switches to match what your PBL file expects. There is some complexity regarding when changes to switches take effect. The easy approach is to change the switches when the board is powered off. That will always work.

NOTE

The recommended frequency for LS2085ARDB/LS2088ARDB is 100MHz.

4.4.9.3.2.3 NOR Flash (virtual) banks

NOR flash is a simple and convenient destination for deploying images so it is frequently used. Many NXP development and reference boards provide a special feature that allows a single NOR flash to be divided into multiple parts called “banks”. This is done by board-level logic that modifies address signals. Because there is only one NOR flash physically, the banks are sometimes called "virtual" banks.

The benefit of this feature is that it allows more than one set of images to be independently deployed to the one NOR flash. This is very helpful during development because you can use the U-Boot image in one bank to program an image set into a different bank. If the new images are flawed, the old images are still functional to let you deploy corrected images.

The logic on the board usually allows the NOR flash to be divided into up to 8 banks, but almost always the feature is used to divide the flash into two halves only. The halves are called bank 0 and bank 4.

This is relevant to SYSCLK and PBLs because PBL files are one of the image types that must be deployed. It is possible to have different PBL files in the two banks, and they may require different SYSCLK frequencies. One must operate the board correctly in order to avoid using the wrong SYSCLK with a PBL.

4.4.9.3.2.4 Switch settings and NOR banks

On the LS2085ARDB/LS2088ARDB revisions D – F, switch SW9 bits 3:5 control which bank the SoC loads from when it powers up. The relevant values are:

Table 53. Switch Settings and NOR Banks

Switch Settings	NOR Banks
off off off	Load from NOR Flash Bank 0
on off off	Load from NOR Flash Bank 4

U-Boot prints which bank is loaded from. The output looks like following.

- For bank0

```
U-Boot 2016.01LS2088A-SDK+ge54c320 (Jul 17 2016 - 22:56:33 +0800)

SoC:  LS2088E Version:1.0 (0x87090010)
Clock Configuration:
       CPU0(A72):1800 MHz  CPU1(A72):1800 MHz  CPU2(A72):1800 MHz
       CPU3(A72):1800 MHz  CPU4(A72):1800 MHz  CPU5(A72):1800 MHz
       CPU6(A72):1800 MHz  CPU7(A72):1800 MHz
```

```
       Bus:      700  MHz  DDR:      1866.667 MT/s     DP-DDR:   1600 MT/s
Reset Configuration Word (RCW):
       00000000: 48303838 48480048 00000000 00000000

I2C:   ready
Model: Freescale Layerscape 2088A RDB Board
Board: LS2085A/LS2088A-RDB, Board Arch: V1, Board version: D, boot from vBank: 4
```

4.4.9.3.2.5 The `qixis_reset` command

U-Boot on the LS2085ARDB/LS2088ARDB has a useful command called `qixis_reset`. The command `qixis_reset` does a hard reset, loading from the bank specified by the switches.

If the switches are set to load from bank 0, then the command `qixis_reset altbank` will cause a reset into bank 4 (without a need to change any switches). This is useful if banks 0 and 4 contain PBL files that require the same SYSCLK.

4.4.9.3.2.6 NOR Flash banks and addresses

The “current” bank is the bank that was loaded and is currently running. The “alternate” bank is the other bank. For example, if you are running from bank 0 then bank 4 is the alternate bank. If you are running from bank 4, bank 0 is the alternate bank. The alternate bank if often called the "other" bank because it is the bank from which you are NOT booted.

Addressing is based on current and alternate/other banks, not banks 0 and 4. This is best explained by an example. Suppose the address of something in the current bank is `0x5_8000_0000`. The corresponding address in the alternate bank is changed in one bit, `0x5_8400_0000`. For example, suppose the byte at `0x5_8000_0000` have value `0xaa` and, while running U-Boot in the current bank, and you read the byte at `0x5_8400_0000` and see `0xbb`. Now, reboot after changing SW9 bits 3:5 so you are running U-Boot from what was the alternate bank and is now the current bank. You will see `0xbb` at `0x5_8000_0000` and `0xaa` at `0x5_8400_0000`.

This scheme is very useful, because it means you can always deploy images to the alternate bank using the same addresses, regardless of which bank happens to be "current". In other words, the steps to write an image into bank 4 using U-Boot running from bank 0 are the same as the steps to write an image to bank 0 using U-Boot running from bank 4.

4.4.9.3.2.7 Overall NOR deployment strategy

Let's take an example where you have a functioning U-Boot in bank 0 and you want to deploy a new image set that requires a different SYSCLK value than the one currently in use with the bank 0 images. It is always best to deploy into the alternate bank.

1. Use U-Boot commands to write the new images to the alternate bank, i.e. write them to the alternate bank addresses. The exact commands are presented in a later section.
2. Power off the board.
3. Change SW7 bits 1:3 to select the new SYSCLK.
4. Change SW9 bits 3:5 to load from bank 4.
5. Power on and test the new images. They are running with bank 4 as the "current" bank.
6. If you are happy with the new images and want to put them into bank 0 also, simply repeat step 1 to write them to the alternate bank (which is now bank 0).
7. Power off the board.
8. Change SW9 bits 3:5 to load from bank 0.
9. Power on. You are now running the new images from bank 0 and they are also deployed to bank 4.

If you are repeatedly (because you are developing) deploying new images that don't require a SYSCLK change, the following strategy can be convenient and is simpler.

1. Boot from bank 0 (i.e. power on with SW9 bits 3:5 selecting bank 0).
2. Load the new images into the alternate bank (bank 4).
3. Enter the `qixis_reset altbank` command. You will boot into your new images (in bank 4) without changing any switches. But take care to look at what U-Boot prints. If your new images were catastrophically bad, the board may automatically boot again into bank 0.
4. Test your new images and repeat this process as needed.

Note that this simpler procedure will fail if the new images require a change to SYSCLK. It will fail for the obvious reason that it contains no change to the SYSCLK frequency.

4.4.9.3.3 NOR Flash layout for bank 0 and bank 4

Images	Size	vbank0	vbank4
RCW + PBI	1MB	0x5_8000_0000	0x5_8400_0000

4.4.9.4 Booting LS2085ARDB/LS2088ARDB

This section sumamrizes booting U-Boot and Linux using images that are already deployed to the board's NOR flash.

4.4.9.4.1 Booting U-Boot on the RDB

By default (per board switch settings), the boot loader (U-Boot) image located in NOR flash bank 0 runs on power on. Press any key while U-Boot is counting down to stop U-Boot from automatically running the "bootcmd" variable and booting Linux.

As the U-Boot boots to its prompt, users can use the commands listed below to deploy new images onto the RDB.

4.4.9.4.2 Booting Linux on the RDB

Booting Linux is controlled by the contents of U-Boot enviroment variable "bootcmd".

U-Boot passes the contents of U-Boot environment variable "bootargs" to Linux as boot-time kernel parameters. The commands in this variable are automatically run and Linux boots after U-Boot counts down a number of seconds given by U-Boot environment variable "bootdelay". Variable bootdelay can be set to -1 to avoid automatically booting Linux.

One can view the values of U-Boot enviroment variables using the U-Boot "printenv" command. The critical variables for booting Linux and their default values are shown below.

1. bootargs: contains parameters that are passed to the Linux kernel before it starts.

   ```
   printenv bootargs
   bootrgs=console=ttyS1,115200 root=/dev/ram0 earlycon=uart8250,mmio,0x21c0600,
   ramdisk_size=0x2000000 default_hugepagesz=2m hugepagesz=2m hugepages=256
   ```

   Notes on these kernel parameters:

   - Select ttyS1 as the console serial port (ttyS0 will not work on early LS2085A RDB/ LS2088A RDB boards, prior to Rev D).
   - Select file system to be a RAM disk populated from an image in the kernel itb file.
   - Allocate huge pages for user space (ODP) use. This is not needed unless you plan to use ODP. Please see ODP documentation for more information.

2. Environment variable "mcinitcmd" contains commands used during U-Boot for Management Complex load. It is not mandatory but very useful. Please refer U-Boot Environment Variables Relating to DPAA2 on page 237 for more information.

   ```
   printenv mcinitcmd
   mcinitcmd=fsl_mc start mc 0x580300000 0x580800000
   ```

3. Environment variable "bootcmd" contains commands used to boot Linux. The image needs to be copied to DDR first.

```
printenv bootcmd
bootcmd=cp.b $kernel_start $kernel_load $kernel_size && bootm $kernel_load
```

U-Boot enviroment variables such as "kernel_load" contain addresses used in the boot process. You can inspect them using the U-Boot "printenv" command. "bootcmd" command may change depending upon mcinitcmd env variable.

For information about the location of images in Flash, see NOR Flash layout for bank 0 and bank 4 on page 224.

4.4.9.5 Deploying Images

This section describes deploying image files on the RDB.

4.4.9.5.1 Updating images on the RDB

The update procedure assumes you have a working U-Boot image on the RDB. You will use U-Boot commands to download and flash new images into the "other" bank of the board's NOR flash. It is assumed that NOR flash is the boot device. This is controlled by switches on the board.

Images on the RDB can be updated by downloading new images from a host system connected to the RDB using any of the board's Ethernet ports, either one of the DPAA2 Ethernet ports on the front of the system or the PCIe Ethernet card on the back.

The following images must be programmed into the NOR flash in order for the U-Boot boot loader to function:

- PBL image (controls SerDes and PLL configurations, etc.)
- PPA Binary
- U-Boot image itself
- Cortina PHY firmware image (for the optical Ethernet ports).

U-Boot can read the other images needed to boot Linux from other devices such as disk drives or a TFTP server. U-Boot is very flexible. This document, however, assumes that these other images are also programmed into the NOR flash.

- Management Complex firmware, an itb format file.
- Management Complex data path control (DTC) file, a dtb format file.
- Management Complex data path layout (DPL) file, a dtb format file.

U-Boot has the capability to program images into the NOR flash. The general procedure is to TFTP the images from a TFTP server via Ethernet into RDB DDR and then program the images into NOR.

The section below describes the U-Boot commands to do this.

Recall that the NOR flash is deviced into banks. The commands below program the images into the "other" bank, i.e. if you have booted bank 0, the commands program bank 4. If you have booted from bank 4, the commands program bank 0. This process ensures that your board remains functional if you program erroneous images into the "other" bank because the good image remains in the current bank.

Normally, you boot from bank 0 and then program bank 4. Then, boot the images in bank 4 to test them.

If desired, you can use the same commands while booted from bank 4 to program bank 0.

4.4.9.5.2 Detailed deployment steps

This section describes in detail the steps needed to deploy a new image set on the target RDB board with the following assumptions: there is already a working U-Boot from previous early access releases in NOR flash bank 0. In summary, the steps are:

1. Place the images files onto the tftp server

2. Boot the RDB from bank 0.
3. Set up networking on the RDB (this assumes there is serial port access to the RDB).
4. Choose the files to be deployed onto the RDB's NOR flash bank 4 (actually the "other" bank).
5. Perform the deployment to bank 4 via TFTP.
6. Boot bank 4 and test the images in it.
7. Optionally, repeat the steps to deploy to bank 0.

Place the images to be deployed onto the TFTP server.

First, you must have a working TFTP server. There are so many ways to do it. The process depends on which operating system your server runs. Even if your server is running Linux, the process of settting up a TFTP server varies from Linux distribution to Linux distribution. Beware of firewall settings on your server.

The SDK images to put onto your TFTP server can be obtainedin two different ways:

1. Simply copy them from the "images" ISO that is available as part of the release.
2. Install the "sources" ISO onto your build server and build all of the images from source code. See "Getting Started with Yocto Project".

Boot from bank 0

Connect a serial cable to the upper RS-232 port and use settings 115200 baud, 8 data bits, 1 stop bit, no parity, no flow control.

Be sure SW9 bits 3:5 are off-off-off to boot from bank 0.

Power on the board.

Press a key using the serial port to stop U-Boot from booting Linux.

Set up networking on the RDB

The RDB must be on the same network as the TFTP server that contains the images you wish to flash. It is wise to test your RDB's networking before starting the image flashing process.

When U-Boot starts, it prints a list of available network interfaces, but the names U-Boot uses for the interfaces vary depending on which U-Boot version you are currently running.

Few early access releases' U-Boot prints something like this: "DPNI1, e1000#0 [PRIME]" where "e1000#0" is the e1000 PCIe card and "DPNI1" depends on your data path layout file but likely corresponds to DPMAC5 (right most copper port).

But later releases print the list of available interfaces using names like "DPMAC1@xgmii [PRIME], DPMAC2@xgmii, DPMAC3@xgmii, DPMAC4@xgmii, DPMAC5@xgmii, e1000#0".

Use any of the interfaces that U-Boot prints for deployment. Select the interface to use by setting the U-Boot "ethact" variable. The example below uses DPMAC5@xgmii.

Make sure the Management Complex (MC) firmware is started before doing U-Boot networking. Again, this varies depending on what version of U-Boot you are currently running. The MC will automatically load via the `mcinitcmd` U-Boot environment variable:

```
=> pri mcinitcmd
mcinitcmd=fsl_mc start mc 0x580300000 0x580800000
```

Unset the `mcinitcmd` if you do not intend to load the MC by default.

At this point, you can test U-Boot networking. Of course, select values that match your network, including the value of ethact.

```
=> setenv ethact DPMAC5@xgmii
=> setenv ipaddr 192.168.1.100
=> setenv netmask 255.255.255.0
=> setenv serverip 192.168.1.254
```

```
=> ping $serverip
Using DPMAC5@xgmii device
host 192.168.1.254 is alive
```

Choose the files you want to deploy

The table below summarizes the images to be programmed and their "other bank" address in the NOR flash.

NOTE

You must select image file names per the instructions below. The table contains symbolic names for the image files.

Binary	Description	**Other** (bank4) address
pbl_img	(RCW + PBL) binary (mandatory)	0x584000000
uboot_img	u-boot bootloader (mandatory)	0x584100000
mcfw_img	MC firmware image (mandatory)	0x584300000
mcdpc_img	Data Path Configuration file (mandatory)	0x584800000
mcdpl_img	Data Path Layout file (mandatory)	0x584700000
cor_img	Cortina PHY firmware (mandatory)	0x585000000
kern_img	Linux kernel + Platform Device Tree + Rootfs	0x585100000
ppa_img	PPA firmware	0x584a00000

Selecting a PBL (RCW) Image

The SDK release supports the following PBL files. Pick one of them according to your needs.

- **`ls2088ardb/ls2088ardb/FFFFFFFF_PP_HH_0x2a_0x41/PBL_0x2a_0x41_1600_600_1600_1600.bin`**
  - Core clock: 1600 MHz
  - Required board SYSCLK: 600 MHz (SW7[1:3] = off-on-off)
  - DDR: 1600 MHz
- **`ls2088ardb/ls2088ardb/FFFFFFFF_PP_HH_0x2a_0x41/PBL_0x2a_0x41_1800_700_1866_1600.bin`**
  - Core clock: 1800 MHz
  - Required board SYSCLK: 700 MHz (SW7[1:3] = off-on-off)
  - DDR: 1866 MHz
- **`ls2088ardb/ls2088ardb/FFFFFFFF_PP_HH_0x2a_0x41/PBL_0x2a_0x41_2000_800_2133_1600.bin` (RevF only)**
  - Core clock: 1000 MHz
  - Required board SYSCLK: 800 MHz (SW7[1:3] = off-on-off)
  - DDR: 2133 MHz

Choose specific files to deploy

The files to deploy are available on the images ISO or as a result of building from source using Yocto. Set U-Boot variables to the names of the files to deploy. The directories in the names will depend on how you set up your TFTP server.

```
=> setenv pbl_img sdk/ls2088ardb/rcw/rcw_0x2a_0x41/PBL_1800_700_1866_1600_0x2a_0x41.bin
=> setenv uboot_img sdk/ls2088ardb/u-boot-ls2088ardb.bin
=> setenv cor_img sdk/ls2088ardb/ls2-phy/CS4340/phy_firmware/cs4315-cs4340-PHY-ucode.txt
=> setenv mcfw_img sdk/ls2088ardb/mc_app/mc.itb
```

```
=> setenv mcdpc_img sdk/ls2088ardb/dpl-examples/dpc-0x2a41.dtb
=> setenv mcdpl_img sdk/ls2088ardb/dpl-examples/dpl-eth.0x2A_0x41.dtb
=> setenv kern_img sdk/ls2088ardb/kernel-ls2088ardb.itb
=> setenv ppa_img sdk/ls2088ardb/ppa.itb
```

Perform the deployment to bank 4 via TFTP

The following U-Boot commands TFTP images, erase old images, and program new images to the NOR flash addresses of the "other" bank.

```
# Flash PBL
=> tftp 0xa0000000 $pbl_img && erase 0x584000000 0x5840FFFFF && cp.b 0xa0000000
0x584000000 $filesize

# Erase old U-Boot environment
=> erase 0x584200000 +0x100000

# Flash U-Boot
=> tftp 0x80000000 $uboot_img && erase 0x584100000 +$filesize && cp.b 0x80000000
0x584100000 $filesize

# Flash Cortina (optical) PHY firmware
=> tftp 0x80000000 $cor_img && erase 0x585000000 +$filesize && cp.b 0x80000000
0x585000000 $filesize

# Flash MC-related images
=> tftp 0x80000000 $mcfw_img && erase 0x584300000 +0x300000 && cp.b 0x80000000 0x584300000
0x300000
=> tftp 0x80000000 $mcdpc_img && erase 0x584800000 +$filesize && cp.b 0x80000000
0x584800000 $filesize
=> tftp 0x80000000 $mcdpl_img && erase 0x584700000 +$filesize && cp.b 0x80000000
0x584700000 $filesize

# Flash FIT image with kernel, device tree, and file system image
=> tftp 0xa0000000 $kern_img && erase 0x585100000 +$filesize && cp.b 0xa0000000
0x585100000 $filesize

# Flash PPA image
=> tftp 0x80000000 $ppa_img && erase 0x584a00000 +$filesize && cp.b 0x80000000
0x584a00000 $filesize
```

Boot bank 4 and test the images in it

If the new images in bank 4 require a different SYSCLK value than the images in bank 0, you must use the following steps.

1. Power down the board.
2. Set SW7 bits 1:3 to select the SYSCLK frequency needed for the bank 4 images.
3. Set SW9 bits 3:5 to on-off-off to boot from bank 4. (bank 0 is off-off-off)
4. Power on the board.

If the new bank 4 images require the same SYSCLK frequency as the bank 0 images, there is a short cut. Enter the U-Boot command

```
=> qixis_reset altbank
```

to boot bank 4. You can enter

```
=> qixis_reset
```

from bank 4 U-Boot to boot bank 0 again.

After booting bank 4, press a key to stop Linux from automatically booting.

Use the U-Boot "printenv" to inspect the default U-Boot environment variable values. You may want to adjust some of them according to your names, e.g. the network settings variables such as "ipaddr" and "netmask".

Even if you make no changes, do a U-Boot "saveenv" command to update the values in NOR flash.

A complete U-Boot boot log follows.

```
U-Boot 2016.01LS2088A-SDK+g4cd72d5 (Oct 18 2016 - 03:54:37 +0800)

SoC:  LS2088E Version:1.0 (0x87090010)

Optionally, repeat the steps to deploy to bank 0

You can deploy images to bank 0 by booting U-Boot from bank 4 and using the same flash programming steps documented above. The addresses in NOR flash do not change because they always represent the "other" bank, i.e. the bank you have not booted.

4.4.9.5.3 Deploying the full file system

The images ISO contains a compressed tar file with a large number of Yocto packages built, including native GNU tools.

It is large enough that it must be deployed to a mass storage device such as a SATA drive, USB drive, or SD card.

This can be done by booting the normal RAM disk file system. Choose a mass storage device. This example will use /dev/sdc. The example target system happens to have two SATA drives and a USB drive (/dev/sdc). Then perform these steps.

On the RDB booted from the RAM disk:

```
# bring up networking (example uses rightmost copper port) and set
# the time and date using any method
ifconfig ni0 192.168.1.100/24
rdate -s 192.168.1.254

# Use umount to ummount any /dev/sdc partitions that happen to be mounted
# and then create a partition on /dev/sdc.
fdisk /dev/sdc
o    - new DOS partition table
n    - new partition
```

```
p    - primary
<cr> - default partition number
<cr> - default partition first sector
<cr> - default partition last sector
w   - write partition table and exit

# Be sure /dev/sdc1 did get get mounted.  Then make a file system on it
# and mount that file system.
umount /run/media/sdc1   (if needed)
mkfs.ext4 /dev/sdc1
mkdir /mnt/newroot
mount /dev/sdc1 /mnt/newroot
```

On the machine with the images ISO, scp the full file system tar file to the RDB.

```
scp full-rootfs/LS2088A_SDK_AARCH64_20160719_ROOTFS_Image.tar.gz root@192.168.1.100:/mnt/newroot
```

Back on the RDB, untar the file system.

```
cd /mnt/newroot
tar pzxf LS2088A_SDK_AARCH64_20160719_ROOTFS_Image.tar.gz
sync    # Might take some time for USB or SD
```

Reboot the RDB with bootargs and bootcmd set as follows.

```
setenv bootargs console=ttyS1,115200 root=/dev/sdc1 rootwait earlycon=uart8250,mmio,0x21c0600
ramdisk_size=0x2000000 default_hugepagesz=2m hugepagesz=2m hugepages=256 setenv bootcmd 'fsl_mc
apply dpl 0x580700000 && cp.b $kernel_start $kernel_load $kernel_size && bootm
$kernel_load:kernel@1 - $kernel_load:fdt@1'
```

4.4.9.6 AQ405 Firmware Update

This chapter is required only if a user needs to program or update the AQ405 firmware on the LS2085ARDB/LS2088ARDB. This is already programmed on boards received from the factory. Unless a firmware update is required, please ignore these steps.

LS2085ARDB/LS2088ARDB has the AQ405, which contains a copper PHY and it needs firmware in order to be programmed; this firmware is permanent and needs to be programmed once. Over time, AQ405 firmware upgrades may be required. The following sections provide instructions on how to check the firmware version and upgrade it if needed.

4.4.9.6.1 Check firmware version

Run the following U-Boot commands to check the AQ405 firmware version. The firmware version should be 0x203 0x52.

```
=> mdio read FSL_MDIO1 0  0x1e.0x20
Reading from bus FSL_MDIO1
PHY at address 0:
30.32 - 0x203

=> mdio read FSL_MDIO1 0  0x1e.0xc885
Reading from bus FSL_MDIO1
PHY at address 0:
 30.51333 - 0x52
```

4.4.9.6.2 Update new firmware

Assumption: The host machine used to download images is running a TFTP server, with server IP 192.168.1.1, and all images to be downloaded are available in the tftpboot folder. Also, the host machine must be connected to the RDB system using the PCIe NIC card as described in Board preparation on page 219.

1. Download AQ_API.bin from host machine:

```
tftp 0x80300000 AQ_API.bin
```

2. Download AQ28nm-FW_2.3.52_Freescale_T2085RDB_030415.cld from host machine:

```
tftp 0x80000000 AQ28nm-FW_2.3.52_Freescale_T2085RDB_030415.cld
```

NOTE

Download images in the order mentioned above (1 followed by 2)

3. Run the following commands to update the new firmware:

```
go 0x80300000 FSL_MDIO1 0x0 0x80000000 $filesize
```

Check for the following logs on U-Boot prompt:

```
=> go 0x80300000 FSL_MDIO1 0x0 0x80000000 $filesize
## Starting application at 0x80300000 ...
Actual U-Boot ABI version 8

```

4.4.9.7 Supported RCW Binaries

LS2088A

LS2088A supports following RCW binaries:

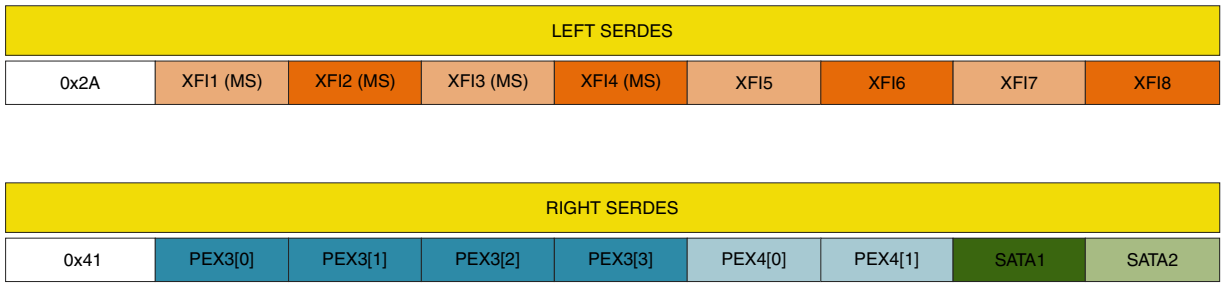
Table 54. RCW binary

SoC	Binary Name	Descripton	Required SYSCLK
LS2088A	PBL_0x2a_0x41_1600_600_1600_1600.bin	Core: 1600 MHz, Platform: 600 MHz, DDR: 1600 MHz, DP DDR 1600 MHz	100 MHz, SW7[1:3] = 010
LS2088A	BL_0x2a_0x41_1600_600_1600_1600.bin	Core: 1800 MHz, Platform: 700 MHz, DDR: 1866 MHz, DP DDR 1600 MHz	100 MHz, SW7[1:3] = 010
LS2088A	PBL_0x2a_0x41_2000_800_2133_1600.bin	Core: 1800MHz, Platform: 800MHz, DDR: 2133 MHz, DP DDR 1600 MHz	100 MHz, SW7[1:3] = 010

NOTE

The RCW's provided with the release enable the following features:

1. The figure below shows the SERDES configuration supported for LS2088A. Note that LS2088A supports upto 5 ports out of the 8 available on the RDB at a time



2. Boot location as NOR flash
3. Enables 4 UART without flow control
4. Enables I2C1, I2C2, I2C3, I2C4, SDHC, IFC, PCIe, SATA

4.4.9.7.1 Generating 500MHz RCW/PBL binary using QCVS tool

QCVS is a tool which provides a graphical user interface (GUI) for editing a PBL (RCW) files in decoded form. The PBL (RCW) file can be also be created from scratch or imported from an existing reset configuration word.

Please refer to QorIQ Configuration and Validation Suite for more information.

Steps for generating 500MHz RCW/PBL file using 533MHz PBL (RCW) file:

1. Create project and import the 533MHz file as outlined in *PBL Configuration using QCVS* (document: AN5260)
2. Update PLL configuration to set SYS_PLL_RAT to 10:1, CGA_PLLx_RAT to 18:1 and CGB_PLLy_RAT to 18:1 (here x,y can be 1, 2)

PLL CONFIGURATION (Bits 143-0)

CGB_PLL2_RAT [63-58]	0b010010 - 18:1 (Async mode)
SYS_PLL_SPD [128]	0b0 - High speed operation (vco_d...
MEM_PLL_SPD [129]	0b0 - High speed operation (vco_d...
MEM2_PLL_SPD [130]	0b0 - High speed operation (vco_d...
CGA_PLL1_SPD [132]	0b0 - High speed operation (vco_d...
CGA_PLL2_SPD [133]	0b0 - High speed operation (vco_d...
CGB_PLL1_SPD [135]	0b0 - High speed operation (vco_d...
CGB_PLL2_SPD [136]	0b0 - High speed operation (vco_d...

3. Re-generate the PBL (RCW) file

4.4.9.7.2 Generating RCW for DSPI access

The SDK release does not provide a RCW file for the LS2088A DSPI access. If required, a user can generate the needed file be modifying the release PBL (RCW) file using the QCVS tool.

QCVS is a tool which provides a graphical user interface (GUI) for editing a PBL (RCW) files in decoded form. The PBL (RCW) file can be also be created from scratch or imported from an existing reset configuration word.

Refer to QorIQ Configuration and Validation Suite for more information.

Steps for generating RCW for DSPI access file:

1. Create project and import the release file (e.g. `PBL_1800_700_1866_1600_0x2a_0x41.bin`) as outlined in *PBL Configuration using QCVS* (document: AN5260)
2. Update RCW field configuration to set below table:

BIT(s)	Field Name	Setting
389-388	IIC3_BASE	11
393-392	SPI_BASE_BASE	00
395-394	SPI_PCS_BASE	00

3. Re-generate the PBL (RCW) file

4.4.9.8 U-Boot DPAA2 Commands

U-Boot contains a command called "fsl_mc". The primary purposes of this command are to load and start the Management Complex (MC) and to apply its Data Path Control (DPC) file.

The command is summarized below.

```
=> help fsl_mc
fsl_mc - DPAA2 command to manage Management Complex (MC)
Usage:
fsl_mc start mc [MC_FW_addr] [DPC_addr] - Start Management Complex
fsl_mc apply DPL [DPL_addr] - Apply DPL file
fsl_mc start aiop [AIOP_FW_addr] - Start AIOP
```

The addresses can be in NOR flash or DDR. The latter is used when MC files are loaded from a boot device like a disk drive.

Normally, users will not use fsl_mc to load and start the AIOP. Instead, this should be done using the "aiop_tool" Linux user space command. The fsl_mc command is used to load and start the AIOP only for low-level testing.

MC must be started before using DPAA2 networking in U-Boot, Linux, or both

DPAA2 networking depends on the MC, so DPAA2 networking cannot be used until the MC is loaded, supplied with a DPC file, and started. This is true for both U-Boot and Linux.

Here is an example that assumes the MC firmware image and Data Path Configuration (DPC) image are both in NOR flash.

fsl_mc start mc 0x580300000 0x580800000

U-Boot environment variable "mcinitcmd" can be used to automate loading and starting the MC, e.g. it can be set to contain the command above. Refer to the U-Boot Environment Variables Relating to DPAA2 on page 237 section for more information.

U-Boot DPAA2 networking does not rely on the Data Path Layout (DPL) file

U-Boot dynamically creates and destroys the objects it needs for DPAA2 networking. Users should not use the "fsl_mc apply DPL" command before using U-Boot networking.

Linux DPAA2 networking does reply on the DPL

Immediately before booting Linux use "fsl_mc apply DPL" command to apply the DPL (assuming DPL is present on NOR flash). It defines the initial set of DPAA2 objects for Linux. U-Boot networking is not available after executing this command.

```
=> fsl_mc apply DPL 0x580700000
```

As an example, the command above can be used in the U-Boot environment variable "bootcmd".

4.4.9.9 U-Boot Environment Variables Relating to DPAA2

1. DPAA2-specific Environment Variables

   - ***mcboottimeout***: Defines Management Complex boot timeout in milliseconds. If this variable is not defined the complile-time value, CONFIG_SYS_LS_MC_BOOT_TIMEOUT_MS will be the default. Normally, users do not need to set this variable because the default is acceptable.
   - ***mcmemsize***: Defines amount of system DDR to be use by the Management Complex. If this variable is not defined, the compile-time value CONFIG_SYS_LS_MC_DRAM_BLOCK_MIN_SIZE will be the default. Normally, users do not need to set this variable because the default is acceptable.
   - ***mcinitcmd***: Contains commands to load and start the Management Complex automatically before the U-Boot count down to boot starts. If this variable is defined, its contents are "run". The default value assumes that the Management Complex (MC) firmware and Data Path Control file are stored in NOR flash at fixed addresses. The default value is "fsl_mc start mc 0x580300000 0x580800000". Users may change this variable as needed to load the MC files from sources other than NOR into DDR and then start the MC using the fsl_mc command. For example, the files may be on a disk drive.

2. Impliciations for DPAA2 Environment variables that are not specific to DPAA2

   - ***bootcmd***: Contains commands that are automatically executed when the U-Boot "boot" command is run. This happens automatically when the user does not interrupt U-Boot's initial count down. In normal usage, bootcmd should contain the command to apply the Management Complex Data Path Layout (DPL) file because this must be done before booting Linux. The default value of bootcmd assumes that the DPL file is stored in NOR flash at a fixed address. The default is "fsl_mc apply dpl 0x580700000 && cp.b $kernel_start $kernel_load $kernel_size && bootm $kernel_load".

4.4.10 P2041RDB

4.4.10.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.10.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options for the P2040/P2041 device. The table below lists the default switch settings. For a description of these settings, see P2041RDB Reference Manual, Section 22 Switch Settings.

Table 55. Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	ON [1]	OFF [0]	ON [1]	ON [1]	OFF [0]	ON [1]	OFF [0]	OFF [0]
SW2	OFF	OFF	ON	OFF	OFF	ON	OFF	OFF
SW3	OFF	ON	OFF	ON	OFF	ON	ON	ON

Note that with the default SW1 settings, the following are selected.

SW1[1:5] = 10110:

RCW configuration source is eLBC GPCM 16-bit NOR Flash

SW1[6:8] = 100:

SYSCLK output frequency is 83.33MHz.

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 56. Boot Device Scenarios

Alternate Boot Devices	Change the following switch settings
SD card boot	SW1 [1:5] = 01100
SPI Flash boot	SW1 [1:5] = 10100
NAND Flash boot	SW1 [1:5] = 10010

4.4.10.3 U-Boot Environment Variables

4.4.10.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;fsl_fm1_xaui_phy:xfi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm1_xaui_phy:xfi
```

4.4.10.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.10.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for P2041 version information (e.g., P2041E version 2.0) and also for the version of FMan microcode currently flashed on the P2041RDB (e.g. microcode version 106.1.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.0:

```
fsl_fman_ucode_p2041_r1.0_106_1_15.bin
```

- For silicon revision 1.1:

```
fsl_fman_ucode_p2041_r1.1_106_1_15.bin
```

- For silicon revision 2.0:

```
fsl_fman_ucode_p2041_r2.0_106_1_18.bin
```

NOTE

(i) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iii) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.10.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains RCW binaries for use on the P2041RDB:

- RR_PH_0x19/rcw_5g_1200mhz.bin
- RR_PH_0x19/rcw_5g_1500mhz.bin
- RR_PX_0x09/rcw_14g_1500mhz.bin (default)

The RCW directories' names for the P2041RDB conform to the following naming convention:

```
ab_cd_e
```

Table 57. P2041RDB Naming Convention Legend

Slot	Convention
a	'R' if RGMII@DTSEC4 is supported 'N' if not available/not used
b	'R' if RGMII@DTSEC5 is supported 'N" if not available/not used
c [What is available in Slot 1] d [What is availabel in Slot 2 or SATA]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'S' if SGMII 'H' if SATA 'A' is AURORA
e	Hex value of serdes protocol value

For exmaple,

```
RR_PH_0x19
```

means:

- RGMII@DTSEC4
- RGMII@DTSEC5
- PCIE [Slot 1]
- SATA [Slot 2 not used]
- SERDES Protocol is 0x19

Below is a table that maps the different ports available on P2041RDB and their names in different environments.

Table 58. Port Map

Label on Panel of the P2041 RDB	Port in U-boot	Port in Linux	FMAN Address
GETH1-SGMII	FM1@DTSEC1	fm1-gb0	0xffe4e0000
GETH2-SGMII	FM1@DTSEC2	fm1-gb1	0xffe4e2000
GETH3-SGMII	FM1@DTSEC3	fm1-gb2	0xffe4e4000

Table continues on the next page...

Table 58. Port Map (continued)

GETH4-RGMII	FM1@DTSEC4	fm1-gb3	0xffe4e6000
GETH5-RGMII	FM1@DTSEC5	fm1-gb4	0xffe4e8000
No label (Supported by XAUI Riser Card)	FM1@TGEC1	fm1-10g	0xffe4f0000

4.4.10.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xfe0000000	0xfeffffffff	eLBC	256 MB
0xff4000000	0xff41fffff	Buffer manager software portal	2 MB
0xff4200000	0xff43fffff	Queue manager software portal	2 MB
0xfffdf0000	0xfffdf0fff	FPGA	4 KB
0xf00000000	0xf01ffffff	DCSR	32 MB
0xffa000000	0xffa0fffff	NAND	1 MB
0xc20000000	0xc2fffffff	Serial Rapid I/O 1	256 MB
0xc00000000	0xc1fffffff	PCI Express 1	512 MB
0xff8000000	0xff800ffff	PCI Express 1 I/O	64 KB
0xc40000000	0xc5fffffff	PCI Express 3	512 MB
0xff8020000	0xff802ffff	PCI Express 3 I/O	64 KB
0x00000000	0x7fffffff	Memory controller	2 GB

4.4.10.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for P2041RDB, SW2[2]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU0:  P2041E, Version: 2.0, (0x82180120)
Core:  e500mc, Version: 3.2, (0x80230032)
Clock Configuration:
       CPU0:1500 MHz, CPU1:1500 MHz, CPU2:1500 MHz, CPU3:1500 MHz,
       CCB:750  MHz,
       DDR:666.667 MHz (1333.333 MT/s data rate) (Asynchronous), LBC:93.750 MHz
       FMAN1: 583.333 MHz
       QMAN:  375 MHz
       PME:   375 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 12600000 00000000 241c0000 00000000
       00000010: 648ea0c1 c3c02000 de800000 40000000
       00000020: 00000000 00000000 00000000 d0030f07
       00000030: 00000000 00000000 00000000 00000000
Board: P2041RDB, CPLD version: 4.0 vBank: 0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>cpld reset
```

- Switch to alternate bank:

```
=>cpld reset altbank
```

The table below shows the P2041RDB NOR flash memory map.

Table 59. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768 KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128 KB
0xeff00000	0xeff1ffff	FMAN Ucode (current bank)	128 KB

0xe8000000	0xe801ffff	RCW (current bank)	128 KB

4.4.10.8 Programming a New U-Boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *cpld reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>cpld reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>cpld reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
```

```
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>cpld reset altbank
```

4.4.10.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.10.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.10.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.10.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.10.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.10.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.10.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

   ```
   =>tftp 1000000 <platform_name>-usdpaa.dtb
   =>erase e8800000 +$filesize
   =>cp.b 1000000 e8800000 $filesize
   ```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.10.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
0 - Vitesse VSC8641 <--> FM1@DTSEC5
1 - Vitesse VSC8641 <--> FM1@DTSEC4
2 - Vitesse VSC8221 <--> FM1@DTSEC1
3 - Vitesse VSC8221 <--> FM1@DTSEC2
FM_TGEC_MDIO:
0 - Teranetics TN2020 <--> FM1@TGEC1
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 4 dTSEC interfaces and on the 10GEC interface. If you see “Generic” reported, it is an indication that something is there but the P2041 can’t communicate with the device/port.

Check SGMII Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC1 1
Reading from bus FSL_MDIO0
PHY at address 2:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

Example:

```
=> mdio read FM1@DTSEC1  30
Reading from bus FSL_MDIO0
PHY at address 2:
```

```
30 - 0x25
```

The MAC interface (“fiber side”) link information is in Register #30 on the PHY. The last nibble is of interest. Bit #2 (from the left) is ‘Link Interlock Complete’ (Clause 37).

Check SGMII link Status for Internal PHY

The “TBI PHY” on-chip also has link information. The PHY address is programmed in TBI Physical Address Register (TBIPA) at offset 0x01C in the dTSEC register space.

```
=> md fe4e001c
fe4e001c: 00000008 00000000 00000000 00000000    ..............
```

The TBI PHY address is 0x8. In the TBI MII Register Set, the Status Register (SR) is register 1. So we check PHY=8, REG=1.

These additional registers in the MDIO register space may also be useful:

Offset 0x124 - MII Management Command Register (MIIMCOM)

Offset 0x12c - MII Management Control Register (MIIMCON)

Offset 0x130 - MII Management Status Register (MIISTAT)

Example:

```
=> mm fe4e1124
fe4e1124: 00000001 ? 1                   <==  Prepare for a read by writing a "1" to bit 31
fe4e1128: 0000021e ? 0801                <==  Write PHY address and Register address
fe4e112c: 00001240 ?
fe4e1130: 00000025 ? x
=> mm fe4e1124
fe4e1124: 00000001 ? 0                   <==  Prepare for a read by writing a  "0"  to bit 31
fe4e1128: 00000801 ? x
=> mm fe4e1124
fe4e1124: 00000000 ? 1                   <==  Transistion bit 31 from "0" to "1" in order to read
fe4e1128: 00000801 ?                     <==  Read PHY 8, REG 1
fe4e112c: 00001240 ?                     <==  Not used for read, only used for write cycles
fe4e1130: 0000017d ?                     <==  Data returned from read cycle
```

Here, 0x17d is the result of the read cycle. The ‘Link Status’ bit is bit #2 (from the left) of the last nibble. In this example, the last nibble is d=b'1101', therefore the 'Link Status' bit is "1".

Check XAUI link status for External PHY

In order to check the status of the XAUI link, you can use the *mdio read* command. Since this is a Clause 45 device, we pass three arguments to the *mdio read* command.

```
mdio read <PORT address> <DEVICE Address>.<REGISTER Address>
```

Example:

```
=> mdio read FM1@TGEC1  4.1
Reading from bus FM_TGEC_MDIO
PHY at address 0:
4.1 - 0x6
```

The MAC interface ("fiber side") link information is in Device#4, Register #1 on the PHY. The 'PHY XS Transmit Link Status' bit is bit #2 (from the left) of the last nibble.

Check XAUI Lane Synchronization

Check SERDES register 'Lane Alignment Status' bit to see if the SERDES lanes are correctly synchronized. The 'Lane Alignment Status' bit is bit #2 (from the left) of the 1st nibble. If the lanes are correctly synchronized, this bit is "1" and when the lane synchronization is lost or not acquired, this bit is a "0".

Example:

```
=>md fe0ea250 4
fe0ea250: c800000f 000f0000 00000000 00000000    ................
```

4.4.10.11 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 brd + dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

If your network driver is not working, check your kernel messages. You should not see any errors reported by the FSL FMan MAC based driver:

```
fsl_mac: fsl_mac: FSL FMan MAC API based driver ()
fsl_mac ffe4e0000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e0000.ethernet: FMan MAC address: 00:04:9f:03:11:1e
fsl_mac ffe4e2000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e2000.ethernet: FMan MAC address: 00:04:9f:03:11:1f
fsl_mac ffe4e4000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e4000.ethernet: FMan MAC address: 00:04:9f:03:11:20
fsl_mac ffe4e6000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e6000.ethernet: FMan MAC address: 00:04:9f:03:11:21
fsl_mac ffe4e8000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e8000.ethernet: FMan MAC address: 00:04:9f:03:11:22
```

4.4.11 P3041/P5020DS

4.4.11.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.11.2 Switch Settings

The Development System has user selectable switches for evaluating different boot options for the P3041/P5020 device. The table below lists the default switch settings. For a description of these settings, see P3041/5020DS Hardware Getting Started Guide.

Table 60. Hydra P3041 Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF [0]	ON [1]	ON [1]	OFF [0]	ON [1]	OFF [0]	ON [1]	OFF [0]
SW2	OFF	OFF	ON	OFF	OFF	OFF	OFF	ON
SW3	OFF	ON	OFF	OFF	OFF	OFF	ON	ON
SW4	ON	ON	ON	ON	OFF	ON	OFF	ON
SW5	OFF	OFF	OFF	ON	OFF	ON	OFF	OFF
SW6	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	OFF	OFF	OFF	ON	OFF
SW9	ON	ON	ON	OFF	OFF	OFF	OFF	OFF
SW10	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF

Table 61. Super Hydra P3041 Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF	ON	ON	OFF	ON	OFF	ON	OFF
SW2	OFF	OFF	ON	OFF	OFF	OFF	OFF	ON
SW3	OFF	ON	OFF	OFF	OFF	OFF	OFF	ON
SW4	ON	ON	ON	ON	OFF	ON	OFF	ON
SW5	OFF	OFF	OFF	ON	OFF	ON	OFF	OFF
SW6	OFF	OFF	OFF	OFF	OFF	OFF	OFF	ON
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	OFF	OFF	OFF	ON	OFF
SW9	ON	ON	ON	OFF	OFF	OFF	OFF	OFF
SW10	OFF	OFF	OFF	ON	OFF	OFF	OFF	OFF
SW11	OFF	OFF	ON	OFF	OFF	ON	OFF	OFF
SW12	ON	OFF	ON	ON	OFF	ON	OFF	ON
SW13	ON	ON	ON	OFF	OFF	ON	OFF	ON

Table 62. Hydra P5020 Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF	ON	ON	OFF	ON	OFF	ON	OFF
SW2	OFF	OFF	ON	OFF	OFF	OFF	OFF	ON

Table continues on the next page...

Table 62. Hydra P5020 Default Switch Settings (continued)

SW3	OFF	ON	OFF	OFF	OFF	ON	ON	OFF
SW4	ON	ON	ON	ON	ON	OFF	ON	ON
SW5	OFF	OFF	OFF	ON	OFF	ON	OFF	OFF
SW6	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	OFF	OFF	ON	ON	OFF
SW9	ON	ON	ON	OFF	OFF	OFF	OFF	OFF
SW10	OFF	ON	OFF	ON	OFF	OFF	OFF	OFF

Table 63. Super Hydra P5020 Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF	ON	ON	OFF	ON	OFF	ON	OFF
SW2	OFF	OFF	ON	OFF	OFF	OFF	OFF	ON
SW3	OFF	ON	OFF	OFF	OFF	ON	OFF	OFF
SW4	ON	ON	ON	ON	ON	OFF	ON	ON
SW5	OFF	OFF	OFF	ON	OFF	ON	OFF	OFF
SW6	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	OFF	OFF	OFF	ON	OFF
SW9	ON	ON	ON	OFF	OFF	OFF	OFF	OFF
SW10	OFF	OFF	OFF	ON	OFF	OFF	OFF	OFF
SW11	OFF	OFF	OFF	OFF	OFF	ON	OFF	OFF
SW12	ON	OFF	ON	ON	OFF	ON	OFF	ON
SW13	ON	OFF	ON	OFF	OFF	ON	OFF	ON

NOTE

Please note the following for the Super Hydra P3041 and P5020 :

SW1-11 have ON = 1 and OFF = 0

SW12 and SW13 have ON = 0 and OFF = 1

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 64. Boot Device Scenarios

Alternate Boot Device	Change the following switch settings (OFF=0/ON=1)
SD card boot	SW1 [1:5] = 00110.
SPI Flash boot	SW1 [1:5] = 00101.
NAND flash boot	SW1[1:5] = 01001. SW7[1:4] =1001.

4.4.11.3 U-Boot Environment Variables

4.4.11.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;usb2:dr_mode=peripheral,phy_type=utmi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;usb2:dr_mode=peripheral,phy_type=utmi
```

NOTE

USB2 has an OTG connector on P3041/P5020, but the OTG function is not available on these boards, so the default mode for USB2 is set to '*device*' by adding '*usb2:dr_mode=peripheral,phy_type=utmi*' in hwconfig. If host mode is needed, please remove the define for '*usb2...*' from hwconfig. Please avoid connecting USB2 to another host when USB2 is working in host mode. This might cause damage to the two hosts.

4.4.11.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.11.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for P3041/P5020 version information (e.g., P3041E version 2.0) and also for the version of FMan microcode currently flashed on the P3041DS/P5020DS (e.g. microcode version 106.1.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.0:

```
fsl_fman_ucode_p3041_r1.0_106_1_15.bin
fsl_fman_ucode_p5020_r1.0_106_1_15.bin
```

- For silicon revision 1.1:

```
fsl_fman_ucode_p3041_r1.1_106_1_15.bin
```

- For silicon revision 2.0:

```
fsl_fman_ucode_p3041_r2.0_106_1_18.bin
fsl_fman_ucode_p5020_r2.0_106_1_18.bin
```

NOTE

(i) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iii) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.11.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK contains RCW binaries for use on the P3041/P5020DS:

- RR_HXAPNRP_0x33/rcw_12g_1500mhz.bin (P3041DS)
- RR_HXAPNSP_0x36/rcw_15g_1500mhz.bin (P3041DS - default)
- RR_HXAPNRP_0x33/rcw_12g_2000mhz.bin (P5020DS)
- RR_HXAPNSP_0x36/rcw_15g_200mhz.bin (P5020DS - default)

The RCW directories' names for the P3041/P5020DS conform to the following naming convention:

```
ab_cdefghi_j
```

Table 65. P3041/P5020DS Naming Convention Legend

Slot	Convention
a	'R' if RGMII@DTSEC4 is supported 'N' if not available/not used
b	'R' if RGMII@DTSEC5 is supported 'N" if not available/not used
c [What is available in Slot 1] d [What is availabel in Slot 2] e [What is available in Slot 3] f [What is available in Slot 4] g [What is available in Slot 5] h [What is available in Slot 6] i [What is available in Slot 7]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'H' if SATA 'A' is AURORA
j	Hex value of serdes protocol value

For exmaple,

```
NR_HXAPNSP_0x36
```

means:

- No RGMII@DTSEC4
- RGMII@DTSEC5
- SATA [Slot 1 not used]
- XAUI on Slot 2
- AURORA on Slot 3
- PCIe on Slot 4
- Slot 5 is not used
- SGMII on Slot 6
- PCIe on Slot 7
- SERDES Protocol is 0x35

Below is a table that maps the different ports available on P3041/P5020DS and their names in different environments.

Table 66. Port Map

Label on P3041/P5020DS	Port in U-Boot	Port in Linux	FMan Address
N/A	FM1@DTSEC1	fm1-gb0	0xffe4e0000
N/A	FM1@DTSEC2	fm1-gb1	0xffe4e2000
N/A	FM1@DTSEC3	fm1-gb2	0xffe4e4000
N/A	FM1@DTSEC4	fm1-gb3	0xffe4e6000
N/A	FM1@DTSEC5	fm1-gb4	0xffe4e8000
N/A	FM1@TGEC1	fm1-10g	0xffe4f0000

4.4.11.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xfe0000000	0xfeffffffff	eLBC	256 MB
0xff4000000	0xff41fffff	Buffer manager software portal	2 MB
0xff4200000	0xff43fffff	Queue manager software portal	2 MB
0xfffdf0000	0xfffdf0fff	FPGA	4 KB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xf00000000	0xf01ffffff	DCSR	32 MB
0xffa000000	0xffa0fffff	NAND	1 MB
0xc20000000	0xc2fffffff	Serial Rapid I/O 1	256 MB
0xc00000000	0xc1fffffff	PCI Express 1	512 MB
0xff8000000	0xff800ffff	PCI Express 1 I/O	64 KB
0xc40000000	0xc5fffffff	PCI Express 3	512 MB
0xff8020000	0xff802ffff	PCI Express 3 I/O	64 KB
0x00000000	0x7fffffff	Memory controller	2 GB

4.4.11.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for P3041/P5020DS, SW7[0:3]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU0:  P3041E, Version: 2.0, (0x82190320)
Core:  e500mc, Version: 3.2, (0x80230032)
Clock Configuration:
       CPU0:1500 MHz, CPU1:1500 MHz, CPU2:1500 MHz, CPU3:1500 MHz,
       CCB:750  MHz,
       DDR:666.667 MHz (1333.333 MT/s data rate) (Asynchronous), LBC:93.750 MHz
       FMAN1: 583.333 MHz
       QMAN:  375 MHz
       PME:   375 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 12600000 00000000 241c0000 00000000
       00000010: d8984a01 03002000 de800000 41000000
       00000020: 00000000 00000000 00000000 10070000
       00000030: 00000000 00000000 00000000 00000000
Board: P3041DS, Sys ID: 0x1c, Sys Ver: 0x12, FPGA Ver: 0x05, vBank: 4
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>pixis reset
```

- Switch to alternate bank:

```
=>pixis_reset altbank
```

The table below shows the P3041/P5080DS NOR flash memory map

Table 67. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768 KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128 KB
0xeff00000	0xeff1ffff	FMAN Ucode (current bank)	128 KB
0xed300000	0xefeffffff	Rootfs (alternate bank)	44 MB

4.4.11.8 Programming a New U-Boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *pixis reset* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
```

```
=>protect on <u-boot_start_addr> +$filesize
=>pixis_reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>pixis_reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>pixis_reset altbank
```

4.4.11.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.11.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.11.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
```

```
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.11.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
```

```
=>bootm 1000000 - c00000
```

Now the board will boot up with NFS filesystem.

4.4.11.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

   ```
   #fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to create the filesystems.

   ```
   # mkfs.vfat /dev/sdb1
   # mkfs.ext2 /dev/sdb2
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdb2 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

   ```
   # cp uImage and uImage.dtb to /temp/boot folder
   # umount /temp
   ```

8. Plug in the SD card to the target board and power on.

4.4.11.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

   ```
   # fdisk /dev/sdx
   ```

3. Use the mkfs command to create the filesystems.

   ```
   # mkfs.ext2 /dev/sdx1
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdx1 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure copy the target kernel image and dtb to sata.

   ```
   # cp uImage and target.dtb to /temp/boot folder
   # umount /temp
   ```

8. Connect the SATA hard drive to the target board and power on.

4.4.11.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

```
=>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>erase e9300000 +$filesize
=>cp.b 1000000 e9300000 $filesize
```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

```
=>tftp 1000000 hv.uImage
=>erase e8700000 +$filesize
=>cp.b 1000000 e8700000 $filesize
```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.12 P4080DS

4.4.12.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.12.2 Switch Settings

The P4080 Development System has user selectable switches for evaluating different boot options for the P4080 device. The table below lists the default switch settings. For a description of these settings, see P4080DS User Guide.

Table 68. Default Switch Settings

	1	2	3	4	5	6	7	8

Table continues on the next page...

Table 68. Default Switch Settings (continued)

SW1	OFF[0]	ON [1]	ON [1]	OFF [0]	ON [1]	OFF [0]	ON [1]	ON [1]
SW2	ON	ON	ON	ON	ON	ON	ON	ON
SW3	OFF	OFF	OFF	OFF	ON	ON	OFF	OFF
SW4	ON	ON	ON	ON	ON	ON	ON	OFF
SW5	ON	ON	ON	ON	ON	ON	ON	ON
SW6	OFF	OFF	OFF	OFF	OFF	OFF	ON	OFF
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	ON	OFF	OFF	OFF	OFF
SW9	ON	ON	ON	OFF	OFF	ON	OFF	OFF
SW10	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 69. Boot Device Scenarios

Alternate Boot Devices	**Change the following switch settings (0=OFF / 1=ON)**
SPI boot	SW1 [1:5] = 00101
SD Flash boot	SW1 [1:5] = 00110

4.4.12.3 U-Boot Environment Variables

The P4080DS is preloaded with U-Boot and Linux images. The following sections will guide the users on how to set the U-Boot environment and configure the U-Boot network parameters.

4.4.12.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;fsl_fm2_xaui_phy:xfi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm2_xaui_phy:xfi
```

4.4.12.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.12.4 Frame Manager (FMan) Microcode

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for P4080 version information (e.g., P4080E version 3.0) and also for the version of FMan microcode currently flashed on the P4080DS (e.g. microcode version 106.2.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 2.0:

```
fsl_fman_ucode_p4080_r2.0_106_2_15.bin
```

- For silicon revision 3.0:

```
fsl_fman_ucode_p4080_r3.0_106_2_18.bin
```

NOTE

(i) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iii) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.12.5 RCW (Reset Configuration Word) and Ethernet Interfaces

The following section provides guidance on how to configure the RCW and Ethernet interfaces based on P4080DS capabilities.

QorIQ SDK 2.0 contains RCW binaries for use on the P4080DS:

- N_RRRSS_0x16/rcw_all_1500mhz_rev{2,3}.bin
- R_PPSXX_0xe/rcw_2sgmii_1500mhz_rev{2,3}.bin
- R_PPSXN_0x10/rcw_13g_1500mhz_rev{2,3}.bin (default)
- R_PPSXN_0x10/rcw_5g_1500mhz_rev{2,3}.bin

The RCW directories' names for the P4080DS conform to the following naming convention:

```
a_bcdef_g
```

Table 70. P4080DS Naming Convention Legend

Label	Convention
a	'R' if RGMII is supported 'N' if not available/not used

Table continues on the next page...

Table 70. P4080DS Naming Convention Legend (continued)

b [what is available in Slot 1] c [what is available in Slot 2] d [what is available in Slot 3] e [what is available in Slot 4] f [what is available in Slot 5]	For the Slots (b...f) 'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'A' is AURORA
g	Hex value of serdes protocol value

For example,

```
R_PPSXX_0xe
```

means:

- RGMII is enabled
- PCIe on slot 1
- PCIe on slot 2
- SGMII on slot 3
- XAUI on slot 4
- XAUI on slot 5

Below is a table that maps the different ports available on P4080DS and their names in different environments.

Table 71. Port Map

Label on ATX chassis	Port in U-boot	Port in Linux	FMAN Address
N/A	FM1@DTSEC2	fm1-gb1	0xffe4e2000
N/A	FM1@TGEC1	fm1-10g	0xffe4f0000
N/A	FM2@DTSEC3	fm2-gb2	0xffe5e4000
N/A	FM2@DTSEC4	fm2-gb3	0xffe5e6000
N/A	FM2@TGEC1	fm2-10g	0xffe5f0000

4.4.12.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xfe0000000	0xfeffffff	eLBC	256 MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xff4000000	0xff41fffff	Buffer manager software portal	2 MB
0xff4200000	0xff43fffff	Queue manager software portal	2 MB
0xfffdf0000	0xfffdf0fff	FPGA	4 KB
0xf00000000	0xf01ffffff	DCSR	32 MB
0xffa000000	0xffa0fffff	NAND	1 MB
0xc20000000	0xc2fffffff	Serial Rapid I/O 1	256 MB
0xc00000000	0xc1fffffff	PCI Express 1	512 MB
0xff8000000	0xff800ffff	PCI Express 1 I/O	64 KB
0xc40000000	0xc5fffffff	PCI Express 3	512 MB
0xff8020000	0xff802ffff	PCI Express 3 I/O	64 KB
0x00000000	0x7fffffff	Memory controller	2 GB

4.4.12.7 Flash Bank Usage

The NOR flash on the board can be seen as eight flash banks. The board DIP switch (for P4080DS, SW7[0:3]) configuration preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log.

```
CPU0:  P4080E, Version: 3.0, (0x82080030)
Core:  e500mc, Version: 3.1, (0x80230031)
Clock Configuration:
       CPU0:1499.985 MHz, CPU1:1499.985 MHz, CPU2:1499.985 MHz, CPU3:1499.985 MHz,
       CPU4:1499.985 MHz, CPU5:1499.985 MHz, CPU6:1499.985 MHz, CPU7:1499.985 MHz,
       CCB:799.992 MHz,
       DDR:649.994 MHz (1299.987 MT/s data rate) (Asynchronous), LBC:99.999 MHz
       FMAN1: 599.994 MHz
       FMAN2: 599.994 MHz
```

```
       QMAN:  399.996 MHz
       PME:   599.994 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 105a0000 00000000 1e1e181e 0000cccc
       00000010: 3842440c 3c3c2000 de800000 e1000000
       00000020: 00000000 00000000 00000000 008b6000
       00000030: 00000000 00000000 00000000 00000000
Board: P4080DS, Sys ID: 0x17, Sys Ver: 0x01, FPGA Ver: 0x0c, vBank: 4
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>pixis_reset
```

- Switch to alternate bank:

```
=>pixis_reset altbank
```

The table below shows the P4080DS NOR flash memory map.

Table 72. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128KB
0xeff00000	0xeff1ffff	FMAN Ucode (current bank)	128KB
0xed300000	0xefefffff	Rootfs (alternate bank)	44MB

4.4.12.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *pixis_reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>pixis_reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>pixis_reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>pixis_reset altbank
```

4.4.12.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.12.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
=>saveenv
```

NOTE

ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.12.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
```

```
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.12.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
```

```
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.12.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.12.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.12.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

   ```
   =>tftp 1000000 <platform_name>-usdpaa.dtb
   =>erase e8800000 +$filesize
   =>cp.b 1000000 e8800000 $filesize
   ```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

4.4.13 P5040DS

4.4.13.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.13.2 Switch Settings

The Development System has user selectable switches for evaluating different boot options for the P5040 device. The table below lists the default switch settings. For a description of these settings, see P5040DS Hardware Getting Started Guide.

Table 73. Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	OFF	ON	ON	OFF	ON	OFF	ON	OFF
SW2	ON	OFF	OFF	OFF	ON	ON	OFF	ON
SW3	OFF	ON	OFF	OFF	OFF	ON	OFF	OFF
SW4	ON	ON	ON	ON	ON	OFF	OFF	ON
SW5	OFF	OFF	OFF	ON	OFF	ON	OFF	OFF
SW6	OFF	OFF	OFF	OFF	OFF	OFF	ON	ON
SW7	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW8	ON	OFF	ON	OFF	OFF	OFF	ON	OFF
SW9	ON	ON	ON	OFF	OFF	OFF	OFF	OFF
SW10	OFF	OFF	OFF	ON	OFF	OFF	OFF	OFF
SW11	OFF	OFF	ON	ON	ON	OFF	OFF	ON
SW12	ON	OFF	ON	ON	OFF	ON	OFF	ON
SW13	OFF	ON	ON	ON	ON	OFF	OFF	ON

NOTE

SW1-11 have ON = 1 and OFF = 0

SW12 and SW13 have ON = 0 and OFF = 1

Note that with the default settings, the following are selected:

SW1[1:5] = 01101:

RCW configuration source is eLBC GPCM 16-bit NOR flash.

SW1[6:8] = 010:

1.5V DDR3 technology

Continued Boot

Disabled NAND Flash ECC

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 74. Boot Device Scenarios

Alternate Boot Devices	Change these DIP switch settings
SD card booting	SW1 [1:5] = 00110
SPI booting Scenario	SW1 [1:5] = 00101
NAND booting Scenario	SW1[1:5] = 01001 SW7[1:4] = 1001

4.4.13.3 U-Boot Environment Variables

4.4.13.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;fsl_fm2_xaui_phy:xfi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm2_xaui_phy:xfi
```

4.4.13.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
```

```
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.13.4 Frame Manager Microcode (FMan Ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for P5040 version information (e.g., P5040E version 2.1) and also for the version of FMan microcode currently flashed on the P5040DS (e.g. microcode version 106.1.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.0:

```
fsl_fman_ucode_p5040_r1.0_106_1_15.bin
```

- For silicon revision 2.0:

```
fsl_fman_ucode_p5040_r2.0_106_1_15.bin
```

- For silicon revision 2.1:

```
fsl_fman_ucode_p5040_r2.1_106_1_18.bin
```

NOTE

(i)Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iii) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.13.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains the following RCW binary for use on the P5040DS:

- RR_XXSNSpP_0x02/rcw_26g_2267mhz.bin (default)

The RCW directories' names for the P5040DS conform to the following naming convention:

```
ab_cdefghi_j
```

Table 75. P5040DS Naming Convention Legend

Slot	Convention
a	'R' if FM1@DTSEC5 is supported 'N' if not available/not used
b	'R' if FM2@DTSEC5 is supported 'N" if not available/not used
c [What is available in Slot 1] d [What is available in Slot 2] e [What is available in Slot 3] f [What is available in Slot 4] g [What is available in Slot 5] h [What is available in Slot 6] i [What is available in Slot 7]	'N' if not available/not used 'p' if PCIe x2 'P' if PCIe x4 'X' if XAUI 'R' if SRIO 'S' if SGMII 'H' if SATA 'A' is AURORA
j	Hex value of serdes protocol value

For example,

```
RR_XXSNSpP_0x02
```

means:

- RGMII FM1@DTSEC5
- RGMII FM2@DTSEC5
- XAUI on slots 1 and 2
- PCIe on slots 6 and 7

- SGMII on slots 3 and 5
- SERDES Protocol is 0x02

Below is a table that maps the different ports available on P5040DS and their names in different environments.

Table 76. Port Map

Label on P5040DS	Port in U-boot	Port in Linux	FMAN Address
N/A	FM1@DTSEC3	fm1-gb2	0xffe4e4000
N/A	FM1@DTSEC4	fm1-gb3	0xffe4e6000
N/A	FM1@DTSEC5	fm1-gb4	0xffe4e8000
N/A	FM1@TGEC1	fm1-10g	0xffe4ef0000
N/A	FM2@DTSEC3	fm2-gb2	0xffe5e4000
N/A	FM2@DTSEC4	fm2-gb3	0xffe5e6000
N/A	FM2@DTSEC5	fm2-gb4	0xffe5e8000
N/A	FM2@TGEC1	fm2-10g	0xffe5ef0000

4.4.13.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xfe0000000	0xfeffffffff	eLBC	256 MB
0xff4000000	0xff41fffff	Buffer manager software portal	2 MB
0xff4200000	0xff43fffff	Queue manager software portal	2 MB
0xfffdf0000	0xfffdf0fff	FPGA	4 KB
0xf00000000	0xf01ffffff	DCSR	32 MB
0xffa000000	0xffa0fffff	NAND	1 MB
0xc20000000	0xc2fffffff	Serial Rapid I/O 1	256 MB
0xc00000000	0xc1fffffff	PCI Express 1	512 MB
0xff8000000	0xff800ffff	PCI Express 1 I/O	64 KB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xc40000000	0xc5fffffff	PCI Express 3	512 MB
0xff8020000	0xff802ffff	PCI Express 3 I/O	64 KB
0x00000000	0x7fffffff	Memory controller	2 GB

4.4.13.7 Flash Bank Usage

The NOR flash on the board can be seen as eight flash banks. The board DIP switch configuration (for P5040DS, SW7[1:4]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU0:  P5040E, Version: 2.1, (0x820c0021)
Core:  e5500, Version: 1.2, (0x80240012)
Clock Configuration:
       CPU0:2266.667 MHz, CPU1:2266.667 MHz, CPU2:2266.667 MHz, CPU3:2266.667 MHz,
       CCB:800  MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), LBC:100  MHz
       FMAN1: 600 MHz
       FMAN2: 600 MHz
       QMAN:  400 MHz
       PME:   400 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 8cd80000 00000000 a2a29200 00440000
       00000010: 089c4400 00283000 de800000 61000000
       00000020: 00000000 00000000 00000000 10070000
       00000030: 00000000 00000000 00000000 00000000
Board: P5040DS, Sys ID: 0x20, Sys Ver: 0x02, FPGA Ver: 0x03, vBank: 4
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>pixis_reset
```

- Switch to alternate bank:

```
=>pixis_reset altbank
```

The table below shows the P5040DS NOR flash memory map.

Table 77. NOR flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128KB
0xeff00000	0xeff1ffff	FMAN Ucode (current bank)	128KB
0xed300000	0xefeffffff	Rootfs (alternate bank)	44MB
0xed000000	0xed2fffff	Guest image #3 (alternate bank)	3MB
0xecd00000	0xecffffff	Guest image #2 (alternate bank)	3MB

0xe8020000	0xe86fffff	Linux.uImage (current bank)	~7MB
0xe8000000	0xe801ffff	RCW (current bank)	128K

4.4.13.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *pixis_reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>pixis_reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location

of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>pixis_reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *pixis_reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>pixis_reset altbank
```

4.4.13.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.13.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.13.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

   ```
   =>tftp 1000000 <uImage name>
   =>protect off <kernel_start_addr> +$filesize
   =>erase <kernel_start_addr> +$filesize
   =>cp.b 1000000 <kernel_start_addr> $filesize
   =>protect on <kernel_start_addr> +$filesize
   ```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

   ```
   =>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>protect off <ramdisk_start_addr> +$filesize
   =>erase <ramdisk_start_addr> +$filesize
   =>cp.b 2000000 <ramdisk_start_addr> $filesize
   =>protect on <ramdisk_start_addr> +$filesize
   ```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

   ```
   =>tftp c00000 <platform dtb name>
   =>protect off <dtb_start_addr> +$filesize
   =>erase <dtb_start_addr> +$filesize
   =>cp.b c00000 <dtb_start_addr> $filesize
   =>protect on <dtb_start_addr> +$filesize
   ```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.13.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 1000000 <uImage name>
   =>tftp c00000 <platform dtb name>
   =>bootm 1000000 - c00000
   ```

   Now the board will boot up with NFS filesystem.

4.4.13.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

   ```
   #fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to create the filesystems.

   ```
   # mkfs.vfat /dev/sdb1
   # mkfs.ext2 /dev/sdb2
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdb2 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

   ```
   # cp uImage and uImage.dtb to /temp/boot folder
   # umount /temp
   ```

8. Plug in the SD card to the target board and power on.

4.4.13.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

   ```
   # fdisk /dev/sdx
   ```

3. Use the mkfs command to create the filesystems.

   ```
   # mkfs.ext2 /dev/sdx1
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdx1 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure copy the target kernel image and dtb to sata.

   ```
   # cp uImage and target.dtb to /temp/boot folder
   # umount /temp
   ```

8. Connect the SATA hard drive to the target board and power on.

4.4.13.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

```
=>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>erase e9300000 +$filesize
=>cp.b 1000000 e9300000 $filesize
```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

```
=>tftp 1000000 hv.uImage
=>erase e8700000 +$filesize
=>cp.b 1000000 e8700000 $filesize
```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.14 T1023RDB

4.4.14.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.14.2 Switch Settings

The T1023RDB has user selectable switches for evaluating different boot options for the T1023 device. The table below lists the default switch settings. For a description of these settings, see T1023RDB User Guide.

Table 78. Default Switch Settings (NOR boot on Rev-C)

	1	2	3	4	5	6	7	8

Table continues on the next page...

Table 78. Default Switch Settings (NOR boot on Rev-C) (continued)

SW1	ON [0]	ON [0]	ON [0]	OFF [1]	ON [0]	OFF [1]	OFF [1]	OFF [1]
SW2	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
SW3	OFF	OFF	OFF	ON	ON	ON	ON	OFF

Note that with the default settings, the following are selected:

on Rev-B: SW2[1:8] = '00100010', SW3[1] ='1' for SPI boot (NOR flash is not available on Rev-B board.)

on Rev-C: SW1[1:8] = '00010111', SW2[1] ='1' for NOR boot

```
For Rev-C:
   SW3[5] = '0' for bank0(or 'switch bank0' by software)
   SW3[5] = '1' for bank4(or 'switch bank4' by software)

   SW3[3] = '1' for SD card(or 'switch sd' by software)
   SW3[3] = '0' for eMMC (or 'switch emmc' by software)
```

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 79. Boot Device Scenarios

Alternate Boot Devices	**Change the following switch settings (0 = ON, 1 = OFF)**
NOR boot (default boot on Rev-C)	SW1 [1:8] = 0001 0111 SW2 [1:8] = 1111 1111 SW3 [1:8] = 1110 0001
NAND boot	SW1 [1:8] = 1000 0010 SW2 [1:8] = 1011 1101 SW3 [1:8] = 0111 0001 on Rev-B: shunt rework header pin 1-3 and 2-4
SPI boot (default boot on Rev-B)	SW1 [1:8] = 0010 0010 SW2 [1:8] = 1011 1101 SW3 [1:8] = 0110 0001 on Rev-B: shunt rework header pin 1-2 and 3-4
SD boot	SW1 [1:8] = 0010 0000 SW2 [1:8] = 0011 1101 SW3 [1:8] = 0110 0001

4.4.14.3 U-Boot Environment Variables

4.4.14.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=null
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=null
```

4.4.14.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
```

```
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.14.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T1023 version information (e.g., T1023E version 1.0) and also for the version of FMan microcode currently flashed on the T1023RDB (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.0:

```
fsl_fman_ucode_t1024_r1.0_106_4_18.bin
fsl_fman_ucode_t1024_r1.0_107_4_2.bin
fsl_fman_ucode_t1024_r1.0_108_4_9.bin
```

NOTE

(i) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(ii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

4.4.14.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK contains RCW binaries for use on T1023RDB:

- RNSS_NPP_77/rcw_77_1400MHz.bin (default)
- RNSS_NPP_77/rcw_77_1200MHz.bin

The RCW directories' names for the T1023RDB conform to the following naming convention:

```
abcd_efg_h
```

Table 80. T1023RDB Naming Convention Legend

Slot	Convention
a	'R' if RGMII1 @DTSEC4 is supported 'N' if not available/not used
b	'R' if RGMII2 @DTSEC3 is supported 'N" if not available/not used

Table continues on the next page...

Table 80. T1023RDB Naming Convention Legend (continued)

c	'S' if FM1@DTSEC1 1G SGMII is supported 'N" if not available/not used
d	'S' if FM1@DTSEC3 2.5G SGMII is supported 'N" if not available/not used
e [What is availabel in Mini-PCI connector 1] f [What is availabel in Mini-PCI connector 2] g	'N' if not available/not used 'P' if PCIe is available 'X' if XAUI is available 'R' if SRIO is available 'S' if SGMII is available 'H' if SATA is available 'A' is AURORA is available
h	Hex value of SerDes protocol

For example,

```
RNSS_NPP_77
```

means:

- 1G RGMII@DTSEC4
- 1G SGMII@DTSEC1
- 2.5G SGMII@DTSEC3
- PCIE [Mini-PCI connector 1]
- PCIE [Mini-PCI connector 2]
- SerDes Protocol is 0x77

The QorIQ SDK release supports SerDes 0x77 default configuration.

- `RNSS_NPP_77 (1x 2.5G SGMII + 1x 1G SGMII + 1x 1G RGMII + 2x PCIe)`

When using the default configuration, the network interfaces, which include one 1Gbps RGMII ports, one 1Gbps SGMII ports and one 2.5G SGMII port labeled as the following in U-Boot:

FM1@DTSEC4

FM1@DTSEC1

FM1@DTSEC3

Below is a table that maps the different ports available on T1023 RDB and their names in different environments.

Table 81. Port Map

Label on 1U box	Port in U-boot	Port in Linux	FMan Address	Comments

Table continues on the next page...

Table 81. Port Map (continued)

ETH1	FM1@DTSEC4	fm1-mac4	0xffe4e6000	1Gbps RGMII (RTL8211F PHY)
ETH2	FM1@DTSEC1	fm1-mac1	0xffe4e0000	1Gbps SGMII (RTL8211F PHY)
ETH3	FM1@DTSEC3	fm1-mac3	0xffe4e4000	2.5Gbps SGMII (AQR105 PHY)

4.4.14.6 System Memory Map

System memory map on T1023RDB

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xF_FF80_0000	0xF_FF80_FFFF	IFC - NAND Flash	64KB
0xF_FE00_0000	0xF_FEFF_FFFF	CCSRBAR	16MB
0xF_F802_0000	0xF_F802_FFFF	PCI Express 3 I/O Space	64KB
0xF_F801_0000	0xF_F801_FFFF	PCI Express 2 I/O Space	64KB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64KB
0xF_F600_0000	0xF_F7FF_FFFF	Queue manager software portal	32MB
0xF_F400_0000	0xF_F5FF_FFFF	Buffer manager software portal	32MB
0xF_E800_0000	0xF_EFFF_FFFF	IFC - NOR Flash	128MB
0xF_0000_0000	0xF_003F_FFFF	DCSR	4MB
0xC_2000_0000	0xC_2FFF_FFFF	PCI Express 3 Mem Space	256MB
0xC_1000_0000	0xC_1FFF_FFFF	PCI Express 2 Mem Space	256MB
0xC_0000_0000	0xC_0FFF_FFFF	PCI Express 1 Mem Space	256MB
0x0_0000_0000	0x0_7FFF_FFFF	DDR Memory	2GB

4.4.14.7 Flash Bank Usage

The NOR flash (only on Rev-C) on the board can be seen as 8 flash banks. The board DIP switch configuration (for T1023RDB, SW3[5:7]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log (only Rev-C board supports NOR flash, NOR is unavailable on Rev-B):

```
CPU0:  T1023E, Version: 1.0, (0x85490010)
Core:  e5500, Version: 2.1, (0x80241021)
Single Source Clock Configuration
Clock Configuration:
       CPU0:1400 MHz, CPU1:1400 MHz,
       CCB:400  MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), IFC:100  MHz
       FMAN1: 700 MHz
       QMAN:  400 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 0810000e 00000000 00000000 00000000
       00000010: 3b800003 00000012 ec02f000 21000000
       00000020: 00000000 00000000 00000000 00022800
       00000030: 00000130 04020200 00000000 00000006
Board: T1023RDB, RevC, boot from NOR vBank0
SERDES Reference Clocks:
SD1_CLK1=100.00MHZ, SD1_CLK2=125.00MHz
I2C:   ready
SPI:   ready
DRAM:  Detected UDIMM Fixed DDR4 on board
2 GiB (DDR4, 32-bit, CL=11, ECC off)
Flash: 128 MiB
L2:    256 KiB enabled
Corenet Platform Cache: 256 KiB enabled
Using SERDES1 Protocol: 119 (0x77)
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=> switch bank0
or set DIP-switch SW3[5:7]=000
```

- Switch to alternate bank:

```
=> switch bank4
or set DIP-switch SW3[5:7]=100
```

The table below shows the T1023RDB NOR flash memory map.

4.4.14.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>reset
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
```

```
=>protect on <rcw_start_addr> +$filesize
=>reset
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <ucode_start_addr>. <ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <ucode_start_addr> +$filesize
=>erase <ucode_start_addr> +$filesize
=>cp.b 1000000 <ucode_start_addr> $filesize
=>protect on <ucode_start_addr> +$filesize
=>reset
```

4.4.14.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.14.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.14.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.14.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 1000000 <uImage name>
   =>tftp c00000 <platform dtb name>
   =>bootm 1000000 - c00000
   ```

   Now the board will boot up with NFS filesystem.

4.4.14.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

   ```
   #fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to create the filesystems.

   ```
   # mkfs.vfat /dev/sdb1
   # mkfs.ext2 /dev/sdb2
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdb2 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

   ```
   # cp uImage and uImage.dtb to /temp/boot folder
   # umount /temp
   ```

8. Plug in the SD card to the target board and power on.

4.4.14.9.5 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

```
=>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>erase e9300000 +$filesize
=>cp.b 1000000 e9300000 $filesize
```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

```
=>tftp 1000000 hv.uImage
=>erase e8700000 +$filesize
=>cp.b 1000000 e8700000 $filesize
```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.14.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
1 - RealTek RTL8211FS <--> FM1@DTSEC4
3 - RealTek RTL8211FS <--> FM1@DTSEC1
FM_TGEC_MDIO:
2 - Aquantia AQR105 <--> FM1@DTSEC3
```

The results above show that U-Boot was able to see PHYs on each of the 3 DTSEC interfaces.

Check RGMII Link Status for External PHY

In order to check the status of a RGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC4 1
Reading from bus FSL_MDIO0
PHY at address 2:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

4.4.14.11 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

If your network driver is not working, check your kernel messages. You should not see any errors reported by the FSL FMan MAC based driver:

```
fsl_mac: fsl_mac: FSL FMan MAC API based driver ()
fsl_mac ffe4e0000.ethernet: FMan MEMAC
fsl_mac ffe4e0000.ethernet: FMan MAC address: 00:04:9f:03:9e:5a
fsl_mac ffe4e4000.ethernet: FMan MEMAC
fsl_mac ffe4e4000.ethernet: FMan MAC address: 00:04:9f:03:9e:5c
fsl_mac ffe4e6000.ethernet: FMan MEMAC
fsl_mac ffe4e6000.ethernet: FMan MAC address: 00:15:17:be:d6:2d
```

4.4.15 T1024RDB

4.4.15.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.15.2 Switch Settings

The T1024RDB has user selectable switches for evaluating different boot options for the T1024 device. The table below lists the default switch settings. For a description of these settings, see T1024RDB User Guide.

Table 83. Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	ON [0]	ON [0]	ON [0]	OFF [1]	ON [0]	ON [0]	OFF [1]	OFF [1]
SW2	OFF	ON	OFF	OFF	OFF	OFF	OFF	OFF
SW3	ON	OFF	OFF	ON	ON	ON	ON	OFF

Note that with the default settings, the following are selected.

SW1[1:8] = 0001 0011:

NOR Boot mode is selected with default RCW 0x95 in bank0.

SW2[7] = 1:

T1024 uses DDR3L (1.35V).

For 2.5G SGMII: Turn off the board, switch from bank0 to bank4 to use RCW 0x135, set SW3[5] = OFF(1) and SW3[2] = OFF(1)

For 10G Base-T: Turn off the board, switch from bank4 to bank0 to use RCW 0x95, and set SW3[5] = ON(0) and SW3[2] = ON(0)

NOTE: Ignore the above switch settings for SW3[5] and SW3[2], when board is turned on while switching to bank0 using cpld reset or switching to bank4 using cpld reset altbank.

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 84. Boot Device Scenarios

Alternate Boot Devices	**Change the following switch settings** **(0 = ON, 1 = OFF)**
NAND boot	SW1 [1:8] = 1000 1000 SW2 [1:8] = 1011 1111 SW3 [1:8] = 0111 0001
SPI boot	SW1 [1:8] = 0010 0010 SW2 [1:8] = 1011 1111 SW3 [1:8] = 0110 0001
SD Flash boot	SW1 [1:8] = 0010 0000 SW2 [1:8] = 0011 1111 SW3 [1:8] = 0110 0001

4.4.15.3 U-Boot Environment Variables

4.4.15.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1
```

4.4.15.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.15.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T1024 version information (e.g., T1024E version 1.0) and also for the version of FMan microcode currently flashed on the T1024RDB (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.0(the version info please refer to sdk release image):

```
fsl_fman_ucode_t1024_r1.0_106_4_18.bin (*)
fsl_fman_ucode_t1024_r1.0_107_4_2.bin
fsl_fman_ucode_t1024_r1.0_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.15.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK contains RCW binaries for use on T1024RDB:

- RRX_PPP_95/rcw_95_1400MHz.bin (default RCW in bank0 for 10G XFI)
- RRX_PPP_95/rcw_95_1200MHz.bin
- RNS_NPP_135/rcw_135_1400MHz.bin (alternate RCW in bank4 for 2.5G SGMII)
- RNS_NPP_135/rcw_135_1200MHz.bin

The RCW directories' names for the T1024RDB conform to the following naming convention:

```
abc_def_g
```

Table 85. T1024RDB Naming Convention Legend

Slot	Convention
a	'R' if RGMII1 @DTSEC4 is supported 'N' if not available/not used

Table continues on the next page...

Table 85. T1024RDB Naming Convention Legend (continued)

b	'R' if RGMII2 @DTSEC3 is supported 'N" if not available/not used
c	'X' if FM1@TGEC1, XFI 10G Base-T is supported 'S' if FM1@DTSEC3 2.5G SGMII is supported 'N" if not available/not used
d [What is available in PCIe Slot] e [What is availabel in Mini-PCI connector 1] f [What is availabel in Mini-PCI connector 2]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'H' if SATA 'A' is AURORA
g	Hex value of serdes protocol value

For example,

```
RRX_PPP_95
```

means:

- RGMII@DTSEC4
- RGMII@DTSEC3
- XFI 10G, FM1@TGEC1
- PCIE [Slot 1]
- PCIE [Mini-PCI connector 1]
- PCIE [Mini-PCI connector 2]
- SERDES Protocol is 0x95

The QorIQ SDK release supports SerDes 0x95 default configuration.

```
• RRX_PPP_95 (1x 10G XFI + 2x 1G RGMII + 3x PCIe)
```

The QorIQ SDK release also supports SerDes 0x135 for 2.5G SGMII configuration.

```
• RNS_NPP_135 (1x 2.5G SGMII + 1x 1G RGMII + 2x PCIe)
```

When using the default configuration, the network interfaces, which include two 1Gbps RGMII ports and one 10G XFI 10G Base-T port labeled as the following in U-Boot:

FM1@DTSEC3

FM1@DTSEC4

FM1@TGEC1

Below is a table that maps the different ports available on T1024RDB and their names in different environments.

Table 86. Port Map

Label on 1U box	Port in U-boot	Port in Linux	FMan Address	Comments
ETH0	FM1@DTSEC4	fm1-mac4	0xffe4e6000	1Gbps RGMII (RTL8211E PHY)
ETH1	FM1@DTSEC3	fm1-mac3	0xffe4e4000	1Gbps RGMII (RTL8211E PHY)
ETH2	FM1@TGEC1	fm1-mac1	0xffe4e0000	10Gbps Base-T (AQR105 PHY, use rcw_0x95)
ETH3	FM1@DTSEC3	fm1-mac3	0xffe4e4000	2.5Gbps SGMII (AQR105 PHY, use rcw_0x135)

4.4.15.6 System Memory Map

System memory map on T1024RDB

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xF_FFDF_0000	0xF_FFDF_0FFF	IFC - CPLD	4KB
0xF_FF80_0000	0xF_FF80_FFFF	IFC - NAND Flash	64KB
0xF_FE00_0000	0xF_FEFF_FFFF	CCSRBAR	16MB
0xF_F802_0000	0xF_F802_FFFF	PCI Express 3 I/O Space	64KB
0xF_F801_0000	0xF_F801_FFFF	PCI Express 2 I/O Space	64KB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64KB
0xF_F600_0000	0xF_F7FF_FFFF	Queue manager software portal	32MB
0xF_F400_0000	0xF_F5FF_FFFF	Buffer manager software portal	32MB
0xF_E800_0000	0xF_EFFF_FFFF	IFC - NOR Flash	128MB
0xF_0000_0000	0xF_003F_FFFF	DCSR	4MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xC_2000_0000	0xC_2FFF_FFFF	PCI Express 3 Mem Space	256MB
0xC_1000_0000	0xC_1FFF_FFFF	PCI Express 2 Mem Space	256MB
0xC_0000_0000	0xC_0FFF_FFFF	PCI Express 1 Mem Space	256MB
0x0_0000_0000	0x0_FFFF_FFFF	DDR Memory	4GB

4.4.15.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for T1024RDB, SW3[5:7]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU0:  T1024E, Version: 1.0, (0x85480010)
Core:  e5500, Version: 2.1, (0x80241021)
Single Source Clock Configuration
Clock Configuration:

Board: T1024RDB, Board rev: 0x03 CPLD ver: 0x05, boot from NOR vBank0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=> cpld reset
or set DIP-switch SW3[5:7]=000
```

- Switch to alternate bank:

```
=> cpld reset altbank
or set DIP-switch SW3[5:7]=100
```

The table below shows the T1024RDB NOR flash memory map.

Table 87. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768 KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128 KB
0xeff00000	0xeff1ffff	FMAN Micro code (current bank)	128 KB
0xefe00000	0xefe3ffff	QE firmware (current bank)	256KB
0xed300000	0xefefffff	Rootfs (alternate bank)	43 MB

0xe8800000	0xe88fffff	Hardware device tree (current bank)	1 MB
0xe8020000	0xe86fffff	Linux.uImage (current bank)	7 MB + 875 KB
0xe8000000	0xe801ffff	RCW (current bank)	128 KB

4.4.15.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is

no need to switch into the alternate bank after each configuration, i.e. type the command *cpld reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>cpld reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>cpld reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <ucode_start_addr>. <ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <ucode_start_addr> +$filesize
=>erase <ucode_start_addr> +$filesize
=>cp.b 1000000 <ucode_start_addr> $filesize
=>protect on <ucode_start_addr> +$filesize
=>cpld reset altbank
```

4.4.15.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.15.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
=>saveenv
```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.15.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.15.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters

on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.15.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.15.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
2 - RealTek RTL8211E <--> FM1@DTSEC4
6 - RealTek RTL8211E <--> FM1@DTSEC3
FM_TGEC_MDIO:
1 - Generic 10G PHY <--> FM1@TGEC1
```

The results from the above mdio list command show that U-Boot was able to see PHYs on each of the 2 dTSEC and on the 10GEC interface. “Generic 10G PHY” is the normal display when using AQR105 PHY on T1024RDB.

Check RGMII Link Status for External PHY

In order to check the status of a RGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC4 1
Reading from bus FSL_MDIO0
PHY at address 2:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

4.4.15.11 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

If your network driver is not working, check your kernel messages. You should not see any errors reported by the FSL FMan MAC based driver:

```
fsl_mac: fsl_mac: FSL FMan MAC API based driver ()
fsl_mac ffe4e0000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e0000.ethernet: FMan MAC address: 00:04:9f:03:11:1e
fsl_mac ffe4e2000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e2000.ethernet: FMan MAC address: 00:04:9f:03:11:1f
fsl_mac ffe4e4000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e4000.ethernet: FMan MAC address: 00:04:9f:03:11:20
fsl_mac ffe4e6000.ethernet: FMan dTSEC version: 0x08240101
fsl_mac ffe4e6000.ethernet: FMan MAC address: 00:04:9f:03:11:21
```

4.4.16 T1040D4RDB/T1042D4RDB

4.4.16.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.16.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options for T104xD4RDB development system. The table below lists the default switch settings for NOR flash boot.

Table 88. Default Switch Settings

	1	2	3	4	5	6	7	8
SW1	ON [0]	ON [0]	ON [0]	OFF [1]	ON [0]	ON [0]	OFF [1]	OFF [1]
SW2	OFF	ON	OFF	OFF	OFF	ON	ON	OFF
SW3	OFF	OFF	OFF	ON	ON	ON	ON	OFF

NOTE

* PCIe slots modes: All the PCIe devices work as Root Complex.

* For reduce SoC core personalities for T1040/T1042 which is T1020/T1022, set switch SW3[8]=ON

* For single source clocking mode, set SW3[1] = ON and use appropriate RCW

* For `cfg_dram_type` to work with DDR4(1.2V), set SW2[7] = 0; to work with DDR3L(1.35V), set SW2[7] = 1.

Table 89. Frequency settings in MHz

SYSCLK	CPU Core (e5500)	CCB	DDR	FMan	DDRCLK	QMAN	PME
100	1400	600	800 (1600MT/s)	600	66.66	300	300

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 90. Boot Device Scenarios

Alternate Boot Devices	Change these DIP switch settings (0=ON/1=OFF)
a) NAND boot	• SW1 [1:8] = 1000 1000 • SW2 [1:8] = 0011 1001 • SW3 [1:8] = 1111 0001
a) SPI boot	• SW1 [1:8] = 0010 0010 • SW2 [1:8] = 1011 1001 • SW3 [1:8] = 1110 0001
b) SD boot	• SW1 [1:8] = 0010 0000 • SW2 [1:8] = 0011 1001 • SW3 [1:8] = 1110 0001

NOTE

* For reduce SoC core personalities for T1040/T1042 which is T1020/T1022, set switch SW3[8]=0

* For single source clocking mode, set SW3[1] = 0 and use appropriate RCW

4.4.16.3 U-Boot Environment Variables

4.4.16.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.

- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The "hwconfig" default setting enables DDR chip select interleaving as well as USB1 and USB2 configuration:

```
hwconfig=fsl_ddr:bank_intlv=cs0_cs1;usb1:dr_mode=host,phy_type=utmi;usb2:dr_mode=host,phy_
type=utmi
```

NOTE

For USB gadget set "dr_mode=peripheral"

4.4.16.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.16.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T1040 version information (e.g., T1040E version 1.1) and also for the version of FMan microcode currently flashed on the T104XD4RDB (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

For silicon revision1.0:

```
fsl_fman_ucode_t1040_r1.0_106_4_15.bin (*)
fsl_fman_ucode_t1040_r1.0_107_4_2.bin
```

For silicon revision 1.1:

```
fsl_fman_ucode_t1040_r1.1_106_4_18.bin (*)
fsl_fman_ucode_t1040_r1.1_107_4_2.bin
fsl_fman_ucode_t1040_r1.1_108_5_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.16.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains the following RCW binary for use on the T1040D4RDB/T1020D4RDB:

```
t1040d4rdb/ RR_P_66/rcw_1400MHz.rcw (default)
t1040d4rdb/ RR_P_66/rcw_1400MHz_single_source.rcw
t1040d4rdb/ RR_P_66/rcw_sben_1400MHz.rcw
t1040d4rdb/ RR_P_66/rcw_sben_1400MHz_single_source.rcw
```

QorIQ SDK 2.0 contains the following RCW binary for use on the T1042D4RDB/T1022D4RDB:

```
t1042d4rdb/RR_P_86/rcw_1400MHz.rcw (default)
t1042d4rdb/RR_P_86/rcw_1400MHz_single_source.rcw
t1042d4rdb/RR_P_86/rcw_sben_1400MHz.rcw
t1042d4rdb/RR_P_86/rcw_sben_1400MHz_single_source.rcw
```

The RCW directories' names for the T1040D4RDB/T1042D4RDB conform to the following naming convention:

```
ab_c_d
```

Table 91. T1040D4RDB/T1042D4RDB RCW Directories Naming Convention Legend

Label	Convention

Table continues on the next page...

Table 91. T1040D4RDB/T1042D4RDB RCW Directories Naming Convention Legend (continued)

a	'R' if RGMII@MAC4 or RGMII@MAC2 is supported 'N' if not available/not used
b	'R' if RGMII@MAC5 is supported 'N" if not available/not used
c [What is available in Slot 1]	'P' if PCIe 'S' if SGMII 'Q' if QSGMII
d	Hex value of serdes1 protocol value

Note: For SerDes protocol 0x66, RGMII is available on FM@MAC4 and FM@MAC5

For example,

```
RR_P_66
```

means:

- RGMII@mac4
- RGMII@mac5
- One PCIe slot
- SERDES Protocol is 0x66

The RCW filenames for the T1040D4RDB/T1042D4RDB conform to the following naming convention:

```
rcw_x.rcw
rcw_x_clockmode.rcw
```

Table 92. T1040D4RDB/T1042D4RDB RCW Files Naming Convention Legend

Label	Convention
x	Core frequency
clockmode	"single_source" for single source clocking. If "single_source" is not present, it means separate clock source for sysclk and ddrclk

NOTE

* RR_P_66 is the default configuration for T1040D4RDB/T1020D4RDB.

* RR_P_86 is the default configuration for T1042D4RDB/T1022D4RDB

When using the default configuration, the network interfaces, are labeled as the following in U-Boot:

For T1040D4RDB:

FM1@DTSEC3 (SGMII)

FM1@DTSEC4 (RGMII)

FM1@DTSEC5 (RGMII)

For T1042D4RDB:

FM1@DTSEC1 (SGMII)

FM1@DTSEC2 (SGMII)

FM1@DTSEC3 (SGMII)

FM1@DTSEC4 (RGMII)

FM1@DTSEC5 (RGMII)

Below is a table that maps the different ports available on T1040D4RDB and their names in different environments.

Table 93. Port Map for T1040D4RDB

Label on Panel of T1040 RDB	Port in U-Boot	Port in Linux	FMan Address
ETH0	FM1@DTSEC4	fm1-gb3	0xfe4e6000
ETH1	FM1@DTSEC5	fm1-gb4	0xfe4e8000
ETH2	FM1@DTSEC3	fm1-gb2	0xfe4e4000
ETH3	Not supported in U-Boot		0xfe4e0000
ETH4	Not supported in U-Boot		
ETH5	Not supported in U-Boot		
ETH6	Not supported in U-Boot		
ETH7	Not supported in U-Boot		0xfe4e2000
ETH8	Not supported in U-Boot		
ETH9	Not supported in U-Boot		
ETH10	Not supported in U-Boot		

NOTE

ETH3-ETH10 belong to the switch. They are not visible as interfaces in Linux. Switch control software is required to control them.

4.4.16.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
`0xfffdf0000`	`0xfffdfffff`	IFC - CPLD	4 KB
`0xfff800000`	`0xfff80ffff`	IFC - NAND Flash	64 KB
`0xffe000000`	`0xffeffffff`	CCSRBAR	16 MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xff8030000	0xff803ffff	PCI Express 4 I/O Space	64 KB
0xff8020000	0xff802ffff	PCI Express 3 I/O Space	64 KB
0xff8010000	0xff801ffff	PCI Express 2 I/O Space	64 KB
0xff8000000	0xff800ffff	PCI Express 1 I/O Space	64 KB
0xff6000000	0xff7ffffff	Queue manager software portal	32 MB
0xff4000000	0xff5ffffff	Buffer manager software portal	32 MB
0xfe8000000	0xfefffffff	IFC - NOR Flash	128 MB
0xf00000000	0xf003fffff	DCSR	4 MB
0xc30000000	0xc3fffffff	PCI Express 4 Mem Space	265 MB
0xc20000000	0xc2fffffff	PCI Express 3 Mem Space	265 MB
0xc10000000	0xc1fffffff	PCI Express 2 Mem Space	265 MB
0xc00000000	0xc0fffffff	PCI Express 1 Mem Space	265 MB
0x000000000	0x0fffffffff	DDR	2 GB

4.4.16.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for T1040RDB, SW3[5:7]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

For T1040D4RDB:

```
CPU0:  T1040E, Version: 1.1, (0x85280011)
Core:  e5500, Version: 2.1, (0x80241021)
```

```
Clock Configuration:
       CPU0:1400 MHz, CPU1:1400 MHz, CPU2:1400 MHz, CPU3:1400 MHz,
       CCB:600  MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), IFC:150  MHz
       QE:300  MHz
       FMAN1: 600 MHz
       QMAN:  300 MHz
       PME:   300 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 0c18000e 0e000000 00000000 00000000
       00000010: 66000002 40000002 ec027000 01000000
       00000020: 00000000 00000000 00000000 00030810
       00000030: 00000000 0342580f 00000000 00000000
Board: T1040D4RDB
Board rev: 0x01 CPLD ver: 0x03, vBank: 4
```

For T1042D4RDB:

```
CPU0:  T1042E, Version: 1.1, (0x85280211)
Core:  e5500, Version: 2.1, (0x80241021)
Clock Configuration:
       CPU0:1400 MHz, CPU1:1400 MHz, CPU2:1400 MHz, CPU3:1400 MHz,
       CCB:600  MHz,
       DDR:800  MHz (1600 MT/s data rate) (Asynchronous), IFC:150  MHz
       QE:300  MHz
       FMAN1: 600 MHz
       QMAN:  300 MHz
       PME:   300 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 0c18000e 0e000000 00000000 00000000
       00000010: 86000002 40000002 ec027000 01000000
       00000020: 00000000 00000000 00000000 00030810
       00000030: 00000000 01fe580f 00000000 00000000
Board: T1042D4RDB
Board rev: 0x01 CPLD ver: 0x02, vBank: 4
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>cpld reset
```

- Switch to alternate bank:

```
=>cpld reset altbank
```

The table below shows the T1040D4RDB/T1042D4RDB NOR flash memory map.

Table 94. NOR flash memory map

Range Start	Range End	Definition	Size
0xEFF40000	0xEFFFFFFF	U-Boot (current bank)	768 KB
0xEFF20000	0xEFF3FFFF	U-Boot env (current bank)	128 KB
0xEFF00000	0xEFF0FFFF	FMAN Ucode (current bank)	64 KB
0xEFF10000	0xEFF1FFFF	QE Ucode (current bank)	64 KB
0xED300000	0xEFEFFFFF	rootfs (alt bank)	43MB
0xEC800000	0xEC8FFFFF	Hardware device tree (alternate bank)	1 MB
0xEC700000	0xEC7FFFFF	HV.uImage (alternate bank)	1 MB
0xEE020000	0XEC7FFFFF	Linux.uImage (alt bank)	7MB+875KB
0xEC000000	0xEC01FFFF	RCW (alternate bank)	128 KB
0xEBF40000	0xEBFFFFFF	U-Boot (alternate bank)	768 KB
0xEBF20000	0xEBF3FFFF	U-Boot env (alternate bank)	128 KB
0xEBF00000	0xEBF1FFFF	FMAN ucode (alternate bank)	64 KB
0xEBF10000	0XEBF1FFFF	QE Ucode (alt bank)	64 KB
0xE9300000	0xEBEFFFFF	rootfs (current bank)	43MB
0XE8800000	0XE88FFFFF	Hardware device tree (current bank)	1 MB
0xE8020000	0xE86FFFFF	Linux.uImage (current bank)	7MB+875KB
0xE8000000	0xE801FFFF	RCW (current bank)	128 KB

4.4.16.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *cpld reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>cpld reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>cpld reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>cpld reset altbank
```

4.4.16.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.16.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

```
=>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
=>saveenv
```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

```
=>tftp 1000000 <uImage_name>
=>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>tftp 2000000 <platform_dtb_name>
=>bootm 1000000 5000000 2000000
```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.16.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

```
=>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
=>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
=>saveenv
```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
```

```
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.16.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.16.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.16.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.16.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

   ```
   =>tftp 1000000 <platform_name>-usdpaa.dtb
   =>erase e8800000 +$filesize
   =>cp.b 1000000 e8800000 $filesize
   ```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.16.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
0 - RealTek RTL8211E <--> FM1@DTSEC3
1 - RealTek RTL8211E <--> FM1@DTSEC4
2 - RealTek RTL8211E <--> FM1@DTSEC5
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 3 dTSEC interfaces. If you see “Generic” reported, it is an indication that something is there but the T1040 can’t communicate with the device/port.

Check SGMII Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC3 1
Reading from bus FSL_MDIO0
PHY at address 0:
1 - 0x796d
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0," and we would see 0x7969.

Check SGMII link Status for Internal PHY

The SGMII PCS on-chip also has link information. In this section we'll check for a valid link for FM1 EMAC3 (listed as FM1@DTSEC3 in U-Boot). For this check, if you want to see a valid link reported, connect the interface to a link partner. For FM1 EMAC3 (FM1@DTSEC3), the register we want to read is SGMII Status Register (MDIO_SGMII_SR). In particular, we will check MDIO_SGMII_SR[LINK_STAT]. The register MDIO_SGMII_SR is in the SerDes SGMII MDIO register space at

offset 0x1. Note that for SGMII PCS we are using a Clause 22 device. We will use the following registers in the in the Ethernet MAC controller register space to perform the read:

Offset 0x34 Management interface control register (MDIO_CTL)

Offset 0x38 Management interface data register (MDIO_DATA)

We will program MDIO_CTL so that a read of MDIO_DATA will return the contents of MDIO_SGMII_SR. The first step is to identify the values needed to write to MDIO_CTL:

Since 0x1 is the Offset of MDIO_SGMII_SR is the SGMII MDIO register space set MDIO_CTL[DEV_ADDR] = 0x1.

The SGMII MDIO register space is selected when the associated SGMIInCR1[MDEV_PORT] matches the Ethernet MAC PHY address (MDIO_CTL[PHY_ADDR]). So we will set:

```
MDIO_CTL[DEV_ADDR] = 0x1
MDIO_CTL[PHY_ADDR] = SGMIInCR1[MDEV_PORT]
```

NOTE

SGMII Protocol Control Register 1 (SGMIInCR1, n = A, B, ..., F) is in the SerDes register space.

In T1040RM see table 31.1.1.5 "MDIO port mapping for FM" for the mapping of PCD MDIO Slave to MAC MDIO Master. For this example, we're using MAC MDIO master FM1- MAC3 and PCS MDIO slave SGMIIC (i.e., SGMIInCR1 where n=C). Read SGMIICCR1:

```
=> md fe0ea624
fe0ea624: 000008bf 00000000 00000000 80000000 ................
```

So SGMIIACR1[MDEV_PORT] = 0.

So we will program MDIO_CTL with the following values:

```
MDIO_CTL[DEV_ADDR] = 0x1
MDIO_CTL[PHY_ADDR] = SGMIICCR1[MDEV_PORT] = 0
```

Read of FM1-EMAC3 MDIO_SGMII_SR:

```
=> mm fe4e5034 <== FM1 (offset 0x400000) MDIO-3 for EMAC3 (offset 0xe5000) MDIO_CTL
(offset 0x34)
fe4e5034: 00000003 ? 8001 <== Set MDIO_CTL[READ] = 1 MDIO_CTL[PHY_ADDR] = 0 and
MDIO_CTL[DEV_ADDR] = 1
fe4e1038: 00001001 ? x
=> md fe4e5030 <== Read MDIO_DATA (offset 0x38) for contents of
MDIO_SGMII_SR
fe4e5030: 40001408 00000001 0000002d 0000002d @...............
```

The above shows that MDIO_SGMII_SR = 0x0000002d and so MDIO_SGMII_SR[LINK_STAT] = 1 indicating that the link is valid.

4.4.16.11 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 brd + dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

If your network driver is not working, check your kernel messages. You should not see any errors reported by the FSL FMan MAC API based driver:

```
fsl_mac: fsl_mac: FSL FMan MAC API based driver ()
fsl_mac ffe4e0000.ethernet: FMan MEMAC
fsl_mac ffe4e0000.ethernet: FMan MAC address: 00:e0:0c:00:81:00
fsl_mac ffe4e2000.ethernet: FMan MEMAC
fsl_mac ffe4e2000.ethernet: FMan MAC address: 00:e0:0c:00:81:01
fsl_mac ffe4e4000.ethernet: FMan MEMAC
fsl_mac ffe4e4000.ethernet: FMan MAC address: 00:e0:0c:00:81:02
fsl_mac ffe4e6000.ethernet: FMan MEMAC
fsl_mac ffe4e6000.ethernet: FMan MAC address: 00:e0:0c:00:81:03
fsl_mac ffe4e8000.ethernet: FMan MEMAC
fsl_mac ffe4e8000.ethernet: FMan MAC address: 00:e0:0c:00:81:04
```

4.4.17 T2080QDS

4.4.17.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.17.2 Switch Settings

The QDS has user selectable switches for evaluating different boot options for the T2080QDS device. The table below lists the default switch settings. For a description of these settings, see T2080QDS Reference Manual.

Table 95. T2080QDS Default Switch Settings

Switch	1	2	3	4	5	6	7	8
SW1	OFF	OFF	OFF	ON	OFF	OFF	ON	ON
SW2	ON	ON	ON	ON	ON	ON	ON	OFF
SW3	OFF	OFF	ON	OFF	ON	ON	ON	OFF
SW4	ON	OFF	ON	ON	ON	ON	ON	ON
SW5	ON	OFF	OFF	OFF	ON	ON	ON	ON
SW6	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW7	OFF	ON	ON	OFF	OFF	ON	ON	OFF
SW8	OFF	OFF	OFF	ON	OFF	ON	ON	OFF
SW9	ON	OFF	ON	OFF	OFF	OFF	ON	OFF
SW10	ON	ON	ON	OFF	ON	OFF	OFF	OFF
SW11	ON	ON	ON	ON	ON	ON	OFF	OFF
SW12	ON	ON	ON	ON	ON	ON	ON	ON

4.4.17.3 U-Boot Environment Variables

4.4.17.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig=fsl_ddr:ctlr_intlv=cacheline,bank_intlv=auto;usb1:dr_mode=host,phy_type=utmi
```

VID support for T2080QDS

The fuse status register provides the values from on-chip voltage ID efuses programmed at the factory. These values define the voltage requirements for the chip, specifically VDD (core voltage). U-Boot reads FUSESR and translates the values into the appropriate commands to set the voltage output value of an external voltage regulator. B4860QDS has a a IR36021 programmable digital Power Controller, which is programmed as per the value read from the fuses.

There is an environment variable also provided to override the fuse specified voltage.

```
"t208xqds_vdd_mv"
```

For example:

```
=> setenv t208xqds_vdd_mv 1050
=> save
=> reset
```

The commands above will override the Voltage with 1.05V.

NOTE

you also can use u-boot command "vdd_override" to set the VDD. However, The core voltage should be the VID value or Recommended value.

4.4.17.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
```

```
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.17.4 Frame Manager (FMan) Microcode

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T2080 version information (e.g., T2080E version 1.1) and also for the version of FMan microcode currently flashed on the T2080QDS (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 1.1:

```
fsl_fman_ucode_t2080_r1.1_106_4_18.bin (*)
fsl_fman_ucode_t2080_r1.1_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.17.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains RCW binaries for use on the T2080QDS:

- RR_PNNPPH_66_15/rcw_66_15_1800MHz.bin (default RCW, Core/Platform/DDR = 1800MHz/600MHz/1866MT/s)

- RR_PNSNNR_6C_2D/rcw_6c_2d_1800MHz.bin

The RCW directories' names for the T2080QDS conform to the following naming convention:

```
ab_cdefgh_i_j
```

Table 96. T2080QDS Naming Convention Legend

Slot	Convention
a	'R' if RGMII1@DTSEC3 is supported 'N' if not available/not used
b	'R' if RGMII2@DTSEC4 is supported 'N" if not available/not used
c [What is available in Slot 1] d [What is availabel in Slot 2] e [What is available in Slot 3] f [What is available in Slot 4] g [What is available in Slot 5] h [What is available between SATA or SRIO]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'F' if XFI 'H' if SATA 'A' is AURORA
i	'hex value of serdes1 protocol value'
j	'hex value of serdes2 protocol value'

For exmaple,

```
RR_PNNPPH_66_15
```

means:

- RGMII1@DTSEC3
- RGMII2@DTSEC4
- PCIE [Slot 1]
- Slot 2 and 3 are not used
- PCIE [Slot 4]
- PCIE [Slot 5]
- SATA
- serdes1 protocol is 0x66
- serdes2 protocol is 0x15

When using the default configuration, the network interfaces, which include RGMII1, RGMII2 and 4 XFI interfaces, are labeled as the following in U-Boot:

FM1@DTSEC3(MAC3)

FM1@DTSEC4(MAC4)

FM1@TGEC1(MAC9)

FM1@TGEC2(MAC10)

FM1@TGEC3(MAC1)

FM1@TGEC4(MAC2)

4.4.17.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Discription	Size
0xF_FFDF_0000	0xF_FFDF_0FFF	IFC - QIXIS FPGA	4 KB
0xF_FF80_0000	0xF_FF8F_FFFF	IFC - NAND Flash	1 MB
0xF_FE00_0000	0xF_FEFF_FFFF	CCSR BAR	16 MB
0xF_F803_0000	0xF_F803_FFFF	PCI Express 4 I/O Space	64 KB
0xF_F802_0000	0xF_F802_FFFF	PCI Express 3 I/O Space	64 KB
0xF_F801_0000	0xF_F801_FFFF	PCI Express 2 I/O Space	64 KB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64 KB
0xF_F600_0000	0xF_F7FF_FFFF	Qman	32 MB
0xF_F400_0000	0xF_F5FF_FFFF	Bman	32 MB
0xF_E800_0000	0xF_EFFF_FFFF	IFC - NOR Flash	128 MB
0xF_0000_0000	0xF_003F_FFFF	DCSR	4 MB
0xC_4000_0000	0xC_4FFF_FFFF	PCI Express 4 Mem Space	256 MB
0xC_3000_0000	0xC_3FFF_FFFF	PCI Express 3 Mem Space or Serial Rapid I/O 2	256 MB
0xC_2000_0000	0xC_2FFF_FFFF	PCI Express 2 Mem Space or Serial Rapid I/O 1	256 MB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Discription	Size
0xC_0000_0000	0xC_1FFF_FFFF	PCI Express 1 Mem Space	512 MB
0x0_0000_0000	0x0_FFFF_FFFF	Memory controller	4 GB

4.4.17.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for T2080QDS, SW6[1:4]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps the first bank with the second bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, please refer to the U-Boot log.

```
CPU0:  T2080E, Version: 1.1, (0x85380011)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1800 MHz, CPU1:1800 MHz, CPU2:1800 MHz, CPU3:1800 MHz,
       CCB:600  MHz,
       DDR:933.333 MHz (1866.667 MT/s data rate) (Asynchronous), IFC:150  MHz
       FMAN1: 700 MHz
       QMAN:  300 MHz
       PME:   600 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 0c070012 0e000000 00000000 00000000
       00000010: 6c2d0002 00000000 ec027000 c1000000
       00000020: 00000000 00000000 00000000 000307fc
       00000030: 00000000 00000000 00000000 00000004
Board: T2080QDS, Sys ID: 0x28, Board Arch: V1, Board Version: A, boot from vBank4
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>qixis
```

- Switch to alternate bank:

```
=>qixis altbank
```

The table below shows the T2080QDS NOR flash memory map.

Table 97. NOR flash memory map

4.4.17.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *qixis* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *qixis*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>qixis altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *qixis*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
```

```
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>qixis altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *qixis*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>. <fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>qixis altbank
```

4.4.17.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.17.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.17.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

   ```
   =>tftp 1000000 <uImage name>
   =>protect off <kernel_start_addr> +$filesize
   =>erase <kernel_start_addr> +$filesize
   =>cp.b 1000000 <kernel_start_addr> $filesize
   =>protect on <kernel_start_addr> +$filesize
   ```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

   ```
   =>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>protect off <ramdisk_start_addr> +$filesize
   =>erase <ramdisk_start_addr> +$filesize
   =>cp.b 2000000 <ramdisk_start_addr> $filesize
   =>protect on <ramdisk_start_addr> +$filesize
   ```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

   ```
   =>tftp c00000 <platform dtb name>
   =>protect off <dtb_start_addr> +$filesize
   =>erase <dtb_start_addr> +$filesize
   =>cp.b c00000 <dtb_start_addr> $filesize
   =>protect on <dtb_start_addr> +$filesize
   ```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

   ```
   =>boot
   ```

   or

   ```
   => bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
   ```

4.4.17.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

   ```
   <nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
   ```

   b. Restart the NFS service:

   ```
   /etc/init.d/nfs restart
   ```

   NOTE

   nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

   ```
   =>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
   ip=<board_ipaddr>:<tftp_serverip>:
   <your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
   =>setenv netdev <ethx>
   =>saveenv
   ```

   NOTE

   <ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

   ```
   =>tftp 1000000 <uImage name>
   =>tftp c00000 <platform dtb name>
   =>bootm 1000000 - c00000
   ```

   Now the board will boot up with NFS filesystem.

4.4.17.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

   ```
   #fdisk /dev/sdb
   ```

3. Use the mkfs.ext2 command to create the filesystems.

   ```
   # mkfs.vfat /dev/sdb1
   # mkfs.ext2 /dev/sdb2
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdb2 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

   ```
   # cp uImage and uImage.dtb to /temp/boot folder
   # umount /temp
   ```

8. Plug in the SD card to the target board and power on.

4.4.17.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

   ```
   # fdisk /dev/sdx
   ```

3. Use the mkfs command to create the filesystems.

   ```
   # mkfs.ext2 /dev/sdx1
   ```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

   ```
   # mkdir /temp
   # mount /dev/sdx1 /temp
   # cd /temp
   ```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

   ```
   # mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
   ```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

   ```
   # cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
   # sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   # rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
   ```

7. Make sure copy the target kernel image and dtb to sata.

   ```
   # cp uImage and target.dtb to /temp/boot folder
   # umount /temp
   ```

8. Connect the SATA hard drive to the target board and power on.

4.4.17.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

```
=>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>erase e9300000 +$filesize
=>cp.b 1000000 e9300000 $filesize
```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

```
=>tftp 1000000 hv.uImage
=>erase e8700000 +$filesize
=>cp.b 1000000 e8700000 $filesize
```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.18 T2080RDB

4.4.18.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.18.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options for the T2080 device. The table below lists the default switch settings. For a description of these settings, see T2080RDB User Guide.

Table 98. Default Switch Settings

	1	2	3	4	5	6	7	8

Table continues on the next page...

Table 98. Default Switch Settings (continued)

SW1	ON [0]	ON [0]	ON [0]	OFF [1]	ON [0]	ON [0]	OFF [1]	OFF [1]
SW2	OFF	ON	OFF	OFF	OFF	OFF	OFF	OFF
SW3	OFF	OFF	OFF	ON	ON	ON	ON	OFF

Note that with the default settings, the following are selected.

(SW1[1:8] SW2[1]) = 000100111:

NOR Boot mode is selected

SW3[1] = 1:

SYSCLK clock source

SW3[5:7] = 000:

NOR flash bank 0 select.

Below are additional switch settings for alternate boot devices. Please note that changing the boot device configuration may require additional changes in the RCW or in other code images.

Table 99. Boot Device Scenarios

Alternate Boot Devices	**Change the following switch settings (0=ON / 1=OFF)**
NAND boot	SW1 [1:8] = 1000 0010 SW2 [1:8] = 1011 1111 SW3 [1:8] = 1111 0001
SPI boot	SW1 [1:8] = 0010 0010 SW2 [1:8] = 1011 1111 SW3 [1:8] = 1110 0001
SD Flash boot	SW1 [1:8] = 0010 0000 SW2 [1:8] = 0011 1111 SW3 [1:8] = 1110 0001

4.4.18.3 U-Boot Environment Variables

4.4.18.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig=fsl_ddr:ctlr_intlv=cacheline,bank_intlv=auto;usb1:dr_mode=host,phy_type=utmi
```

If you plan to use optical 10G interfaces, you must add information to "hwconfig". This is important. The optical interface will operate erratically without it. It is easiest to do this using the U-Boot "*editenv*" command. Whatever you type will be appended to "hwconfig". The text you need to append is:

```
;fsl_fm1_xaui_phy:xfi
```

Once you have appended the text, you should see the following:

```
=>print hwconfig
hwconfig = fsl_ddr:ctlr_intlv=cacheline,bank_intlv=cs0_cs1;fsl_fm1_xaui_phy:xfi
```

4.4.18.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.18.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T2080 version information (e.g., T2080E version 1.1) and also for the version of FMan microcode currently flashed on the T2080RDB (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

For silicon revision 1.1:

```
fsl_fman_ucode_t2080_r1.1_106_4_18.bin (*)
fsl_fman_ucode_t2080_r1.1_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.18.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK 2.0 contains RCW binaries for use on the T2080RDB:

- RRFFXX_P_66_15/rcw_66_15_1800MHz.bin (default RCW, Core/Platform/DDR = 1800MHz/600MHz/1866MT/s)
- RRFFXX_P_66_1F/rcw_66_1f_1800MHz.bin
- RRFFXX_P_66_27/rcw_66_27_1800MHz.bin

The RCW directories' names for the T2080RDB conform to the following naming convention:

```
abcdef_g_h_i
```

Table 100. T2080RDB Naming Convention Legend

Label	Convention
a	'R' indicates RGMII1 @ DTSEC3 is supported
b	'R' indicates RGMII2 @ DTSEC4 is supported
c,d	'F' indicates 10G SFP+ fiber ports are supported
e,f	'X' indicates 10G Base-T copper ports are supported

Table continues on the next page...

Table 100. T2080RDB Naming Convention Legend (continued)

g	'P' indicates PCIe4 x4 in the PCI slot
h	SerDes1 protocol value (in hexadecimal)
i	SerDes2 protocol value (in hexadecimal).

For example,

```
RRFFXX_P_66_1F
```

means:

- RGMII1 @ DTSEC3
- RGMII2 @ DTSEC4
- 10G SFP+ fiber ports
- 10G Base-T copper ports
- PCIe4 x4
- SerDes1 protocol 0x66
- SerDes2 protocol 0x1F

Below is a table that maps the different ports available on T2080RDB and their names in different environments.

Table 101. Port Map

Label on 1U box	Port in U-boot	Port in Linux	FMAN Address	Comments
ETH0	FM1@GTEC1	fm1-mac9	0xfe4f0000	10G Base-T SFP+ (Cortina4315)
ETH1	FM1@GTEC2	fm1-mac10	0xfe4f2000	10G Base-T SFP+ (Cortina4315)
ETH2	FM1@GTEC3	fm1-mac1	0xfe4e0000	10G Base-T (AQ1202)
ETH3	FM1@GTEC4	fm1-mac2	0xfe4e2000	10G Base-T (AQ1202)
ETH4	FM1@DTSEC3	fm1-mac3	0xfe4e4000	1G RGMII (RTL8211E)
ETH5	FM1@DTSEC4	fm1-mac4	0xfe4e6000	1G RGMII (RTL8211E)

4.4.18.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
`0xfffdf0000`	`0xfffdf0fff`	IFC - CPLD	4 KB

Table continues on the next page...

Table continued from the previous page...

Start Physical Address	End Physical Address	Definition	Size
0xfff800000	0xfff80ffff	IFC - NAND Flash	64 KB
0xffe000000	0xffeffffff	CCSR	16 MB
0xff8030000	0xff803ffff	PCI Express 4 I/O Space	64 KB
0xff8020000	0xff802ffff	PCI Express 3 I/O Space	64 KB
0xff8010000	0xff801ffff	PCI Express 2 I/O Space	64 KB
0xff8000000	0xff800ffff	PCI Express 1 I/O Space	64 KB
0xff6000000	0xff7ffffff	QMan	32 MB
0xff4000000	0xff5ffffff	BMan	32 MB
0xfe8000000	0xfeffffffff	IFC - NOR Flash	128 MB
0xf00000000	0xf003fffff	DCSR	4 MB
0xc40000000	0xc4fffffff	PCI Express 4 Mem Space	256 MB
0xc30000000	0xc3fffffff	PCI Express 3 Mem Space Rapid I/O 2	256 MB
0xc20000000	0xc2fffffff	PCI Express 2 Mem Space Rapid I/O 1	256 MB
0xc00000000	0xc1fffffff	PCI Express 1 Mem Space	512 MB
0x000000000	0x0fffffff	DDR	4 GB

4.4.18.7 Flash Bank Usage

The NOR flash on the board can be seen as two flash banks. The board DIP switch configuration (for T2080RDB, SW3[5:7]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software (or via the dip switch) and effectively swaps bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log:

```
CPU0:  T2080E, Version: 1.1, (0x85380011)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1799.820 MHz, CPU1:1799.820 MHz, CPU2:1799.820 MHz, CPU3:1799.820 MHz,
       CCB:599.940 MHz,
       DDR:933.310 MHz (1866.620 MT/s data rate) (Asynchronous), IFC:149.985 MHz
       FMAN1: 699.930 MHz
       QMAN:  299.970 MHz
       PME:   599.940 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 1207001b 15000000 00000000 00000000
       00000010: 66150002 00000000 ec027000 c1000000
       00000020: 00800000 00000000 00000000 000307fc
       00000030: 00000000 00000000 00000000 00000004
Board: T2080RDB, Board rev: 0x01 CPLD ver: 0x03, boot from NOR vBank0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>cpld reset
```

- Switch to alternate bank:

```
=>cpld reset altbank
```

The table below shows the T2080RDB NOR flash memory map.

Table 102. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xeff40000	0xefffffff	U-Boot (current bank)	768 KB
0xeff20000	0xeff3ffff	U-Boot env (current bank)	128 KB

4.4.18.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *cpld reset altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>cpld reset altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>cpld reset altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *cpld reset*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>.

<fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>cpld reset altbank
```

4.4.18.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.18.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.18.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   ```

```
=>saveenv
```

Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.18.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

Now the board will boot up with NFS filesystem.

4.4.18.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.18.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.18.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.19 T4240QDS

4.4.19.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.19.2 Switch Settings

The Development System has user selectable switches for evaluating different boot options for the T4240 device. The table below lists the default switch settings. For a description of these settings, see T4240QDS User guide.

Table 103. T4240QDS Default Switch Settings

Switch	1	2	3	4	5	6	7	8
SW1	OFF	OFF	OFF	ON	OFF	ON	ON	ON
SW2	ON	ON	ON	ON	ON	ON	ON	OFF
SW3	OFF	OFF	OFF	OFF	ON	ON	OFF	OFF
SW4	OFF	ON	OFF	ON	OFF	OFF	OFF	OFF
SW5	ON	ON	ON	OFF	OFF	OFF	ON	OFF
SW6	OFF	OFF	OFF	OFF	ON	ON	ON	ON
SW7	ON	ON	ON	ON	ON	OFF	ON	OFF
SW8	ON	ON	OFF	OFF	ON	ON	OFF	ON
SW9	OFF	OFF	OFF	ON	ON	ON	ON	ON

NOTE

- PCIe slots modes: All the PCIe devices work as Root Complex.
- Boot location: NOR flash.
- RCW source: NOR flash.

4.4.19.3 U-Boot Environment Variables

4.4.19.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, is as follows:

```
hwconfig=fsl_ddr:ctlr_intlv=3way_4KB,bank_intlv=auto;fsl_fm1_xaui_phy:xfi;fsl_fm2_xaui_phy:xfi;usb
1:dr_mode=host,phy_type=utmi
```

4.4.19.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.19.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T4240 version information (e.g., T4240E version 2.0) and also for the version of FMan microcode currently flashed on the T4240QDS (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 2.0:

```
fsl_fman_ucode_t4240_r2.0_106_4_18.bin (*)
fsl_fman_ucode_t4240_r2.0_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.19.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK contains RCW binaries for use on the T4240QDS:

- RR_SSFFPRPH_27_55_5_11/rcw_27_55_5_11_1800MHz.bin
- RR_XXQQPRPH_1_37_5_11/rcw_1_37_5_11_1800MHz.bin
- RR_XXSSPRPH_1_27_5_11/rcw_1_27_5_11_1800MHz.bin (default)
- RR_XXXXPRPR_1_1_5_5/rcw_1_1_5_5_1800MHz.bin
- RR_SSFFPRPH_27_55_5_11/rcw_27_55_5_11_1666MHz_rev2.bin
- RR_XXQQPRPH_1_37_5_11/rcw_1_37_5_11_1666MHz_rev2.bin
- RR_XXSSPRPH_1_27_5_11/rcw_1_27_5_11_1666MHz_rev2.bin
- RR_XXXXPRPR_1_1_5_5/rcw_1_1_5_5_1666MHz_rev2.bin

The RCW directories' names for the T4240QDS conform to the following naming convention:

```
ab_cdefghij_k_l_m_n
```

Table 104. T4240QDS Naming Convention Legend

Slot	Convention

Table continues on the next page...

Table 104. T4240QDS Naming Convention Legend (continued)

a	'R' if RGMII@FM2-DTSEC5 is supported 'N' if not available/not used
b	'R' if RGMII@FM1-DTSEC5 or RGMII@FM2-DTSEC6 is supported 'N" if not available/not used
c [What is available in Slot 1] d [What is availabel in Slot 2] e [What is available in Slot 3] f [What is available in Slot 4] g [What is available in Slot 5] h [What is available in Slot 6] i [What is available in Slot 7] j [What is available in Slot 8]	'N' if not available/not used 'P' if PCIe 'X' if XAUI 'R' if SRIO 'S' if SGMII 'H' if SATA 'F' XFI 'A' is AURORA
k	SerDes1 protocol value (decimal notation)
l	SerDes2 protocol value (decimal notation)
m	SerDes3 protocol value (decimal notation)
n	SerDes4 protocol value (decimal notation)

For example,

```
RR_SSFSPRPH_27_55_5_11
```

means:

- RGMII@FM2-DTSEC5
- RGMII@FM2-DTSEC6
- SGMII in Slot 1
- SGMII in Slot 2
- XFI in Slot 3
- SGMII in Slot 4
- PCIe in Slot 5
- SRIO in Slot 6
- PCIe in Slot 7
- SATA [Slot 8 not used]
- SerDes1 Protocol is 27
- SerDes2 Protocol is 55
- SerDes3 Protocol is 5
- SerDes4 Protocol is 11

4.4.19.6 System Memory Map

After system startup, the boot loader maps physical memory space:

Start Physical Address	End Physical Address	Discription	Size
0xF_FFDF_0000	0xF_FFDF_0FFF	IFC - QIXIS	4 KB
0xF_FF80_0000	0xF_FF8F_FFFF	IFC - NAND Flash	1 MB
0xF_F803_0000	0xF_F803_FFFF	PCI Express 4 I/O Space	64 KB
0xF_F802_0000	0xF_F802_FFFF	PCI Express 3 I/O Space	64 KB
0xF_F800_0000	0xF_F800_FFFF	PCI Express 1 I/O Space	64 KB
0xF_F600_0000	0xF_F7FF_FFFF	Qman	32 MB
0xF_F400_0000	0xF_F5FF_FFFF	Bman	32 MB
0xF_E000_0000	0xF_E7FF_FFFF	IFC - NOR Flash	128 MB
0xF_0000_0000	0xF_003F_FFFF	DCSR	4 MB
0xC_6000_0000	0xC_7FFF_FFFF	PCI Express 4 Mem Space	512 MB
0xC_4000_0000	0xC_5FFF_FFFF	PCI Express 3 Mem Space	512 MB
0xC_3000_0000	0xC_3FFF_FFFF	Serial Rapid I/O 2	256 MB
0xC_2000_0000	0xC_2FFF_FFFF	Serial Rapid I/O 1	256 MB
0xC_0000_0000	0xC_1FFF_FFFF	PCI Express 1 Mem Space	512 MB
0x0_0000_0000	0x0_7FFF_FFFF	Memory controller	2 GB

4.4.19.7 Flash Bank Usage

The NOR flash on the board can be seen as eight flash banks. The board DIP switch configuration (for T4240QDS, SW6[1:4]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps

bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log.

```
CPU0:  T4240E, Version: 2.0, (0x82480020)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1800 MHz, CPU1:1800 MHz, CPU2:1800 MHz, CPU3:1800 MHz,
       CPU4:1800 MHz, CPU5:1800 MHz, CPU6:1800 MHz, CPU7:1800 MHz,
       CPU8:1800 MHz, CPU9:1800 MHz, CPU10:1800 MHz, CPU11:1800 MHz,
       CCB:733.333 MHz,
       DDR:933.333 MHz (1866.667 MT/s data rate) (Asynchronous), IFC:183.333 MHz
       FMAN1: 733.333 MHz
       FMAN2: 733.333 MHz
       QMAN:  366.667 MHz
       PME:   533.333 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 1607001b 18101b16 00000000 00000000
       00000010: 04362858 30548c00 ec020000 f5000000
       00000020: 00000000 ee0000ee 00000000 000307fc
       00000030: 00000000 00000000 00000000 00000028
Board: T4240QDS, Sys ID: 0x1e, Sys Ver: 0x12, vBank: 0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=>qixis_reset
```

- Switch to alternate bank:

```
=>qixis_reset altbank
```

The table below shows the T4240QDS NOR flash memory map.

Table 105. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xEC000000	0xEC01FFF	RCW (alternate bank)	128KB
0xEFF40000	0xEFFFFFFF	U-Boot (current bank)	768KB
0xEFF20000	0xEFF3FFFF	U-Boot env (current bank)	128KB
0xEFF00000	0xEFF1FFFF	FMAN microcode (current bank)	128KB
0xEFE00000	0xEFE3FFFF	CORTINA PHY code (current bank)	256KB

Table continues on the next page...

4.4.19.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, there is no need to switch into the alternate bank after each configuration, i.e. type the command *qixis altbank* only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

By default, an existing U-Boot is run in bank 0 after the system is powered on or after a hard reset is performed. To flash U-Boot to the alternate bank, first switch to bank 0 by performing a hard reset or by typing *qixis*. Then use the following commands to flash a new U-Boot into the alternate bank and then switch to that alternate bank where the new U-Boot is flashed:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
=>qixis altbank
```

The commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections.

Programming a New RCW

To program a new RCW, first switch to bank 0 by performing a hard reset or by typing *qixis*. Next, load the new RCW to RAM by downloading it via TFTP and then copying it to flash at address <rcw_start_addr>. <rcw_start_addr> is the location of RCW in the alternate bank. Execute the following commands at the U-Boot prompt to program the RCW to flash and reset to alternate bank.

```
=>tftp 1000000 <rcw_file_name>.bin
=>protect off <rcw_start_addr> +$filesize
=>erase <rcw_start_addr> +$filesize
=>cp.b 1000000 <rcw_start_addr> $filesize
=>protect on <rcw_start_addr> +$filesize
=>qixis altbank
```

Programming a New Microcode

To program a new microcode, first switch to bank 0 by performing a hard reset or by typing *qixis*. Next, load the new microcode to RAM by downloading it via TFTP and then copying it to flash at address <fman_ucode_start_addr>.

<fman_ucode_start_addr> is the location of ucode in the alternate bank. Then execute the following commands at the U-Boot prompt to program the ucode to flash and reset to alternate bank.

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
=>qixis altbank
```

4.4.19.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.19.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.19.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   ```

```
=>saveenv
```

Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

   The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.19.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

Now the board will boot up with NFS filesystem.

4.4.19.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.19.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.19.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

Target Deployment - for hv-2p mode deployment:

```
=>tftp 1000000 <platform_name>-usdpaa.dtb
=>erase e8800000 +$filesize
=>cp.b 1000000 e8800000 $filesize
```

Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

   Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.20 T4240RDB

4.4.20.1 Overview

This guide provides board-specific configuration and instructions for different methods of deploying U-Boot, Linux kernel and root file system to the target board.

4.4.20.2 Switch Settings

The RDB has user selectable switches for evaluating different boot options for the T4240 device. The table below lists the default switch settings. For a description of these settings, see T4240RDB User Guide.

Table 106. Default Switch Settings

Switch	1	2	3	4
SW1	OFF [1]	OFF [1]	ON [0]	ON [0]
SW2	OFF	OFF	OFF	OFF
SW3	OFF	OFF	OFF	OFF
SW4	OFF	OFF	OFF	OFF

Note that with the default switch settings, the following are selected:

Table 107. Default Settings

Switch	Default Setting
SW1[1:4] = 0011	SYSCLK output frequency is 66.67 MHz DDRCLK is 133.33 MHz CPU 1800 MHz
SW3[4]= 1	RCW configuration source is I2C EEPROM Flash
SW4[1:2]= 11	Normal power on/off T4240 mode is selected

NOTE

For the T4240RDB, OFF = 1 and ON = 0.

4.4.20.3 U-Boot Environment Variables

4.4.20.3.1 U-Boot Environment Variable “hwconfig”

Environment variable "hwconfig" is used within the U-Boot bootloader to convey information about desired hardware configurations. It is an ordinary environment variable in that:

- It can be set from the U-Boot prompt using the "*setenv*" command.
- It can be removed from the U-Boot environment by setting it to an empty value, i.e.

```
=>setenv hwconfig
```

- It can be modified from the U-Boot command prompt using the "*editenv*" command.
- It can be saved in the U-Boot environment via the "*saveenv*" command.

Variable "hwconfig" is set to a sequence of *option:value* entries separated by semicolons.

The default setting for DDR, which enables chip select interleaving and cacheline interleaving, as well as the USB1 configuration is as follows:

```
hwconfig=fsl_ddr:ctlr_intlv=3way_4KB,bank_intlv=auto;usb1:dr_mode=host,phy_type=utmi
```

4.4.20.3.2 Configuring U-Boot Network Parameters

To support TFTP based deployments, set up the U-Boot environment once, and save it, so that settings persist on subsequent resets.

```
=>setenv ipaddr <board_ipaddress>
=>setenv serverip <tftp_serverip>
=>setenv gatewayip <your_gatewayip>
=>setenv ethaddr <mac addr0>
=>setenv eth1addr <mac addr1>
=>setenv eth2addr <mac addr2>
=>setenv eth3addr <mac addr3>
=>setenv eth4addr <mac addr4>
=>setenv eth5addr <mac addr5>
=>setenv ethprime <ethx>
=>setenv ethact <ethx>
=>setenv netmask 255.255.x.x
=>saveenv
```

NOTE

(i) <ethx> is the Ethernet port on the board connected to the Linux boot server.

(ii) "netmask" is subnet mask for the Linux boot server's network.

Below is one example of the MAC address configuration corresponding to the set up above. Change these values to MAC addresses appropriate for your board.

```
=>setenv ethaddr 00:04:9F:02:00:FD
=>setenv eth1addr 00:04:9F:02:01:FD
=>setenv eth2addr 00:04:9F:02:02:FD
=>setenv eth3addr 00:04:9F:02:03:FD
=>setenv eth4addr 00:04:9F:02:04:FD
```

```
=>setenv eth5addr 00:04:9F:02:05:FD
=>saveenv
```

NOTE

For boards with more network interfaces, additional environment variables need to be set (e.g., eth6addr, eth7addr,...).

Now the flashed version of U-Boot is ready for performing TFTP based deployments.

4.4.20.4 Frame Manager Microcode (FMan ucode)

There are microcode binaries for the Frame Manager hardware block that is in QorIQ products. Specific platforms require specific binaries, and those also have to match specific software versions (i.e., match Frame Manager Driver version). See the U-Boot log for T4240 version information (e.g., T4240E version 2.0) and also for the version of FMan microcode currently flashed on the T4240RDB (e.g. microcode version 106.4.18). For QorIQ SDK 2.0, one of the following FMan microcode binaries should be used:

- For silicon revision 2.0

```
fsl_fman_ucode_t4240_r2.0_106_4_18.bin (*)
fsl_fman_ucode_t4240_r2.0_108_4_9.bin
```

NOTE

(i) (*) Denotes the default FMan Microcode.

(ii) Refer to the "readme" and release notes in the microcode git repository for a description of the various microcode releases.

(iii) For instructions on how to flash a new FMan microcode image, see Programming a new U-Boot, RCW, and FMan Microcode.

(iv) Using a microcode binary from an older SDK (e.g., SDK 1.9) with a Linux kernel from SDK 2.0 is not supported.

4.4.20.5 RCW (Reset Configuration Word) and Ethernet Interfaces

QorIQ SDK contains the following RCW binary for use on the T4240RDB:

• SSFFPPH_27_55_1_9/rcw_27_55_1_9_1800MHz.bin (default)

• SSFFPPH_27_55_1_9/rcw_27_55_1_9_1666MHz.bin

The RCW directory name for T4240RDB conform to the following naming convention:

```
abcdefg_h_i_j_k
```

So the default,

```
SSFFPPH_27_55_1_9
```

means:

Table 108. T4240RDB Directory Legend

Slot	Convention

Table continues on the next page...

Table 108. T4240RDB Directory Legend (continued)

a	'S' indicates FM1 @ DTSEC1 DTSEC2 DTSEC3 DTSEC4 ports are supported
b	'S' indicates FM2 @ DTSEC1 DTSEC2 DTSEC3 DTSEC4 ports are supported
c	'F' indicates FM1 @ TGEC1 TGEC2 SFP+ fiber ports are supported
d	'F' indicates FM2 @ TGEC1 TGEC2 SFP+ fiber ports are supported
e	'P' indicates PCIe x8 in the PCI slot
f	'P' indicates PCIe x4 in the PCI slot
g	'H' indicates SATA port is supported
h	'27' indicates SerDes1 protocol 0x1B
i	'55' indicates SerDes2 protocol 0x37
j	'1' indicates SerDes3 protocol 0x1
k	'9' indicates SerDes4 protocol 0x9

Below is a table that maps the different ports available on the T4240RDB and their names in different environments.

Table 109. Port Map

Label on Panel of T4240 RDB	Port in U-Boot	Port in Linux
ETH0	FM1@ DTSEC1	fm1-mac1
ETH1	FM1@ DTSEC2	fm1-mac2
ETH2	FM1@ DTSEC3	fm1-mac3
ETH3	FM1@ DTSEC4	fm1-mac4
ETH4	FM2@ DTSEC1	fm2-mac1
ETH5	FM2@ DTSEC2	fm2-mac2
ETH6	FM2@ DTSEC3	fm2-mac3
ETH7	FM2@ DTSEC4	fm2-mac4
ETH8	FM2@ TGEC1	fm2-mac9
ETH9	FM2@ TGEC2	fm2-mac10
ETH10	FM1@ TGEC2	fm1-mac10
ETH11	FM1@ TGEC1	fm1-mac9

4.4.20.6 System Memory Map

After system startup, the boot loader maps physical memory space as shown below.

Start Physical Address	End Physical Address	Definition	Size
0xff8030000	0xff803ffff	PCI Express 4 I/O Space	64 KB
0xff8020000	0xff802ffff	PCI Express 3 I/O Space	64 KB
0xff8000000	0xff800ffff	PCI Express 1 I/O Space	64 KB
0xff6000000	0xff7ffffff	QMan	32 MB
0xff4000000	0xff5ffffff	BMan	32 MB
0xfe0000000	0xfe7ffffff	IFC - NOR Flash	128 MB
0xf00000000	0xf003fffff	DCSR	4 MB
0xc60000000	0xc7fffffff	PCI Express 4 Mem Space	512 MB
0xc40000000	0xf5fffffff	PCI Express 3 Mem Space	512 MB
0xc00000000	0xc1fffffff	PCI Express 1 Mem Space	512 MB
0x000000000	0x07fffffff	Memory Controller	2 GB

4.4.20.7 Flash Bank Usage

The NOR flash on the board can be seen as eight flash banks. The board DIP switch configuration (for T4240RDB, SW3[1:3]) preselects bank 0 as the hardware default bank.

To protect the default U-Boot in bank 0, it is a convention employed by NXP to deploy work images into the alternate bank, and then switch to the alternate bank for testing. Switching to the alternate bank can be done in software and effectively swaps bank 0 with the alternate bank, thereby putting the alternate bank in the bank 0 address range until further configuration or until a reset occurs. This protects banks 0 and keeps the board bootable under all circumstances.

To determine the current bank, refer to the U-Boot log.

```
CPU0:  T4240E, Version: 2.0, (0x82480020)
Core:  e6500, Version: 2.0, (0x80400120)
Clock Configuration:
       CPU0:1800 MHz, CPU1:1800 MHz, CPU2:1800 MHz, CPU3:1800 MHz,
       CPU4:1800 MHz, CPU5:1800 MHz, CPU6:1800 MHz, CPU7:1800 MHz,
       CPU8:1800 MHz, CPU9:1800 MHz, CPU10:1800 MHz, CPU11:1800 MHz,
       CCB:733.333 MHz,
```

```
       DDR:933.333 MHz (1866.667 MT/s data rate) (Asynchronous), IFC:183.333 MHz
       FMAN1: 733.333 MHz
       FMAN2: 733.333 MHz
       QMAN:  366.667 MHz
       PME:   533.333 MHz
L1:    D-cache 32 KiB enabled
       I-cache 32 KiB enabled
Reset Configuration Word (RCW):
       00000000: 16070019 18101916 00000000 00000000
       00000010: 6c6e0848 00448c00 6c020000 f5000000
       00000020: 00000000 ee0000ee 00000000 000287fc
       00000030: 00000000 50000000 00000000 00000028
Board: T4240RDB, Board rev: 0x04 CPLD ver: 0x0401, vBank: 0
```

Bank switching can be done in U-Boot using the following statements:

- Switch to bank 0:

```
=> cpld reset
```

- Switch to alternate bank:

```
=> cpld reset altbank
```

The table below shows the T4240RDB 128MB Nor flash memory map. The flash memory used is configured in a 16-bit port size.

Table 110. NOR Flash Memory Map

Range Start	Range End	Definition	Size
0xEC000000	0xEC01FFF	RCW (alternate bank)	128KB
0xEFF40000	0xEFFFFFFF	U-Boot (current bank)	768KB
0xEFF20000	0xEFF3FFFF	U-Boot env (current bank)	128KB
0xEFF00000	0xEFF1FFFF	FMAN microcode (current bank)	128KB
0xEFE00000	0xEFE3FFFF	CORTINA PHY code (current bank)	256KB
0xED300000	0xEFDFFFFF	rootfs (alternate bank)	44MB
0xED000000	0xED2FFFFF	Guest image #3(alternate bank)	3MB
0xECD00000	0xECFFFFFF	Guest image #2 (alternate bank)	3MB
0xECA00000	0xECCFFFFF	Guest image #1 (alternate bank)	3MB

Table continues on the next page...

Table 110. NOR Flash Memory Map (continued)

0xEC900000	0xEC9FFFFF	HV config device tree (alternate bank)	1MB
0xEC800000	0xEC8FFFFF	Hardware device tree (alternate bank)	1MB
0xEC700000	0xEC7FFFFF	HV.uImage (alternate bank)	1MB
0xEC020000	0xEC6FFFFF	Linux.uImage (alternate bank)	6MB + 875KB
0xE8000000	0xE801FFFF	RCW (current bank)	128KB
0xEBF40000	0xEBFFFFFF	U-Boot (alternate bank)	768KB
0xEBF20000	0xEBF3FFFF	U-Boot env (alternate bank)	128KB
0xEBF00000	0xEBF1FFFF	FMAN microcode (alternate bank)	128KB
0xEBE00000	0xEBE3FFFF	CORTINA PHY code (alternate bank)	256KB
0xE9300000	0xEBDFFFFF	rootfs (current bank)	44MB
0xE9000000	0xE92FFFFF	Guest image #3 (current bank)	3MB
0xE8D00000	0xE8FFFFFF	Guest image #2 (current bank)	3MB
0xE8A00000	0xE8CFFFFF	Guest image #1 (current bank)	3MB
0xE8900000	0xE89FFFFF	HV config device tree (current bank)	1MB
0xE8800000	0xE88FFFFF	Hardware device tree (current bank)	1MB
0xE8700000	0xE87FFFFF	HV.uImage (current bank)	1MB
0xE8020000	0xE86FFFFF	Linux.uImage (current bank)	6MB + 875KB

For board revision T4240RDB-PD, the NOR flash can be split into two logical halves by setting the *FBANK_SEL* signal. The *FBANK_SEL* signal is controlled by setting SW3[3]. The table below displays how the addresses are changed when using *FBANK_SEL*.

Table 111. Logical NOR Banks

Setting	NOR bank used
SW3[3] = on	Boot from vbank0
SW3[3] = off	Boot from vbank4

NOTE

T4240RDB-PB does not support *FBANK_SEL* feature.

4.4.20.8 Programming a New U-boot, RCW, FMan Microcode

The following three sections will discuss how to individually update U-Boot, RCW, and FMan Microcode. For specific addresses, please refer to the NOR Flash Memory Map as a reference. If the user intends to flash all three at once, reset the board only after U-Boot, RCW and FMan Microcode have all been programmed.

Prior to continuing with the following instructions, please refer to Configuring U-Boot Network Parameters to make sure all necessary U-Boot parameters have been set.

Programming a New U-Boot

Use the following commands to flash a new U-Boot:

```
=>tftp 1000000 <u-boot_file_name>.bin
=>protect off <u-boot_start_addr> +$filesize
=>erase <u-boot_start_addr> +$filesize
=>cp.b 1000000 <u-boot_start_addr> $filesize
=>protect on <u-boot_start_addr> +$filesize
```

After implementing the commands, reset the board to boot it up. Note that the commands above will only program a new U-Boot. Programming a new RCW and a new microcode will be discussed in the next sections. If the user intends on programming a new U-Boot as well as a new RCW and Microcode, wait to reset the board until commands for programming all three sections have been implemented.

Programming a New RCW

At the U-Boot prompt, use the following commands to program a new RCW:

```
=>tftp  1000000  <rcw_file_name>.bin
=>i2c  write  0x1000000  0x50  0  $filesize
```

After implementing the commands above, reset the board to boot it up. Note that the commands above will only program a new RCW.

Programming a New Microcode

Execute the following commands at the U-Boot prompt to program the ucode:

```
=>tftp 1000000 <ucode_file_name>.bin
=>protect off <fman_ucode_start_addr> +$filesize
=>erase <fman_ucode_start_addr> +$filesize
=>cp.b 1000000 <fman_ucode_start_addr> $filesize
=>protect on <fman_ucode_start_addr> +$filesize
```

After implementing the commands above, reset the board to boot it up. Note that the commands above will only program a new microcode.

4.4.20.9 Deployment

Each of these guides will step you through the deployment method of your choice. Please refer to the board's NOR Flash Memory Map within *Flash Bank Usage* as reference for specific addresses.

4.4.20.9.1 Ramdisk Deployment from TFTP

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment. Before performing ramdisk deployment, the U-Boot environment variables need to be configured.

   Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for ramdisk deployment from TFTP:

   ```
   =>setenv bootargs 'root=/dev/ram rw console=ttyS0,115200 ramdisk_size=10000000 log_buf_len=128K'
   =>saveenv
   ```

   NOTE

   ramdisk_size needs to be set if the ramdisk uncompress file size is bigger than default setting. It should be more than ramdisk uncompress file size. The file size information is printed in Yocto Project build log.

2. **Booting Up the System**

   Execute the following commands to TFTP the images to the board, then boot into Linux.

   ```
   =>tftp 1000000 <uImage_name>
   =>tftp 5000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>tftp 2000000 <platform_dtb_name>
   =>bootm 1000000 5000000 2000000
   ```

   Now the board will boot into Linux using the images generated by Yocto Project.

4.4.20.9.2 Ramdisk Deployment from Flash

Programming the kernel and ramdisk into flash will allow you to boot up the board afterwards without the need to re-download images.

1. **Setting U-Boot Environment**

   The images generated by Yocto Project allow you to perform ramdisk deployment from flash. Before performing ramdisk deployment from flash, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment from flash:

   ```
   =>setenv ramargs 'setenv bootargs root=/dev/ram rw console=ttyS0,115200'
   =>setenv bootcmd 'run ramargs; bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>'
   =>saveenv
   ```

   Now U-Boot is ready for flash deployment.

2. **Programming Kernel ITB to NOR Flash**

The kernel should be downloaded to the RAM using TFTP then copied to the flash address <kernel_itb_addr>. At the U-Boot prompt, use the following commands to program the kernel to flash:

```
=>tftp 1000000 <uImage name>
=>protect off <kernel_start_addr> +$filesize
=>erase <kernel_start_addr> +$filesize
=>cp.b 1000000 <kernel_start_addr> $filesize
=>protect on <kernel_start_addr> +$filesize
```

3. **Programming Ramdisk to NOR Flash**

   The ramdisk should be downloaded to the RAM then copied to the flash address <ramdisk_start_addr>. At the U-Boot prompt, use the following commands to program the ramdisk to flash:

```
=>tftp 2000000 fsl-image-core-<platform>.ext2.gz.u-boot
=>protect off <ramdisk_start_addr> +$filesize
=>erase <ramdisk_start_addr> +$filesize
=>cp.b 2000000 <ramdisk_start_addr> $filesize
=>protect on <ramdisk_start_addr> +$filesize
```

4. **Programming Device Tree File to NOR Flash**

   The dtb file should be downloaded to the RAM, then copied to the flash address <dtb_start_addr>. At the U-Boot prompt, use the following commands to program the dtb file to flash:

```
=>tftp c00000 <platform dtb name>
=>protect off <dtb_start_addr> +$filesize
=>erase <dtb_start_addr> +$filesize
=>cp.b c00000 <dtb_start_addr> $filesize
=>protect on <dtb_start_addr> +$filesize
```

5. **Booting Up the System**

   The kernel can boot up automatically after the board is powered on, or the following command can be used to boot up the board at U-Boot prompt:

```
=>boot
```

   or

```
=> bootm <kernel_start_addr> <ramdisk_start_addr> <dtb_start_addr>
```

4.4.20.9.3 NFS Deployment

1. **Generating File System with Yocto Project**

   Use Yocto Project to generate a tar.gz type file system, and uncompress it for NFS deployment.

2. **Setting Host NFS Server Environment**

   a. On the Linux host NFS server, add the following line in the file /etc/exports:

```
<nfs_root_path> <board_ipaddress>(rw,no_root_squash,async)
```

   b. Restart the NFS service:

```
/etc/init.d/nfs restart
```

NOTE

nfs_root_path: the NFS root directory path on NFS server.

3. **Setting U-Boot Environment**

   The NFS file system generated by Yocto Project allows you to perform NFS deployment. Before performing NFS deployment, the U-Boot environment variables need to be configured. Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for NFS deployment:

```
=>setenv bootargs root=/dev/nfs rw nfsroot=<tftp_serverip>:<nfs_root_path>
ip=<board_ipaddr>:<tftp_serverip>:
<your_gatewayip>:<your_netmask>:<board_name>:eth0:off console=ttyS0,115200
=>setenv netdev <ethx>
=>saveenv
```

NOTE

<ethx> is the port connected on the Linux boot network.

   Now U-Boot is ready for NFS deployment.

4. **Booting up the System**

   TFTP the kernel image to the board, then boot it up.

```
=>tftp 1000000 <uImage name>
=>tftp c00000 <platform dtb name>
=>bootm 1000000 - c00000
```

   Now the board will boot up with NFS filesystem.

4.4.20.9.4 SD Deployment

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SD card, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootfile uImage
# setenv fdtfile uImage.dtb
# setenv bootcmd 'setenv bootargs root=/dev/mmcblk0p2 rw rootdelay=5 console=$consoledev,
$baudrate;mmcinfo;ext2load mmc 0:2 $loadaddr   /boot/$bootfile;ext2load mmc 0:2 $fdtaddr /boot/
$fdtfile;bootm $loadaddr - $fdtaddr'
# save
```

Deploy Filesystem to the SD Card

Once the U-Boot network parameters have been set, follow the steps below to deploy the filesystem to the SD card:

1. Connect the card reader with SD card to the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdb", one MS-DOS partition(sdb1 and this partition usually for u-boot) and one ext2 partition(sdb2) in the SD card.

```
#fdisk /dev/sdb
```

3. Use the mkfs.ext2 command to create the filesystems.

```
# mkfs.vfat /dev/sdb1
# mkfs.ext2 /dev/sdb2
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdb2 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure the kernel image and dtb file are in /temp/boot directory, then umount the /temp.

```
# cp uImage and uImage.dtb to /temp/boot folder
# umount /temp
```

8. Plug in the SD card to the target board and power on.

4.4.20.9.5 Harddisk Deployment

The Linux kernel and filesystem can be put to the SATA hard disk for production deployment (harddisk deployment).

Setting U-Boot Environment

You can place the ext2 filesystem and kernel on the SATA harddisk, then the kernel can boot up automatically after the board is powered on or after reset. Prior to this deployment, make sure U-Boot parameters have been set up:

```
# setenv bootcmd 'setenv bootargs root=/dev/sdx1 rw console=ttyS0,115200;sata init;ext2load sata
0:1 1000000 /boot/uImage;ext2load sata 0:1 c00000 /boot/target.dtb;bootm 1000000 - c00000'
# save
```

Deploying Filesystem to the Harddisk

Once U-Boot network parameters have been set, follow the steps below to start Harddisk deployment. We need one ext2 partition. To make this we need one Linux Host PC.

1. Connect the SATA hard drive with Serial ATA cable and turn on the Linux Host PC.
2. Create the partitions by "fdisk /dev/sdx, one ext2 partition(sdx1) in the Hard disk. The sdx is sda, sdb, sdc, ... depending your host

```
# fdisk /dev/sdx
```

3. Use the mkfs command to create the filesystems.

```
# mkfs.ext2 /dev/sdx1
```

4. Create temp directory in host PC and mount the ext2 partition to the temp.

```
# mkdir /temp
# mount /dev/sdx1 /temp
# cd /temp
```

5. Mount the target board type .iso (eg. QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso) to get the tarball (eg. QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz) on host PC.

```
# mount -o loop QorIQ-SDK-<Version>-PPCE6500-<release date>-yocto.iso /work
```

6. Copy the file system to harddisk by extracing the QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz. Remove the tarball after extracting rootfs.

```
# cp QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz .
# sudo tar -zxvf QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
# rm QorIQ_SDK_<Version>_E6500_<release date>_ROOTFS_Image.tar.gz
```

7. Make sure copy the target kernel image and dtb to sata.

```
# cp uImage and target.dtb to /temp/boot folder
# umount /temp
```

8. Connect the SATA hard drive to the target board and power on.

4.4.20.9.6 Hypervisor Deployment

Introduction

Use the mux_server to connnect to the board to ensure that individual UART streams are decoded correctly on the host side.

```
./mux_server "/dev/ttySx"<port number 1> <port number 2> <port number 3> &
socat -,raw,echo=0 tcp:0:<port number 1>
socat -,raw,echo=0 tcp:0:<port number 2>
socat -,raw,echo=0 tcp:0:<port number3>
```

NOTE

Note: 'ttySx' should be replaced with the actual serial device that is used. The port number 1 relates to the U-Boot console, port number 2 related to Linux partition 1, port number 3 related to Linux partition 2. The total number of port numbers is 10.

For example, we assume mux_server has been run with three port numbers, starting at 15000:

```
socat -,raw,echo=0 tcp:0:15000 socat -,raw,echo=0 tcp:0:15001 socat -,raw,echo=0 tcp:0:15002
```

NOTE

The Linux-based mux_server utility is provided to support multiplexing and demultiplexing capabilities. The mux_server runs on a host system and attaches to the target system via a serial or network communications channel Configuring U-Boot for hv-2p Deployment.

Refer to Configuring U-Boot Network Parameters on page 102 to set the U-Boot environment variables. In addition, execute the following commands at the U-Boot prompt to prepare for hypervisor deployment:

```
=>setenv bootargs config-addr=0xfe8900000 console=ttyS0,115200
=>setenv bootcmd 'bootm 0xfe8700000 - 0xfe8800000'
=>saveenv
```

Now U-Boot is ready for hypervisor deployment.

Hypervisor Deployment

Now, the kernel, hypervisor image, device tree, hypervisor device tree and ramdisk filesystem can be flashed onto the board. These steps should be done assuming the user already has switched to the alternate bank.

1. **Programming Kernel to Flash**

   TFTP the kernel image to RAM, then copy it to the flash address 0xe8020000. Execute the following commands at the U-Boot prompt to program the kernel to flash:

   ```
   =>tftp 1000000 uImage
   =>erase e8020000 +$filesize
   =>cp.b 1000000 e8020000 $filesize
   ```

2. **Programming Ramdisk Filesystem to Flash**

   TFTP the ramdisk file system to RAM, then copy it to the flash at address 0xe9300000. Execute the following commands at U-Boot prompt to program the ramdisk to flash:

   ```
   =>tftp 1000000 fsl-image-core-<platform>.ext2.gz.u-boot
   =>erase e9300000 +$filesize
   =>cp.b 1000000 e9300000 $filesize
   ```

3. **Programming Hypervisor Image to Flash**

   TFTP the hypervisor images to RAM, then copy it to the flash at address 0xe8700000. Execute the following commands at U-Boot prompt to program the hypervisor image to flash:

   ```
   =>tftp 1000000 hv.uImage
   =>erase e8700000 +$filesize
   =>cp.b 1000000 e8700000 $filesize
   ```

4. **Programming Kernel dtb to Flash**

   TFTP the kernel dtb file to ram, then copy it to the flash at address 0xe8800000. Execute the following commands at U-Boot prompt to program the kernel dtb to flash:

   Target Deployment - for hv-2p mode deployment:

   ```
   =>tftp 1000000 <platform_name>-usdpaa.dtb
   =>erase e8800000 +$filesize
   =>cp.b 1000000 e8800000 $filesize
   ```

   Note: Program "hv-2p-lnx-lnx.dtb" to 0xe8800000

5. **Booting Up the System**

Note:The hv-2p configuration needs to run with <platform_name>-usdpaa.dtb. As of now, all the DPAA devices on this platform are given to USDPAA partition. The kernel can boot up automatically after the board is powered on with the correct U-Boot environment. The following command can also be used to boot up the board at U-Boot prompt:

```
=>boot
```

4.4.20.10 Check 'Link Up' for Serial Ethernet Interfaces

If you are experiencing problems with your Ethernet interfaces, this section provides some basic checks that can be performed in U-Boot to help diagnose the cause of the networking errors.

Check Communication to External PHY

In order to check if U-Boot can communicate with the PHYs on the board, use the U-Boot command *mdio list*. The U-Boot command *mdio list* will display all manageable Ethernet PHYs.

Example:

```
=> mdio list
FSL_MDIO0:
0 - Vitesse VSC8662 <--> FM1@DTSEC1
1 - Vitesse VSC8662 <--> FM1@DTSEC2
2 - Vitesse VSC8662 <--> FM1@DTSEC3
3 - Vitesse VSC8662 <--> FM1@DTSEC4
4 - Vitesse VSC8662 <--> FM2@DTSEC1
5 - Vitesse VSC8662 <--> FM2@DTSEC2
6 - Vitesse VSC8662 <--> FM2@DTSEC3
7 - Vitesse VSC8662 <--> FM2@DTSEC4
FM_TGEC_MDIO:
16 - Cortina CS4315/CS4340 <--> FM1@TGEC1
17 - Cortina CS4315/CS4340 <--> FM1@TGEC2
18 - Cortina CS4315/CS4340 <--> FM2@TGEC2
19 - Cortina CS4315/CS4340 <--> FM2@TGEC1
```

The results from the above *mdio list* command show that U-Boot was able to see PHYs on each of the 1G and 10G interfaces. If you see “Generic” reported, it is an indication that something is there but the T4240 can’t communicate with the device/port.

Check SGMII Link Status for External PHY

In order to check the status of a SGMII link, you can use the *mdio read* command. Since this is a Clause 22 device, we pass two arguments to the *mdio read* command.

```
mdio read <PHY address> <REGISTER Address>
```

Example:

```
=> mdio read FM1@DTSEC1 1
Reading from bus FSL_MDIO0
PHY at address 0:
1 - 0x79ed
```

The link partner (“copper side”) link status bit is in Register #1 on the PHY. The 'Link Status' bit is bit #2 (from the left) of the last nibble. In the above example the nibble of interest is "d" (d = b'1101'), and therefore the 'Link Status' = 1, which means 'link up'. If the link were down this bit would be a "0."

Check SGMII link Status for Internal PHY

The SGMII PCS on-chip also has link information. In this section we'll check for a valid link for FM1 EMAC1 (listed as FM1@DTSEC1 in U-Boot). For this check, if you want to see a valid link reported, connect the interface to a link partner.

For FM1 EMAC1 (FM1@DTSEC1), the register we want to read is SGMII Status Register (MDIO_SGMII_SR). In particular, we will check MDIO_SGMII_SR[LINK_STAT]. The register MDIO_SGMII_SR is in the SerDes SGMII MDIO register space at offset 0x1.

Note that for SGMII PCS we are using a Clause 22 device.

We will use the following registers in the in the Ethernet MAC controller register space to perform the read:

```
Offset 0x34 Management interface control register (MDIO_CTL)
Offset 0x38 Management interface data register (MDIO_DATA)
```

We will program MDIO_CTL so that a read of MDIO_DATA will return the contents of MDIO_SGMII_SR. The first step is to identify the values needed to write to MDIO_CTL:

Since 0x1 is the Offset of MDIO_SGMII_SR is the SGMII MDIO register space set MDIO_CTL[DEV_ADDR] = 0x1.

The SGMII MDIO register space is selected when the associated SGMIInCR1[MDEV_PORT] matches the Ethernet MAC PHY address (MDIO_CTL[PHY_ADDR]). So we will set:

```
MDIO_CTL[DEV_ADDR] = 0x1
MDIO_CTL[PHY_ADDR] = SGMIInCR1[MDEV_PORT]
```

Note that SGMII Protocol Control Register 1 (SGMIInCR1, n = A, B, ..., H) is in the SerDes register space.

In T4240RM see table 18.1.1.5 "MDIO port mapping" for the mapping of PCD MDIO Slave to MAC MDIO Master. For this example, we're using MAC MDIO master FM1-MAC1 and PCS MDIO slave SGMIIA (i.e., SGMIInCR1 where n=A).

Read SGMIIACR1:

```
=> md fe0ea604
fe0ea604: 000008bf 00000000 00000000 80000000    ................
```

So SGMIIACR1[MDEV_PORT] = 0.

So we will program MDIO_CTL with the following values:

```
MDIO_CTL[DEV_ADDR] = 0x1
MDIO_CTL[PHY_ADDR] = SGMIIACR1[MDEV_PORT] = 0
```

Read of FM1-EMAC1 MDIO_SGMII_SR:

```
=> mm fe4e1034                   <== FM1 (offset 0x400000) EMAC1 (offset 0xe1000) MDIO_CTL (offset
0x34)
fe4e1034: 00000003 ? 8001         <== Set MDIO_CTL[READ] = 1 MDIO_CTL[PHY_ADDR] = 0 and
MDIO_CTL[DEV_ADDR] = 1
fe4e1038: 00001001 ? x
=> md fe4e1030                    <== Read MDIO_DATA (offset 0x38) for contents of MDIO_SGMII_SR
fe4e1030: 40001408 00000001 0000000d 0000000d    @...............
```

The above shows that MDIO_SGMII_SR = 0x0000000d and so MDIO_SGMII_SR[LINK_STAT] = 1 indicating that the link is valid.

Check XFI Link Status for Internal PHY

The XFI PCS on-chip also has link information. In this section we'll checkfor a valid link for FM1 EMAC9 (listed as FM1@TGEC1 in U-Boot). For this check,if you want to see a valid link reported, connect the interface to a link partner.

For FM1 EMAC9 (FM1@TGEC1), the register we want to read is XFI 10GBASE-R PCS Status 1 (MDIO_XFI_PCS_10GR_SR1). In particular, we will check MDIO_XFI_PCS_10GR_SR1[RX_LINK_STAT]. The register MDIO_XFI_PCS_10GR_SR1 is in the SerDes XFI PCS register space at offset 0x20.

Note that for XFI PCS, we are using Clause 45 device.

We will use the following registers in the Ethernet MAC controller register space to perform the read:

```
Offset 0x30 Management interface control register (MDIO_CTRL)
Offset 0x38 Management interface data register (MDIO_DATA)
Offset 0x3C Management interface address register (MDIO_ADDR)
```

We will program MDIO_CTRL and MDIO_ADDR so that a read of MDIO_DATA will return the contents of MDIO_XFI_PCS_10GR_SR1. The first step is to identify the values needed to write to MDIO_ADDR and MDIO_CTL:

Since 0x20 is the Offset of MDIO_XFI_PCS_10GR_SR1 in XFI PCS register space we set MDIO_ADDR[REGADDR] = 0x20.

The XFI PCS register space is selected when the associated XFInCR1[MDEV_PORT] matches the Ethernet MAC port address (MDIO_CTL[PORT_ADDR]) and the MDIO_CTL[DEV_ADDR] is 0x3.

To summarize, we will set:

```
MDIO_ADDR[REGADDR] = 0x20
MDIO_CTL[DEV_ADDR] = 0x3
MDIO_CTL[PORT_ADDR] = XFInCR1[MDEV_PORT]
```

Note that XFI Protocol Control Register1 (XFInCR1, n = A, B, C, D) is in the SerDes register space.

In T4240RM see table 18.1.1.5 "*MDIO port mpaping*" for the mapping of PCD MDIO Slave to MAC MDIO Master. For this example, we're using MAC MDIO master FM1-MAC9 and PCS MDIO slave XFIC (i.e., XFInCR1 where n=C).

Read XFICCR1:

```
=> md fe0ea6e4
fe0ea6e4: 00000000 00000000 00000000 80000000    ................
```

So XFICCR1[MDEV_PORT] = 0.

So we will program MDIO_ADDR and MDIO_CTL with the following values:

```
MDIO_ADDR[REGADDR] = 0x20
MDIO_CTL[DEV_ADDR] = 0x3
MDIO_CTL[PORT_ADDR] = XFICCR1[MDEV_PORT] = 0
```

Read of FM1-EMAC9 MDIO_XFI_PCD_10GR_SR1:

```
=> mm fe4f103c                      <== FM1 (offset 0x400000) EMAC9 (offset 0xf1000) MDIO_ADDR
(offset 0x3c)
fe4f103c: 00000002 ? 20             <== Set MDIO_ADDR[REGADDR] = 0x20
fe4f1040: 00000000 ? x
=> mm fe4f1034                      <== FM1 (offset 0x400000) EMAC9 (offset 0xf1000) MDIO_CTL
```

```
(offset 0x34)
fe4f1034: 00000003 ? 8003           <== Set MDIO_CTL[READ] = 1, MDIO_CTL[PORT_ADDR] = 0,
MDIO_CTL[DEV_ADDR] = 0x3
fe4f1038: 00001001 ? x
=> md fe4f1030                      <== Read MDIO_DATA (offset 0x38) for contents of
MDIO_XFI_PCS_10GR_SR1
fe4f1030: 40001448 00000003 00001001 00001001    @..H............
```

The above shows that MDIO_XFI_PCS_10GR_SR1 = 0x00010001 and so MDIO_XFI_PCS_10GR_SR1[RX_LINK_STAT] = 1 indicating that 10GBase-R PCS receive link is up.

4.4.20.11 Basic Networking Ping Test

In Linux, in order to check that your network driver is set up, follow the commands below:

```
#ip addr show
#ip addr add <ip address of board>/24 brd + dev <port in Linux>
#ip link set <port in Linux> up
#ping <serverip>
```

If your network driver is not working, check your kernel messages. You should not see any errors reported by the FSL FMan MAC API based driver:

```
fsl_mac: fsl_mac: FSL FMan MAC API based driver ()
fsl_mac ffe4e0000.ethernet: FMan MEMAC
fsl_mac ffe4e0000.ethernet: FMan MAC address: 00:e0:0c:00:38:00
fsl_mac ffe4e2000.ethernet: FMan MEMAC
fsl_mac ffe4e2000.ethernet: FMan MAC address: 00:e0:0c:00:38:01
fsl_mac ffe4e4000.ethernet: FMan MEMAC

fsl_mac ffe5e0000.ethernet: FMan MEMAC
fsl_mac ffe5e0000.ethernet: FMan MAC address: 00:e0:0c:00:38:08
fsl_mac ffe5e2000.ethernet: FMan MEMAC
fsl_mac ffe5e2000.ethernet: FMan MAC address: 00:e0:0c:00:38:09
fsl_mac ffe5e4000.ethernet: FMan MEMAC
fsl_mac ffe5e4000.ethernet: FMan MAC address: 00:e0:0c:00:38:0a
fsl_mac ffe5e6000.ethernet: FMan MEMAC
fsl_mac ffe5e6000.ethernet: FMan MAC address: 00:e0:0c:00:38:0b
fsl_mac ffe5f0000.ethernet: FMan MEMAC
fsl_mac ffe5f0000.ethernet: FMan MAC address: 00:e0:0c:00:38:0e
fsl_mac ffe5f2000.ethernet: FMan MEMAC
fsl_mac ffe5f2000.ethernet: FMan MAC address: 00:e0:0c:00:38:0f
```

Chapter 5
System Recovery

NOTE

The following instructions can also be used for NOR flash recovery.

5.1 Environment Setup

5.1.1 Environment Setup (Common)

The section describes the related setup for system recovery

1. Required Materials
   - Target board
   - The related recovery image files
2. Host PC setup

   The host PC should have a serial-terminal program capable of running at 115,200bps, 8-N-1, for communicating with U-Boot running on the target board.
3. Target board setup
   a. Power off the target board system if the power is already on.
   b. If U-Boot runs on this board, and U-Boot commands will be used to reflash the U-Boot images, connect the target board to the network via the eTSEC port on the board.
   c. Connect the target board to the host machine via the serial port with an RS-232 cable and the joined NXP adapter cable, if needed.
   d. Set up the serial terminal in the host machine with 115,200bps, 8-N-1, no flow control.
   e. Verify all the switches and jumpers are set up correctly to default values described in <Hardware configurations> as described in the Switch Settings section of the board's Software Deployment Guide
   f. Connect the JTAG cable for your CodeWarrior TAP or Gigabit TAP to the board if you will be using the CodeWarrior Flash Programmer to recover the board image.
   g. Power on the board.

5.2 Image Recovery

5.2.1 Recover system with already working U-Boot

Target Board Setup

1. Power off the target board system if the power is already on.
2. Connect the target board to the network via the eTSEC port on the board.
3. Connect the target board to the host machine via the serial port with an RS-232 cable and the joined NXP adaptor cable, if needed.

4. Set up the serial terminal in the host machine with 115,200bps, 8-N-1, no flow control.
5. Verify all the switches and jumpers are setup correctly to default value described in the board's "Switch Settings" section in the board's Software Deployment Guide.
6. Power on the board.

Refer to the “Programming a New U-Boot…” section in the Software Deployment Guide for the target board to be recovered.

5.2.2 Recover system using CodeWarrior Flash Programmer

Environment Setup

Required Materials

- Target board.
- CodeWarrior for Power Architecture v10.x (for Windows or Linux)
- CodeWarrior TAP or Gigabit TAP run control device.
- The related recovery image files.

Host PC setup

The host PC is assumed to be running Windows 7, or one of the supported distributions of Linux (refer to the CodeWarrior PA10 Release Notes for the list of supported Linux distributions).

This machine should have latest CodeWarrior PA10 installed and working correctly. If the run control device is a CodeWarrior TAP used over USB, then the USB drivers should be installed automatically when the device is plugged in. If the run control device is a CodeWarrior TAP used over Ethernet, or a Gigabit TAP, then both the host PC and TAP should be connected to the network, and communications between them should be verified.

Target board setup

1. Power off the Target board system if the power is already on.
2. Connect the Target board to the host machine via the serial port with an RS-232 cable and the joined NXP adaptor cable, if needed.
3. Set up the serial terminal in the host machine with 115,200bps, 8-N-1, no flow control.
4. Verify all the switches and jumpers are set up correctly to default values described in the "Switch Settings" section in the board's Software Deployment Guide.
5. Connect the TAP's JTAG cable to the board.
6. Power on the board.

System Recovery

1. Start the CodeWarrior PA10 or ARMv7 IDE.
2. For LS102x targets, see Chapter 3 of *Getting Started for ARMv7 Processors.pdf* in the CodeWarrior ARMv7 installation for steps on creating a BareBoard Core0 project for the LS102x processor on this target board. For other QorIQ targets, see Quick Start for PA 10 Processors.pdf in the CodeWarrior PA10 installation for steps on creating a BareBoard AMP Core0 project for the QorIQ processor on this target board. In the "Debug Target Settings Page", of the procedure for creating a new project, uncheck the 'Download' option, and enable the 'Download SRAM' option, if available.
3. Select your CodeWarrior TAP or Gigabit TAP as your debug connection type. For CodeWarrior TAP, select “USB” or “Ethernet” as the connection medium.
4. Build the project.
5. Bring up the Target Tasks view: go to Window>Show View>Other>Debug>Target Task.

6. Import the Flash Profile:
   a. In the Target Tasks view, click on the Import button. A file-browser window will appear, showing the "Flash_Programmer" folder.
   b. Open the "Flash_Programmer" folder, then the folder associated with the processor family on this target board.
   c. Select the configuration file for the particular target and flash device to be programmed on this target board, and click OK to import it. This file will appear in the Target Tasks view.
7. In the board's Software Deployment Guide, locate the “Flash Bank Usage” section for the target board to be recovered.
   a. Identify the NOR/NAND/SPI flash memory map that applies to the flash to be programmed. For the following steps, if the target flash supports multiple banks, choose the starting addresses for ‘Bank0’ or ‘current bank’, as appropriate.
   b. Identify the starting address for the u-boot image.
   c. Identify the starting address for the RCW image (if applicable).
   d. Identify the starting address for the PPA image (if applicable).
   e. Identify the starting address for the ucode/microcode (if applicable).
   f. Identify the starting address for the dtb image.
   g. Identify the starting address for the RamDisk image.
   h. Identify the starting address for the Linux Kernel image.

      For example:

Images	**Size**	**vbank0**	**vbank4**
RCW + PBI	1MB	0x5_8000_0000	0x5_8400_0000
U-boot boot loader	1MB	0x5_8010_0000	0x5_8410_0000
U-boot Env	1MB	0x5_8020_0000	0x5_8420_0000
MC FW	4MB	0x5_8030_0000	0x5_8430_0000
MC DPL Blob	1MB	0x5_8070_0000	0x5_8470_0000
MC DPC Blob	1MB	0x5_8080_0000	0x5_8480_0000
Unused	4MB	0x5_8090_0000	0x5_8490_0000
Reserved	1MB	0x5_80F0_0000	0x5_84F0_0000
Cortina PHY FW	1MB	0x5_8100_0000	0x5_8500_0000
FIT Images (Linux, device tree, and rfs)	40MB	0x5_8110_0000	0x5_8510_0000
Unused	7MB	0x5_8390_0000	0x5_8790_0000
Primary Protected Application (PPA)	2MB	0x5_80a0_0000	0x5_84a0_0000
Secure Boot Headers	3MB	0x5_80c0_0000	0x5_84c0_0000

      For example:

Table 112. T4240QDS NOR flash

Binaries	Starting Address
U-Boot	0xEFF40000
RCW	0xE8000000
ucode	0xEFF00000
dtb	0xE8800000
RamDisk (rootfs)	0xE9300000
Linux Kernel (uImage)	0xE8020000

8. Configure Flash Programmer.
   a. Double-click on the file name that was imported with the flash profile, to bring up the Flash Programmer Task view.
   b. Click on 'Add Action'>'Program/Verify'.
   c. Set 'File Type' to "Binary".
   d. Click on 'File System' and navigate to the folder containing the u-boot binary image.
   e. Enable "Erase sectors before program".
   f. Enable "Apply address offset", and enter the starting address where this binary recovery image will be flashed (see the tables in the previous step for examples).
   g. (OPTIONAL) Enable 'Verify after program' to verify that the flash programming was successful.
   h. Repeat steps (starting with Click 'Add Action') above for each binary image file to be programmed into flash.
9. Execute Flash Programming.
   a. In the Target Tasks view, right-click on the imported filename and select the green Execute button to launch the programmer.
   b. If Execute is not green, the debugger is not running. The debugger must be running for this flash programmer to work.
   c. When finished flashing, terminate the debugger.
10. This is the end of the process. Now the boot loader, kernel and root file system are programmed to flash.
11. Reset or power-cycle the board and verify that u-boot appears in the board's serial terminal.

Chapter 6
DPAA2-specific Software

6.1 DPAA2 Software Overview

6.1.1 Introduction

This document provides an overview of the software and tools for the DPAA2 networking hardware that is provided on NXP SoCs such as LS2088A. These SoCs are called "DPAA2 SoCs" because they contain the hardware that is required to support the DPAA2 networking architecture. As will be described below, this hardware includes Queue Manager/Buffer Manager (QBMan), the Wire Rate I/O Processor (WRIOP), and the Management Complex (MC).

DPAA2 is an architecture in which some facilities (and thus the hardware that supports them) are optional. For this reason, this document may describe features that are not available on all DPAA2 SoCs.

Intended audience

This document is intended for software developers and architects who want to develop software for DPAA2 SoCs. The document assumes that users will be familiar with Linux-based development, computer networking, and also with the ARM™ architecture

Definitions and acronyms

- AIOP: Advanced I/O Processor hardware
- DCE: Decompression, Compression Engine hardware
- DPAA2: Datapath Acceleration Architecture, second version
- DPAA2 SoC: An SoC that contains the DPAA2 hardware
- GPP: General Purpose Processor
- MC: Management Complex
- NADK: Networking Application Development Kit
- PME: Pattern Matching Engine hardware
- QBMan: Queue Manager and Buffer Manager hardware
- SDK: Software Development Kit
- SEC: Security Engine hardware
- USDPAA: User Space Datapath Acceleration Architecture
- WRIOP: Wire Rate I/O Processor hardware

DPAA2 in the NXP SDK

NXP provides a Linux-based software development kit (SDK) for SoCs. The core of the SDK is an embedded-oriented Linux distribution containing components such as:

- U-Boot boot loader
- Linux kernel with networking support
- GNU tool chain for ARMv8™
- Large set of standard Linux user space packages including shells, initialization scripts, servers, etc.

- Yocto-based package management in an embedded-style source-based Linux distribution

NXP supports and builds upon standard Linux with drivers and additional packages and capabilities including support for the DPAA2 networking hardware such as:

- Management complex firmware for the DPAA2 architecture. DPAA2 is a networking peripheral subsystem architecture and will be discussed at length in later sections.
- Restool: a DPAA2 object management tool
- A DPAA2 Linux Ethernet driver
- Linux kernel support for treating DPAA2 containers as plug-and-play busses with VFIO support
- Integrated kernel-based control of DPAA2 L2 switch objects
- Kernel support for DPAA2 acceleration objects including cryptographic offload
- And more

6.1.2 DPAA2 Hardware

6.1.2.1 Introduction

This section introduces the DPAA2 hardware components and explains their relationship to the DPAA hardware found on previous NXP SoCs. Finally, it shows the DPAA2 hardware blocks in the context of a specific SoC, the LS2088A.

Note that the DPAA2 hardware is configured via DPAA2 objects as will be described below. This section on hardware provides background information to give context to the discussion of the DPAA2 objects. Most developers will deal with the DPAA2 objects and not directly with all aspects of the DPAA2 hardware blocks.

6.1.2.2 DPAA2 hardware

The DPAA2 hardware provides network interfaces, hardware-based queuing, layer 2 switching, more general switching, networking-related accelerators, and also memory dedicated to packet processing.

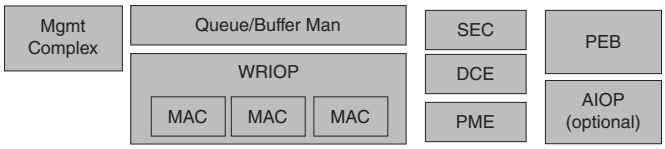

Figure 7. DPAA2 hardware components

See DPAA2 hardware components. The DPAA2 hardware contains the following components:

Management Complex (MC)

The DPAA2 hardware is abstracted by DPAA2 objects with the help of the Management Complex. This means that users need not study the details of the DPAA2 hardware blocks in order to develop drivers for or use DPAA2 capabilities. This software and solution oriented focus is one of the key differences between the first DPAA and DPAA2.

Queue and Buffer Manager (QBMan)

QBMan provides hardware-based buffer and queue management.

WRIOP

WRIOP provides hardware that serves as the basis for network interfaces. It includes Ethernet MACs, packet header key generators, parsers, table look up units, and an interface to the buffer and queue managers.

Accelerators (optional)

Accelerators that interface to QBMan are a key part of DPAA2. They include a cryptographic and security accelerator (SEC), a pattern matching accelerator (PME), a data compression/decompression accelerator (DCE), and a generic DMA engine. The set of accelerators may vary from SoC to SoC and new types of accelerators may be added.

PEB (optional)

PEB is a memory devoted to high-performance packet processing. It can be used to store in-flight packets and other items.

AIOP (optional)

AIOP is a fully programmable multicore engine with tightly coupled hardware accelerators that is specialized for efficient packet processing. It uses techniques somewhat similar to hardware multithreading to provide multiple "tasks" per core. The hardware supports efficient task switching to hide latencies associated with using accelerators and other hardware. The AIOP supports C language programming. It is optional in the DPAA2 architecture and thus is not available on all DPAA2 SoCs.

DPAA2 versus DPAA

DPAA2 is the latest generation of the Datapath Acceleration Architecture (DPAA) hardware. It is an evolution of the DPAA present in previous SoCs.

DPAA2 changes relative to DPAA include:

- DPAA2 contains a hardware block called the Management Complex. It facilitates and simplifies hardware resource allocation and hardware configuration.
- The hardware buffer and queue managers (QMan and BMan) are integrated into a single hardware block called QBMan.
- DPAA2 session context can be maintained per frame, rather than per frame queue, which allows multiple accelerator sessions to share a single frame queue pair. This single frame queue pair then reduces the number of frame queues needed, making session establishment more efficient because frame queues do not need to be initialized per session.
- Software portals are enhanced to make it easier and more efficient for General Purpose Processing (GPP) core software to share them.
- WRIOP in DPAA2 replaces FMan as the hardware block that provides Ethernet interfaces. WRIOP is designed to be more partitionable, in that it allows GPP software to more independently manage separate network interfaces.
- WRIOP and QBMan contain new features that support autonomous L2 switching functionality:
  - WRIOP: L2 address learning and forwarding unit.
  - QBMan: packet replication facility.
- WRIOP does not contain a generic programmable engine like the one present in FMan, and instead DPAA2 has a new hardware block called AIOP that is specifically designed to perform this function.

6.1.2.3 LS2088A block diagram

The LS2088A is an ARMv8-A 64-bit SoC. It contains eight ARM Cortex-A57 cores and numerous peripherals. The LS2088A is an example of a DPAA2 SoC because it contains the required DPAA2 hardware blocks: WRIOP, QBMan, and MC.

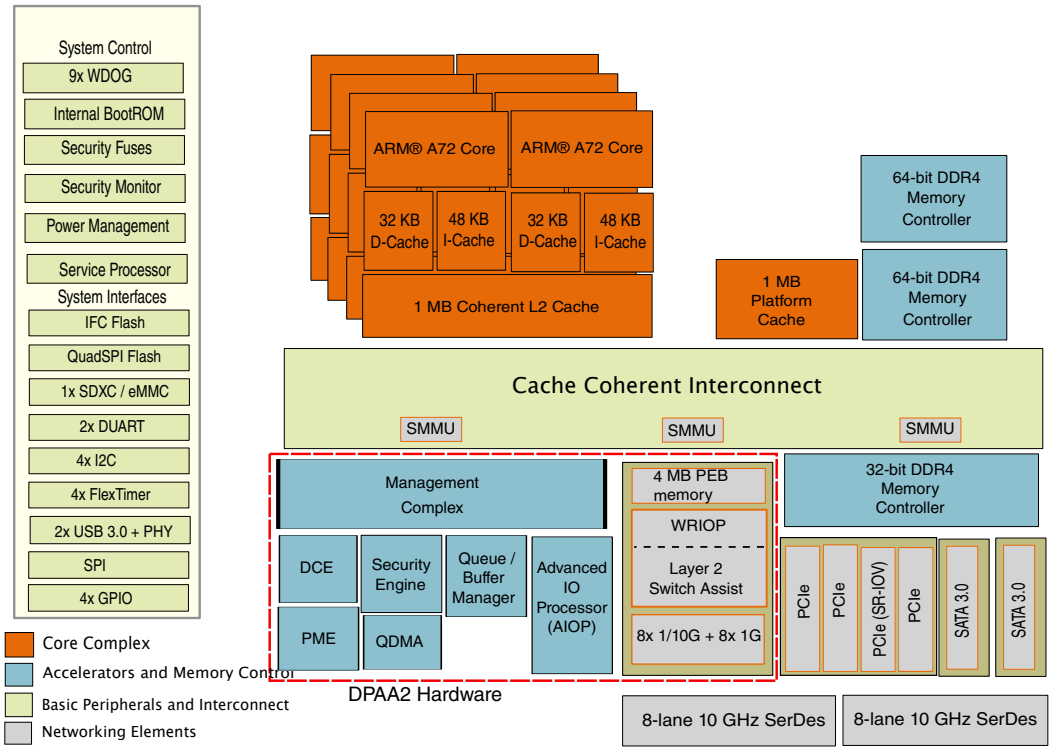

Figure 8. LS2088A SoC

The LS2088A contains standard-ARM components in addition to the cores, such as:

- ARM generic timer
- GIC-500 interrupt controller
- MMU-500 System Memory Management Unit (I/O MMU)

It also contains conventional hardware blocks including:

- DDR controllers
- Flash controller
- SDxC/eMMC controller
- USB controller
- PCIe controller
- SATA controller
- Other blocks visible in the diagram.

Finally, the following DPAA2 components are highlighted in the figure:

- QMan/BMan: hardware queue and buffer management
- WRIOP: Ethernet interfaces
- Management complex: DPAA2 objects and their management
- Accelerators: SEC, PME, and DCE

6.1.3 DPAA2 Linux Software

6.1.3.1 Introduction

This section provides a high-level summary of the most important DPAA2 software associated with the Linux operating system.

6.1.3.2 Linux and DPAA2

This section summarizes major Linux DPAA2 software. See Linux DPAA2 software which shows the software in relation to some standard Linux software.

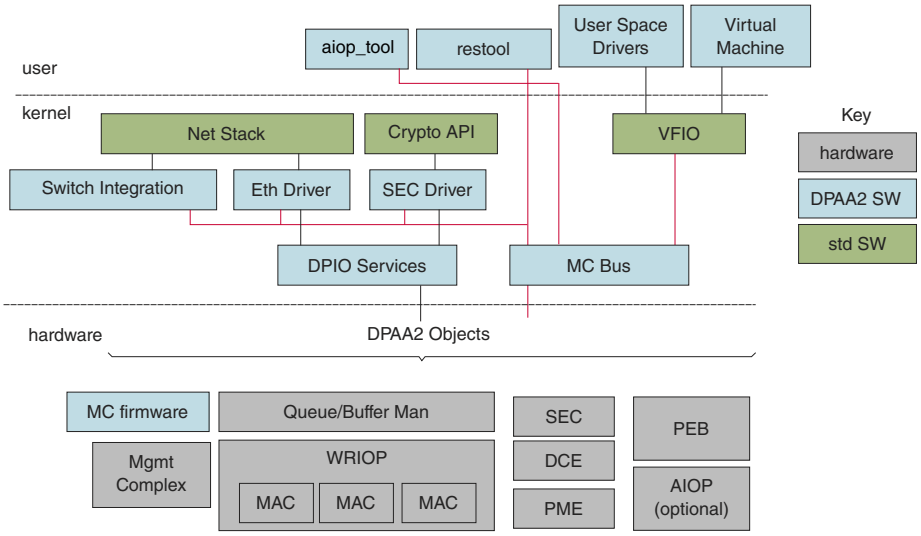

Figure 9. Linux DPAA2 software

Ethernet Driver

DPAA2 software includes a conventional Ethernet driver for use by the Linux network stack. This driver is controlled via standard Linux means such as the "ifconfig" or "ip" commands and also "ethtool". It operates in a manner that will be familiar to Linux users. Drivers in DPAA2 manage DPAA2 "objects" as will be described below. These objects are best regarded as hardware. They are formed from hardware resources.

DPIO Services

DPAA2 drivers such as the Ethernet driver in the Linux kernel use the DPIO services Linux component to do I/O. The DPIO services layer manages the kernel's DPIO objects. DPIO objects contain DPAA2 software portals (which are hardware components). The software portals can be shared by multiple higher-level drivers.

DPAA2 Objects and Management Complex (MC) Firmware

The DPAA2 hardware is presented to software in terms of DPAA2 objects that are realized by means of firmware running on the Management Complex. This will be explained in depth in DPAA2 Networking Subsystem Deeper Dive on page 416 and also immediately below.

MC Bus and Restool

The DPAA2 objects appear as devices on a special software-defined bus called the MC bus. Linux has a driver for this bus (and interactions with VFIO). This software is analogous to PCIe bus software. Like PCIe, the MC bus supports plug and play.

The "restool" utility is a Linux user space command that allows DPAA2 objects to be managed: created, destroyed, queried for status, etc.

SEC Driver

The SEC driver provides the standard Linux kernel cryptographic API but implemented by the SEC hardware by means of a special DPAA2 object. Other accelerators can be handled in the same way, but Linux tends to not provide standard (hardware-independent) kernel-level APIs for them so they are not discussed here.

Switch Integration

Finally, DPAA2 objects exist that perform L2 and more general network switching. These hardware elements can be configured using standard Linux mechanisms such as "bridge". As will be discussed later, there are two types of switch-related DPAA2 objects: DPSW and DPDMUX. There is kernel-based management support for both.

AIOP Tool

AIOP Tool (aiop_tool) is a user space command line utility that allows programs (images) to be loaded onto the AIOP and started. It also supports stopping and resetting the AIOP. Of course, aiop_tool is used only on DPAA2 SoCs that have an AIOP.

It is also possible for user space programs to manage these aspects of AIOP via programmatic means. The aiop_tool utility is most useful during development of AIOP software and for AIOP applications that happen not to be tightly integrated with control software running in user space on the GPP cores.

From the point of view of software running on the GPP cores, AIOP programs may be thought of as firmware that defines the functionality that the AIOP will provide to an overall system.

.

6.1.3.3 DPAA2, Management Complex, and drivers

DPAA2 is the architecture that describes network interfaces and other networking services for an SoC with DPAA2 hardware. It is discussed in depth in DPAA2 Networking Subsystem Deeper Dive on page 416. For now, think of DPAA2 as hardware for networking that is presented in terms of DPAA2 objects. The objects provide specific high-level features or services such as network interfaces or L2 switches.

The objects are managed by means of firmware running on a hardware block called the Management Complex. Software on general purpose cores must load firmware onto the Management Complex before networking can be done using DPAA2 hardware.

Normally, the MC firmware is loaded early in the boot process so that boot loaders can make use of DPAA2 objects and peform networking operations such as network-based booting.

Since the objects represent hardware, they require driver software on general purpose cores. NXP provides drivers for U-Boot and standard Linux and thus both support Ethernet networking out of the box. For example, one can use Linux networking without delving into the details of DPAA2 and its objects just as one can use Linux networking via a PCIe Ethernet card (whose manufacturer provides a driver) without delving into the design of the card.

DPAA2 and its objects are fully documented so it is possible to write drivers for other operating systems, applications, or boot loaders, e.g. ODP, DPDK, UEFI firmware, etc. Many of these drivers exist or are roadmap items.

6.1.3.4 DPAA2 and plug-and-play

There is another analogy between DPAA2 objects and PCIe devices. PCIe devices appear to operating systems as plug-and-play devices on a bus. The operating system can scan the bus to discover and identify the devices on it. It can then use the device identities to associate drivers with devices and bring them into service.

DPAA2 objects work in a similar way. They are placed into datapath containers (DPRC) that can be scanned in an analogous manner. Then objects are associated with drivers and placed into service.

The Linux kernel is provided with a container with its DPAA2 objects. Containers can also be provided to other software including virtual machines and even arbitrary user space processes. This is how the hardware that objects encapsulate can be directly assigned to virtual machines and user space processes. This allows them highly efficient access to hardware but in a secure fashion due to the involvement of the SoC IO-MMU.

This, also, is analogous to PCIe devices in standard Linux; DPAA2 objects can be directly assigned to virtual machines and user space processes using a standard Linux architecture called VFIO which allows devices to be mapped into the address space of user space processes and also enables IO-MMU configuration to constrain the memory to which devices can read and write data via their DMA engines.

Like PCIe devices, DPAA2 objects are also mapped using VFIO. NXP supplies the extensions to VFIO in Linux that makes this possible.

6.1.3.5 Datapath layout files and restool

As mentioned elsewhere, DPAA2 containers are like PCIe busses in that they can be scanned for objects/devices. But containers and PCIe busses are populated very differently. PCIe busses are populated physically, e.g. by plugging a card into a slot.

Objects are encapsulations of DPAA2 hardware resources that must be created via management complex firmware and then assigned to a container. There are several ways to do this:

1. the datapath layout file
2. restool
3. Management Complex commands

Datapath layout (DPL) file

Containers and objects can be defined statically in a file called a datapath layout file (DPL) that is passed to the management complex when it is initially booted. The DPL can specify containers, objects, and connections between objects. When an OS such as Linux boots, it will discover the populated containers.

restool

The utility called “restool” is a NXP-created Linux user space command that allows inspection and dynamic management of containers and objects. With it, one can

- Display the current set of containers and objects
- Create and destroy containers
- Create and destroy objects
- Assign objects to containers
- Create links among objects

One can use a sequence of restool command invocations to create the same container and object state that a DPL might specify. The difference is that restool is dynamic.

Management Complex commands

Finally, objects and containers can be manipulated by software running on general purpose cores by sending commands to the Management Complex. This is, in fact, what restool does. Command line arguments to restool define an operation. The restool utility simply forms a command and passes it to the Management Complex. Other drives can also do this.

6.1.4 DPAA2 Networking Subsystem Deeper Dive

This section provides additional detail on the DPAA2 architecture and the DPAA2 object services paradigm.

This paradigm simplifies using the DPAA2 hardware IP blocks through abstraction and encapsulation. DPAA2 objects are objects in the sense that they:

- Encapsulate specific abstract functionality, e.g. L2 switching.

- Are composed of allocated hardware sub-components of the DPAA2 hardware peripherals, and then mostly abstract their functionality .
- Present functionality in terms of specific attributes and methods, meaning operations on the objects.

NOTE

DPAA2 objects are not associated with object-oriented programming languages, instead they are collections of hardware resources allocated for a specific purpose. General purpose processing (GPP) core software can configure objects by sending them commands expressed in terms of hardware-level descriptors. GPP software can also include C language functions that prepare and interpret the descriptors. No use of object-oriented programming languages is required. For the most part, Linux drivers are written in C as usual

This section:

- Presents the DPAA2 object model at a concept level and describes how objects are created, destroyed, conveyed, configured, and used
- Lists the objects types and their purposes
- Outlines how the Management Complex implements and provides the objects
- Explains what software components use the various DPAA2 object types, and how they use them. The users are often application software running on general purpose processors (cores) or on the optional AIOP.

Driver-level software on GPPs works with the abstracted objects, rather than directly with the hardware. For example, the GPP software deals with L2 switch and network interface objects rather than WRIOPs .

DPAA2 objects express and abstract the DPAA2 hardware into software-managed objects that are:

- Application-oriented in terminology and use, rather than hardware-oriented
- Based on concepts that are generally familiar to programmers and system architects
- Simpler than direct management of the hardware
- Indicate the architectural intent of the hardware blocks

DPAA2 object services are provided by software that runs as firmware on a DPAA2 hardware block called the Management Complex. Users do not need to program the Management Complex in order to use the Network Object Services; they simply use the NXP-supplied firmware. This firmware runs on the Management Complex instead of a general purpose core in order to simplify the integration of the NXP software with customer software. DPAA2 object concept below shows at a concept level how the Management Complex provides objects that perform specific services; the objects have attributes and interfaces that appear as hardware.

Figure 10. DPAA2 object concept

6.1.4.1 DPAA2 hardware abstraction example

This section introduces the DPAA2 objects and the abstractions they provide by means of an example. Example scenario shows a system constructed using the DPAA2 hardware on a DPAA2 SoC such as the LS2088A. The goal is to run two KVM virtual machines (VMs) on the SoC. The two virtual machines each have a hardware network interface that they can directly access (i.e. a dedicated interface) connected to a DPAA2 L2 switch. These VMs can communicate with each other via the L2 switch, and they can communicate externally via the MAC on the L2 switch. So, the L2 switch has three ports, one for an off-SoC connection (connected to a MAC), and two for the VMs.

In addition, there are two network interfaces with MAC addresses for off-SoC communication that are used by the host Linux. The host Linux instance and the virtual machines all run on the Cortex-A72 cores on the LS2088A. In this example, each network interface is associated with an Ethernet driver working with Linux.

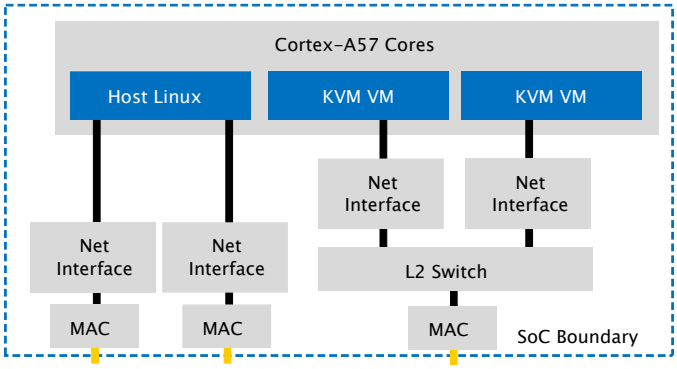

Figure 11. Example scenario

DPAA2 hardware shows the DPAA2 hardware blocks. This figure bears little resemblance to Example scenario. It provides little guidance to how the example scenario could be realized because the hardware blocks are conceptually distant from a natural statement of what is desired in the example. The DPAA2 objects are much closer, as will be seen below.

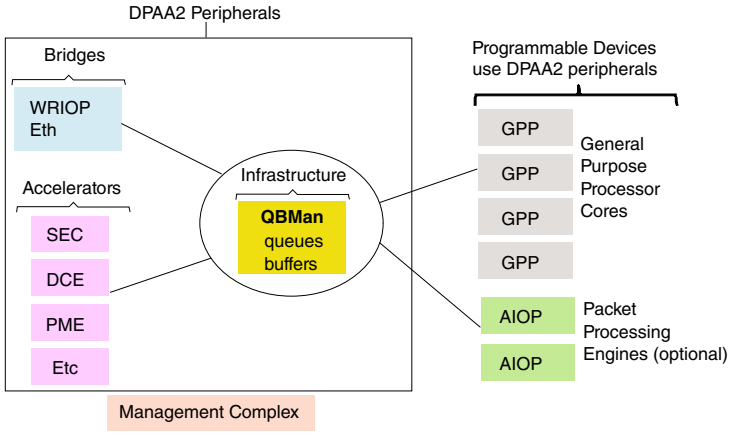

Figure 12. DPAA2 hardware

Example scenario based on DPAA2 objects shows how the example can be realized using the DPAA2 object abstractions of the DPAA2 hardware; this figure is much closer to the goal expressed in Example scenario and its components are described below:

- The host Linux is shown in more detail on the left. The network stack and two instances of the Ethernet drivers appear in the figure above the hardware boundary. Also, the figure shows the stacks and drivers for the two virtual machines.
- The DPAA2 objects appear below the hardware boundary
- The DPNI (Datapath Network Interface) objects correspond directly to the network interfaces in Example scenario. The DPSW (Datapath Switch) object corresponds to the L2 switch.
- The DPMAC (Datapath MAC) objects represent Ethernet MACs within WRIOP. These are hardware components that connect to PHY hardware, and provide Ethernet physical layer termination, i.e. Ethernet connections to the SoC.
- The DPIO (Datapath I/O) objects include QBMan software portals, and they allow GPP core software to read and write packets from the DPNIs. DPIOs are described in more detail later in this document.

See Object summary on page 421 for a summary of the DPAA2 objects.

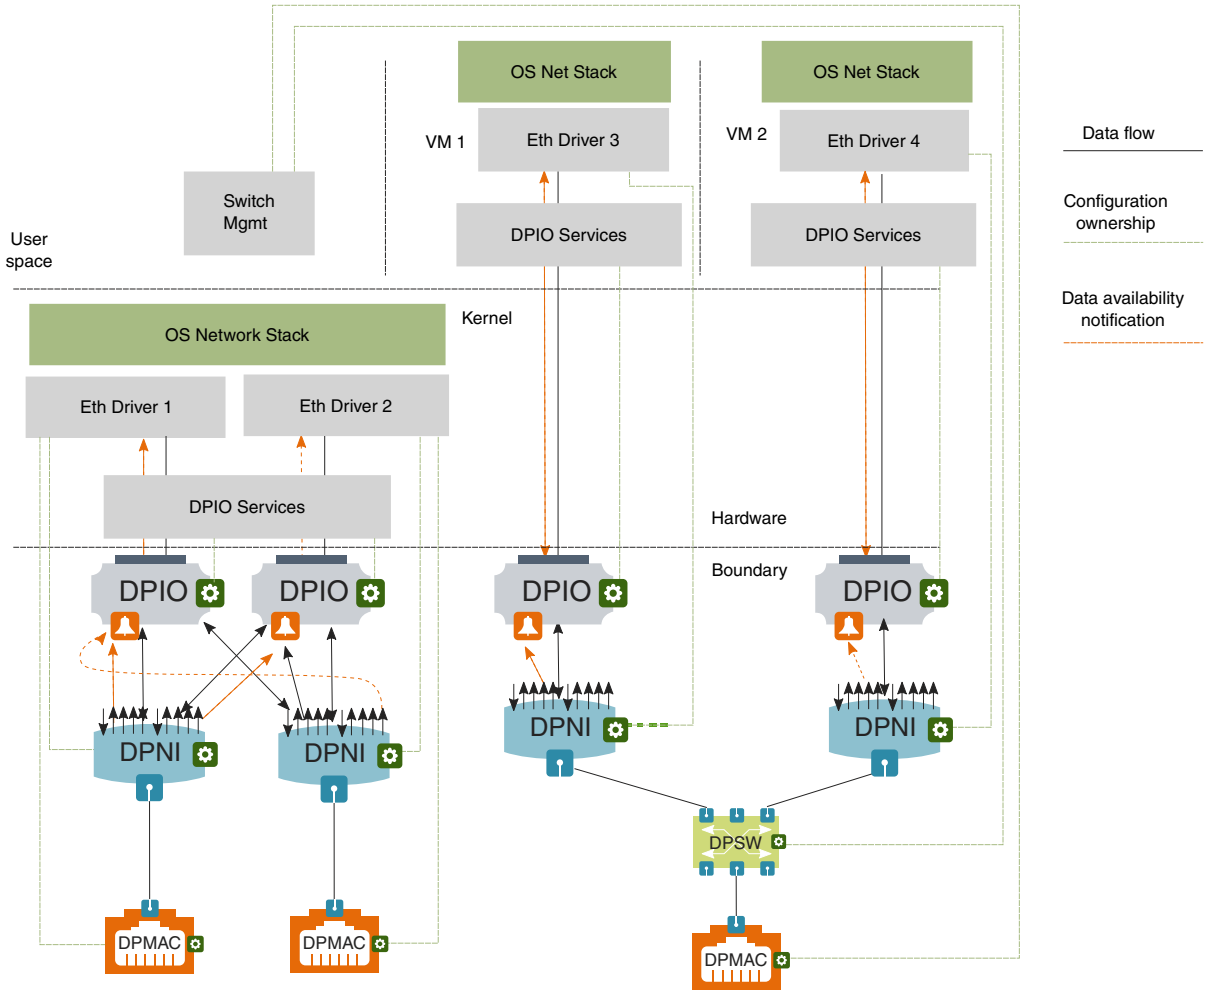

Figure 13. Example scenario based on DPAA2 objects

Objects are partitioned among software owners

Software management of DPAA2 objects is distributed. Software components that use a particular set of objects independently manage the objects in their set. The green boxes on the object icons in Example scenario based on DPAA2 objects represent management interfaces, and the green dashed lines show what software component owns the management of each object. For example, the DPSW is shown as managed by switch management software running on the general purpose processing cores.

Objects can be directly assigned

The virtual machines directly access and manage the objects their software uses, and they do this with minimal host kernel involvement; this enhances efficiency while preserving access isolation. In the figure, the virtual machines have directly assigned hardware-based network interfaces.

DPNI objects provide network interfaces

DPNI objects interact with drivers to allow software to send and receive network frames, usually Ethernet frames. DPNIs are central to DPAA2's concept of network interfaces, but they do not act alone. In general, network drivers manage several

objects as part of managing network interfaces. DPNI ingress shows a high-level outline of DPNI ingress frame processing, and the following steps give insight into how objects work together.

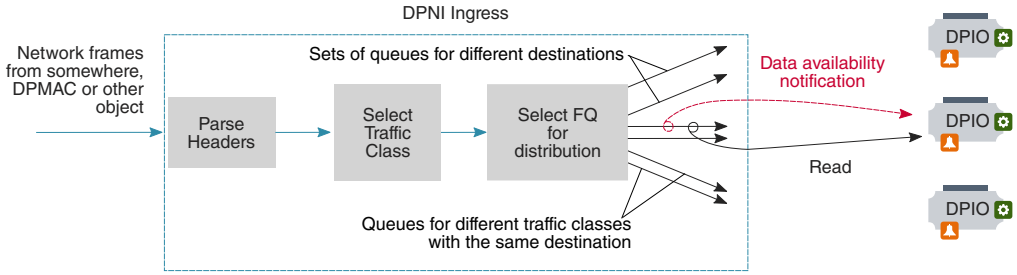

Figure 14. DPNI ingress

1. A frame arrives at DPNI from another object, a MAC (DPMAC), a switch (DPSW) or other object.
2. DPNI parses the packet to locate the header from which lookup keys can be generated.
3. A lookup selects a traffic class (priority) for the frame; this priority causes a specific set of queues (implemented as QMan frame queues) to be selected.
4. DPNI must select a destination for the frame, using either another lookup or an RSS-style hashing operation; this lookup causes a specific queue within the previously selected set to be selected.
5. The frame is enqueued onto the queue, and the queue represents the destination indirectly. At this point, DPIO objects enter the process.
6. Every queue is configured to deliver data availability notifications to a specific DPIO, and these notifications tell the driver software using the DPIO that one or more frames are available to read from a specific queue.
7. Driver software responds by using a DPIO (actually any of its DPIOs) to read a burst of one or more frames from the queue.

Egress is simpler. The driver software uses a DPIO to enqueue a frame to a specific egress queue within DPNI; the queue is selected based on the desired traffic class.

Multiple DPIOs provide parallelism

It is common to assign queues in network interfaces to specific cores, and then to distribute the traffic between them using techniques like RSS or explicit flow steering. DPAA2 supports this process by using multiple DPIOs. See DPIO parallelism for an example involving a single network interface and two cores.

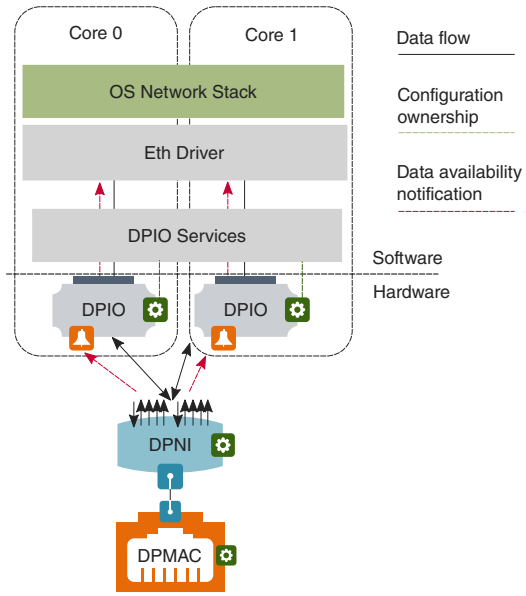

Figure 15. DPIO parallelism

The DPNI is configured so that each of its egress queues send its data availability notifications to one DPIO or another in a balanced way. A core receives an interrupt from its DPIO telling it to read a data availability notification, and then it then uses its DPIO to read a burst of one or more frames. In Linux terms, it starts a NAPI burst.

DPIO services

Notice in Example scenario based on DPAA2 objects that the host operating system on the left has two network interfaces. It has two DPIOs also, but either DPIO can be used for I/O to either of the interfaces. DPIOs are designed to be shared across network interfaces that belong to the same software component, such as the Linux kernel. For this reason, the Linux kernel contains a software layer called DPIO Services that facilitates driver instances performing I/O from a resource that might be shared across a network interface, and also might be shared across cores or software threads. Giving more DPIOs to the DPIO Services layer can increase performance, and using the same DPIO on a core for more than one network interface need not decrease performance because each core is physically able to do only one thing at a time.

6.1.4.1.1 Object summary

This section summaries the DPAA2 objects and shows a standard icon for each used in the illustrations that follow. See DPAA2 object summary and icons.

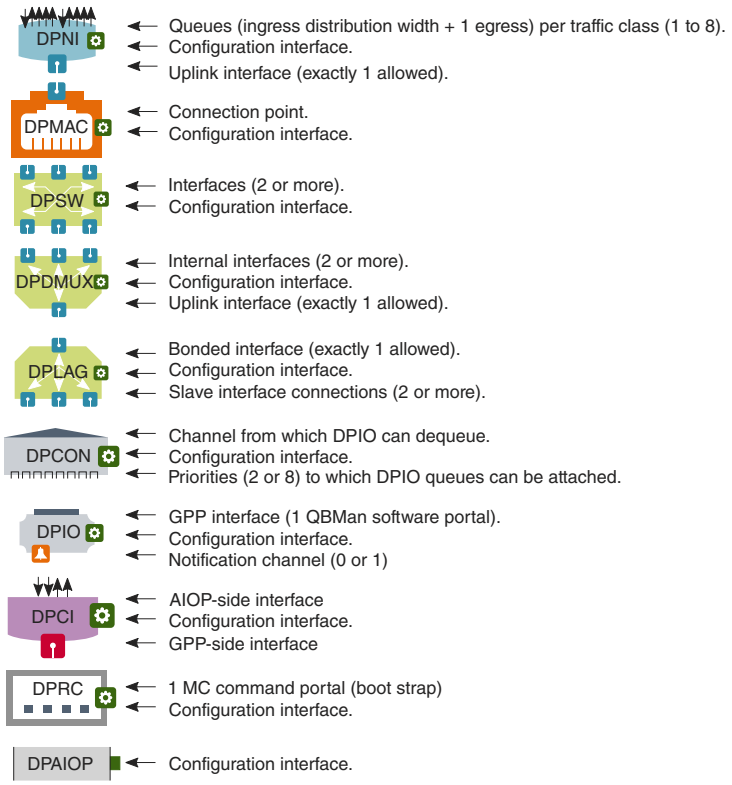

Figure 16. DPAA2 object summary and icons

DPNI

A DPNI object is the key to network interfaces. On ingress, it receives frames from a DPMAC or another object such as a DPSW, parses headers, determines the frame's traffic class, and enqueues the frame onto a frame queue selected based on the traffic class and other header values. This supports both hash-based distribution of frames to multiple cores, and also direct flow steering of frames to specific cores.

DPNI can generate a per-queue data availability notification when a frame is enqueued. On egress, the DPNI dequeues frames from frame queues and transmits them to an external port using a DPMAC, or to another DPAA2 object such as a DPSW.

DPMAC

The DPMAC object represents an Ethernet MAC, a hardware device that connects to a PHY and allows physical transmission and reception of Ethernet frames.

DPSW

The DPSW object provides the functionality of a general layer 2 switch. It receives packets on one port and sends them on another. It can also send packets out on multiple ports for the purposes of broadcast, multi-cast, or mirroring.

DPDMUX

The DPDMUX is another type of switch. It differs from a DPSW in several ways. A DPDMUX may have only a single uplink port. Also, it can be programmed to direct packets based on header values above layer 2.

DPLAG

The DPLAG object provides link aggregation. It combines two or more uplinks into a single downlink.

DPCON

The DPCON object allows multiple DPNIs to be aggregated into a single device that appears to a GPP core or AIOP software as single interface that carries frames from multiple DPNIs; it combines two or more network interfaces into one. It provides a hardware-based scheduling off load because the hardware selects the order based on the priority in which frames from the multiple DPNIs are provided to software on GPP cores or AIOP.

DPCON is also useful for software that polls for input frames; it allows a single interface to be polled instead of multiple interfaces.

DPCON objects are also used by Linux Ethernet drivers for priority-based frame delivery.

DPIO

General purpose processing core software uses a DPIO object to perform hardware queuing operations, such as enqueue and dequeue, and hardware buffer management operations, such as acquire and release. It also allows data availability notifications to be received. DPIOs can generate interrupts. The DPIO object is unusual in that GPP core software is expected to directly access portions of the DPIO's hardware (QBMan software portals) for run time operations, in addition to supporting configuration operations from the management complex.

Note that AIOP software does not rely on DPIO objects; they are used only by software on the general purpose processing cores.

DPBP

The Datapath Buffer Pool object represents a QBMan buffer pool. It is used mainly as a resource by network drivers, but it is an active entity because it can send buffer pool depletion notifications to GPP core software.

DPCI

The Datapath Communication Interface provides general purpose processing core software with a transport mechanism typically for control and configuration command interfaces to AIOP applications. The AIOP service layer implements the AIOP-side of the transport, but the commands are application-specific. Note that AIOP is optional in DPAA2 and is not present on some SoCs.

DPRC

The DPRC object allows the Management Complex to track sets of objects in use by the same software component. The objects in the set are said to be in the same container. It also facilitates the assignment of sets of objects to specific software components, such as a virtual machine or a user space application using user space drivers. The software component can query containers in order to discover objects at run time, and this enables plug-and-play drivers that interface to objects.

Some objects include DMA-capable hardware. All objects in the same DPRC share a common ICID, and a common set of IO-MMU mappings. A number of key features of DPRCs include:

- **Direct access.** All the objects and resources in a container are private to the container, and software components get direct access to the registers (as abstracted by the Management Complex) of the hardware objects.
- **Dynamic discovery.** A software context that is given a DPRC can dynamically discover the objects and resources placed in the container using MC commands.
- **Hot plug/unplug.** Objects can be dynamically plugged and unplugged into DPRCs.
- **Security.** A software context can only see the objects in its DPRC, and cannot affect other containers or the proper operation of other software contexts. DMA transactions from MC objects are isolated using the system IOM-MU.

DPMCP

The DPMCP object represents a Management Complex command portal and is used by drivers to send commands to manage objects.

DPAIOP

DPAIOP is a configuration object that aids in loading programs onto the AIOP, running the AIOP, resetting the AIOP, and receiving status, error, and log information from AIOP programs. Note that the AIOP is optional in DPAA2 and is not present on some SoCs.

Objects for accelerators

There are also objects associated with accelerators such as SEC, PME, and DCE. These objects provide software with interfaces to the accelerator hardware. For this reason, the accelerator interface objects end in "I".

- DPSECI - SEC (security/cryptographic coprocessor) interface.
- DPDCEI - DCE (data compression engine) interface.
- DPDMAI - DMA engine interface.

Software uses queues associated with an object to send a buffer to an accelerator for processing and to receive the result.

New types of objects

NXP will create new types of objects over time to address new needs and use cases as they arise.

6.1.4.2 Management Complex: How DPAA2 objects are created and managed

This section outlines how the Management Complex creates and manages DPAA2 objects.

The best way to think of DPAA2 hardware, in particular WRIOP and QBMan, is that it provides many low-level resources ranging from Ethernet MACs to look up tables to frame queues and so on. Software's mission is to assemble the right set of these low-level resources, and configure them collectively to achieve a goal.

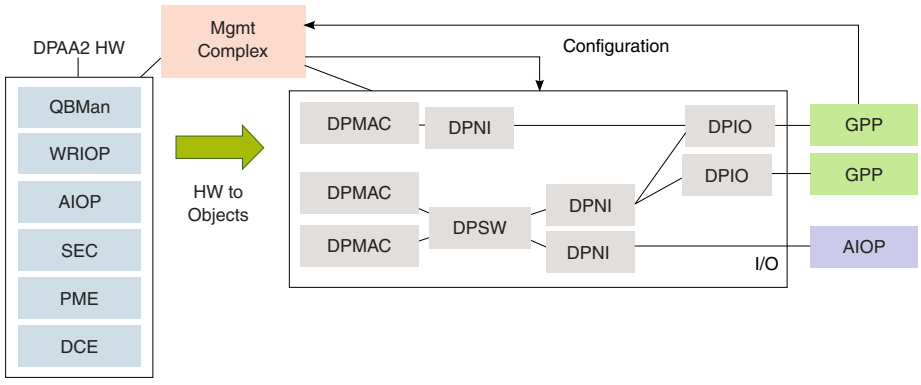

Figure 17. Management Complex creates objects from hardware sub-components

Think of the low-level resources as “atom resources” because they are always allocated as a unit. DPAA2 objects are then “composite resources,” or collections of atom resources that are then configured to achieve a common goal, like being an L2 switch as shown in Realizing an L2 switch.

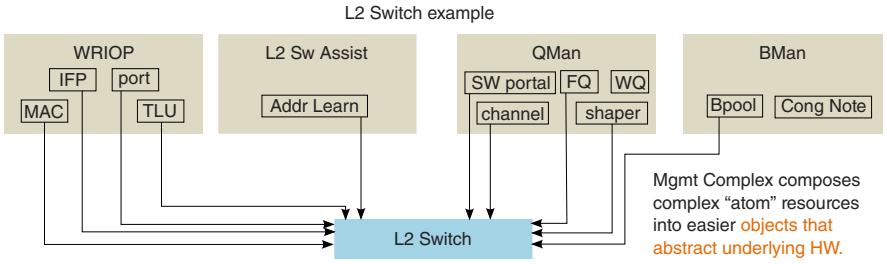

Figure 18. Realizing an L2 switch

The creation method for a DPAA2 object involves allocating the necessary atom resources and configuring them enough to place the object in an initial idle state. Object methods and other interfaces then allow it to be further configured and used. For example, forming an L2 switch from DPAA2 atom resources is quite complex. The NXP firmware running on the Management Complex implements the methods necessary, and hides this complexity from GPP (and AIOP) developers.

Continuing the example, an L2 switch object can also be shutdown and disassembled by its methods. Its atom-resources are then placed back into the pools of atom resources that the Management Complex firmware manages.

Hardware directly visible to software

Clearly, DPAA2 provides abstractions. The objects are best thought of as being hardware, and most actually are collections or encapsulations of hardware resources that are allocated and configured to achieve a higher-level and more abstract purpose than would be clear from a direct view of the hardware resources. An example of an abstract purpose is “be an L2 switch” (DPSW).

It can be helpful to focus on exactly what is visible to driver-level software running on the general purpose cores and AIOP, especially since what is visible is a mixture of direct access to hardware and indirect access to hardware via abstractions. This discussion will be biased towards the view of objects from drivers running on general purpose processing cores (such as in U-Boot and Linux).

Also the discussion will avoid details of individual objects since this is an overview with the purpose of clarifying objects in general.

DPAA2 visibility boundary describes in one diagram what is directly visible to the driver layer software.

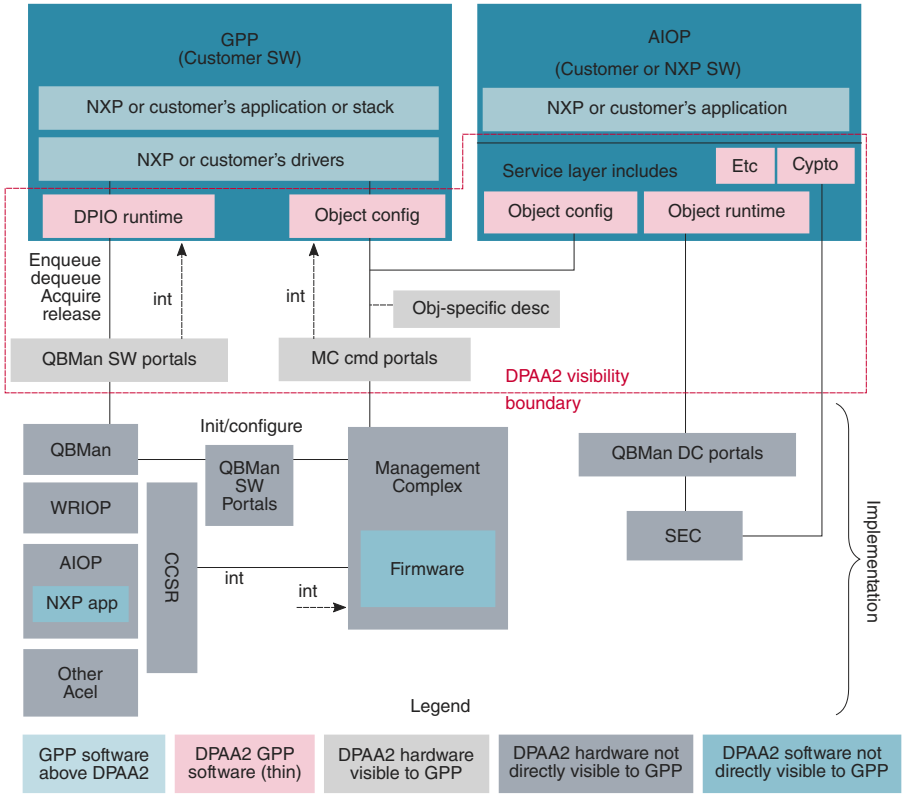

Figure 19. DPAA2 visibility boundary (AIOP not present on all DPAA2 SoCs)

There is quite a lot in the figure above, so it is best to break it down. What driver level software can see and do is dictated by its function.

This begins with the Management Complex (MC) itself. The discussion below will focus on the services that the MC provides to other software in the system. There will be no discussion of MC firmware's internal design.

See Management complex visibility in DPAA2. The first step is that general purpose processing core software (usually a boot loader) must load the opaque firmware image onto the Management Complex and then start it running. This involves direct access to portions of the Management Complex hardware: registers defining the location of the Management Complex's portion of DDR, image location, address translation, and run state control.

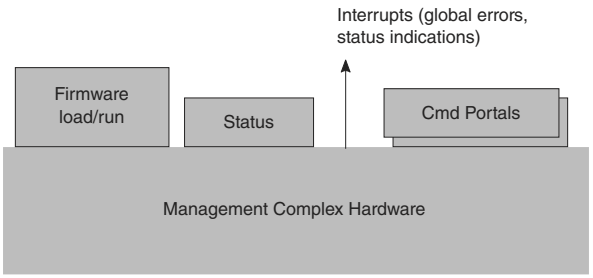

Figure 20. Management Complex visibility in DPAA2

The driver software also requires visibility to global status, particularly to status for global errors. Changes in the state of this status can be signaled by interrupts to the general purpose processing cores so the Management Complex can produce these interrupts.

Finally, the Management Complex exists to serve its masters, the general purpose processor core (and AIOP when present) software that “owns” objects, i.e. has been allocated access rights to them via container ownership and hierarchy. The service is provided by responding to commands so driver software needs a way to deliver commands to the Management Complex. In addition, this process must be secure in that the Management Complex must know, in a way that cannot be spoofed, an ID of the software sending the command. This is to allow the Management Complex to enforce object access rights.

Driver software delivers commands to the Management Complex via hardware called Management Complex command portals. SoC hardware provides significant numbers (at least 10s) of these portals because:

- They can be directly assigned to multiple different drivers, all of which independently use the Management Complex’s services. If they each have their own command portal, they do not have to coordinate with each other.
- Each independent driver instance has its own ID (ICID) that is securely associated with the command portal to prevent spoofing. This prevents a driver from being able to access for configuration an object that it does not "own".

To send a command to the Management Complex, driver software creates a descriptor and enqueues a pointer to it to the command portal.

Next consider objects. See DPAA2 objects.

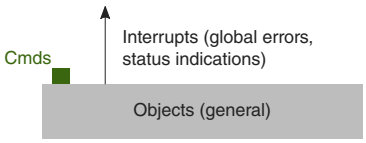

Figure 21. DPAA2 objects

Objects are created either via the DPL file or driver software sending a command to the Management Complex instructing it to create an object (as in restool). The Management Complex supplies a globally unique ID for the new object.

Object command interfaces are abstractions. There is no hardware that directly represents object command portals. Objects are usually hardware, but in most cases that hardware does not directly expose a hardware-level programming model to driver software. Instead, driver software configures objects via an indirect mechanism; it sends a command to the Management Complex. The command is a descriptor that includes the ID of the object as well as the definition of the operation to be performed.

The Management Complex automatically gets the ID of the requestor when it reads the command. The command portal securely adds it. The Management Complex then checks that the requestor is authorized to configure the object and, if so, performs the configuration on behalf of the requestor.

So, object configuration is a visible part of DPAA2, but the configuration of the individual hardware subcomponents that make up an object is not.

The fundamental programming model for object configuration is the commands that can be sent to the Management Complex to configure the object. Each object type has a different purpose so each object type’s configuration programming model is defined by the descriptor set that describes the commands to configure the particular type of object.

NXP also provides C callable APIs that basically allocate and populate descriptors and pass them as commands to the Management Complex. The APIs bear a close relationship to the more fundamental descriptors.

Many object types have nothing but a configuration space, but this is not always true. Some objects also provide I/O interfaces. The DPIO object is a prime example. See DPIO object and I/O interfaces.

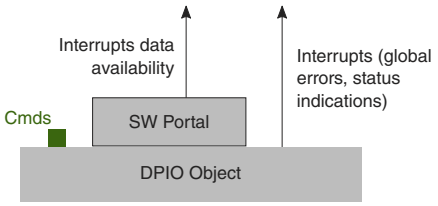

Figure 22. DPIO object and I/O interfaces

As has been stated before, DPAA2 objects are usually opaque bundles of hardware sub-resources allocated and configured to achieve a more abstract purpose. A DPIO object includes a hardware sub-resource called a QBMan software portal but this hardware is not opaque to the driver software running on the general purpose processing cores. The reason is performance. Software portals are the hardware mechanism for actually doing I/O with DPAA2 peripherals so driver software must directly access them. There are also data availability interrupts associated with DPIOs. These indicate availability of data to read using the software portals.

NOTE

Software portals actually support more than I/O (enqueue onto queues and dequeue from them). They also support commands. The simplest examples are buffer acquires and releases. Without going into full detail, software portals actually support commands that require privilege (example: initialize a frame queue) and commands that do not (example: acquire a buffer). Driver software on general purpose processing cores (and AIOP) uses only the unprivileged commands. The privileged commands are not part of the visible architecture. They are used only by Management Complex firmware.

In summary, the visible architecture includes both hardware and abstractions as follows:

- Management Complex hardware associated with loading and running images
- Management Complex hardware associated with accessing global status
- Management Complex global interrupt
- Management Complex hardware command portals
- Objects themselves (abstraction):
  - Object configuration interface and command set as defined by descriptors (abstraction)
  - Object error interrupts
  - Some objects (like DPIO) also have additional interfaces that are hardware directly accessed by driver software. DPIO's QBMan software portals are an example. They can produce interrupts.

6.1.4.2.1 Object creation, the datapath layout file, and restool

DPAA2 objects can be created in multiple ways. First, they can be specified in a Datapath Layout (DPL) file that the Management Complex reads and applies before Linux boots. This file contains the specific list of objects that are to be automatically created as the system initializes.

DPAA2 objects also can be created and destroyed dynamically by sending commands to the Management Complex through its command portals via a kernel driver. For Linux, a user space command line tool called "restool" uses this interface to allow interactive and dynamic creation of objects. It also allows destruction and some additional configurations to be done.

Restool also shows information about objects and what they are connected to.

6.1.4.2.2 DPRC objects, plug and play, and the fsl-mc Linux "bus"

As mentioned previously, it is common for a GPP software component to manage multiple objects. The DPIO parallelism diagram shows a simple example of the Linux kernel managing a set of objects to provide a pair of network interfaces. The

DPRC (Datapath Resource Container) is a special object that serves to organize other objects, and also the hardware sub-components from which objects can be dynamically created; the hardware sub-components include frame queues, channels, buffer pools, etc. Containers can be created and filled with objects and resources and then passed to the software component, such as a virtual machine, that will use them.

The software that was assigned a DPRC can enumerate the objects inside it; this is a form of dynamic hardware discovery that relates to plug-and-play. For example, an operating system can scan a DPRC and associate all DPNI objects found within with an Ethernet driver that will use them to form network interfaces. The Ethernet driver then uses a dynamic allocator within the kernel to aquire other objects such as DPBPs that it needs to operate.

The device discovery analogy is strong enough that Linux exposes DPRCs assigned to it as a bus in sysfs-- much like physical buses like PCI. The same sysfs mechanism that allow a physical PCI device to be assigned (bound) to virtual machines are also used to assign containers to virtual machines. Objects can even be dynamically added and removed from DPRCs. This is analogous to hot plug and unplug on a bus.

Many DPAA2 objects are DMA-capable so that they can autonomously read and write memory. SoCs like the LS2088A contain an IO-MMU, so objects must express an identifier (that they cannot control) when they perform DMA operations. This identifier is called an ICID in DPAA2, and it serves as a key for the IO-MMU to associate I/O virtual addresses with I/O physical addresses. In DPAA2, ICIDs are attributes of DPRCs, and all objects in a DPRC express the same ICID value.

A GPP software context (a virtual machine or application) will typically be assigned a single DPRC that contains all the fsl-mc resources that the software context can access or use. As mentioned elsewhere, there are two general types of resources that can be in a container:

- **Resources:** Resources are primitive resources that can't be further decomposed, and are uninitialized and unpurposed. Some examples are MC portals, QBman portals, frame queues, buffer pools, etc. Generally primitives are “fungible,” in that there is nothing distinctive among the same kind of primitives. However, some primitives may be non-fungible, such as an external port or MAC.
- **Objects:** Objects are created and configured with a purpose, typically constructed of multiple resources. Some examples of objects are network interfaces, an L2 switch, or a crypto instance. A DPRC is itself an fsl-mc object.

NOTE

See documentation of the Linux restool facility for more information related to this topic.

Management Complex (MC) initialization and boot

The MC is normally enabled and initialized by system boot firmware such as U-Boot. The boot firmware is responsible for reserving a region of memory (DDR) for the fsl-mc, and then loading the MC firmware into memory, loading a datapath layout file (see below for DPL overview info), and writing a bit to enable/start the MC. See Management Complex initialization and boot.

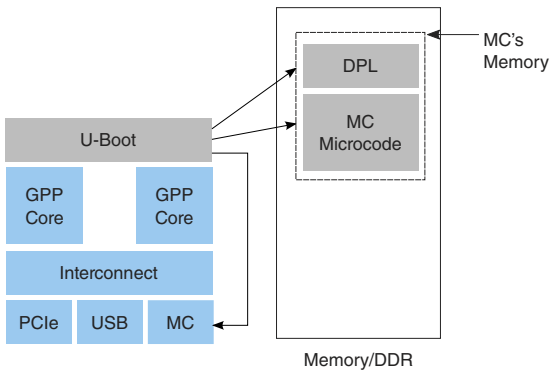

Figure 23. Management Complex initialization and boot

Management Complex datapath layout file (DPL)

As mentioned above, a datapath layout file (DPL) must be supplied to the Management Complex when it is booted. The DPL contains the definitions of initial objects and containers/DPRCs to create.

A DPL is defined in a text file in device tree syntax (DTS) format and then compiled into a standardized DTB binary format (used by ePAPR compliant device trees).

See the *DPAA2 User Manual* for more information and examples on the datapath layout file.

Boot loader use of the MC

In typical usage, the boot loader loads the MC firmware image and starts the MC running. At this time, it supplies a data path control (DPC) file that supplies the MC image with basic configuration information that allows it to operate.

The boot loader can now use the services of the MC in order to access network devices. It is a good approach to have the boot loader dynamically create the objects it needs and destroy them (releasing resources) before starting the operating system. This way, the operating system is not forced to operate with the constraints of objects and DPRCs established by the boot loader. The OS can see a "green field".

Optionally, the boot loader can apply the data path layout (DPL) file mentioned above just before starting this OS. This approach allows the DPL to be written only to serve the operating system's needs and not the boot loader's, which tend to be much simpler.

DPRCs are hierarchical

The MC manages DPRCs in a hierarchical relationship. There is a single root DPRC at the root of the hierarchy. That DPRC can have child DPRCs, children can have grandchildren, and so on. The root DPRC belongs to the root software context of the system, usually an OS or hypervisor. The root DPRC can further allocate its resources to its child DPRCs and assign them to other entities such as user space applications or virtual machines.

In this example there are 3 DPRCs/containers managed by the Management Complex: a root container “root” with 2 children “foo” and “bar”. The DPRCs all contain 3 objects, a DPNI, DPBP, and DPIO. There are 3 software contexts: the host Linux, a user space application, and Linux in a KVM virtual machine. Each software context is assigned a DPRC that it can use and manage; see DPRC hierarchy for a figure that illustrates this example.

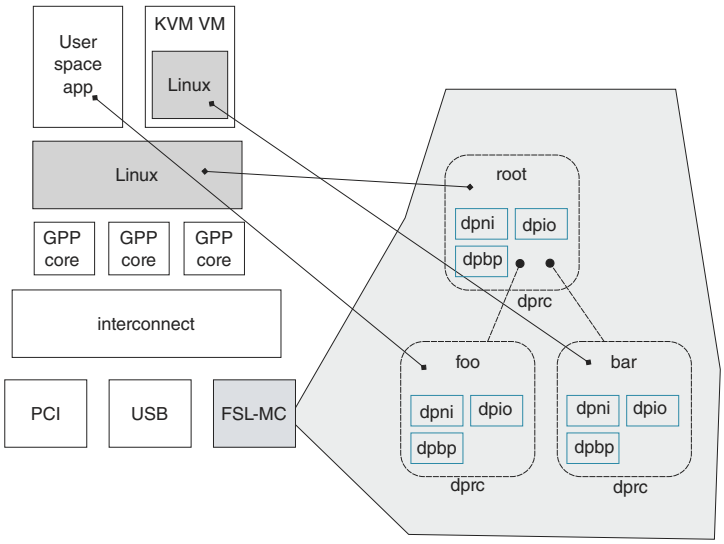

Figure 24. DPRC hierarchy

The container hierarchy allows the parent to manage the resources of the children. If the OS in the KVM VM crashes, the parent (Linux) can reset and clean up the VM's DPRC. If the user space application terminates, the parent (Linux) has the option of destroying the container.

6.1.4.3 Objects and topology

As mentioned elsewhere, objects have a topological relationship with each other. See Object topology example for an example.

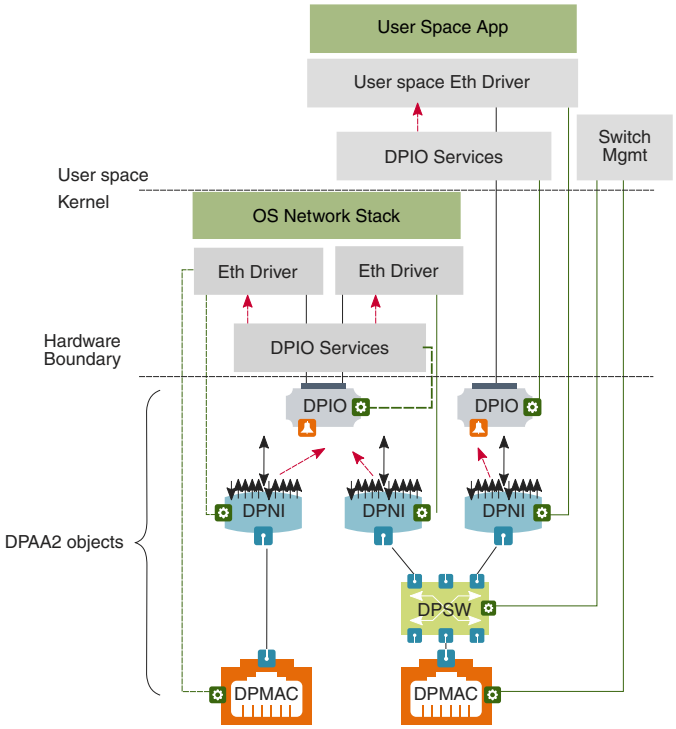

Figure 25. Object topology example

- There are three network interfaces managed by the DPAA2 Linux Ethernet driver. Each of the network interfaces uses a DPNI object.
- All of the Ethernet drivers happen to have a distribution width of one (an example), so they cannot load balance to multiple cores or threads; this was done to simplify the diagram and discussion. If a network interface has a distribution width greater than one, then many times it is connected to more than one DPIO but this is not required.
- Two of the network interfaces are connected to a switch; two DPNIs are connected to a DPSW. This allows both network interfaces to communicate outside of the SoC using the DPMAC that is also connected to the DPSW, and they can also communicate with each other using the DPSW.
- One of the network interfaces is directly assigned to a user space process, and has a user space Ethernet driver. This network interface could also be directly assigned to a KVM virtual machine under Linux.
- Two of the DPNIs have Linux network stack drivers; they interface to the Linux network stack. One of them has its own DPMAC, and a traditional type of controller represented by its DPNI being directly connected to a DPMAC.
- The two DPNIs connected to the Linux network stack share a single DPIO; this is possible when they can cooperatively use a layer of GPP software that provides DPIO services. The hardware that makes up a DPIO is a QBMan software portal and, optionally, a QMan channel for data availability notifications. QBMan software portals are a relatively scarce hardware resource, so they are designed to be sharable, in particular for NAPI-compliant Linux Ethernet drivers.
- It is a key assumption of DPAA2 that objects are managed (or “owned”) by a single software entity. Independent software entities can independently manage the objects they own, and this allows software to be decoupled from other entities.
- The management relationship between objects and software entities is not defined or imposed by DPAA2; DPAA2 defines the objects and what they do, and not what software uses them. Customer GPP core software is allowed to determine the management relationship; a single monolithic software entity that manages all of the objects can be created.

- The Linux DPAA2 Ethernet driver design defines the set of objects needed to provide a network interface. The green lines show the management relationships for Linux network interfaces and switches. Note that switches are managed independently from the network interfaces that connect to it.

The *DPAA2 User Manual* provides a complete description of the rules that govern object topology.

6.1.4.4 AIOP in DPAA2

This section describes AIOP in the DPAA2 architecture and how it uses DPAA2 objects. The figure below shows an example in which the Linux kernel network stack has a single Ethernet interface, a user space application has a single directly assigned Ethernet interface, and AIOP has two Ethernet interfaces.

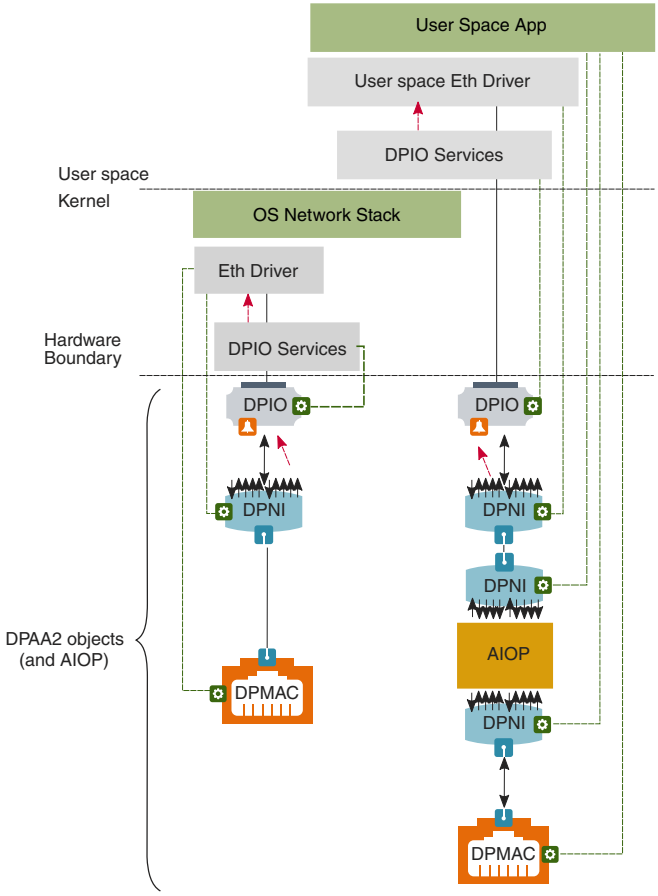

Figure 26. AIOP in DPAA2

AIOP runs software and uses objects in a manner that is similar to general purpose processing cores. In this example configuration, the AIOP's software has access to two Ethernet interfaces. One is connected to a MAC for an external connection to outside the SoC. The other is connected point-to-point to the general purpose processing core user space application's Ethernet interface.

So, there are two Ethernet interfaces involved on the path between the AIOP and the user space application. This is logical because there is software running in both places. Thus, each software component should see and control its own Ethernet Interface. Both software components do Ethernet I/O without being coupled to what their Ethernet interface is connected to.

One difference is that AIOP software is focused on packet processing. It does not actively manage or configure its own Ethernet interfaces. Usually, a control application on the general purpose processing cores takes that role. Also, the AIOP does not use DPIO objects.

Note that AIOP itself is not a DPAA2 object. It is an active entitiy that uses other DPAA2 objects. However, there is a DPAIOP object that general purpose processing core software can use to manage the AIOP, e.g. start it, stop it, load images onto it, get error status from it, etc.

In addition, there are DPAA2 objects (not shown) that facilitate passing commands (rather than packets) between general purpose processing core software and AIOP software.

AIOP Service Layer

NXP provides an AIOP software library called the "AIOP Service Layer". This library's main purpose is to provide very lightweight drivers for hardware components that AIOP software must access. These include components such as Ethernet intefaces, the QBMan buffer manager, timers, table lookup units, etc.

6.2 Introduction

This section provides instructions to enable users to execute usage examples provided in the SDK release. The section also provides information about key release files that users need to be familiar with to run the release examples.

6.2.1 Acronyms and definitions

AIOP	Advanced I/O Processor
ACL	Access Control List Permissions granting access to and allowing operations on a given object; a table type
CAAM	Cryptographic Acceleration and Assurance Module
DCE	Data Compression/Decompression Engine
DPAA	Data Path Acceleration Architecture
DPAA2	Data Path Acceleration Architecture, second generation
DPC	Data Path Configuration file
DPDMUX	Datapath De-multiplexer DPAA2 object modelling an EVB
DPL	Data Path Layout file
DPNI	DPAA2 object modelling a network interface
EVB	Edge Virtual Bridge
FDB	Forwarding Database A table used by an L2 switch to store MAC addresses learned and the respective ports on which they were learned
GPP	General Purpose Processor
MC	Management Complex
NAT	Network Address Translation
ODP	Open Data Plane
QBMan	Queue and Buffer Manager
RCW	Reset Configuration Word Sets up clocks and ratios, IP pin muxing on boards; resides in non-volatile memory (e.g. NOR) on boards
SEC	Security Engine

STP	Spanning Tree Protocol A network protocol preventing loop formation when switches or bridges are interconnected via multiple paths
VEB	Virtual Ethernet Bridge
VEPA	Virtual Ethernet Port Aggregator (defined in IEEE 802.1Qbg)
WRIOP	Wire Rate I/O Processor

6.3 DPAA2 Software

For information about the DPAA2 software, see the DPAA2 Software Overview that is part of the release documentation. For customers that are unfamiliar with DPAA2 concepts, it is recommended to read that content before proceeding.

6.4 Data Path Resource Containers

Many sections refer to Data Path Resource Containers (DPRC), so a brief introduction to the concept may be helpful. DPRCs are part of the DPAA2 object architecture that is described in the DPAA2 Software Overview that is part of the Linux SDK documentation set.

DPRCs are communicated to software entities as a part of their start up process; this is true for software entities such as:

- The host Linux kernel (that may provide KVM services to virtual machines)
- Linux kernel instances that run in virtual machines
- ODP applications
- AIOP applications

DPRCs contain DPAA2 objects that are used by the software entity that owns the DPRC. For example, DPNI objects are used as network interfaces.

As an example, see RDB DPL on page 438. The DPRC called “dprc@1” is supplied to the host Linux kernel. It contains one DPNI object. The DPNI object binds to the DPAA2 Linux kernel Ethernet driver, and causes two standard Linux Ethernet interfaces to exist and be visible using “ifconfig”. See later sections in this document for additional details and explanations on the use of objects by various types of software entities.

As mentioned previously, DPRCs must be created and populated with the initial set of DPAA2 objects prior to the startup of the software entity that will use the DPRC.

6.4.1 Creating DPRCs

There are two ways to create and populate DPRCs:

1. Statically: by means of a control file called a datapath layout (DPL) file. Key Release Files: RCW, DPC and DPL on page 436 describes the DPL files that are supplied as examples with the Linux SDK.
2. Dynamically: by means of the Linux command line utility called restool. See DPRCs and restool section, and also the document titled *Standard Linux Documentation.*

A software entity behaves exactly the same way on startup regardless of whether its DPRC was created statically using a DPL or dynamically using restool. The DPL method is convenient for situations when the desired DPRCs are known in advance. DPRCs defined within the DPL are created and populated automatically with no need for a subsequent use of restool.

6.4.2 DPRCs and Hot Plug

A DPRC must be supplied to a software entity when the software entity is started; this implies prior creation of the DPRC. However, it is also possible to dynamically alter the contents of a DPRC *after* the software entity that is using it is already running; this is a form of hot plug.

For example, restool can be used to dynamically create a DPNI object and then assign it to a DPRC. If that DPRC is being used by a Linux kernel instance, this will cause that kernel to dynamically detect a new network interface and bind it to the Linux kernel Ethernet driver; the “ifconfig” command will now show a newly created network interface.

It is also possible to dynamically destroy or unassign objects within an in-use DPRC; this is a form of hot unplug. Hot plug and unplug are advanced topics, and not covered further here. The key take-away is that dynamically creating and populating a DPRC *before* supplying it to software entity when it is started is a very different use case than hot plug/unplug. The latter use case involves changing the contents of a DPRC *while it is in use* by a software entity.

6.5 Key Release Files: RCW, DPC and DPL

This section describes the key binaries that are available on the RDB. These include the reset configuration word (RCW), the data path configuration (DPC) and the data path layout (DPL) files.

6.5.1 RCW (LS2088A)

The reset configuration word (RCW) resides in non-volatile memories (e.g. NOR, QSPI, SDHC). It gives flexibility to accommodate a large number of configuration parameters to support a high degree of configurability of the SoC. Configuration parameters generally include:

- Frequencies of various blocks including cores/DDR/interconnect.
- IP pin-muxing configurations
- Other SoC configurations

The following binaries are provided:

- `PBL_1600_600_1600_1600_0x2a_0x41.bin`
  - Core: 1600 MHz
  - Platform: 600 MHz
  - DDR: 1600 MHz
- `PBL_1800_700_1866_1600_0x2a_0x41.bin`
  - Core: 1800 MHz
  - Platform: 700 MHz
  - DDR: 1866MHz

The RCWs provided with the release enable the following features:

- The figure below shows the SERDES configuration supported for LS2088A. Note that LS2088A supports upto 5 ports out of the 8 available on the RDB at a time.

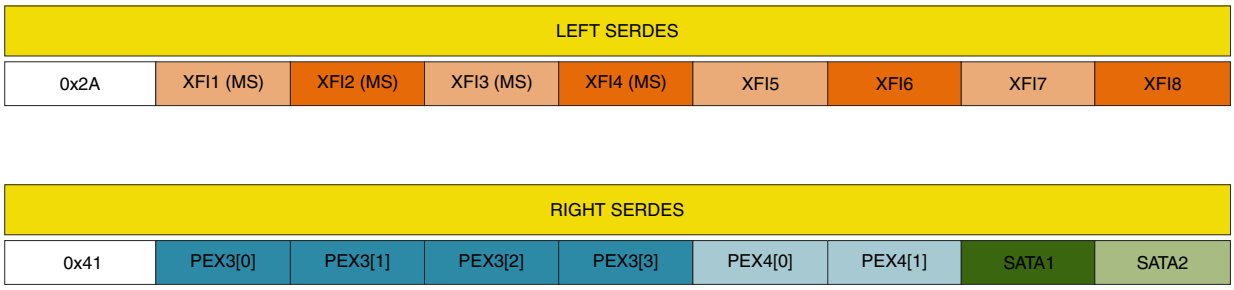

Figure 27. SERDES

- Boot location as NOR flash
- Enables 4 UART without flow control
- Enables I2C1, I2C2, I2C3, I2C4, SDHC, IFC, PCIe, SATA

6.5.2 Data path configuration file (DPC)

The data path configuration (DPC) contains board-specific and system-specific information that overrides the default DPAA hardware configuration.

The SDK release provides one example data path configuration (DPC) file. The file is named dpc-0x2a41.dts. This file specifies the following information:

- default logging mode for the MC
- default LS2085ARDB/LS2088ARDB MACs
- default number of DPAA channels with 2 and 8 work-queues

The DPC is based on a text source file (similar to a device tree source file (DTS)) and compiled with the DTC utility to form a binary structure (blob, similar to DTB). The DPC file should be compiled to a binary blob using standard DTC tool.

The DPC binary (dpc-0x2a41.dtb) is located in the IMAGE iso under *dpl-examples/ls2088a/RDB/*.

6.5.3 Data path layout file (DPL)

The data path layout file (DPL) defines the containers created during MC initialization. A prerequisite for the DPL to define the containers created during MC initialization is that the device tree compiler (dtc) tool is installed on the host system, since the dtc command is used to compile the DPL.

As described in Creating DPRCs on page 435, the example DPL source code is provided in the *dpl-examples* package.

This release provides one example data path layout (DPL) files to be used with the RDB:

- dpl-eth.0x2A_0x41.dts – used for simple Ethernet scenarios

The DPL file specifies the basic resources needed for a simple usecase; other resources are created and managed dynamically using restool capabilities. For each of the use cases included in this document, there is a diagram that depicts the objects that are necessary for that usecase.

The DPL is based on a text source file (similar to a device tree source file (DTS)) and compiled with the DTC utility to form a binary structure (blob, similar to DTB). The DPL file should be compiled to a binary blob using standard DTC tool.

Using a static DPL is not a requirement since restool can be used to dynamically create/manage objects and resources.

6.5.3.1 RDB DPL

The source for the RDB DPL is in the *dpl-examples* package:

- dpl-examples/LS2088a/RDB/dpl-eth.0x2A_0x41.dts

The figure below shows a graphical view of the container configuration:

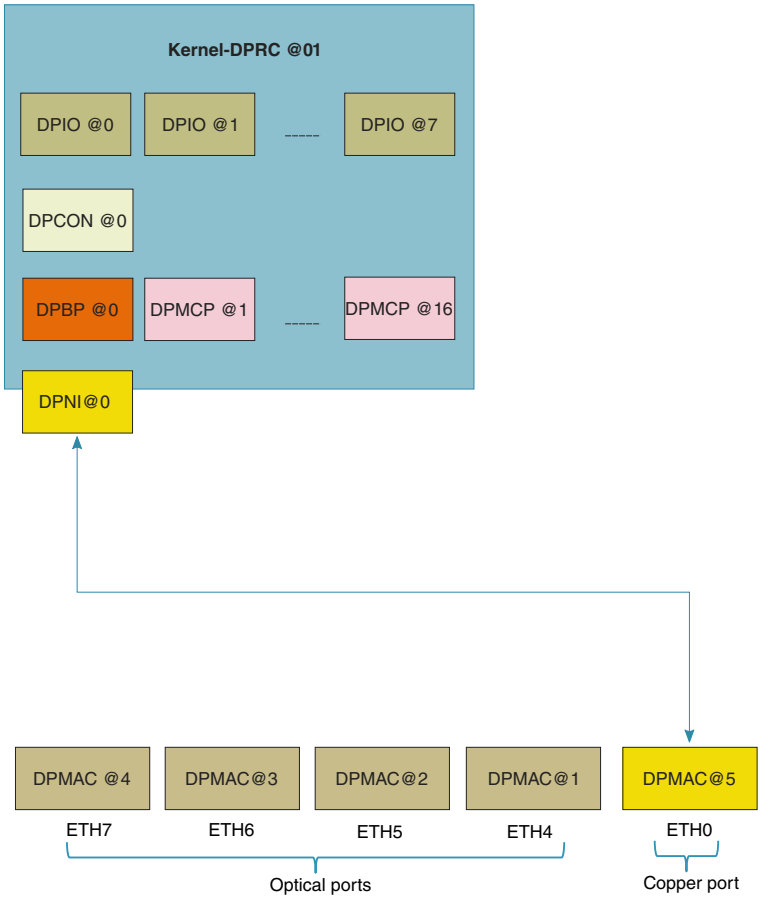

Figure 28. RDB DPL container configuration

6.5.3.2 DPRCs and restool

The release provides a Linux command-line tool called restool that can be used for examining the resource containers used for managing DPAA2 objects and resources. See the DPAA2 Overview for an overview of DPAA2 and the data path resource containers (DPRCs). Also see the Stardard Linux Documentation for details about functionality and use of restool.

Given below is an example of using restool:

List dprc:

```
$ restool dprc list
dprc.1
```

List all objects in container dprc.1:

```
$ restool dprc show dprc.1
dprc.1 contains 33 objects:
object          label           plugged-state
dpio.7                          plugged
dpio.6                          plugged
dpio.5                          plugged
dpio.4                          plugged
dpio.3                          plugged
dpio.2                          plugged
dpio.1                          plugged
dpio.0                          plugged
dpni.0                          plugged
dpbp.0                          plugged
dpmac.5                         plugged
dpmac.4                         plugged
dpmac.3                         plugged
dpmac.2                         plugged
dpmac.1                         plugged
dpcon.0                         plugged
dpmcp.0                         plugged
dpmcp.16                        plugged
dpmcp.15                        plugged
dpmcp.14                        plugged
dpmcp.13                        plugged
dpmcp.12                        plugged
dpmcp.11                        plugged
dpmcp.10                        plugged
dpmcp.9                         plugged
dpmcp.8                         plugged
dpmcp.7                         plugged
dpmcp.6                         plugged
dpmcp.5                         plugged
dpmcp.4                         plugged
dpmcp.3                         plugged
dpmcp.2                         plugged
dpmcp.1                         plugged
```

6.6 Linux Ethernet

This chapter provides guidelines on exercising creation, functionality and statistics of Linux DPAA2 Ethernet interfaces.

6.6.1 Features overview

The following is an overview of the functionality of the Linux DPAA2 Ethernet driver that will be described in this chapter:

- Primary MAC address change
- Scatter-gather support
- Checksum offload
- MAC filtering
- Large frame support
- GRO – generic receive offload
- Egress traffic shaping
- Rx hashing
- Interface statistics

6.6.2 Compiling and selecting Kconfig options

The DPAA2 Ethernet driver is by default selected by the kernel configuration shipped with the SDK, with a set of sensible compile-time defaults. The driver path in the kernel config file is: `" Device Drivers -> Staging drivers -> Freescale DPAA2 devices -> Freescale DPAA2 Ethernet" (CONFIG_FSL_DPAA2_ETH)`.

The following Kconfig selects are also available, but not checked by default:

- "Enable Rx error queue" `(CONFIG_FSL_DPAA2_ETH_USE_ERR_QUEUE)` - This configures a separate queue for presenting Rx Error frames to the Ethernet driver running on the GPP. By default this option is disabled and Rx Error frames are dropped in hardware and counted for statistics inspection. Rx Error processing increases the GPP load and so it is only necessary in debugging situations when inspection of actual frames is required.
- "Enable debugfs support" `(CONFIG_FSL_DPAA2_ETH_DEBUGFS)`. This option depends on two others: "NXP QBMAN Debug API" `(CONFIG_FSL_QBMAN_DEBUG)` and "Debug Filesystem" `(CONFIG_DEBUG_FS)`. If selected with its

dependencies, this option enables a number of Ethernet driver statistics under DebugFS nodes `(/sys/kernel/debug/dpaa2-eth/*)` that are not normally visible to the user.

6.6.3 Creating a DPAA2 network interface

This section documents the resource utilization and the necessary steps for creating a DPAA2 network interface (DPNI) in Linux.

A DPNI can be created either statically through the DPL file or dynamically using the 'restool' utility.

6.6.3.1 DPAA2 objects dependencies

This section documents the steps to create a DPNI and related objects in order to have a fully functional network interface. It describes the dependencies a DPNI has on other DPAA2 objects.

This is of interest to anyone who changes a static DPL file or uses *restool* commands to dynamically createdynamically create DPNI objects and their dependencies.

The DPAA2 object definition allows for flexibile software architectures. The Linux drivers, in particular the Ethernet driver, are additionally bound by requirements from the kernel architecture. This enforces a certain usage model of the DPAA2 objects that the DPNI interacts with; in particular, it affects the number of various other DPAA2 objects that a DPNI needs.

Generally, the Linux Ethernet driver requires private DPAA2 resources (e.g. Frame Queues) and objects (e.g. DPCON objects), distinct from other DPNIs. There are exceptions, such as the DPIO or DPMAC, which are not owned by the DPNI. To create a DPNI, either statically in DPL or dynamically using 'restool', the following types of objects may need to be instantiated in the current container (i.e., made available if they are not already):

- DPBP
- DPMCP
- DPCON
- DPIO
- DPMAC

The significance and number of these objects per DPNI are detailed in the following table:

Object	Private to DPNI?	Cardinality	Comments
DPBP	Yes	1 per DPNI	Each network interface (NI) has private buffer pools, not shared with other NIs.
DPMCP	Yes	1 per DPNI 1 per DPMAC	MC command portals (MCPs) are used to send commands to, and receive responses from, the MC firmware. One such example is configuring DPNI functionality like hashing or checksumming, but DPNI statistics are also queried via the MCPs. Like the DPNI, each DPMAC also requires one private DPMCP.

Table continues on the next page...

Table continued from the previous page...

Object	Private to DPNI?	Cardinality	Comments
DPCON	Yes	Rx hash size/ number of transmitter queues (“num_queues”) of the DPNI.	DPCONs are used to distribute Rx or Tx Confirmation traffic to different GPPs, via affine DPIO objects. The implication is that one DPCON must be available for each GPP we want to distribute Rx or Tx Confirmation traffic to. Rx and Tx Confirmation share the same DPCONs if they are available. (If for example GPP #0 processes both types of traffic, one DPCON is enough. If in addition GPP #1 processes only Tx Confirmation traffic, then a second DPCON is necessary.) Since we must be able to distinguish between traffic from different NIs arriving on the same GPP, the DPCONs must be private to the DPNIs. These design constraints may cause a relatively large consumption of DPCONs by DPNIs with large Rx distribution width. The DPNI's Rx distribution width is implemented by the "num_queues" property (see Rx hashing on page 449 for extra information). Notes: DPCONs' main hardware resource are the Work Queues (WQs). The DPCONs come in 2 flavours: 2-WQ and 8-WQ DPCONs, depending on the number of traffic class priorities the object is going to support. (Note: the Ethernet driver only supports one traffic class at the moment, so using 2-WQ DPCONs is safe and enough.) The MC firmware can convert any number of 8-WQ DPCONs to four times as many 2-WQ DPCONs, depending on the static configuration provided at boot. Since WQs are a limited hardware resource, DPCONs tend to be limited, too, especially the 8-WQ flavor. The DPNIs being one of the major consumers of DPCONs, the current SDK ships with a default configuration where a number of the 8-WQ DPCONs are converted to 2-WQ DPCONs, thereby increasing their availability. Note that DPIO objects themselves transparently consume DPCONs (one per DPIO object), which therefore must be substracted from the total number available to the DPNIs (they need not be explicitly declared in the DPL, but they are simply not available to the rest of the system). The system can provide up to 64 8-WQ DPCONs (and up to 256 2-WQ DPCONs and combinations thereof). So for a container with 8 DPIOs, only up to 56 8-WQ DPCONs will be in fact available for DPNI configuration.
DPIO	No	One per running GPP	DPIOs are used to provide data availability notifications to the GPPs. For each GPP that we want to distribute traffic to, there must be an affine DPIO. While DPIOs are the source of data availability interrupts, the DPCONs are used (among other things) to identify the NI that has produced ingress data to that GPP. Due to a known limitation, the number of DPIOs in a container must not be less than the number of running GPPs. The static DPL in this release defensively provides 8 DPIOs at boot-time, one for each running GPP.

Table continues on the next page...

Table continued from the previous page...

Object	Private to DPNI?	Cardinality	Comments
DPMAC	No	User-defined.	DPMACs are proxy objects which link DPNIs to external PHYs on the board. DPMACs effectively decouple DPNIs from the PHYs they are linked to (if they are indeed linked to an external PHY, which is in fact transparent to the DPNI). As such, the DPMACs are not "owned" by a DPNI, which is unaware of their presence, but they can be "connected" to the DPNI, via the DPL file or 'restool'. DPMACs can be connected to other types of objects, too, such as the EVB. Having DPMACs connected to external PHYs depends on the board wiring and is strictly confined to the SerDes configuration. See also: DPMAC configuration on page 444.

6.6.3.2 Static DPNI definition

The default DPL provides a simple DPNI object definition, under the dpni@0 node as follows:

```
dpni@0 {
   options = "";
   num_queues = <1>;
   num_tcs = <1>;
};
```

The DPNI object is linked to a DPMAC object, also created in the DPL, via the “connections” node as follows:

```
connections {
   connection@5{
       endpoint1 = "dpni@0";
       endpoint2 = "dpmac@5";
   };
};
```

The DPNI object can be more complex, as in the following enhanced example of a DPNI node:

```
dpni@1 {
     options = "DPNI_OPT_HAS_KEY_MASKING";
     num_tcs = <1>;
     num_queues = <8>;
     mac_filter_entries = <64>;
};
```

In this example, dpni@1 has more options declared than dpni@0 in the previous example. In addition, it can distribute traffic to more GPPs than dpni@0, as declared by the “num_queues” attribute.

The following section describes the DPNI bindings in the DPL file.

6.6.3.2.1 DPNI bindings

.

- The num_queues attribute indicates the number of queues to be used for transmission as well as the number of Rx queues (hash distribution size). This also implicitly defines the number of queues used for Tx Confirmation, since each "sender" uses a dedicated queue for confirmations. This may impact the number of necessary DPCON objects - see "DPAA2 objects dependencies" chapter for details on resourcing the DPNI.

- num_tcs represents the number of traffic classes; it must have a value of 1, since the driver does not support priority classes yet.
- Other possible attributes are listed below. Unless otherwise stated, attributes with value <0> receive a default, non-trivial, value from the MC firmware and can be skipped from the DPL altogether.
  - fs_entries
  - vlan_filter_entries
  - mac_filter_entries

Note: See MC documentation for all available options and supported values.

6.6.3.3 DPMAC configuration

This section is a brief introduction to DPMAC objects and their relation to the DPNIs.

DPMACs are essentially proxies to external PHYs, which are board-level components and therefore not managed by the MC firmware.

DPMACs can be connected to other DPAA2 objects, such as DPNI, DPDMUX and DPSW. For example, to statically connect a DPMAC to a DPNI in the DPL file, the “connections” node is used:

```
connection@5{
     endpoint1 = "dpni@0";
     endpoint2 = "dpmac@5";
};
```

In this DPL example, DPNI0 is connected to DPMAC5, which the MC thereon connects to a lane depending on the current SerDes. Unlike most other DPAA2 objects, the id of the DPMAC (in this example, “5”) is relevant as the MC uses it to identify a physical MAC (at the moment, there is no other property of the DPMAC object to do that).

6.6.3.4 Dynamically creating a DPNI

This chapter documents the steps to create a DPNI using the *restool* utility and the *restool* wrapper scripts.

6.6.3.4.1 Using restool to create a DPNI

DPNIs can be dynamically created and plugged into the Linux container using the restool utility. Before creating a DPNI, one must create a number of DPAA2 objects (dependencies), for which multiple *restool* commands are needed. This section provides simple examples of commands that should be used to create a working DPNI (Linux network interface) and its dependencies. Usage of the restool wrapper shell scripts bundled with the SDK is encouraged, because of their better ease-of-use.

In order to create an object, the “restool create” command must be executed and then the new object can be assigned to a container. For example, to create a DPBP object:

```
$ restool dpbp create
dpbp.1 is created under dprc.1
$ restool dprc assign dprc.1 --object=dpbp.1 --plugged=1
```

For automation purposes, the “--script" flag can be used, reducing the verbosity of the command output. Object properties can be specified at creation time as follows:

```
$ restool --script dpio create --channel-mode="DPIO_LOCAL_CHANNEL" --num-priorities=8
dpio.8
```

To create a DPNI, a number of DPMCP, DPBP and other dependencies are required, if they do not exist already in the container - refer to the DPNI Resource Utilization chapter for details on the types and number of DPNI dependencies. The

static DPL from the current release already defines 8 DPIO objects, one for each running GPP, so adding new DPIOs is not normally required. Also, the maximum number of DPMACs supported on LS2088A are already created in the static (default) DPLs, so adding new ones is not necessary in the default configuration.

The general steps to create and configure a DPNI using restool are:

1. Create DPAA2 object dependencies (DPBPs, DPCONs, DPMCPs, etc);
2. Create and parametrize the DPNI;
3. Connect the DPNI to another object (typically but not necessarily a DPMAC).

The restool wrapper shell scripts automatically take care of the DPNI resourcing and parametrization, therefore we encourage their use instead of bare *restool* for complex objects like the DPNI.

6.6.3.4.2 Restool Wrapper Scripts

User-friendly scripts are provided in the release rootfs to assist dynamic creation of DPNIs and associated dependencies. They also implement parameter restrictions and workarounds related to known limitations of the DPAA2 objects in the current SDK release.

The following scripts are available to interact with DPNI and DPMAC objects, respectively Linux network interfaces: ls-addni, ls-listni, ls-listmac.

1. **ls-addni**

   This script creates a new DPNI object, required dependencies (potentially DPBP, DPMCP, DPCON, DPMAC, depending on the options being passed to the script) and an associated Linux network interface. The script can be used to connect the newly-created DPNI to another DPNI, DPMAC or DPDMUX, which must be already created and not currently connected.

   The script supports a multitude of parameters to fine-tune configuration of the DPNI; in fact, it is intended to support every parameter as *restool* itself for creating DPNIs. An empty list of options will choose sensible defaults for maximal performance of the new DPNI, such as Rx hashing to the maximum number of cores.

   Adding a new DPNI has the effect of discovering the new object on the Linux mc-bus and probing it as a new Ethernet device. This results in a new Linux network interface becoming available. The new interface has the name ni<X>, with the same id as the just-created dpni.<X>. The actual value of the ni id <X> cannot be controlled, i.e. the user cannot request a specific ni<X>.

   Utilization examples:

   - ```
     # ls-addni dpmac.6
     Will allocate 8 DPCON objects for this hash size
     [   33.782201] fsl_dpaa2_eth dpni.1: Probed interface ni1
     Created interface: ni1 (object:dpni.1, endpoint: dpmac.6)
     ```

     This is probably the most typical usage example. It creates a network interface (ni1) and the underlying dpni (dpni.1) and connects it to an external MAC (dpmac.6).

     Connecting DPNIs to DPMACs is not the only option, though:

   - ```
     # ls-addni -n
     Will allocate 8 DPCON objects for this hash size
     [  159.132755] fsl_dpaa2_eth dpni.2: Probed interface ni2
     Created interface: ni2 (object:dpni.2, endpoint: none)
     ```

     This command creates the unconnected object dpni.2 and the respective Linux interface ni2. Not being connected to anything, there is little practical use for this interface; therefore, a command such as the following would be used:

   - ```
     # ls-addni dpni.2
     Will allocate 8 DPCON objects for this hash size
     ```
     ```

```
[  301.162763] fsl_dpaa2_eth dpni.3: Probed interface ni3
Created interface: ni3 (object:dpni.3, endpoint: dpni.2)
```

This command creates another network interface ni3 (and the underlying dpni.3 object) and connects it with the previously created ni2 (dpni.2) interface.

Notes:

ls-addni --help list all supported options.

Although it is technically possible to connect a DPNI to itself, the wrapper scripts do not support this;

2. **ls-listni**

   This script lists all the dpni objects available in the root and child containers, the associated network interface name, the end point and the label.

   Output after running the above examples (dpni.0 had been statically defined in the DPL):

```
# ls-listni
dprc.1/dpni.3 (interface: ni3, end point: dpni.2)
dprc.1/dpni.2 (interface: ni2, end point: dpni.3)
dprc.1/dpni.1 (interface: ni1, end point: dpmac.6)
dprc.1/dpni.0 (interface: ni0, end point: dpmac.5)
```

3. **ls-listmac**

   This script lists all the dpmac objects available in the root and child containers, the associated network interface name, the end point and the label.

   Output after running the above examples (dpni.0 had been connected to dpmac.5 in the static DPL):

```
# ls-listmac
dprc.1/dpmac.8
dprc.1/dpmac.7
dprc.1/dpmac.6 (end point: dpni.1)
dprc.1/dpmac.5 (end point: dpni.0)
dprc.1/dpmac.4
dprc.1/dpmac.3
dprc.1/dpmac.2
dprc.1/dpmac.1
```

6.6.4 DPAA2 Ethernet features

This section presents the individual functions of the Linux DPAA2 Ethernet driver.

6.6.4.1 Bring up the bootstrap DPNI interface

From Linux, interfaces are visible through the '`ifconfig`' command. The DPAA2 interfaces are named as "`ni<X>`", where X is the number of the underlying DPNI device in the DPL file or as dynamically created with 'restool'.

The default DPL file shipped with the current BSP release contains one statically-defined DPNI object (DPNI.0), visible in Linux as interface "ni0".

DPNI.0 is configured with a minimal set of resources – e.g. it can only receive traffic on GPP0 – and its intended uses are network boot and low-bandwidth traffic. For fully-featured DPNI objects, dynamic configuration is recommended (see Dynamically creating a DPNI on page 444).

For IP connectivity between ni0 and an external host, first assign a valid IP address to ni0 as in the following example:

```
$ ifconfig ni0 192.168.1.2
```

Assuming the remote peer has address 192.168.1.1, ping to test as shown:

```
$ ping 192.168.1.1
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=87.0 ms
```

Notes:

- A SSH server is running by default and can be connected to, via ssh or scp, for example:

```
$ scp root@192.168.1.2:/bin/sh . # copy remote /bin/sh over
```

- A tftpd server is also installed; with the current configuration it must be explicitly started first. The steps to start tftpd, bound to local address 192.168.1.2, on port 69 (note the "." at the end, indicating the current directory, from where it will serve files to tftp clients):

```
$ udpsvd -vE 192.168.1.2 69 tftpd .
```

- The steps to connect an external tftp client to the RDB board depend on the actual tftp client. For example, to use the tftp client from the RDB board itself and get <some_filename> from a remote server, use the following command:

```
$ busybox tftp -g -r <some_filename> 192.168.1.1
# Note the explicit invocation of the Busybox tftp
```

6.6.4.2 Primary MAC address change

Changing the primary MAC address of a Linux Ethernet interface is supported without the need to bring down the interface.

For example:

```
$ ifconfig ni0 hw ether 02:00:C0:01:02:0a
```

```
$ ip link set dev ni0 address 02:00:C0:01:02:0b
```

6.6.4.3 Scatter/gather configuration

The Ethernet driver supports scatter/gather (S/G) on both the transmit and receive side. The S/G option can be configured through ethtool on Tx; on Rx, S/G support is always on. For example, in order to see the current state of the device features and hardware offloads for device ni0 :

```
$ ethtool -k ni0
Features for ni0:
[…]
scatter-gather: on
        tx-scatter-gather: on
[…]
```

In order to change the S/G status of the Linux Ethernet interface ni0:

```
$ ethtool -K ni0 sg off
Actual changes:
scatter-gather: off
        tx-scatter-gather: off
generic-segmentation-offload: off [requested on]

$ ethtool -K ni0 sg on
Actual changes:
```

```
scatter-gather: on
        tx-scatter-gather: on
generic-segmentation-offload: on
```

Notes:

- S/G support on the *egress* path, together with High DMA, which is also supported, allows for efficiently transmitting TCP segments from user-space, without copying them to kernel-space first ("Tx zero-copy").
- Egress S/G is necessary for other kernel features such as generic segmentation offload (GSO, implicitly turned on).
- The Ethernet driver support for S/G frames on the *ingress* path is transparent to the user.

6.6.4.4 Checksum offload configuration

The Ethernet driver supports hardware offloading of both Rx checksum validation and Tx checksum generation for TCP and UDP over IPv4/IPv6. The hardware checksum offload can be configured through ethtool.

For viewing the current state of the feature use the "-k" flag:

```
$ ethtool –k ni0
Features for ni0:
[…]
rx-checksumming: on
tx-checksumming: on
        tx-checksum-ipv4: on
        tx-checksum-ipv6: on
[…]
```

The checksum offload can be controlled separately on Rx and Tx paths as follows:

```
$ ethtool –K ni0 rx on|off
$ ethtool –K ni0 tx on|off

$ ethtool -k ni0 | grep tx-checksumming
tx-checksumming: off
```

6.6.4.5 MAC filtering

The DPAA2 hardware supports unicast and multicast MAC filters on the ingress path. In Linux, MAC unicast filtering can be accomplished with the help of MACVLAN interfaces. Kernel configuration and DPNI configuration are required to enable this feature, as follows:

- To enable support in the kernel, CONFIG_MACVLAN must be selected at compile-time, from the kernel menuconfig:
  `"Device Drivers -> Network device support -> Network core driver support -> MAC-VLAN support" .`

The Linux Ethernet driver allows adding and deleting of MAC filters via the standard "ip" command. An example of adding/deleting a MAC unicast address is the following:

```
$ ip link add link ni0 address <macvlan_mac_addr> ni0.1 type macvlan
$ ifconfig ni0.1 up
[…]
$ ip link delete ni0.1 type macvlan
```

Adding a multicast address is also possible using the "ip" command as follows:

```
$ ip maddr add 01:00:00:00:00:01 dev ni0
```

6.6.4.6 Large frame support

The DPAA2 hardware supports large frames. The Ethernet driver correlates between the Layer-2 maximum frame length (MFL) and Layer-3 MTUs. The maximum MTU that a Linux user can request on a DPAA2 Ethernet interface is 10222 bytes.

Notes:

- Outgoing packets larger than the current MTU are going to be fragmented by the kernel stack.
- All Ethernet devices on the same LAN must have the same MTU

6.6.4.7 Generic receive offload

The DPAA2 Ethernet driver is integrated with the kernel's generic receive offload (GRO) support. GRO is enabled by default and is configurable via "ethtool":

```
$ ethtool -k ni0 | grep generic-receive-offload
 generic-receive-offload: on
$ ethtool -K ni0 gro off
$ ethtool -k ni0 | grep generic-receive-offload
 generic-receive-offload: off
```

NOTE

For better performance, GRO should be disabled on the receiving interfaces in certain scenarios such as IP Forwarding.

6.6.4.8 Egress traffic shaping

The DPAA2 Ethernet interface supports traffic shaping in the egress path. Egress shaping can be set or cleared via a per-interface entry in SysFS:

```
$ echo M N > /sys/class/net/ni0/tx_shaping
```

where:

M is the maximum throughput, expressed in Mbps.

N is the maximum burst size, expressed in bytes, at most 64000.

To remove shaping, use M=0, N=0.

6.6.4.9 Rx hashing

The DPAA2 Ethernet driver supports hash distribution of ingress flows, based on some L2/L3/L4 fields. Rx hashing is enabled bydefault if num_queues has a value larger than 1. The distribution key is not user configurable, but can be viewed through ethtool:

```
$ ethtool -n ni1 rx-flow-hash <proto_type>
```

The hashing configuration is the same for all protocols.

NOTE

The ni0 interface present by default (via the static DPL) has num_queues = <1>, so Rx hashing is not available on ni0 unless it is dynamically destroyed and re-created.

For full details and examples on dynamic DPNI creation using *restool*, refer to this chapter. The interfaces created using those examples do support Rx hashing.

6.6.4.9.1 Rx hashing size

The hashing size (number of target GPPs to which the ingress traffic is distributed) is configured through the " `num_queues` " option in the DPNI node.

Also worth noting is that enough DPCON objects must be available when a DPNI is probed, in order to sustain the required hashing size. For details on the resource utilization of the DPNI, refer to DPAA2 objects dependencies on page 441.

6.6.4.10 Rx flow steering

The DPAA2 Ethernet driver supports steering of ingress traffic, directing flows to specific GPPs based on exact-match operations on some of the common L2/L3/L4 fields. The advantage versus Rx hashing on page 449 is cache locality of ingress data: the user-space applications that actually process the traffic make better use of the local GPP's cache than if the traffic were processed on another GPP. The disadvantage stems from the static configuration of flow affinity and from the fact that flow characteristics (e.g. L4 ports) must be known in advance, which is not always possible in real scenarios.

Configuration is done via standard "ethtool" support as follows:

```
$ ethtool -N ni1 flow-type <proto_type> <header_field> <value> [m <mask>] action <cpu_id>
```

Steering is supported on a subset of fields: SMAC, DMAC, VLAN tag, IP SRC, IP DST, IP next proto, L4 ports. Masking of header fields is also supported.

For example, in order to set up flow steering based on destination IP:

```
$ ethtool -N ni1 flow-type ip4 dst-ip 192.168.1.0 action 0
```

or subnet:

```
$ ethtool -N ni1 flow-type ip4 dst-ip 192.168.2.0 m 0.0.0.255 action 1
```

NOTE

Currently, flow steering can be enabled only if hashing is also enabled. Flow steering is only available for L2/L3/L4 fields that are also part of the Rx hash key. Additionally, the MC firmware and Linux Ethernet driver will only configure flow-steering if `DPNI_OPT_HAS_KEY_MASKING` is set in the "options" list of the DPNI object either via the DPL node or via restool - e.g.:

```
dpni@1 {
[…]
    options = "DPNI_OPT_HAS_KEY_MASKING";
[…]
};
```

respectively:

```
restool dpni create [...] --options=DPNI_OPT_HAS_KEY_MASKING
```

The examples in this paragraph are using dpni@1/n1 as reference because at Linux boot, the default ni0 interface enabled via the static DPL does not declare Rx Flow Steering in its capabilities list, so Rx Flow Steering would not be available on ni0 unless it is dynamically destroyed and re-created. For full details and examples on dynamic DPNI creation using *restool*, refer to this chapterDynamically creating a DPNI on page 444. The interfaces created using those examples do support Rx Flow Steering.

6.6.4.11 Flow Control Pause Frames

The DPAA2 Ethernet interfaces support sending and responding to pause frames, as part of the Ethernet flow control mechanism. The behavior of the pause frames is described in the IEEE 802.3x standard. In a nutshell, in a scenario involving a full duplex link, if the sender is sending at a higher rate than the receiver can process frames, the receiver can choose to send a special kind of frame, called pause frame, which asks the sender to halt the transmission of traffic for a specified period of time.

Pause frame control is integrated into ethtool. By default it's enabled for both Tx and Rx.

```
~# ethtool -a ni0
Pause parameters for ni0:
Autonegotiate:  on
RX:             on
TX:             on

~# ethtool -A ni0 rx off
~# ethtool -a ni0
Pause parameters for ni0:
Autonegotiate:  on
RX:             off
TX:             on
```

Currently, there's no support in configuring pause frame autonegotiation independently from link general autonegotiation. Hence, if link autonegotiation (e.g. rate and duplex) is on, it is on pause frames as well, and viceversa.

Pause frames are interpreted at the MAC level. Therefore, the counters for pause frames are visible when configuring netdevice objects for DPMAC objects using the `CONFIG_FSL_DPAA2_MAC_NETDEVS=y` kernel option. This option will bring up a set of additional Linux network interfaces named `macX`, one for each probed DPMAC object in the system.

```
~# ethtool -S mac1 | grep pause
     rx pause: 106731474
     tx b-pause: 15287253
```

If the driver is configured with Tx pause frames on, the hardware will start sending pause frames when the interface enters a congestion state on the Rx side.

If the driver is configured with Rx pause frames on, it will respond to any pause frames received on the line by reducing the send rate.

6.6.4.12 Busy Poll

Busy polling is a mechanism to reduce the latency on the network receive path. When enabled, it allows the socket layer code to directly poll the receive queue of a network device. During this time, network interrupts are disabled, thus removing delays caused by interrupt handling and context switches. The side effect is an increased CPU utilization.

Busy polling is disabled by default. There are 2 requirements to enable it:

- Add the `SO_BUSY_POLL` option to the socket. This can be done in the userspace application, per socket. In order to enable it globally, set `sysctl.net.core.busy_read` to a value greater than 0. This parameter controls the number of microseconds to wait for packets on the device queue for socket reads. It also sets `SO_BUSY_POLL` to all created sockets by default.

  ```
  ~# sysctl -w net.core.busy_read=50
  ```

- Set `sysctl.net.core.busy_poll` to a value greater than 0. This parameter controls the number of microseconds to wait for packets on the device queue socket poll and select.

  ```
  ~# sysctl -w net.core.busy_poll=50
  ```

Checking whether the driver supports busy polling is done via ethtool:

```
~# ethtool -k ni0 | grep busy-poll
busy-poll: on [fixed]
```

6.6.4.13 Interface statistics

DPAA2 Ethernet interface counters can be read via either of two standard tools, but there is a subtle difference:

- " `ifconfig ni0` " counters reflect packets received by the Ethernet driver – i.e. those frames that have passed through the Rx filters (if any are active) and have been effectively processed by the Ethernet driver on the GPP, and possibly by the kernel stack. These are software counters, maintained by the Ethernet driver and the networking stack.
- " `ethtool -S ni0` " counters reflect more detailed counters, from two categories:
  1. Statistics maintained by the DPAA2 hardware. These largely correspond in meaning to the standard "ifconfig" counters, but the values may be different from the "ifconfig" counters - i.e. they may reflect frames that have not been received on the GPP, such as those dropped by the ingress policer or due to MAC filtering. Also noteworthy is that retrieving these counters requires a series of calls into the MC firmware, which could make the operation potentially slower.
  2. Advanced counters, specific to the DPAA2 Ethernet driver. These are software-maintained driver-specific counters which do not fit into the standard " `ifconfig` " set.

     The following detailed counters are presented by the '`ethtool -S`' command:

     a. Hardware-maintained counters:
        - `rx frames`: number of valid frames presented to the DPNI hardware and not dropped (see "rx frames dropped" below);
        - `rx bytes`: number of bytes comprised within the "rx frames" counter;
        - `rx frames dropped`: number of valid frames but dropped because e.g. of MAC filtering;
        - `rx err frames`: number of frames with various physical errors; frames dropped because of insufficient buffers to DMA them into are counted here;
        - `rx mcast frames`: number of valid multicast frames;
        - `rx mcast bytes`: number of bytes included in "rx mcast frames";
        - `rx bcast frames`: number of valid broadcast frames;
        - `rx bcast bytes`: number of bytes included in "rx bcast frames";
        - `tx frames`: number of valid frames presented for transmission;
        - `tx bytes`: number of bytes included in "tx frames";
        - `tx err frames`: number of frames with Tx errors;

     b. Software-maintained, driver-specific counters:
        - `tx conf frames`: number of frames presented back to the Ethernet driver in the Tx confirmation queues. In an idle system, this counter should be equal to "tx frames";
        - `tx conf bytes`: number of bytes comprised by the "tx conf frames" counter;
        - `tx sg frames`: number of egress frames in scatter-gather format; these are a subset of "tx frames", the difference being contiguous frames;
        - `tx sg bytes` : number of bytes comprised in "tx sg frames";
        - `rx sg frames`: number of frames received in scatter-gather format; typically this reflects frames larger than the largest buffer that can be used at the time of reception;
        - `rx sg bytes`: number of bytes comprised in "rx sg frames";

- `tx portal busy`: number of times the Ethernet driver had to retry the frame enqueue command (on the egress path) due to QBMan portal being busy;
- `portal busy`: number of times the Ethernet driver had to retry the frame dequeue command (on the ingress path) due to QBMan portal being busy;
- `cdan` : number of Channel Dequeue Available Notifications (CDANs) received by the Ethernet driver (Rx and Tx Conf paths). Each CDAN corresponds to one DPIO interrupt and triggers a NAPI processing cycle which can process Rx or Tx Conf frames (or both).

6.7 Setting up Ethernet Switch Capability

6.7.1 Ethernet Switch overview

The following switch features are supported:

- Dynamic learning
- Adding/deleting static FDB entries
- Adding/deleting static multicast entries
- Configuring multicast groups
- Flooding of broadcast and multicast traffic
- Forwarding of unicast traffic that is both VLAN tagged and untagged
- Setting STP state of ports

Important notes:

- Learning is supported and enabled by default.
- Learned FDB entries cannot be displayed.
- There is no support to flush the FDB.

Acronyms and abbreviations:

- DPSW - DPAA2 object modelling an L2 Switch
- DPNI - DPAA2 object modelling a network interface

6.7.2 Switch object creation

A switch object can be created:

- Dynamically using the restool as described in Using restool for dynamic object creation on page 453 or
- Statically in a DPL file as described in Using the data path layout file (DPL) on page 455

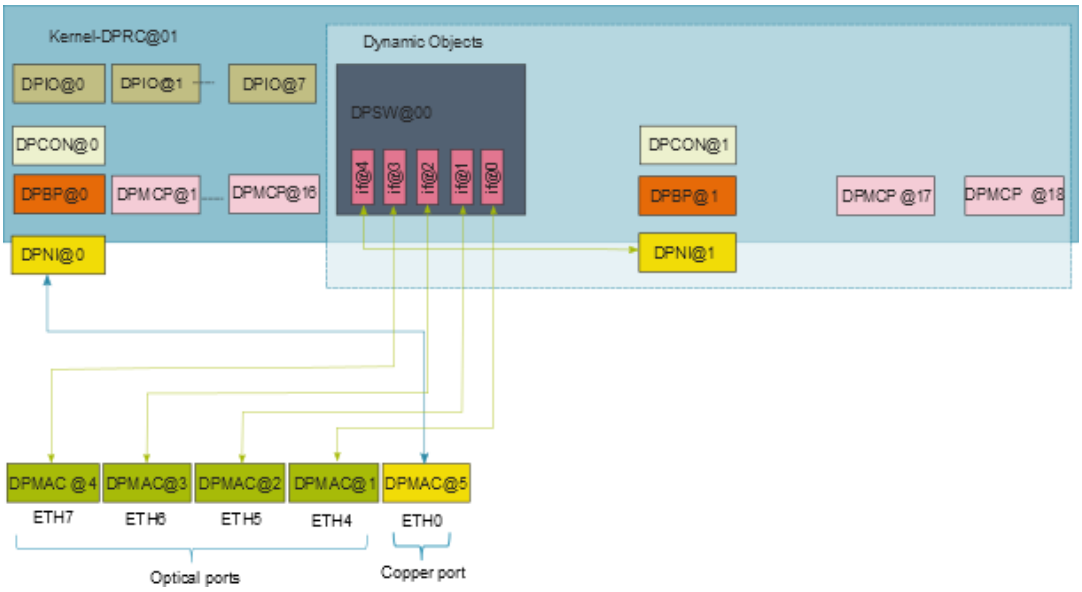
6.7.2.1 Using restool for dynamic object creation

A switch can be created at run-time, using restool. Before creating the switch, a number of DPAA2 objects (dependencies) have to be added, for which multiple restool commands are needed. Switch requires at least a DPMCP object, which is created like:

```
$ restool dpmcp create
```

The following section describes the main commands to create a switch starting from the **dpl-eth.0x2A_0x41.dtb** DPL file.

Figure 29. Dynamic DPSW demo



NOTE

When a new object is created via restool, an object with the id of the first available resource will be returned.

NOTE

Depending on the board type, DPMAC availability varies. For more details please refer to **Limitations and Known Issues**.

6.7.2.1.1 Creating a DPSW

The switch object is created by this command:

```
$ restool dpsw create --num-ifs=5 --max-vlans=16 --max-fdbs=1 --options="DPSW_OPT_CTRL_IF_DIS"
```

The command specifies some configuration options, including the number of ports in the switch, the maximum number of VLANs that can be used on the switch – including VLAN1 used implicitly, plus the number of FDBs.

For all the configuration options and parameters see the help output:

```
$ restool dpsw create -h
```

Currently VLAN private FDBs are not supported; a single shared FDB is used. Also control traffic is not supported, so option DPSW_OPT_CTRL_IF_DIS has to be specified.

6.7.2.1.2 Connecting the switch

Linking the switch ports to other objects is done with:

```
restool dprc connect "$RC" --endpoint1="$SW".0 --endpoint2=dpmac.1
restool dprc connect "$RC" --endpoint1="$SW".1 --endpoint2=dpmac.2
restool dprc connect "$RC" --endpoint1="$SW".2 --endpoint2=dpmac.3
restool dprc connect "$RC" --endpoint1="$SW".3 --endpoint2=dpmac.4
restool dprc connect "$RC" --endpoint1="$SW".4 --endpoint2="$NI"
```

In the context of the configuration script, these commands create the following layout:

- sw0p0 (dpsw@1/if@0) <-> dpmac@1 (SFP+ port, labeled ETH4 on RDB front panel)
- sw0p1 (dpsw@1/if@1) <-> dpmac@2 (SFP+ port, labeled ETH5 on RDB front panel)
- sw0p2 (dpsw@1/if@2) <-> dpmac@3 (SFP+ port, labeled ETH6 on RDB front panel)
- sw0p3 (dpsw@1/if@3) <-> dpmac@4 (SFP+ port, labeled ETH7 on RDB front panel)
- sw0p4 (dpsw@1/if@4) <-> dpni@1

For SerDes **0x2A_0x41**, DPMACs 1-4 are mapped to the optical PHYs while DPMACs 5-8 are mapped to the copper PHYs. User can choose to connect any of the optical or copper ports and any NIs to the switch.

6.7.2.1.3 Enabling the switch

This command plugs the switch object on the bus, in the Linux resource container. The switch driver probes the switch and presents the associated network interfaces in Linux.

```
$ restool dprc assign "$RC" --object="$SW" --plugged=1
```

After enabling the switch it can be configured from Linux using the commands specified in Commands supported on page 457.

6.7.2.1.4 Restool wrapper scripts

For user convenience the **ls-addsw** script is provided to assist creation of a new DPSW object.

To replicate the setup described in sectionConnecting the switch on page 454 the following commands are required:

```
$ ls-addni -n
$ ls-addsw -i=5 dpmac.1 dpmac.2 dpmac.3 dpmac.4 dpni.1
```

The first command creates a new DPNI object and the second the DPSW object. DPMACs are already defined in the DPL file. To display the DPNIs and DPMACs available one can use *ls-listni* or *ls-listmac* commands. The DPIO, DPBP, DPCON and DPMCP objects that are dependencies for the new objects are created by the script, without user intervention.

For all the script options and parameters see the help:

```
$ ls-addsw -h
```

The endpoints are connected in the specified order to switch ports. If there are less endpoints than the number of interfaces, the user can later add the rest using *ls-addni* or *restool* commands.

6.7.2.2 Using the data path layout file (DPL)

A switch object may be defined statically in the DPL, allowing it to be created automatically during platform initialization. Below is an example of switch definition in the DPL:

```
dpsw@0 {
      compatible = "fsl,dpsw";
      options = "DPSW_OPT_CTRL_IF_DIS";
      max_vlans = <0x10>;
      max_fdbs = <0x1>;
      num_fdb_entries = <0x400>;
      fdb_aging_time = <0x12c>;
      num_ifs = <0x5>;
      max_fdb_mc_groups = <32>;
};
```

This example is for a 5-port switch that includes support for up to 16 VLAN IDs, including VLAN 1 (that is internally used by the switch), up to 1024 FDB entries, and up to 32 multicast groups.

Links are defined in the DPL 'connections' section as follows:

```
connections {
       connection@1 {
             endpoint1 = "dpsw@0/if@0";
             endpoint2 = "dpmac@1";
        };
        connection@2 {
             endpoint1 = "dpsw@0/if@1";
             endpoint2 = "dpmac@2";
        };
        connection@3 {
             endpoint1 = "dpsw@0/if@2";
             endpoint2 = "dpmac@3";
        };
        connection@4 {
            endpoint1 = "dpsw@0/if@3";
            endpoint2 = "dpmac@4";
        };
        connection@5 {
             endpoint1 = "dpsw@0/if@4";
             endpoint2 = "dpni@1";
       };
};
```

The generated layout is the one described in Connecting the switch on page 454.

6.7.3 Setting up the driver

To compile the driver, you enable the **FSL_DPAA2_ETHSW** option in the kernel's config. It can be found in *menuconfig* under the following items:

```
| -> Device Drivers
|   -> Network device support
|     -> Ethernet driver support
|       -> Freescale devices
|         -> Freescale DPAA Ethernet
|           -> Layerscape DPAA Ethernet Switch
```

The driver is enabled in the default kernel configuration file. The driver registration is signaled in the kernel log by this message:

```
MC object device driver dpaa2_ethsw registered
```

After deploying the driver and instantiating a DPSW, the system should present following Linux interfaces (actual number of interfaces depends on the specified number of switch ports):

```
sw0         Link encap:Ethernet HWaddr 00:00:00:00:00:00
            inet6 addr: fe80::200:ff:fe00:0/64 Scope:Link
            UP BROADCAST RUNNING MASTER MULTICAST MTU:1500 Metric:1
            RX packets:0 errors:0 dropped:0 overruns:0 frame:0
            TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
            collisions:0 txqueuelen:1000
            RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)
```

```
sw0p0      Link encap:Ethernet HWaddr 00:00:00:00:00:00
           UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
           RX packets:0 errors:0 dropped:0 overruns:0 frame:0
           TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
           collisions:0 txqueuelen:1000
           RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

sw0p1      Link encap:Ethernet HWaddr 00:00:00:00:00:00
           UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
           RX packets:0 errors:0 dropped:0 overruns:0 frame:0
           TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
           collisions:0 txqueuelen:1000
           RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

sw0p2      Link encap:Ethernet HWaddr 00:00:00:00:00:00
           UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
           RX packets:0 errors:0 dropped:0 overruns:0 frame:0
           TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
           collisions:0 txqueuelen:1000
           RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

sw0p3      Link encap:Ethernet HWaddr 00:00:00:00:00:00
           UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
           RX packets:0 errors:0 dropped:0 overruns:0 frame:0
           TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
           collisions:0 txqueuelen:1000
           RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

sw0p4      Link encap:Ethernet HWaddr 00:00:00:00:00:00
           UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
           RX packets:0 errors:0 dropped:0 overruns:0 frame:0
           TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
           collisions:0 txqueuelen:1000
           RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)
```

There is one ***sw0pX*** interface for each switch port, plus one ***sw0*** master interface that provides control over the whole switch. All these interfaces are used to manage the switch and its ports; they cannot be used to perform I/O. Any I/O through the switch must be performed using the interfaces linked to the switch.

6.7.4 Commands supported

The switch management commands supported are:

- ifup/ifdown (using ifconfig or similar)
- setting large frame size limit (using ifconfig or similar)
- retrieving statistics (using ifconfig or similar)
- configuring FDB (using bridge fdb)
- configuring multicast groups (using bridge fdb)
- configuring VLANs (using bridge vlan)
- configuring learning (using bridge link set)

6.7.4.1 Interface control

Any of the switch ports, or the switch as a whole, can be enabled/disabled using any of the following commands:

```
$ ifconfig { sw0pX | sw0 } { up | down }
$ ip link set { sw0pX | sw0 } { up | down }
```

6.7.4.2 Maximum frame size configuration

The DPAA2 hardware supports large frames. Ethernet switch driver correlates between the Layer-2 maximum frame length (MFL) and Layer-3 MTUs. The maximum MTU that a Linux user can request on a DPAA2 Ethernet switch interface is 10218 bytes and has to be set on each port individually.

```
$ ifconfig <sw0pX> mtu <NN>
$ ip link set { sw0pX | dev sw0pX } mtu <NN>
```

Notes:

- Frames larger than the configured MTU will be dropped, so connected Ethernet devices need to have the same setting.
- All Ethernet devices on the same LAN must have the same MTU to avoid traffic loss.

6.7.4.3 Learning control

The switch is set by default to enable learning, and the learning can be controlled using this command:

```
$ bridge link set dev sw0p0 learning { on | off }
```

NOTE

The command is executed on a switch port, although it does affect the learning function at switch level. Turning off learning does not remove the learned entries.

To establish a static topology, learning should be disabled before injecting any traffic.

6.7.4.4 FDB static entries

The default switch configuration does not include any static entries; these can be added using the *bridge fdb add* command, as shown below:

```
$ bridge fdb add 00:00:05:00:00:11 dev sw0p0
```

This command adds the MAC address of ni0 as a static entry in the FDB on the first switch port, linked to ni0.

6.7.4.5 Multicast entries

Multicast groups can be configured via bridge `fdb add|append|delete` commands:

```
$ bridge fdb add 01:00:05:00:00:13 dev sw0p1
$ bridge fdb append 01:00:05:00:00:13 dev sw0p2
$ bridge fdb append 01:00:05:00:00:13 dev sw0p3
$ bridge fdb append 01:00:05:00:00:13 dev sw0p4

$ bridge fdb del 01:00:05:00:00:13 dev sw0p4
```

The commands add all external ports, one by one, to the `01:00:05:00:00:13` multicast group. The last command removes the last port from the group.

6.7.4.6 VLAN configuration

The switch starts up with VLAN 1 configured as the default VLAN. All untagged traffic received on any switch port is classified to VLAN 1, and all frames classified in VLAN 1 are sent out untagged on all ports. Additional VLANs can be added on the switch using these commands:

```
$ bridge vlan add vid 2 dev sw0p0
$ bridge vlan add vid 2 dev sw0p1
$ bridge vlan add vid 2 dev sw0p2
$ bridge vlan add vid 2 dev sw0p3
$ bridge vlan add vid 2 dev sw0p4
```

This example includes all five ports in VLAN 2. After running these commands the switch should allow frames tagged with vid 2 to pass through the switch; not all ports have to be included in the VLAN.

To remove a port from a given VLAN use the following command:

```
$ bridge vlan del vid 2 dev sw0p0
```

To remove a VLAN completely from the switch run the following command:

```
$ bridge vlan del vid 2 dev sw0 self
```

6.7.4.7 Port statistics

Switch port statistics are available through `ip` or similar tools:

```
$ ip -s link
[...]
6: sw0: <NO-CARRIER,NOARP,MASTER,UP> mtu 1500 qdisc noop state DOWN mode DEFAULT group default qlen

```

6.8 Setting Up Edge Virtual Bridge Capability

6.8.1 EVB overview

An edge virtual bridge allows the sharing of a physical connection between multiple entities (virtual hosts). It can act as a VEB or as a VEPA.

In VEB mode, traffic is forwarded between connected virtual hosts or between virtual hosts and uplink.

In VEPA mode, all traffic from virtual hosts is forwarded to uplink, bridging functions (including 'hairpin' forwarding) being performed by an external device.

Features supported:

- VEB/VEPA mode
- Traffic steering according to MAC, VLAN (in VEPA mode only) or MAC+VLAN
- Static FDB entries management (add/delete/show)
- Static multicast FDB entries management (add/delete/show)
- Flooding of broadcast and multicast traffic

6.8.2 EVB object creation

EVB objects can be created as follows:

- Dynamically using the restool as described in Using restool for dynamic object creation on page 460
- Statically in a DPL file as described in Using the data path layout file (DPL) on page 462

6.8.2.1 Using restool for dynamic object creation

A DPDMUX can be instantiated at run-time, using restool.

The following section describes the main commands to create an EVB and its dependencies starting from the **dpl-eth.0x2A_0x41.dtb** DPL file.

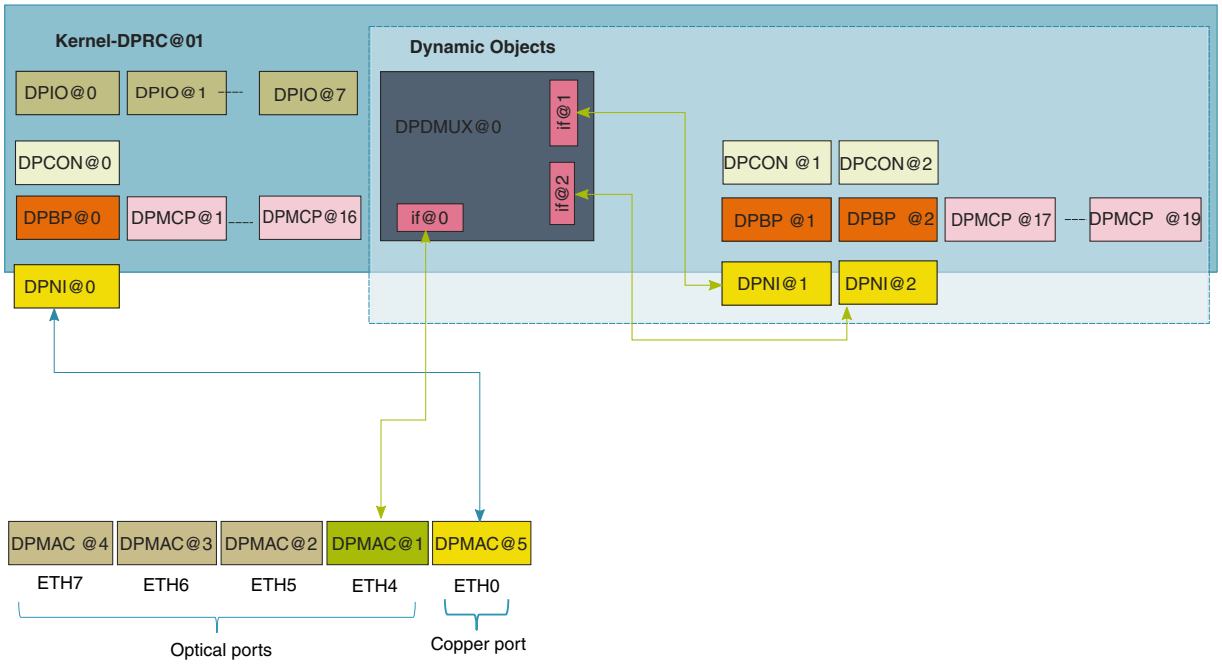

Figure 30. Dynamic DPDMUX demo

NOTE

When a new object is created using restool, an object with the ID of the first available resource is returned.

NOTE

Depending on the board type, DPMAC availability varies. For more details please refer to **Limitations and Known Issues**.

6.8.2.1.1 Creating a DPDMUX

The EVB is created by this command:

```
$ restool dpdmux create --num-ifs=2 --control-if=0                        \
          --options=DPDMUX_OPT_BRIDGE_EN --method=DPDMUX_METHOD_MAC       \
          --max-dmat-entries=8 --max-mc-groups=8 --manip=DPDMUX_MANIP_NONE
```

The command must specify the number of downlinks and the ID of the uplink (ranges for 0 to [number of downlinks -1]). The other parameters are optional. For more information about the available options see the output of the command:

```
$ restool dpdmux create -h
```

6.8.2.1.2 Connecting the EVB

Linking the EVB ports to other objects is done with:

```
$ restool dprc connect "$RC" --endpoint1="$MUX".0 --endpoint2="$MAC"
$ restool dprc connect "$RC" --endpoint1="$MUX".1 --endpoint2="$NI1"
$ restool dprc connect "$RC" --endpoint1="$MUX".2 --endpoint2="$NI2"
```

$RC represents the container for the objects, $MUX is the object identified for the EVB. The uplink is the endpoint with the id specified by *control-if* parameter at creation time.

6.8.2.1.3 Enabling the EVB

This command plugs the EVB object on the bus, in the Linux resource container. The EVB driver probes the switch and presents the associated network interfaces in Linux.

```
$ restool dprc assign "$RC" --object="$MUX" --plugged=1
```

6.8.2.1.4 Restool wrapper scripts

For user convenience the **ls-addmux** script is provided to assist creation of a new DPDMUX object.

Example to replicate setup in section Connecting the EVB on page 462 :

```
# ls-addmux -d=2 -u=0 dpmac.1
[ 4298.023745] dpaa2_evb dpdmux.0: probed evb device with 2 ports
Created EVB: evb0 (object: dpdmux.0, uplink: dpmac.1)
```

This command creates EVB evb0 (and the corresponding dpdmux.0 object) with two downlinks and the uplink connected to dpmac.1.

After creating the DPDMUX, its downlinks can be connected to DPNIs using **ls-addni** script:

```
# ls-addni dpdmux.0.1
Will allocate 8 DPCON objects for this hash size
[ 5118.645253] fsl_dpaa2_eth dpni.1: Probed interface ni1
Created interface: ni1 (object:dpni.1, endpoint: dpdmux.0.1)
# ls-addni dpdmux.0.2
Will allocate 8 DPCON objects for this hash size
[ 5122.169030] fsl_dpaa2_eth dpni.2: Probed interface ni2
Created interface: ni2 (object:dpni.2, endpoint: dpdmux.0.2)
```

6.8.2.2 Using the data path layout file (DPL)

A DPDMUX instance can statically be defined in the DPL file:

```
dpdmux@0 {
       compatible = "fsl,dpdmux";
       options = "DPDMUX_OPT_BRIDGE_EN";
       method = "DPDMUX_METHOD_MAC";
       manip = "DPDMUX_MANIP_NONE";
       control_if = <0>;
       num_ifs = <2>;
       max_dmat_entries = <8>;
       max_mc_groups = <8>;
};
```

Links are defined in the DPL 'connections' section:

```
connection@1{
        endpoint1 = "dpdmux@0/if@0";
        endpoint2 = "dpmac@1";
};
connection@2{
        endpoint1 = "dpni@1";
        endpoint2 = "dpdmux@0/if@1";
};
connection@3{
        endpoint1 = "dpni@2";
        endpoint2 = "dpdmux@0/if@2";
};
```

Based on the above configuration the DPDMUX ports are linked to:

- evb0 (dpdmux@1/if@0) <-> dpmac@1
- evb0p0 (dpdmux@1/if@1) <-> dpni@1
- evb0p1 (dpdmux@1/if@2) <-> dpni@2

NOTE

DPDMUX ports connected to a DPMAC must be configured before the others (e.g. connected to DPNIs).

6.8.3 Setting up the EVB driver

Driver compilation is enabled by default and is controlled by the FSL_DPAA2_EVB option in the kernel's config. This can be found in *menuconfig* under the following items:

```
| -> Device Drivers
|     -> Staging drivers
|         -> Freescale Management Complex (MC) bus driver
|             -> Freescale DPAA2 devices
|                 -> DPAA2 Edge Virtual Bridge
```

The kernel log will display a message when an EVB is probed as follows:

```
dpaa2_evb dpdmux.0: probed evb device with 2 ports
```

After deploying the driver and configuring an EVB (via DLP or restool), the system should present the following Linux interfaces after typing the 'ifconfig command':

```
evb0     Link encap:Ethernet HWaddr 00:00:00:00:00:00
         UP BROADCAST RUNNING MASTER MULTICAST MTU:1500 Metric:1
         RX packets:0 errors:0 dropped:0 overruns:0 frame:0
         TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
         collisions:0 txqueuelen:1000
         RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)

evb0p0   Link encap:Ethernet HWaddr 00:00:00:00:00:00
         UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
         RX packets:0 errors:0 dropped:0 overruns:0 frame:0
         TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
         collisions:0 txqueuelen:1000
         RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)
```

```
evb0p1   Link encap:Ethernet HWaddr 00:00:00:00:00:00
         UP BROADCAST RUNNING SLAVE MULTICAST MTU:1500 Metric:1
         RX packets:0 errors:0 dropped:0 overruns:0 frame:0
         TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
         collisions:0 txqueuelen:1000
         RX bytes:0 (0.0 B) TX bytes:0 (0.0 B)
```

Interface ***evb0*** represents the uplink and is also the handler for the EVB. Each other EVB port has its own interface. They are used for management and cannot be used for I/O. Any I/O through the EVB must be performed using the connected interfaces.

An EVB only forwards traffic to links that are enabled (peer interface is up) and only if the filtering rules on the peer interface do not lead to the frame being discarded. One way to ensure that all traffic subject to forwarding rules is actually forwarded by the EVB is to set the peer interface in promiscuous mode, as follows:

```
$ ip link set ni0 up promisc on
```

6.8.4 EVB commands supported

EVB management can be performed using the following generic Linux networking tools:

- interface up/down (using ifconfig or similar)
- configuring FDB (using bridge fdb)
- configuring VLANs (using bridge vlan)
- configuring multicast groups (using bridge fdb)
- port statistics retrieval (ethtool or similar)

6.8.4.1 EVB interface control

Any of the EVB ports, or the EVB as a whole, can be enabled/disabled using any of the following commands:

```
$ ifconfig { evb0pX | evb0 } { up | down }
$ ip link set { evb0pX | evb0 } { up | down }
```

6.8.4.2 EVB FDB entries

The EVB method DPDMUX_METHOD_MAC allows configuration of FDB entries via a bridge utility as follows:

```
$ bridge fdb add 02:00:c0:a8:50:01 dev evb0p0
$ bridge fdb show
02:00:c0:a8:50:01 self permanent
01:00:5e:00:00:01 self permanent
```

The EVB method DPDMUX_METHOD_C_VLAN_MAC also allows configuration of FDB entries via a bridge utility as follows:

```
$ bridge fdb add 02:00:c0:a8:50:02 vlan 10 dev evb0p0 vlan 10
$ bridge fdb show dev evb0p0
02:00:c0:a8:50:02 self permanent
01:00:5e:00:00:01 self permanent
```

6.8.4.3 EVB VLAN assignment

The EVB method DPDMUX_METHOD_C_VLAN allows port VLAN assignment via a bridge utility as follows:

```
$ bridge vlan add vid 10 dev evb0p2
$ bridge vlan show dev evb0p2
port vlan ids
evb0p2 10
$ bridge vlan del vid 10 dev evb0p2
```

NOTE

This method is allowed only for VEPA mode.

6.8.4.4 EVB port statistics

EVB port statistics are available through *ip* or similar tools as follows:

```
$ ip -s link
[...]
9: evb0: <BROADCAST,MULTICAST,MASTER,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UNKNOWN mode
DEFAULT group default qlen 1000
       link/ether 00:00:00:00:00:00 brd ff:ff:ff:ff:ff:ff
       RX: bytes packets errors dropped overrun mcast
       0         0       0      0       0       0
       TX: bytes packets errors dropped carrier collsns
       384       6       0      0       0       0
10: evb0p0: <BROADCAST,MULTICAST,SLAVE,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast master evb0 state
UNKNOWN mode DEFAULT group default qlen 1000
       link/ether 00:00:00:00:00:00 brd ff:ff:ff:ff:ff:ff
       RX: bytes packets errors dropped overrun mcast
       252       6       0      0       0       0
       TX: bytes packets errors dropped carrier collsns
       0         0       0      0       0       0
[...]
```

6.8.5 Forwarding methods overview

A DPAA2 DPDMUX instance can forward traffic using information from various fields in the frame headers:

- Forwarding by destination MAC address
- Forwarding by VLAN tag
- Forwarding by VLAN tag and destination MAC adress

6.8.5.1 Forwarding by destination MAC address

This method forwards frames according to the destination MAC address and the static rules added into the EVB forwarding database.

It is configured specifying *--method="DPDMUX_METHOD_MAC"* when the DPDMUX is created. It is the default value for the *ls-addmux* script.

Entries are configured in the FDB using *bridge fdb* command. See EVB FDB entries on page 464 section for more information.

Configuration example:

```
# Create a MUX with 2 downlinks and uplink connected to dpmac.1;
# forwarding method is by default DPDMUX_METHOD_MAC
$ ls-addmux -b -d=2 -u=0 dpmac.1
```

```
# Create a ni (dpni.1) and links it to evb0p0
$ ls-addni dpdmux.0.1

# Create a ni (dpni.2) and links it to evb0p1
$ ls-addni dpdmux.0.2

# Check MUX configuration
# $ restool dpdmux info dpdmux.0

# Configure ni1
$ ip netns add ns1
$ ip link set ni1 netns ns1
$ ip netns exec ns1 ifconfig ni1 192.168.10.10/24 up
$ ip netns exec ns1 ip link set ni1 promisc on

# Configure ni2
$ ip netns add ns2
$ ip link set ni2 netns ns2
$ ip netns exec ns2 ifconfig ni2 192.168.10.12/24 up
$ ip netns exec ns2 ip link set ni2 promisc on

# Connectivity checks [downlink - uplink ]
$ ip netns exec ns1 ping 192.168.10.13 -c 1
[..]
--- 192.168.10.13 ping statistics ---
1 packets transmitted, 1 received, 0% packet loss, time 0ms

# Check EVB port statistics
$ ip -s link
[...]
4: evb0: <BROADCAST,MULTICAST,MASTER,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UNKNOWN mode
DEFAULT group default qlen 1000
    link/ether 00:00:00:00:00:00 brd ff:ff:ff:ff:ff:ff
    RX: bytes  packets  errors  dropped overrun mcast
    436        6        0       0       0       0
    TX: bytes  packets  errors  dropped carrier collsns
    460        6        0       0       0       0
5: evb0p0: <BROADCAST,MULTICAST,SLAVE,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast master evb0 state UP
mode DEFAULT group default qlen 1000
    link/ether 00:00:00:00:00:00 brd ff:ff:ff:ff:ff:ff
    RX: bytes  packets  errors  dropped overrun mcast
    364        6        0       0       0       0
    TX: bytes  packets  errors  dropped carrier collsns
    376        5        0       0       0       0
6: evb0p1: <NO-CARRIER,BROADCAST,MULTICAST,SLAVE,UP> mtu 1500 qdisc pfifo_fast master evb0 state
DOWN mode DEFAULT group default qlen 1000
    link/ether 00:00:00:00:00:00 brd ff:ff:ff:ff:ff:ff
    RX: bytes  packets  errors  dropped overrun mcast
    0          0        0       0       0       0
    TX: bytes  packets  errors  dropped carrier collsns
    0          0        0       0       0       0
```

6.8.5.2 Forwarding by VLAN tag

This method forwards frames according to the VLAN tag of the frame, as set into the customer tag of the double-tagged frames.

It is configured specifying *--method="DPDMUX_METHOD_C_VLAN"* when EVB is in VEPA mode (*--options="DPDMUX_OPT_BRIDGE_EN"* is not set).

EVB port VLAN assignment is done with "*bridge vlan* command. See EVB VLAN assignment on page 465 section for more information.

Configuration example:

```
# Create a MUX with DPDMUX_METHOD_C_VLAN forwarding method,
# configured as a VEPA and with 2 downlinks and uplink connected
# to dpmac.1
$ ls-addmux -m=DPDMUX_METHOD_C_VLAN -d=2 -u=0 dpmac.1

# Create a ni (dpni.1) and link it to evb0p0
$ ls-addni dpdmux.0.1

# Create a ni (dpni.2) and link it to evb0p1
$ ls-addni dpdmux.0.2

# Configure ni1
$ ip netns add ns1
$ ip link set ni1 netns ns1
$ ip netns exec ns1 ip link add link ni1 name ni1.6 type vlan id 6
$ ip netns exec ns1 ifconfig ni1.6 192.168.6.10
$ ip netns exec ns1 ip link set ni1 up
$ ip netns exec ns1 ip link set ni1 promisc on

# Configure ni2
$ ip netns add ns2
$ ip link set ni2 netns ns2
$ ip netns exec ns2 ip link add link ni2 name ni2.7 type vlan id 7
$ ip netns exec ns2 ifconfig ni2.7 192.168.7.12
$ ip netns exec ns2 ip link set ni2 up
$ ip netns exec ns2 ip link set ni2 promisc on

# For the downlinks interfaces also add the VLAN ids
$ bridge vlan add vid 6 dev evb0p0
$ bridge vlan add vid 7 dev evb0p1

# Connectivity checkings [example for downlink - uplink ]
$ ip netns exec ns1 ping -I ni1.6 192.168.6.13 -c 1

# Check VLAN assignment
$ bridge vlan show
```

6.8.5.3 Forwarding by VLAN tag and destination MAC adress

This method forwards frames according to the VLAN tag and the destination MAC address of the frame .

It is configured specifying *--method="DPDMUX_METHOD_C_VLAN_MAC"* when the DPDMUX is created.

Entries are configured in the FDB using *bridge fdb* command. See EVB FDB entries on page 464 section for more information.

Configuration example:

```
# Create a MUX with DPDMUX_METHOD_C_VLAN_MAC forwarding method,
# configured as a VEB and with 2 downlinks and uplink connected
# to dpmac.1
$ ls-addmux -b -m=DPDMUX_METHOD_C_VLAN_MAC -d=2 -u=0 dpmac.1

# Create a ni (dpni.1) and link it to evb0p0
$ ls-addni dpdmux.0.1

# Create a ni (dpni.2) and link it to evb0p1
$ ls-addni dpdmux.0.2

# Configure ni1
$ ip netns add ns1
$ ip link set ni1 netns ns1
```

```
$ ip netns exec ns1 ip link add link ni1 name ni1.6 type vlan id 6
$ ip netns exec ns1 ifconfig ni1.6 192.168.6.10
$ ip netns exec ns1 ip link set ni1 up
$ ip netns exec ns1 ip link set ni1 promisc on

# Configure ni2
$ ip netns add ns2
$ ip link set ni2 netns ns2
$ ip netns exec ns2 ip link add link ni2 name ni2.7 type vlan id 7
$ ip netns exec ns2 ifconfig ni2.7 192.168.7.12
$ ip netns exec ns2 ip link set ni2 up
$ ip netns exec ns2 ip link set ni2 promisc on

# For the downlinks interfaces, you would also need to add
# the downlinks MACs to fdb table
$ bridge fdb add 4a:64:0a:af:14:a2 dev evb0p0 vlan 6
$ bridge fdb add 62:9c:86:0f:f7:cf dev evb0p1 vlan 7

# Connectivity checkings [example for downlink - uplink ]
$ ip netns exec ns1 ping -I ni1.6 192.168.6.13 -c 1

# Check EVB FDB entries
$ bridge fdb show
```

6.9 Security Engine (SEC)

This paragraph describes the software for the SEC hardware block that is part of the DPAA2 family of SoCs.

6.9.1 DPAA2 CAAM driver specifics

Module Loading

The dpaa2-caam driver is built as a module that is registered when a `dpseci` object is created dynamically with `restool`. Without any parameter, the DPSECI object being created has 2 pairs of (rx,tx) queues.

```
# restool dpseci create && restool dprc assign dprc.1 --object=dpseci.0 --plugged=1
```

To create 8 (maximum) number of queues:

```
restool dpseci create --num-queues=8 --priorities=1,2,3,4,5,6,7,8 && restool dprc assign dprc.1 --
object=dpseci.0 --plugged=1
```

You can check more options:

```
restool dpseci create --help
```

You can check the list of algorithms registered by the dpaa2-caam driver as below:

```
# grep dpaa2-caam /proc/crypto
```

Enabling congestion management

Congestion management can be enabled when working with a MC that has a DPSECI object version greater or equal to 5.1. The first MC that will feature congestion management will have version 10.3. Enabling congestion management is done while creating the DPSECI object:

```
restool dpseci create --num-queues=8 --priorities=1,2,3,4,5,6,7,8 --options="DPSECI_OPT_HAS_CG" &&
restool dprc assign dprc.1 --object=dpseci.0 --plugged=1
```

Please note that this release features a MC with the version 10.2 and therefore it does not support congestion management activation. To use congestion management please use a newer version for both MC and restool. Using the current release restool with the above command will result in error.

Kernel configuration

Kernel Configure Tree View Options	Description
-- Cryptographic API [*] Hardware crypto devices -->> <*> Freescale DPAA2 CAAM ---	**Enables dpaa2 caam device driver**

Source files

The driver source files are maintained in the Linux kernel source tree: `drivers/crypto/dpaa2-caam`.

Features overview

The following is an overview of the functionalities of the Linux DPAA2 CAAM SEC driver:

Authenticated encryption with associated data (AEAD) algorithms

These algorithms are used in applications where the data to be encrypted overlaps, or partially overlaps, the data to be authenticated, as is the case with the IPSec protocol. These algorithms are implemented in the driver such that the hardware makes a single pass over the input data, and both encryption and authentication data are written out simultaneously. Note that, on decryption, integrity verification is performed in h/w, when available. The AEAD algorithms are mainly for use with IPSec ESP. The CAAM driver currently supports offloading the following AEAD algorithms:

authenc(hmac(sha512), rfc3686(ctr(aes)))
authenc(hmac(sha384), rfc3686(ctr(aes)))
authenc(hmac(sha256), rfc3686(ctr(aes)))
authenc(hmac(sha224), rfc3686(ctr(aes)))
authenc(hmac(sha1), rfc3686(ctr(aes)))
authenc(hmac(md5), rfc3686(ctr(aes)))
authenc(hmac(sha512), cbc(des)))
authenc(hmac(sha384), cbc(des)))
authenc(hmac(sha256), cbc(des)))
authenc(hmac(sha224), cbc(des)))
authenc(hmac(sha1), cbc(des)))
authenc(hmac(md5), cbc(des)))
authenc(hmac(sha512), cbc(des3_ede)))
authenc(hmac(sha384), cbc(des3_ede)))
authenc(hmac(sha256), cbc(des3_ede)))
authenc(hmac(sha224), cbc(des3_ede)))
authenc(hmac(sha1), cbc(des3_ede)))
authenc(hmac(md5), cbc(des3_ede)))
authenc(hmac(sha512), cbc(aes)))
authenc(hmac(sha384), cbc(aes)))
authenc(hmac(sha256), cbc(aes)))
authenc(hmac(sha224), cbc(aes)))
authenc(hmac(sha1), cbc(aes)))
authenc(hmac(md5), cbc(aes)))
gcm(aes)

i.e., all combinations of AES-CBC, (3)DES-EDE, RFC3686-CTR-AES with MD-5, SHA-1,-224,-256,-384, and -512.

Cipher encryption algorithms

The CAAM driver currently supports offloading the following encryption algorithms:

rfc3686(ctr(aes)
ctr(aes)
cbc(des)
cbc(3des)
cbc(aes)

Authentication algorithms

CAAM driver support both keyed and unkeyed hash algoritms, as follows:

hmac(md5)
hmac(sha1)
hmac(sha512)
hmac(sha384)
hmac(sha256)
hmac(sha224)
sha1
sha384
sha256
sha224
sha512
md5

How to test the driver

To test the driver, in the kernel configuration menu, under `"Cryptographic API -> Cryptographic algorithm manager"`, ensure that run-time self-tests are not disabled, i.e. the "`Disable run-time self tests`" (`CONFIG_CRYPTO_MANAGER_DISABLE_TESTS`) entry is not set. This will run standard test vectors against the driver after the driver registers its supported algorithms with the kernel crypto API. To verify if the 'selftest' fields have 'passed', the /proc/crypto entries should be checked. An entry such as this:

```
name : md5
driver : md5-dpaa2-caam
module : kernel
priority : 3000
refcnt : 1
selftest : passed
internal : no
type : ahash
async : yes
blocksize : 64
digestsize : 16
```

means the driver has successfully registered support for the algorithm with the kernel crypto API. Note that although a test vector may not exist for a particular algorithm supported by the driver, the kernel will emit messages saying which algorithms weren't tested, and mark them as 'passed' anyway. The drivers capablilits can also be tested with tcrypt testing framework available in linux kernel by selecting "`Cryptographic API --> Testing module`" (also `Disable run-time self tests` should be unchecked). A kernel module will be generated: crypto/tcrypt.ko This has to be copied on the target. Then on target, after a dpseci object is registered:

```
insmod tcrypt.ko mode=10
```

Other values for tcrypt mode parameter:

functional:
mode=155-157, 181-190;
speed ("sec" - seconds - param. is optional):
mode=400 [sec=1] - xxx(md5,sha*) ahash_speed
mode=500 [sec=1] - xxx(aes) acipher_speed
mode=501 [sec=1] - xxx(3des) acipher_speed
mode=502 [sec=1] - xxx(des) acipher_speedetc.

`unavailable`

There is no need to rmmod, tcrypt does not stay "resident", it exits after running the tests. That's why you'll see:

```
#insmod: ERROR: could not insert module tcrypt.ko: Resource temporarily
```

For algorithms not supported, you'll see errors as follows:

```
[ 2650.067737] failed to load transform for rmd128: -2
[ 2650.076480] failed to load transform for rmd160: -2
[ 2650.085099] failed to load transform for rmd256: -2
[ 2650.093739] failed to load transform for rmd320: -2
```

These are expected. Algorithm names registered by DPSECI driver (DPAA2-CAAM) are ending in `"-dpaa2-caam"`.

To verify the operation and correctness of the driver, other than noting the performance advantages due to the crypto offload, one can also ensure the h/w is doing the crypto by looking for driver messages in `dmesg`. The driver emits console messages at initialization time:

```
# dmesg | grep fsl_dpaa2_caam
[    4.988889] MC object device driver fsl_dpaa2_caam registered
[ 1172.598591] fsl_dpaa2_caam dpseci.0: Opened dpseci object successfully
[ 1172.619979] fsl_dpaa2_caam dpseci.0: prio 0: rx queue 135, tx queue 119
[ 1172.626633] fsl_dpaa2_caam dpseci.0: prio 1: rx queue 136, tx queue 128
[ 1172.633278] fsl_dpaa2_caam dpseci.0: prio 2: rx queue 137, tx queue 129
[ 1172.639915] fsl_dpaa2_caam dpseci.0: prio 3: rx queue 138, tx queue 130
[ 1172.646555] fsl_dpaa2_caam dpseci.0: prio 4: rx queue 139, tx queue 131
[ 1172.653195] fsl_dpaa2_caam dpseci.0: prio 5: rx queue 140, tx queue 132
[ 1172.659831] fsl_dpaa2_caam dpseci.0: prio 6: rx queue 141, tx queue 133
[ 1172.666470] fsl_dpaa2_caam dpseci.0: prio 7: rx queue 142, tx queue 134
[ 1172.694319] fsl_dpaa2_caam dpseci.0: DPSECI version 3.0
[ 1172.700617] fsl_dpaa2_caam dpseci.0: algorithms registered in /proc/crypto
[ 1172.707971] fsl_dpaa2_caam dpseci.0: hash algorithms registered in /proc/crypto
```

Given a time period when crypto requests are being made, the SEC h/w will fire completion notification interrupts:

```
# cat /proc/interrupts | grep DPIO
```

If the number of interrupts fired increment, then the h/w is being used to do the crypto. If the numbers do not increment, then check if the algorithm being exercised is supported by the driver.

6.9.2 DPAA2 security engine use cases

Running OpenSSL

OpenSSL 1.0.2h and cryptodev module version 1.8 are available in SDK.

Testing OpenSSL with offload on SEC engine is done through cryptodev API. Cryptodev uses ioctl's to map user-space crypto requests to Linux kernel which executes them internally and then returns the results back to user-space. OpenSSL recognizes the cryptodev module automatically if it is loaded in the kernel so no special configuration is required for OpenSSL.

First, register dpseci driver:

```
# restool dpseci create --num-queues=8
      --priorities=1,2,3,4,5,6,7,8 && restool dprc assign dprc.1 --object=dpseci.0
      --plugged=1
```

Check that algorithms have been registered:

```
# cat /proc/crypto | grep dpaa2-caam
```

Load cryptodev module:

```
# modprobe cryptodev
```

Check that openssl has support for cryptodev engine:

```
# openssl engine
```

Check interrupts before running openssl tests:

```
# cat /proc/interrupts | grep DPIO
```

Run openssl tests:

```
# openssl speed -evp sha1 -engine cryptodev –elapsed
# openssl speed -evp md5 -engine cryptodev -elapsed
# openssl speed -evp aes-128-cbc -engine cryptodev -elapsed
# openssl speed -evp aes-256-cbc -engine cryptodev -elapsed
# openssl speed -evp aes-192-cbc -engine cryptodev –elapsed
# openssl speed -evp des-cbc -engine cryptodev –elapsed
```

Check interrupts after running openssl tests. Increased interrupts numbers confirm that execution was actually done with the SEC engine:

```
# cat /proc/interrupts
```

Running IPSec

DPNI configuration

Before running any configuration script on the boards you must ensure that there are 2 fully-feature configured DPNIs. The provided static DPL file configures only a single reduced-feature DPNI. To bypass this problem please remove any DPNIs from the DPL and configure the DPNIs dynamically. To do that write these commands after Linux boot at the command prompt:

```
$ ls-addni dpmac.2
$ ls-addni dpmac.1
```

Hardware setup

2 LS2080 boards;

Network simulator: Spirent TestCenter Performance Analysis System

Test Configuration

Linux Ipv4 SEC Forward Configuration

128 tunnels (bi-directional) configuration:

Spirent TestCenter configuration:

Port 1 to Port 2: Src: 192.85.1.2 – 192.85.1.9 Dst: 192.86.1.2 – 192.86.1.9

Port 2 to Port 1: Src: 192.86.1.2 – 192.86.1.9 - Src: 192.85.1.2 – 192.85.1.9

Linux configuration: The Linux configuration file is listed below.

On left gateway(Encrypt) board, run: bash iproute_128tunnels.sh left

On right gateway(Decrypt) board run: iproute_128tunnels.sh right

Running the Test

After Spirent Testcenter application is configured and the testing Ethernet interfaces are connected to the traffic generator, start to generate traffic to measure IPv4 SEC & Forward throughput.

6.10 Decompression Compression Engine (DCE)

Introduction

This section describes the software interface to DCE (Decompression Compression Engine) accelerator available on the LS2088A SoC.The interface is designed to simplify interaction with DCE as much as possible without loss of flexibility and acceleration offered by DCE hardware.

Hardware Overview

This section gives an overview of the operation of the DCE hardware to provide basic fundamentals for software developers using the driver API. More detailed information is available in the hardware reference manual.

The DCE is a hardware accelerator that is part of the Datapath Acceleration Architecture version 2 (DPAA2). The DCE is one of the DPAA2 accelerators that include others like security and pattern matching engines. These accelerators are connected using a queue manager (QMan) and buffer manager (BMan) that allows data to be exchanged between software and accelerators.

Software enqueues data to a TX frame queue leading to DCE. DCE receives the data and processes it. It then enqueues a response on an RX frame queue leading back to software. The software then provides a DCE object that abstracts the details of frame queue configuration and usage, as well as other hardware details. This object is called DPDCEI.

Software Elements

The DCE driver APIs are documented in the release API Reference Manual. Instructions to run example kernel module, as well as expected output, is documented in later sections of this document.

SDK 2.0 release supports only kernel-based DCE software. User space driver and example applications are planned for future releases.

6.10.1 The DCE application

The `fsl-dce-api-time-trial` application is included in the release as an example application of the DCE. It performs basic compression and decompression and prints performance metrics.

The application sends as many work units to DCE as possible in a given number of seconds. The work units are sent asynchronously to the DCE and are configured for DCE to perform compression. Processed work units from the DCE invoke an applicaiton call back routine. The applicaiton keeps a count of outstanding work units and throttles back if the count exceeds a pre-determined threshhold. Once all work units have been sent the test waits for all processed work units from DCE to be received. The test then calculates and prints compression related performance data and checks its integrity. Performance numbers are then printed. The test runs then takes the compressed data from DCE and sends it back through the DCE - the work units configured to be decompressed this time. Decompression performance results are calculated and printed once all work units have gone through the decompression step. The test also compares the decompressed data against the original data for validity.

To keep the test logic simple, the data sent to DCE for compression is the same for all work units. This is important to know as the data used for compression or decompression is one of the factors that impacts DCE performance. Other factors like the work unit size and compression level also affect DCE performance. Users can specifiy the latter via paramters to the DCE applicaiton.

The test can be packaged as a loadable module and it takes optional parameters that specify time length for test in seconds, the size of each work unit, whether the test should run in verbose mode, and the compression level from 0 to 3. 3 being the best possible compression and 0 being no compression.

6.10.2 Running the DCE test application

Create DCE compression and decompression objects. Assign to appropriate resource container (dprc)

```
$ restool dpdcei create --engine=DPDCEI_ENGINE_COMPRESSION --priority=1
/* dpdcei.0 is created under dprc.1 */

$ restool dpdcei create --engine=DPDCEI_ENGINE_DECOMPRESSION --priority=1
/* dpdcei.1 is created under dprc.1 */

$ restool dprc assign dprc.1 --object=dpdcei.0 --plugged=1
$ restool dprc assign dprc.1 --object=dpdcei.1 --plugged=1
```

In this example the DCE API was built as a module so it must be loaded before we can load the test which depends on it

```
$ insmod fsl-dce-api.ko
fsl_dce_api: module is from the staging directory, the quality is unknown, you have
been warned.
fsl_dce_api dpdcei.0: dpdcei probe
fsl_dce_api dpdcei.0: DPDCEI: id=0, engine=COMPRESSION
fsl_dce_api dpdcei.0: dpdcei: probed object 0
fsl_dce_api dpdcei.1: dpdcei probe
fsl_dce_api dpdcei.1: DPDCEI: id=1, engine=DECOMPRESSION
fsl_dce_api dpdcei.1: dpdcei: probed object 1 MC object device driver
fsl_dce_api registered
```

Insert the test module to run the test

```
$ insmod fsl-dce-api-time-trial.ko
fsl_dce_api_time_trial: module is from the staging directory, the quality is unknown,
you have been warned.
```

Compression results are output by the test application upon completion

```
Running compression test for 30 seconds ...
Number of work units 2320000, work unit size 8192, compression ratio (out/in) 31%
DCE Driver API & DCE performance = 5039559827 bit/s and time is 30170 ms
```

Decompression results from the test are shown below

```
Running decompression test for 30 seconds ...
Number of work units 2720000, work unit size 2612, decompression ratio (out/in) 313%
DCE Driver API & DCE performance = 5908449453 bit/s and time is 30170 ms
```

Remove the test application and clean-up resources using the following commands

```
$ rmmod fsl-dce-api-time-trial.ko
dce_api_time_trial_exit
$ echo dpdcei.0 > /sys/bus/fsl-mc/drivers/fsl_dce_api/unbind
$ echo dpdcei.1 > /sys/bus/fsl-mc/drivers/fsl_dce_api/unbind
$ restool dprc assign dprc.1 --object=dpdcei.1 --plugged=0
$ restool dprc assign dprc.1 --object=dpdcei.0 --plugged=0
$ rmmod fsl-dce-api
$ restool dpdcei destroy dpdcei.0
dpdcei.0 is destroyed
$ restool dpdcei destroy dpdcei.1
dpdcei.1 is destroyed
$
```

6.11 DPAA2 Standard Linux Documentation

Following is a summary of relevant documentation from standard Linux sources and formats. It provides links to these documents, provides a snapshot of the document, or both.

6.11.1 Kernel Documentation Directory

The Linux kernel source code contains a documentation directory, and there is some information there that is relevant to DPAA2. It is possible to see the upstream versions of these documents by going to http://lkernel.org and browsing the Linux source code trees.

- Kernel Management Complex (MC) bus driver: This document is in-flight to kernel.org so a copy is provided below rather than a link to kernel.org.

DPAA2 Overview
--------------

DPAA2 is a hardware architecture designed for high-speeed network
packet processing.  DPAA2 consists of sophisticated mechanisms for
```

```
processing Ethernet packets, queue management, buffer management,
autonomous L2 switching, virtual Ethernet bridging, and accelerator
(e.g. crypto) sharing.

A DPAA2 hardware component called the Management Complex (or MC) manages the
DPAA2 hardware resources.  The MC provides an object-based abstraction for
software drivers to use the DPAA2 hardware.

The MC uses DPAA2 hardware resources such as queues, buffer pools, and
network ports to create functional objects/devices such as network
interfaces, an L2 switch, or accelerator instances.

The MC provides memory-mapped I/O command interfaces (MC portals)
which DPAA2 software drivers use to operate on DPAA2 objects:

         +--------------------------------------+
         |                  OS                  |
         |                        DPAA2 drivers |
         |                             |        |
         +-----------------------------|--------+
                                       |
                                       | (create,discover,connect
                                       |  config,use,destroy)
                                       |
                        DPAA2          |
         +-------------------------| mc portal |-+
         |                         |        |
         |   +- - - - - - - - - - -V- - -+  |
         |   |                           |  |
         |   |   Management Complex (MC) |  |
         |   |                           |  |
         |   +- - - - - - - - - - - - - -+  |
         |                                  |
         | Hardware                Hardware |
         | Resources               Objects  |
         | ---------               -------  |
         | -queues                 -DPRC    |
         | -buffer pools           -DPMCP   |
         | -Eth MACs/ports         -DPIO    |
         | -network interface      -DPNI    |
         |  profiles               -DPMAC   |
         | -queue portals          -DPBP    |
         | -MC portals              ...     |
         |  ...                             |
         |                                  |
         +----------------------------------+

The MC mediates operations such as create, discover,
connect, configuration, and destroy.  Fast-path operations
on data, such as packet transmit/receive, are not mediated by
the MC and are done directly using memory mapped regions in
DPIO objects.

Overview of DPAA2 Objects
-------------------------
The section provides a brief overview of some key objects
in the DPAA2 hardware.  A simple scenario is described illustrating
the objects involved in creating a network interfaces.
```

```
-DPRC (Datapath Resource Container)

    A DPRC is an container object that holds all the other
    types of DPAA2 objects.  In the example diagram below there
    are 8 objects of 5 types (DPMCP, DPIO, DPBP, DPNI, and DPMAC)
    in the container.

    +---------------------------------------------------------+
    | DPRC                                                    |
    |                                                         |
    |  +-------+  +-------+  +-------+  +-------+  +-------+  |
    |  | DPMCP |  | DPIO  |  | DPBP  |  | DPNI  |  | DPMAC |  |
    |  +-------+  +-------+  +-------+  +---+---+  +---+---+  |
    |  | DPMCP |  | DPIO  |                                   |
    |  +-------+  +-------+                                   |
    |  | DPMCP |                                             |
    |  +-------+                                             |
    |                                                         |
    +---------------------------------------------------------+

    From the point of view of an OS, a DPRC is bus-like.  Like
    a plug-and-play bus, such as PCI, DPRC commands can be used to
    enumerate the contents of the DPRC, discover the hardware
    objects present (including mappable regions and interrupts).

     dprc.1 (bus)
       |
       +--+--------+-------+-------+-------+
          |        |       |       |       |
        dpmcp.1  dpio.1  dpbp.1  dpni.1  dpmac.1
        dpmcp.2  dpio.2
        dpmcp.3

    Hardware objects can be created and destroyed dynamically, providing
    the ability to hot plug/unplug objects in and out of the DPRC.

    A DPRC has a mappable mmio region (an MC portal) that can be used
    to send MC commands.  It has an interrupt for status events (like
    hotplug).

    All objects in a container share the same hardware "isolation context".
    This means that with respect to an IOMMU the isolation granularity
    is at the DPRC (container) level, not at the individual object
    level.

    DPRCs can be defined statically and populated with objects
    via a config file passed to the MC when firmware starts
    it.  There is also a Linux user space tool called "restool"
    that can be used to create/destroy containers and objects
    dynamically.

-DPAA2 Objects for an Ethernet Network Interface

    A typical Ethernet NIC is monolithic-- the NIC device contains TX/RX
    queuing mechanisms, configuration mechanisms, buffer management,
    physical ports, and interrupts.  DPAA2 uses a more granular approach
    utilizing multiple hardware objects.  Each object has specialized
    functions, and are used together by software to provide Ethernet network
    interface functionality.  This approach provides efficient use of finite
    hardware resources, flexibility, and performance advantages.
```

```
The diagram below shows the objects needed for a simple
network interface configuration on a system with 2 CPUs.

          +---+---+ +---+---+
             CPU0     CPU1
          +---+---+ +---+---+
              |         |
          +---+---+ +---+---+
             DPIO     DPIO
          +---+---+ +---+---+
                \     /
                 \   /
                  \ /
               +---+---+
                  DPNI  --- DPBP,DPMCP
               +---+---+
                   |
                   |
               +---+---+
                 DPMAC
               +---+---+
                   |
                port/PHY

Below the objects are described.  For each object a brief description
is provided along with a summary of the kinds of operations the object
supports and a summary of key resources of the object (mmio regions
and irqs).

   -DPMAC (Datapath Ethernet MAC): represents an Ethernet MAC, a
    hardware device that connects to an Ethernet PHY and allows
    physical transmission and reception of Ethernet frames.
       -mmio regions: none
       -irqs: dpni link change
       -commands: set link up/down, link config, get stats,
         irq config, enable, reset

   -DPNI (Datapath Network Interface): contains TX/RX queues,
    network interface configuration, and rx buffer pool configuration
    mechanisms.
       -mmio regions: none
       -irqs: link state
       -commands: port config, offload config, queue config,
        parse/classify config, irq config, enable, reset

   -DPIO (Datapath I/O): provides interfaces to enqueue and dequeue
    packets and do hardware buffer pool management operations.  For
    optimum performance there is typically one DPIO per CPU.  This allows
    each CPU to perform simultaneous enqueue/dequeue operations.
       -mmio regions: queue operations, buffer mgmt
       -irqs: data availability, congestion notification, buffer
              pool depletion
       -commands: irq config, enable, reset

   -DPBP (Datapath Buffer Pool): represents a hardware buffer
    pool.
       -mmio regions: none
```

```
            -irqs: none
            -commands: enable, reset

        -DPMCP (Datapath MC Portal): provides an MC command portal.
         Used by drivers to send commands to the MC to manage
         objects.
            -mmio regions: MC command portal
            -irqs: command completion
            -commands: irq config, enable, reset

    Object Connections
    ------------------
    Some objects have explicit relationships that must
    be configured:

       -DPNI <--> DPMAC
       -DPNI <--> DPNI
       -DPNI <--> L2-switch-port
          A DPNI must be connected to something such as a DPMAC,
          another DPNI, or L2 switch port.  The DPNI connection
          is made via a DPRC command.

              +-------+  +-------+
              | DPNI  |  | DPMAC |
              +---+---+  +---+---+
                  |          |
                  +==========+

       -DPNI <--> DPBP
          A network interface requires a 'buffer pool' (DPBP
          object) which provides a list of pointers to memory
          where received Ethernet data is to be copied.  The
          Ethernet driver configures the DPBPs associated with
          the network interface.

    Interrupts
    ----------
    All interrupts generated by DPAA2 objects are message
    interrupts.  At the hardware level message interrupts
    generated by devices will normally have 3 components--
    1) a non-spoofable 'device-id' expressed on the hardware
    bus, 2) an address, 3) a data value.

    In the case of DPAA2 devices/objects, all objects in the
    same container/DPRC share the same 'device-id'.
    For ARM-based SoC this is the same as the stream ID.

DPAA2 Linux Driver Overview
---------------------------

This section provides an overview of the Linux kernel drivers for
DPAA2-- 1) the bus driver and associated "DPAA2 infrastructure"
drivers and 2) functional object drivers (such as Ethernet).

As described previously, a DPRC is a container that holds the other
types of DPAA2 objects.  It is functionally similar to a plug-and-play
bus controller.

Each object in the DPRC is a Linux "device" and is bound to a driver.
```

```
The diagram below shows the Linux drivers involved in a networking
scenario and the objects bound to each driver.  A brief description
of each driver follows.

                                          +------------+
                                          | OS Network |
                                          |   Stack    |
                +------------+            +------------+
                | Allocator  |. . . . . . |  Ethernet  |
                |(dpmcp,dpbp)|            |   (dpni)   |
                +-.----------+            +---+---+----+
                  .          .                ^   |
                  .           .     <data avail, |   |<enqueue,
                 .             .     tx confirm> |   | dequeue>
    +-------------+             .               |   |
    | DPRC driver |              .          +---+---V----+     +----------+
    |   (dprc)    |               . . . . . .| DPIO driver|     |   MAC    |
    +----------+--+                          |  (dpio)    |     | (dpmac)  |
               |                             +------+-----+     +-----+---+
               |<dev add/remove>                    |                 |
               |                                    |                 |
          +----+--------------+                     |              +--+---+
          |   mc-bus driver   |                     |              | PHY  |
          |                   |                     |              |driver|
          | /fsl-mc@80c000000 |                     |              +--+---+
          +-------------------+                     |                 |
                                                    |                 |
 ================================ HARDWARE =========|=================|======
                                                   DPIO               |
                                                     |                |
                                                   DPNI---DPBP        |
                                                     |                |
                                                   DPMAC              |
                                                     |                |
                                                    PHY ---------------+
 ===================================================|=======================

A brief description of each driver is provided below.

    mc-bus driver
    -------------
    The mc-bus driver is a platform driver and is probed from an
    "/fsl-mc@xxxx" node in the device tree passed in by boot firmware.
    It is responsible for bootstrapping the DPAA2 kernel infrastructure.
    Key functions include:
       -registering a new bus type named "fsl-mc" with the kernel,
        and implementing bus call-backs (e.g. match/uevent/dev_groups)
       -implemeting APIs for DPAA2 driver registration and for device
        add/remove
       -creates an MSI irq domain
       -do a device add of the 'root' DPRC device, which is needed
        to bootstrap things

    DPRC driver
    -----------
    The dprc-driver is bound to DPRC objects and does runtime management
    of a bus instance.  It performs the initial bus scan of the DPRC
    and handles interrupts for container events such as hot plug.
```

```
Allocator
----------
Certain objects such as DPMCP and DPBP are generic and fungible,
and are intended to be used by other drivers.  For example,
the DPAA2 Ethernet driver needs:
   -DPMCPs to send MC commands, to configure network interfaces
   -DPBPs for network buffer pools

The allocator driver registers for these allocatable object types
and those objects are bound to the allocator when the bus is probed.
The allocator maintains a pool of objects that are available for
allocation by other DPAA2 drivers.

DPIO driver
-----------
The DPIO driver is bound to DPIO objects and provides services that allow
other drivers such as the Ethernet driver to receive and transmit data.
Key services include:
    -data availability notifications
    -hardware queuing operations (enqueue and dequeue of data)
    -hardware buffer pool management

There is typically one DPIO object per physical CPU for optimum
performance, allowing each CPU to simultaneously enqueue
and dequeue data.

The DPIO driver operates on behalf of all DPAA2 drivers
active in the kernel--  Ethernet, crypto, compression,
etc.

Ethernet
--------
The Ethernet driver is bound to a DPNI and implements the kernel
interfaces needed to connect the DPAA2 network interface to
the network stack.

Each DPNI corresponds to a Linux network interface.

MAC driver
----------
An Ethernet PHY is an off-chip, board specific component and is managed
by the appropriate PHY driver via an mdio bus.  The MAC driver
plays a role of being a proxy between the PHY driver and the
MC.  It does this proxy via the MC commands to a DPMAC object.
```

6.11.2 DPAA2 Resource Management Tool (restool) User Manual

Restool is a Linux user space program that allows DPAA2 objects to be created, destroyed, and manipulated. Its primary documentation is in the style of a Linux man page.

The Management Complex architecture uses a hardware object called a “container” (or DPRC) to hold I/O resources and hardware objects for use by GPP software contexts.

DPRCs can be created and populated in two different ways:

- at MC initialization during system boot in a configuration file called a “DPL file”
- dynamically at runtime

This document describes how restool can be used to do dynamic management of MC resources in the context of Linux. Key resource management operations include:

- listing containers and their contents
- creating/destroying containers
- creating/destroying new MC objects
- move object between parent container and child container
- establishing connections between MC objects

6.11.2.1 DPRC commands

6.11.2.1.1 list command

The **list** command lists all containers in the system.

SYNTAX:

restool dprc list

ARGUMENTS:

none

EXAMPLE:

List all the containers in the system

```
$ restool dprc list
  dprc.1
      dprc.2
      dprc.3
```

The container hierarchy (parent-child relationships) is shown by indentation.

6.11.2.1.2 show command

The **show** command displays the contents (objects and resources) of a DPRC/container.

SYNTAX:

restool dprc show <*container*>

restool dprc show <*container*> **--resources**

restool dprc show <*container*> **--resource-type**=<resource-type>

ARGUMENTS:

<*container*>

A string specifying the target dprc—e.g. “dprc.2”.

The container argument value “mc.global” is special and refers to the global

container of resource pools inside the Management Complex.

--resources

Display a container’s resource count for each resource (instead of displaying

objects/resources)

--resource-type <resource-type>

Specifies the type of resource to list. The resource-type argument is a string specifying

the resource name—e.g. “mcp”.

EXAMPLE :

Show all objects in dprc 2:

```
$ restool dprc show dprc.2
dprc.2 contains 6 objects:
object label plugged state
dpni.7 xyz  plugged
dpni.8 abc  plugged
dpio.2 plugged
dpio.3 unplugged
dpcon.9 plugged
dpbp.1 plugged
```

Show all resources in dprc 2:

```
$ restool dprc show dprc.2 --resources
bpid: 16
fqid: 100
channel: 4
qpr: 2
cgid: 2
```

Show dprc with no objects in it:

```
$ restool dprc show dprc.4
(empty)
```

Show all buffer pool IDs in dprc 2:

```
$ restool dprc show dprc.2 --resource-type=bp
bp.35 - bp.36
bp.50
bp.52 - bp.63
```

Show all MC portal IDs in the global MC container:

```
$ restool dprc show mc.global --resource-type=mcp
mcp.30 - mcp.250
```

6.11.2.1.3 info command

The **info** command displays detailed information about a specific container.

SYNTAX:

restool dprc info <*dprc-object*> [**--verbose**]

ARGUMENTS :

<*dprc-object*>

Specifies which container to show detailed info for. The object argument is a string

specifying the container name—e.g. “dprc.2”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dprc info dprc.2
container id: 2
icid: 2
portal id: 5
version: 0.0
dprc options: 0x3
    DPRC_CFG_OPT_SPAWN_ALLOWED
    DPRC_CFG_OPT_ALLOC_ALLOWED
object label: nadk’s dprc

$ restool dprc info dprc.2 --verbose
container id: 2
icid: 2
portal id: 5
version: 0.0
dprc options: 0x3
    DPRC_CFG_OPT_SPAWN_ALLOWED
    DPRC_CFG_OPT_ALLOC_ALLOWED
object label: nadk-usage-dprc
number of mappable regions: 1
number of interrupts: 1
interrupt 0's mask: 0
interrupt 0's status: 0x1
```

6.11.2.1.4 create command

The **create** command creates a new child DPRC under the specified parent. The name/id of the

object created is displayed to stdout.

SYNTAX:

restool dprc create <parent-container> [**--options**=<*options-mask*>] [**--label**=<*object’s-label*>]

OPTIONS :

<parent-container>

--options=<*options-mask*>

Where <options-mask> is a comma separated list of DPRC options:

```
            DPRC_CFG_OPT_SPAWN_ALLOWED
            DPRC_CFG_OPT_ALLOC_ALLOWED
            DPRC_CFG_OPT_OBJ_CREATE_ALLOWED
            DPRC_CFG_OPT_TOPOLOGY_CHANGES_ALLOWED
            DPRC_CFG_OPT_IOMMU_BYPASS
            DPRC_CFG_OPT_AIOP
            DPRC_CFG_OPT_IRQ_CFG_ALLOWED
```

--label=<*object’s-label*>

Specify a label for the newly created object. It is kind of an alias for that object.

Length of the string is 15 characters maximum.

Say --label=”nadk’s dprc”

EXAMPLE:

Create a child DPRC under parent dprc.1 with default options:

```
$ restool dprc create dprc.1
dprc.9 is created under dprc.1
```

Create a child DPRC under parent dprc.1 with default options, with label “nadk’s dprc”:

```
$ restool dprc create dprc.1 --label=”nadk’s dprc”
dprc.11 is created under dprc.1
```

6.11.2.1.5 destroy command

The **destroy** command destroys the specified DPRC.

SYNTAX:

restool dprc destroy <container> **--help**

OPTIONS:

<container>

--help

Displays help for the command.

EXAMPLE:

Destroy a specified DPRC, say dprc.2:

```
$ restool dprc destroy dprc.2
dprc.2 is destroyed
```

6.11.2.1.6 assign command

The **assign** command moves an object or resource from a parent container to a child container. Object (dpni, dpbp, etc) assignment is always explicit and the exact object id to be assigned must be specified. Resources (e.g. mcp, bp, fq, etc) are assigned by type and count.

SYNTAX:

restool dprc assign <parent-*container*> [**--child**=<child-*container*>] **--object**=<*object*> **--plugged**=<*state*>

This syntax changes the plugged state. The child-container must be the same as parent-container, or omit --target option. It is not possible to change the plugged state of a dprc.

restool dprc assign <parent-*container*> [**--child**=<child-*container*>] **--object**=<*object*>

This syntax moves one object from parent-container to another, so the target-container must be different from the parent-container. Limitation: cannot move dprc from one container to another.

restool dprc assign <parent-*container*> [**--child**=<child-*container*>] --resource-type=<*type*> **-- count**=<*number*>

This syntax moves a resource from parent-container to a child-container. If the childcontainer is the same as the parent-container, the resource will be taken from the parent of parent-container and will be assigned to the parent-container.

ARGUMENTS :

<*container*>

Specifies the parent container from which the object will be moved.

--object=<*object*>

Specifies the object to assign— value is a string specifying object name and ID (e.g. dpni.5)

--child=<*child-container*>

Specifies the destination container for the operation. Valid values are any child container. (The target container may be the same as the parent container, allowing “assign to self”)

--plugged=<*state*>

Specifies the plugged state of the object (valid values are 0 or 1)

--resource-type=<*type*>

String specifying the resource type to assign (e.g “mcp”, “fq”, “cg”, etc). To see valid resources that may be assigned use the “dprc show <container> --resources” command.

--count=<*number*>

Number of resources to assign.

EXAMPLE:

Set the plugged state of dpni.5. Note source and destination containers are the same.

```
$ restool dprc assign dprc.1 --object=dpni.5 --child=dprc.1
--plugged=1
$ restool dprc assign dprc.1 --object=dpni.5 --plugged=1
```

Unset the plugged state of dpni.5. Note source and destination containers are the same.

```
$ restool dprc assign dprc.1 --object=dpni.5 --child=dprc.1
--plugged=0
$ restool dprc assign dprc.1 --object=dpni.5 --plugged=0
```

Move dpni.5 from dprc.1 (parent) to dprc.3 (child):

```
$ restool dprc assign dprc.1 --object=dpni.5 --child=dprc.3
```

Move 3 mcp resources from dprc.1 (parent) to dprc.2 (child):

```
$ restool dprc assign dprc.1 --resource-type=mcp --count=3
--child=dprc.2
```

6.11.2.1.7 unassign command

The **unassign** command moves an object or resource from a child container to a parent container

SYNTAX:

restool dprc unassign <*container*> **--object**=<*object*> [**--child**=<child-*container*>]

restool dprc unassign <*container*> **--resource-type**=<*type*> **--count** <*number*> [**--child**=<child-*container*>]

ARGUMENTS :

<container>

Specifies the container to which the object will be moved.

--object=*<object>*

Specifies the object to unassign— value is a string specifying object name and ID (e.g.

dpni.5)

--child=<child-*container*>

Specifies the container from which the object/resource will be moved from.

--plugged=*<plugged-state>*

Specifies the plugged state of the object (valid values are 0 or 1)

--resource-type=*<type>*

String specifying the resource type to assign (e.g “mcp”, “fq”, “cg”, etc)

--count=*<number>*

Number of resources to unassign.

EXAMPLE:

Unassign 3 mcp resources from dprc.2 (child) to dprc.1 (parent):

```
$ restool dprc unassign dprc.1 --resource-type=mcp --count=3
--child=dprc.2
```

Unassign dpni.5 from dprc.3 (child) to dprc.1 (parent):

```
$ restool dprc unassign dprc.1 --object=dpni.5 --child=dprc.3
```

6.11.2.1.8 set-quota command

The **set-quota** command sets quota policies for a child container, specifying the number of resources a child may take from its parent container. But remember a parent can assign any number of resource to its child if it wants to, and if it has enough resources to assign. So the quota is effective only when the child dprc does have enough resource and it wants to borrow resource from its parent. It could only “borrow” the quota number of resources from its parent.

SYNTAX:

restool dprc set-quota *<parent-container>* **--resource-type**=*<type>* **--count**=*<number>*

--child-container=*<container>*

ARGUMENTS :

<parent-container>

Specifies the parent container.

--resource-type=*<type>*

String specifying the resource type to set the quota for (e.g “mcp”, “fq”, “cg”, etc)

--count=*<number>*

Max number of resources the child is able to allocate.

--child-container=<*container*>

EXAMPLE:

Set a quota of 10 mcp resource that child container dprc.5 may take from parent dprc.1:

```
$ restool dprc set-quota dprc.1 --resource-type=mcp --count=10
   --child-container=dprc.5
```

6.11.2.1.9 set-label command

The **set-label** command sets label for any objects excluding dprc.1

SYNTAX:

restool dprc set-label <*object*> **--label**=<*label*>

ARGUMENTS :

<*object*>

Specifies the object to be set.

--label=<*label*>

String specifying the label, maximum length is 15 characters.

EXAMPLE:

Set label of dprc.4 to “mountain view”:

```
$ restool dprc set-label dprc.4 --label=”mountain view”
```

6.11.2.1.10 connect command

The **connect** command connects 2 objects, creating a link between them.

SYNTAX:

restool dprc connect <*container*> **--endpoint1**=<*object*> **--endpoint2**=<*object*>

ARGUMENTS :

<*container*>

A string specifying the target dprc—e.g. “dprc.2”.

--endpoint1=<*object*>

Specifies the first endpoint object.

--endpoint2=<*object*>

Specifies the second endpoint object.

EXAMPLE:

The connect command connects a network object such as a DPNI to a peer object such as a DPMAC or DPSW port.

Connect dpni.2 to dpmac.5:

```
$ restool dprc connect dprc.2 --endpoint1=dpni.2 --endpoint2=dpmac.5
```

Connect dpni.2 to dpsw.1 interface 7:

```
$ restool dprc connect dprc.2 --endpoint1=dpni.2 --endpoint2=dpsw.1.7
```

6.11.2.1.11 disconnect command

The **disconnect** command removes the link between two objects. Either endpoint can be specified as the target of the operation.

SYNTAX:

restool dprc disconnect <*container*> **--endpoint**=<*object*>

ARGUMENTS:

<*container*>

A string specifying the target dprc—e.g. “dprc.2”

--endpoint=<*object*>

Specifies the first endpoint object.

EXAMPLE:

Remove the link between dpni.2 and dpmac.5

```
$ restool dprc disconnect dprc.2 –endpoint=dpni.2
```

6.11.2.1.12 generate-dpl command

The **generate-dpl** command prints to the standard output a DPL syntax file describing the specified container

SYNTAX:

restool dprc generate-dpl <*container*>

ARGUMENTS:

<*container*>

A string specifying the target dprc—e.g. “dprc.2”

EXAMPLE:

```
Generate a DPL for dprc.1
```

```
$ restool dprc generate-dpl dprc.1
```

6.11.2.2 DPNI Commands

6.11.2.2.1 help command

The **help** command displays usage information for the DPNI object

SYNTAX:

restool dpni help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpni help
usage: restool dpni <command> [--help][ARGS…]
Where <command> can be:
    info - displays detailed information about a DPNI object.
    create - creates a child DPNI under the root DPRC
    destroy - destroys a child DPNI under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.2.2 info command

The **info** command displays detailed information about a specific dpni object.

SYNTAX:

restool dpni info <*dpni-object*> [**--verbose**]

ARGUMENTS :

<*dpni-object*>

Specifies which dpni object to show detailed info for. The dpni-object argument is a

string specifying the object name—e.g. “dpni.7”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpni info dpni.7
dpni version: 5.0
dpni id: 7
plugged state: plugged
endpoint: dpmac.2, link is down
link status: 0 - down
mac address: 00:00:00:00:00:07
dpni_attr.options value is: 0x190
    DPNI_OPT_DIST_HASH
    DPNI_OPT_UNICAST_FILTER
    DPNI_OPT_MULTICAST_FILTER
max senders: 8
max traffic classes: 1
max distribution's size per RX traffic class:
    class 0's size: 15
max unicast filters: 16
max multicast filters: 64
max vlan filters: 0
max QoS entries: 0
max QoS key size: 0
max distribution key size: 4

$ restool dpni info dpni.7 --verbose
dpni version: 5.0
dpni id: 7
plugged state: plugged
endpoint: dpmac.2, link is down
link status: 0 - down
```

```
    mac address: 00:00:00:00:00:07
    dpni_attr.options value is: 0x190
        DPNI_OPT_DIST_HASH
        DPNI_OPT_UNICAST_FILTER
        DPNI_OPT_MULTICAST_FILTER
    max senders: 8
    max traffic classes: 1
    max distribution's size per RX traffic class:
        class 0's size: 15
    max unicast filters: 16
    max multicast filters: 64
    max vlan filters: 0
    max QoS entries: 0
    max QoS key size: 0
    max distribution key size: 4
    number of mappable regions: 0
    number of interrupts: 1
    interrupt 0's mask: 0
    interrupt 0's status: 0
```

6.11.2.2.3 create command

The **create** command creates a new DPNI. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpni create --mac-addr=<*addr*> [OPTIONS]

ARGUMENTS :

--mac-addr=<*addr*>

String specifying primary MAC address (e.g., 00:00:05:00:00:05)

OPTIONS :

--max-senders=<*number*>

maximum number of different senders; will be used as the number of dedicated TX flows;

In case it isn't power-of-2 it will be ceiling to the next power-of-2 as HW demand it; 0 will

be treated as 1

--options=<*options-mask*>

Where <*options-mask*> is a comma separated list of DPNI options:

```
            DPNI_OPT_ALLOW_DIST_KEY_PER_TC
            DPNI_OPT_TX_CONF_DISABLED
            DPNI_OPT_PRIVATE_TX_CONF_ERR_DISABLED
            DPNI_OPT_DIST_HASH
            DPNI_OPT_DIST_FS
            DPNI_OPT_UNICAST_FILTER
            DPNI_OPT_MULTICAST_FILTER
            DPNI_OPT_VLAN_FILTER
            DPNI_OPT_IPR
            DPNI_OPT_IPF
            DPNI_OPT_VLAN_MANIPULATION
            DPNI_OPT_QOS_MASK_SUPPORT
            DPNI_OPT_FS_MASK_SUPPORT
```

--max-tcs=<*number*>

Specifies the maximum number of traffic-classes

--max-dist-per-tc=<*dist-size*>,<*dist-size*>,…

Comma separated list of counts specifying the maximum distribution's size per RX traffic-

class

--max-unicast-filters=<*number*>

maximum number of unicast filters; 0 will be treated as 16

--max-multicast-filters=<*number*>

maximum number of multicast filters; 0 will be treated as 64

--max-vlan-filters=<*number*>

maximum number of vlan filters; '0' will be treated as '16'

--max-qos-entries=<*number*>

if max_tcs > 1, declares the maximum entries for the QoS table; '0' will be treated as '64'

--max-qos-key-size=<*number*>

maximum key size for the QoS look-up; '0' will be treated as '24' which enough for IPv4 5-tuple

--max-dist-key-size=<*number*>

maximum key size for the distribution; '0' will be treated as '24' which enough for IPv4 5-tuple

EXAMPLE:

Create a DPNI, specifying MAC address, with all default options:

```
$ restool dpni create --mac-addr=00:00:05:00:00:05
dpni.9 is crated under dprc.1
```

Create a DPNI, specifying MAC address, and some options:

```
$ restool dpni create --mac-addr=00:00:05:00:00:05
--options=DPNI_OPT_MULTICAST_FILTER,DPNI_OPT_UNICAST_FILTER
dpni.11 is created under dprc.1
```

6.11.2.2.4 destroy command

The **destroy** command destroys a DPNI.

SYNTAX:

restool dpni destroy <*dpni-object*>

ARGUMENTS :

<*dpni-object*>

Specifies which DPNI to destroy.

EXAMPLE:

```
$ restool dpni destroy dpni.9
dpni.9 is destroyed
```

6.11.2.3 DPIO Commands

6.11.2.3.1 help command

The **help** command displays usage information for the DPIO object

SYNTAX:

restool dpio help

ARGUMENTS:

none

EXAMPLE:

```
    $ restool dpio help
    usage: restool dpio <command> [--help][ARGS…]
    Where <command> can be:
    info - displays detailed information about a DPIO object.
    create - creates a DPIO under the root DPRC
    destroy - destroys a DPIO under the root DPRC

    For command-specific help, use the --help option available for each command.
```

6.11.2.3.2 info command

The **info** command displays detailed information about a specific dpio object.

SYNTAX:

restool dpio info <*dpio-object*> [**--verbose**]

ARGUMENTS :

<*dpio-object*>

Specifies which dpio object to show detailed info for. The dpio-object argument is a

string specifying the object name—e.g. “dpio.7”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
# restool dpio info dpio.1
    dpio version: 3.0
    dpio id: 1
    plugged state: plugged
    offset of qbman software portal cache-enabled area: 0x20000
    offset of qbman software portal cache-inhibited area: 0x4020000
    qbman software portal id: 0x2
    dpio channel mode is: DPIO_LOCAL_CHANNEL
    number of priorities is: 0x8
    # restool dpio info dpio.1 --verbose
    dpio version: 3.0
    dpio id: 1
    plugged state: plugged
    offset of qbman software portal cache-enabled area: 0x20000
    offset of qbman software portal cache-inhibited area: 0x4020000
    qbman software portal id: 0x2
    dpio channel mode is: DPIO_LOCAL_CHANNEL
```

```
    number of priorities is: 0x8
    number of mappable regions: 2
    number of interrupts: 1
    interrupt 0's mask: 0
    interrupt 0's status: 0x8
```

6.11.2.3.3 create command

The **create** command creates a new DPIO. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpio create [OPTIONS]

OPTIONS :

--channel-mode=<*mode*>

Where <*mode*> is one of:

```
            DPIO_LOCAL_CHANNEL
            DPIO_NO_CHANNEL
```

Default value is DPIO_LOCAL_CHANNEL .

--num-priorities=<*number*>

Valid values for <*number*> are 1-8. Default value is 8.

EXAMPLE:

Create a DPIO with all default options:

$ restool dpio create

dpio.10 is created under dprc.1

Create a DPIO, specifying number of priorities:

```
    $ restool dpni create –num-priorities=4
    dpio.2 is created under dprc.1
```

6.11.2.3.4 destroy command

The **destroy** command destroys a DPIO.

SYNTAX:

restool dpio destroy <*dpio-object*>

ARGUMENTS :

<*dpio-object*>

Specifies which DPIO to destroy.

EXAMPLE:

```
    $ restool dpio destroy dpio.9
    dpio.9 is destroyed
```

6.11.2.4 DPSW Commands

text

6.11.2.4.1 help command

The **help** command displays usage information for the DPSW object

SYNTAX:

restool dpsw help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpsw help
    usage: restool dpsw <command> [--help][ARGS…]
    Where <command> can be:
    info - displays detailed information about a DPSW object.
    create - creates a DPSW under the root DPRC
    destroy - destroys a DPSW under the root DPRC

    For command-specific help, use the --help option available for each command.
```

6.11.2.4.2 info command

The **info** command displays detailed information about a specific dpsw object.

SYNTAX:

restool dpsw info <*dpsw-object*> [**--verbose**]

ARGUMENTS :

<*dpsw-object*>

Specifies which object to show detailed info for. The dpsw-object argument is a string

specifying the object name—e.g. “dpsw.2”

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
    $ restool dpsw info dpsw.1
dpsw version: 6.0
dpsw id: 1
plugged state: unplugged
endpoints:
endpoint state: -1
        interface 0: No object associated
endpoint state: -1
        interface 1: No object associated
endpoint state: -1
        interface 2: No object associated
endpoint state: -1
        interface 3: No object associated
dpsw_attr.options value is: 0x1
        DPSW_OPT_FLOODING_DIS
max VLANs: 8
max FDBs: 8
DPSW frame storage memory size: 0
```

```
number of interfaces: 4
current number of VLANs: 1
current number of FDBs: 1
```

6.11.2.4.3 create command

The **create** command creates a new DPSW. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpsw create --num-ifs=<*number*> [OPTIONS]

ARGUMENTS :

--num-ifs=<*number*>

Number of external and internal interfaces.

OPTIONS :

--options=<*options-mask*>

Where <*options-mask*> is a comma separated list of DPSW options:

```
            DPSW_OPT_FLOODING_DIS
```

```
            DPSW_OPT_MULTICAST_DIS
```

```
            DPSW_OPT_CTRL_IF_DIS
```

```
            DPSW_OPT_FLOODING_METERING_DIS
```

```
            DPSW_OPT_METERING_EN
```

--max-vlans=<*number*>

Maximum Number of VLAN's. Default is 16.

--max-fdbs=<*number*>

Maximum Number of FDB's. Default is 16.

--num-fdb-entries=<*number*>

Number of FDB entries. Default is 1024.

--fdb-aging-time=<*number*>

Default FDB aging time in seconds. Default is 300 seconds.

--max-fdb-mc-groups=<*number*>

Number of multicast groups in each FDB table. Default is 32.

EXAMPLE:

Create a 4-port switch with all default options:

```
    $ restool dpsw create --num-ifs=4
    dpsw.8 is created under dprc.1
```

Create a 4-port switch with options:

```
$ restool dpsw create –num-ifs=4 –max-vlans=8 –max-fdb-mc-groups=300
--options=DPSW_OPT_TC_DIS,DPSW_OPT_FLOODING_DIS
dpsw.2 is created under dprc.1
```

6.11.2.4.4 destroy command

The **destroy** command destroys a DPSW.

SYNTAX:

restool dpsw destroy <*dpsw-object*>

ARGUMENTS :

<*dpsw-object*>

Specifies which DPSW to destroy.

EXAMPLE:

```
$ restool dpsw destroy dpsw.8
dpsw.8 is destroyed
```

6.11.2.5 DPBP Commands

6.11.2.5.1 help command

The **help** command displays usage information for the DPBP object

SYNTAX:

restool dpbp help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpbp help
usage: restool dpbp <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPBP object.
create - creates a DPBP under the root DPRC
destroy - destroys a DPBP under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.5.2 info command

The **info** command displays detailed information about a specific dpbp object.

SYNTAX:

restool dpbp info <*dpbp-object*> [**--verbose**]

ARGUMENTS :

<*dpbp-object*>

Specifies which dpbp object to show detailed info for. The dpbp-object argument is a

string specifying the object name—e.g. “dpbp.3”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpbp info dpbp.1
dpbp version: 2.0
dpbp id: 1
plugged state: plugged
buffer pool id: 0
```

6.11.2.5.3 create command

The **create** command creates a new DPBP. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpbp create [OPTIONS]

OPTIONS:

--container=<*container_name*>

Specifies the parent container name. e.g. dprc.2, dprc.3 etc.

If it is not specified, the new object will be created under the default dprc.

EXAMPLE:

Create a DPBP:

```
$ restool dpbp create
dpbp.2 is created under dprc.1
```

6.11.2.5.4 destroy command

The **destroy** command destroys a DPBP.

SYNTAX:

restool dpbp destroy <*dpbp-object*>

ARGUMENTS :

<*dpbp-object*>

Specifies which DPBP to destroy.

EXAMPLE:

```
$ restool dpbp destroy dpbp.2
dpbp.2 is destroyed
```

6.11.2.6 DPCON Commands

text

6.11.2.6.1 help command

The **help** command displays usage information for the DPCON object.

SYNTAX:

restool dpcon help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpcon help
usage: restool dpcon <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPCON object.
create - creates a DPCON under the root DPRC
destroy - destroys a DPCON under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.6.2 info command

The **info** command displays detailed information about a specific dpcon object.

SYNTAX:

restool dpcon info <*dpcon-object*> [**--verbose**]

ARGUMENTS :

<*dpcon-object*>

Specifies which dpcon object to show detailed info for. The dpcon-object argument is

a string specifying the object name—e.g. “dpcon.8”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpcon info dpcon.1
dpcon version: 2.0
dpcon id: 1
plugged state: plugged
qbman channel id to be used by dequeue operation: 40
number of priorities for the DPCON channel: 8
```

6.11.2.6.3 create command

The **create** command creates a new DPCON. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpcon create [OPTIONS]

OPTIONS :

--num-priorities=<*number*>

Specifies the number of priorities, valid values are 1-8. Default is 1.

EXAMPLE:

Create a DPCON with 4 priorities:

```
$ restool dpcon create --num-priorites=4
dpcon.8 is created under dprc.1
```

6.11.2.6.4 destroy command

The **destroy** command destroys a DPCON.

SYNTAX:

restool dpcon destroy <*dpcon-object*>

ARGUMENTS :

<*dpcon-object*>

Specifies which DPCON to destroy.

EXAMPLE:

```
$ restool dpcon destroy dpcon.9
```

dpcon.9 is destroyed

6.11.2.7 DPCI Commands

6.11.2.7.1 help command

The **help** command displays usage information for the DPCI object.

SYNTAX:

restool dpci help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpci help
usage: restool dpci <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPCI object.
create - creates a DPCI under the root DPRC
destroy - destroys a DPCI under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.7.2 info command

The **info** command displays detailed information about a specific dpci object.

SYNTAX:

restool dpci info <*dpci-object*> [**--verbose**]

ARGUMENTS :

<*dpci-object*>

Specifies which dpci object to show detailed info for. The dpci-object argument is a

string specifying the object name—e.g. “dpci.8”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpci info dpci.1
dpci version: 2.0
dpci id: 1
plugged state: plugged
num_of_priorities: 2
connected peer: dpci.4
peer's num_of_priorities: 2
link status: 0 - down
```

6.11.2.7.3 create command

The **create** command creates a new DPCI. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpci create [OPTIONS]

OPTIONS :

--num-priorities=<*number*>

Specifies the number of priorities, valid values are 1 or 2. Default is 1.

EXAMPLE:

Create a DPCI with 4 priorities:

```
$ restool dpci create --num-priorites=2
dpci.8 is created under dprc.1
```

6.11.2.7.4 destroy command

The **destroy** command destroys a DPCI.

SYNTAX:

restool dpci destroy <*dpci-object*>

ARGUMENTS :

<*dpci-object*>

Specifies which DPCI to destroy.

EXAMPLE:

```
$ restool dpci destroy dpci.9
```

dpci.9 is destroyed

6.11.2.8 DPSECI Commands

6.11.2.8.1 help command

The **help** command displays usage information for the DPSECI object.

SYNTAX:

restool dpseci help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpseci help
usage: restool dpseci <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPSECI object.
create - creates a DPSECI under the root DPRC
destroy - destroys a DPSECI under the root DPRC
For command-specific help, use the --help option available for each command.
```

6.11.2.8.2 info command

The **info** command displays detailed information about a specific dpseci object.

SYNTAX:

restool dpseci info <*dpseci-object*> [**--verbose**]

ARGUMENTS :

<*dpseci-object*>

Specifies which dpseci object to show detailed info for. The dpseci-object argument is

a string specifying the object name—e.g. “dpseci.8”

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpseci info dpseci.1
dpseci version: 2.0
dpseci id: 1
plugged state: plugged
number of priorities: 1
dpci id: 1
```

6.11.2.8.3 create command

The **create** command creates a new DPSECI. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpseci create [OPTIONS]

OPTIONS :

--priorities=<*priority1,priority2*>

DPSEC support 2 priorities that can be individually set. Valid values for <*priority1*> and <*priority2*> are 1-8. Default is 1.

EXAMPLE:

Create a DPSECI with 4 priorities:

```
$ restool dpseci create --priorites=2,4
dpseci.9 is created under dprc.1
```

6.11.2.8.4 destroy command

The **destroy** command destroys a DPSECI.

SYNTAX:

restool dpseci destroy <*dpseci-object*>

ARGUMENTS :

<*dpseci-object*>

Specifies which DPSECI to destroy.

EXAMPLE:

```
$ restool dpseci destroy dpseci.9
```

dpseci.9 is destroyed

6.11.2.9 DPDMUX Commands

6.11.2.9.1 help command

The **help** command displays usage information for the DPDMUX object.

SYNTAX:

restool dpdmux help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpdmux help
usage: restool dpdmux <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPDMUX object.
create - creates a DPDMUX under the root DPRC
destroy - destroys a DPDMUX under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.9.2 info command

The **info** command displays detailed information about a specific dpdmux object.

SYNTAX:

restool dpdmux info <*dpdmux-object*> [**--verbose**]

ARGUMENTS :

<*dpdmux-object*>

Specifies which dpdmux object to show detailed info for. The dpdmux-object

argument is a string specifying the object name—e.g. “dpdmux.2”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpdmux info dpdmux.0
dpdmux version: 4.1
dpdmux id: 0
plugged state: plugged
endpoints:
endpoint state: 0
        interface 0: dpmac.1, link is down
endpoint state: 0
        interface 1: dpni.0, link is down
endpoint state: 0
        interface 2: dpni.1, link is down
dpdmux_attr.options value is: 0x2
        DPDMUX_OPT_BRIDGE_EN
DPDMUX address table method: DPDMUX_METHOD_MAC
DPDMUX manipulation type: DPDMUX_MANIP_NONE
number of interfaces (excluding the uplink interface): 3
DPDMUX frame storage memory size: 0
control interface ID: 0
```

6.11.2.9.3 create command

The create command creates a new DPDMUX. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpdmux create --num-ifs=<*number*> [OPTIONS]

ARGUMENTS :

--num-ifs=<*number*>

Number of virtual interfaces (excluding the uplink interface).

OPTIONS :

--method=<*dmat_method*>

Where <*dmat_method*> defines the method of the DPDMUX address table. A valid value is one of the following:

```
            DPDMUX_METHOD_NONE
            DPDMUX_METHOD_C_VLAN_MAC
            DPDMUX_METHOD_MAC
            DPDMUX_METHOD_C_VLAN
            DPDMUX_METHOD_S_VLAN
```

Default is `DPDMUX_METHOD_C_VLAN_MAC`

--manip=<*manip*>

Where <*manip*> defines the DPDMUX required manipulation operation. A valid value is one of the following:

```
            DPDMUX_MANIP_NONE
```

```
            DPDMUX_MANIP_ADD_REMOVE_S_VLAN
```

Default is DPDMUX_MANIP_NONE

--options=<*options-mask*>

```
            DPDMUX_OPT_BRIDGE_EN
```

Default is 0 (don't set any options)

--max-dmat-entries=<*number*>

max entries in DPDMUX address table. Default is 64.

--max-mc-groups=<*number*>

Number of multicast groups in DPDMUX table. Default is 32 groups.

EXAMPLE:

Create a DPDMUX with all default options:

```
$ restool dpdmux create --num-ifs=4
    dpdmux.11 is created under dprc.1
```

6.11.2.9.4 destroy command

The **destroy** command destroys a DPDMUX.

SYNTAX:

restool dpdmux destroy <*dpdmux-object*>

ARGUMENTS :

<*dpdmux-object*>

Specifies which DPDMUX to destroy.

EXAMPLE:

```
    $ restool dpdmux destr
```

6.11.2.10 DPMCP Commands

6.11.2.10.1 help command

The **help** command displays usage information for the DPMCP object.

SYNTAX:

restool dpmcp help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpmcp help
usage: restool dpmcp <command> [--help][ARGS…]
Where <command> can be:
    info - displays detailed information about a DPMCP object.
    create - creates a DPMCP under the root DPRC
    destroy - destroys a DPMCP under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.10.2 info command

The **info** command displays detailed information about a specific dpmcp object.

SYNTAX:

restool dpmcp info <*dpmcp-object*> [**--verbose**]

ARGUMENTS :

<*dpmcp-object*>

Specifies which dpmcp object to show detailed info for. The dpmcp-object argument

is a string specifying the object name—e.g. “dpmcp.8”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpmcp info dpmcp.5
dpmcp version: 1.0
dpmcp object id/portal id: 5
plugged state: plugged
```

6.11.2.10.3 create command

The **create** command creates a new DPMCP. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpmcp create

EXAMPLE:

Create a DPMCP:

```
$ restool dpmcp create
dpmcp.15 is created under dprc.1
$ restool dpmcp create
MC error: No resource (status 0x8)
// when you see this error, it usually means no free portal available at this time.
```

6.11.2.10.4 destroy command

The **destroy** command destroys a DPMCP.

SYNTAX:

restool dpmcp destroy <*dpmcp-object*>

ARGUMENTS :

<*dpmcp-object*>

Specifies which DPMCP to destroy.

EXAMPLE:

```
$ restool dpmcp destroy dpmcp.9
dpmcp.9 is destroyed
```

6.11.2.11 DPMAC Commands

6.11.2.11.1 help command

The **help** command displays usage information for the DPMAC object.

SYNTAX:

restool dpmac help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpmac help
usage: restool dpmac <command> [--help][ARGS…]
Where <command> can be:
    info - displays detailed information about a DPMAC object.
    create - creates a DPMAC under the root DPRC
    destroy - destroys a DPMAC under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.11.2 info command

The **info** command displays detailed information about a specific dpmac object.

SYNTAX:

restool dpmac info <*dpmac-object*> [**--verbose**]

ARGUMENTS:

<*dpmac-object*>

Specifies which dpmac object to show detailed info for. The dpmac-object argument

is a string specifying the object name—e.g. “dpmac.8”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpmac info dpmac.5
dpmcp version: 2.0
```

```
    dpmac object id/phy id: 5
    plugged state: plugged
```

6.11.2.11.3 create command

The **create** command creates a new DPMAC. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpmac create --mac-id=<*number*>

--mac-id=<*number*>

Specifies the mac id.

EXAMPLE:

Create a DPMAC with valid portal id:

```
    $ restool dpmac create --mac-id=15
    dpmac.15 is created under dprc.1
```

6.11.2.11.4 destroy command

The **destroy** command destroys a DPMAC.

SYNTAX:

restool dpmac destroy <*dpmac-object*>

ARGUMENTS :

<*dpmac-object*>

Specifies which DPMAC to destroy.

EXAMPLE:

```
    $ restool dpmac destroy dpmac.9
    dpmac.9 is destroyed
```

6.11.2.12 DPDCEI Commands

6.11.2.12.1 help command

The **help** command displays usage information for the DPDCEI object.

SYNTAX:

restool dpdcei help

ARGUMENTS:

none

EXAMPLE:

```
    $ restool dpdcei help
    usage: restool dpdcei <command> [--help][ARGS…]
    Where <command> can be:
    info - displays detailed information about a DPDCEI object.
    create - creates a DPDCEI under the root DPRC
    destroy - destroys a DPDCEI under the root DPRC
```

```
For command-specific help, use the --help option available for each command.
```

6.11.2.12.2 info command

The **info** command displays detailed information about a specific dpdcei object.

SYNTAX:

restool dpdcei info <*dpdcei-object*> [**--verbose**]

ARGUMENTS :

<*dpdcei-object*>

Specifies which dpdcei object to show detailed info for. The dpdcei-object argument

is a string specifying the object name, e.g. “dpdcei.2”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpdcei info dpdcei.5
dpdcei version: 0.0
dpdcei id: 5
plugged state: plugged
DPDCEI engine: DPDCEI_ENGINE_COMPRESSION
```

6.11.2.12.3 create command

The **create** command creates a new DPDCEI. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpdcei create --engine=<*engine*> --priority=<*number*>

--engine=<*engine*>

Compression or decompression engine to be selected.

A valid value is one of the following:

```
            DPDCEI_ENGINE_COMPRESSION
```

```
            DPDCEI_ENGINE_DECOMPRESSION
```

--priority=<*number*>

Priority for DCE hardware processing (valid values 1-8)

EXAMPLE:

Create a DPDCEI:

```
$ restool dpdcei create --engine=DPDCEI_ENGINE_COMPRESSION --priority=2
dpdcei.0 is created under dprc.1
$ restool dpdcei create --engine=DPDCEI_ENGINE_COMPRESSION --priority=3
dpdcei.1 is created under dprc.1
```

6.11.2.12.4 destroy command

The **destroy** command destroys a DPDCEI.

SYNTAX:

restool dpdcei destroy <*dpdcei-object*>

ARGUMENTS :

<*dpdcei-object*>

Specifies which DPDCEI to destroy.

EXAMPLE:

```
$ restool dpdcei destroy dpdcei.9
dpdcei.9 is destroyed
```

6.11.2.13 DPAIOP Commands

6.11.2.13.1 help command

The **help** command displays usage information for the DPAIOP object.

SYNTAX:

restool dpaiop help

ARGUMENTS:

none

EXAMPLE:

```
$ restool dpaiop help
usage: restool dpaiop <command> [--help][ARGS…]
Where <command> can be:
info - displays detailed information about a DPAIOP object.
create - creates a DPAIOP under the root DPRC
destroy - destroys a DPAIOP under the root DPRC

For command-specific help, use the --help option available for each command.
```

6.11.2.13.2 info command

The **info** command displays detailed information about a specific dpaiop object.

SYNTAX:

restool dpaiop info <*dpaiop-object*> [**--verbose**]

ARGUMENTS :

<*dpaiop-object*>

Specifies which dpaiop object to show detailed info for. The *dpaiop-object* argument

is a string specifying the object name—e.g. “dpaiop.8”.

--verbose

Shows extended/verbose information about the object

EXAMPLE:

```
$ restool dpaiop info dpaiop.5
```

dpmcp version: 1.0

dpmcp id: 5

plugged state: plugged

dpaiop server layer version: 2.1.3

DPAIOP state: DPAIOP_STATE_RUNNING

6.11.2.13.3 create command

The **create** command creates a new DPAIOP. The name/id of the object created is displayed to stdout.

SYNTAX:

restool dpaiop create --aiop-id=<*number*> --aiop-container=<*container-name*>

ARGUMENTS :

--aiop-container=<*container-name*>

Specifies the AIOP container name, e.g. dprc.3, dprc.4, etc.

OPTIONS :

--aiop-id=<*number*>

Specifies the AIOP ID. Currently aiop container could only hold one dpaiop. Valid

number is 0. Default number is 0.

EXAMPLE:

Create a DPAIOP:

```
$ restool dpaiop create --aiop-id=0 --aiop-container=dprc.3
dpaiop.0 is created under dprc.3

$ restool dpaiop create --aiop-container=dprc.3
dpaiop.0 is created under dprc.3
```

6.11.2.13.4 destroy command

The **destroy** command destroys a DPAIOP.

SYNTAX:

restool dpaiop destroy <*dpaiop-object*>

ARGUMENTS :

<*dpaiop-object*>

Specifies which DPAIOP to destroy.

EXAMPLE:

```
$ restool dpio destroy dpaiop.9
dpaiop.9 is destroyed
```

6.11.2.14 Limitation

CR:ENGR00364876 DPNI: calling dprc_disconnect on a DPNI<->DPNI connection isn't fully disconnected

CR:ENGR00364611 0x3e8 error code for connect command when connection is already present

CR:ENGR00364610 allow dprc connect/disconnect across different DPRCs

Objects that are in use (i.e. plugged) should not be destroyed, but restool and MC allows this, resulting in an undefined result. Now restool does not allow plugged objects to be destroyed.

CR: ENGR00356070 - “dpsw create” fail, “dpdmux create” has limited functionality, In MC firmware 8.0.0, failure in dpmac create, dpdmux create/destroy, dpseci create, dpsw create

CR: ENGR00342091 – “dpdmux create” issue

CR:ENGR00356428 - dprc unassign does not work

CR: ENGR00356708 - mc hang before mcp resources are exhausted, there is only 256 (0-255) portals availvle while it claims 512 MC portals (0-511)

CR: ENGR00361302 - dprc's label has garbage info

CR:ENGR00361796 – cannot create dpseci

ENGR361940 kernel crashes with restool v0.9

6.12 DPAA2 User Manual

DPAA2 is a hardware-level networking architecture found on some NXP SoCs. This section provides technical information on this architecture mainly for software developers.

6.12.1 DPAA2 User Manual PDF

Click here to access the DPAA2 User Manual PDF.

6.13 DPAA2 API Reference Manual

The following sections contains general APIs for DPAA2.

6.13.1 DPAA2 API Reference Manual PDF

Click here to access the DPAA2 API Reference Manual PDF.

6.14 AIOP

6.14.1 AIOP Sample Applications

The Advanced I/O Processor (AIOP) hardware, an optional component of the DPAA2 architecture, is a C-programmable engine that enables power efficient packet-oriented processing. This section provides sample applications that can be used by customers to exercise functionality of offloading packet processing in AIOP.

6.14.1.1 Creating AIOP containers

This section describes how to dynamically create Data Path Resource Containers owned by AIOP and how to load AIOP ELF by using AIOP Tool.

cd /usr/aiop/scripts

In this folder there are two scripts based on restool available:

- `dynamic_aiop_only.sh` - script used by reference applications only with AIOP side, not interacting with other components
- `dynamic_aiop_root.sh` - script used by reference applications that interact with Linux Kernel running on GPPS

Scripts do not require any command line argument as input. Sample execution flow is shown below:

```
# ./dynamic_aiop_only.sh
Creating AIOP Container
Assigned dpbp.1 to dprc.2
Assigned dpbp.2 to dprc.2
Assigned dpbp.3 to dprc.2
Assigned dpni.1 to dprc.2
Connecting dpni.1<------->dpmac.1
Assigned dpni.2 to dprc.2
Connecting dpni.2<------->dpmac.2
AIOP Container dprc.2 created
----- Contents of AIOP Container: dprc.2 -----
dprc.2 contains 5 objects:
object          label           plugged-state
dpni.2                          plugged
dpni.1                          plugged
dpbp.3                          plugged
dpbp.2                          plugged
dpbp.1                          plugged
-----
==================================================
Creating AIOP Tool Container
Assigned dpaiop.0 to dprc.3
Assigned dpmcp.22 to dprc.3
AIOP Tool Container dprc.3 created
----- Contents of AIOP Tool Container: dprc.3 -----
dprc.3 contains 2 objects:
object          label           plugged-state
dpaiop.0                        plugged
dpmcp.22                        plugged
-----
==================================================
Performing VFIO mapping for AIOP Tool Container (dprc.3)
Performing vfio mapping for dprc.3
[  796.531485] vfio-fsl-mc dprc.3: Binding with vfio-fsl_mc driver
[  796.540756] vfio-fsl-mc dpaiop.0: Binding with vfio-fsl_mc driver
[  796.547364] vfio-fsl-mc dpmcp.22: Binding with vfio-fsl_mc driver
========== Summary ================================
 AIOP Container: dprc.2
 AIOP Tool Container: dprc.3
==================================================
```

To load the AIOP binary by using AIOP Tool, the AIOP Tool Container is necessary. In the above case is `dprc.3`. The following command should be executed:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_reflector.elf
AIOP Image (aiop_reflector.elf) loaded successfully.
```

To ensure that AIOP image is indeed loaded and running, the AIOP console can be checked by executing one of the following commands:

```
# aiop_tool status -g dprc.3
AIOP Tile Status:
         Major Version: 2, Minor Version: 1
         Service Layer:- Major Version: 0, Minor Version: 7, Revision: 1
         State: DPAIOP_STATE_RUNNING

root@ls2085ardb:~# cat /dev/fsl_aiop_console
        . . .
```

6.14.1.2 AIOP Packet Reflector application

6.14.1.2.1 AIOP Packet Reflector overview

The purpose of this sample application is to demonstrate a simple application data path on the AIOP. The application is a basic reflector for every IPv4 frame and works much like the NADK Packet Reflector application, except that it runs on the AIOP.

The application performs the following functions:

- Configure the fields used for the initial order scope hash generation. The fields are: the source address, the destination address, the protocol type fields from the IP header and the source port and the destination port from the L4 header. For every packet received by WRIOP a hashed Initial Ordering Scope (IOS) will be generated based on these values.
- Set Concurrent Execution (XC) as the initial packets processing mode. In the initial stage of processing, the packets are processed concurrently by many cores in their ordering scope.
- Drop non IPv4 packets.
- Switch the source and destination MAC and IP addresses of the received packets.
- Transition into Exclusive execution (XX) in order to restore packet order. This is optional and can be deactivated through define EXCLUSIVE_MODE
- Reflect back the packet on the same interface from which it was received.

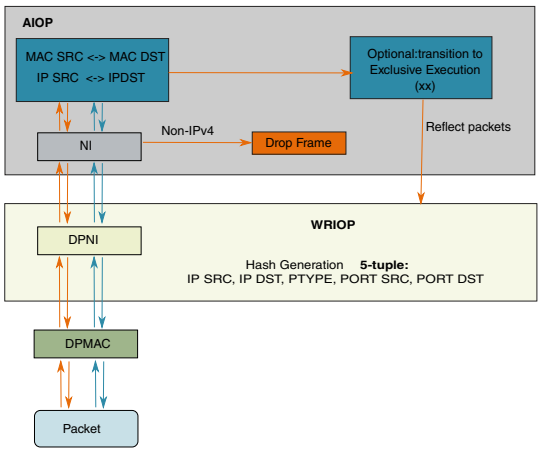

Figure 31. AIOP Packet Reflector overview

6.14.1.2.2 Running the Reflector application

The reflector application should be runnning on the RDB.

The ELF for AIOP reflector is `/usr/aiop/bin/aiop_reflector.elf`. This can be loaded via AIOP Tool as section Creating AIOP Containers describes. For this application the script `dynamic_aiop_only.sh` must be executed before loading the image:

```
# ./dynamic_aiop_only.sh
```

To load the AIOP Reflector Application, execute the following command:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_reflector.elf
```

To check if the AIOP Reflector Application loaded successfully, execute the following command in the Linux command shell:

```
# cat /dev/fsl_aiop_console | grep REFLECTOR
```

The command output should display information about the Network Interfaces (NIs) that were successfully configured: NI instance (e.g. NI 0) together with the associated MAC address.

```
REFLECTOR : Successfully configured ni0 (dpni.2)
REFLECTOR : dpni.2 <---connected---> dpmac.2 (MAC addr: 00:00:00:00:00:07)
REFLECTOR : Successfully configured ni1 (dpni.1)
REFLECTOR : dpni.1 <---connected---> dpmac.1 (MAC addr: 00:00:00:00:00:06)
```

NOTE

Although the AIOP container contains multiple three DPNIs (DPNI6, DPNI7 and DPNI10), the AIOP Reflector will use only the DPNIs that have a DPMAC as endpoint (on which it can succesfully configure the order scope). The others will be skipped in application initialization.

During frame processing, the AIOP Logger will print the following brief information about every reflected packet:

- AIOP Core number on which the frame was processed
- Received MAC source and destination addresses
- Received IP source and destination addresses

```
# busybox tail –f /dev/fsl_aiop_console

RX on NI 0 | CORE:15
      MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-06
      IP_SRC: 192.85.1.1 IP_DST: 192.0.0.1

RX on NI 0 | CORE:14
      MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-06
      IP_SRC: 192.85.1.2 IP_DST: 192.0.0.1

 . . .

RX on NI 0 | CORE:9
      MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-06
      IP_SRC: 192.85.1.3 IP_DST: 192.0.0.1
```

6.14.1.2.3 Generating traffic to test AIOP Reflector application

An external traffic source is needed to pass traffic to the reflector application. This could be another RDB or some other traffic generator. Two optical 10G ports need to be connected to MAC1 and MAC2 of RDB-1.

The following graphic illustrates how traffic moves from a packet generator to RDB-1 board

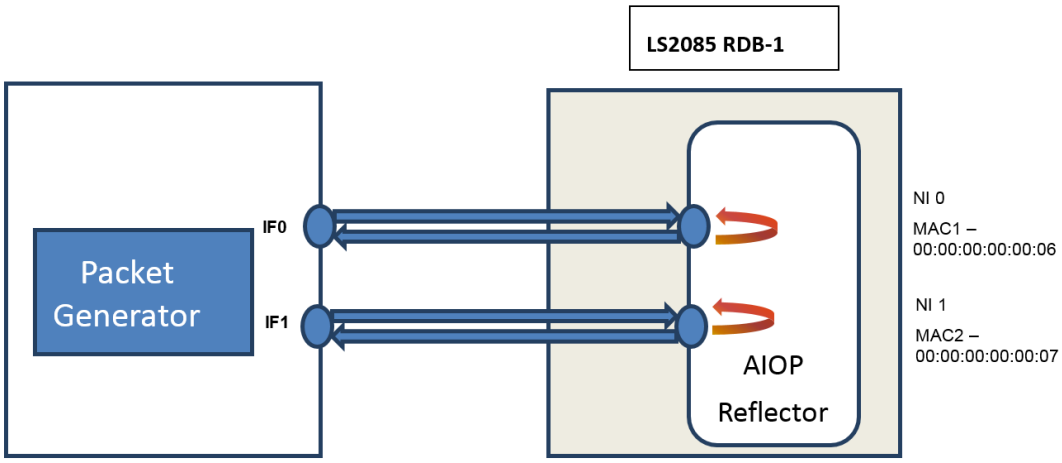

Figure 32. Generating traffic for AIOP Packet Reflector

When using a Packet Generator to inject traffic, connect one port of the packet generator to MAC1 of RDB-1 and a second port to MAC2 of RDB-1.

On RDB-1 ensure that both AIOP network interfaces are in link up state:

```
$ cat /dev/fsl_aiop_console | grep REFLECTOR
REFLECTOR : ni0 link is UP
REFLECTOR : ni1 link is UP
```

Generate an IPv4 frames for each of the two ports:

```
        MAC source:         ANY
        MAC destination:    00:00:00:00:00:06 for MAC1
                            00:00:00:00:00:07 for MAC2
        IP source:          ANY
        IP destination:     ANY
```

On RDB-1, the AIOP Logger will print a brief information about every frame that is being reflected.

6.14.1.3 AIOP Packet Classifier application

6.14.1.3.1 AIOP Packet Classifier overview

The purpose of this sample application is to demonstrate how to perform a simple Classification on the AIOP. The application will apply a Classification criteria for every IPv4 frame and will reflect back only accepted frames.

There are three execution modes listed below:

- Exclusive execution (XX): This mode forces atomic processing of packets. Each packet is processed in order of its arrival before the next packet is processed.
- Concurrent execution (XC): This mode processes packets within a flow concurrently on the AIOP. Packets may become misordered as part of this parallel processing. To restore packet order, the data path transitions to exclusive execution mode before transmitting the forwarded packets.
- Unordered. In this mode, packet ordering is not considered and concurrent packet processing takes place.

The application performs the following functions:

- Put network interfaces in promiscuous mode in order to allow packet reception regardless of its MAC destination address.

- Configure the fields used for the initial order scope hash generation. The fields are: the source address, the destination address, the protocol type fields from the IP header and the source port and the destination port from the L4 header. For every packet received by WRIOP a hashed Initial Ordering Scope (IOS) will be generated based on these values.
  - Set Concurrent Execution (XC) as the initial packets processing mode. In the initial stage of processing, the packets are processed concurrently by many cores in their ordering scope.
  - Classify the packets to enable different processing modes to be run based on the type of traffic. Classification is based on the following fields: IPv4 source and destination addresses, Protocol number, Source and Destination Layer 4 ports. The packets processing mode is selected as a result of the classification as follows:
  - TCP packets are processed in exclusive execution mode (XX)
  - UDP packets are processed in concurrent execution mode (XC). In order to keep the UDP packets in order, the application must transition to exclusive execution mode before sending packets to the destination port.
  - SCTP packets are processed with no respect regarding their arrival order (Unordered).
  - The packets not matching the classification criteria are dropped.

In order to determine the processing mode in which a packet should be processed, when a lookup hit is obtained, the lookup result will return the new processing mode to which the application should transition

- Switch the source and destination MAC and IP addresses of the received packets.

Reflect back the accepted packets on the same interface from which they were received

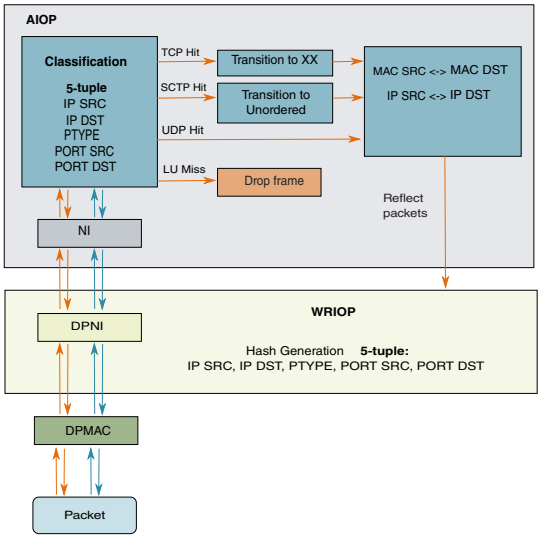

Figure 33. AIOP Packet Classifier overview

The Exact Match table in AIOP that will be used for table lookup will be populated with the following entries:

IP Source Address	IP Destination Address	Protocol Type	Source Port	Destination Port
198.20.1.1	198.19.1.0	6 (TCP)	1024	1025
198.20.1.1	198.19.1.64	17 (UDP)	1024	1025
198.20.1.1	198.19.1.128	132 (SCTP)	1024	1025

For each entry in the table a mask with value 0xE0 is applied on the last byte of the IP Destination address, allowing a number of 32 IP Destination Address to be received. The following traffic flows will generate a HIT in the Classification table:

IP Source Address	IP Destination Address	Protocol Type	Source Port	Destination Port
198.20.1.1	198.19.1.0 .. 198.19.1.31	6 (TCP)	1024	1025
198.20.1.1	198.19.1.64 .. 198.19.1.95	17 (UDP)	1024	1025
198.20.1.1	198.19.1.128 .. 198.19.1.159	132 (SCTP)	1024	1025

6.14.1.3.2 Running the Classifier application

The classifier application should be run on the RDB-1 system.

The ELF for AIOP Classifier is `/usr/aiop/bin/aiop_classifier.elf`. This can be loaded via AIOP tool as section Creating AIOP Containers describes. For this application the script `dynamic_aiop_only.sh` must be executed before loading the image:

```
# ./dynamic_aiop_only.sh
```

To load the AIOP Classifier Application, execute the following command:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_classifier.elf
```

To check if the AIOP Classifier Application loaded successfully, execute the following command in the Linux command shell:

```
# cat /dev/fsl_aiop_console | grep CLASSIFIER
```

The command output should display information about the Network Interfaces (NIs) that were successfully configured: NI instance (e.g NI 0) together with the associated MAC address.

```
CLASSIFIER : Successfully configured exact table match
CLASSIFIER : Successfully configured ni0 (dpni.2)
CLASSIFIER : dpni.2 <---connected---> dpmac.2 (MAC addr: 00:00:00:00:00:07)
CLASSIFIER : Successfully configured ni1 (dpni.1)
CLASSIFIER : dpni.1 <---connected---> dpmac.1 (MAC addr: 00:00:00:00:00:06)
```

NOTE

Although the AIOP container contains multiple NIs the AIOP Reflector will use only the NIs that have a DPMAC as endpoint (on which it can succesfully configure the order scope).

During frame processing, the AIOP Logger will print the following brief information about every reflected packet:

- AIOP Core number on which the frame was processed
- Received MAC source and destination addresses

- Received IP source and destination addresses

```
# busybox tail -f /dev/fsl_aiop_console

RX on NI 0 | CORE:15
   MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-06
   IP_SRC: 198.20.1.1 IP_DST: 198.19.1.0

RX on NI 0 | CORE:14
   MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-06
   IP_SRC: 198.20.1.1 IP_DST: 198.19.1.64

. . .

RX on NI 1 | CORE:9
   MAC_SA: 00-10-94-00-00-02 MAC_DA: 00-00-00-00-00-07
   IP_SRC: 198.20.1.1 IP_DST: 198.19.1.128
```

6.14.1.3.3 Generating traffic to test AIOP Classifier application

An external traffic source is needed to pass traffic to the classifier application. This could be another RDB or some other traffic generator. Two optical 10G ports need to be connected to MAC1 and MAC2 of RDB-1.

The following graphic illustrates how traffic moves from a packet generator to RDB-1 board.

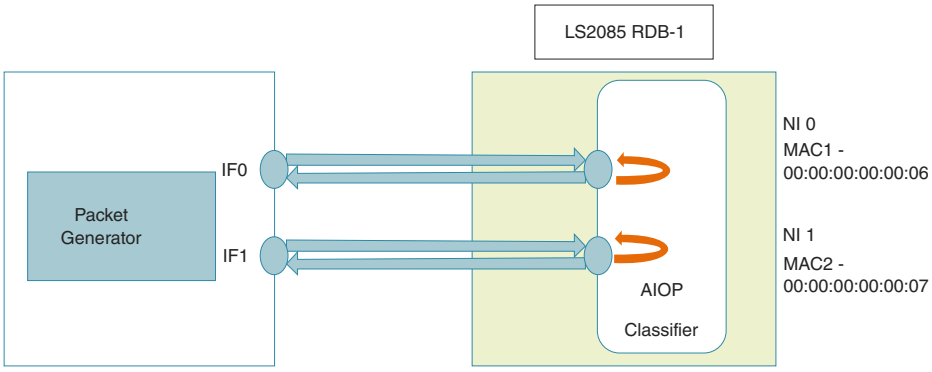

Figure 34. Generating traffic for AIOP Classifier

When using a Packet Generator to inject traffic, connect one port of the packet generator to MAC1 of RDB-1 and a second port to MAC2 of RDB-1.

On RDB-1 ensure that both AIOP network interfaces are in link up state:

```
$ cat /dev/fsl_aiop_console | grep CLASSIFIER
...
CLASSIFIER : ni0 link is UP
CLASSIFIER : ni1 link is UP
```

Generate IPv4 frames for each of the two ports:

- MAC source: ANY
- MAC destination: ANY

- For IP & Layer 4, the accepted values are show in the following table:

IP Source Address	IP Destination Address	Protocol Type	Source Port	Destination Port
198.20.1.1	198.19.1.0 .. 198.19.1.31	6 (TCP)	1024	1025
198.20.1.1	198.19.1.64 .. 198.19.1.95	17 (UDP)	1024	1025
198.20.1.1	198.19.1.128 .. 198.19.1.159	132 (SCTP)	1024	1025

The AIOP Logger will print a brief information about every frame that passed the Classification criteria.

NOTE

Traffic can be generated using frames available in the provided classifier.pcap file. The traffic available is shown in the table below.

IP Source Address	IP Destination Address	Protocol Type	Source Port	Destination Port
198.20.1.1	198.19.1.0 .. 198.19.1.63	6 (TCP)	1024	1025
198.20.1.1	198.19.1.64 .. 198.19.1.127	17 (UDP)	1024	1025
198.20.1.1	198.19.1.128 .. 198.19.1.191	132 (SCTP)	1024	1025

This file can be used to generate the traffic from a traffic generator (e.g.: a packet generator or another RDB board). Location on board for this file, after bringup, is in `/usr/aiop/traffic_files/classifier.pcap`. On RDB-1, the AIOP Reflector Classifier Application will drop half of the frames in each range as a result of classification look-up miss.

6.14.1.4 AIOP Control Flow application

6.14.1.4.1 AIOP Control Flow overview

The purpose of this sample application is to demonstrate a simple AIOP-GPP communication using a DPNI-DPNI connection. The application filters ICMP and ARP request frames and sends them to GPP where Linux Kernel replies with ICMP Echo Reply and ARP Response.

Application has the following required connections:

- DPNI to DPNI connection: a network interface from AIOP that provides connection to another network interface on GPP
- DPNI to DPMAC connection: a network interface from AIOP connected to external traffic (physical wired connection, e.g. XFI or SGMII as links)

The application performs the following functions:

Initialization:

All network interfaces are in promiscuous mode.

Depending on a network interface's' connected endpoint object type, there are two different frame processing callbacks.

NOTE

Failures in performing the above actions lead to dropping the packets received on that network interface or in no link between AIOP and GPP.

Runtime

For every packet received on AIOP network interface connected to external traffic:

- Drop non IPv4 packets and non ARP packets
- Detect, using Parser, if packets received are either ICMP Echo Request or ARP Request. In this case send packets to Linux Kernel using GPP connection
- For ARP or IPv4 packets other than ICMP Echo Request and ARP Request: switch the source and destination MAC and IP addresses of the received packets and reflect back the packet on the same interface from which it was received.

For every packet received from GPP:

- Drop all packets that are not ICMP Echo Reply and not ARP response
- Print brief information about the accepted packets
- Forward ICMP Echo Reply and ARP response packets to the NI havingconnected to traffic generatorDPMAC as endpoint and callback config and callback configured.

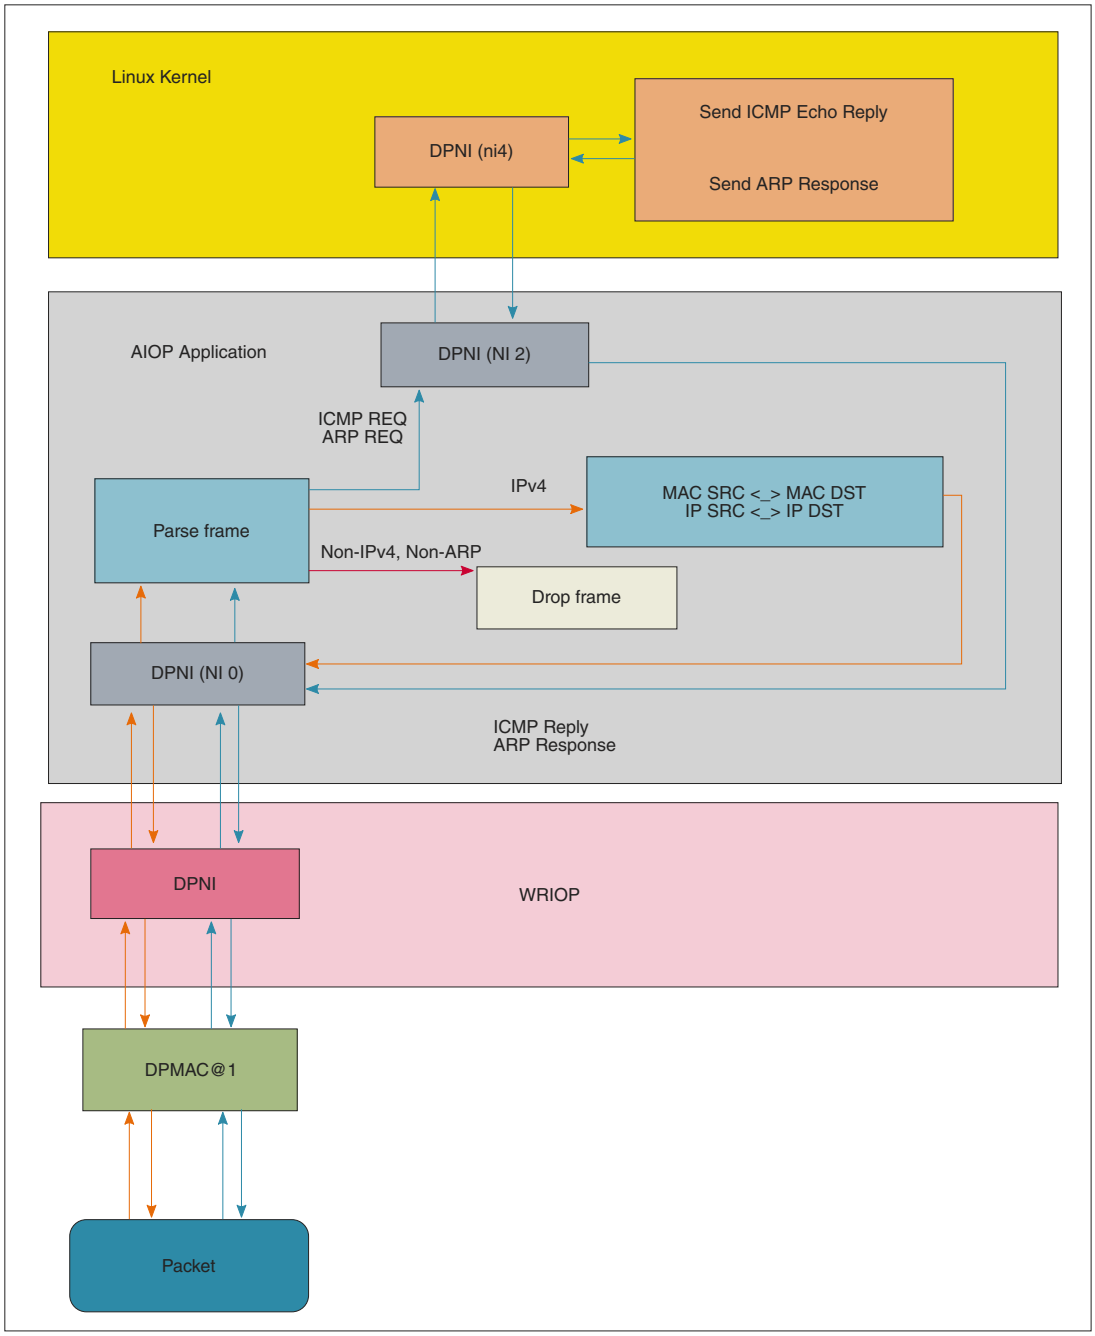

Figure 35. AIOP Control Flow overview

6.14.1.4.2 Running the Control Flow application

The ELF for AIOP Classifier is `/usr/aiop/bin/aiop_control_flow.elf`. This can be loaded via AIOP tool as section Creating AIOP Containers describes. For this application the script `dynamic_aiop_root.sh` must be executed before loading the image:

```
# ./dynamic_aiop_root.sh
```

To load the AIOP Classifier Application, execute the following command:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_control_flow.elf
```

To check if AIOP Control Flow Application loaded successfully execute the following command in the Linux command shell:

```
$ cat /dev/fsl_aiop_console | grep CONTROL_FLOW
```

The command output should display the number of NIs that were successfully configured together with the specific MAC addresses that are provided to the AIOP Control Flow Application:

```
CONTROL_FLOW : Successfully configured ni0 (dpni.2)
CONTROL_FLOW : dpni.2 <---connected---> dpni.0
CONTROL_FLOW : Successfully configured ni1 (dpni.1)
CONTROL_FLOW : dpni.1 <---connected---> dpmac.1 (MAC addr: 00:00:00:00:00:06)
```

On RDB board, to enable AIOP-GPP communication via DPNI-DPNI, it is required to configure the Linux network interface:

```
# ip link set dev ni0 down
# ip addr flush dev ni0
# ip addr add 6.6.6.1/8 dev ni0
# ip link set dev ni0 up
```

After executing the commands for configuring Linux network interface, in AIOP console will be displayed a message for the NI 0 (DPNI 2) link up due to a DPNI link event:

```
CONTROL_FLOW : ni0 link is UP
```

It is also required to create a static entry in the ARP table, so that Linux responds directly to AIOP:

```
# arp -s 6.6.6.10 <MAC_address_of_traffic_generator>
# arp -n
Address     HWtype     HWaddress                              Flags Mask     Iface
6.6.6.10    ether      <MAC_address_of_traffic_generator>     CM             ni4
```

During frame processing, the AIOP Logger will print the following brief information about every received packet on all interfaces:

- Received MAC source and destination addresses
- Received IP source and destination addresses
- Traffic generator IP address is 6.6.6.10
- For ARP Frames AIOP Logger will print: operation code (OPCODE), Sender and Target Protocol Address.
- For ICMP Frames AIOP Logger will print: ICMP Type and ICMP Code.

```
RX on NI 0
   MAC_SA: 00-00-00-00-00-02 MAC_DA: 02-00-c0-a8-48-01
   IP_SRC: 6.6.6.10 IP_DST: 6.6.6.1
   ICMP_TYPE: 8 ICMP_CODE: 0
```

```
RX on NI 0
   MAC_SA: 00-00-00-00-00-02 MAC_DA: 02-00-c0-a8-48-01
   ARP_OPCODE: 1 S_ADDR: 6.6.6.10 T_ADDR: 6.6.6.1

RX on NI 0
   MAC_SA: 00-00-00-00-00-06 MAC_DA: 00-10-94-00-00-10
   IP_SRC: 192.0.0.1 IP_DST: 192.85.1.2

. . .
```

Assign an IP address to the Linux interface for SSH connections to RDB-1 board, for example using the following command:

```
# ip addr add 192.168.1.20/24 dev eth0
# ip link set dev eth0 up
```

Alternatively, if the DHCP server is active on the network, run following command to get an IP address automatically, for example using the following command:

```
# udhcpc -i eth0
```

6.14.1.4.3 Generating traffic to test AIOP Control Flow application

An external traffic source is needed to pass traffic to the control flow application. This could be another RDB or some other traffic generator. The following graphic illustrates traffic flow between Packet Generator and RDB board.

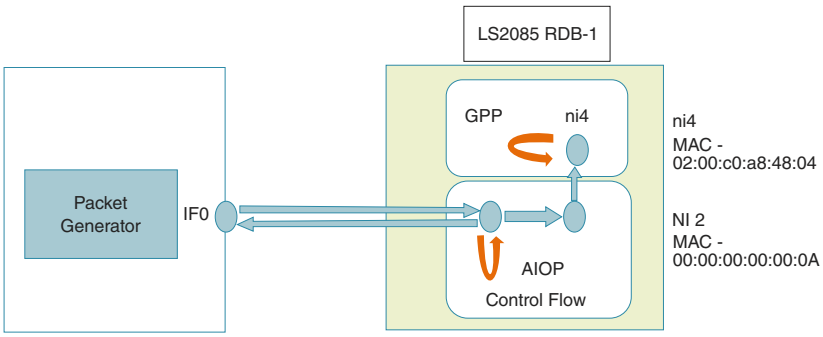

Figure 36. Generating traffic for AIOP Control Flow

When using a Packet Generator to inject traffic, connect one port of the packet generator to MAC1 of RDB-1.

Generate IPv4 frames for each of the two ports:

- MAC source: 00:00:00:00:00:02 (MAC address of the traffic generator)
- MAC destination: 02:00:C0:A8:48:00 (MAC of ni0 in Linux)
- For ARP and ICMP, the values that are sent to Linux GPP are:

IP Source Address	IP Destination Address	Protocol Type	ICMP Type	ICMP Code
6.6.6.10	6.6.6.1	01 (ICMP)	08 (Echo Request)	00

For other ICMP fields use any value:

Protocol Type	Sender Hardware Address	Sender Protocol Address	Target Hardware Address	Target Protocol Address
00 01 (ARP Request)	<<MAC Address of Traffic Generator>>	6.6.6.10	00:00:00:00:00:00	6.6.6.1

- For TCP or UDP use any data in IP source/destination and header specific.

Traffic can be injected in board only after the network interface connected to trafficgenerator (external traffic) is up due to internal event in AIOP:

```
CONTROL_FLOW : ni0 link is UP
```

Open two AIOP consoles (using SSH). On one of them show the AIOP Logger using command described below. When injecting traffic, on RDB-1, the AIOP Logger will print a brief information about every frame that is being processed.

```
$ busybox tail -f /dev/fsl_aiop_console
```

On the other console start packet capture, using the following command, to sniff communication between AIOP and GPP:

```
$ tcpdump -i ni1 -w aiop_control_flow.pcap
```

6.14.1.5 AIOP Header Manipulation application

6.14.1.5.1 AIOP Header Manipulation overview

The purpose of this application is to demonstrate how to perform a simple GRE tunneling using header manipulation operations available in AIOP. Application offers support only for IPv4 packets and requires one DPNI interface, acting as tunnel interface. The packet header content is used to determine the type of operation to be performed on the packet: encapsulation or decapsulation

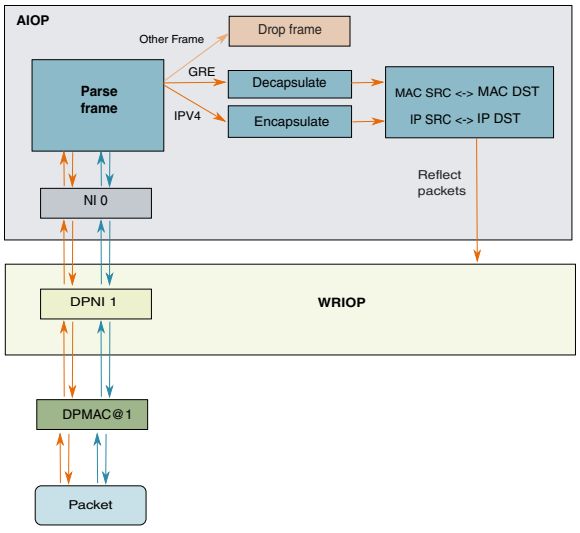

Figure 37. AIOP Header Manipulation overview

The application performs the following operations:

- For regular IPv4 packets without inner IP header: creates a basic IP header, computes outer IP checksum, creates a basic GRE header (all flags 0, GRE version 0, encapsulated protocol: IPv4), inserts these headers between ETH and IP headers and switches the source and destination MAC addresses

- For packets having an inner IP and GRE headers: deletes the outer IP and GRE headers, switches the source and destination MAC and IP addresses
- Discards non-IPv4 and non-GRE packets
- Re-runs parser and prints the packet after header manipulation occurred. This is optional and can be deactivated by defining the macro RERUN_PARSER
- Sends back packets on same network interface they were received from.

6.14.1.5.2 Running the Header Manipulation application

The ELF for AIOP Classifier is `/usr/aiop/bin/aiop_header_manip.elf`. This can be loaded via AIOP tool as described in Creating AIOP containers on page 515. For this application the script `dynamic_aiop_only.sh` must be executed before loading the image:

```
# ./dynamic_aiop_only.sh
```

To load the AIOP Classifier Application, execute the following command:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_header_manip.elf
```

To check if the AIOP Classifier Application loaded successfully, execute the following command in the Linux command shell:

```
# cat /dev/fsl_aiop_console | grep HEADER_MANIP
```

The command output should display information about the Network Interfaces (NIs) that were successfully configured: NI instance (e.g ni0) together with the associated MAC address.

```
HEADER_MANIP : Successfully configured ni0 (dpni.6)
HEADER_MANIP : dpni.6 <---connected---> dpmac.1 (MAC addr: 00:00:00:00:00:06)
```

NOTE

Although the AIOP container contains multiple NIs the AIOP Reflector will use only the NIs that have a DPMAC as endpoint (on which it can succesfully configure the order scope).

During packet processing, the AIOP Logger prints the following brief information about every received packet on all interfaces:

- Received IP source and destination addresses (for the inner header and for the outer IP header in case packet is encapsulated)
- GRE Flags, version and encapsulated protocol, in case the packet is encapsulated.

If parser re-running was enabled the information above is printed, in order to show the result of encapsulation/decapsulation header manipulation operations performed.

```
# busybox tail -f /dev/fsl_aiop_console

Decapsulated Frame | FD Len 124 | SEG Len 124

  OUTER IP HEADER
    PROTO: 6 IP_SRC: 10.18.1.1, IP_DST: 198.168.2.21, TOTAL LEN: 106, IHL: 20
```

6.14.1.5.3 Generating traffic to test AIOP Header Manipulation application

An external traffic source is needed to pass traffic to the classifier application. This could be another RDB or some other traffic generator. One optical 10G ports need to be connected to MAC1 or MAC2 of RDB-1.

The following diagram illustrates how traffic moves from a packet generator to RDB-1 board.

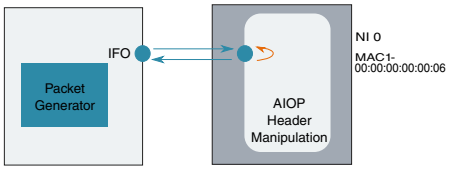

Figure 38. Generating traffic for AIOP Header Manipulation

When using a Packet Generator to inject traffic, connect one port of the packet generator to MAC1 of RDB-1.

On RDB-1 ensure that both AIOP network interface is in link up state:

```
$ cat /dev/fsl_aiop_console | grep HEADER_MANIP
HEADER_MANIP: NI 0 link is UP
```

Generate IPv4 packets:

- Common values:
  - MAC destination: 00:00:00:00:00:06 (address of MAC1)
  - MAC source: ANY
  - Outer IP source: ANY
  - Outer IP destination: ANY
- For GRE encapsulated packets:
  - Version: 0
  - GRE Flags and version: 0x0000
  - GRE Encapsulated Protocol: 0x0800 (IP)
  - Inner IP source: ANY
  - Inner IP destination: ANY

On RDB-1, the AIOP Logger prints brief information about every packet that is being encapsulated/decapsulated and if parser re-running is enabled the AIOP Logger prints brief information about the packet after the GRE encapsulation/decapsulation header manipulations occurred.

The encapsulated packets using GRE by AIOP application have the following pre-defined values:

- Outer IP Version: 4
- Outer IP source: 122.122.122.122
- Outer IP destination: 138.138.138.138
- GRE Version: 0
- GRE Flags and version: 0x0000
- GRE Protocol Type: 0x0800 (IP)
- Inner IP source: IP source from original packet
- Inner IP destination: IP destination from original packet

The packets that were decapsulated by AIOP will have the inner IP source and destination addresses and MAC addresses swapped.

6.14.1.6 AIOP Statistics application

6.14.1.6.1 AIOP Statistics overview

The purpose of this application is to demonstrate the usage of the AIOP atomic operations in order to update software definedstatistics counters. There are two types of statistics counters:

- Global: total number of the received packets, total number of the received bytes , total number of the accepted packets, total number of the rejected packets
- Per-flow: total number of the recived packets and total number of the received bytes, for each packet matching the applied classification criteria

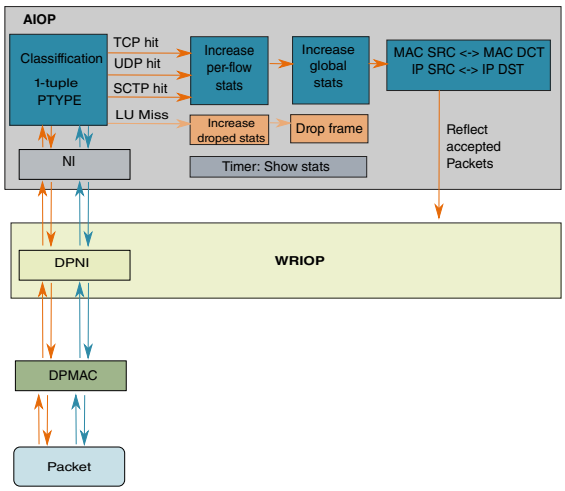

Figure 39. AIOP Statistics overview

The application performs the following operations:

- Classifies the packets to enable different counters update. Classification is based only on the Protocol Number field. Only the TCP, UDP and SCTP protocols are accepted. The packets not matching the classification criteria are dropped and number of dropped packets is increased. [GI1]
- Increases the global statistics and the statistics for each packet matching the classification criteria (per-flow statistics).
- Swap the MAC and IP addresses
- Sends back packets on same network interface they were received from.

- By default, the global and per flow statistics are displayed at every 60 seconds. In order achieve this, a timer is used. The timer time interval, measured in seconds, can be changed by setting the value of the macro definition APP_TMAN_TIMER_DURATION, at compile time.

Note: Both global and per-flow statistics are stored in the DP-DDR (Data Path DDR) memory partition. For the global statistics, a contiguous block of memory is obtained and for each flow a buffer from DP-DDR is obtained by using pool-based allocation.

6.14.1.6.2 Running the AIOP Statistics application

The statistics application should be run on the RDB-1 system.

The ELF for AIOP reflector is `/usr/aiop/bin/aiop_statistics.elf`. This can be loaded via AIOP tool as section Creating AIOP Containers describes. For this application the script `dynamic_aiop_only.sh` must be executed before loading the image:

```
# ./dynamic_aiop_only.sh
```

To load the AIOP Statistics Application, execute the following command:

```
# aiop_tool load -g dprc.3 -f /usr/aiop/bin/aiop_statistics.elf
```

To check if the AIOP Statistics Application loaded successfully, execute the following command in the Linux command shell:

```
# cat /dev/fsl_aiop_console | grep STATISTICS
```

The command output should display information about the Network Interfaces (NIs) that were successfully configured: NI instance (e.g ni0) together with the associated MAC address.

```
STATISTICS : Created TMI id=0x2
STATISTICS : Created timer for showing statistics, handle=0x102
STATISTICS : Application initialized successfully
STATISTICS : Successfully configured ni0 (dpni.2)
STATISTICS : dpni.2 <---connected---> dpmac.2 (MAC addr: 00:00:00:00:00:07)
STATISTICS : Successfully configured ni1 (dpni.1)
STATISTICS : dpni.1 <---connected---> dpmac.1 (MAC addr: 00:00:00:00:00:06)
STATISTICS : ni1 link is UP
```

Once the application started, at every 60 seconds (or at the time interval defined by APP_TMAN_TIMER_DURATION macro) the AIOP Logger prints all statistics counters values. Default value should be 0 for all counters.

```
AIOP received 47753801 packets (5921471324 bytes)
        12585359 dropped packets, 35168442 accepted packets, 35168442 transmitted packets
         * PROTO=0x6: received: 12601479 packets (1562583396 bytes)
         * PROTO=0x11: received: 12608080 packets (1563401920 bytes)
         * PROTO=0x84: received: 9958883 packets (1234901492 bytes)
```

6.14.1.6.3 Generating traffic to test AIOP Statistics application

An external traffic source is needed to inject packets into the application. This could be another RDB-1 or some other traffic generator. One optical 10G port needs to be connected to MAC1 or MAC2 port of the RDB

The following diagram illustrates how traffic moves from a packet generator to RDB-1 board.

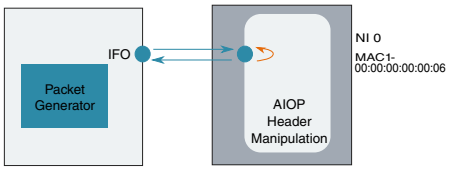

Figure 40. Generating traffic for AIOP Statistics

When using a Packet Generator to inject traffic, connect one port of the packet generator to MAC1 of RDB-1 and a second port to MAC2 of RDB-1.

On RDB-1 ensure that both AIOP network interfaces are in link up state:

```
$ cat /dev/fsl_aiop_console | grep STATISTICS
STATISTICS : NI 0 link is UP
```

Generate IPv4 frames for each of the two ports:

- MAC source: ANY
- MAC destination: 00:00:00:00:00:06 (address of MAC1)
- For IP & Layer 4, the accepted values are show in the following table:

IP Source Address	IP Destination Address	Protocol Type	Source Port	Destination Port
ANY	ANY	6 (TCP)	ANY	ANY
ANY	ANY	17 (UDP)	ANY	ANY
ANY	ANY	132 (SCTP)	ANY	ANY

On RDB-1, the AIOP Logger prints at every 60 seconds (or at the time interval configured with the APP_TMAN_TIMER_DURATION macro) the global statistics and the per-flow statistics for each matched protocol (TCP, UDP and SCTP).

6.14.2 AIOP Tool User's Guide

6.14.2.1 Introduction

This document contains information about the usage of AIOP Tool application, including compilation and execution steps. This document is a part of the series intended to help developers use DPAA2 software on NXP's LS family of network processors. This document is intended to get users up and running quickly.

6.14.2.1.1 Conventions

This document uses the following conventions:

`Courier`	`Is used to identify commands, explicit command parameters, code examples, expressions, data types, and directives.`

6.14.2.1.2 Definitions and acronyms

AIOP	Advanced I/O Processor
DPAA	Data Path Acceleration Architecture
DPRC	Data Path Resouce Container
GPP	General Purpose Processor (or, in context of Linux applications, user-space)
MC	Management Complex
ODP	Open Data Plane Software

6.14.2.2 DPAA2 Software

For information about the DPAA2 software, see the DPAA2 Software Overview on page 410 section. For users that are unfamiliar with DPAA2 software, it is recommended to read that content before proceeding.

6.14.2.3 Product Description

6.14.2.3.1 Overview

What is AIOP?

AIOP or Advanced I/O Processor is an optional component of the DPAA2 architecture. It is a C-programmable engine that is optimized for packet processing and can be used on a SoC in conjunction with the general purpose cores and the other elements of the DPAA2 architecture. AIOP executes a software image containing the packet processing logic.

What is AIOP Tool?

AIOP Tool is a Linux user space application which performs the following operations on an AIOP:

1. Loading an image on an AIOP
2. Starting (running) the image on an AIOP after it has been loaded
3. Extracting state information for an AIOP
4. Getting and setting time of day on an AIOP

6.14.2.3.2 Product features

AIOP Tool provides following broad functions:

- Provides a command line interface for executing a set of operations
  - Command line will accept an operation from user, along with the appropriate corresponding arguments.
  - The DPRC to work on is also accepted as an argument on the command line.
- Operation for Loading AIOP Image to an AIOP
  - Command line will accept an AIOP image file.
  - Whether a reset of the AIOP should be done before loading or not can be controlled using a toggle argument passed on command line. For performing reset of AIOP before load operation, an optional toggle argument can be passed to the load operation.
    - Current hardware revision (rev1) doesn't support reset and it is expected to work in subsequent releases. Thus, in future, the same tool can be used without any modifications.
  - Result of load API call will be provided to the caller.

- Operation for Resetting the AIOP
  - On execution, this would put the AIOP in Reset state for loading another image.
    - In the current hardware revision (rev1), this is not supported and would result in error. In subsequent versions of LS family hardware, this is expected to be operational. Once that is done, with the combination of load and run operations, multiple images can be loaded on AIOP (serially) without a hardware reset.
  - Response value of API execution will be provided to caller.
- Operation for getting and setting time of day on AIOP
  - Once an AIOP is running, 2 operations for getting and setting the time of day on AIOP are available.
  - Success or failure of the API calls would be provided to caller in case of time setting. In case of time getting operation, time since epoch would be shown.
- Operation for printing AIOP status
  - On execution of this operation, status of the AIOP is provided to the caller. This includes the current state and version information.
- Help menu will be printed by command line for displaying usage of above operations and their corresponding arguments.

6.14.2.4 System Requirements

This chapter describes the environment requirements for executing the AIOP Tool.

6.14.2.4.1 Environment required

1. MC Firmware version 9.0.x for LS2085A (RDB and QDS) EAR-6.0
2. Uboot and Linux compatible with LS2085A (RDB and QDS) EAR-6.0
3. AIOP image (ELF) is required as input to the tool

6.14.2.5 AIOP Tool Usage

6.14.2.5.1 Run time pre-requisites

Besides the environment pre-requisites listed in Environment required on page 534, the following execution time pre-requisites exist:

1. AIOP Tool requires a DPRC which has an AIOP included in it. It should be a non-root DPRC containing at least a dpmcp and dpaiop object.
   - This DPRC can be statically defined (static DPL) or dynamically created (using `restool`).
   - Please refer Steps For Dynamic DPRC Suitable For AIOP Tool Using restool on page 540 below for steps for dynamically creating a suitable DPRC using `restool`.
   - Also, refer `dynamic_AIOP_dpl.sh` script delivered as part of the EAR 6.0 ODP release. This is a script version of dynamic DPRC creation steps mentioned in Steps For Dynamic DPRC Suitable For AIOP Tool Using restool on page 540.
2. VFIO support in Linux kernel
   - AIOP is a hardware device which AIOP Tool attempts to access from Linux userspace. For exchanging information between AIOP Tool and AIOP, a secure memory area is required which can be accessed by both. Linux VFIO or Virtual Function I/O, provides a framework for securely exposing certain memory area which is equally accessible by AIOP Tool and AIOP hardware. VFIO would map the addressing understood by AIOP hardware to that of addressing managed by user-space application.

- This application assumes that the `dpaiop` device would be mapped into VFIO driver so as to use DMA mapping between AIOP Tool and AIOP hardware and for pushing SMMU addresses for AIOP hardware's access to user-space memory
- Refer Sample VFIO Binding Script on page 540 for a sample script to perform binding of a DP object with VFIO.

3. Valid AIOP image for loading
   - For sample, refer to `cmdif_integ_dbg.elf` image provided along with '`aiopsl`' repo. This can be verified using GPP application `odp_cmdif_demo` in ODP.

6.14.2.5.2 Environment setting

For executing the AIOP Tool, a valid DPRC is required. There are three ways to define a DPRC:

1. Provide DPRC through '`-g`' command line tool. For e.g., `aiop_tool <sub-command> -g dprc.4`.
2. If not provided through command line, the binary expects the environment variable `DPRC` defined.
3. If neither an argument nor environment variable is provided, binary assumes a default value of DPRC as `dprc.5`. (Current hard-coded in the code)

6.14.2.5.3 Command line arguments

All variants of the execution follow a standard pattern:

```
aiop_tool <sub-command> <Arguments>
```

`<Sub-command>` includes `help`, `load`, `gettod`, `settod`, `status` and `reset`.

`<Arguments>` are either mandatory (for e.g., image file path), or optional (for e.g., DPRC name).

All variants assume that the VFIO binding has already been performed on the command line for the DPRC on which command would be executed. Further, following samples/snippets assume that DPRC would be passed on command line, though all three methods mentioned in Environment setting on page 535 are valid.

Following table describes all the variants of the AIOP Tool execution.

Argument/command pattern	Description
`aiop_tool` **`help`**	Displays help including various sub-commands and their output.

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Argument/command pattern</th><th>Description</th></tr>
<tr><td><code>aiop_tool load</code></td><td>Loading a valid ELF image onto the AIOP and starting it.
Valid arguments are:
<table>
<tr><td>-g <DPRC name></td><td>Name of the DPRC containing the AIOP object. This is a non-root DPRC which is dedicated to the AIOP Tool.</td></tr>
<tr><td>-f <aiop image file></td><td>[Mandatory] Name, with path, of the AIOP image file to be loaded on the AIOP</td></tr>
<tr><td>-r</td><td>[Optional] Reset toggle; If provided, AIOP Tool will perform reset of AIOP before attempting load. By default, this would not be done.</td></tr>
<tr><td>-v</td><td>Verbose Output (More informative with INFO level messages)</td></tr>
<tr><td>-d</td><td>Debug Output (DEBUG level messages)</td></tr>
</table>Following is the expected output of the command:
• In case of incorrect parameters (incorrect DPRC, wrong file path, or incorrect parameter), failure would be reported along with help usage.
• Success of failure, as reported by MC’s API; the AIOP Tool would convert the error into a readable string.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Argument/command pattern</th><th>Description</th></tr>
<tr><td>aiop_tool gettod</td><td>Obtaining the Time of day on the AIOP.
Valid arguments are:<table><tr><td>-g <DPRC name></td><td>Name of the DPRC containing the AIOP Object. This is a non-root DPRC which is dedicated to the AIOP Tool.</td></tr><tr><td>-v</td><td>Verbose Output (More informative with INFO level messages)</td></tr><tr><td>-d</td><td>Debug Output (DEBUG level messages)</td></tr></table>Following is the expected output of the command:
In case of incorrect parameters (incorrect DPRC), failure would be reported along with usage help.
Time of day (64Bit value) as returned by MC’s API in case of success.<pre>Time of day: 184082</pre>
Failure, as reported by MC’s API; the AIOP Tool would convert the error into a readable string.</td></tr>
<tr><td>aiop_tool settod</td><td>Set time on the AIOP.
Valid arguments are:<table><tr><td>-g <DPRC name></td><td>Name of the DPRC containing the AIOP Object. This is a non-root DPRC which is dedicated to the AIOP Tool.</td></tr><tr><td>-t sec_since_epoch</td><td>[Mandatory] Time, in milli-seconds, since epoch.</td></tr><tr><td>-v</td><td>Verbose Output (More informative with INFO level messages)</td></tr><tr><td>-d</td><td>Debug Output (DEBUG level messages)</td></tr></table>Following is the expected output of the command:
In case of incorrect parameters (incorrect DPRC, non-integer time), failure would be reported along with usage help.
Success of failure as reported by MC’s API; the AIOP Tool would convert the error into readable string.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Argument/command pattern</th><th>Description</th></tr>
<tr><td>aiop_tool status</td><td>Valid arguments are:
<table><tr><td>-g <DPRC name></td><td>Name of the DPRC containing the AIOP Object. This is a non-root DPRC which is dedicated to the AIOP Tool.</td></tr><tr><td>-v</td><td>Verbose Output (More informative with INFO level messages)</td></tr><tr><td>-d</td><td>Debug Output (DEBUG level messages)</td></tr></table>
Following is the expected output of the command:
• In case of incorrect parameters (incorrect DPRC), failure would be reported along with usage help.
• Status, including current state, SL version.
<pre>AIOP running status:
  Major Version: 2, Minor Version: 1
  Service Layer:- Major Version: 0,
Minor Version: 7, Revision: 0
  State: DPAIOP_STATE_RUNNING</pre>• Success of failure as reported by MC’s API; the AIOP Tool would convert the error into readable string.</td></tr>
<tr><td>aiop_tool reset</td><td>Reset the AIOP. This is current feature support, dependent on support by hardware.
Valid arguments are:
<table><tr><td>-g <DPRC name></td><td>Name of the DPRC containing the AIOP Object. This is a non-root DPRC which is dedicated to the AIOP Tool.</td></tr><tr><td>-v</td><td>Verbose Output (More informative with INFO level messages)</td></tr><tr><td>-d</td><td>Debug Output (DEBUG level messages)</td></tr></table>
Following is the expected output of the command:
• In case of incorrect parameters (incorrect DPRC), failure would be reported along with usage help.
• Success of failure as reported by MC’s API; the AIOP Tool would convert the error into readable string.</td></tr>
</table>

6.14.2.5.4 Command execution samples

1. Obtaining status of AIOP

```
$ aiop_tool status -g dprc.4
AIOP running status:
  Major Version: 0, Minor Version: 0
  Service Layer:- Major Version: 0, Minor Version: 0, Revision: 0
  State: DPAIOP_STATE_RESET_DONE
```

   Before loading the image, for this version where hardware Reset operation is not supported, the state DPAIOP_STATE_RESET_DONE can be verified using above example.

2. Loading an ELF image on AIOP

```
$ aiop_tool load -g dprc.4 -f cmdif_integ_dbg.elf
AIOP Image (cmdif_integ_dbg.elf) loaded successfully.
```

   The `load` sub-command loads as well as runs an AIOP. Once the image has been loaded, after a few seconds, the status output would look similar to:

```
$ aiop_tool status -g dprc.4
AIOP running Status:
  Major Version: 2, Minor Version: 1
  Service Layer:- Major Version: 0, Minor Version: 7, Revision: 0
  State: DPAIOP_STATE_RUNNING
```

3. Get time of day from AIOP

```
$ aiop_tool gettod -g dprc.4
Time of day: 184082
```

4. Set time of day on AIOP

```
$ aiop_tool gettod -g dprc.4 -t 100010
<No output, if successful>
```

6.14.2.6 Known Limitations

1. Current hardware revision doesn't support Reset operation for AIOP. This restriction enforces that for loading an image through AIOP Tool, the state of the AIOP should be `DPAIOP_STATE_ RESET_DONE`.
2. It assumed that the DPRC passed to AIOP Tool has a single AIOP (`dpaiop`) and MC portal (`dpmcp`). This application would parse the contents of DPRC and stop on first found instances of `dpaiop` and `dpmcp` – even if multiple instances have been defined. The order of finding would be dependent on how objects are parsed from the sysfs directory.
3. Due to a limitation of the MC API, AIOP Tool instance doesn't automatically exit once executed (not a run-to-completion model). As soon as the AIOP image is successfully loaded, the AIOP Tool application will keep looping without relieving the foreground shell. Following are some consequences of this limitations:
   a. Once executed, the AIOP Tool application sits in foreground without releasing the Linux Shell it ran on. To obtain the Linux shell on which AIOP Tool was executed, AIOP Tool application should be pushed into background (or started in background) through Linux shell semantics.
   b. Once executed and backgrounded, another instance of the AIOP Tool over same DPRC cannot be executed. This also implies that status requests for the AIOP cannot be done, either through same instance or through another instance of the application. To obtain the AIOP status, use other available methods.

6.14.2.7 Sample VFIO Binding Script

```
#/*
# * Sample bind script for VFIO.
# */

DPRC_4=/sys/bus/fsl-mc/devices/dprc.4

if [ -e /sys/module/vfio_iommu_type1 ];
then
    echo "#1) Enabling interrupts"
    echo 1 > /sys/module/vfio_iommu_type1/parameters/allow_unsafe_interrupts
else
    echo "No VFIO support available."
    exit
fi

if [ -e $DPRC_4 ];
then
    echo "#1.1) dprc container driver override"
    echo vfio-fsl-mc > /sys/bus/fsl-mc/devices/dprc.4/driver_override
    echo "#1.2) Bind dprc.4 to VFIO driver"
    echo dprc.4 > /sys/bus/fsl-mc/drivers/vfio-fsl-mc/bind
fi

if [ -e /dev/vfio ];
then
    ls /dev/vfio/
else
    echo "No VFIO support available."
fi
```

6.14.2.8 Steps For Dynamic DPRC Suitable For AIOP Tool Using restool

Assuming that a DPL is available which has AIOP container defined in it, this section provides information and sample commands for creating a DPRC which is suitable for use with the AIOP Tool.

AIOP Tool expects a DPRC which contains at least one dpmcp and a dpaiop object. Further, the DPRC should be a non-root DPRC – so that user-space application (AIOP Tool) can access its content.

All the commands would be performed using `restool` compatible with the MC version for which AIOP Tool is targeted. The sample steps below assume that there are enough resources to create a MC portal (`dpmcp`) and the AIOP object (`dpaiop`).

1. Creating a new DPRC which is child object of root DPRC, `dprc.1`.

   ```
   $ restool dprc create dprc.1 --
   options=DPRC_CFG_OPT_SPAWN_ALLOWED,DPRC_CFG_OPT_ALLOC_ALLOWED,DPRC
   _CFG_OPT_IRQ_CFG_ALLOWED
   ```

   The output would be similar to:

   ```
   dprc.2 is created under dprc.1
   ```

   Note the new DPRC name, `dprc.2`, in the above output sample. Steps hereafter assume that new DPRC is `dprc.2`; please replace DPRC name in subsequent steps where required.

State of newly created DPRC can be confirmed using following command:

```
$ restool dprc info dprc.2
```

Output would be similar to:

```
container id: 2
icid: 26
portal id: 3
version: 5.1
dprc options: 0x43
DPRC_CFG_OPT_SPAWN_ALLOWED
DPRC_CFG_OPT_ALLOC_ALLOWED
DPRC_CFG_OPT_IRQ_CFG_ALLOWED
```

2. *In case dpaiop object already exists in any DPRC, skip to Step 3 below.* The steps below are for creating a `dpaiop` object in the `dprc.1`. This requires information about the AIOP container (`dprc.3` has been assumed below).

```
$ restool dpaiop create --aiop-id=0 --aiop-container=dprc.3
```

In the above command, it is assumed that the AIOP container is dprc.3. The output would be similar to:

```
dpaiop.0 is created under dprc.3
```

The `dpaiop.0` object would be available in the `dprc.1` after this command.

3. Assuming that a `dpaiop` object, `dpaiop.0`, is available in the root `dprc.1`; Unplug the `dpaiop.0` in the `dprc.1` so that it can be assigned to a new DPRC.

```
$ restool dprc assign dprc.1 --child=dprc.1 --object=dpaiop.0 --
plugged=0
```

Check the status of dpaiop.0 object using

```
restool dprc show dprc.1
```

to confirm if it has been put in '`unplugged`' state. If `dpaiop` object is already part of another DPRC, it has to be assigned to unplugged and assigned to `dprc.1` before it can be assigned to a targeted container. Steps for that would be similar to:

Unplugging the dpaiop object state

```
$ restool dprc assign <dprc.X> --object=dpaiop.0 --plugged=0
```

Above command sample assumes dpaiop.0 is present in `dprc.X` Thereafter, move the dpaiop.0 object to dprc.1

```
$ restool dprc unassign dprc.1 --child=dprc.X --object=dpaiop.0
```

Hereafter, `dpaiop.0` is available in `dprc.1` to be moved to a target DPRC – as described in steps below.

4. Assign the `dpaiop.0` object to `dprc.2` and toggle state to `plugged`. This would work only if `dpaiop.0` is already unplugged in root DPRC.

```
$ restool dprc assign dprc.1 --child=dprc.2 --object=dpaiop.0 --
plugged=1
```

Check the status of `dpaiop.0` object using

```
restool dprc show dprc.2
```

to confirm if it has been put in 'plugged' state.

5. Create a new MC portal object

```
$ restool dpmcp create
```

This result in an output similar to:

```
dpmcp.4 is created under dprc.1
```

New MC portal dpmcp.4 has been created under root DPRC. This needs to be moved to dprc.2 – as shown in next step.

NOTE

Note: It is possible to re-use an existing MC portal using steps similar to those shown below. It is possible that dpmcp object is already bound to certain driver (for e.g. VFIO driver), in which case, it needs to be unbound before being moved out.

6. Move dpmcp.4 from dprc.1 to dprc.2 and move to 'plugged' state.

```
$ restool dprc assign dprc.1 --child=dprc.2 --object=dpmcp.4 --
plugged=1
```

Check the status of dpmcp.4 object using

```
restool dprc show dprc.2
```

to confirm if it has been moved into dprc.2 and put into 'plugged' state.

7. Confirm that both the objects, dpmcp.4 and dpaiop.0, are part of dprc.2

```
$ restool dprc show dprc.2
```

Output would be similar to:

```
dprc.2 contains 2 objects:
object       label      plugged-state
dpaiop.0                plugged
dpmcp.4                 plugged
```

Hereafter, the DPRC dprc.2 is ready to be used with AIOP Tool once VFIO binding is done. See Sample VFIO Binding Script on page 540 above for information on VFIO binding.

6.14.4 AIOP Program Profiling

6.14.4.1 Overview

This document describes techniques for performance enhancements for software developed for AIOP. The reader should understand basic AIOP architecture and service layer API.

The structure of this document is the following:

- Explain the performance capabilities and limits of different processing elements of AIOP that should be taken into account at design time and in optimization time.
- Specific methods for identifying bottlenecks for different processing elements and memory subsystem

Readers should also have access to the CodeWarrior Development Studio for Advanced Packet Processing product inside a larger software suite called CodeWarrior Development Suites for Networked Applications (CW4NET), which includes the AIOP Analysis Tool and Scenarios tool.

AIOP Analysis Tool trace examples are used throughout this document. Users should be familiar with this tool since it is regularly used to debug and profile AIOP. Meanwhile, the Scenarios Tool is crucial when measuring memory bandwidth.

6.14.4.2 AIOP Program Design: Budgets Per Processing Elements

AIOP developers must consider the available capacity for each hardware element and design their programs accordingly.

For example, the LS2085A AIOP has 16 cores running at 800 MHz. This means that 800 x 16 = 12,800 million core cycles per second are available.

If instructions per cycle (IPC) is about 0.75 for each core, cores can execute about 10,000 million instructions per second. In order to handle 10 million frames per second, a budget of 1,000 instructions per each frame is available.

In order to achieve 17 million packets per second (MPPS) (which is approximately line rate for 2 x 10GE for 128-byte packet), maximum 588 instructions can be used to process a packet.

The Performance Capacity per Resource table below shows performance budgets for some AIOP operations.

Table 113. Performance Capacity per Resource

	Use case and other Information	**Performance capacity – Rev1**
Cores	16 x 800 MHz MCPS (million cycles per second) x 0.75 IPC = 9600 Instraction per second	16x800Mhz
OSM (Ordering Scope Manager)	Enter/exit pair, transitions	80 MOPS (million operations per second)
TMan (Timers Manager)	Timer commands per second (assuming 10M timers)	1 M [Timer fires/sec]
	Timer tasks initiated per second (assuming 10M timers)	1 M [commands/sec]
STE (Stats Engine)	Number of STE commands per second	68 M [commands/sec]
CDMA/FDMA (Context/Frame DMA)	17 MPPS packet presentations/ enqueues with 3 CDMA operation combined	
Tables	Exact Match (EM) key size up to 124 B;	51 MOPS

Table continues on the next page...

Table 113. Performance Capacity per Resource (continued)

	LPM key sizes, 4 byte EM + 4 byte LPM (IPv4) or 4byte EM + 16 byte LPM (IPv6)	17 MOPS
	Management commands on a 10 K rules balanced tree on PEB	500 K [commands/sec]
	Total 5 lookups at 17 MPPS: 3 Exact Match + 1 LPM + 1 MFLU	
	17 MOPS. ACL key size up to 56 B	17 MOPS
Parser	Max parser performance capacity	34 MOPS
	Max accesses to CTLU at 17 Mpps, including parser	6
	Typical use case at 17 Mpps	5 lookups + 1 parser

6.14.4.3 AIOP Program Profiling and Performance Tuning

AIOP programs have tight performance requirements and developers need to profile their applications in order to improve their performance characteristics.

There are two stages in profiling AIOP applications:

1. Finding bottlenecks in the application
2. Fixing bottlenecks found for each specific application

An AIOP task is a sequence of jobs executing on different processing elements. The performance of the overall task is dictated by the performance of the weakest element, which makes the weakest element a bottleneck of the application.

Take for example a task that involves receiving a frame, doing a look up, and sending the frame to another interface.

This task uses the core, FDMA, CDMA and TLU processing elements. Assuming that the core is going to run for 1000 cycles per task and that the task has 2 FDMA jobs, 2 CDMA jobs and one LPM CTLU job, how many tasks per second can the AIOP handle?

To answer this question, calculate the number of jobs each processing element can handle. Use the following assumptions to solve the example above:

- 16 cores running at 800 MHz
- Based on table for rev1, we can see that AIOP can perform 17 million of operations of 3 FDMAs + 2 CDMAs per second
- CTLU can perform 17 million LPM lookups per second

Because there are 16 x 800 MHz = 12,800 million cycles per second, 12,800/1,000 = 12.8 million tasks per second can be processed.

FDMA/CDMA: 17 millions per second = throughput of 17 million tasks

CTLU: 17/1 = throughput of 17 million tasks

Based on this analysis, the estimated maximum performance boundary for this application will be 12.8 tasks per second and its bottleneck is core performance. We do not take into account other possible artifacts, such as synchronization constrains etc. just for simplification of initial analysis.

The analysis above is very useful for initial estimation during the design and implementation stages as it allows the programmer to design the program with specific performance goals in mind. For more information on performance

characteristics of different processing elements see AIOP Program Design: Budgets Per Processing Elements on page 543.

Installing the AIOP Analysis Tool

In order to find bottlenecks within applications, AIOP tools are used; one in particular is the AIOP Analysis Tool.

The AIOP Analysis Tool is a component of CodeWarrior Development Studio for Advanced Packet Processing product inside a larger software suite called CodeWarrior Development Suites for Networked Applications (CW4NET). The AIOP Analysis Tool is available for download on the NXP Semiconductors website.

To download the AIOP Analysis Tool, click on the "Downloads" tab and under "CodeWarrior Development Studio for Advanced Packet Processing", select "Latest Version". Click on "CodeWarrior for Advanced Packet Processing Evaluation / Updates" and download the installer. After the download is complete, run the installer:

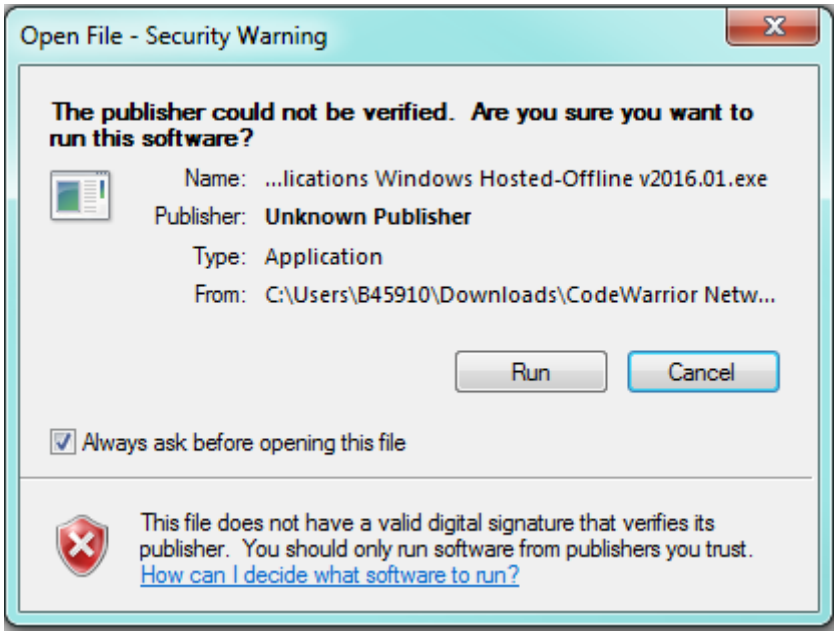

Figure 41. CodeWarrior for Networked Applications Installer

After running the installer, follow the Setup Wizard and Click "Next":

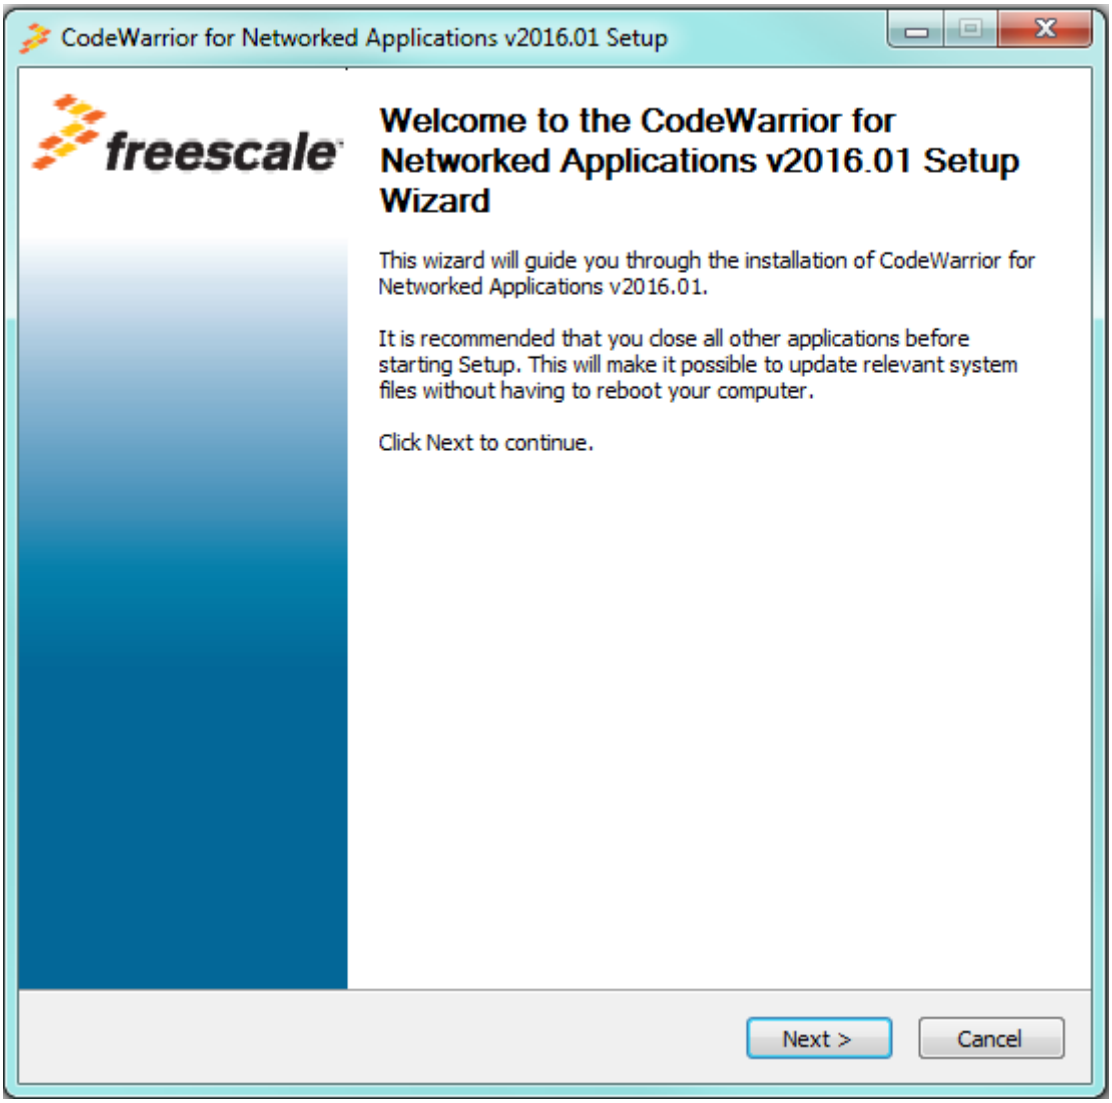

Figure 42. CodeWarrior for Networked Applictions Setup Wizard

The AIOP Analysis Tool has to be selected within the components to install. After confirming the selection, the installer will download the tools automatically according to the selection:

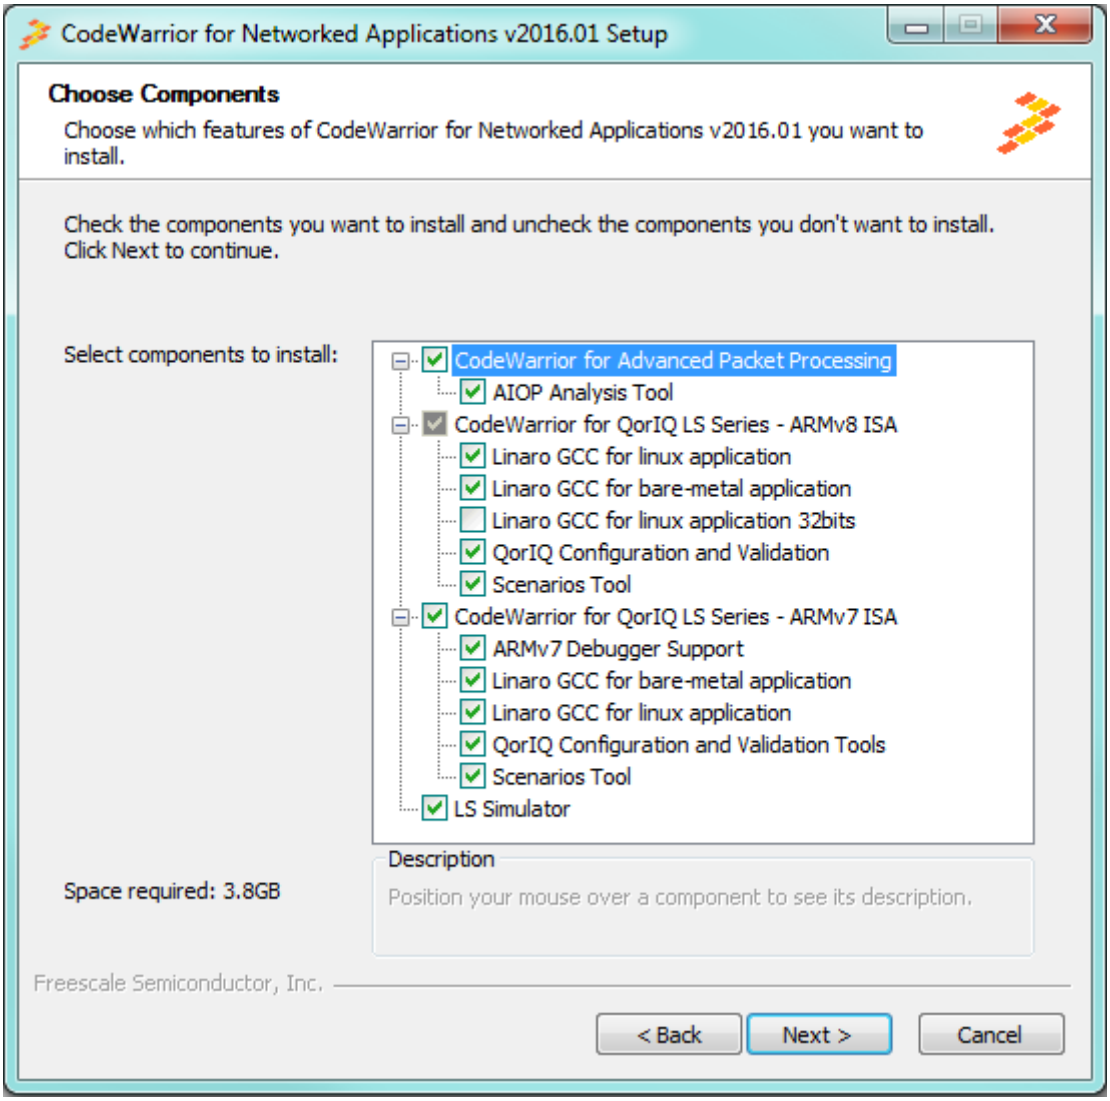

Figure 43. CodeWarrior for Networked Applictions Tool Selection

For more information, please refer to the CodeWarrior Development Studio for Advanced Packet Processing.

Bottleneck analysis of existing application

This section explains in detail how to find bottlenecks within applications using the AIOP Analysis Tool. This tool captures the scheduler trace, presents it in graphical way and provides some statistics based on this trace.

The figure below shows a code snippet and its associated trace for a simple reflector program:

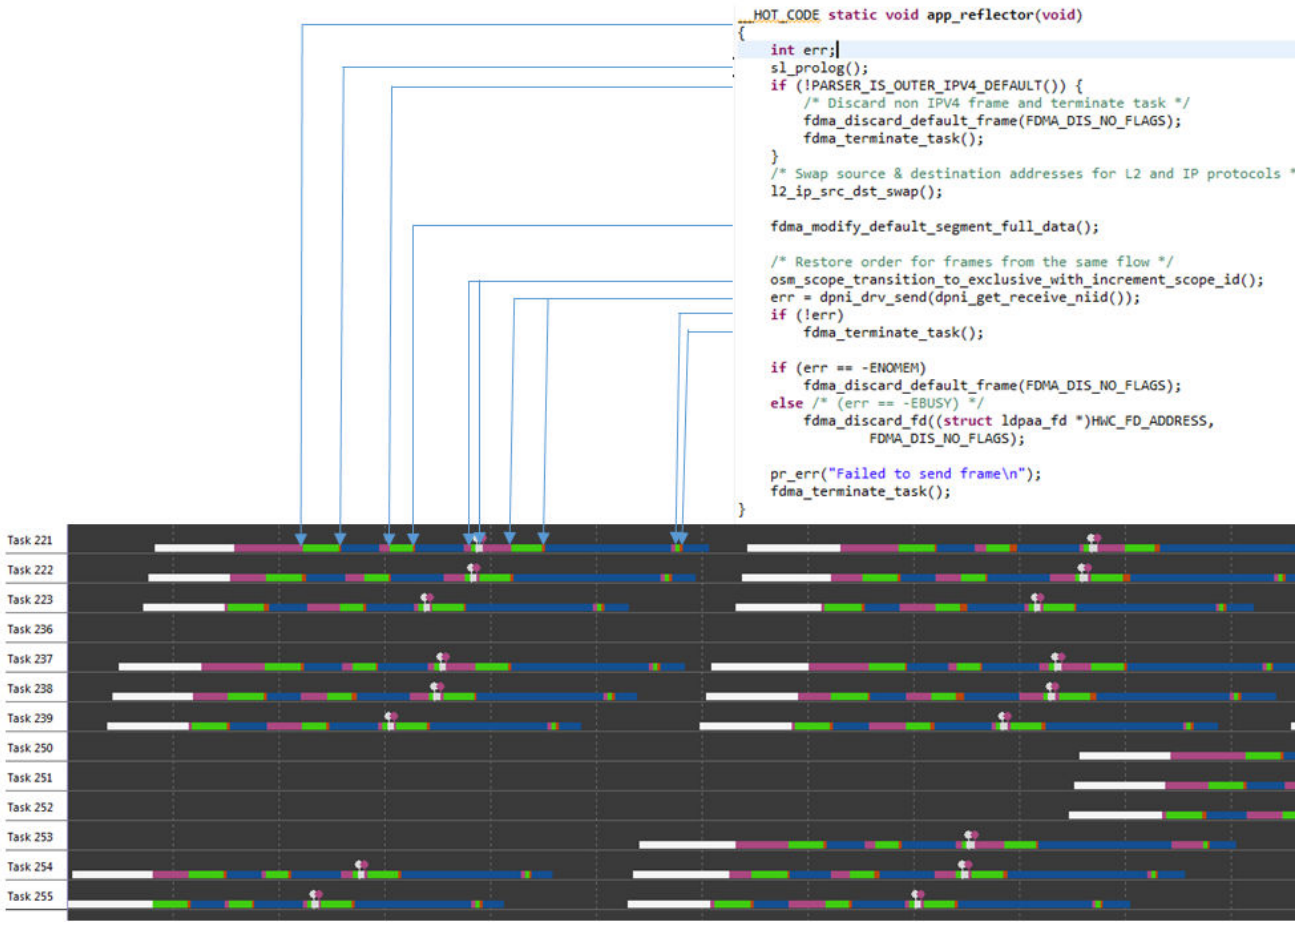

Figure 44. Trace of Reflector Application

The trace measures the length of each job in the task and shows the utilization of resources. (hover the mouse to highlight a specific job):

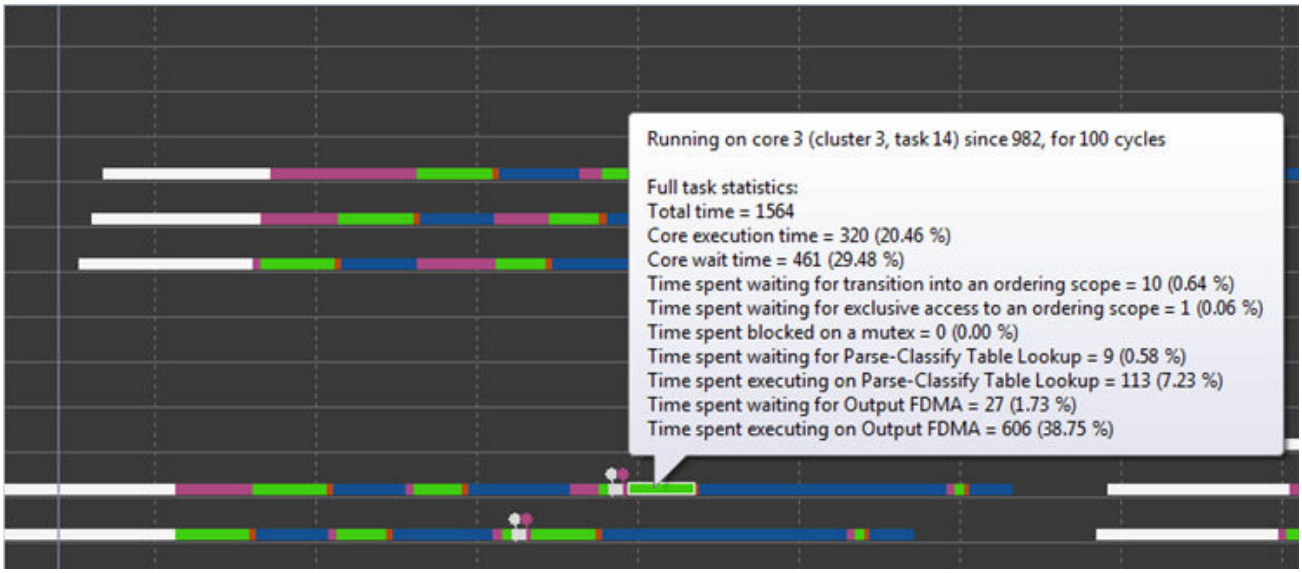

Figure 45. Task Information

What is the bottleneck of this application? In the following sections, we will show how you can find bottlenck based on this trace

6.14.4.4 FDMA/CDMA

The implementation of the CDMA/FDMA module is the following:

- FDMA and CDMA are actually one hardware block sharing the same resources.
- Thread = an FDMA/CDMA context which executes job on behalf of a task. 64 are present in rev1.
- Foreground slot = a HW execution resource that is loaded with a thread (and its context) in order to perform work on the thread (execute its command). 16 are present in rev1.
- Background slot = a HW resource that holds a suspended thread. This is a thread that is assigned (from a software point of view), but is blocked waiting for a high latency action to complete.
- Thread switching = moving FDMA threads between foreground (execution) and background (suspended) slots.

In the trace window we can see the number of assigned threads. This number is not precise due to how we measure it, but it can provide a good estimate.

Table 114. FDMA/CDMA Jobs

Core 13	63.12% Utilization
Core 14	63.97% Utilization
Core 15	63.23% Utilization
PC-CTLU	1.43 job average
TL-CTLU	11.86 job average
P.FDMA	3.65 job average
CDMA	20.91 job average
O.FDMA	10.49 job average
Total tasks	167
Tasks created	9,060,691.863 tasks/sec
Tasks finished	8,666,748.738 tasks/sec

We see here that the following number of threads are utilized:

1.43 + 11.86 + 3.65 + 20.91 + 10.49 = 48.34

48 is smaller than 64 so we are not running short of number of FDMA/CDMA threads.

Example of overall task analysis

Here we look at task trace of a reflector application and and analyzing it trying to find a bottlneck.

First, determine how many tasks are executing in parallel with the AIOP by looking at the following trace:

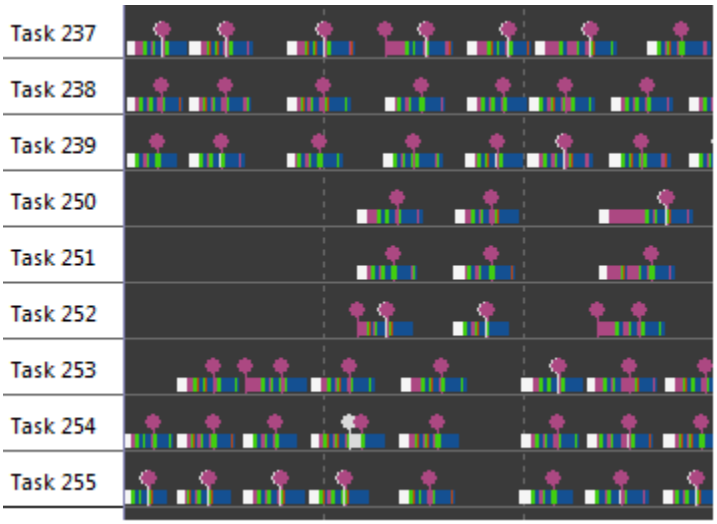

Figure 46. Trace Analysis

For simplicity we show only snapshot of tasks with higher numbers. Task scheduler begins scheduling with those tasks as well. Trace tool only shows tasks that were active at some point.

On core 15, only 6 tasks (Task 250 to Task 255) are executing, instead of 16 tasks. There are two possible reasons for this:

- The AIOP is underutilized; not enough traffic is sent to it.
- The FDMA/CDMA is a bottleneck as *only FDMA/CDMA can push back* to the work scheduler.

If enough traffic is sent to saturate the AIOP, but not all AIOP tasks are utilized, then the FDMA/CDMA is the bottleneck of your application.

Bottlenecks caused by CDMA/FDMA:

- Run out of Foreground slots. This may happen when memory becomes very congested and the CDMA waits for transactions for a long time. This bottleneck can be identified by looking at the average number of CDMA/FDMA jobs. If this number is close to the number of threads, then the bottleneck is within the CDMA/FDMA.
- Runs out of Threads. This happens when all CDMA/FDMA foreground slots are busy executing. This condition rarely happens as the previous condition happens first.

Strategies for reducing FDMA/CDMA bottlenecks

- Reduce the size of the initial presentation. The FDMA block is sensitive to presentation size; reducing presentation size from 128 to 64 Bytes may significantly reduce the pressure on the FDMA. For example, the figure below shows that task creation job (which is using FDMA) for 64 Byte presentation takes 233 cycles, while a 128-Byte presentation can take over 500 cycles. For IPv6 frames (or for any bigger header frames), initially present a bigger area or re-represent more data after determining that one is dealing with an IPv6 frame.

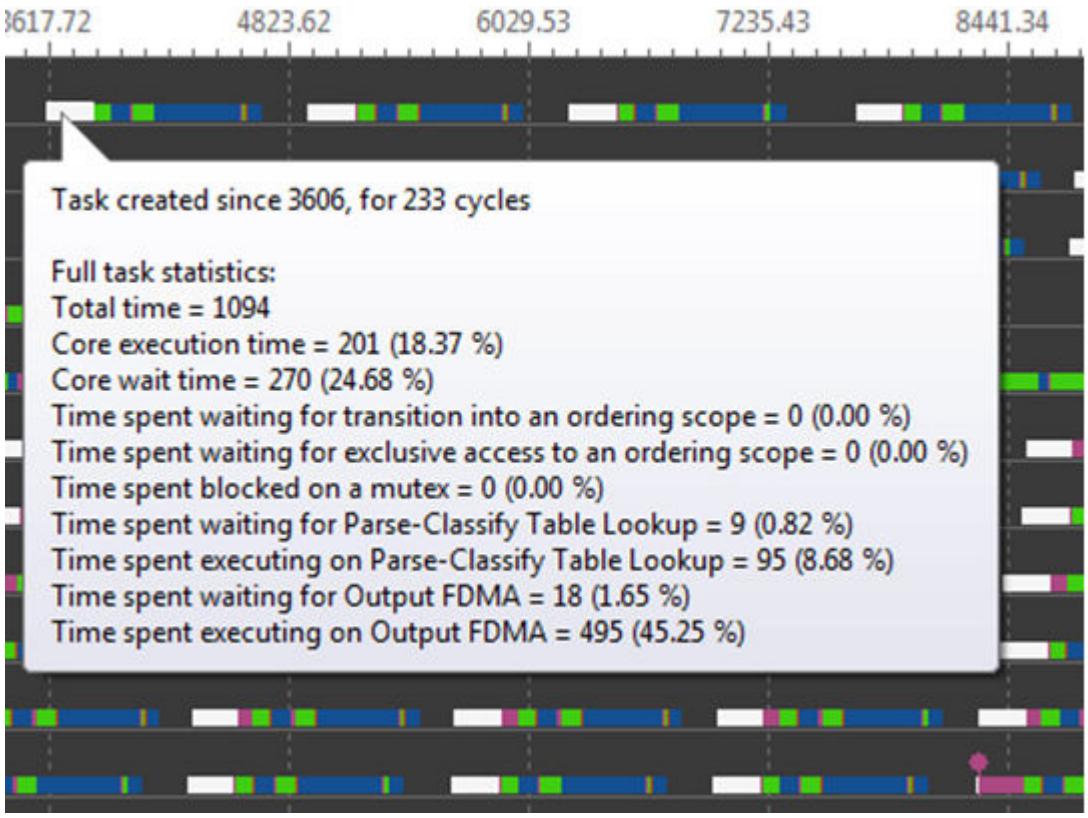

Figure 47. Task Creation Job Using FDMA

- Reduce the number of CDMA calls. Look for opportunities to combine one or more reads or writes. This will reduce pressure on the CDMA block and memory. For example, when reading two integers, a and c, in struct such as:

```
struct {
int a;
int b;
int c;}
```

  It is better to read both integers in one read, even if that means also reading c.

- Mutex – Mutex on rev1 can be called 12 million times per second when multiple Mutex IDs are used and about 5 million times per second if a single ID is used.
- Try to align and pack all CDMA accesses. For example, when reading 64 bytes of data per packet, place it in DDR memory with a 64-byte alignment. In any case, try not to cross 64-byte boundaries when possible, as it will cause two accesses instead of one.
- Allow sufficient headroom for frame changes (inserts). There is an API that can override some parameters in the default storage profile, which should be called during the early initialization stage dpni_drv_register_rx_buffer_layout_requirements().
- Call once for multiple changes. For example multiple changes in a frame header can be made using a single FDMA call.
- Do not represent segments (for example frame data segments) when possible.
- While a frame is open for the AIOP task, it may be edited with FDMA commands, but the changes may not be visible to consumers outside the AIOP. There is no need to do an FDMA store command unless those updates must be visible to consumers outside the AIOP (e.g. an external memory).
- Some FDMA commands have options to encapsulate other commands, creating compound commands. Use compound commands when appropriate. See the table below.

Table 115. FDMA Compound Commands

Command	Combined Options
Present (open) Frame	Present frame data segment
Enqueue Frame	Terminate task Discard frame (when enqueue fails) Relinquish OSM exclusivity in current scope right after the enqueue to QMan is issued
Replace Segment Data	Represent Segment Data Close segment
Concatenate Frames	Close concatenated frame
Split Frame	Close new frame Present new frame data segment
Replicate Frame	Enqueue new frame, optionally Relinquish OSM exclusivity Discard source frame

6.14.4.5 Core Profiling

Strategies for reducing core bottlenecks

Core bottlenecks are easily identified by examining the core load in the trace tool. If the core load gets close to 100% percent, it means that the bottleneck is core cycles. Generally, it is a good problem to have after the final optimization stage as the core is the most valuable resource. If the application has a bottleneck with the core, that means the core is being used to its maximum. This table is an example of usage of trace tool for core profiling:

Table 116. Core Utilization

Range Time	1118954.00 cycles
Core 0	99.60% Utilization
Core 1	83.13% Utilization
Core 2	93.11% Utilization
Core 3	99.61% Utilization
Core 4	99.62% Utilization
Core 5	86.42% Utilization
Core 6	83.14% Utilization
Core 7	89.74% Utilization
Core 8	86.37% Utilization
Core 9	86.43% Utilization

Table continues on the next page...

Table 116. Core Utilization (continued)

Core 10	83.15% Utilization
Core 11	89.72% Utilization
Core 12	86.43% Utilization
Core 13	89.68% Utilization
Core 14	89.83% Utilization
Core 15	99.92% Utilization

Example task analysis for core utilization

What can be done to resolve this problem?

First, look at the trace, identify all core jobs and check that job lengths are reasonable and expected. If you find something not expected, examine code that is executed for this job and try to find ShRAM accesses, make sure code is running from iRAM (for performance sensitive code), no accesses to PEB, DDR or regicters are made in your code. Access to DDR can take up to 200 cycles and should be avoided.

It is a good idea to measure IPC of your program so that you know that it is in a reasonable range. We use scenario tool to measure it on AIOP. In order to measure IPC directly in a running program, open the following scenario: `aiop_throughput_IPC_ssram_access` (*warning: you must disable run-time stack check in AIOP by undefining STACK_OVERFLOW_DETECTION as this feature is utilizing the same resources as this scenario)*

The IPC for each core is measured based on the following formula:

INSTR_COMPLETED / (PLATFORM_CLK - CTS_NO_TASK_CYCLES)

Based on the formula, divide the *number of instructions completed by each specific core* by the *number of cycles that core was executing tasks* (was not idle).

After measurement, the result is similar to the figure below:

IPC:core0	IPC:core1	IPC:core7	IPC:core8
0.58505	0.584909	0.584624	0.584829
0.585066	0.584925	0.584643	0.584851
0.585033	0.584884	0.584592	0.584803
0.585045	0.584917	0.584611	0.584821
0.585035	0.584905	0.584606	0.584838
0.585051	0.584911	0.584616	0.584803
0.585045	0.584902	0.58462	0.584821
0.58505	0.584915	0.584626	0.584822
0.585058	0.584908	0.584635	0.58484
0.585043	0.584924	0.584619	0.584834

Figure 48. Example IPC for Each Core

Generally, if the IPC is lower than 0.70, we need to investigate why. One of the most common reasons for low IPC would be accessing ShRAM (Shared SRAM) in the program. However if the resulting IPC is a really low number, then the code must not be running from IRAM.

Here is how one can calculate the approximate IPC based on number of ShRAM accesses and accelerator calls. In the previous scenario, we can look at following data:

Instructions per packet	Shared SRAM accesses per packet	Accel calls per packet
198	10	4
198	10	4
198	9.99998	4
198	10	4
198	9.99999	4
198	10	4
198	9.99999	4
198	10	4
198	10	4
198	9.99999	4
198	10	4
198	10	4

Figure 49. Packet Information: ShRAM Accesses and Accelerator Calls

The formula below was used to approximate the number of cycles spent by the core as a function of the number of ShRAM accesses, accelerator calls, and instructions executed.

N_Core_Cycles = (N_Instr * CPI) + (N_ShRAM * 12) + N_Accel_Calls * 4

In our case we get:

N_Core_Cycles = 198 * 1 + 10 *12 + 4*4 = 332

IPC ~ 198/332 = 0.596

For the example above, this low IPC is due to a high number of ShRAM accesses.

Improving core performance

- Inline the code where possible, especially for functions that are part of a “hot path”. Most of SL APIs are already in-lined.
- Reduce the number of accesses to shared memory. Shared memory has 12 cycles latency and 10 accesses will incur at least 120 cycles.
- Place all per-packet code in IRAM. For that, qualify such code with `__HOT_CODE`. For example:

```
__HOT_CODE uint64_t shbp_acquire(uint64_t bp, struct icontext *ic)
{
    struct shbp shbp;
    uint32_t offset;
    uint64_t buf;
    int err;
```

Figure 50. Example of `__HOT_CODE`

- Never place any performance sensitive code in DDR.
- Avoid floating-point operations and operands. The e200 core emulates floating-point operations/operands, which causes performance to be very low. Use fixed-point operations instead, when required.

- Use all available cores and maximize possible tasks per core. Typically, it will not be an issue to use all the cores, but using all tasks could be challenging sometimes because of stack size. If the stack requires more than ~1500 available entries to maximize the number of tasks, do the following:
  1. Run the stack static analysis tool and check where you use most of the stack
  2. Restructure your code, so that:

     `a() -> b() ->c()` chain that will require a lot of stack

     is replaced with the following:

```
a();
b();
c();
```

6.14.4.6 Memory profiling

AIOP programs may use different types of memories:

- external (DDR, PEB)
- internal (ShRAM, Workspace)

DP-DDR (DDR3 controller)

DDR memories are the first suspect to be oversubscribed. During the design stage of the system, developers should keep DDR bandwidth in mind.

The bandwidth of DP-DDR is 4 Bytes x 1.6 GHz = 6.4 GB/s

In a perfect situation where everything is aligned, accesses are all 32 bytes in length. However, this is not usually the case, but this number can provide a good starting point.

Example task analysis for DDR usage

So, let's assume we have context data in DP-DDR. It has 32 byte size and it accesses each frame with 17 MFPS.

We will get 32 x 17 MFPS = 544 MB/s, which is 544 MB/s / 6.4 GB/s = 8.5% of bandwidth

What happens when tables are placed into this memory?

The following is how look-up hardware accesses memories:

- LPM IPv4 takes 4*(1+alpha/2) memory accesses
- LPM IPv6 takes 6*(1+alpha/2) memory accesses
- EM takes (1+alpha/2) memory accesses

Alpha is the fill factor which goes from 0 to 1. The worst case condition is when alpha is 1. This means the tables fully utilize the CTLU memory.

Each access is 64 bytes.

Assume that the EM table has been placed in DP-DDR. Calculate the load on DP-DDR when running at 17 MFPS load.

The load will be:

1 x 64 x 17 MFPS / 6.4 GB/s = 0.17 = 17%

DP-DDR can safely be loaded up to 60%. However at 60% load, expect a spike in latency of DP-DDR. For example, it is impossible to place the LPM table there at 17 MFPS:

4 x 64 x 17 MFPS / 6.4 GB/s = 0.61 = 61%

Improving memory bottlenecks

Recommendations for table placement

The decision for each table placement should be made based on the following parameters:

1. Frequency—how often the table is accessed.
2. Size of the table—big tables will not fit in PEB.
3. Availability of bandwidth or place in specific memory.

Some guidelines:

- If DP-DDR is populated, it should be utilized as much as possible up to 60% of bandwidth, in order to reduce pressure on system DDR

For small tables that are used relatively frequently PEB could be the best candidate.

For System DDR, the L3 cache must be enabled in rev1.

For example:

Small (several hundred entries) ACL tables that are accessed per packet at a very high rate (millions times per second) should go to PEB memory.

Big LPM tables that are accessed infrequently should be placed in DP-DDR. The same table that is accessed higher than 60% DP-DDR utilization should be placed in System-DDR.

As a practical approach, we suggest not to use DP-DDR at the first stage of development and leave this optimization for later stages of development.

Recommendations for data placement

Data can be placed in several types of memory:

- System DDR
  - Direct access by core (not recommended) is ~200 cycles
- DP-DDR
  - Direct access by core (not recommnded) is ~200 cycles
- Shared RAM
  - ~10-15 cycles access
- PEB
  - ~40 cycles access by core (not recommnded)

When deciding about placement of different types of data, first consider how this data scales:

- Data scaling with number of flows
  - As number of flows is typically high (more than thousands), it should be placed in DDR
- Frequently accessed data that is scaling as number of interfaces or application instances
  - Such data should be placed in ShRAM (as statically defined data). Exceptions could be made for data that is accessed in bulk. In that case, place the data in PEB, so that it could be brought from DMA to local memory as a whole structure and then several data fields can be accessed with zero latency

6.14.4.7 CTLU - Parser

The CTLU or parser becomes a bottleneck of the application when tasks wait for the CTLU or parser for a long time. For example, the trace below shows this situation:

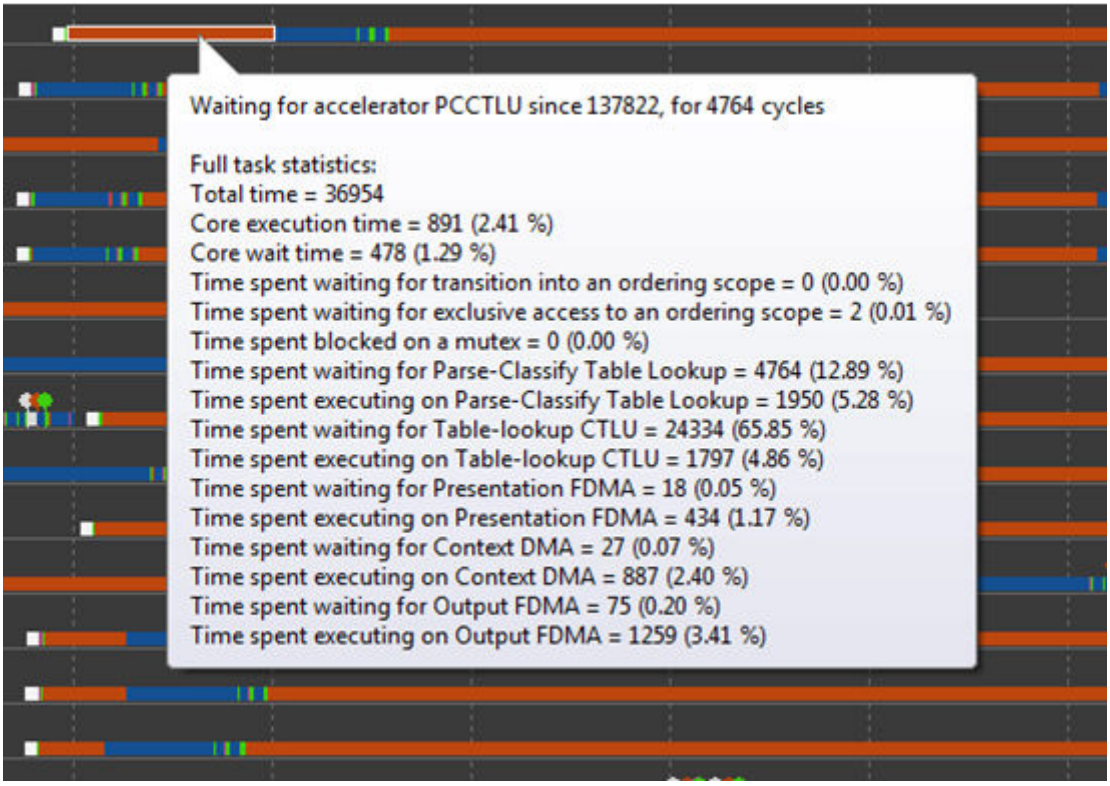

Figure 51. CTLU - Parser Bottleneck Example

Based on the trace above, it is evident that the wait time for the parser (PCCTLU - "Parse Classify CTLU") is very significant. The following are reasons for the long wait time:

- Too many calls to the parser/TLU
- The memory that the TLU works with experiences high load, which results in high latency. For memory issues, refer to the Memory profiling on page 555 section.

Example task analysis for CTLU usage

Improving CTLU bottlenecks

Listed below are some ideas on how to alleviate load on the parser:

- One of the features of DPNI is to calculate gross running checksum for ingress frames. So, when frame is received form by AIOP, it has associated valid gross running checksum. It is a checksum of the entire frame. Once we change frame data, the checksum becomes invalid unless we update it. If the parser is called with validation flags enabled, and the gross running sum was set to 0, it will first recalculate the gross running sum of the entire frame. When appropriate, do not invalidate (set to 0) the gross running sum field if the parser will later be called with the validation flags enabled.
- In case a VLAN header was added or removed, it is possible to call the software functions `parser_push_vlan_update()` or `parser_pop_vlan_update()` to update the workspace parse results instead of calling the hardware parser routines. This method should be used when the ratio of calls to the hardware parser routine is beyond the performance capacity. See the AIOP Program Design: Budgets Per Processing Elements on page 543 section.

6.14.4.8 OSM

It is assumed the reader is already familiar with the details of OSM operation and use. Here we are only concerned with refining the use of OSM to enable best performance. It is also assumed the reader has a basic familiarity with the AIOP analysis tool to view what is going on with task/job scheduling within the AIOP.

OSM is used to add order constraints on the scheduling of jobs of a task within the AIOP based on network ordering requirements of the packet being processed. Therefore the goal in optimizing performance when using OSM is to minimize how often the task scheduler will block a task's progress based on order constraints. In other words OSM *inhibits* jobs of a task from being scheduled and optimization minimizes the time it does so.

The image below demonstrates using the AIOP analysis tool to show how contention in an ordering scope looks like. The mouse when hovered over the pink bar in Task 251 shows additional information about this phase of a task execution. It shows in this example that the task was blocked for 1412 cycles because it needs exclusive phase of a particular ordering scope but it is blocked because other tasks are ahead of it.

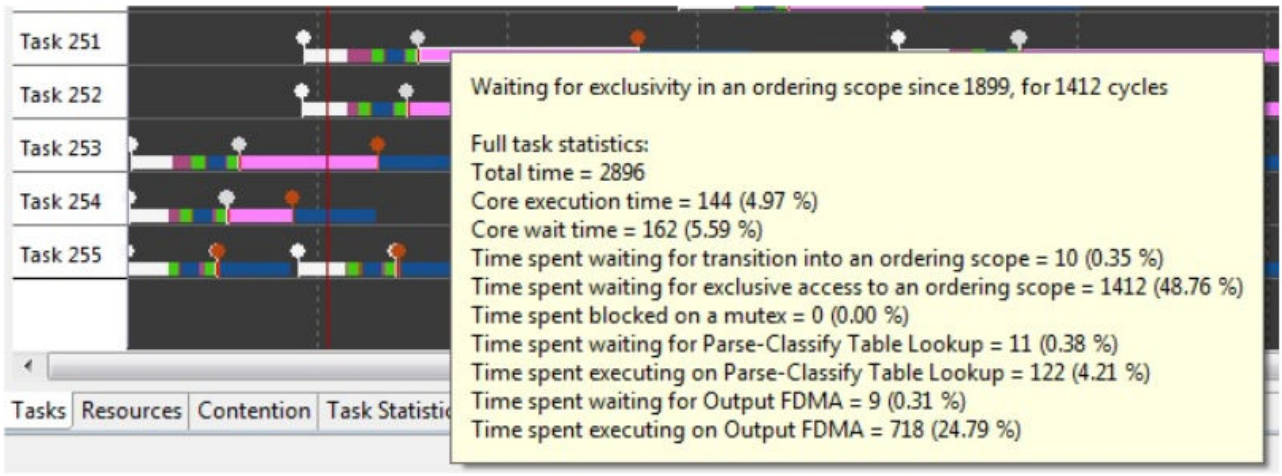

Figure 52. Task Waiting on Ordering

The obvious optimization here is to reduce the number of tasks in the same ordering scope at a given time and to minimize the time each of these tasks keeps the exclusive phase of any ordering scope. An optimized software design will do both as much as possible while remaining correct. Also in a perfect optimization, all tasks would be in different ordering scopes or all tasks would use zero cycles in the exclusive phases of an ordering scope but this is never possible. The AIOP analysis tool will help the software designer to gain experience in the practical use of ordering scopes.

Example task analysis for OSM

Consider a simple example of a task. This task extracts the destination IP address as a key and does a TLU lookup based on that key. The lookup result is a reference to system memory that contains an ARP table entry. The entry is copied from system memory to local workspace. A hit counter in the entry is incremented and the system copy updated to reflect that. The entry also contains a MAC address which is used to replace the destination MAC address in the packet received and then forwarded.

```
key.dst = _presentation_with_vlan.ipv4hdr.dst_addr;
key_desc.em_key = (void*)&key;
table_lookup_by_key(TABLE_ACCEL_ID_CTLU, tid_arp, key_desc, sizeof(struct simple_key),
&lookup_result);
cdma_read( (void*)&arp_entry, lookup_result.opaque0_or_reference, 16);
arp_entry.hits++;
cdma_write(lookup_result.opaque0_or_reference + offsetof(struct arp_entry, hits),
(void*)&arp_entry.hits, 8);
memcpy(&_initial_presentation.ethhdr.da, &arp_entry.mac, 6);
```

```
fdma_modify_default_segment_full_data();
fdma_store_and_enqueue_default_frame_fqid( DESTINATION_FQ, FDMA_EN_TC_TERM_BITS);
```

This is a made up example which does no error checking. Assume from this simple example that forwarded frame is required to be in the same order as the frame arrived on a network interface for any flow. This is not a very realistic example but it will suit the purpose of observing the performance when OSM operations are included.

The simple method to meet the order requirement in this application is to run all packets as if they are in a single flow (single common initial scope ID) and in exclusive mode for the duration.

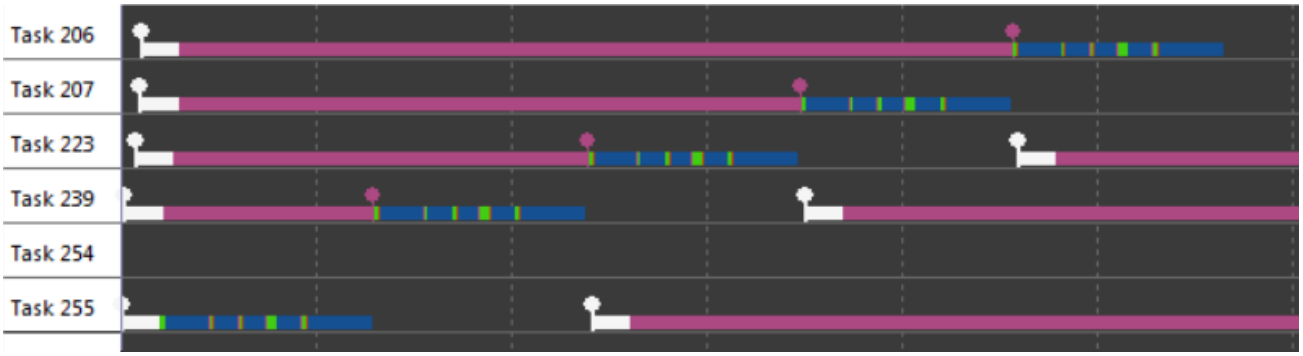

Figure 53. Tasks Executing Sequentially

A snapshot from the AIOP analysis tool shows the result of running all packets as if they are from a single flow in the exclusive phase of a common ordering scope. In this image, blue bars are hardware jobs, green are software jobs, and red is blocked. It is immediately obvious each packet is processed one at a time until done before a subsequent packet starts processing. This is the baseline to improve upon.

Spread based on flow

AIOP tasks will run in parallel more effectively if tasks of different flows begin in different initial scope IDs. In this way they, by definition, do not compete. To demonstrate this, the example of the previous section is repeated, all tasks start as exclusive, but now the packets come from 32 different flows and each flow defines an initial scope ID.

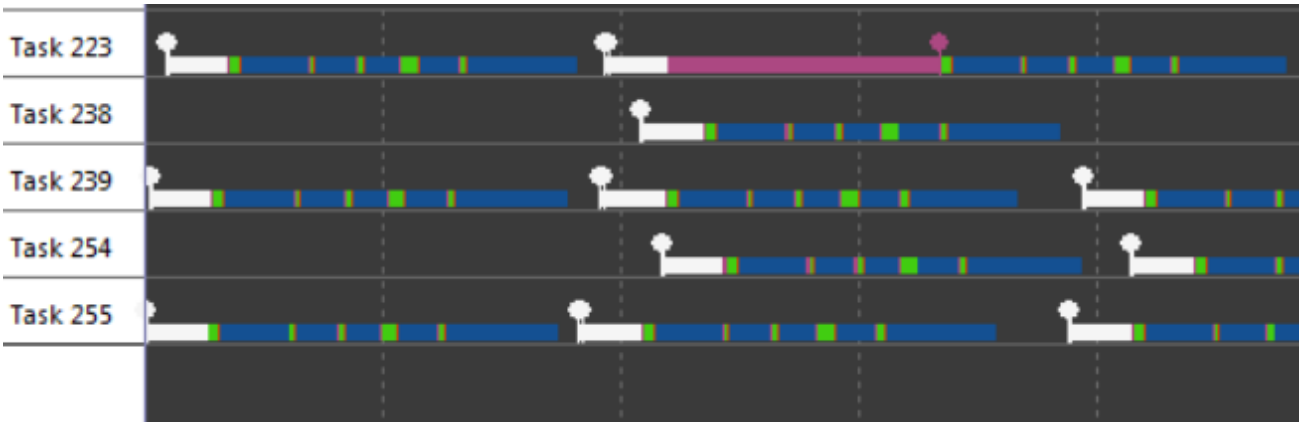

Figure 54. Tasks in Different Flows Running Parallel

As seen from the AIOP analysis tool trace, many operations are occurring in parallel. Both hardware jobs (blue) and software jobs (green) are happening in parallel. In this snippet only one task is observed as blocked. This is the most simple and effective way to improve parallel operation in the AIOP. However, it is never possible to know that ingress traffic will be in a large number of flows at any instant in time.

The DPNI may or may not allow sufficient distribution (spread) of flows. However for every application there is a unique key comprised of header fields to uniquely identify a flow. This unique key is reduced to a hash and used as a new scope ID

when classification must be refined within the AIOP. This would be step one of a task and it can be performed in concurrent mode of the initial scope ID to maintain parallel operation.

Either way, if DPNI does or does not provide sufficient spread of flow, it is the application responsibility to pick what header fields uniquely identifies a flow. Use dpni_drv_set_order_scope() to specify initial order scope construction from header fields so that tasks are created with the best possible initial order scope ID. This is the preferred and best performing method. If that is not possible then the user may create a key composition ID (KeyID) from the header fields required during application initialization and use that KeyID to generate a hash suitable for order scope ID after tasks are launched. See key_composition_rule_create().

Run concurrent where possible

In general an AIOP task begins execution in the concurrent phase of the initial ordering scope and delays transition to a subsequent scope in the exclusive phase as long as it is practical. In our example task it is possible to run concurrently up to the point where the ARP table is read and updated. Consider a single flow where our example application runs concurrently and then moves to exclusive after the TLU lookup.

```
osm_scope_transition_to_exclusive_with_increment_scope_id();
```

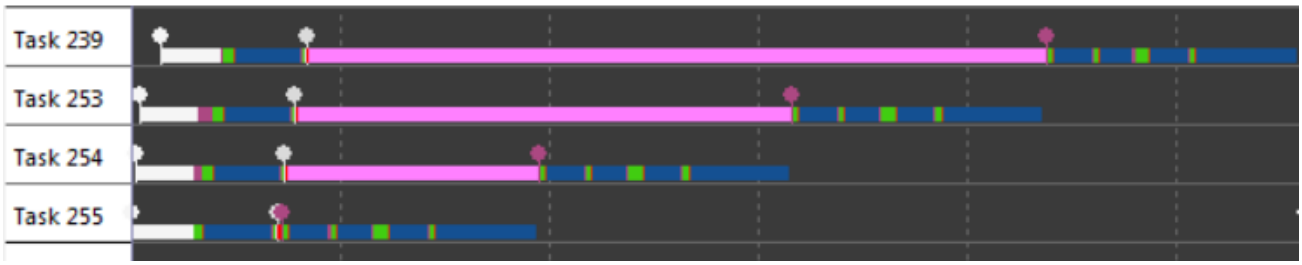

Figure 55. Tasks in a Flow Blocking for Exclusivity

The TLU will perform lookup operations in an atomic fashion. Take advantage of this characteristic of the AIOP accelerators by using them from a concurrent phase of an ordering scope where ever possible. As can be seen in the AIOP analysis tool snippet, the first hardware job, in this case a TLU lookup, is performed in parallel with other tasks. The remainder of the task is run exclusively and parallel operation ceases.

Relinquish exclusivity quickly

In our example application the read-modify-write of the ARP table entry must be done exclusively. However the MAC address update does not because the data and frame are private to the task. A relinquish exclusivity is inserted following the ARP update and another transition to exclusive is inserted prior to forwarding to remain ordered.

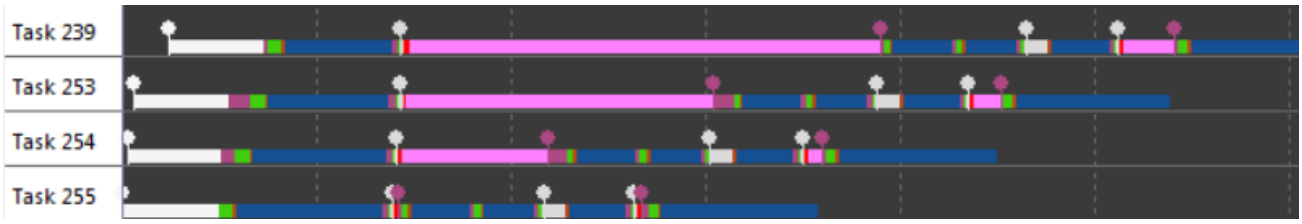

Figure 56. Tasks of a Flow Relinquishing Exclusivity Affect

Consider alternatives

Our example takes advantage of OSM to create an exclusive phase to perform a critical operation, namely to read-modify-write the ARP table entry. Note this is an *ordered* excusive operation. That is tasks will update their ARP entry in the order of packet arrival. In this example the update is just a hit counter and does not require update in order.

It is possible to take advantage of two properties of the hardware accelerators here. First, the sequential update of the ARP entry hit counter can be performed by the STE (statistics engine). Second, the atomic operation of CDMA commands can

assure consistent values regardless of other readers or writers. Our example can take advantage of these properties to rewrite our ARP entry handling.

NOTE

The atomic operation of CDMA read and write operations is a specific enhancement over the first revision of the silicon. This atomic behavior allows a reader to be certain a writer will not corrupt an entry; the value read will be valid but not ordered with respect to the writer.

Rewriting this section will look like the following:

```
cdma_read( (void*)&arp_entry, lookup_result.opaque0_or_reference, 16);
ste_inc_counter( (lookup_result.opaque0_or_reference + offsetof(struct arp_entry,
hits)),STE_MODE_64_BIT_CNTR_SIZE);
```

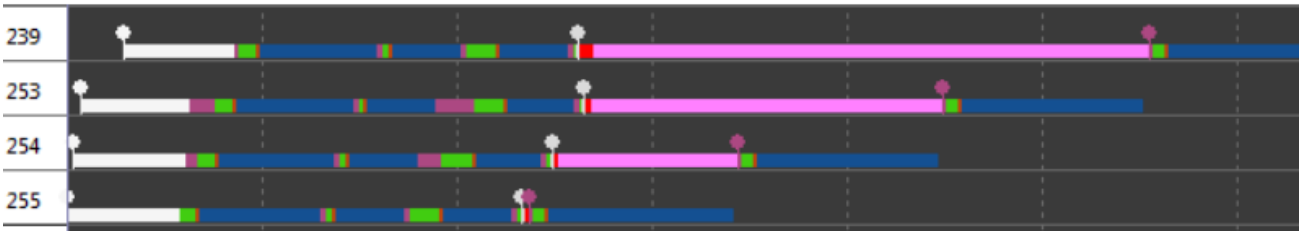

Figure 57. Tasks of a Flow Making Use of Atomic Accelerator Operations

In our alternative method of using STE, all hardware accelerations with the exception of forwarding can now operate in parallel even though all packets are of a single flow. Cycle count for the first four packets forwarding is down to about 3,000 cycles.

OSM Capacity

OSM itself is a resource of limited capacity. To maintain maximum task throughput the number of transitions and enter/exit scope pairs should be limited to a total of about five. Beyond that the maximum task rate will start to decline. It is rare that a task of a complexity to require more than five OSM operations will be limited by OSM before it is limited by other hardware accelerator throughput. However the AIOP analysis tool will be the designer's main insight into where bottlenecks are occurring within the AIOP.

Use osm_scope_enter_to_exclusive_with_new_scope_id() and osm_scope_enter_to_exclusive_with_increment_scope_id() instead which pick the best hardware options by default and have little software overhead

Additional Guidelines

Experience with insight provided by using the AIOP analysis tool will guide the user to best practices for improving parallel operation and relieving bottlenecks.

- Primarily use transition increment forms of OSM commands as they are the best performers and naturally partition an application's overall design into steps from ingress to egress.
- Reduce cycles in exclusive phases as much as possible.
- Use accelerators in concurrent phases as much as possible.
- Create new scope IDs to refine (distribute) flows.
- Take advantage of atomic accelerator characteristics in concurrent phases.
- Avoid using the osm_scope_enter() function as its many options and overhead take many cycles.
  - Use osm_scope_enter_to_exclusive_with_new_scope_id() and osm_scope_enter_to_exclusive_with_increment_scope_id() instead which pick the best hardware options by default and have little software overhead

- Consider splitting a long operation requiring the exclusive phase into multiple exclusive phases.

These are only guidelines to consider while experience will guide the designer. The AIOP analysis tool gives insight into the behavior of tasks. Often times the interaction between decisions is not obvious and some trial and error is required for best results.

6.14.4.9 Statistics Engine

The statistics engine will stall the core when it is overloaded. It is relatively easy to see this scenario on trace – core jobs will become much longer around statistics engine (STE) calls and the IPC will go down. In order to isolate an STE bottleneck, remove some STE calls and measure the IPC of the application. If the IPC grows significantly, then an STE bottleneck is being experienced.

Below are important rules that developers need to be aware of when implementing statistics counters on AIOP during the design stage of an application. The most important factor that these rules address is DDR bandwidth limitation.

1. Though seemingly simple, it is important to use as few counters as possible. Reduce counters if possible, and make counters optional where possible.
2. Frequently used counters should not be placed in DDR but rather in internal memory (PEB or ShRAM in some cases).
3. If the context is not “read-only” and a lock of some sort (mutex or OSM based) is taken, it is good practice to put counters in that context and update them by the core without using STE (statistics engine). Similarly, if the number of counters is big, it is good practice to update them using the CDMA engine.
4. Use compound STE operations, which allows two counters to be updated in one operation.

There are restrictions on alignments of counters that the STE API has to follow. It can be found at STE section of AIOP Service Layer API Reference Manual.

6.14.4.10 IP Fragmentation (IPF)

For best performance it is recommended to work concurrently, and move to Exclusive Mode (XX) ordering only before enqueuing the last fragment. From this point (moving to exclusive before enqueue of the last fragment) transition to concurrent is not allowed. This way fragments of different frames will be interleaved but ordering will be kept between the last fragments of different frames.

6.14.4.11 IP Reassembly (IPR)

- Ordering scope
  - Call the IPR in Concurrent mode (XC)
  - Do a per-frame flow distribution, according to the IP identification field
  - Have at least two available OSM scope levels when calling IPR
- Place the lookup tables on the PEB memory
- The input frame (fragment) should be stored in a single buffer
- The frame buffer size should be larger or equal to (16 * <max number of fragments>) + any offset, headroom and annotation
- API configuration parameters
  - Do not enable external statistics
  - Use timeout mode to be per reassembled frame
- Send in-order fragments (relevant to the sender side, usually in closed systems)

Table 117. IPR configuration options for best performance

Flags and options	Best Performance
IPR_MODE_TABLE_LOCATION_PEB	Set
IPR_MODE_EXTENDED_STATS_EN	Cleared
IPR_MODE_IPV4_TO_TYPE	Set
IPR_MODE_IPV6_TO_TYPE	Set

6.14.4.12 IPSec

IPSec module supports IPSec encaspulation and decapsulation as a part of service layer. There are several ideas on how to achive the best performance for IPSec:

- Use tunnel mode.
- Use IPv4 frames and outer header.
- Do not enable transport mode pad check.
- Do not use the DSCP set option for tunnel mode.
- Use the system DDR as the IPsec FM context memory (currently not programmable).
- Do not enable UDP encapsulation in transport mode
- Enable reuse buffer mode

The following table describes the IPsec functional module configuration parameters value for achieving the best performance.

Table 118. IPsec Configuration Options for Best Performance

Flags & options	Best performance
IPSEC_FLG_TUNNEL_MODE	Set
IPSEC_FLG_TRANSPORT_PAD_CHECK	Cleared
IPSEC_FLG_BUFFER_REUSE	Set
IPSEC_ENC_OPTS_NAT_EN	Cleared
IPSEC_ENC_OPTS_NUC_EN	Cleared
IPSEC_FLG_ENC_DSCP_SET	Cleared
IPSEC_FLG_LIFETIME_KB_CNTR_EN	Cleared
IPSEC_FLG_LIFETIME_PKT_CNTR_EN	Cleared
IPSEC_FLG_LIFETIME_SEC_CNTR_EN	Cleared
IPSEC_OPTS_ESP_ESN	Cleared
IPSEC_OPTS_ESP_IPVSN	Cleared
IPSEC_DEC_OPTS_ARSNONE	Set
IPSEC_DEC_OPTS_ARS32	Cleared
IPSEC_DEC_OPTS_ARS128	Cleared
IPSEC_DEC_OPTS_ARS64	Cleared

6.14.4.13 Appendix A

DDR bandwidth measurement

The Scenarios Tools allows a real time measurement of DDR bandwidth for all the controllers. Use this tool as a help guide for the configuration procedure.

As an example, in the LS2085A, there are three DDR controllers. In ***Scenarios Tools*** those are called DDRC1, DDRC2 and DDRC3.

DDRC1 and DDRC2 are for system memory and DDRC3 is for DP-DDR.

Add the utilization measurement as shown below, then press the green “Launch” button in the toolbar.

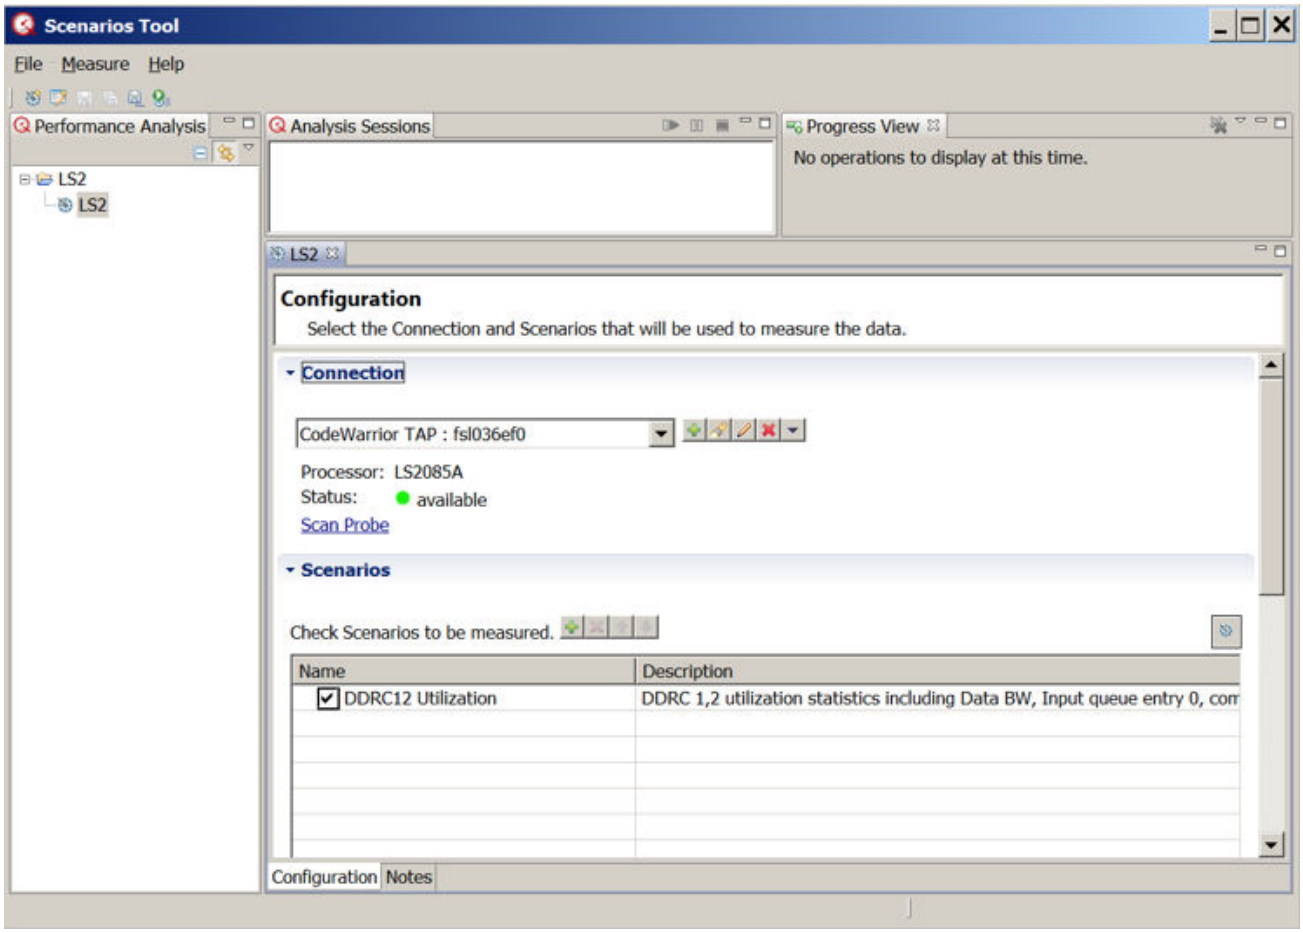

Figure 58. Utilization Measurement in Scenarios Tool

The measurement will complete in a few seconds, and the table of results will be displayed, as shown below.

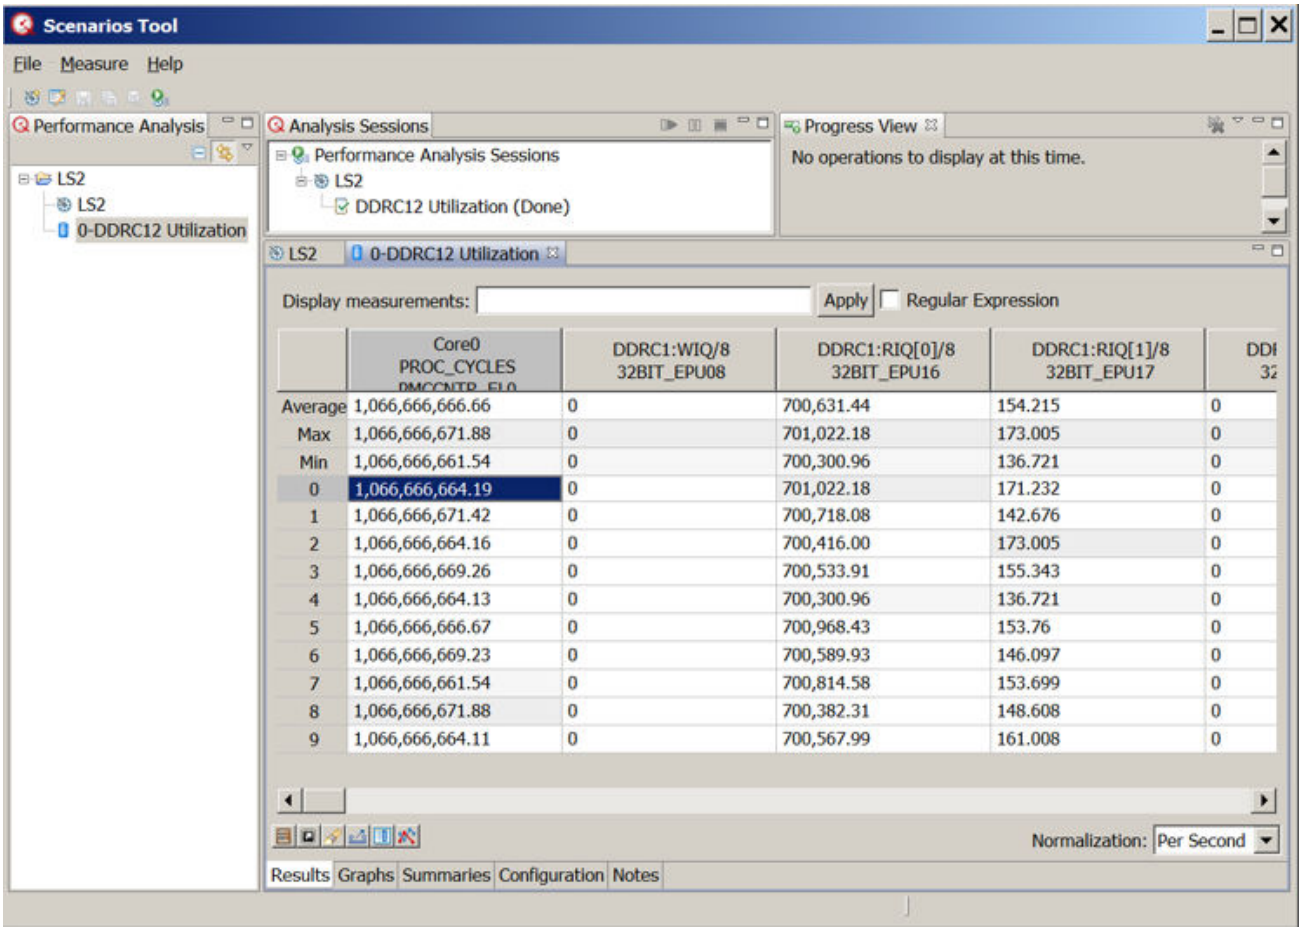

Figure 59. Utilization Measurement Table of Results

The initial table display will show all measured events and metrics. Use the Measurement Chooser dialog to select the measurements of interest, in this case the utilization metrics.

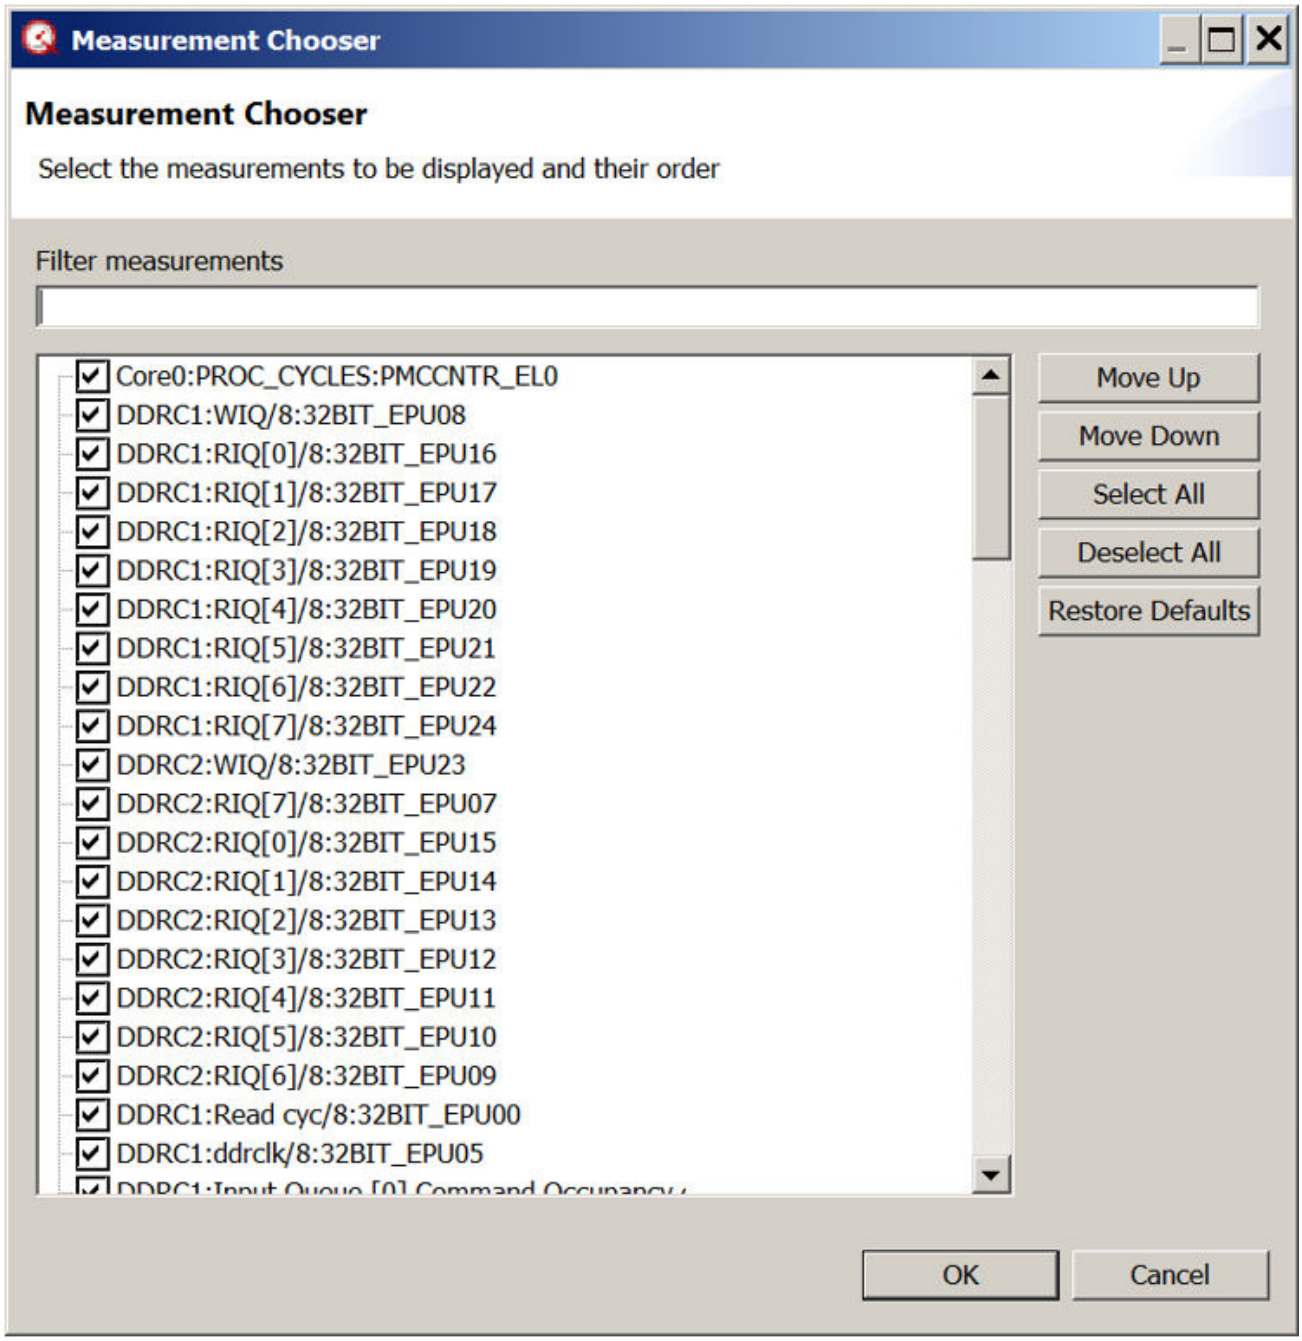

Figure 60. Measurement Chooser Dialog

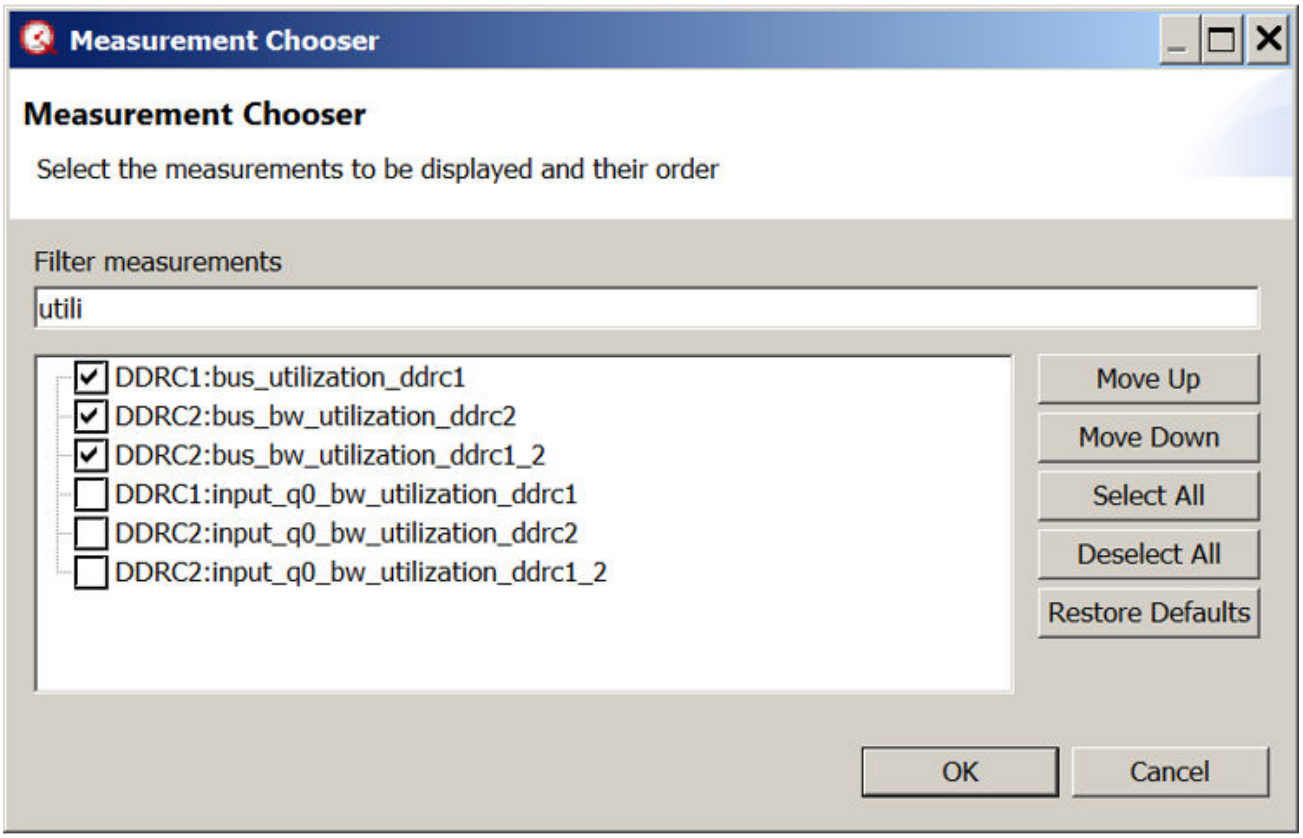

Figure 61. Selecting Utilization Metrics

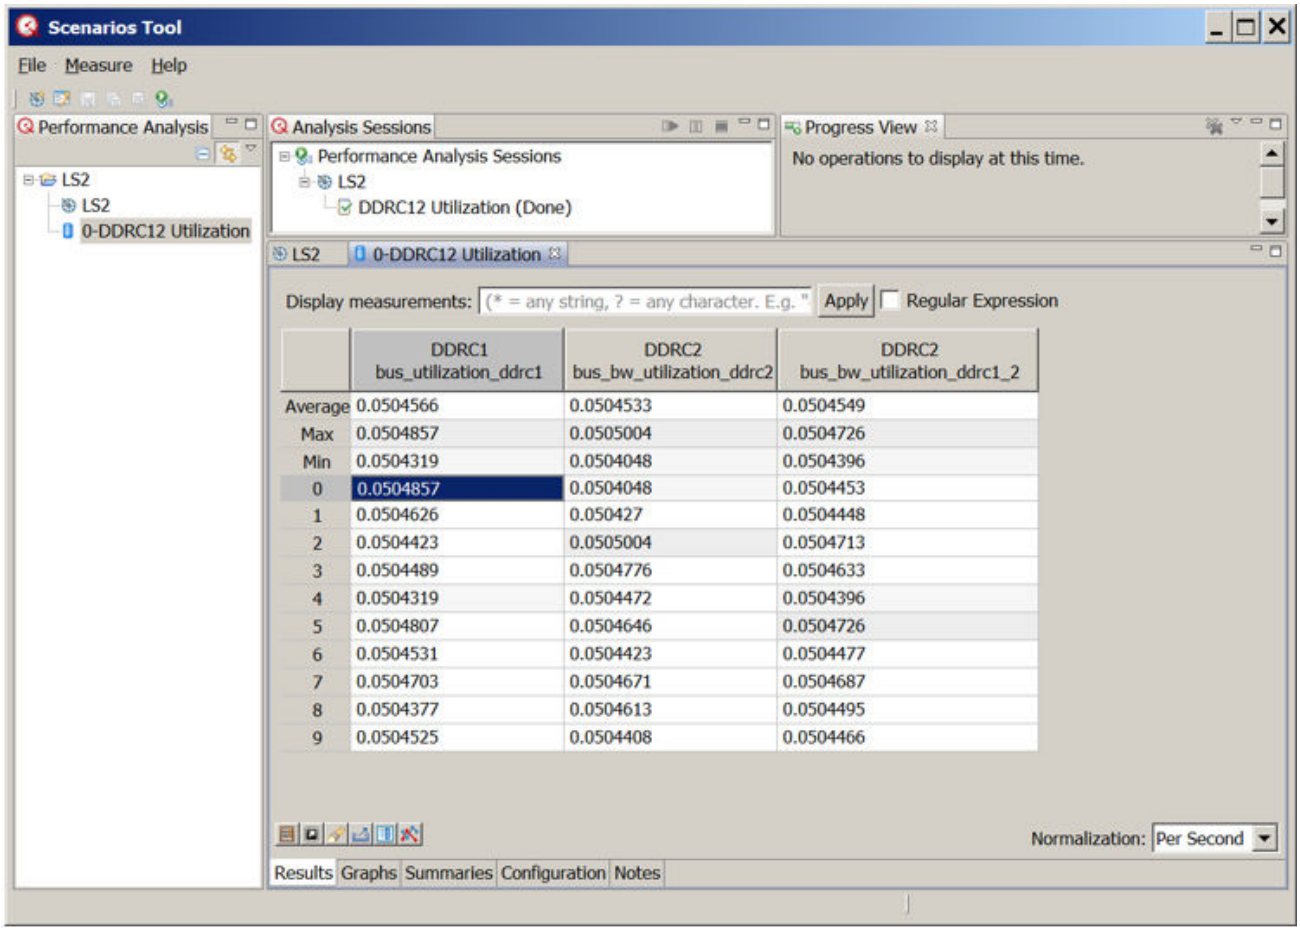

Figure 62. Example of DDR Utilization

In last figure, observe that DDR1 and DDR2 are only 5% utilized. Generally, utilization of lower than 65% is considered to be low and not affecting latency.

Chapter 7
Linux Kernel Drivers

7.1 Audio

7.1.1 Synchronous Audio Interface (SAI) LS1021A

Description

The following describes how to configure and test SAI audio driver for LS1021A TWR board. The integrated I2S module is NXP's Synchronous Audio Interface (SAI). The codec is SGTL5000 stereo audio codec.

RCW configuration

Refer to the below table for the RCW binary files name and location for LS1021A TWR boards.

Board	RCW binary
LS1021A TWR	ls1021atwr/RSR_PPS_70/rcw_1000.bin

Kernel Configure Options Tree View

Kernel Configure Tree View Options	Description
Device Drivers ---> <*> I2C support ---> [*] Enable compatibility bits for old user-space [*] I2C device interface [*] I2C bus multiplexing support Multiplexer I2C Chip support ---> <*> Philips PCA954x I2C Mux/switches [*] Autoselect pertinent helper modules I2C Hardware Bus support ---> <*> IMX I2C interface <*> Voltage and Current Regulator Support ---> [*] Regulator debug support [*] Provide a dummy regulator if regulator lookups fail [*] Fixed voltage regulator support <*> Sound card support <*> Advanced Linux Sound Architecture -> [*] OSS PCM (digital audio) API [*] OSS PCM (digital audio) API - Include plugin system [*] Support old ALSA API [*] Verbose procfs contents ALSA for SoC audio support ---> <*> SoC Audio for Freescale VF610 CPUs ---> <*> SoC Audio support for VF610 boards with sgtl5000	Enable ALSA SOC driver, I2C driver and EDMA driver.

Kernel Configure Tree View Options	Description
<*> DMA Engine support ---> <*> Freescale eDMA engine support support	

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_I2C_IMX	y/m/n	y	I2C driver needed for configuring SGTL5000
CONFIG_SOUND	y/m/n	y	Enable sound card support
CONFIG_SND	y/m/n	y	Enable advanced Linux sound architecture supports
CONFIG_SND_PCM_OSS	y/m/n	y	Enable OSS digital audio
CONFIG_SND_PCM_OSS_PLUGINS	y/m/n	y	Support conversion of channels, formats and rates
CONFIG_SND_SUPPORT_OLD_API	y/m/n	y	Enable support old ALSA API
CONFIG_SND_SOC_FSL_SAI	y/m/n	y	Enable SAI module support
CONFIG_SND_VF610_SOC	y/m/n	y	Enable ALSA SOC support
CONFIG_SND_SOC_VF610_SGTL5000	y/m/n	y	Enable ALSA SOC support
CONFIG_SND_SOC_SGTL5000	y/m/n	y	Enable codec sgtl5000 support
CONFIG_FSL_EMDA	y/m/n	y	Enable EDMA engine support

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
sound/soc/fsl	ALSA SOC driver source

Verification in Linux

1. The following messages will be shown in the kernel boot process.

```
sgtl5000 1-000a: sgtl5000 revision 0x11
sgtl5000 1-000a: Failed to get supply 'VDDD': -19
1-000a: 1200 mV normal
sgtl5000 1-000a: Using internal LDO instead of VDDD
```

```
......

......
ALSA device list:
  #0: FSL-VF610-TWR-BOARD
```

2. If the device nodes don't already exist, create directory /dev/snd/, and create device nodes with the following commands in /dev/snd/ directory.

```
mknod controlC0 c 116 0
mknod pcmC0D0c c 116 24
mknod pcmC0D0p c 116 16
```

3. On LS1021A TWR board, the HEADPHONES interface is J14. The MIC is on chip.
4. Run the following aplay or mplayer commands to test playback. Run the following arecord command to test record.

```
aplay -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo.wav
mplayer 44k-16bit-stereo.wav

arecord -d 10 -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo-10s.wav
aplay -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo-10s.wav
```

5. Use alsamixer to adjust the volume for playing by the options “PCM”. Use alsamixer to choose LINE IN or MIC.

7.1.2 Synchronous Audio Interface (SAI) LS1012A

Description

This document describes how to configure and test SAI audio driver for LS1012A FRDM board. The integrated I2S module is NXP's Synchronous Audio Interface (SAI). The codec is SGTL5000 stereo audio codec.

RCW configuration

Refer to the below table for the RCW for Audio on the LS1012A FRDM board.

Board	RCW
LS1012A FRDM	Bit 364, EC1_EXT_SAI2_TX = 1; Bit 365, EC1_EXT_SAI2_RX =1; Bit 366-367, EC1_BASE = 00

Kernel Configure Options Tree View

Verification in Linux

1. The following messages will be shown in the kernel boot process:

```
sgtl5000 5-000a: sgtl5000 revision 0x11
sgtl5000 5-000a: Using internal LDO instead of VDDD
......
asoc-simple-card sound:  sgtl5000 <-> 2b60000.sai mapping ok
......
ALSA device list:
  #0: 2b60000.sai-sgtl5000
```

2. If the device nodes don't already exist, create directory /dev/snd/, and create device nodes with the following commands in /dev/snd/ directory.

```
mknod controlC0 c 116 0
mknod pcmC0D0c c 116 24
mknod pcmC0D0p c 116 16
```

3. On LS1012A FRDM board, the LineOut interface is J8 and the LineIn interface is J13
4. Run the following aplay commands to test playback. Run the following arecord command to test record.

```
aplay -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo.wav

arecord -d 10 -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo-10s.wav
aplay -f S16_LE -r 44100 -t wav -c 2 44k-16bit-stereo-10s.wav
```

5. Use alsamixer to adjust the volume for playing by the option “PCM” and recording gain by the option "Mic" . Use alsamixer to choose LINE IN or MIC.

7.2 Display Interface Unit (DIU)

7.2.1 DIU Display Device Driver User Manual

Description
This manual describes how to use the DIU.

Module Loading

The DIU device driver supports kernel built-in and module.

U-Boot Environment

In order to enable DIU after building the U-Boot image, define the below environment variable:

```
=>video-mode="fslfb:1024x768-32@60,monitor=dvi"
```

Testing at the U-Boot Level

1. Build U-Boot image with DIU and burn it to the NOR flash.
2. Build the U-Boot image with default option:
3. Make T1042D4RDB_defconfig

```
make
```

4. Setting the DIU output to DVI port: See the "U-Boot Environment" section of the SoC's Software Deployment Guide.
5. Connect to DVI port then power on. The U-Boot will look like the following:

```
U-Boot 2015.01-00582-g14d9d27 (Apr 08 2015 - 10:19:12)
CPU0: T1042E, Version: 1.1, (0x85280211)
Core: e5500, Version: 2.1, (0x80241021)
Clock Configuration:
CPU0:1200 MHz, CPU1:1200 MHz, CPU2:1200 MHz, CPU3:1200 MHz,
CCB:600 MHz,
DDR:800 MHz (1600 MT/s data rate) (Asynchronous), IFC:150 MHz
QE:300 MHz
FMAN1: 600 MHz
QMAN: 300 MHz
PME: 300 MHz
L1: D-cache 32 KiB enabled
I-cache 32 KiB enabled
Reset Configuration Word (RCW):
00000000: 0c18000c 0c000000 00000000 00000000

Kernel

Special DTS

```
display@180000 {
compatible = "fsl,t1040-diu", "fsl,diu";
reg = <0x180000 1000>;
interrupts = <74 2 0 0>;
};
```

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

`Device Drivers --->`
`  Graphics Support --->`
`  Frame buffer Devices --->`
`  < > Permedia3 support`
`  < > Fujitsu carmine frame buffer support`
`  <*> Freescale DIU framebuffer support`
`  < > Freescale DCU framebuffer support`
	FSL DIU display support

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
`drivers/video/fbdev/ fsl-diu-fb.c` `include/linux/fsl-diu-fb.h`	FSL DIU framebuffer device driver

Testing at Kernel Level

1. Configure and rebuild the kernel as configuration list above.

```
Make corenet64_fmanv3l_smp_defconfig
Make
```

2. Boot up Linux kernel. The display relative to DIU will look like the following:

```
Freescale Display Interface Unit (DIU) framebuffer driver
graphics fb0: Panel0 registered successfully
graphics fb1: Panel1 AOI0 registered successfully
graphics fb2: Panel1 AOI1 registered successfully
```

```
graphics fb3: Panel2 AOI0 registered successfully
graphics fb4: Panel2 AOI1 registered successfully
```

Known Bugs, Limitations, or Technical Issues

All IPs need to go into idle when the system is going into deep sleep state. If the DIU driver is not enabled in the kernel, but is enabled in U-Boot, deep sleep will fail.

7.2.2 DCU Display Device Driver User Manual

Description

This manual describes how to use the Two Dimensional Animation and Compositing Engine (2D-ACE or DCU) and frame buffer on TWR-LS1021A board.

Module Loading

The DCU device driver supports kernel built-in and module.

U-Boot Configuration

Please use 'ls1021atwr_lpuart_config' to build the uboot.

Runtime options.

Env Variable	Description	Sub Option		Option Description
bootargs	Kernel command line argument passed to kernel	HDMI	console=ttyLP0,115200 hdmi	select LPUART0 as the system console
		LCD	console=ttyLP0,115200	

Kernel Configure Options

Tree View

Below are the Kernel Configure Tree View options need to be set/unset while doing "make menuconfig" for kernel and enable DCU/HDMI drivers and Linux Penguin Logo picture.

```
Device Drivers  --->

   < > Multimedia support  ----
       Graphics support  --->
           <*> Support for frame buffer devices  --->
               <*> Si Image SII9022 DVI/HDMI Interface Chip
               <*> Freescale DCU framebuffer support
                   …

               Console display driver support  --->
                   <*> Framebuffer Console support
                   [*] Map the console to the primary display device
                   [*] Framebuffer Console Rotation
           [*] Bootup logo  --->
               --- Bootup logo
```

```
               [*] Standard black and white Linux logo
               [*] Standard 16-color Linux logo
               [*] Standard 224-color Linux logo
   < > Sound card support  ----
```

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Special Configure needs to be enabled ("Y") for LS1021A. Please find in below table with default value as "N"

Option	Values	Default Value	Description
CONFIG_ FB_FSL_SII902X	y/m/n	y	Si Image SII9022 DVI/HDMI Interface Chip
CONFIG_FB_FSL_DCU	y/m/n	y	NXP DCU framebuffer supportt
CONFIG_LOGO	y/m/n	y	Bootup logo
CONFIG_LOGO_LINUX_MONO	y/m/n	y	Standard black and white Linux logo
CONFIG_LOGO_LINUX_VGA16	y/m/n	y	Standard 16-color Linux logo
CONFIG_LOGO_LINUX_CLUT224	y/m/n	y	Standard 224-color Linux logo
CONFIG_FRAMEBUFFER_CONSOLE	y/m/n	y	Framebuffer Console support

Device Tree Binding

Special Configure needs to be enabled ("Y") for LS1021A. Please find in below table with default value as "N"

arch/arm/boot/dts/ls1021a.dtsi

```
dcu0: dcu@2ce0000 {
            compatible = "fsl,vf610-dcu";
             reg = <0x0 0x2ce0000 0x0 0x10000>;
             interrupts = <GIC_SPI 172 IRQ_TYPE_LEVEL_HIGH>;
             clocks = <&platform_clk 0>;
             clock-names = "dcu";
             scfg-controller = <&scfg>;
              big-endian;
              status = "disabled";
};
```

arch/arm/boot/dts/ls1021a-twr.dts

```
&dcu0 {
        display = <&display>;
        status = "okay";

        display: display@0 {
                bits-per-pixel = <24>;

                display-timings {
                        native-mode = <&timing0>;
                        timing0: nl4827hc19 {
                                clock-frequency = <10870000>;
                                hactive = <480>;
                                vactive = <272>;
                                hback-porch = <2>;
                                hfront-porch = <2>;
                                vback-porch = <2>;
```

```
                                vfront-porch = <2>;
                                hsync-len = <41>;
                                vsync-len = <4>;
                                hsync-active = <1>;
                                vsync-active = <1>;
                        };
                };
        };
};
```

Ramdisk:

Please use the 'fsl-image-x11-ls1021a(XXXXX)rootfs.ext2.gz.gz' ramdisk from each release images, or you can just use the ramdisk image which has 'x11' label.

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/video/fsl-dcu-fb.c	NXP DCU driver

Testing LCD/DHMI at Uboot Level

1. Display with LCD:

```
=> setenv video-mode  "fslfb:480x272-32@60,monitor=twr_lcd"
=> save
=> setenv stdout vga
```

2. Display with HDMI:

```
=> setenv video-mode  "fslfb:640x480-32@60,monitor=hdmi"
=> save
=> setenv stdout vga
```

Testing LCD at Kernel Level

1. Configure and rebuild the kernel as configuration list above, let the DCU driver built into the Kernel Image.
2. Boot up Linux kernel, upon the kernel has been uncompressed, the TFT Panel will display the Linux Penguin Logo.
3. And then after the root filesystem has been monted, and the Xwindows Desktop will be display.
4. Or also you can start the Xwindow using:

```
root@ls1021atwr:~# killall matchbox-window-manager
root@ls1021atwr:~# xinit /etc/init.d/xserver-nodm restart
```

5. Just plug out and plug in the HDMI to test the hot plug.

Testing HDMI at Kernel Level

1. 1.Configure and rebuild the kernel as configuration list above, let the HDMI and DCU drivers built into the Kernel Image.
2. Boot up Linux kernel, upon the kernel has been uncompressed, the TFT Panel won't display any picture correctly.
3. And then after the root filesystem has been monted, and the Xwindows Desktop will be displayed on the HDMI Monitor.

4. Or also you can start the Xwindow using:

```
root@ls1021atwr:~# killall matchbox-window-manager
root@ls1021atwr:~# xinit /etc/init.d/xserver-nodm restart

Note: Please unplugged the TWR-LDC_RGB daughter board when testing the
HDMI.
```

Known Bugs, Limitations, or Technical Issues

Unplug the SD card before testing the DCU/HDMI, or the system will hang.

7.3 DMA Controller

7.3.1 Direct Memory Access Driver (PowerQUICC, QorIQ)

Description

NXP Platform DMA Controller are integrated with the MPC85xx and QorIQ cpu.

Module Loading

The MPC8xxx DMA support code is compiled into the kernel.

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description
Device Drivers ---> DMA Engine supportt ---> <*> Freescale Elo and Elo Plus DMA support [*] Network: TCP receive copy offload <*> DMA Test client	NXP Platform DMA support

Compile-time Configuration Options

7.3.2 Enhanced Direct Memory Access Driver (ARM)

7.3.2.1 eDMA User Manual

Description

The SoC integrates NXP's Enhanced Direct Memory Access module. Slave device such as I2C or SAI can deploy the DMA functionality to accelerate the transfer and release the CPU from heavy load.

Kernel Configure Options

Tree View

Below are the configure options need to be set/unset while doing "make menuconfig" for kernel

Kernel Configure Tree View Options	Description
Device Drivers ---> [*] DMA Engine support ---> --->*> <*> Freescale eDMA engine support	DMA engine subsystem driver and eDMA driver support

Identifier

Below are the configure identifiers which are used in kernel source code and default configuration files.

Option	Values	Default Value	Description
CONFIG_FSL_EDMA	y/m/n	n	eDMA Driver

Device Tree Binding

Device Tree Node

Below is an example device tree node required by this feature. Note that it may has differences among platforms.

```
edma0: edma@2c00000 {
                        #dma-cells = <2>;
                        compatible = "fsl,vf610-edma";
                        reg = <0x0 0x2c00000 0x0 0x10000>,
                                <0x0 0x2c10000 0x0 0x10000>,
                                <0x0 0x2c20000 0x0 0x10000>;
                        interrupts = <GIC_SPI 135 IRQ_TYPE_LEVEL_HIGH>,
                                        <GIC_SPI 135 IRQ_TYPE_LEVEL_HIGH>;
                        interrupt-names = "edma-tx", "edma-err";
                        dma-channels = <32>;
                        big-endian;
                        clock-names = "dmamux0", "dmamux1";
                        clocks = <&platform_clk 1>,
                                <&platform_clk 1>;
                };
```

Device Tree Node Binding for Slave Device

Below is the device tree node binding for a slave device which deploy the eDMA functionality.

```
i2c0: i2c@2180000 {
```

```
                        #address-cells = <1>;
                        #size-cells = <0>;
                        compatible = "fsl,vf610-i2c";
                        reg = <0x0 0x2180000 0x0 0x10000>;
                        interrupts = <GIC_SPI 88 IRQ_TYPE_LEVEL_HIGH>;
                        clock-names = "i2c";
                        clocks = <&platform_clk 1>;
                        dmas = <&edma0 1 39>,
                               <&edma0 1 38>;
                        dma-names = "tx", "rx";
                        status = "disabled";
                };
```

Source Files

The following source files are related the this feature in Linux kernel.

Table 119. Source Files

Source File	Description
drivers/dma/fsl-edma.c	The eDMA driver file

Verification in Linux

1. Use the slave device which deploy the eDMA functionality to verify the eDMA driver, below is a verification with the I2C salve.

```
root@ls1021aqds:~# i2cdetect 0
WARNING! This program can confuse your I2C bus, cause data loss and worse!
I will probe file /dev/i2c-0.
I will probe address range 0x03-0x77.

7.4 DPAA 1.x Devices

7.4.1 DPAA Primer for Software Architecture

7.4.1.1 DPAA Primer

Multicore processing, or multiple execution thread processing, introduces unique considerations to the architecture of networking systems, including processor load balancing/utilization, flow order maintenance, and efficient cache utilization. Herein is a review of the key features, functions, and properties enabled by the QorIQ DPAA (Data Path Acceleration Architecture) hardware and demonstrates how to best architect software to leverage the DPAA hardware.

By exploring how the DPAA is configured and leveraged in a particular application, the user can determine which elements and features to use. This streamlines the software development stage of implementation by allowing programmers to focus their technical understanding on the elements and features that are implemented in the system under development, thereby reducing the overall DPAA learning curve required to implement the application.

Our target audience is familiar with the material in **QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual**.

Benefits of the DPAA

The primary intent of the DPAA is to provide intelligence within the IO portion of the System On Chip (SOC) to route and manage the processing work associated with traffic flows to simplify ordering and load balance concerns associated with multi core processing. The DPAA hardware inspects ingress traffic and extracts user defined flows from the port traffic. It then steers specific flows (or related traffic) to a specific core or set of cores.

Architecting a networking application with a multicore processor presents challenges (such as workload balance and maintaining flow order), which are not present in a single core design. Without hardware assistance, the software must implement techniques that are inefficient and cumbersome, reducing the performance benefit of multiple cores. To address workload balance and flow order challenges, the DPAA determines and separates ingress flows then manages the temporary, permanent, or semi-permanent flow-to-core affinity. The DPAA also provides a work priority scheme, which ensures ingress critical flows are addressed properly and frees software from the need to implement a queuing mechanism on egress. As the hardware determines which core will process which packet, performance is boosted by direct cache warming/stashing as well as by providing biasing for core-to-flow affinity, which ensures that flow-specific data structures can remain in the core's cache.

By understanding how the DPAA is leveraged in a particular design, the system architect can map out the application to meet the performance goals and to utilize the DPAA features to leverage any legacy application software that may exist. Once this application map is defined, the architect can focus on more specific details of the implementation.

7.4.1.1.1 General Architectural Considerations

As the need for processing capability has grown, the only practical way to increase the performance on a single silicon part is to increase the number of general purpose processing cores (CPUs). However, many legacy designs run on a single processor; introducing multiple processors into the system creates special considerations, especially for a networking application.

7.4.1.1.2 Multicore Design

Multicore processing, or multiple execution thread processing, introduces unique considerations. Most networking applications are split between data and control plane tasks. In general, control plane tasks manage the system within the broad network of equipment. While the control plane may process control packets between systems, the control plane process is not involved in the bulk processing of the data traffic. This task is left to the data plane processing task or program.

The general flow of the data plane program is to receive data traffic (in general, packets or frames), process or transform the data in some way and then send the packets to the next hop or device in the network. In many cases, the processing of the traffic depends on the type of traffic. In addition, the traffic usually exists in terms of a flow, a stream of traffic where the packets are related. A simple example could be a connection between two clients that, at the packet level, is defined by the source and destination IP address. Typically, multiple flows are interleaved on a single interface port; the number of flows per port depends on the interface bandwidth as well as on the bandwidth and type of flows involved.

7.4.1.1.3 Parse/classification Software Offload

The DPAA provides intelligence within the IO subsection of the SoC (system-on-chip) to split traffic into user-defined queues. One benefit is that the intelligence used to divide the traffic can be leveraged at a system level.

In addition to sorting and separating the traffic, the DPAA can append useful processing information into the stream; offloading the need for the software to perform these functions (see the following two figures).

Note that the DPAA is not intended to replace significant packet processing or to perform extensive classification tasks. However, some applications may benefit from the streamlining that results from the parse/classify/distribute function within the DPAA. The ability to identify and separate flow traffic is fundamental to how the DPAA solves other multicore application issues.

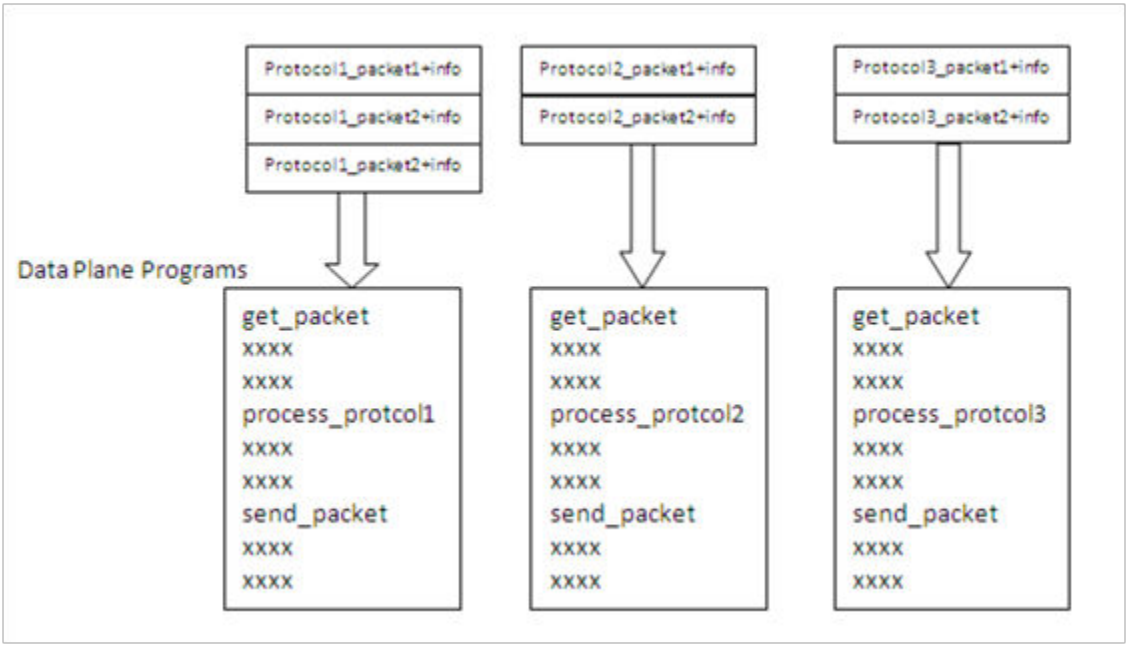

Figure 63. Hardware-sorted Protocol Flow

7.4.1.1.4 Flow Order Considerations

In most networking applications, individual traffic flows through the system require that the egress packets remain in the order in which they are received. In a single processor core system, this requirement is easy to implement. As long as the data plane software follows a run-to-completion model on a per-packet basis, the egress order will match the ingress packet order. However, if multiple processors are implemented in a true symmetrical multicore processing (SMP) model in the system, the egress packet flow may be out of order with respect to the ingress flow. This may be caused when multiple cores simultaneously process packets from the same flow.

Even if the code flow is identical, factors such as cache hits/misses, DRAM page hits/misses, interrupts, control plane and OS tasks can cause some variability in the processing path, allowing egress packets to “pass” within the same flow, as shown in this figure

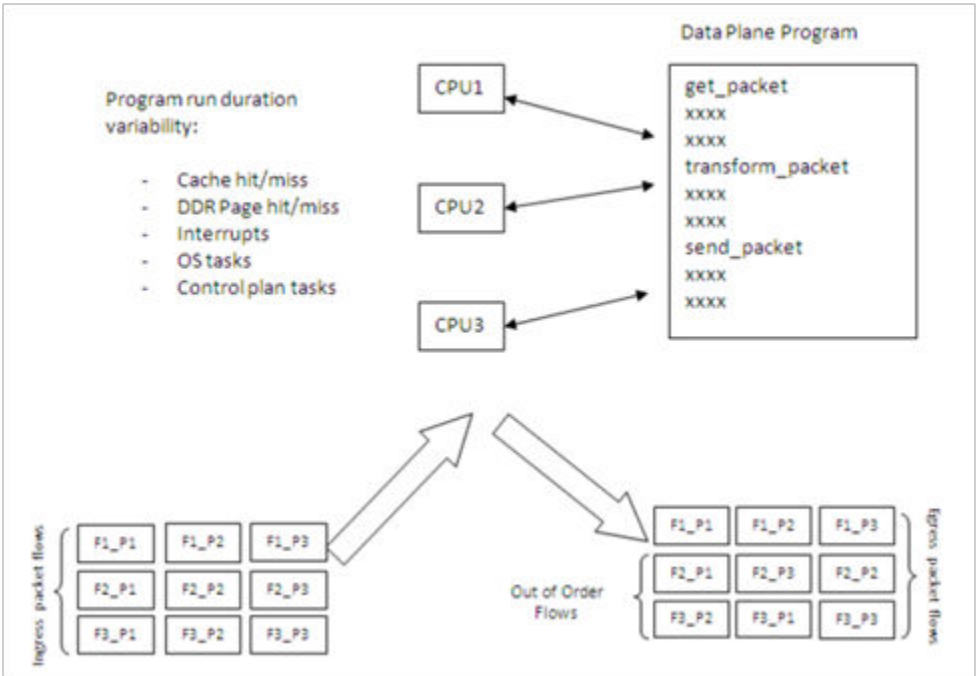

Figure 64. Multicore Flow Reordering

For some applications, it is acceptable to reorder the flows from ingress to egress. However, most applications require that order is maintained. When no hardware is available to assist with this ordering, the software must maintain flow order. Typically, this requires additional code to determine the sequence of the packet currently being processed, as well as a reference to a data structure that maintains order information for each flow in the system. Because multiple processors need to access and update this state information, access to this structure must be carefully controlled, typically by using a lock mechanism that can be expensive with regard to program cycles and processing flow (see the next figure). One of goals of the DPAA architecture is to provide the system designer with hardware to assist with packet ordering issues.

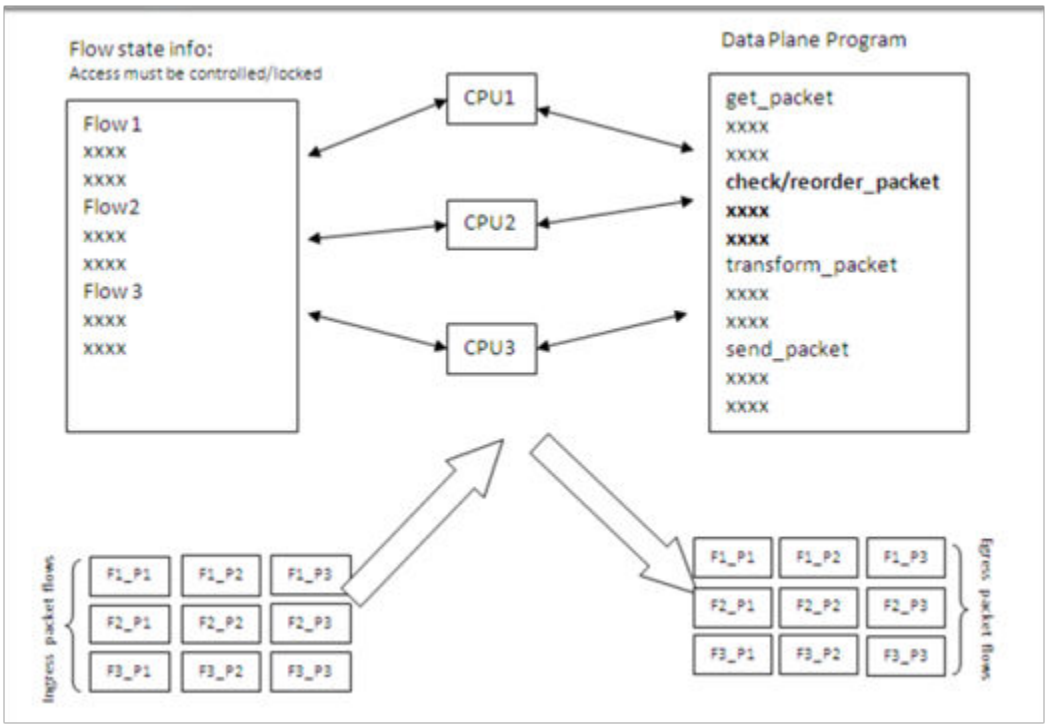

Figure 65. Implementing Order in Software

7.4.1.1.5 Managing Flow-to-Core Affinity

Multicore processing, or multiple execution thread processing, introduces unique considerations to the architecture of networking systems, including processor load balancing/utilization, flow order maintenance, and efficient cache utilization. Herein is a review of the key features, functions, and properties enabled by the QorIQ DPAA (Data Path Acceleration Architecture) hardware and demonstrates how to best architect software to leverage the DPAA hardware.

In a multicore networking system, if the hardware configuration always allows a specific core to process a specific flow then the binding of the flow to the core is described as providing flow affinity. If a specific flow is always processed by a specific processor core then for that flow the system acts like a single core system. In this case, flow order is preserved because there is a single thread of operation processing the flow; with a run-to-completion model, there is no opportunity for egress packets to be reordered with respect to ingress packets.

Another benefit of a specific flow being affined to a core is that the cache local to that core (L1 and possibly L2, depending on the specific core type) is less likely to miss when processing the packets because the core's data cache will not fetch flow state information for flows to which it is not affined. Also, because multiple processing entities have no need to access the same individual flow state information, the system need not lock the access to the individual flow state data. The DPAA offers several options to define and manage flow-to-core affinity.

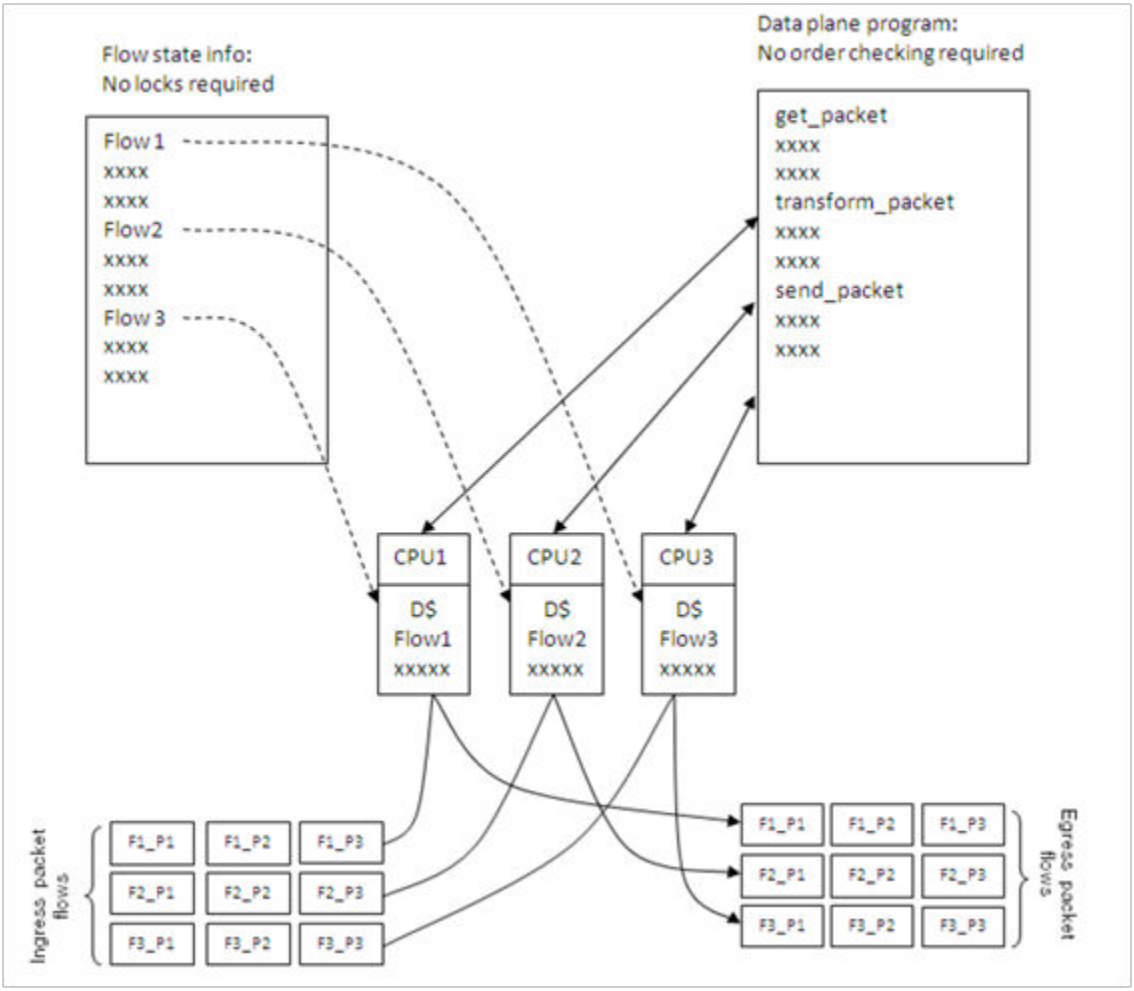

Figure 66. Managing Flow-to-Core Affinity

Many networking applications require intensive, repetitive algorithms to be performed on large portions of the data stream(s). While software in the processor cores could perform these algorithms, specific hardware offload engines often better address specific algorithms. Cryptographic and pattern matching accelerators are examples of this in the QorIQ family. These accelerators act as standalone hardware elements that are fed blocks or streams of data, perform the required processing, and then provide the output in a separate (or perhaps overwritten) data block within the system. The performance boost is significant for tasks that can be done by these hardware accelerators as compared to a software implementation.

In DPAA-equipped SoCs, these offload engines exist as peers to the cores and IO elements, and they use the same queuing mechanism to obtain and transfer data. The details of the specific processing performed by these offload engines is beyond the scope of this document; however, it is important to determine which of these engines will be leveraged in the specific application. The DPAA can then be properly defined to implement the most efficient configuration/definition of the DPAA elements.

7.4.1.2 DPAA Goals

A brief overview of the DPAA elements in order to contextualize the application mapping activities. For more details on the DPAA architecture, see the **QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual**

The primary goals of the DPAA are as follows:

- To provide intelligence within the IO portion of the SoC.
- To route and manage the processing work associated with traffic flows.

- To simplify the ordering and load balance concerns associated with multicore processing.

The DPAA achieves these goals by inspecting and separating ingress traffic into Frame Queues (FQs). In general, the intent is to define a flow or set of flows as the traffic in a particular FQ. The FQs are associated to a specific core or set of cores via a channel. Within the channel definition, the FQs can be prioritized among each other using the Work Queue (WQ) mechanism. The egress flow is similar to the ingress flow. The processors place traffic on a specific FQ, which is associated to a particular physical port via a channel. The same priority scheme using WQs exists on egress, allowing higher priority traffic to pass lower priority traffic on egress without software intervention.

7.4.1.3 FMan Overview

The FMan inspects traffic, splits it into FQs on ingress, and sends traffic from the FQs to the interface on egress.

On ingress traffic, the FMan is configured to determine the traffic split required by the PCD (Parse, Classify, Distribute) function. This allows the user to decide how he wants to define his traffic: typically, by flows or classes of traffic. The PCD can be configured to route all traffic on one port to a single queue or with a higher level of complexity where large numbers of queues are defined and managed. The PCD can identify traffic based on the specific content of the incoming packets (usually within the header) or packet reception rates (policing).

The parse function is used to identify which fields within the data frame determine the traffic split. The fields used may be defined by industry standards, or the user may employ a programmable soft parse feature to accommodate proprietary field (typically header) definition(s). The results of the parse function may be used directly to determine the frame queue; or, the contents of the fields selected by the parse function may be used as a key to select the frame queue. The parse function employs a programmed mask to allow the use of selected fields.

The resultant key from the parse function may be used to assign traffic to a specific queue based on a specific exact match definition of fields in the header. Alternatively, a range of queues can be defined either by using the resultant key directly (if there are a small number of bits in the key) or by performing a hash of the key to use a large number of bits in the flow identifier and create a manageable number of queues.

The FMan also provides a policer function, which is rate-based and allows the user to mark or drop a specific frame that exceeds a traffic threshold. The policing is based on a two-rate, three-color marking algorithm (RFC2698). The sustained and peak rates as well as the burst sizes are user-configurable.

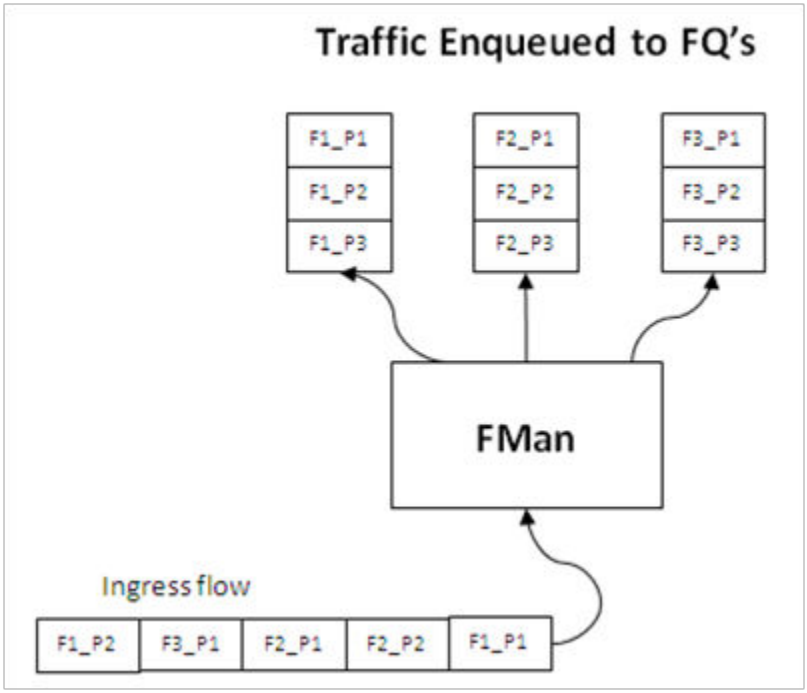

Figure 67. Ingress FMan Flow

The figure above shows the FMan splitting ingress traffic on an external port into a number of queues. However, the FMan works in a similar way on egress: it receives traffic from FQs then transmits the traffic on the designated external port. Alternatively, the FMan can be used to process flows internally via the offline port mechanism: traffic is dequeued (from some other element in the system), processed, then enqueued onto a frame queue processing further within the system.

On ingress traffic, the FMan generates an internal context (IC) data block, which it uses as it performs the PCD function. Optionally, some or all of this information may be added into the frames as they are passed along for further processing. For egress or offline processing, the IC data can be passed with each frame to be processed. This data is mostly the result of the PCD actions and includes the results of the parser, which may be useful for the application software. See the QorIQ DPAA Reference Manual for details on the contents of the IC data block.

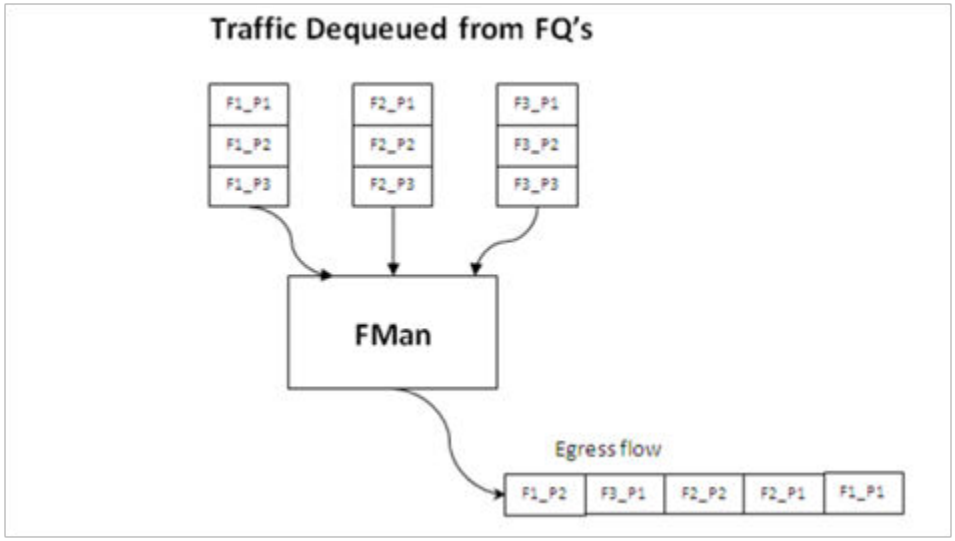

Figure 68. FMan Egress Flow

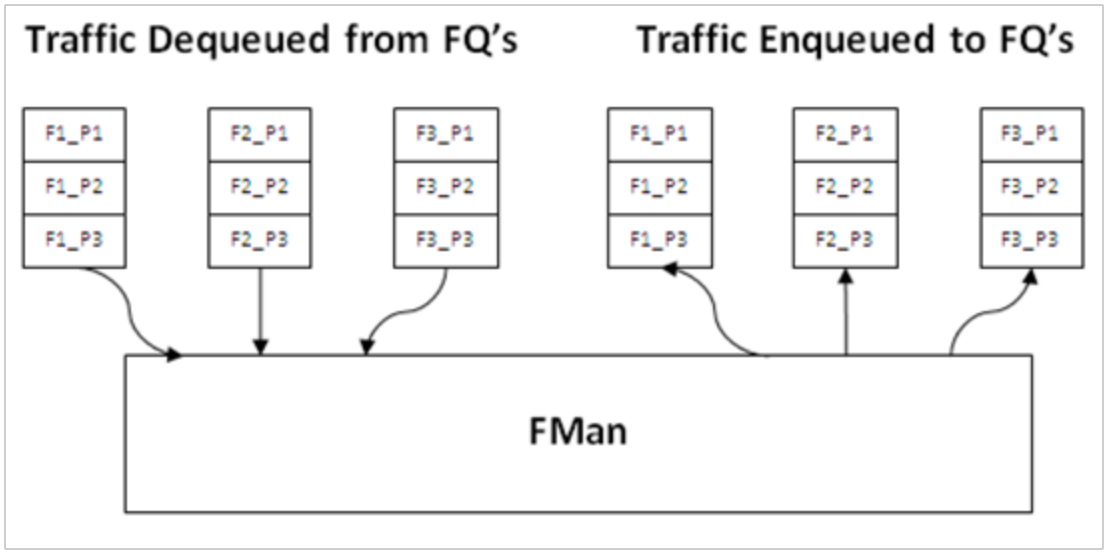

Figure 69. FMan Offline Flow

7.4.1.4 QMan Overview

The QMan links the FQs to producers and consumers (of data traffic) within the SoC. The producers/consumers are either FMan, acceleration blocks, or CPU cores.

All the producers/consumers have one channel, each of which is referred to as a dedicated channel. Additionally, there are a number of pool channels available to allow multiple cores (not FMan or accelerators) to service the same channel. Note that there are channels for each external FMan port, the number of which depends on the SoC, as well as the internal offline ports.

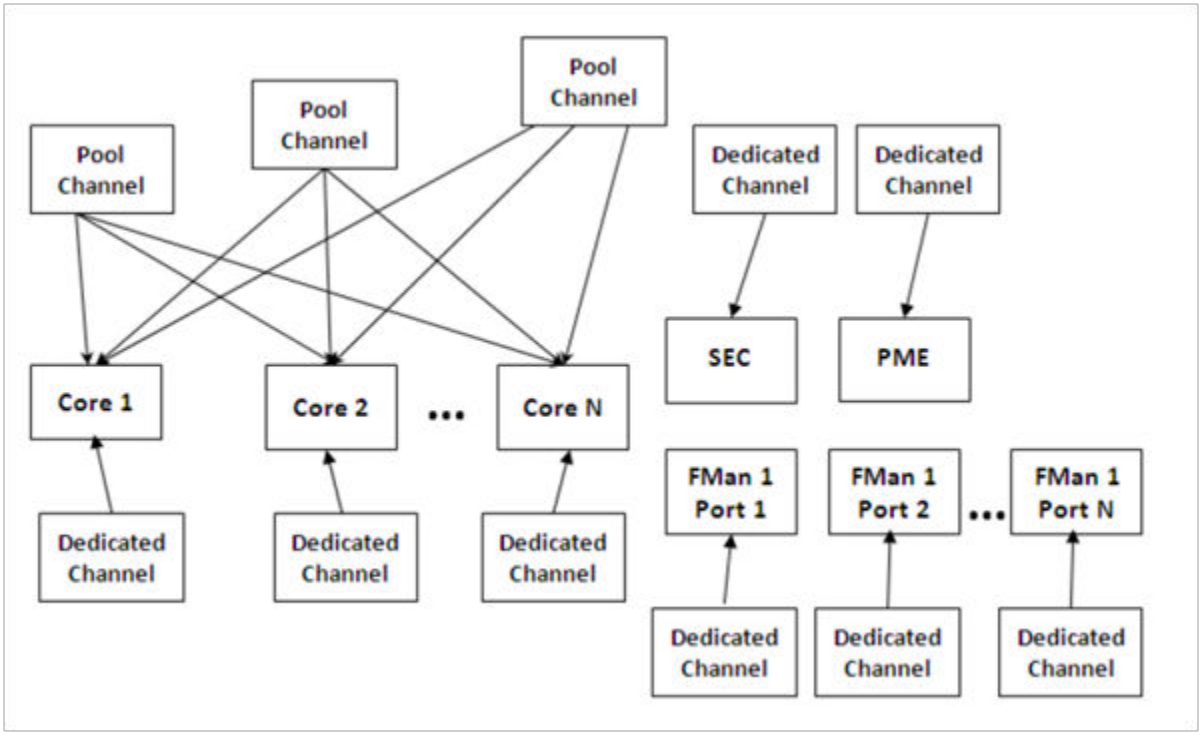

Figure 70. DPAA Channel Types

Each channel provides for eight levels of priority, each of which has its own work queue (WQ). The two highest level WQs are strict priority: traffic from WQ0 must be drained before any other traffic flows; then traffic from WQ1 and then traffic from the other six WQs is allowed to pass. The last six WQs are grouped together in two groups of three, which are configurable in a weighted round robin fashion. Most applications do not need to use all priority levels. When multiple FQs are assigned to the same WQ, QMan implements a credit-based scheme to determine which FQ is scheduled (providing frames to be processed) and how many frames (actually the credit is defined by the number of bytes in the frames) it can dequeue before QMan switches the scheduling to the next FQ on the WQ. If a higher priority WQ becomes active (that is, one of the FQs in the higher priority WQ receives a frame to become non-empty) then the dequeue from the lower priority FQ is suspended until the higher priority frames are dequeued. After the higher priority FQ is serviced, when the lower priority FQ restarts servicing, it does so with the remaining credit it had before being pre-empted by the higher priority FQ.

When the DPAA elements of the SoC are initialized, the FQs are associated with WQs, allowing the traffic to be steered to the desired core (dedicated connect channel), set of cores (pool channel), FMan, or accelerator, using a defined priority.

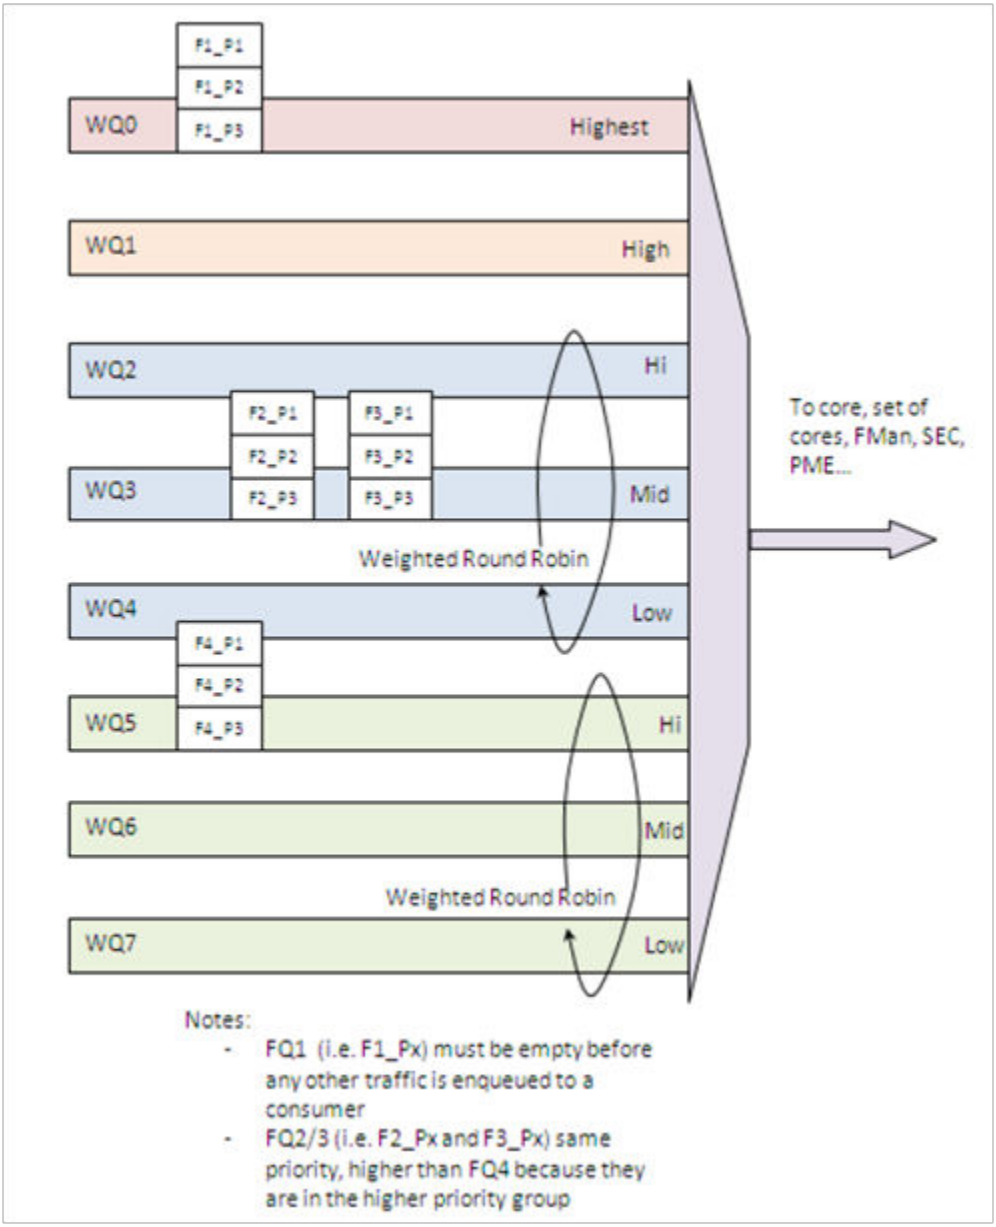

Figure 71. Prioritizing Work

QMan: Portals

A single portal exists for each non-core DPAA producer/consumer (FMan, SEC, and PME). This is a data structure internal to the SoC that passes data directly to/from the consumer's direct connect channel.

Software portals are associated with the processor cores and are, effectively, data structures that the cores use to pass (enqueue) packets to or receive (dequeue) packets from the channels associated with that portal (core). Each SoC has at least as many software portals as there are cores. Software portals are the interface through which the DPAA provides the data processing workload for a single thread of execution.

The portal structure consists of the following:

- The Dequeue Response Ring (DQRR) determines the next packet to be processed.
- The Enqueue Command Ring (EQCR) sends packets from the core to the other elements.
- The Message Ring (MR) notifies the core of the action (for example, attempted dequeue rejected, and so on).

- The Management command and response control registers.

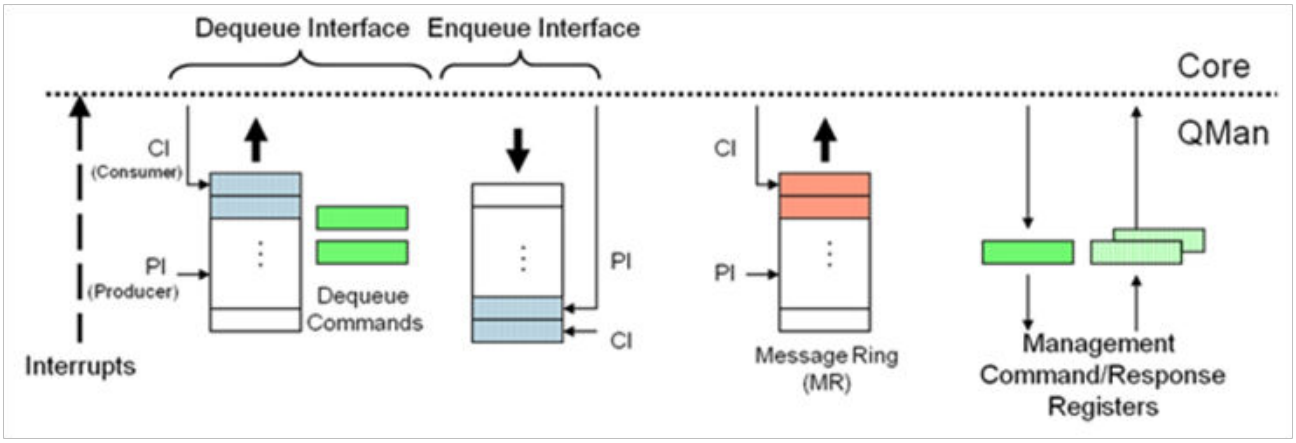

Figure 72. Processor Core Portal

On ingress, the DQRR acts as a small buffer of incoming packets to a particular core. When a section of software performs a get packet type operation, it gets the packet from a pointer provided as an entry in the DQRR for the specific core running that software. Note that the DQRR consolidates all potential channels that may be feeding frames to a particular core. There are up to 16 entries in each DQRR. Each DQRR entry contains:

- a pointer to the packet to be processed,
- an identifier of the frame queue from which the packet originated,
- a sequence number (when configured),
- and additional FMan-determined data (when configured).

When configured for push mode, QMan attempts to fill the DQRR from all the potential incoming channels. When configured in pull mode, QMan only adds one DQRR entry when it is told to by the requesting core. Pull mode may be useful in cases where the traffic flows must be very tightly controlled; however, push mode is normally considered the preferred mode for most applications.

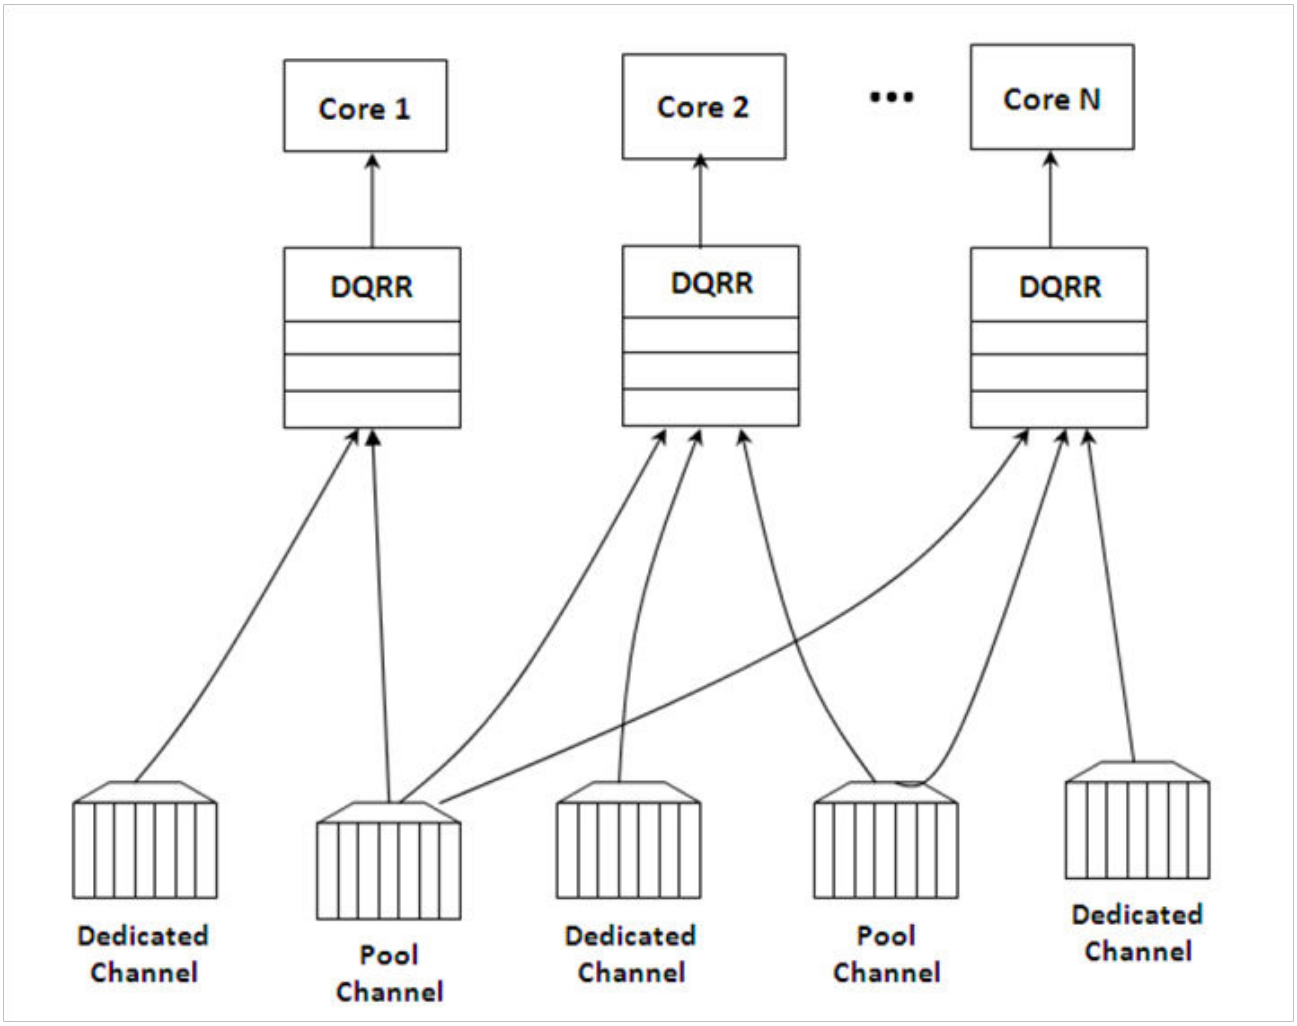

Figure 73. Ingress Channel to Portal Options

The DQRRs are tightly coupled to a processor core. The DPAA implements a feature that allows the DQRR mechanism to pre-allocate, or stash, the L1 and/or L2 cache with data related to the packet to be processed by that core. The intent is to have the data required for packet processing in the cache before the processor runs the “get packet” routine, thereby reducing the overall time spent processing a particular packet.

The following is data that may be warmed into the caches:

- The DQRR entry
- The packet or portion of the packet for a single buffer packet
- The scatter gather list for a multi-buffer packet
- Additional data added by FMan
- FQ context (A and B)

The FQ context is a user-defined space in memory that contains data associated with the FQ (per flow) to be processed. The intent is to place in this data area the state information required when processing a packet for this flow. The FQ context is part of the FQ definition, which is performed when the FQ is initialized.

The cache warming feature is enabled by configuring the capability and some definition of the FQs and QMan at system initialization time. This can provide a significant performance boost and requires little to no change in the processing flow.

When defining the system architecture, it is highly recommended that the user enable this feature and consider how to maximize its impact.

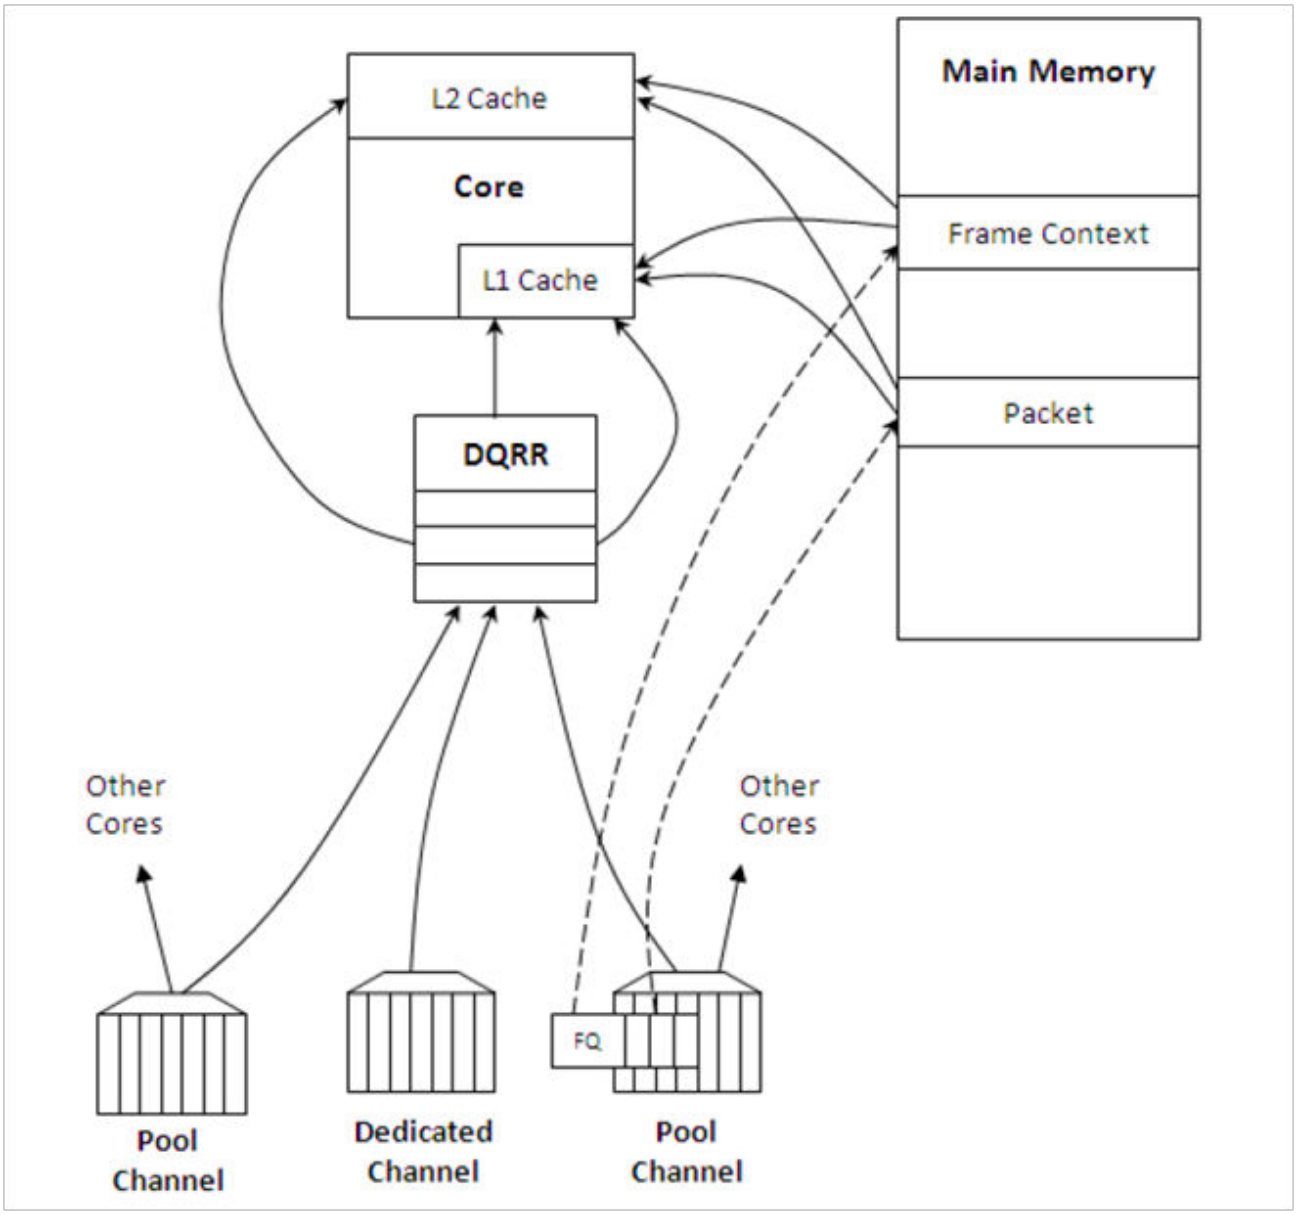

Figure 74. Cache Warming Options

In addition to getting packet information from the DQRR, the software also manages the DQRR by indicating which DQRR entry it will consume next. This is how the QMan determines when the DQRR (portal) is ready to process more frames. Two basic options are provided. In the first option, the software can update the ring pointer after one or several entries have been consumed. By waiting to indicate the consumption of multiple frames, the performance impact of the write doing this is minimized. The second option is to use the discrete consumption acknowledgment (DCA) mode. This mode allows the consumption indication to be directly associated with a frame enqueue operation from the portal (that is, after the frame has been processed and is on the way to the egress queue). This tracking of the DQRR Ring Pointer CI (Consumer Index) helps implement frame ordering by ensuring that QMan does not dequeue a frame from the same FQ (or flow) to a different core until the processing is completed.

7.4.1.5 QMan Scheduling

The QMan links the FQs to producers and consumers (of data traffic) within the SoC.

QMan: Queue schedule options

The primary communication path between QMan and the processor cores is the portal memory structure. QMan uses this interface to schedule the frames to be processed on a per-core basis. For a dedicated channel, the process is straightforward: the QMan places an entry in the DQRR for the portal (processor) of the dedicated channel and dequeues the frame from an FQ to the portal. To do this, QMan determines, based on the priority scheme (previously described) for the channel, which frame should be processed next and then adds an entry to the DQRR for the portal associated with the channel.

When configured for push mode, once the portal requests QMan to provide frames for processing, QMan provides frames until halted. When the DQRR is full and more frames are destined for the portal, QMan waits for an empty slot to become available in the DQRR and then adds more entries (frames to be processed) as slots become available.

When configured for pull mode, the QMan only adds entries to the DQRR at the direct request of the portal (software request). The command to the QMan that determines if a push or pull mode is implemented and tells QMan to provide either one or from one to three (up to three if there are that many frames to be dequeued) frames at a time. This is a tradeoff of smaller granularity (for one frame only) versus memory access consolidation (if the up to three frames option is selected).

When the system is configured to use pool channels, a portal may get frames from more than one channel and a channel may provide frames (work) to more than one portal (core). QMan dequeues frames using the same mechanism described above (updating DQRR) and QMan also provides for some specific scheduling options to account for the pool channel case in which multiple cores may process the same channel.

QMan: Default Scheduling

The default scheduling is to have an FQ send frames to the same core for as long as that FQ is active. An FQ is active until it uses up its allocated credit or becomes empty. After an FQ uses its credit, it is rescheduled again, until it is empty. For its schedule opportunity, the FQ is active and all frames dequeued during the opportunity go to the same core. After the credit is consumed, QMan reactivates that FQ but may assign the flow processing to a different core. This provides for a sticky affinity during the period of the schedule opportunity. The schedule opportunity is managed by the amount of credit assigned to the FQ.

NOTE

A larger credit assigned to an FQ provides for a stickier core affinity, but his makes the processing work granularity larger and may affect load balancing.

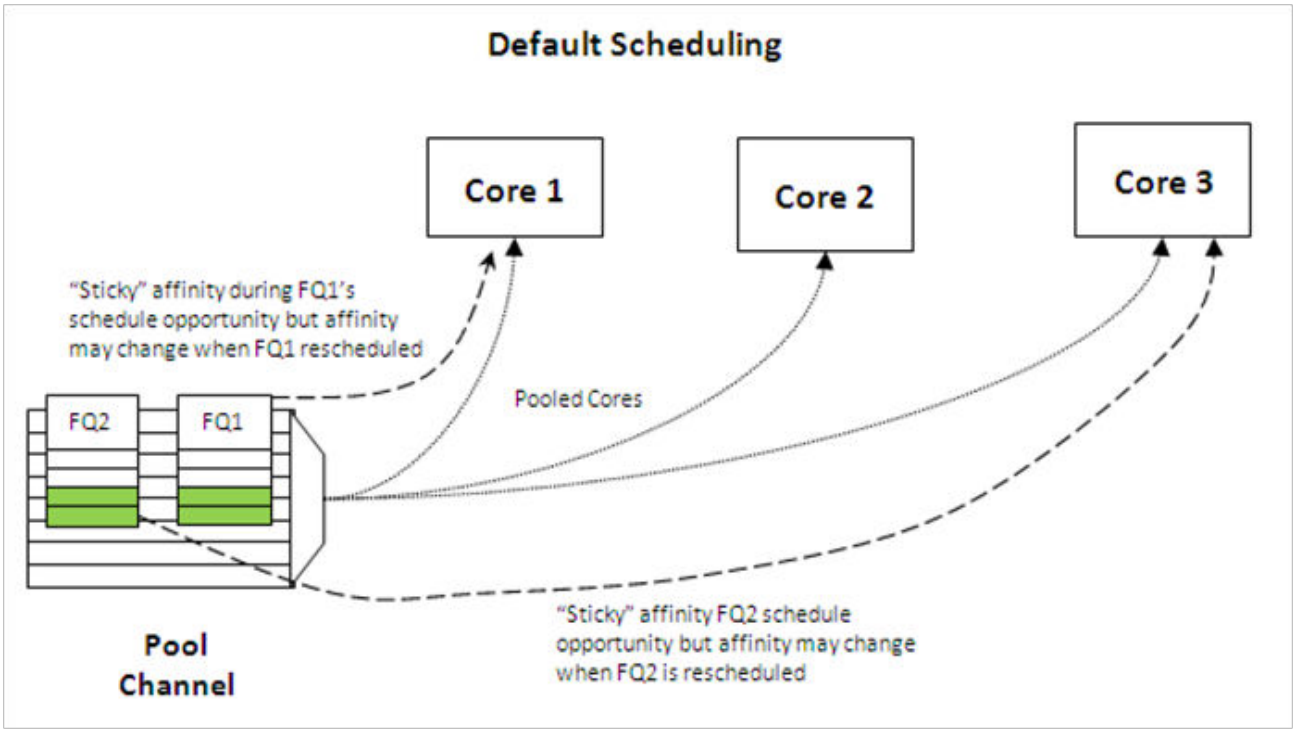

Figure 75. Default Scheduling

QMan: Hold Active Scheduling

With the hold active option, when the QMan assigns an FQ to a particular core, that Q is affined to that core until it is empty. Even after the FQ's credit is consumed, hen it is rescheduled with the next schedule opportunity, the frames go to the same core for processing. This effectively makes the flow-to-core affinity stickier than the default case, ensuring the same flow is processed by the same core for as long as there are frames queued up for processing. Because the flow-to-core affinity is not hard-wired as in the dedicated channel case, the software may still need to account for potential order issues. However, because of flow-to-core biasing, the flow state data is more likely to remain in L1 or L2 cache, increasing hit rates and thus improving processing performance. Because of the specific QMan implementation, only four FQs may be in held active state at a given time.

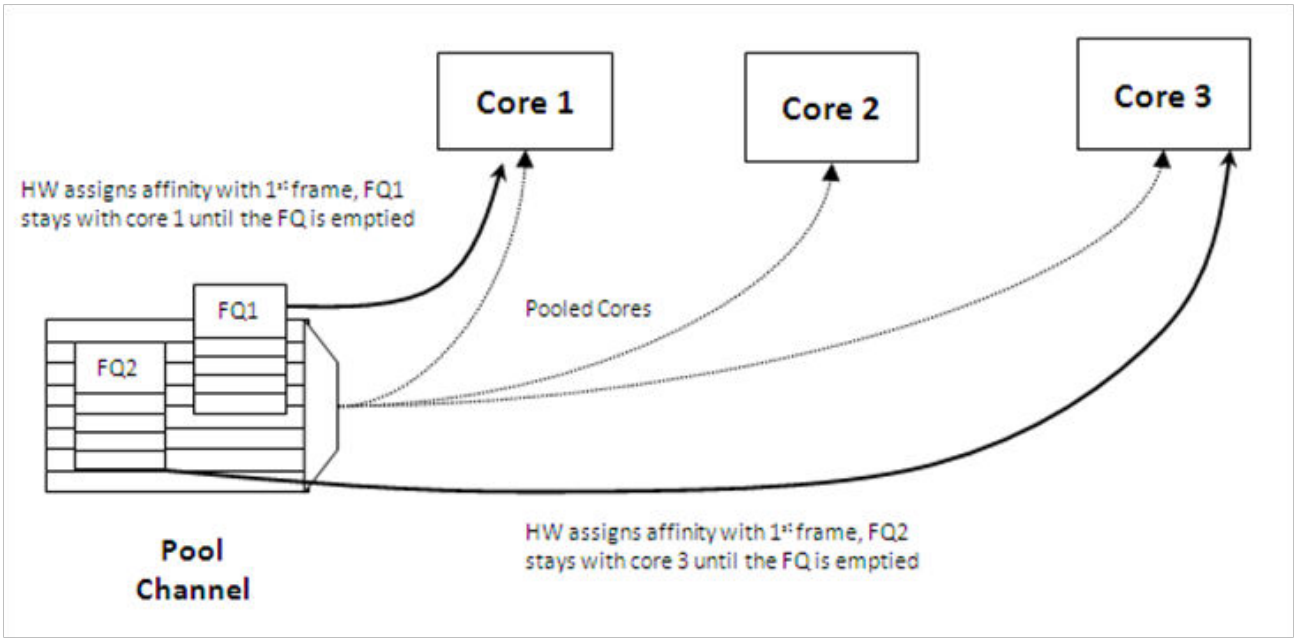

Figure 76. Hold Active Scheduling

QMan: Avoid blocking scheduling

Avoid blocking scheduling QMan can also be scheduled in the avoid blocking mode, which is mutually exclusive to hold active. In this mode, QMan schedules frames for an FQ to any available core in the pool channel. For example, if the credit allows for three frames to be dequeued, the first frame may go to core 1. But, when that dequeue fills core 1's DQRR, QMan finds the next available DQRR entry in any core in the pool. With avoid blocking mode there is no biasing of the flow to core affinity. This mode is useful if a particular flow either has no specific order requirements or the anticipated processing required for a single flow is expected to consume more than one core's worth of processing capability.

Alternatively, software can bypass QMan scheduling and directly control the dequeue of frame descriptors from the FQ. This mode is implemented by placing the FQ in parked state. This allows software to determine precisely which flow will be processed (by the core running the software). However, it requires software to manage the scheduling, which can add overhead and impact performance.

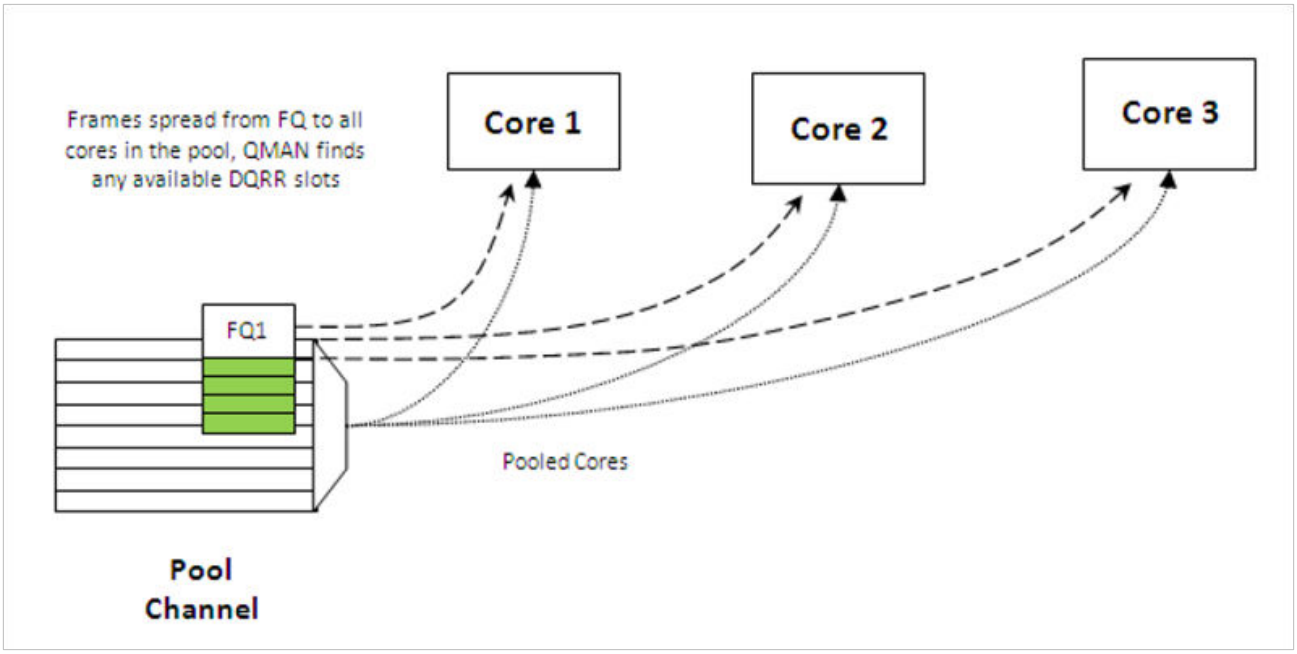

Figure 77. Avoid Blocking Scheduling

QMan: Order Definition/ Restoration

The QMan provides a mechanism to strictly enforce ordering. Each FQ may be defined to participate in the process of an order definition point and/or an order restoration point. On ingress, an order definition point provides for a 14 bit sequence number assigned to each frame (incremented per frame) in a FQ in the order in which they were received on the interface. The sequence number is placed in the DQRR entry for the frame when it is dequeued to a portal. This allows software to efficiently determine which packet it is currently processing in the sequence without the need to access a shared (between cores) data structure. On egress, an order restoration point delays placing a frame onto the FQ until the expected next sequence number is encountered. From the software standpoint, once it has determined the relative sequence of a packet, it can enqueue it and resume other processing in a fire-and-forget manner.

NOTE

The order definition points and order restoration points are not dependent on each other; it is possible to have one without the other depending on application requirements. To effectively use these mechanisms, the packet software must be aware of the sequence tagging.

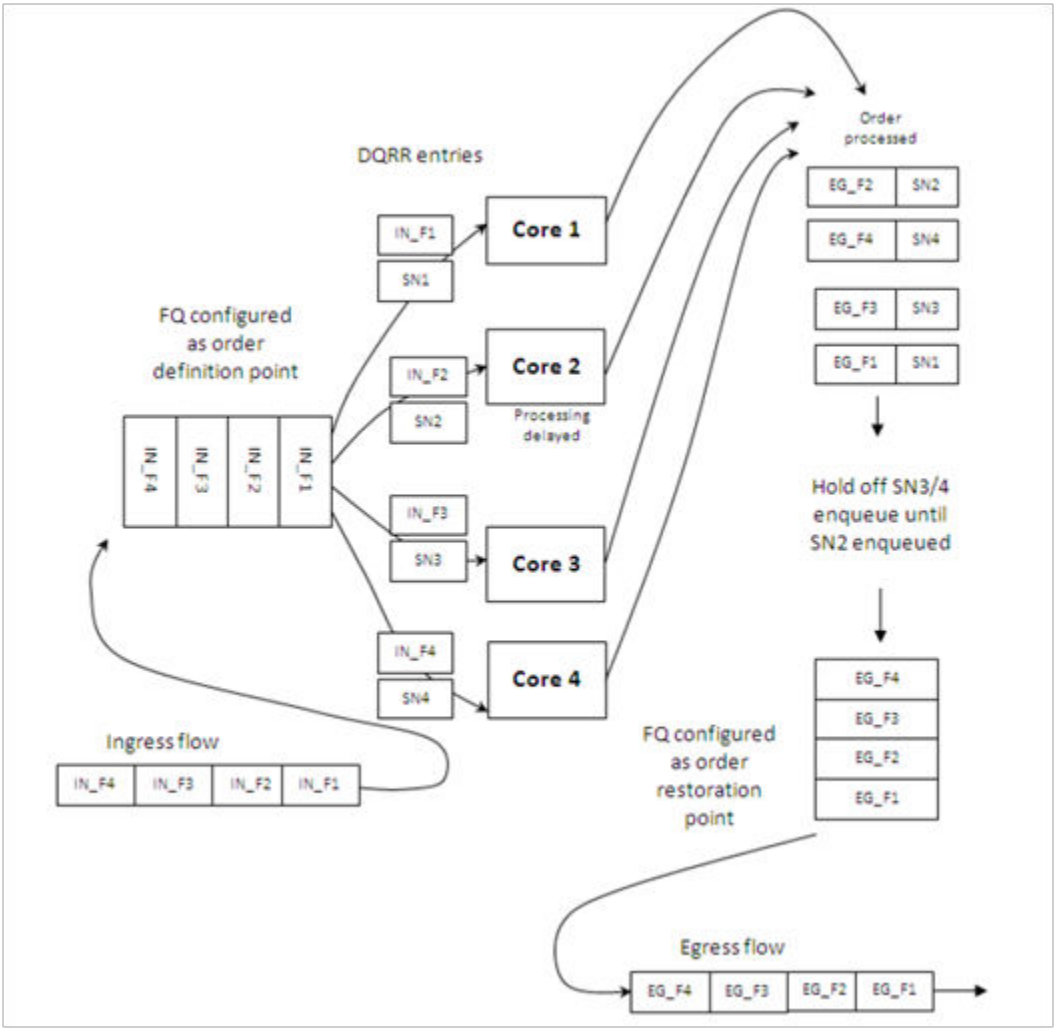

Figure 78. Order Definition/Restoration

As processors enqueue packets for egress, it is possible that they may skip a sequence number because of the nature of the protocol being processed. To handle this situation, each FQ that participates in the order restoration service maintains its own Next Expected Sequence Number (NESN). When the difference between the sequence number of the next expected and the most recently received sequence number exceeds the configurable ORP threshold, QMan gives up on the missing frame(s) and autonomously advances the NESN to bring the skew within threshold. This causes any deferred enqueus that are currently held in the ORP link list to become unblocked and immediately enqueue them to their destination FQ. If the “skipped” frame arrives after this, the ORP can be configured to reject or immediately enqueu the late arriving frame.

7.4.1.6 BMan

The BMan block manages the data buffers in memory. Processing cores, FMan, SEC and PME all may get a buffer directly from the BMan without additional software intervention. These elements are also responsible for releasing the buffers back to the pool when the buffer is no longer in use.

Typically, the FMan directly acquires a buffer from the BMan on ingress. When the traffic is terminated in the system, the core generally releases the buffer. When the traffic is received, processed, and then transmitted, the same buffer may be used throughout the process. In this case, the FMan may be configured to release the buffer automatically, when the transmit completes.

The BMan also supports single or multi-buffer frames. Single buffer frames generally require the adequately defined (or allocated) buffer size to contain the largest data frame and minimize system overhead. Multi-buffer frames potentially allow

better memory utilization, but the entity passed between the producers/consumers is a scatter-gather table (that then points to the buffers within the frame) rather than the pointer to the entire frame, which adds an extra processing requirement to the processing element.

The software defines pools of buffers when the system is initialized. The BMan unit itself manages the pointers to the buffers provided by the oftware and can be configured to interrupt the software when it reaches a condition where the number of free buffers is depleted (so that software may provide more buffers as needed).

7.4.1.7 Order Handling

The DPAA helps address packet order issues that may occur as a result of running an application in a multiple processor environment. And there are several ways to leverage the DPAA to handle flow order in a system. The order preservation technique maps flows such that a specific flow always executes on a specific processor core.

For the case that DPAA handles flow order, the individual flow will not have multiple execution threads and the system will run much like a single core system. This option generally requires less impact to legacy, single-core software but may not effectively utilize all the processing cores in the system because it requires using a dedicated channel to the processors. The FMan PCD can be configured to either directly match a flow to a core or to use the hashing to provide traffic spreading that offers a permanent flow-to-core affinity.

If the application must use pool channels to balance the processing load then the software must be more involved in the ordering. The software can make use of the order restoration point function in QMan, which requires the software to manage a sequence number for frames enqueued on egress. Alternatively, the software can be implemented to maintain order by biasing the stickiness of flow affinity with default or hold active scheduling; lock contention and cache misses can be biased to increase performance.

If there are no order requirements then load balancing can be achieved by associating the non-ordered traffic to a pool of cores.

NOTE

All of these techniques may be implemented simultaneously on the same SoC; as long as the flow definition is precise enough to split the traffic types, it is simply a matter of proper defining the FQs and associating them to the proper channels in the system.

Using the exact match flow definition to preserve order

The simplest technique for preserving order is to route the ingress traffic of an individual flow to a particular core. For the particular flow in question, the system appears as a legacy, single-core programming model and, therefore, has minimal impact on the structure of the software. In this case, the flow definition determines the core affinity of a flow.

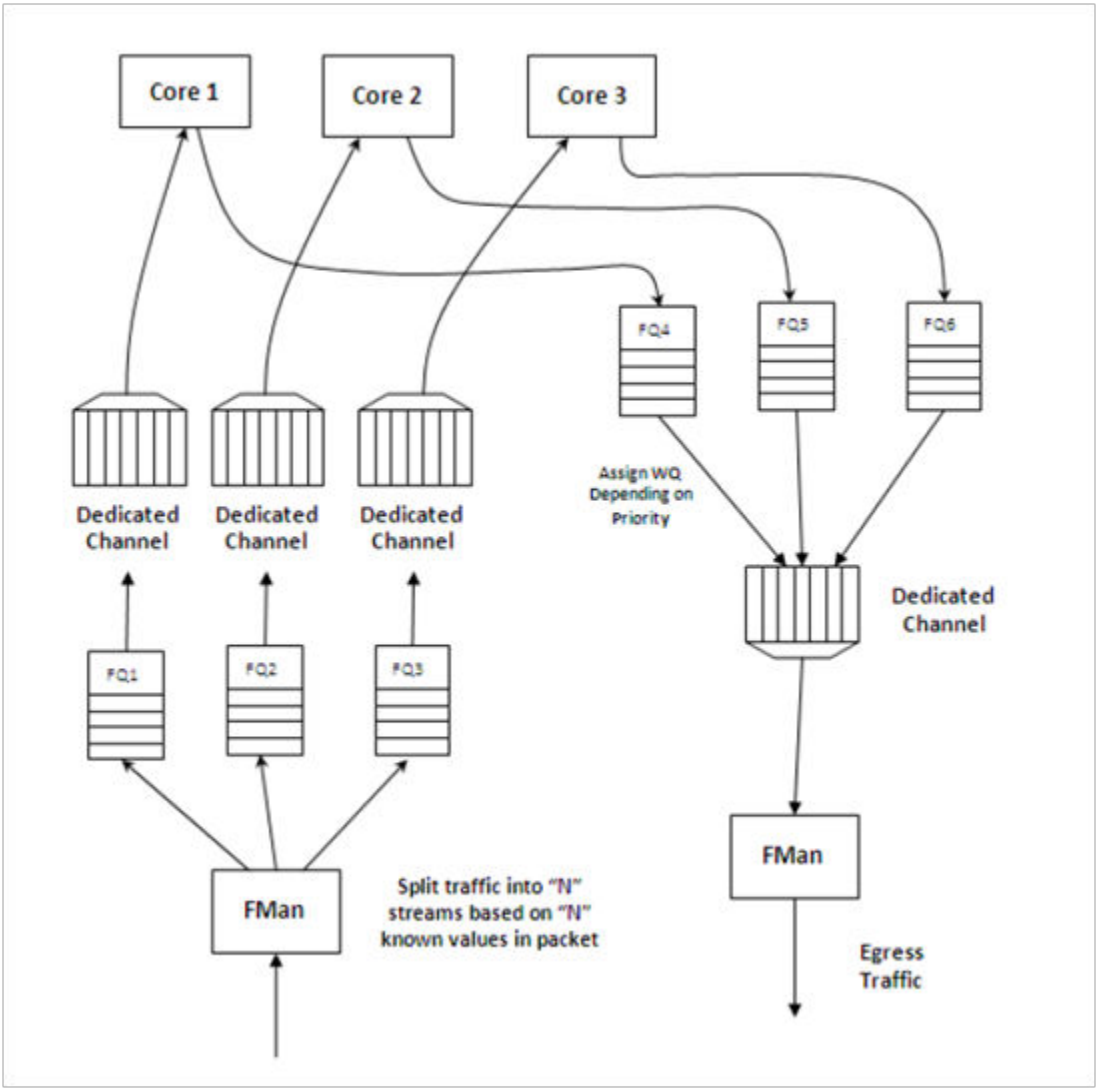

Figure 79. Direct Flow-to-Core Mapping (Order Preserved)

This technique is completely deterministic: the DPAA forces specific flows to a specific processor, so it may be easier to determine the performance assuming the ingress flows are completely understood and well defined. Notice that a particular processor core may become overloaded with traffic while another sits idle for increasingly random flow traffic rates.

To implement this sort of scheme, the FMan must be configured to exactly match fields in the traffic stream. This approach can only be used for a limited number of total flows before the FMan's internal resources are consumed.

In general, this sort of hard-wired approach should be reserved for either critical out-of-band traffic or for systems with a small number of flows that can benefit from the highly deterministic nature of the processing.

Using hashing to distribute flows across cores

The FMan can be configured to extract data from a field or fields within the data frame, build a key from that, and then hash the resultant key into a smaller number. This is a useful technique to handle a larger number of flows while ensuring that a particular flow is always associated with a particular core. An example is to define a flow as an IPv4 source + IPv4 destination address. Both fields together constitute 64 bits, so there are 264 possible combinations for the flow in that definition. The FMan then uses a hash algorithm to compress this into a manageable number of bits. Note that, because the hash algorithm is consistent, packets from a particular flow always go to the same FQ. By utilizing this technique, the flows can be spread in a pseudo-random, consistent (per flow) manner to a smaller number of FQs. For example, hashing the 64 bits down to 2

bits spreads the flows among four queues. Then these queues can be assigned to four separate cores by using a dedicated channel; effectively, this appears as a single-core implementation to any specific flow.

This spreading technique works best with a large number of possible flows to allow the hash algorithm to evenly spread the traffic between the FQs. In the example below, when the system is only expected to have eight flows at a given time, there is a good chance the hash will not assign exactly two flows per FQ to evenly distribute the flows between the four cores shown. However, when the number of flows handled is in the hundreds, the odds are good that the hash will evenly spread the flows for processing.

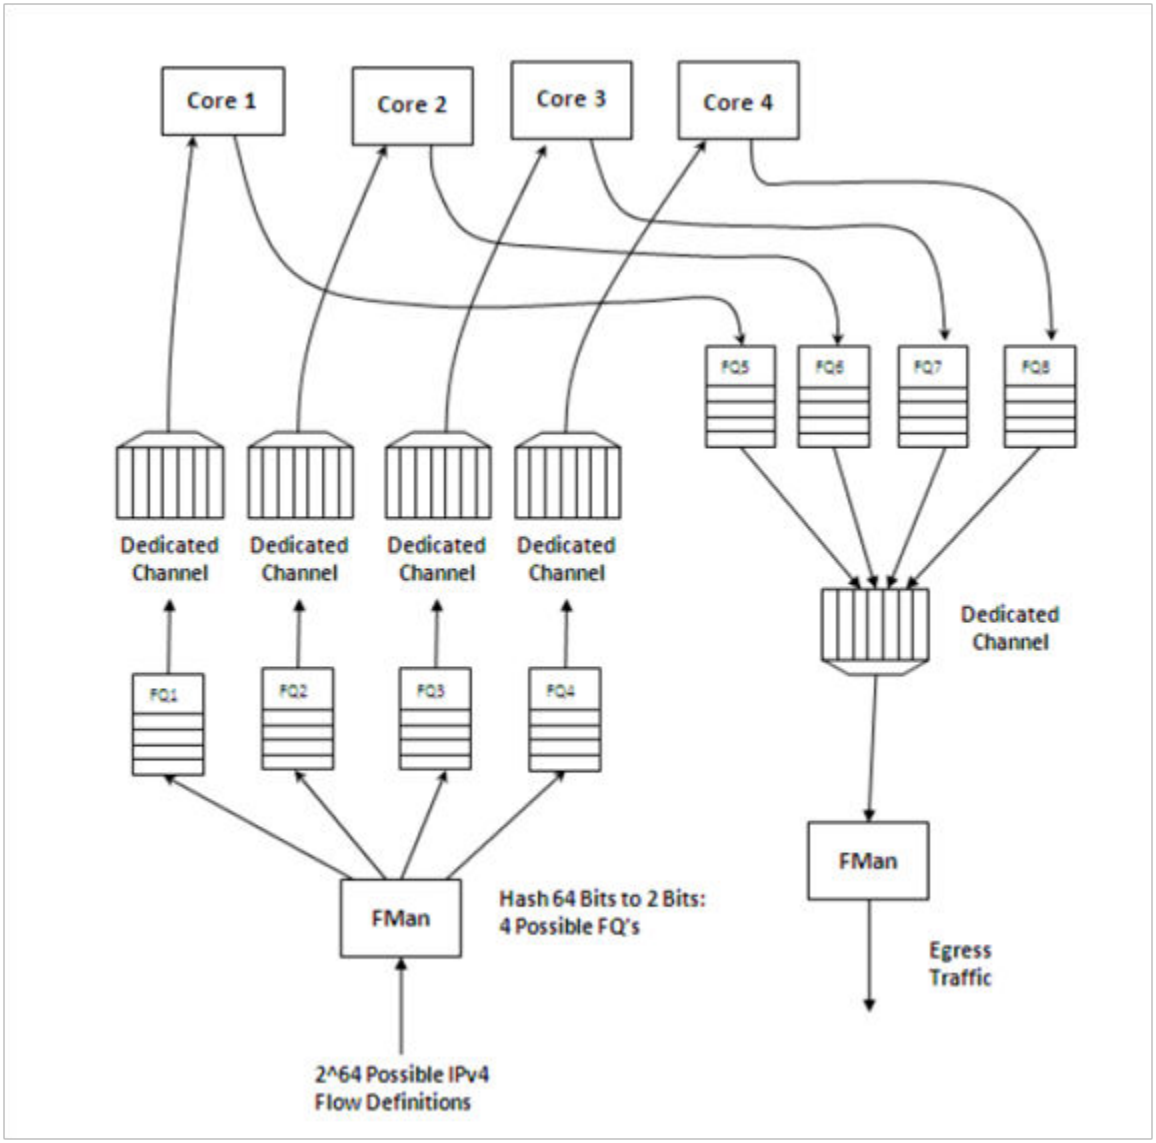

Figure 80. Simple flow distribution via hash (order preserved)

To optimize cache warming, the total number of hash buckets can be increased with flow-to-core affinity maintained. When the number of hash values is larger than the number of expected flows at a given time, it is likely though not guaranteed that each FQ will contain a single flow. For most applications, the penalty of a hash collision is two or more flows within a single FQ. In the case of multiple flows within a single FQ, the cache warming and temporary core affinity benefits are reduced unless the flow order is maintained per flow.

Note that there are 24 bits architected for the FQ ID, so there may be as many as 16 million FQs in the system. Although this total may be impractical, this does allow for the user to define more FQs than expected flows in order to reduce the likelihood of a hash collision; it also allows flexibility in assigning FQID's in some meaningful manner. It is also possible to hash some

fields in the data frame and concatenate other parse results, possibly allowing a defined one-to-one flow to FQ implementation without hash collisions.

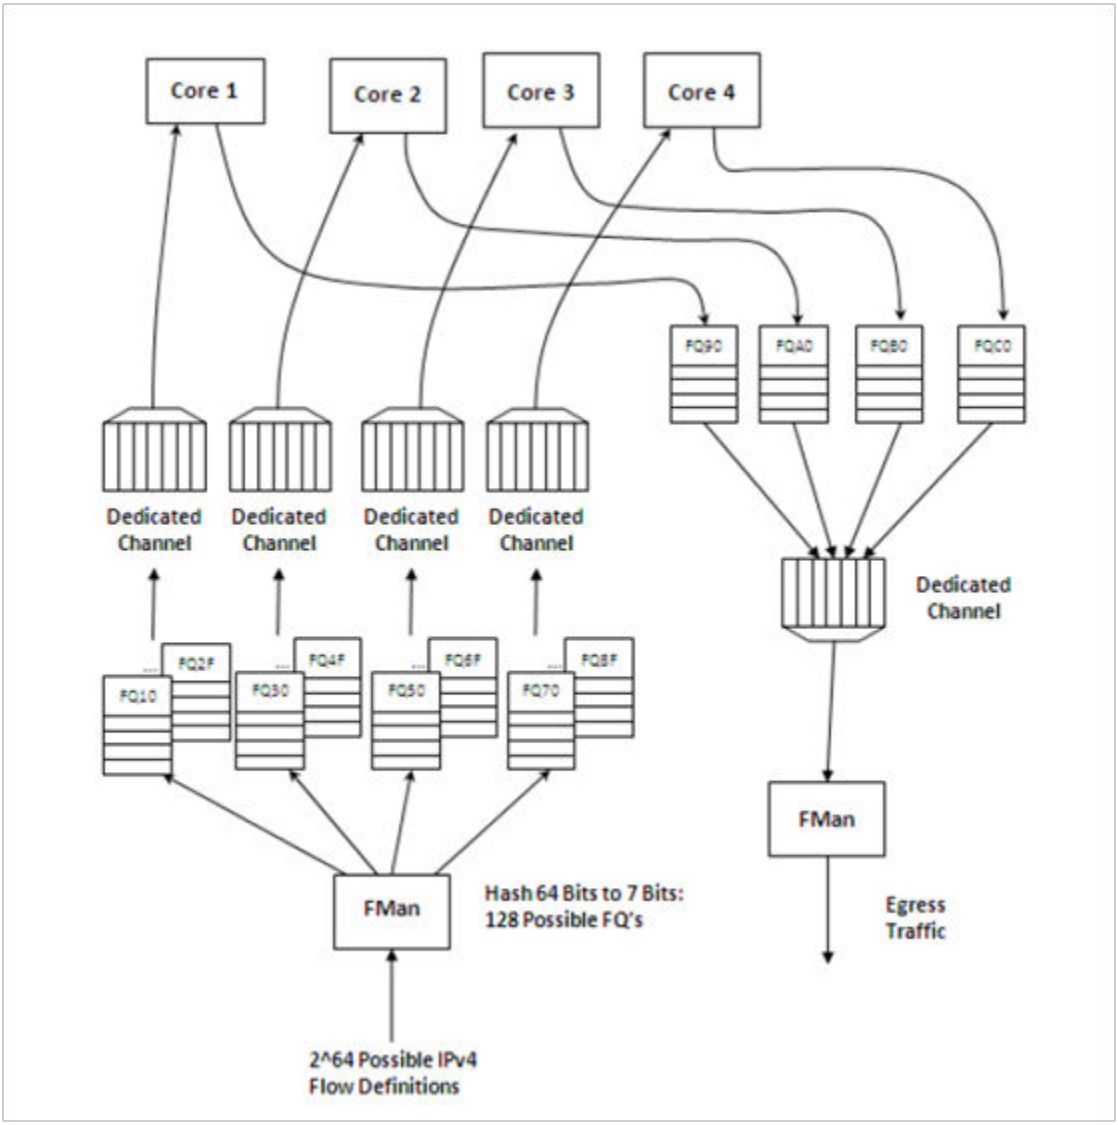

Figure 81. . Using hash to assign one flow per FQ (order preserved and cache stashing effective)

7.4.1.8 Pool Channels

A user may employ a pool channel approach where multiple cores may pool together to service a specific set of flows. This alternative approach allows potentially better processing balance, but increases the likelihood that packets may be processed out of order allowing egress packets to pass ingress packets.

So far, the techniques discussed in this white paper have involved assigning specific flows to the same core to ensure that the same core always processes the same flow or set of flows, thereby preserving flow order. However, depending on the nature of the flows being processed (that is, variable frame sizes, difficulty efficiently spreading due to the nature of the flow contents, and so on), this may not effectively balance the processing load among the cores. Alternatively, a user may employ a pool channel approach where multiple cores may pool together to service a specific set of flows. This alternative approach allows potentially better processing balance, but increases the likelihood that packets may be processed out of order allowing egress packets to pass ingress packets. When the application does not require flows to be processed in order, the pool channel approach allows the easiest method for balancing the processing load. When a pool channel is used and order is required, the software must maintain order. The hardware order preservation may be used by the software to implement order

without requiring locked access to shared state information. When the system uses a software lock to handle order then the default scheduling and hold active scheduling tends to minimize lock contention.

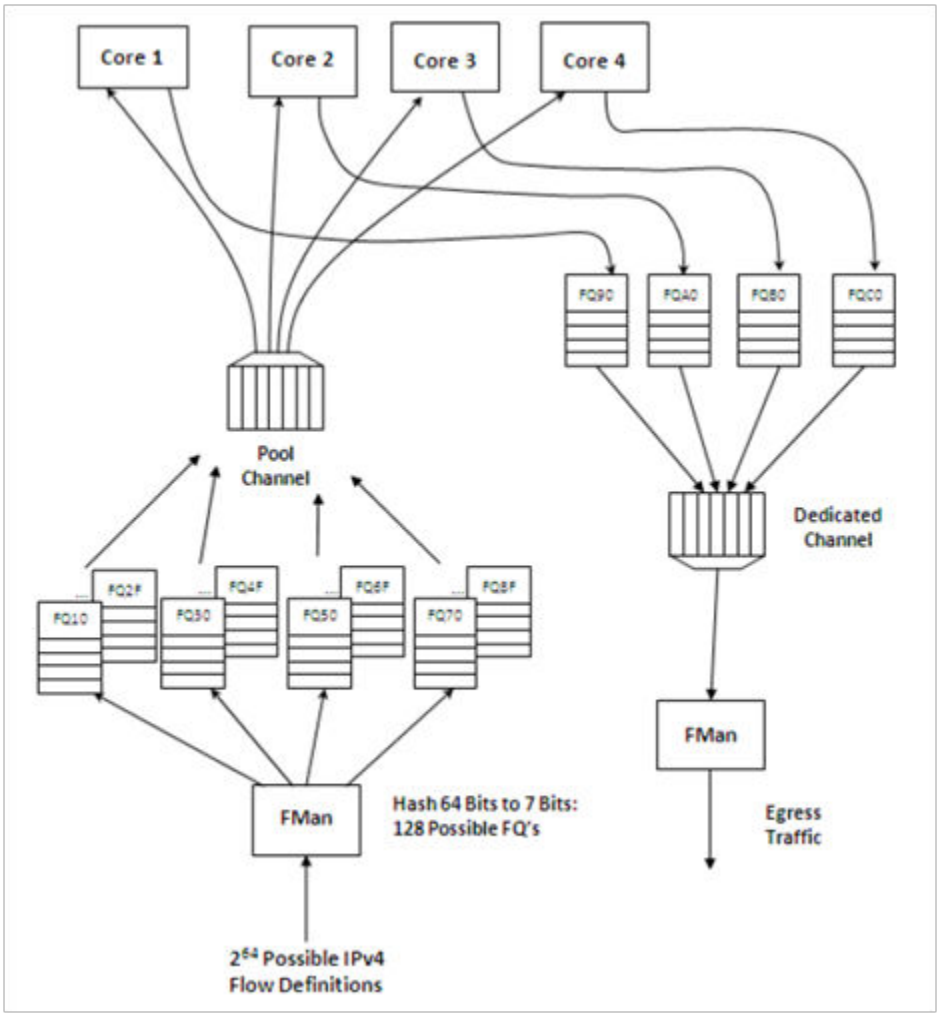

Figure 82. Using pool channel to balance processing

Order preservation using hold active scheduling and DCA mode

As shown in the examples above, order is preserved as long as two or more cores never process frames from the same flow at the same time. This can also be accomplished by using hold active scheduling along with discrete consumption acknowledgment (DCA) mode associated with the DQRR. Although flow affinity may change for an FQ with hold active scheduling when the FQ is emptied, if the new work (from frames received after the FQ is emptied) is held off until all previous work completes, then the flow will not be processed by multiple cores simultaneously, thereby preserving order.

When the FQ is emptied, QMan places the FQ in hold suspended state, which means that no further work for that FQ is enqueued to any core until all previously enqueued work is completed. Because DCA mode effectively holds off the consumption notification (from the core to QMan) until the resultant processed frame is enqueued for egress, this implies processing is completely finished for any frames in flight to the core. After all the in-flight frames have been processed, QMan reschedules the FQ to the appropriate core.

NOTE

After the FQ is empty and when in hold active mode, the affinity is not likely to change. This is because the indication of “completeness” from the core currently processing the flow frees up some DQRR slots that could be used by QMan when it restarts enqueuing work for the flow. The possibility of the flow-to-core affinity changing when the FQ empties is only discussed as a worst case possibility with regards to order preservation.

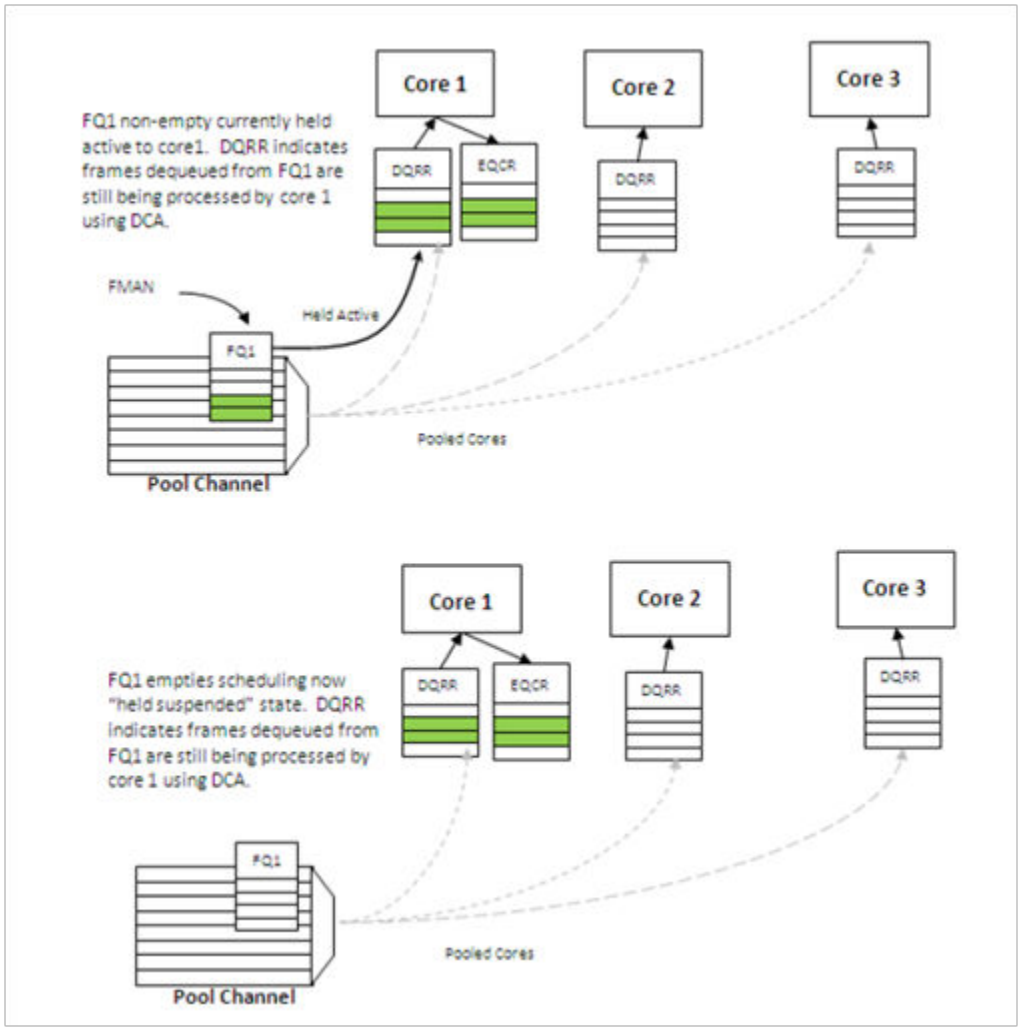

Figure 83. Hold active to held suspended mode

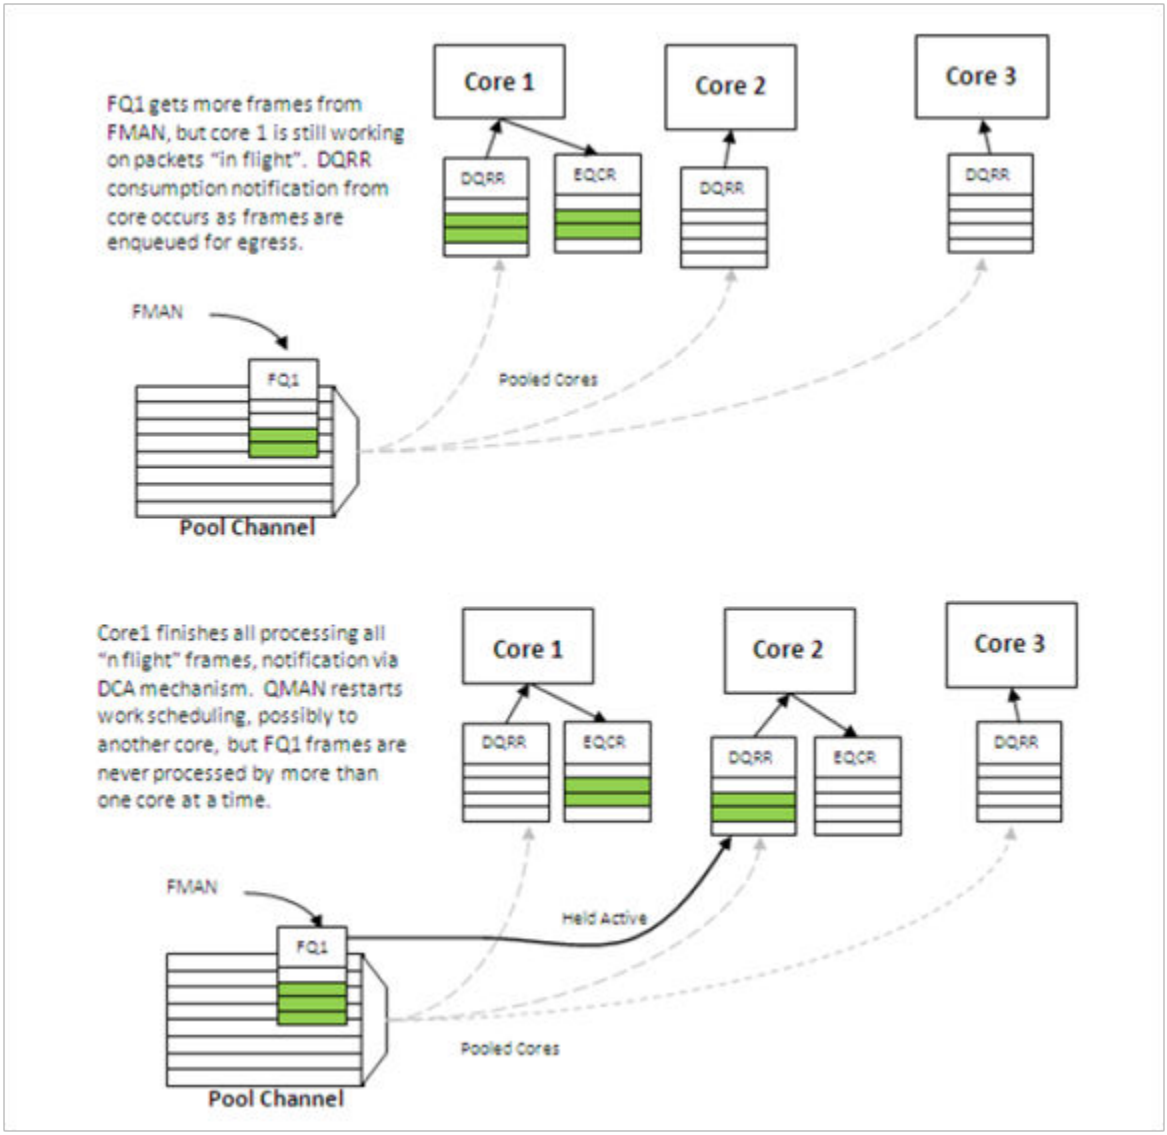

Figure 84. Held suspended to hold active mode

Congestion management

From an overall system perspective, there are multiple potential overflow conditions to consider. The maximum number of frames active in the system (the number of frames in flight) is determined by the amount of memory allocated to the Packed Frame Queue Descriptors (PQFD's). Each PQFD is 64 bytes and can identify up to three frames, so the total number of frames that can be identified by the PQFDs is equal to the amount of memory allocated for PQFD space divided by 64 bytes (per entry) multiplied by three (frames per entry).

A pool of buffers may deplete in BMan. This depends on how many buffers have been assigned by software for BMan. BMan may raise an interrupt to request more buffers when in a depleted state for a given pool; the software can manage the congestion state of the buffer pools in this manner.

In addition to these high-level system mechanisms, congestion management may also be identified specific to the FQs. A number of FQs can be grouped together to form a congestion group (up to 256 congestion groups per system for most DPAA SoCs). These FQs need not be on the same channel. The system may be configured to indicate congestion either by consider the aggregate number of bytes within the FQ's in the congestion group or by the aggregate number of frames within the congestion group. The frame count option is useful when attempting to manage the number of buffers in a buffer pool as they

are used by a particular core or group of cores. The byte count is useful to manage the amount of system memory used by a particular core or group of cores.

When the total number of frames/bytes within the frames in the congestion group exceeds the set threshold, subsequent enqueues to any of the FQs in the group are rejected; in general, the frame is dropped. For the congestion group mechanism, the decision to reject is defined by a programmed weighted random early discard (WRED) algorithm programmed when the congestion group is defined.

In addition, a specific FQ can be set to a particular maximum allowable depth (in bytes); after the threshold is reached enqueue attempts will be rejected. This is a maximum threshold: there is no WRED algorithm for this mechanism. Note that, when the FQ threshold is not set, a specific FQ may fill until some other mechanism (because it's part of a congestion group or system PQFD depletion or BMAN depletion) prevents the FQ from getting frames. Typically, FQs within a congestion group are expected to have a maximum threshold set for each FQ in the group to ensure a single queue does not get stuck and unfairly consume the congestion group. Note that, when an FQ does not have a queue depth set and/or is not a part of a congestion group, the FQ has no maximum depth. It would be possible for a single queue to have all the frames in the system, until the PQFD space or the buffer pool is exhausted.

7.4.1.9 Application Mapping

The first step in application mapping is to determine how much processing capability is required for tasks that may be partitioned separately.

Processor core assignment

Consider a typical networking application with a set of distinct control and data plane functionality. Assigning two cores to perform control plane tasks and six cores to perform data plane tasks may be a reasonable partition in an eight-core device. When initially identifying the SoC required for the application, along with the number of cores and frequencies required, the designer makes some performance assumptions based on previous designs and/or applicable benchmark data.

Define flows

Next, define what flows will be in the system. Key considerations for flow definition include the following:

- Total number of flows expected at a given time within the system
- Desired flow-to-core affinity, ingress flow destination
- Processor load balancing
- Frame sizes (may be fixed or variable)
- Order preservation requirement
- Traffic priority relative to the flows
- Expected bandwidth requirement of specific flows or class of flows
- Desired congestion handling

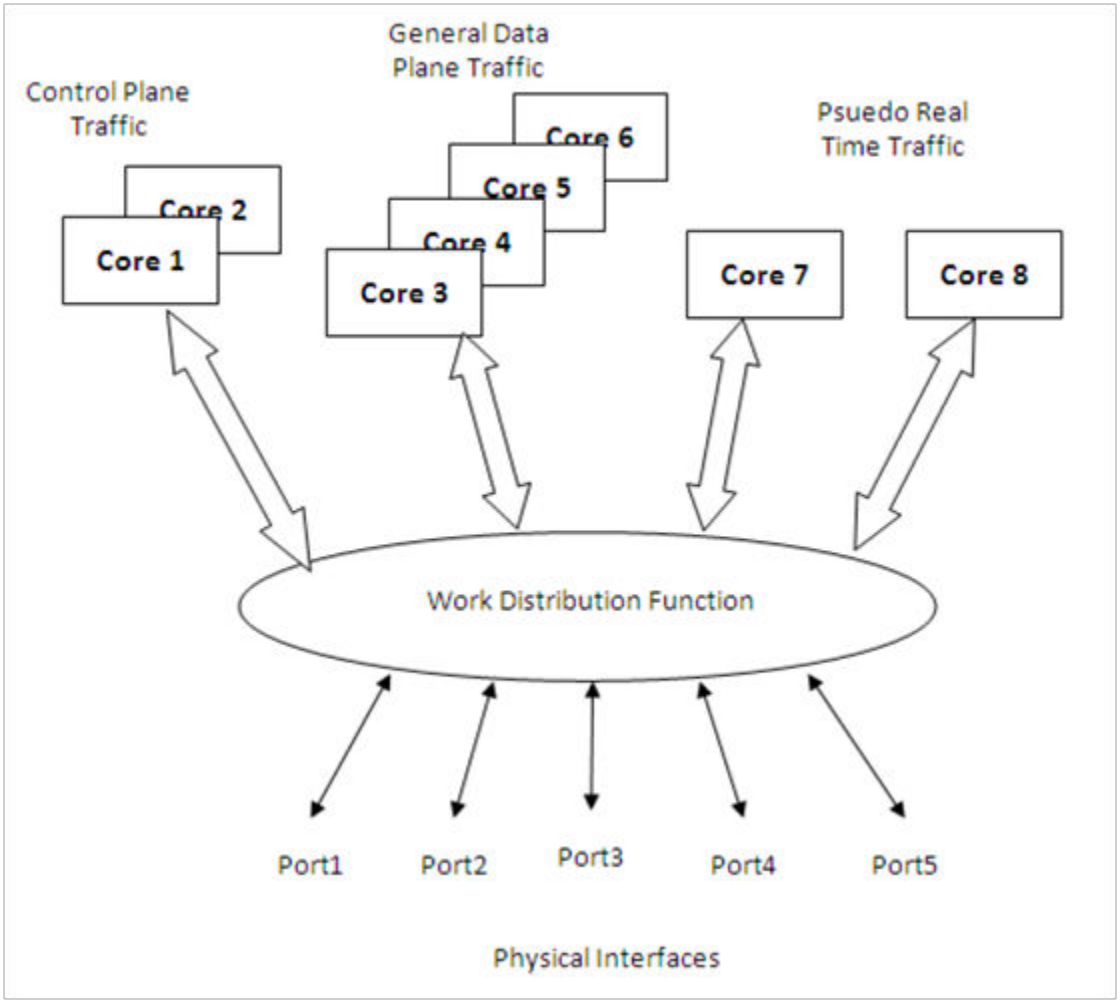

Figure 85. Example Application with Three Classes

In the figure above, two cores are dedicated to processing control plane traffic, four cores are assigned to process general data traffic and special time critical traffic is split between two other cores. In this case, assume the traffic characteristics in the following table. With this system-level definition, the designer can determine which flows are in the system and how to define the FQs needed.

Table 120. Traffic characteristics

Characteristic	Definition
Control plane traffic	• Terminated in the system and any particular packet sent has no dependency on previous or subsequent packets (no order requirement). • May occur on ports 1, 2 or 3. • Ingress control plane traffic on port three is higher priority than the other ports. • Any ICMP packet on ports 1, 2 or 3 is considered control plane traffic. • Control plane traffic makes up a small portion of the overall port bandwidth.

Table continues on the next page...

Table 120. Traffic characteristics (continued)

Characteristic	Definition
General data plane traffic	• May occur on ports 1, 2 or 3 and is expected to comprise the bulk of the traffic on these ports. • The function performed is done on flows and egress packets must match the order of ingress packets. • A flow is identified by the IP source address. • The system can expect up to 50 flows at a time. • All flows have the same priority and a lower priority than any control plane traffic. • It is expected that software will not always be able to keep up with this traffic and the system should drop packets after some amount of packets are within the system.
Pseudo real-time traffic	• A high amount of determinism is required by the function. • This traffic only occurs on port 4 and port 5 and is identified by a proprietary field in the header; any traffic on these ports without the proper value in this field is dropped. • All valid ingress traffic on port 4 is to be processed by core 7, ingress traffic on port 5 processed by core 8. • There are only two flows, one from port 4 to port 5 and one from port 5 to port 4, egress order must match ingress order. • The traffic on these flows are the highest priority.

Identify ingress and egress frame queues (FQs)

For many applications, because the ingress flow has more implications for processing, it is easier to consider ingress flows first. In the example above, the control plane and pseudo real-time traffic FQ definitions are fairly straightforward. For the control plane ingress, one FQ for lower priority traffic on ports 1 and 2 and one for the higher priority traffic would work. Note that two ports can share the same queue on ingress when it does not matter for which core the traffic is destined. For ingress pseudo real-time traffic, there is one FQ on port 4 and one FQ on port 5.

The general data plane ingress traffic is more complicated. Multiple options exist which maintain the required ordering for this traffic. While this traffic would certainly benefit from some of the control features of the QMan (cache warming, and so on), it is best to have one FQ per flow. Per the example, the flow is identified by the IP source (32-bits), which consists of too many bits to directly use as the FQID. The hash algorithm can be used to reduce the 32-bits to a smaller number; in this case, six bits would generate 64 queues, which is more than the anticipated maximum flows at a given time. However, this is not significantly more than maximum flow expected, so more FQs can be defined to reduce hash collisions. Note that, in this case, a hash collision implies that two flows are assigned to the same FQ. As the ingress FQs fill directly from the port, the packet order is still maintained when there is a collision (two flows into one FQ). However, having two flows in the same FQ tends to minimize the impact of cache warming. There may be other possibilities to refine the definition of flows to ensure a one-to-one mapping of flows to FQs (for example, concatenating other fields in the frame) but for this example assume that an 8 bit hash (256 FQs) minimizes the likelihood of two flows in the FQ to an acceptable level.

Consider the case in which, on ingress, there is traffic that does not match any of the intended flow definitions. The design can handle these by placing unidentifiable packets into a separate garbage FQ or by simply having the FMan discard the packets.

On egress control traffic, because the traffic may go out on three different ports, three FQs are required. For the egress pseudo real-time traffic, there is one queue for each port as well.

For the egress data plane traffic, there are multiple options. When the flows are pinned to a specific core, it might be possible to simply have one queue per port. In this case, the cores would effectively be maintaining order. However, for this example, assume that the system uses the order definition/order restoration mechanism previously described. In this case, the system needs to define an FQ for each egress flow. Note that, since software is managing this, there is no need for any sort of hash algorithm to spread the traffic; the cores will enqueue to the FQ associated with the flow. When there are no more than 50 flows in the system at one time, and number of egress flows per port is unknown, the system could define 50 FQs for each port when the DPAA is initialized.

Define PCD configuration for ingress FQs

This step involves defining how the FMan splits the incoming port traffic into the FQs. In general, this is accomplished using the PCD (Parse, Classify, Distribute) function and results in specific traffic assigned to a specific FQID. Fields in the incoming packet may be used to identify and split the traffic as required. For this key optimization case, the user must determine the correct field. The example is as follows:

- For the ingress control traffic, the ICMP protocol identifier is the selector or key. If the traffic is from ports 1 or 2 then that traffic goes to one FQID. If it is from port 3, the traffic goes to a different FQID because this needs to be separated and given a higher priority than the other two ports.
- For the ingress data plane traffic, the IP source field is used to determine the FQID. The PCD is then configured to hash the IP source to 8 bits, which will generate 256 possible FQs. Note that this is the same, regardless of whether the packet came from ports 1, 2, or 3.
- For the ingress pseudo real-time traffic, the PCD is configured to check for the proprietary identifier. If there is a match then the traffic goes to an FQID based on the ingress port. If there is no match then the incoming packet is discarded. Also, the soft parser needs to be configured/programmed to locate the proprietary identifier.

Note that the FQID number itself can be anything (within the 24 bits to define the FQ). To maintain meaning, use a numbering scheme to help identify the type of traffic. For the example, define the following ingress FQIDs:

- High priority control: FQID `0x100`
- Low priority control: FQID `0x200`
- General data plane: FQID `0x1000 – 0x10FF`
- Pseudo real-time traffic: FQID `0x2000` (port 4), FQID `0x2100` (port 5)

The specifics for configuring the PCDs are described in the **DPAA Reference Manual (link)** and in the Software Developer Kit (SDK) used to develop the software.

7.4.1.10 FQ/WQ/Channel

For each class of traffic in the system, the FQs must be defined together with both the channel and the WQ to which they are associated. The channel association affines to a specific processor core while the WQ determines priority.

Consider the following by class of traffic:

- The control traffic goes to a pool of two cores with priority given to traffic on port 3.
- The general data plane traffic goes to a pool of 4 cores.
- The pseudo real-time traffic goes to two separate cores as a dedicated channel.

Note that, when the FQ is defined, in addition to the channel association, other parameters may be configured. In the application example, the FQs from 1000 to 10FF are all assigned to the same congestion group; this is done when the FQ is initialized. Also, for these FQs it is desirable to limit the individual FQ length; this would also be configured when the FQ is initialized.

Because the example application is going to use order definition/order restoration mode, this setting needs to be configured for each FQ in the general data plane traffic (FQID 0x1000-0x10FF). Note that order is not required for the control plane traffic and that order is preserved in the pseudo real-time traffic because the ingress traffic flows are mapped to specific cores.

QMan configuration considerations include the congestion management and pool channel scheduling. A congestion group must be defined as part of QMan initialization. (Note that the FQ initialization is where the FQ is bound to a congestion group.) This is where the total number of frames and the discard policy of the congestion group are defined. Also, consider the QMan scheduling for pool channels. In this case, the default of temporarily attaching an FQ to a core until the FQ is empty will likely work best. This tends to keep the caches current, especially for the general data plane traffic on cores 3-6.

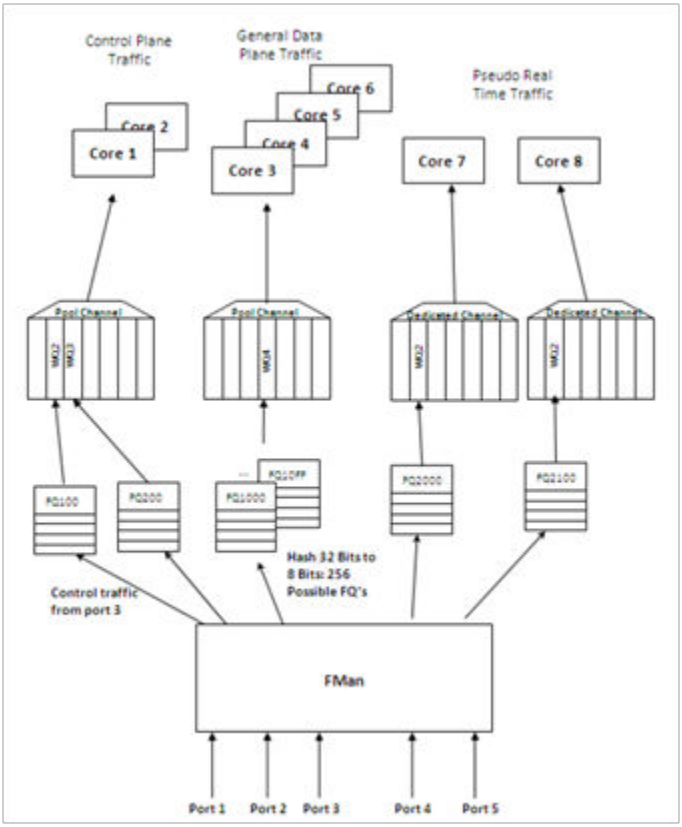

Figure 86. Ingress application map

Define egress FQ/WQ/channel configuration

For egress, the packets still flow through the system using the DPAA, but the considerations are somewhat different. Note that each external port has its own dedicated channel; therefore, to send traffic out of a specific port, the cores enqueue a frame to an FQ associated with the dedicated channel for that port. Depending on the priority level required, the FQ is associated with a specific work queue.

For the example, the egress configuration is as follows:

- For control plane traffic, there needs to be separate queues for each port this traffic may use. These FQs must be assigned to a WQ that is higher in priority then the WQ used for the data plane traffic. The example shown includes a strict priority (over the data plane traffic) for ports 1 and 2 with the possibility of WRED with the data plane traffic on port 3.
- Because the example assumes that the order restoration facility in the FQs will be utilized, there must be one egress FQ for each flow. The initial system assumptions are for up to 50 flows of this type; however, the division by port is unknown, the FQs can be assigned so that there are at least 50 for each port. Note that FQs can be added when the flow is discovered or they can be defined at system initialization time.
- For the pseudo real-time traffic, per the initial assumptions, core 7 sends traffic out of port 4 and core 8 sends traffic out of port 5. As the flows are per core, the order is preserved because of this mapping. These are assigned to WQ2, which allows definition for even higher priority traffic (to WQ1) or lower priority traffic for future definition on these ports.

As stated before, the FQIDs can be whatever the user desires and should be selected to help keep track of what type of traffic the FQ's are associated. For this example:

- Control traffic for ports 1, 2, 3 are FQID 300, 400, 500 respectively.
- Data plane traffic for ports 1, 2, 3 are FQID 3000-303F, 4000-403F, and 5000-503F respectively, this provides for 64 FQ's per port on egress.
- The pseudo real-time traffic uses FQID 6000 for port 4 and 7000 for port 5.

Because this application makes use of the order restoration feature, an order restoration point must be defined for each data plane traffic flow. Also, congestion management on the FQs may be desirable. Consider that the data plane traffic may come in on multiple ports but may potentially be consolidated such that is egresses out a single port. In this case, more traffic may be attempted to be enqueued to a port than the port interface rate may allow, which may cause congestion. To manage this possibility, three congestion groups can be defined each containing all the FQs on each of the three ports that may have the control plus data plane traffic. As previously discussed, it may be desirable to set the length of the individual FQs to further manage this potential congestion.

7.4.2 Queue Manager (QMan) and Buffer Manager (BMan)

7.4.2.1 QMan/BMan Drivers Release Notes

Description

This document describes Linux and USDPAA drivers for the QMan and BMan hardware blocks underlying the QorIQ data path. QMan and BMan have independent drivers but their implementation and interfaces are very much analogous due to the similar CCSR and Corenet programming interfaces for each. As such, we will describe here "the driver", when in fact the description applies to both the QMan and BMan drivers equally and independently.

The driver targets the Linux and USDPAA environments. The majority of the code is shared between the environments. Environmental differences are dealt with by including a compatibility layer in the USDPAA code. This code redefines Linux-specific functionality for use in the other environments (for example `irqs` and `spinlocks`).

The driver has two parts to it, "config" and "portal", corresponding to the two complimentary programming interfaces exposed by the device itself - these are described below. Additionally there is a self-test module for each driver that uses the portal interface to perform some basic tests provided one or more portals are made available to the OS via its device-tree.

CCSR, or "global config"

The CCSR map and associated registers allows the device to be configured and controlled in a global/un-partitioned manner. This includes such basic notions as configuring the device's private memory region(s), configuring the hardware interfaces that are exposed by QMan/BMan to the dependent hardware blocks (CAAM, PME, Fman), managing global device error interrupts, etc. Only one "control" operating system should map to this CCSR register space in the case that a hypervisor is managing multiple guests. Other operating systems like secondary Linux instances or USDPAA applications do not have access to CCSR registers.

Corenet portals

Use of QMan/BMan is via a number of independent portals located within sub-regions of a corenet memory map. Each portal has its own copy of the device interfaces that allow independent and parallel use of QMan/BMan functionality, possibly by different operating systems or by different processors (or threads) within a single operating system. When a hypervisor is managing multiple guests, each guest device tree indicates to the guest the portal it has access to. The device tree specifies a one to one mapping between cores and QMan/BMan portals. This mapping is assumed by the high-level QMan/BMan APIs. This should not be changed unless only low-level QMan/BMan APIs are to be used.

Functionality

Configuration

The QMan device is configured via device-tree nodes and by some compile-time options controlled via Linux's Kconfig system. See the “QMan and BMan Kernel Configure Options” section for more info.

API

For the Linux kernel, the C interface of the QMan and BMan drivers provides access to portal-based functionality for arbitrary higher-layer code, hiding all the mux/demux/locking details required for shared use by multiple driver layers (networking, pattern matching, encryption, IPC, etc.) The driver makes 1-to-1 associations between cpus and portals to improve cache locality and reduce locking requirements. The QMan API permits users to work with Frame Queues and callbacks, independently of other users and associated portal details. The BMan API permits users to work with Buffer Pools in a similar manner.

For USDPAA, the driver associates portals with threads (in the *pthreads* sense), so the above comments about “shared use by multiple driver layers” only applies with respect to code executed within the thread owning a portal. To benefit from cache locality, and particularly from portal stashing, USDPAA-enabled threads are generally expected to be configured to execute

on the same core that the portal is assigned to. Indeed, the USDPAA API for threads to call to initialise a portal takes the core as a function parameter. Please see the USDPAA User Guide for more information (as well as the “Queue Manager, Buffer Manager API Reference Manual”).

DPAA allocator

The DPAA allocator is a purely software-based range-allocator, but this must be explicitly seeded with a hard-coded range of values and is not shared between operating systems. The DPAA allocator is used to allocate all QMan and BMan resource, i.e bman-bpid, qman-fqid, qman-pool, qman-cgrid, ceetm-sp, ceetm-lni, ceetm-lfqid, ceetm-ccgrid.

Sysfs Interface

QMan and BMan have a sysfs interface. Refer to the Queue Manager, Buffer Manager API reference Manual for details

Debugfs Interface

Both the QMan and BMan have a debugfs interface available to assist in device debugging. The code can be built either as a loadable module or statically.

Module Loading

The drivers are statically linked into the kernel. Driver self-tests and the debugfs interface may be built as dynamically loadable modules.

QMan and BMan Kernel Configure Options

Common Kernel Configure Options	Description
CONFIG_STAGING	Required in order to make “staging” drivers such as QMan/BMan available.
CONFIG_FSL_DPA	Required to build either QMan and/or BMan drivers.
CONFIG_FSL_DPA_CHECKING	Compiles in additional sanity-checks, at the expense of minor performance degradation. Recommended for debugging, but not for benchmarking.
CONFIG_FSL_DPA_CAN_WAIT	Compiles in support for interfaces and functionality that allow callers to optionally be put to “sleep” waiting for temporarily blocked resources to become available rather than returning errors. Eg. enqueuing when an enqueue ring is full. This is enabled unconditionally on linux.
CONFIG_FSL_DPA_CAN_WAIT_SYNC	Similar to “_CAN_WAIT”, but supports additional API flags for waiting for asynchronous operatoins to complete. Eg. after starting a volatile dequeue, wait for all dequeues to complete. This is enabled unconditionally on linux.
CONFIG_FSL_DPA_PIRQ_FAST	If set, causes portals to initialise with fast-path interrupt sources enabled. (Otherwise, polling APIs must be called to perform fast-path processing.) This is enabled unconditionally on linux.
CONFIG_FSL_DPA_PIRQ_SLOW	If set, causes portals to initialise with slow-path interrupt sources enabled. (Otherwise, polling APIs must be called to perform slow-path processing.) This is enabled unconditionally on linux.
CONFIG_FSL_DPA_PORTAL_SHARE	Compiles in support for sharing one CPU's portal with all online CPUs that do not have their own. Useful when assigning most portals to USDPAA applications and leaving only a minimum for kernel requirements, in which case Tx events on all CPUs can be handled by the network driver. This is enabled by default, as the microscopic performance overhead of checking this option is not noticable in the kernel environment.

QMan Kernel Configure Options	Description
CONFIG_FSL_QMAN	Required to build the QMan driver
CONFIG_FSL_QMAN_CONFIG	Handles config/CCSR nodes in the device-tree and initialises the corresponding devices
CONFIG_FSL_QMAN_TEST	Builds a self-test kernel module (static or dynamic) that will, if QMan portal nodes are available in the device-tree, exercise one of the portals and panic() the kernel if any errors are detected.
CONFIG_FSL_QMAN_TEST_STASH_POTATO	This requires the presence of multiple unused cpu-affine portals, and performs a "hot potato" style test enqueuing/dequeuing a frame across a series of FQs scheduled to different portals (and cpus). The intention is to test stashing. The "potato" will visit each "spoon" (portal/cpu pair) during the test. Each "potato" frame has a single cacheline of data that is read-modify-written by each cpu/portal before passing it to the next.
CONFIG_FSL_QMAN_TEST_HIGH	This requires the presence of cpu-affine portals, and performs high-level API testing with them (whichever portal(s) are affine to the cpu(s) the test executes on).
CONFIG_FSL_QMAN_TEST_ERRATA	This requires the presence of cpu-affine portals, and performs testing that handling for known hardware-errata is correct.
CONFIG_FSL_QMAN_DEBUGFS	This option enables files in the debugfs filesystem.

BMan Kernel Configure Options	Description
CONFIG_FSL_BMAN	Required to build the BMan driver
CONFIG_FSL_BMAN_CONFIG	Handles config/CCSR nodes in the device-tree and initialises the corresponding devices
CONFIG_FSL_BMAN_TEST	Builds a self-test kernel module (static or dynamic) that will, if BMan portal nodes are available in the device-tree, exercise one of the portals and panic() the kernel if any errors are detected.
CONFIG_FSL_BMAN_TEST_HIGH	Performs high-level API testing.
CONFIG_FSL_BMAN_TEST_THRESH	Multi-threaded testing of BMan pool depletion handling.
CONFIG_FSL_BMAN_DEBUGFS	This option enables files in the debugfs filesystem.

Device-tree nodes

Device tree nodes are used to describe QMan/BMan resources to the driver, some of which are specific to control-plane s/w (i.e. depending on CCSR access) and some of which relate to portal usage for control and data plane s/w.

CCSR, or "global config"

The "fsl,qman" and "fsl,bman" nodes (i.e. these "compatible" property types) indicate the presence and location of the 4Kb "Configuration, Control, and Status Register" (CCSR) space, for use by a single control-plane driver instance to initialise and manage the device. The device-tree usually groups all such CCSR maps as sub-nodes under a parent node that represents the SoCs entire CCSR map, usually named "soc" or "ccsr". For example;

```
soc {
      #address-cells = <1>;
      #size-cells = <1>;
      device_type = "soc";
```

```
        compatible = "simple-bus";

        ddr1: memory-controller@8000{
            [...]
        };
        i2c@118000 {
            [...]
        };
        mpic: pic@40000 {
            [...]
        };

        qman: qman@318000 {
            compatible = "fsl,qman";
            reg = <0x318000 0x1000>;
            interrupts = <16 2 1 3>;
            /* Commented out, use default allocation */
            /* fsl,qman-fqd = <0x0 0x20000000 0x0 0x01000000>; */
            /* fsl,qman-pfdr = <0x0 0x21000000 0x0 0x01000000>; */
        };
        bman: bman@31a000 {
             compatible = "fsl,bman";
             reg = <0x31a000 0x1000>;
             interrupts = <16 2 1 3>;
             /* Same as fsl,qman-*, use default allocation */
             /* fsl,bman-fbpr = <0x0 0x22000000 0x0 0x01000000>; */
        };
        [...]
    };
```

Contiguous memory

The `fsl,qman-fqd`, `fsl,qman-pfdr`, and `fsl,bman-fbpr` properties can be used to specify which contiguous sub-regions of memory should be used for the various memory requirements of QMan/BMan. The properties use 64-bit values, so 4 cells express the address/size 2-tuple to use. In the above example, if uncommented, the QMan/BMan resources would be allocated in the range `0x2000000-0x221fffff`, with 16MB each for QMan FQD and PFDR memory and BMan FBPR memory. If these properties are not specified (or they are commented out) in the device tree, then default values hard-coded within the QMan and BMan drivers are used instead. The linux kernel will reserve these memory ranges early on boot-up. Note that in the case of a hypervisor scenario, these memory ranges are relative to the partition memory space of the control-plane guest OS.

QMan and BMan Corenet portals

The QMan Corenet portal interface in QorIQ P4080/P3041/P5020 provides up to 10 distinct memory-mapped interfaces for use by software to interact efficiently with QMan functionality. The number may be different for other SoCs - the QMan driver determines the available corenet portals from the device tree. The portal nodes are at the physical address scope (unlike the device-tree node for the BMan device itself, which is within the “soc” physical address node that represents CCSR). These nodes indicate the physical address ranges of the cache-enabled and cache-inhibited sub-regions of the portal (respectively), and look something like the following;

```
    qman-portals@ffe4200000 {
        #address-cells = <0x1>;
        #size-cells = <0x1>;
        compatible = "simple-bus";
        qportal0: qman-portal@0 {
            [...]
        };
        [...]
```

```
        qportal3: qman-portal@c000 {
            cell-index = <0x3>;
            compatible = "fsl,qman-portal";
            reg = <0xc000 0x4000 0x103000 0x1000>;
            interrupts = <110 0x2 0 0>;
            fsl,qman-channel-id = <0x3>;
        };
        [...]
    };
```

QMan FQID-range allocation

The "fsl,fqid-range" node (i.e. these "compatible" property types) indicates a range of FQIDs to use for FQID allocation by the QMan driver. The range within the node is specified using a property of the same name, and whose two cells are the starting FQID value and the count. Multiple nodes can be provided to seed the allocator with a discontiguous set of FQIDs.

Eg. to specify that the allocator use FQIDs between 256 and 512 inclusive;

```
    qman-fqids@0 {
        compatible = "fsl,fqid-range";
        fsl,fqid-range = <256 256>;
    };
```

BMan BPID-range allocation

The "fsl,bpool-range" node (i.e. these "compatible" property types) indicates a range of BPIDs to use for BPID allocation by the BMan driver. The range within the node is specified using a property of the same name, and whose two cells are the starting BPID value and the count. Multiple nodes can be provided to seed the allocator with a discontiguous set of BPIDs.

Eg. to specify that the allocator use BPIDs between 32 and 64 inclusive;

```
    bman-bpids@0 {
        compatible = "fsl,bpid-range";
        fsl,bpid-range = <32 32>;
    };
```

Compile-time Configuration Options

The "Kernel Configure Options" above describe the compile-time configuration options for the kernel. The device tree entries are also "compile-time", and are described above.

Source Files

As mentioned earlier, the QMan/BMan drivers support Linux and USDPAA environments. Many of the files have the same contents between the different environments, though the files are located at different paths to satisfy the different build systems for each.

For DPAA QBMan drivers, all the files are located in `drivers/staging/fsl_qbman/ directory`

For the device trees, all files are located in `arch/powerpc/boot/dts/fsl/ and arch/arm64/boot/dts/freescale/`

include/usdpaa/fsl_usd.h	The USDPAA-specific APIs for QMan/BMan (eg. Binding portals to threads, support for UIO-based interrupt handling, etc.)
include/usdpaa/compat.h	The QMan/BMan driver compatibility shims
include/usdpaa/compat_list.h	The QMan/BMan driver compatibility shims, linked-list support.
src/qbman/qman_*.*	The QMan driver
src/qbman/bman_*.*	The BMan driver
src/qbman/dpa_sys.h	USDPAA-specific definitions shared by the QMan/BMan drivers.
src/qbman/dpa_alloc.c	USDPAA support for dpa allocator.
src/qbman/06-usdpaa-uio.rules	Udev rules to create appropriately-named /dev entries when the kernel registers portals as UIO devices.

Build Procedure

The procedure is a standard SDK build, which includes Linux kernel and USDPAA drivers by default.

Test Procedure

The QMan/BMan drivers are used by all Linux kernel software that communicates with datapath functionality such as CAAM, PME, and/or Fman. (The exception is that kernel cryptographic acceleration presently bypasses QMan/BMan interfaces by using the device's own “job queue” interface.) Use of such datapath-based functionality provides test-coverage of user-facing features of the QMan/BMan drivers in the Linux environment. This complements the QMan/BMan unit tests that are run during development but are not part of the release. For USDPAA, all applications and tests use QMan and BMan interfaces in a fundamental way, so all imply a degree of test-coverage.

Additionally, for Linux, the QMan and BMan self-tests target QMan and BMan directly without involving other datapath blocks. If these are built statically into the kernel and the device-tree makes one or more QMan and/or BMan portals available, then the self-tests will run during the kernel boots and log output to the boot console. The output of both QMan and BMan tests resembles the following excerpts;

Detecting the CCSR and portal device-tree nodes;

```
[...]
Qman ver:0a01,01,02
[...]
Bman ver:0a02,01,00
[...]
BMan err interrupt handler present

BMan portal initialised, cpu 0

BMan portal initialised, cpu 1

cb_depletion: bpid=62, depleted=2, cpu=3
cb_depletion: bpid=62, depleted=2, cpu=4
cb_depletion: bpid=62, depleted=2, cpu=5
cb_depletion: bpid=62, depleted=2, cpu=6
cb_depletion: bpid=62, depleted=2, cpu=7
thread 0: draining done.
thread 0: exiting
thread 1: exiting
thread 2: exiting
thread 3: exiting
thread 4: exiting
thread 5: exiting
thread 6: exiting
thread 7: exiting
bman_test_thresh: done
[...]
```

Running the QMan hot potato test;

```
[...]
qman_test_hotpotato starting
Creating 2 handlers per cpu...
Number of cpus: 8, total of 16 handlers
Sending first frame
Received final (8th) frame
qman_test_hotpotato finished
[...]
```

If the self-tests detect any errors, they will `panic()` the kernel immediately, so if the kernel gets beyond the QMan/BMan self-tests then the tests passed.

Changes since SDKv1.7

- Add new CEETM APIs to allow the user to set the LNI and channel shaping rate in bps format directly.

  See API reference manual for details.
- Add new CEETM API to check the LNI/channel shaping enablment.
- Add new CEETM API to set the CQ's weight in the ratio format. The ratio to weight code conversion is done inside this new API
- Add new CEETM API to drain the Class Queue till empty, and call this API inside the function to release CQ so that there will be no frames left in CQ when it is released

Known Bugs, Limitations, or Technical Issues

- QMan and BMan portals are core affine, with each core assigned one QMan and one BMan portal. This assignment also assumes that interrupts associated with these portals are directed to the same cores. This is a fundamental assumption for QMan/BMan drivers. Users should not change the core affinity of portal interrupts for any reason as this would cause the portal to become non-functional and possibly cause a kernel crash.
- QMan enqueue command ring (EQCR) stashing is only supported on QMan rev >= 3.0 on T4240 and B4860, not on other QorIQ Pxxxx silicon. Therefore, run-to-completion software that is attempting an enqueue operation (ie. it is not providing any WAIT flag) should implement its own “back off” after an enqueue returns an EBUSY return code (a 1000-cycle back off is a recommended guide-line). Failure to do so can consume excessive memory bandwidth and reduce overall throughput supported by the system.

7.4.2.2 QMan BMan API Reference

7.4.2.2.1 About this document

This document describes drivers for the Queue Manager and Buffer Manager hardware blocks underlying the datapath architecture within the NXP QorIQ multicore SoC's (P4080, P3041, P5020). There are also explanations given to various aspects of the QMan and BMan hardware itself, insofar as this is essential knowledge in using these devices effectively. The driver descriptions cover some driver implementation details, usage details (loading and configuring), but the main emphasis is on the programming interfaces (APIs) exposed by these drivers.

7.4.2.2.1.1 Suggested Reading

1. *QorIQ* P4080, P3041, P5020 Reference Manuals (P4080RM, P3041RM, P5020RM)
2. Power.org Standard for Embedded Power Architecture Platform Requirements (ePAPR). power.org, 2008.

7.4.2.2.2 Introduction to the Queue Manager and the Buffer Manager

The Queue Manager (QMan) and Buffer Manager (BMan) devices each expose two interfaces to software control. One interface is the Configuration and Control Status Register map (CCSR), which provides global configuration of the device, registers related to global device errors, performance, statistics, debugging, etc. The other interface is the CoreNet interface, which provides a memory map with multiple "portals" located in separable sub-regions for independent/parallel run-time use of the devices.

7.4.2.2.2.1 O/S specifics

The software described in this document is targeted to the Linux kernel and Linux user-space (USDPAA) system targets. However, only Linux supports operating as the controller for the devices, so all interfaces related to CCSR access are Linux-only. Also, remember platform-specific considerations when working with the interfaces described here. See Operating system specifics on page 691for more details.

7.4.2.2.3 Buffer Manager

7.4.2.2.3.1 BMan Overview

7.4.2.2.3.1.1 Buffer Manager's Function

The QorIQ Buffer Manager (BMan) SoC block manages pools of buffers for use by software and hardware in the “Datapath” architecture. On the P4080, BMan maintains state for 64 “Buffer Pools”, which are typically used by hardware blocks for constructing output data for returning to software, where software can not (or does not wish to) pre-allocate an output descriptor. *For non-P4080 specifications, refer to the appropriate QorIQ SoC Reference Manual.*

In particular;

1. provides an efficient use of buffer resources because the output will only occupy as many buffers as required (whereas pre-allocation must provide for the worst-case scenario each time if it wishes to avoid truncation and information-loss),
2. software does not need to provision resources for every queued operation nor handle the complications of recycling unused output buffers, etc.,

3. the footprint for buffer resources for a variety of different flows (and even different guest operating systems) can be "pooled".

With respect to "buffers", BMan really acts as an allocator of any 48-bit tokens the user wishes - BMan does not interpret these tokens at all, it is only the software and hardware blocks that use BMan that may assume these to be memory addresses. In many cases, the BMan acquire and release interfaces are likely to be more efficient than software-managed allocators due to the proximity of BMan's corenet-based interfaces to each CPU and its on-board caching and pre-fetching of pool data. Possible examples include; a BMan-oriented page-allocator for operating system memory-management, a "frame queue" allocator to manage unused QMan frame queue descriptors (FQD), etc. In particular, the frame queue example provides a simple mechanism for sharing a range of frame-queue IDs across different partitions/operating systems in a virtualized environment without needing inter-partition communications in software.

7.4.2.2.3.1.2 BMan's interfaces

The BMan block has a CCSR register space and interrupt line associated with the block for global configuration and management, specifically;

- the private system memory range (invisible to software) needed by BMan,
- software and hardware depletion interrupt thresholds for each pool,
- device error handling uses the global interrupt line and the CCSR register space contains error-capture and error-status registers.

The BMan block also exposes a Corenet memory space for low-latency interaction by the multiple SoC cores, and this corenet region is divided into a geometry of "portals" to allow independent access to BMan functionality in a partitioned (and/or virtualized) environment. Each portal consists of one 16KB cache-enabled and one 4KB cache-inhibited sub-range of the Corenet region, as well as a per-portal interrupt line. There are a variety of possible reasons for using distinct portals;

- for partitioning between distinct guest operating systems,
- to dedicate a portal for each CPU to reduce locking and improve cache-affinity,
- to make distinct portal configurations available,
- to give certain applications their own portal rather than enforcing a mux/demux layer to share a portal between applications,
- [etc.]

Each portal presents the following BMan functionality;

- a "release command ring" (RCR), a pipelined mechanism for software to hardware commands that release buffers to BMan-managed buffer pools,
- a "management command" interface (MC), a low-latency command/response interface for acquiring buffers from buffer pools, and querying the status of all buffer pools,
- an interrupt line and associated status, disable, enable, and inhibit registers.

These portal interfaces will be described in more detail in their respective sections.

7.4.2.2.3.2 BMan configuration interface

The BMan configuration interface is an encapsulation of the BMan CCSR register space and the global/error interrupt line. Whereas BMan portals provide independent channels for accessing BMan functionality, the configuration interface represents the BMan device itself. The BMan configuration interface is presently limited to the device-tree node that represents it, with one exception: an API exists to set per-buffer-pool depletion thresholds. This API is only available in the linux control-plane - that is, a kernel compiled with BMan control support that has the BMan CCSR device-tree node present. In a hypervisor scenario, this implies that only the control-plane linux guest OS can set buffer pool depletion thresholds.

7.4.2.2.3.2.1 BMan Device-Tree Node

The BMan device tree node represents the BMan device and its CCSR configuration space. When a linux kernel has BMan control support compiled in, it will react to this device tree node by configuring and managing the BMan device. The device-tree node sits within the CCSR node ("soc") and is of the following form;

```
soc@fe000000 {
        [...]
        bman: bman@31a000 {
                compatible = "fsl,bman";
                reg = <0x31a000 0x1000>;
                fsl,liodn = <0x20>;
        };
        [...]
  };
```

'compatible' and 'reg' are standard ePAPR properties.

7.4.2.2.3.2.1.1 Free Buffer Proxy Records

As previously mentioned, BMan buffer pools needn't be used only for managing memory buffers, but in fact can manage pools of arbitrary 48-bit token values, whatever those tokens might represent. This is possible because BMan never uses those token values as memory locations - all management of buffer pools is maintained in memory that is private to the BMan block. Specifically, BMan uses some internal memory together with a private range of contiguous system memory for backing store. The internal units of the backing store memory are called "free buffer proxy records" (FBPRs), each of which occupies a 64-byte cacheline of memory, and can hold 8 tokens.

The current driver implementation allows this memory resource to be specified via the 'fsl,bman-fbpr' device-tree property, or by resorting to a default allocation of contiguous memory early during kernel boot. The 'fsl,bman-fbpr' property specifies a 2-tuple of address and size, specifying the physical address range to assign to BMan. The example given configures 16MB for FBPR memory **(262,144 FBPR entries or 2,097,152 buffer tokens)**. These elements are expressed as 64-bit values, so take two cells each:

```
fsl,fbpr = <0x0 0x20000000 0x0 0x01000000>;
```

If the hypervisor is in use, this address range is "guest physical". If the given memory range falls within the range used by the linux control-plane OS, it will attempt to reserve the range against use by the OS.

NOTE

For all BMan and QMan private memory resources, the alignment of the memory region must match its size.

7.4.2.2.3.2.1.2 Logical I/O Device Number (BMan)

Reads and writes to BMan's FBPR memory are subject to processing by the PAMU IO-MMU configuration of the SoC. In particular, BMan has an LIODN (Logical I/O Device Number) register setting that will be used by PAMU authorise and possibly translate memory accesses. The bootloader (u-boot) will program BMan's LIODN register and it will add this value as the "fsl,liodn" property before passing it along to the booted software.

```
fsl,liodn = <0x20>;
```

This property is only used by the hypervisor, in order to ensure that any translation between guest physical and real physical memory for the linux guest OS is similarly applied to BMan transactions. If linux is booted natively (no hypervisor), then the PAMU is either left in bypass mode or it is configured without translation. In any case the LIODN is of little practical importance to the configuration or use of BMan driver software.

7.4.2.2.3.2.2 Buffer Pool Node

The BMan buffer pool device tree node represents one of a BMan device's buffer pools and its associated configuration. When a linux kernel has BMan control support compiled in, it will react to this device tree node by configuring and managing the BMan buffer pool, in particular the pool will be marked as reserved by the driver so that it is not available for dynamic assignment. The device-tree nodes usually sit within a BMan portals parent node ("bman-portals") and is of the following form;

```
                bman-portals@f4000000 {

                        [...]

                        buffer-pool@0 {

                                compatible = "fsl,bpool";

                               fsl,bpid = <0x0>;

                              fsl,bpool-cfg = <0x0 0x100 0x0 0x1 0x0 0x100>;

                                fsl,bpool-thresholds = <0x8 0x20 0x0 0x0>;

                        };

                        [...]

         };
```

7.4.2.2.3.2.2.1 Buffer Pool ID

The BMan device in QorIQ P4080 supports 64 hardware managed buffer pools, so valid IDs range from 0 to 63. For non-P4080 specifications, refer to the appropriate QorIQ SoC Reference Manual. The above example configures buffer pool 0, which is used by the QMan driver as an inter-partition allocator of unused QMan Frame Queue IDs;

```
        fsl,bpid = <0x0>;
```

Buffer pool nodes in the device-tree indicate that the corresponding buffer pool IDs are reserved, ie. that they are not to be used for ad-hoc allocation of unused pools.

7.4.2.2.3.2.2.2 Seeding Buffer Pools

It is also possible to have the control plane linux BMan driver seed the buffer pool with an arbitrary arithmetic sequence of values, using the "fsl,bpool-cfg" property. This property is a 3-tuple of 64-bit values (each taking 2 cells) defining the arithmetic sequence; the count, the increment, and the base.

```
        fsl,bpool-cfg = <0x0 0x100 0x0 0x1 0x0 0x100>;
```

In this example, the QMan FQ allocator implemented using BMan buffer pool ID 0 is seeded with 256 FQIDs in the range [256...511].

7.4.2.2.3.2.2.3 Depletion Thresholds

Each of the 64 buffer pools has CCSR registers related to depletion-handling. A pool is considered "depleted" once the number of buffers in that pool crosses a "depletion-entry" threshold from above, and this ends when the number of buffers subsequently crosses a "depletion-exit" threshold from below (the depletion-exit threshold should be higher than the depletion-entry threshold).

Each pool maintains two independent depletion states - one for software use and another for hardware blocks. Hardware blocks (like CAAM, FMan, PME) use the hardware depletion state primarily for the purpose of implementing push back (e.g. by stalling input-processing, issuing "pause frames", etc). There is a depletion-entry and -exit threshold for each buffer pool related to this hardware depletion state. The software depletion state serves two possible purposes - one is to allow software to implement push back too. The other use of software depletion thresholds is to allow software to manage "replenishment" of buffer pools. It is software that seeds buffer pools with blocks of memory initially and if desired, it can also use this mechanism to selectively provide additional blocks at run-time during depletion.

```
                        fsl,bpool-thresholds = <0x8 0x20 0x0 0x0>;
```

Here, software depletion thresholds have been set for the buffer pool used for the FQ allocator, but hardware depletion thresholds are disabled (the pool is for software use only). The pool will enter depletion when it drops below 8 "buffers" (in this case, FQIDs), and exit depletion when it rises above 32.

7.4.2.2.3.2.3 BMan Portal Device-Tree Node

The BMan Corenet portal interface in QorIQ P4080 provides up to 10 distinct memory-mapped interfaces for use by software to interact efficiently with BMan functionality. Specifically, each portal provides the following sub-interfaces; RCR (Release Command Ring), MC (Management Command), and ISR (Interrupt Status Register). For non-P4080 specifications, refer to the appropriate QorIQ SoC Reference Manual.

The BMan driver determines the available corenet portals from the device tree. The portal nodes are at the physical address scope (unlike the device-tree node for the BMan device itself, which is within the “soc” physical address node that represents CCSR). These nodes indicate the physical address ranges of the cache-enabled and cache-inhibited sub-regions of the portal (respectively), and look something like the following;

```
        bman-portal@0 {
                compatible = "fsl,bman-portal";
                reg = <0xe4000000 0x4000 0xe4100000 0x1000>;
                interrupts = <0x69 2>;
                interrupt-parent = <&mpic>;
                cell-index = <0x0>;
                cpu-handle = <&cpu3>;
        };
```

The most note-worthy property is "cpu-handle", which is used to express an affinity/association between the given BMan portal and the CPU represented by the referenced device-tree node.

7.4.2.2.3.2.3.1 Portal Initialization (BMan)

The driver is informed of the BMan portals that are available to it via the device-tree passed to the system from the boot process. For those portals that aren’t reserved for USDPAA usage via the “fsl,usdpaa-portal” property, it will automatically create TLB entries to map the BMan portal corenet sub-regions as cpu-addressable and cache-inhibited or cache-enabled as appropriate.

The BMan driver will automatically associate initialised BMan portals with the CPU to which they are configured, only a one-per-CPU basis (if multiple portals are configured for the same CPU, only one is used). The purpose of this is to provide a canonical portal that software can use for whichever CPU it is running on, with the advantages of a cpu-affine interface being improved cache-locality and reduced locking. This requires that each CPU have at least one portal device-tree node dedicated to it using the “cpu-handle” property.

7.4.2.2.3.2.3.2 Portal sharing

If there are CPUs that have no affine portal associated with them (for example if most portals have been reserved for USDPAA use), then the driver will select the highest-index portal to be configured for “sharing” with the CPUs that have no affine portal, otherwise called “slave CPUs” in this document. In this mode of operation, a coarser locking scheme is used for the portal in order to properly synchronise use by more than one CPU.

One key point to understand with portal sharing is that hardware-instigated portal events will continue to be processed only by the CPU to which the portal is affine, they are not shared. One consequence of this is that slave CPUs can not use *_irqsource_*() APIs to alter the interrupt-vs-polling state of the portal, nor can they call *_poll_*() APIs to perform run-to-completion servicing of the portal. The sharing of the portal is only to allow software-instigated portal functionality to be available to slave CPUs, such as creating and manipulating objects, performing commands, etc.

7.4.2.2.4 BMan CoreNet portal APIs

The following sections describe interfaces provided by the BMan driver for manipulating portals, as defined in BMan Portal Device-Tree Node on page 626.

7.4.2.2.4.1 BMan High-Level Portal Interface

7.4.2.2.4.1.1 Overview (BMan)

The high-level portal interface provides management and encapsulation of a portal hardware interface. The operations performed on the portal are co-ordinated internally, hiding the user from the I/O semantics, and allowing multiple users/contexts to share portals without collaboration between them. This interface also provides an object representation for buffer pools, with optional assists for cases where the user wishes to track depletion entry and exit events.

This interface provides locking and arbitration of portal operations from multiple software contexts and/or threads (ie. the portal is shared). In cases where a resource is busy, the interface also gives callers the option of blocking/sleeping until the resouce is available. In any case where sleeping is an option, the caller can also specify whether the sleep should be interruptible.

NOTE

Support for blocking/sleeping is limited to linux, it is not available on run-to-completion systems such as USDPAA.

7.4.2.2.4.1.2 Portal management (BMan)

The portal management API provides bman_affine_cpus(), which returns a mask that indicates which CPUs have auto-initialized portals associated with them. See BMan Portal Device-Tree Node on page 626. All other BMan API functions must be executed on CPUs contained within this mask, and any interactions they require with h/w will be performed on the corresponding portals.

```
/**
 * bman_affine_cpus - return a mask of cpus that have portal access
 */
const cpumask_t *bman_affine_cpus(void);
```

7.4.2.2.4.1.2.1 Modifying interrupt-driven portal duties (BMan)

Portals have various servicing duties they must perform in reaction to hardware events. The portal management API allows applications to control which of these duties/events are triggered by interrupt-handling versus those which are performed at the application’s explicit request via bman_poll(). If portal-sharing is in effect (see Portal sharing on page 626), these APIs won’t succeed when called from a slave CPU.

```
#define BM_PIRQ_RCRI    0x00000002      /* RCR Ring (below threshold) */
#define BM_PIRQ_BSCN    0x00000001      /* Buffer depletion State Change */
/**
 * bman_irqsource_get - return the portal work that is interrupt-driven
 *
 * Returns a bitmask of BM_PIRQ_**I processing sources that are currently
 * enabled for interrupt handling on the current cpu's affine portal. These
```

```
 * sources will trigger the portal interrupt and the interrupt handler (or a
 * tasklet/bottom-half it defers to) will perform the corresponding processing
 * work. The bman_poll_***() functions will only process sources that are not in
 * this bitmask. If the current CPU is sharing a portal hosted on another CPU,
 * this always returns zero.
 */
u32 bman_irqsource_get(void);
/**
 * bman_irqsource_add - add processing sources to be interrupt-driven
 * @bits: bitmask of BM_PIRQ_**I processing sources

 * Adds processing sources that should be interrupt-driven, (rather than
* processed via bman_poll_***() functions). Returns zero for success, or
* -EINVAL if the current CPU is sharing a portal hosted on another CPU.
*/
int bman_irqsource_add(u32 bits);
/**
* bman_irqsource_remove - remove processing sources from being interrupt-driven
* @bits: bitmask of BM_PIRQ_**I processing sources
*
* Removes processing sources from being interrupt-driven, so that they will
* instead be processed via bman_poll_***() functions. Returns zero for success,
* or -EINVAL if the current CPU is sharing a portal hosted on another CPU. */
int bman_irqsource_remove(u32 bits);
```

7.4.2.2.4.1.2.2 Processing non-interrupt-driven portal duties (BMan)

If portal-sharing is in effect (see Portal sharing on page 626), these APIs won't succeed when called from a slave CPU.

```
/**
 * bman_poll_slow - process anything that isn't interrupt-driven.
 *
 * This function does any portal processing that isn't interrupt-driven. NB,
 * unlike the legacy wrapper bman_poll(), this function will deterministically
 * check for the presence of portal processing work and do it, which implies
 * some latency even if there's nothing to do. The bman_poll() wrapper on the
 * other hand (like the qman_poll() wrapper) attenuates this by checking for
 * (and doing) portal processing infrequently. Ie. such that qman_poll() and
 * bmna_poll() can be called from core-processing loops. Use bman_poll_slow()
 * when you yourself are deciding when to incur the overhead of processing. If
* the current CPU is sharing a portal hosted on another CPU, this function will
* return -EINVAL, otherwise returns zero for success.
*/
int bman_poll_slow(void);
/**
 * bman_poll - process anything that isn't interrupt-driven.
 *
 * Dispatcher logic on a cpu can use this to trigger any maintenance of the
 * affine portal. This function does whatever processing is not triggered by
 * interrupts. This is a legacy wrapper that can be used in core-processing
 * loops but mitigates the performance overhead of portal processing by
 * adaptively bypassing true portal processing most of the time. (Processing is
 * done once every 10 calls if the previous processing revealed that work needed
 * to be done, or once very 1000 calls if the previous processing revealed no
 * work needed doing.) If you wish to control this yourself, call
 * bman_poll_slow() instead, which always checks for portal processing work.
 */
void bman_poll(void);
```

7.4.2.2.4.1.2.3 Recovery support (BMan)

Note that the following functions require the BMan portal to have been initialized in "recovery mode", which is not possible with the current release. As such, these functions are for future use only (and documented here only because they're declared in the API header).

```
/**
 * bman_recovery_cleanup_bpid  - in recovery mode, cleanup a buffer pool
 */
int bman_recovery_cleanup_bpid(u32 bpid);
/**
 * bman_recovery_exit - leave recovery mode
 */
int bman_recovery_exit(void);
```

7.4.2.2.4.1.2.4 Determining if the release ring is empty

```
/**
 * bman_rcr_is_empty - Determine if portal's RCR is empty
 *
 * For use in situations where a cpu-affine caller needs to determine when all
 * releases for the local portal have been processed by BMan but can't use the
 * BMAN_RELEASE_FLAG_WAIT_SYNC flag to do this from the final bman_release().
 * The function forces tracking of RCR consumption (which normally doesn't
 * happen until release processing needs to find space to put new release
 * commands), and returns zero if the ring still has unprocessed entries,
 * non-zero if it is empty.
 */
int bman_rcr_is_empty(void);
```

7.4.2.2.4.1.3 Pool Management

To work with BMan buffer pools, a pool object must be created. As explained in Depletion State on page 632, the pool may be created with the BMAN_POOL_FLAG_DEPLETION flag and corresponding depletion-entry/exit callbacks if the owner wishes to be notified of changes in the pool's depletion state. Creation of the pool object can also modify the pool's depletion entry and exit thresholds with the BMAN_POOL_FLAG_THRESH flag, so long as the BMAN_POOL_FLAG_DYNAMIC_BPID flag is specified (which will allocate an unreserved BPID) and when running in the control-plane (where reserved BPIDs are tracked). Depletion thresholds for reserved BPIDs can be set in the device-tree within the nodes that reserve them, so support for setting them in the API is not provided. The pool object can also maintain an internal buffer stockpile to optimize releases and acquires of buffers by specifying the BMAN_POOL_FLAG_STOCKPILE flag - actual releases to and acquires from h/w will only occur when the stockpile needs flushing or replenishing, ensuring that the interactions with hardware occur less often and are always optimized to release/acquire the maximum number of buffers at once. If a pool object is being freed and it has been configured to use stockpiling, a flush operation must be performed on the pool object. This will ensure that all buffers in the stockpile are flushed to h/w. The pool object can then be freed. The stockpiling option is recommended wherever possible. One implementation note is that applications will sometimes want to create multiple pool objects for the same BPID in order to have one for each CPU (for performance reasons) - this means that each pool object will have its own stockpile. As a consequence, to drain a buffer pool empty would require that all pool objects for that BPID be drained independently (whereas without stockpiling enabled, only one pool object needs to be drained).

```
struct bman_pool;
/* This callback type is used when handling pool depletion entry/exit. The
 * 'cb_ctx' value is the opaque value associated with the pool object in
 * bman_new_pool(). 'depleted' is non-zero on depletion-entry, and zero on
 * depletion-exit. */
typedef void (*bman_cb_depletion)(struct bman_portal *bm,
                          struct bman_pool *pool, void *cb_ctx, int depleted);
/* Flags to bman_new_pool() */
```

```
#define BMAN_POOL_FLAG_NO_RELEASE    0x00000001 /* can't release to pool */
#define BMAN_POOL_FLAG_ONLY_RELEASE  0x00000002 /* can only release to pool */
#define BMAN_POOL_FLAG_DEPLETION     0x00000004 /* track depletion entry/exit */
#define BMAN_POOL_FLAG_DYNAMIC_BPID  0x00000008 /* (de)allocate bpid */
#define BMAN_POOL_FLAG_THRESH        0x00000010 /* set depletion thresholds */
#define BMAN_POOL_FLAG_STOCKPILE     0x00000020 /* stockpile to reduce hw ops */
/* This struct specifies parameters for a bman_pool object. */
struct bman_pool_params {
        /* index of the buffer pool to encapsulate (0-63), ignored if
         * BMAN_POOL_FLAG_DYNAMIC_BPID is set. */
        u32 bpid;
        /* bit-mask of BMAN_POOL_FLAG_*** options */
        u32 flags;
        /* depletion-entry/exit callback, if BMAN_POOL_FLAG_DEPLETION is set */
        bman_cb_depletion cb;
        /* opaque user value passed as a parameter to 'cb' */
        void *cb_ctx;
        /* depletion-entry/exit thresholds, if BMAN_POOL_FLAG_THRESH is set. NB:
         * this is only allowed if BMAN_POOL_FLAG_DYNAMIC_BPID is used *and*
         * when run in the control plane (which controls BMan CCSR). This array
         * matches the definition of bm_pool_set(). */
        u32 thresholds[4];
};
/**
 * bman_new_pool - Allocates a Buffer Pool object
 * @params: parameters specifying the buffer pool behavior
 *
 * Creates a pool object for the given @params. A portal and the depletion
 * callback field of @params are only used if the BMAN_POOL_FLAG_DEPLETION flag
 * is set. NB, the fields from @params are copied into the new pool object, so
 * the structure provided by the caller can be released or reused after the
 * function returns.
 */
struct bman_pool *bman_new_pool(const struct bman_pool_params *params);
/**
 * bman_free_pool - Deallocates a Buffer Pool object
 * @pool: the pool object to release
 */
void bman_free_pool(struct bman_pool *pool);
/**
 * bman_flush_stockpile - Flush stockpile buffer(s) to the buffer pool
 * @pool: the buffer pool object the stockpile belongs
 * @flags: bit-mask of BMAN_RELEASE_FLAG_*** options
 *
 * Adds stockpile buffers to RCR entries until the stockpile is empty.
 * The return value will be a negative error code if a h/w error occured.
 * If BMAN_RELEASE_FLAG_NOW flag is passed and RCR ring is full,
 * -EAGAIN will be returned.
 */
int bman_flush_stockpile(struct bman_pool *pool, u32 flags);
/**
 * bman_get_params - Returns a pool object's parameters.
 * @pool: the pool object
 *
 * The returned pointer refers to state within the pool object so must not be
 * modified and can no longer be read once the pool object is destroyed.
 */
const struct bman_pool_params *bman_get_params(const struct bman_pool *pool);
/**
 * bman_query_free_buffers - Query how many free buffers are in buffer pool
```

```
 * @pool: the buffer pool object to query
 *
 * Return the number of the free buffers
 */
u32 bman_query_free_buffers(struct bman_pool *pool);
/**
 * bman_update_pool_thresholds - Change the buffer pool's depletion thresholds
 * @pool: the buffer pool object to which the thresholds will be set
 * @thresholds: the new thresholds
 */
int bman_update_pool_thresholds(struct bman_pool *pool, const u32 *thresholds);
```

7.4.2.2.4.1.4 Releasing and Acquiring Buffers

The following API functions allow applications to release buffers to a pool and acquire buffers from a pool. Note that the various "WAIT" flags for bman_release() are only available on linux.

```
/* Flags to bman_release() */
#define BMAN_RELEASE_FLAG_WAIT       0x00000001 /* wait if RCR is full */
#define BMAN_RELEASE_FLAG_WAIT_INT   0x00000002 /* if we wait, interruptible? */
#define BMAN_RELEASE_FLAG_WAIT_SYNC  0x00000004 /* if wait, until consumed? */
/**
 * bman_release - Release buffer(s) to the buffer pool
 * @pool: the buffer pool object to release to
 * @bufs: an array of buffers to release
 * @num: the number of buffers in @bufs (1-8)
 * @flags: bit-mask of BMAN_RELEASE_FLAG_*** options
 *
 * Releases the specified buffers to the buffer pool. If stockpiling is
 * enabled, this may not require a release command to be issued via the RCR
 * ring, otherwise it certainly will. If the RCR ring is full, the function
 * will return -EBUSY unless BMAN_RELEASE_FLAG_WAIT is selected, in which case
 * it will sleep waiting for space to become available in RCR. If
 * BMAN_RELEASE_FLAG_WAIT_SYNC is also specified then it will sleep until
 * hardware has processed the command from the RCR (otherwise the same
 * information can be obtained by polling bman_rcr_is_empty() until it returns
 * TRUE). If the BMAN_RELEASE_FLAG_WAIT_INT is set), then any sleeps will be
 * interruptible. If it is interrupted before producing the release command, it
 * returns -EINTR. Otherwise, it will return zero to indicate the release was
 * successfully issued. (In the case of interruptible sleeps and WAIT_SYNC,
 * check signal_pending() upon return to determine whether the wait was
 * interrupted.)
 */
int bman_release(struct bman_pool *pool, const struct bm_buffer *bufs,
                                u8 num, u32 flags);
/**
 * bman_acquire - Acquire buffer(s) from a buffer pool
 * @pool: the buffer pool object to acquire from
 * @bufs: array for storing the acquired buffers
 * @num: the number of buffers desired (@bufs is at least this big)
 *
 * Acquires buffers from the buffer pool. If stockpiling is enabled, this may
 * not require an acquire command to be issed via the MC interface, otherwise
 * it certainly will. The return value will be the number of buffers obtained
 * from the pool, or a negative error code if a h/w error or pool starvation
 * was encountered.
 */
```

```
int bman_acquire(struct bman_pool *pool, struct bm_buffer *bufs, u8 num,
                        u32 flags);
```

7.4.2.2.4.1.5 Depletion State

It is possible for portals to track depletion state changes to any of the 64 buffer pools supported in BMan. As described in Pool Management on page 629, a pool object can invoke callbacks to convey depletion-entry and depletion-exit events if created with the BMAN_POOL_FLAG_DEPLETION flag.

Conversely, software can issue a portal management command to obtain a snapshot of the depletion and availability status of all BMan 64 pools at once, which is what the following interface does. Here "availability" implies that the pool is not completely empty. Depletion on the other hand is relative to the pools depletion-entry and exit-thresholds. The state of all 64 buffer pools is represented by the following structure types, accessor macros, and bman_query_pools() API;

```
struct bm_pool_state {
          [...]
};
/**
 * bman_query_pools - Query all buffer pool states
 * @state: storage for the queried availability and depletion states
 */
int bman_query_pools(struct bm_pool_state *state);
/* Determine the "availability state" of BPID 'p' from a query result 'r' */
#define BM_MCR_QUERY_AVAILABILITY(r,p) [...]
/* Determine the "depletion state" of BPID 'p' from a query result 'r' */
#define BM_MCR_QUERY_DEPLETION(r,p) [...]
```

7.4.2.2.5 Queue Manager

7.4.2.2.5.1 QMan Overview

7.4.2.2.5.1.1 Queue Manager's Function

The QorIQ Queue Manager (QMan) SoC block manages the movement of data (“frames”) along uni-directional flows (“frame queues”) between different software and hardware end-points (“portals”). This allows software instances to communicate with other software instances and/or datapath hardware blocks (CAAM, PME, FMan) using a hardware-managed queueing mechanism. QMan provides a variety of features in the way this data movement can be managed, including tail-drop or weighted-red congestion/flow-control, congestion group depletion notification, order restoration, and order preservation.

It is beyond the scope of this document to fully explain all the QMan-related notions that are essential to using datapath functionality effectively. But unlike the BMan reference, we will cover at least some of the basic elements here that are fundamental to the software interface, because QMan is more complicated than BMan and some simplistic definitions can be helpful as a place to start. For any more information about what QMan does and how it behaves, please consult the appropriate QorIQ SoC Reference Manual.

7.4.2.2.5.1.2 Frame Descriptors

Frames are represented by "frame descriptors" (or "FD"s) which are 16-byte structures consisting of fields to describe;

- contiguous or scatter-gather data,
- a 32-bit per-frame-descriptor token value (called "cmd/status" because of its common usage in processing data to/from hardware blocks),
- trace-debugging bits,
- a partition ID, used for virtualizing memory access to frame data by datapath hardware blocks (CAAM, PME, FMan),
- a BMan buffer pool ID, used to identify frames whose buffers are sourced from (or are to be recycled to) a BMan buffer pool.

A third ("nested") mode of the scatter-gather representation allows a frame-descriptor to reference more than one frame - this is referred to as a *compound frame*, and is a mechanism for creating an indissociable binding of more than one data descriptor, eg. this is used when sending an input descriptor to PME or CAAM and providing an output descriptor to go with it.

Frame descriptors that are under QMan's control reside in QMan-private resources, comprised of dedicated on-board cache as well as system memory assigned to QMan on initialization. When frames are enqueued to (and dequeued from) frame queues by QMan on behalf of software portals or hardware blocks, the frame descriptor fields are copied in to (and out of) these QMan-private resources.

As with BMan not caring whether the 48-bit tokens it manages are real buffer addresses or not, the same is mostly true for QMan with respect to the frame descriptors it manages. QMan ignores the memory addresses present in the frame descriptor, unless it is dequeued via a portal configured for data stashing and is dequeued from a frame queue that is configured for frame data (or annotation) stashing. However QMan always pays attention to the length field of frame descriptors. In general, the only field that can be safely used as a "pass-through" value without any QMan consequences is the 32-bit cmd/status field.

7.4.2.2.5.1.3 Frame Queue Descriptors (QMan)

Frame queues are uni-directional queues of frames, where frames are enqueued to the tail of the frame queue and dequeued from the head. A frame queue is represented in QMan by a "frame queue descriptor" (or "FQD"), and these reside in a private system memory resource configured for QMan on initialization. A frame queue is referred to by a "frame queue identifier" (or "FQID"), which is literally the index of that FQD within QMan's memory resource. As such, FQIDs form a global name-space, even in an otherwise virtualized environment, so two entities of software can not simultaneously use the same FQID for different purposes.

7.4.2.2.5.1.4 Work Queues

Work queues (or "WQ"s) are uni-directional queues of "scheduled" frame queues. We will see shortly what is meant here by a "scheduled" frame queue, but suffice it to say that QMan supports a fixed collection of work queues, to which QMan appends frame queues when they are due to be serviced. To summarize, multiple FDs can be linked to a single FQ, and multiple FQs can be linked to a single WQ.

7.4.2.2.5.1.5 Channels

A channel is a fixed, hardware-defined association of 8 work queues, also thought of as "priority work queues". This grouping is convenient in that QMan provides sophisticated prioritization support for dequeueing from entire channels rather than specific work queues. Specifically, the 8 work queues within a channel are divided into 3 tiers according to QMan's "class scheduler" logic - work queues 0 and 1 form the high-priority tier and are treated with a strict priority semantic, work queues 2, 3, and 4 form the medium-priority tier and are treated with a weighted interleaved round-robin semantic, and work queues 5, 6, and 7 form the low-priority tier and are also treated with a weighted interleaved round-robin semantic. Apart from the top-tier, the weighting within and between the other two tiers is programmable.

7.4.2.2.5.1.6 Portals

A QMan portal is similar in nature to a BMan portal. There are hardware portals (also called "direct connect portals", or "DCP"s) that allow QMan to be used by other hardware blocks, and there are software portals that allow QMan to be used by logically separated units of software. A software portal consists of two sub-regions of QMan's corenet region, in precisely the same way as with BMan.

7.4.2.2.5.1.7 Dedicated Portal Channels

Each software portal has its own dedicated channel (of 8 work queues), that only it may dequeue from. As a shorthand, one sometimes says that a frame queue is "scheduled to a portal", when what is really meant is that the frame queue is scheduled to a work queue within that portal's *dedicated channel*. Hardware portals also have their own dedicated channels, though sometimes more than one (FMan blocks have multiple dedicated channels).

7.4.2.2.5.1.8 Pool Channels

There are also 15 "pool channels" from which any software portal can dequeue - this is typically used for load-balancing or load-spreading.

7.4.2.2.5.1.9 Portal Sub-Interfaces

Each portal exposes cache-inhibited and cache-enabled registers that can be read and/or written by software to achieve various ends. With some necessary exceptions, the software interface hides most of these details. However an important conceptual point regarding portals is that they have essentially four decoupled sub-interfaces;

- EQCR (EnQueue Command Ring), this is an 8-cacheline ring containing commands from software to QMan. These commands perform enqueues of frame descriptors to frame queues.
- DQRR (DeQueue Response Ring), this is a 16-cacheline ring containing dequeue processing results from QMan to software. These entries usually contain a frame descriptor (except when the dequeue action produced no valid frame descriptor) as well as status information about the dequeue action, the frame queue being dequeued from, and other context for software's use. This ring is unique in that QMan can be configured to stash new ring entries to processor cache, rather than relying on software to (pre)fetch ring entries into cache explicitly.
- MR (Message Ring), this is an 8-cacheline ring containing messages from QMan to software, most notably for enqueue rejection messages and asynchronous retirement processing events. Unlike DQRR, this ring does not support stashing.
- Management commands, consisting of a Command Register (CR) and two Response Register locations (RR0 and RR1), used for issuing a variety of other commands to QMan. EQCR and DQRR (and to a lesser extent, MR) are intended to provide the communications with QMan that represent the fast-path of data processing logic, and the management command interface is where "everything else happens".

7.4.2.2.5.1.10 Frame queue dequeuing

Enqueuing a frame to a frame queue is an unambiguous mechanism; an enqueue command in the EQCR specifies a frame descriptor and a frame queue ID, and the intention is clear. Dequeuing is more subtle, and falls into two general classes depending on *what* one is dequeuing *from* - these are "scheduled" or "unscheduled" dequeues.

7.4.2.2.5.1.10.1 Unscheduled Dequeues

One can dequeue from a specific frame queue, but that frame queue must necessarily be "idle" - or in QMan terminology, "unscheduled". It is an illegal action to attempt to dequeue directly from a frame queue that is in a "scheduled" state. Specifically, unscheduled dequeues require the frame queue to be in the "Parked" or "Retired" state (described in Frame Queue States on page 636).

7.4.2.2.5.1.10.2 Scheduled Dequeues

Conversely, if a frame queue is "scheduled" then, by definition, management of the frame queue is (until further notice) under QMan's control and may at any point change state according to events within QMan or via actions on other software or hardware portals. So a "scheduled dequeue" does not target a specific FQ, but either a specific WQ or collection of channels. QMan processes scheduled dequeue commands within a portal by selecting from among the non-empty WQs, dequeueing a FQ from that selected WQ, and then dequeuing a FD from that FQ.

QMan portals implement two dequeue command modes, "push" and "pull";

7.4.2.2.5.1.10.3 Pull Mode

The "pull" mode is the less conventional of the two, as it is driven by software writing a dequeue command to a single cache-inhibited register that will, in response, perform a single instance of that command and publish its result to DQRR. This "pull" command (PDQCR - Pull DeQueue Command Register) could generate anywhere between 1 and 3 DQRR entries, and software must ensure that it does not write a new command to PDQCR until it knows at least one of these DQRR entries has been published (otherwise writing a new command could clobber the previous command before QMan has prepared its execution). The PDQCR command register can perform scheduled and unscheduled dequeues.

7.4.2.2.5.1.10.4 Push Mode

The "push" mode is the mode that gives software a familiar "DMA-style" interface, ie. where hardware performs work and fills in a kind of "Rx ring" autonomously. In the case of the QMan portal's DQRR sub-interface, this push mode is driven by two dequeue command registers, one for scheduled dequeues (SDQCR - Static DeQueue Command Register), and one for unscheduled dequeues (VDQCR - Volatile DeQueue Command Register). The reason for the static/volatile terminology (rather than scheduled/unscheduled), as well as the presence of two command registers instead of one, relates to how QMan schedules execution of the dequeue commands.

Unlike "pull" mode, QMan is not prodded by a write to the command register each time a dequeue command should occur, it must autonomously execute commands when appropriate. So it is clear that scheduled dequeues can only be performed when the targetted work queue or channels have Truly Scheduled frame queues available to dequeue from. Note that this is not an issue with "pull" mode, as a scheduled dequeue command can be issued when there are no available frame queues and QMan will simply publish a DQRR entry containing no frame descriptor to mark completion of the command - for "push" mode, this semantic cannot work. When in "push" mode, the QMan portal has a (possibly NULL) scheduled dequeue command for dequeuing from a selection of available channels. QMan executes this command only when there is matching scheduled dequeue work available on one of of the channels - ie. the scheduled dequeue command (for channels) is *static*. If software writes SDQCR with a command to dequeue from a specific WQ, the command is executed only once (like the pull command), at which point it reverts to the static dequeue command for channels.

For unscheduled dequeues, a single Parked or Retired frame queue is identified for dequeuing, and as QMan does not manipulate the state of such frame queues in reaction to enqueue or dequeue activity (ie. there is no "scheduling"), there is no mechanism for QMan to "know" when this frame queue becomes non-empty some time in the future. So like "pull" mode, unscheduled dequeues must be done when explicitly demanded by software, and as such they must also (a) expire after a configurable number of frame descriptors are dequeued from frame queue or once it is empty, and (b) even if the frame queue is already empty, a DQRR entry with no frame descriptor should be used to notify software that the unscheduled dequeue command has expired. Ie. the unscheduled command "goes live" when written and becomes inactive once completed - it is *volatile*. Unlike "pull" mode however, the volatile command can perform more than a single dequeue action, and it can even block or flow-control while active, however it always runs to completion and then stops.

As "push" mode supports two dequeue commands (in fact one of them, SDQCR, encompasses two commands in its own right - it has a persistent channel-dequeue command, and an optional one-shot workqueue-dequeue command can be issued without clobbering it), it is worth pointing out that it can service both at once. The VDQCR command register contains a precedence option that QMan uses to determine whether SDQCR or VDQCR work be favoured in the situation where both are active.

7.4.2.2.5.1.10.5 Stashing to Processor Cache

When dequeueing frame queues and publishing entries in DQRR, QMan provides stashing features that involve prepositioning data in processor cache. The main benefit of hardware-instigated stashing is that the data will already be in cache when the processor needs it, avoiding the need to explicitly prefetch it in advance or stalling the processor to fetch it on-demand. As we will see, there is another benefit in the specific case of DQRR stashing.

Each portal supports two types of stashing, for which distinct PAMU entries are configured.

DLIODN

The DLIODN setting configures PAMU authorization and/or translation of transactions to stash DQRR ring entries as they are produced by QMan. The stashing of DQRR entries is not just a performance tweak, it changes the way driver software operates the portal. Rather than needing to invalidate and prefetch the DQRR cachelines to see (or poll for) new DQRR entries, software can simply reread the cached version until it "magically changes". The stashing transaction is then the only implied traffic across the corenet bus (reducing bandwidth) and it is initiated by hardware at the first instant at which a software-initiated prefetch could have seen anything new (minimum possible latency).

Note that if the driver does not enable DQRR stashing, then it is a requirement to manipulate the processor cache directly, so its run time mode of operation must match device configuration. Note also that if DQRR stashing is used, software can not trust the DQRI interrupt source nor read PI index registers to determine that a new DQRR entry is available, as they may race against the stash transaction. On the other hand, software may use the interrupt source to avoid polling for DQRR production unnecessarily, but it does not guarantee that the first read would show the new DQRR entry.

NOTE

P1023 supports DQRR stashing but since it doesn't have Corenet and PAMU, the DLIODN is not applicable to P1023.

FLIODN

QMan can also stash per-frame-descriptor information, specifically;

1. Frame data, pointed to by the frame descriptor
2. Frame annotations, which is anything prior to the data due to a non-zero offset
3. Frame queue context (for the frame queue from which the frame descriptor was dequeued).

In all cases, the FLIODN setting is used by PAMU to authorize/translate these stashing transactions.

7.4.2.2.5.1.11 Frame Queue States

Frame queues are managed by QMan via state-transitions, and some of these states are of interest to software. From software's perspective, a simplification of the frame queue states is to group them as follows;

- **Out of service:** the frame queue is not in use and must be initialized. Neither enqueues nor dequeues are permitted.
- **Parked:** the frame queue is initialized and in an idle state. Enqueues are permitted, as are unscheduled dequeues, neither of which change the frame queue's state. Scheduled dequeues will not result in dequeues from parked frame queues, as a parked frame queue is never linked to a work queue.
- **Scheduled:** the frame queue has been scheduled, implying that hardware will modify its state as/when relevant events occur. Enqueues are permitted, but unscheduled dequeus are not. This is not a real state, but actually a set of states that a frame queue moves between - as hardware performs these moves internally, it's useful to treat them as one, because changes between them are asynchronous to software. The real states are;
  - **Tentatively Scheduled:** the frame queue is not linked to a work queue (yet), the frame queue must therefore be empty and no retirement or force-eligible command has been issued against the frame queue.
  - **Truly Scheduled:** the frame queue is linked to a work queue, either because it has become non-empty or a force-eligible command has occured.
  - **Active:** the frame queue has been selected by a portal for scheduled dequeue and so is removed from the work queue.
  - **Held Active:** the frame queue is still held by the portal after scheduled dequeuing has been performed, it may yet be dequeued from again, depending on scheduling configuration, priorities, etc.
  - **Held Suspended:** the frame queue is still held by the portal after scheduled dequeuing has been performed but another frame queue has been selected "active" and so no further dequeuing will occur on this frame queue.
- **Retired:** the frame queue is being "closed". A frame queue can be put into the retired state as a means of (a) getting it back under software's control (not under QMan's control nor the control of another hardware block), eg. for closing down "Tx" frame queues, and (b) blocking further enqueues to the frame queue so that it can be drained to empty in a deterministic manner. Enqueues are therefore not permitted in this state. Unscheduled dequeues are permitted, and are the only way to dequeue frames from a frame queue in this state.

See the appropriate QorIQ SoC Reference Manual for more detailed information.

7.4.2.2.5.1.12 Hold active

The QMan portal sub-interfaces are generally decoupled or asynchronous in their operation. For example: The processing of software-produced enqueue commands in EQCR is asynchronous to the processing of dequeue commands into DQRR, and both of these are asynchronous to the production of messages into MR and the processing of management commands.

There is however a specific coupling mechanism between EQCR and DQRR to address a certain class of requirements for datapath processing. Consider first that it is possible for multiple portals to dequeue independently from the same data source,

eg. for the purposes of load-balancing, or perhaps idle-time processing of low-priority work. This could occur because multiple portals issue unscheduled dequeue commands from the same Parked (or Retired) frame queue, or because they issue scheduled dequeue commands that target the same pool channels (or the same specific work queue within a pool channel). So we describe here the "hold active" mechanisms that help maintain some synchronicity of hardware dequeue processing (and optionally software *post*-processing) on multiple portals/CPUs.

The unscheduled dequeue case is not covered by the mechanisms described here - QMan will correctly handle multiple unscheduled dequues from the same frame queue, but the "hold active" mechanisms have no effect in this case. For scheduled dequeues however, there are two levels of "hold active" functionality that can be used for software to synchronise multiple portals dequeuing from the same source.

7.4.2.2.5.1.12.1 Dequeue Atomicity

As described in the previous section ("Frame queue states"), the Active, Held Active, and Held Suspended states are for frame queues that have been selected by a portal for *scheduled* dequeuing. These states imply that the frame queue has been detached from the work queue that it was previously "scheduled" to, but not yet moved to the Parked state nor rescheduled to the Tentatively Scheduled or Truly Scheduled state after the completion of dequeuing.

Normally, a frame queue is rescheduled by QMan as soon as it is done dequeuing, potentially even before the resulting DQRR entries are visible to software. However, if the frame queue has been configured for "Held active" behavior, then this will not happen - the frame queue will remain in the Held Active or Held Suspended state once QMan has finished dequeuing from it. QMan will only reschedule or park the frame queue once software consumes all DQRR entries that correspond to that frame queue - the default behavior is to reschedule, but this "held" state of the frame queue allows software an opportunity to request that the final action for the frame queue be to park it instead.

A consequence of this mechanism is that if a DQRR entry is seen that corresponds to a frame queue configured for "held active" behavior, software implicitly knows that there can be no other (unconsumed) DQRR entry on any other portal for that same frame queue. (Proof: if there was, the frame queue would be currently "held" in that portal and not in this one.) For an SMP system where each core has its own portal, this would obviate the need to (spin)lock software context related to a frame queue when handling incoming frames - the "lock" is implicitly obtained when the DQRR entry is seen, and it is implicitly released when the DQRR entries are consumed. This is what is meant by "dequeue atomicity".

7.4.2.2.5.1.12.2 Parking Scheduled FQs

As noted above in Dequeue Atomicity on page 637, if a FQ is currently "held active" in the portal, software can request that it be move to the Parked state once its final DQRR entry is consumed, rather than rescheduled which is the normal behavior. As we will also see in Force Eligible on page 638, this is not necessarily limited to FQs that are configured for "hold active" behavior, but can also be applied to regular FQs by issuing a Force Eligible command on them.

7.4.2.2.5.1.12.3 Order Preservation & Discrete Consumption Acknowledgement

In addition to the dequeue atomicity feature, it is possible to obtain a stronger property from QMan to aid with datapath situations that "spread" incoming data over multiple portals. Specifically, if incoming frames are to be forwarded via subsequent enqueues, then dequeue atomicity does not prevent the forwarded frames from getting out of order. Ie. multiple CPUs (using multiple portals) may be using dequeue atomicity in order to write enqueue commands to their EQCR rings before consuming the DQRR entries, and thus ensuring that EQCR entries are *published* in the same order as the incoming frames. But as there are multiple portals, this does not ensure that QMan will necessarily *process* those EQCR entries in the same order. Indeed if the portals' EQCR rings have significantly varied fill-levels, then there is a reasonable chance that two enqueue commands published in quick succession via different portals could get processed in the opposite order by QMan.

Instead, software can elect to only consume DQRR entries when no forwarding is to be performed on the corresponding frames (eg. when dropping a packet), and for the others, it can encode the EQCR enqueue commands to perform an implicit "Discrete Consumption Acknowledgement" (or "DCA") - the result of which is that QMan will consume the corresponding DQRR entry on software's behalf *once it has finished processing the enqueue command*. This provides a cross-portal, order preservation semantic from end-to-end (from dequeue to enqueue) using hardware assists.

Note, QMan has other functionality called Order Restoration that is completely unrelated to the above - Order Restoration is a mechanism to restore frames into their intended order once they been allowed to get out of order, using sequence numbers

and "reassembly windows" within QMan, see Order Restoration on page 638. The above "hold active" mechanisms are to prevent frames from getting out of order in the first place.

7.4.2.2.5.1.13 Force Eligible

QMan portals support a management command called "Force Eligible" which allows software to regain control of a scheduled frame queue, usually with the intention to park it. When a frame queue is scheduled, QMan is responsible for its state and software can not meaningfully query it, as any snapshots are implicitly out of date by the time software sees them. Software only knows the frame queue state once QMan-generated events indicate that the frame queue is "quiesced" somehow. Moreover, if the frame queue is not configured for "hold active" behavior, then even the presence of DQRR entries does not help in this regard, as the portal may well have rescheduled the frame queue before software sees the first DQRR entry.

When QMan processes a Force Eligible command, it does two things - it tags the frame queue descriptor with a flag that is visible in subsequent DQRR entries, and, if the frame queue is Tentatively Scheduled (because it is empty), it will move the frame queue to the Truly Scheduled state (linked to a work queue). The result is that the frame queue "will receive dequeue processing soon", whether that was already happening or not. Fundamentally, when QMan is dequeuing from the FQ a short while later, it will treat the frame queue as "hold active", even if it isn't configured for hold active treatment. As such, software can request that the FQ be parked rather than rescheduled once the DQRR entry is consumed. See Parking Scheduled FQs on page 637.

7.4.2.2.5.1.14 Enqueue Rejections

Enqueues may be rejected, immediately or after any delay due to order restoration, and the enqueue mechanisms themselves do not provide any meaningful way to convey the rejection event to the software portal. For this reason, Enqueue Rejection Notifications (ERNs) are messages received on a message ring that carry frames that did not successfully enqueue together with the reason for their rejection.

7.4.2.2.5.1.15 Order Restoration

Frame queue descriptors can serve one or both of two complimentary purposes. A small subset of fields in the FQDs are used to implement an "Order Restoration Point", which allows an FQD to act as a reassembly window for out-of-sequence enqueues. FQDs also contain a sequence number field that generates increasing sequence numbers for all frames dequeued from the FQ. This dequeue activity sequence number is also called an "Order Definition Point". The idea is that frames dequeued from a given FQ (ODP) may get out-of-sequence during processing before they're enqueued onto an egress FQ, so the enqueue function allows one to not only specify the desination FQD, but also an ORP that the enqueue command should first pass through - which might hold up the intended enqueue until other, missing, sequence elements are enqueued. Ie. an ORP-enabled enqueue command requires 2 FQID parameters, which need not necessarily be the same - indeed in many networking examples, the Rx FQ serves as both the ODP and the ORP when enqueuing to the Tx FQ. To see why this choice of ORP FQ makes sense, consider that many Rx flows may need to be order-restored independently, even if all of them are ultimately enqueued to the same destination Tx FQ. It's also possible to enqueue using software-generated sequence numbers, ie. without any FQ dequeue activity acting as an ODP. An ODP is any source of sequence numbers starting at zero and wrapping to zero at 0x3fff (2^{14}-1).

ORP-enabled enqueue functions provide various features, such as filling in missing sequence numbers (eg. when dropping frames), advancing the "Next Expected Sequence Number" despite missing frames (that may or may not show up later), etc. These features are options in the enqueue interfaces, eg. see Enqueue Command (without ORP) on page 650, specifically the qman_enqueue_orp() API.

There are also numerous options that can be set in ORP-enabled FQDs, and these are achieved via the same functions that allow you to manipulate FQDs for any other purpose. Eg. see Frame queue management on page 645, specifically the qman_init_fq() API. Care should be taken when using a FQD as both a FQ and an ORP - in particular, a FQD can not be retired and put out-of-service while the ORP component of the descriptor is still in use, and vice versa.

7.4.2.2.5.2 QMan configuration interface

The QMan configuration interface is an encapsulation of the QMan CCSR register space and the global/error interrupt source. Whereas QMan portals provide independent channels for accessing QMan functionality, the configuration interface

represents the QMan device itself. The QMan configuration interface is presently limited to the device-tree node that represents it.

7.4.2.2.5.2.1 QMan device-tree node

The QMan device tree node represents the QMan device and its CCSR configuration space (as distinct from its corenet portals). When a linux kernel has QMan control support built in, it will react to this device tree node by configuring and managing the QMan device. The device-tree node sits within the CCSR node ("soc") and is of the following form;

```
        soc@fe000000 {
                [...]
                qman: qman@318000 {
                        compatible = "fsl,qman";
                        reg = <0x318000 0x1000>;
                        fsl,qman-fqd = <0x0 0x22000000 0x0 0x00200000>;
                        fsl,qman-pfdr = <0x0 0x21000000 0x0 0x01000000>;
                        fsl,liodn = <0x1f>;
                };
                [...]
          };
```

'compatible' and 'reg' are standard ePAPR properties.

7.4.2.2.5.2.1.1 Frame Queue Descriptors

This property configures the memory used by QMan for storing frame queue descriptors. Each FQD occupies a 64-byte cacheline of memory, so as the above example configures 2MB for FQD memory, the valid range of FQIDs is [1...32767];

```
                        fsl,qman-fqd = <0x0 0x22000000 0x0 0x00200000>;
```

The treatment and alignment requirements of this property are the same as in Free Buffer Proxy Records on page 624.

7.4.2.2.5.2.1.2 Packed Frame Descriptor Records

This property configures the memory used by QMan for storing Packed Frame Descriptor Records. Each PFDR occupies a 64-byte cacheline of memory, and can hold 3 Frame Descriptors. QMan maintains an onboard cache for holding recently enqueued (and/or soon to be dequeued) frames, and in responsive systems that remain within their operating capacity (ie. no spikes) it can often be unnecessary for frames to ever be stored in system memory at all. However, to handle spikes or buffering, a storage density of 3 enqueued frames per-cacheline can be used for estimating a suitable allocation of memory to QMan for PFDRs. In the case of handling ERNs (eg. if congestion controls exist elsewhere than on an ingress network interface), then a storage density of 1 ERN per-cacheline should be used. The above example configures 16MB for PFDR memory (786,432 enqueued frames, or 262,144 ERNs);

```
                        fsl,qman-pfdr = <0x0 0x21000000 0x0 0x01000000>;
```

The treatment and alignment requirements of this property are the same as in Free Buffer Proxy Records on page 624.

7.4.2.2.5.2.1.3 Logical I/O Device Number (QMan)

This property is the same as described in Logical I/O Device Number (BMan) on page 624, but for use by QMan when accessing FQD and PFDR memory (rather than BMan's FBPR memory).

7.4.2.2.5.2.2 QMan pool channel device-tree node

Each QMan software portal has its own dedicated channel of work queues. QMan also provides "pool channels" that all software portals can optionally dequeue from - this is described in Portals on page 633. The device-tree should declare pool channels using device-tree nodes as follows;

```
        qman-pool@1 {
                compatible = "fsl,qman-pool-channel";
                    cell-index = <0x1>;
```

```
                fsl,qman-channel-id = <0x21>;
        };
```

7.4.2.2.5.2.2.1 Channel ID

When FQs are initialized for scheduling, the target work queue is identified by the channel id (a hardware-assigned identifier) and by one of the 8 priority levels within that channel. Channel ids are hardware constants, as conveyed by this device-tree property;

```
                fsl,qman-channel-id = <0x21>;
```

7.4.2.2.5.2.3 QMan portal device-tree node

The QMan Corenet portal interface in QorIQ P4080 provides up to 10 distinct memory-mapped interfaces for use by software to interact efficiently with QMan functionality. These are described in Portals on page 633 and Portal Sub-Interfaces on page 634. Refer to the appropriate SoC reference manuals for non-P4080 specifications.

The QMan driver determines the available corenet portals from the device tree. The portal nodes are at the physical address scope (unlike the device-tree node for the BMan device itself, which is within the "soc" physical address node that represents CCSR). These nodes indicate the physical address ranges of the cache-enabled and cache-inhibited sub-regions of the portal (respectively), and look something like the following;

```
        qman-portal@c000 {
                compatible = "fsl,qman-portal";
                reg = <0xf420c000 0x4000 0xf4303000 0x1000>;
                interrupts = <0x6e 2>;
                interrupt-parent = <&mpic>;
                cell-index = <0x3>;
                cpu-handle = <&cpu3>;
                fsl,qman-channel-id = <0x3>;
                fsl,qman-pool-channels = <&qpool1 &qpool2>;
                fsl,liodn = <0x7 0x8>;
        };
```

As with BMan portal nodes, the "cpu-handle" property is used to express an affinity/association between the given QMan portal and the CPU represented by the referenced device-tree node. Unlike BMan however, the "cpu-handle" property is also used by PAMU configuration, to determine which CPU's L1 or L2 cache should receive stashing transactions emanating from this portal. The "fsl,qman-channel-id" property is already documented in Channel ID on page 640, the other QMan-specific portal properties are described below.

7.4.2.2.5.2.3.1 Portal Access to Pool Channels

In QorIQ P4080, P3041, P5020 hardware, all software portals can dequeue from any/all pool channels. Nonetheless, the portal device-tree nodes allow the architect to specify this and optionally limit the range of pool channels a given portal can dequeue from. This can be particularly useful when partitioning multiple guest operating systems, it essentially allows the architect to partition the use of pool channels as they partition the use of portals. In the above example, the portal is only able to dequeue from 2 pool channels;

```
                fsl,qman-pool-channels = <&qpool1 &qpool2>;
```

7.4.2.2.5.2.3.2 Stashing Logical I/O Device Number

This property, when used in QMan portal nodes, declares two LIODN values for use by QMan when performing dequeue stashing to processor cache. These are documented in Stashing to Processor Cache on page 635. This property is filled in automatically by u-boot, and if hypervisor is in use then it will fill in this property for guest device-trees also. PAMU drivers

(linux-native or within the hypervisor) will configure the settings for these LIODNs according to the CPU that stashing should be directed towards, as per the cpu-handle property;

```
                    fsl,liodn = <0x7 0x8>;
                    cpu-handle = <&cpu3>;
```

7.4.2.2.5.2.3.3 Portal Initialization (QMan)

The driver is informed of the QMan portals that are available to it via the device-tree passed to the system from the boot process. For those portals that aren't reserved for USDPAA usage via the "fsl,usdpaa-portal" property, it will automatically create TLB entries to map the QMan portal corenet sub-regions as cpu-addressable and cache-inhibited or cache-enabled as appropriate.

As with the BMan driver, the QMan driver will automatically associate initialised QMan portals with the CPU to which they are configured, only one a one-per-CPU basis (if multiple portals are configured for the same CPU, only one is used). Please see Portal sharing on page 626 for an explanation of this behaviour in the BMan documentation, the QMan behaviour is identical.

7.4.2.2.5.2.3.4 Auto-Initialization

As with the BMan driver, the QMan driver will, by default, automatically initialize QMan portals as they are parsed out of the device-tree. Please see Portal sharing on page 626 for an explanation of this behavior in the BMan documentation. The QMan behavior is identical.

7.4.2.2.6 QMan portal APIs

The following sections describe interfaces provided by the QMan driver for manipulating portals. These are defined in QMan portal device-tree node on page 640, and described in Portals on page 633 and Portal Sub-Interfaces on page 634.

Note, unlike the BMan documentation, we will not include many of the QMan-related data structures within this documentation as they are significantly more elaborate. It is presumed the reader will consult the corresponding header files for structure data details that aren't sufficiently described here.

7.4.2.2.6.1 QMan High-Level Portal Interface

7.4.2.2.6.1.1 Overview (QMan)

The high-level portal interface provides management and encapsulation of a portal hardware interface. The operations performed on the "portal" are coordinated internally, hiding the user from the I/O semantics, and allowing multiple users/contexts to share portals without collaboration between them. This interface also provides an object representation for congestion group records (CGRs), with optional assists for cases where the user wishes to track congestion entry and exit events, eg. to apply back-pressure on the affected frame queues, etc. There is also an object representation for frame queues that internally coordinates FQ operations, demuxes incoming dequeued frames and messages to the corresponding owner's callbacks, and interprets hardware-provided indications of changes to FQ state.

This interface provides locking and arbitration of portal operations from multiple software contexts and/or threads (ie. the portal is shared). In cases where a resource is busy, the interface also gives callers the option of blocking/sleeping until the resouce is available (and in the case of volatile dequeue commands, the caller may also optionally sleep until the volatile dequeue command has finished). In any case where sleeping is an option, the caller can also specify whether the sleep should be interruptible.

NOTE

Support for blocking/sleeping is limited to Linux, it is not available on run-to-completion systems such as USDPAA.

The demux logic within the portal interface assumes ownership of the "contextB" field of frame queue descriptors (FQDs), so users of this interface can not modify this field. However, callers provide the cache line of memory to be used within the driver for each FQ object when calling qman_create_fq(), so they can extend this structure into adjacent cachelines with their own data and use this instead of contextB for their own purposes. Ie. when callbacks are invoked because of dequeued

frames, enqueue rejections, or retirement notifications, those callbacks will find their custom per-FQ data adjacent to the FQ object pointer they are passed. Moreover, if context-stashing is enabled for the portal and the FQD is configured to stash 1 or more cachelines of context, the QMan driver's demux function will be implicitly accelerated because the FQ object will be prefetched into processor cache. Any adjacent data that is covered by the FQ's stashing configuration could likewise lead to acceleration of the owner's dequeue callbacks, ie. by reducing or eliminating cache misses in fast-path processing.

7.4.2.2.6.1.2 Frame and Message Handling

When DQRR or MR ring entries are produced by hardware to software, callbacks that have been provided by the API user are invoked to allow those entries to be handled prior to the driver consuming them. These callbacks are provided in the 'qman_fq_cb' structure type.

```
struct qman_fq_cb {
          qman_cb_dqrr dqrr; /* for dequeued frames */
          qman_cb_mr ern;          /* for software ERNs */
          qman_cb_mr dc_ern; /* for diverted hardware ERNs */
          qman_cb_mr fqr;           /* retirement messages */
};
typedef enum qman_cb_dqrr_result (*qman_cb_dqrr)(struct qman_portal *qm,
                                 struct qman_fq *fq, const struct qm_dqrr_entry *dqrr);
typedef void (*qman_cb_mr)(struct qman_portal *qm, struct qman_fq *fq,
                                 const struct qm_mr_entry *msg);
enum qman_cb_dqrr_result {
          /* DQRR entry can be consumed */
          qman_cb_dqrr_consume,
          /* Like _consume, but requests parking - FQ must be held-active */
          qman_cb_dqrr_park,
          /* Does not consume, for DCA mode only. This allows out-of-order
           * consumes by explicit calls to qman_dca() and/or the use of implicit
           * DCA via EQCR entries. */
          qman_cb_dqrr_defer
};
```

7.4.2.2.6.1.3 Portal management (QMan)

The portal management API provides qman_affine_cpus(), which returns a mask that indicates which CPUs have auto-initialiazed portals associated with them. See QMan portal device-tree node on page 640. All other QMan API functions must be executed on CPUs contained within this mask, and any interactions they require with h/w will be performed on the corresponding portals.

```
/**
 * qman_affine_cpus - return a mask of cpus that have portal access
 */
const cpumask_t *qman_affine_cpus(void);
```

7.4.2.2.6.1.3.1 Modifying interrupt-driven portal duties (QMan)

Portals have various servicing duties they must perform in reaction to hardware events. The portal management API allows applications to control which of these duties/events are triggered by interrupt-handling versus those which are performed at the application's explicit request via qman_poll() (or more specifically, via qman_poll_dqrr() and qman_poll_slow()). If portal-sharing is in effect (see Portal sharing on page 626), these APIs won't succeed when called from a slave CPU.

```
#define QM_PIRQ_CSCI    0x00100000      /* Congestion State Change */
#define QM_PIRQ_EQCI    0x00080000      /* Enqueue Command Committed */
#define QM_PIRQ_EQRI    0x00040000      /* EQCR Ring (below threshold) */
#define QM_PIRQ_DQRI    0x00020000      /* DQRR Ring (non-empty) */
#define QM_PIRQ_MRI     0x00010000      /* MR Ring (non-empty) */
#define QM_PIRQ_SLOW    (QM_PIRQ_CSCI | QM_PIRQ_EQCI | QM_PIRQ_EQRI | \
                         QM_PIRQ_MRI)
```

```
/**
 * qman_irqsource_get - return the portal work that is interrupt-driven
 *
 * Returns a bitmask of QM_PIRQ_**I processing sources that are currently
 * enabled for interrupt handling on the current cpu's affine portal. These
 * sources will trigger the portal interrupt and the interrupt handler (or a
 * tasklet/bottom-half it defers to) will perform the corresponding processing
 * work. The qman_poll_***() functions will only process sources that are not in
 * this bitmask. If the current CPU is sharing a portal hosted on another CPU,
 * this always returns zero.
 */
u32 qman_irqsource_get(void);
/**
 * qman_irqsource_add - add processing sources to be interrupt-driven
 * @bits: bitmask of QM_PIRQ_**I processing sources
 *
 * Adds processing sources that should be interrupt-driven (rather than
* processed via qman_poll_***() functions). Returns zero for success, or
* -EINVAL if the current CPU is sharing a portal hosted on another CPU.
*/
int qman_irqsource_add(u32 bits);
/**
* qman_irqsource_remove - remove processing sources from being interrupt-driven
* @bits: bitmask of QM_PIRQ_**I processing sources
*
* Removes processing sources from being interrupt-driven, so that they will
* instead be processed via qman_poll_***() functions. Returns zero for success,
* or -EINVAL if the current CPU is sharing a portal hosted on another CPU.
*/
int qman_irqsource_remove(u32 bits);
```

7.4.2.2.6.1.3.2 Processing non-interrupt-driven portal duties (QMan)

If portal-sharing is in effect (see Portal sharing on page 626), these APIs won't succeed when called from a slave CPU.

```
/**
* qman_poll_dqrr - process DQRR (fast-path) entries
* @limit: the maximum number of DQRR entries to process
*
* Use of this function requires that DQRR processing not be interrupt-driven.
* Ie. the value returned by qman_irqsource_get() should not include
* QM_PIRQ_DQRI. If the current CPU is sharing a portal hosted on another CPU,
* this function will return -EINVAL, otherwise the return value is >=0 and
* represents the number of DQRR entries processed.
*/
int qman_poll_dqrr(unsigned int limit);
/**
QMan Portal APIs
QMan, BMan API RM, Rev. 0.13
6-34 NXP Confidential Proprietary NXP Semiconductors
Preliminary—Subject to Change Without Notice
* qman_poll_slow - process anything (except DQRR) that isn't interrupt-driven.
*
* This function does any portal processing that isn't interrupt-driven. If the
* current CPU is sharing a portal hosted on another CPU, this function will
* return -EINVAL, otherwise returns zero for success.
*/
void qman_poll_slow(void);
/**
```

```
 * qman_poll - legacy wrapper for qman_poll_dqrr() and qman_poll_slow()
 *
 * Dispatcher logic on a cpu can use this to trigger any maintenance of the
 * affine portal. There are two classes of portal processing in question;
 * fast-path (which involves demuxing dequeue ring (DQRR) entries and tracking
 * enqueue ring (EQCR) consumption), and slow-path (which involves EQCR
 * thresholds, congestion state changes, etc). This function does whatever
 * processing is not triggered by interrupts.
 *
 * Note, if DQRR and some slow-path processing are poll-driven (rather than
 * interrupt-driven) then this function uses a heuristic to determine how often
 * to run slow-path processing - as slow-path processing introduces at least a
 * minimum latency each time it is run, whereas fast-path (DQRR) processing is
 * close to zero-cost if there is no work to be done. Applications can tune this
 * behavior themselves by using qman_poll_dqrr() and qman_poll_slow() directly
 * rather than going via this wrapper.
 */
void qman_poll(void);
```

7.4.2.2.6.1.3.3 Recovery support (QMan)

Note that the following functions require the QMan portal to have been initialized in "recovery mode", which is not possible with the current release. As such, these functions are for future use only (and documented here only because they're declared in the API header).

```
/**
 * qman_recovery_cleanup_fq - in recovery mode, cleanup a FQ of unknown state
 */
int qman_recovery_cleanup_fq(u32 fqid);
/**
 * qman_recovery_exit - leave recovery mode
 */
int qman_recovery_exit(void);
```

7.4.2.2.6.1.3.4 Stopping and restarting dequeues to the portal

```
/**
 * qman_stop_dequeues - Stop h/w dequeuing to the s/w portal
 *
 * Disables DQRR processing of the portal. This is reference-counted, so
 * qman_start_dequeues() must be called as many times as qman_stop_dequeues() to
 * truly re-enable dequeuing.
 */
void qman_stop_dequeues(void);
/**
 * qman_start_dequeues - (Re)start h/w dequeuing to the s/w portal
 *
 * Enables DQRR processing of the portal. This is reference-counted, so
 * qman_start_dequeues() must be called as many times as qman_stop_dequeues() to
 * truly re-enable dequeuing.
 */
void qman_start_dequeues(void);
```

7.4.2.2.6.1.3.5 Manipulating the portal static dequeue command

```
/**
 * qman_static_dequeue_add - Add pool channels to the portal SDQCR
```

```
 * @pools: bit-mask of pool channels, using QM_SDQCR_CHANNELS_POOL(n)
 *
 * Adds a set of pool channels to the portal's static dequeue command register
 * (SDQCR). The requested pools are limited to those the portal has dequeue
 * access to.
 */
void qman_static_dequeue_add(u32 pools);
/**
 * qman_static_dequeue_del - Remove pool channels from the portal SDQCR
 * @pools: bit-mask of pool channels, using QM_SDQCR_CHANNELS_POOL(n)
 *
 * Removes a set of pool channels from the portal's static dequeue command
 * register (SDQCR). The requested pools are limited to those the portal has
 * dequeue access to.
 */
void qman_static_dequeue_del(u32 pools);
/**
 * qman_static_dequeue_get - return the portal's current SDQCR
 *
 * Returns the portal's current static dequeue command register (SDQCR). The
 * entire register is returned, so if only the currently-enabled pool channels
 * are desired, mask the return value with QM_SDQCR_CHANNELS_POOL_MASK.
 */
u32 qman_static_dequeue_get(void);
```

7.4.2.2.6.1.3.6 Determining if the enqueue ring is empty

```
/**
 * qman_eqcr_is_empty - Determine if portal's EQCR is empty
 *
 * For use in situations where a cpu-affine caller needs to determine when all
 * enqueues for the local portal have been processed by QMan but can't use the
 * QMAN_ENQUEUE_FLAG_WAIT_SYNC flag to do this from the final qman_enqueue().
 * The function forces tracking of EQCR consumption (which normally doesn't
 * happen until enqueue processing needs to find space to put new enqueue
 * commands), and returns zero if the ring still has unprocessed entries,
 * non-zero if it is empty.
 */
int qman_eqcr_is_empty(void);
```

7.4.2.2.6.1.4 Frame queue management

Frame queue objects are stored in memory provided by the caller, which makes the API for this object representation a little peculiar at first sight. The motivating factors are memory management and stashing of frame queue context. Another factor is that frame queue objects are the only objects in the QMan (or BMan) high level interfaces that are essentially arbitrary in number, so having the caller provide storage relieves the driver of having to know the best allocation scheme for all applications.

The qman_create_fq() API creates a new frame queue object, using the caller-supplied storage, and in which the caller has already configured the callback functions to be used for handling hardware-produced data - namely, DQRR entries and MR entries, the latter divided according to the type of message (software-enqueue rejections, hardware-enqueue rejections, or frame queue state changes).

```
#define QMAN_FQ_FLAG_NO_ENQUEUE      0x00000001 /* can't enqueue */
#define QMAN_FQ_FLAG_NO_MODIFY       0x00000002 /* can only enqueue */
#define QMAN_FQ_FLAG_TO_DCPORTAL     0x00000004 /* consumed by CAAM/PME/FMan */
#define QMAN_FQ_FLAG_LOCKED          0x00000008 /* multi-core locking */
#define QMAN_FQ_FLAG_AS_I            0x00000010 /* query h/w state */
```

```
#define QMAN_FQ_FLAG_DYNAMIC_FQID    0x00000020 /* (de)allocate fqid */
struct qman_fq {
        /* Caller of qman_create_fq() provides these demux callbacks */
        struct qman_fq_cb {
                qman_cb_dqrr dqrr;      /* for dequeued frames */
                qman_cb_mr ern;         /* for s/w ERNs */
                qman_cb_mr dc_ern;      /* for diverted h/w ERNs */
                qman_cb_mr fqs;         /* frame-queue state changes*/
        } cb;
          /* Internal to the driver, don't touch. */
          [...]
};
/**
 * qman_create_fq - Allocates a FQ
 * @fqid: the index of the FQD to encapsulate, must be "Out of Service"
 * @flags: bit-mask of QMAN_FQ_FLAG_*** options
 * @fq: memory for storing the 'fq', with callbacks filled in
 *
 * Creates a frame queue object for the given @fqid, unless the
 * QMAN_FQ_FLAG_DYNAMIC_FQID flag is set in @flags, in which case a FQID is
 * dynamically allocated (or the function fails if none are available). Once
 * created, the caller should not touch the memory at 'fq' except as extended to

 * adjacent memory for user-defined fields (see the definition of "struct
 * qman_fq" for more info). NO_MODIFY is only intended for enqueuing to
 * pre-existing frame-queues that aren't to be otherwise interfered with, it
 * prevents all other modifications to the frame queue. The TO_DCPORTAL flag
 * causes the driver to honour any contextB modifications requested in the
 * qm_init_fq() API, as this indicates the frame queue will be consumed by a
 * direct-connect portal (PME, CAAM, or FMan). When frame queues are consumed by

 * software portals, the contextB field is controlled by the driver and can't be

 * modified by the caller. If the AS_SI flag is specified, management commands
 * will be used on portal @p to query state for frame queue @fqid and construct
 * a frame queue object based on that, rather than assuming/requiring that it be
 * Out of Service.
 */
int qman_create_fq(u32 fqid, u32 flags, struct qman_fq *fq);
#define QMAN_FQ_DESTROY_PARKED       0x00000001 /* FQ can be parked or OOS */
/**
 * qman_destroy_fq - Deallocates a FQ
 * @fq: the frame queue object to release
 * @flags: bit-mask of QMAN_FQ_DESTROY_*** options
 *
 * The memory for this frame queue object ('fq' provided in qman_create_fq()) is
 * not deallocated but the caller regains ownership, to do with as desired. The
 * FQ must be in the 'out-of-service' state unless the QMAN_FQ_DESTROY_PARKED
 * flag is specified, in which case it may also be in the 'parked' state.
 */
void qman_destroy_fq(struct qman_fq *fq, u32 flags);
```

7.4.2.2.6.1.4.1 Querying a FQ object

The following functions do not interact with h/w, they simply return the state that the QMan driver tracks within the FQ object.

```
/**
 * qman_fq_fqid - Queries the frame queue ID of a FQ object
 * @fq: the frame queue object to query
 */
```

```
u32 qman_fq_fqid(struct qman_fq *fq);
enum qman_fq_state {
        qman_fq_state_oos,
        qman_fq_state_parked,
        qman_fq_state_sched,
        qman_fq_state_retired
};
#define QMAN_FQ_STATE_CHANGING       0x80000000 /* 'state' is changing */
#define QMAN_FQ_STATE_NE             0x40000000 /* retired FQ isn't empty */
#define QMAN_FQ_STATE_ORL            0x20000000 /* retired FQ has ORL */
#define QMAN_FQ_STATE_BLOCKOOS       0xe0000000 /* if any are set, no OOS */
#define QMAN_FQ_STATE_CGR_EN         0x10000000 /* CGR enabled */
/**
 * qman_fq_state - Queries the state of a FQ object
 * @fq: the frame queue object to query
 * @state: pointer to state enum to return the FQ scheduling state
 * @flags: pointer to state flags to receive QMAN_FQ_STATE_*** bitmask
 *
 * Queries the state of the FQ object, without performing any h/w commands.
 * This captures the state, as seen by the driver, at the time the function
 * executes.
 */
void qman_fq_state(struct qman_fq *fq, enum qman_fq_state *state, u32 *flags);
```

7.4.2.2.6.1.4.2 Initialize a FQ

The qman_init_fq() API requires that the caller fill in the details of the Initialize FQ command that they desire, and uses the 'struct qm_mcc_initfq' structure type to this end. This structure is quite elaborate, please consult the API header file and SDK examples for more informatoin.

```
#define QMAN_INITFQ_FLAG_SCHED       0x00000001 /* schedule rather than park */
#define QMAN_INITFQ_FLAG_NULL        0x00000002 /* zero 'contextB', no demux */
#define QMAN_INITFQ_FLAG_LOCAL       0x00000004 /* set dest portal */
/**
 * qman_init_fq - Initialises FQ fields, leaves the FQ "parked" or "scheduled"
 * @fq: the frame queue object to modify, must be 'parked' or new.
 * @flags: bit-mask of QMAN_INITFQ_FLAG_*** options
 * @opts: the FQ-modification settings, as defined in the low-level API
 *
 * @opts: the FQ-modification settings
*
* Select QMAN_INITFQ_FLAG_SCHED in @flags to cause the frame queue to be
* scheduled rather than parked. Select QMAN_INITFQ_FLAG_NULL in @flags to
* configure a frame queue that will not demux to a 'struct qman_fq' object when
* dequeued frames or messages arrive at a software portal, but which will
* instead trigger the portal's 'null_cb' callbacks (see qman_create_portal()).
* NB, @opts can be NULL.
 *
 * Note that some fields and options within @opts may be ignored or overwritten
 * by the driver;
 * 1. the 'count' and 'fqid' fields are always ignored (this operation only
 * affects one frame queue: @fq).
 * 2. the QM_INITFQ_WE_CONTEXTB option of the 'we_mask' field and the associated
 * 'fqd' structure's 'context_b' field are sometimes overwritten;
 *   - if @flags contains QMAN_INITFQ_FLAG_NULL, then context_b is initialized
 *     to zero by the driver,
 *   - if @fq was not created with QMAN_FQ_FLAG_TO_DCPORTAL, then context_b is
 *     initialized to a value used by the driver for demux.
 *   - if context_b is initialized for demux, so is context_a in case stashing
```

```
 *     is requested (see item 4).
 * (So caller control of context_b is only possible for TO_DCPORTAL frame queue
 * objects.)
 * 3. if @flags contains QMAN_INITFQ_FLAG_LOCAL, the 'fqd' structure's
 * 'dest::channel' field will be overwritten to match the portal used to issue
 * the command. If the WE_DESTWQ write-enable bit had already been set by the
 * caller, the channel workqueue will be left as-is, otherwise the write-enable
 * bit is set and the workqueue is set to a default of 4. If the "LOCAL" flag
 * isn't set, the destination channel/workqueue fields and the write-enable bit
 * are left as-is.
 * 4. if the driver overwrites context_a/b for demux, then if
 * QM_INITFQ_WE_CONTEXTA is set, the driver will only overwrite
 * context_a.address fields and will leave the stashing fields provided by the
 * user alone, otherwise it will zero out the context_a.stashing fields.
 */
int qman_init_fq(struct qman_fq *fq, u32 flags, struct qm_mcc_initfq *opts);
```

7.4.2.2.6.1.4.3 Schedule a FQ

```
/**
 * qman_schedule_fq - Schedules a FQ
 * @fq: the frame queue object to schedule, must be 'parked'
 *
 * Schedules the frame queue, which must be Parked, which takes it to
 * Tentatively-Scheduled or Truly-Scheduled depending on its fill-level.
 */
int qman_schedule_fq(struct qman_fq *fq);
```

```
/**
 * qman_retire_fq - Retires a FQ
 * @fq: the frame queue object to retire
 * @flags: FQ flags (as per qman_fq_state) if retirement completes immediately
 *
 * Retires the frame queue. This returns zero if it succeeds immediately, +1 if
 * the retirement was started asynchronously, otherwise it returns negative for
 * failure. When this function returns zero, @flags is set to indicate whether
 * the retired FQ is empty and/or whether it has any ORL fragments (to show up
 * as ERNs). Otherwise the corresponding flags will be known when a subsequent
 * FQRN message shows up on the portal's message ring.
 *
 * NB, if the retirement is asynchronous (the FQ was in the Truly Scheduled or
 * Active state), the completion will be via the message ring as a FQRN - but
 * the corresponding callback may occur before this function returns!! Ie. the
 * caller should be prepared to accept the callback as the function is called,
 * not only once it has returned.
 */
int qman_retire_fq(struct qman_fq *fq, u32 *flags);
```

7.4.2.2.6.1.4.5 Put a FQ out of service

```
/**
 * qman_oos_fq - Puts a FQ "out of service"
 * @fq: the frame queue object to be put out-of-service, must be 'retired'
 *
 * The frame queue must be retired and empty, and if any order restoration list
```

```
 * was released as ERNs at the time of retirement, they must all be consumed.
 */
int qman_oos_fq(struct qman_fq *fq);
```

7.4.2.2.6.1.4.6 Query a FQD from QMan

The following functions perform query commands via the QMan software portal to obtain information about the FQD corresponding to the given FQ object. The data structures used by the query are quite elaborate, please consult the API header file and SDK examples for more information.

```
/**
 * qman_query_fq - Queries FQD fields (via h/w query command)
 * @fq: the frame queue object to be queried
 * @fqd: storage for the queried FQD fields
 */
int qman_query_fq(struct qman_fq *fq, struct qm_fqd *fqd);
/**
 * qman_query_fq_np - Queries non-programmable FQD fields
 * @fq: the frame queue object to be queried
 * @np: storage for the queried FQD fields
 */
int qman_query_fq_np(struct qman_fq *fq, struct qm_mcr_queryfq_np *np);
```

7.4.2.2.6.1.4.7 Unscheduled (volatile) dequeuing of a FQ

```
#define QMAN_VOLATILE_FLAG_WAIT      0x00000001 /* wait if VDQCR is in use */
#define QMAN_VOLATILE_FLAG_WAIT_INT  0x00000002 /* if wait, interruptible? */
#define QMAN_VOLATILE_FLAG_FINISH    0x00000004 /* wait till VDQCR completes */
/**
 * qman_volatile_dequeue - Issue a volatile dequeue command
 * @fq: the frame queue object to dequeue from (or NULL)
 * @flags: a bit-mask of QMAN_VOLATILE_FLAG_*** options
 * @vdqcr: bit mask of QM_VDQCR_*** options, as per qm_dqrr_vdqcr_set()
 *
 * Attempts to lock access to the portal's VDQCR volatile dequeue functionality.
 * The function will block and sleep if QMAN_VOLATILE_FLAG_WAIT is specified and
 * the VDQCR is already in use, otherwise returns non-zero for failure. If
 * QMAN_VOLATILE_FLAG_FINISH is specified, the function will only return once
 * the VDQCR command has finished executing (ie. once the callback for the last
 * DQRR entry resulting from the VDQCR command has been called). If @fq is
 * non-NULL, the corresponding FQID will be substituted in to the VDQCR command,
 * otherwise it is assumed that @vdqcr already contains the FQID to dequeue
 * from.
 */
int qman_volatile_dequeue(struct qman_fq *fq, u32 flags, u32 vdqcr)
```

7.4.2.2.6.1.4.8 Set FQ flow control state

```
/**
 * qman_fq_flow_control - Set the XON/XOFF state of a FQ
 * @fq: the frame queue object to be set to XON/XOFF state, must not be 'oos',
 * or 'retired' or 'parked' state
 * @xon: boolean to set fq in XON or XOFF state
 *
 * The frame should be in Tentatively Scheduled state or Truly Schedule sate,
 * otherwise the IFSI interrupt will be asserted.
```

```
 */
int qman_fq_flow_control(struct qman_fq *fq, int xon);
```

7.4.2.2.6.1.5 Enqueue Command (without ORP)

```
#define QMAN_ENQUEUE_FLAG_WAIT       0x00010000 /* wait if EQCR is full */
#define QMAN_ENQUEUE_FLAG_WAIT_INT   0x00020000 /* if wait, interruptible? */
#define QMAN_ENQUEUE_FLAG_WAIT_SYNC  0x00000004 /* if wait, until consumed? */
#define QMAN_ENQUEUE_FLAG_WATCH_CGR  0x00080000 /* watch congestion state */
#define QMAN_ENQUEUE_FLAG_DCA        0x00008000 /* perform enqueue-DCA */
#define QMAN_ENQUEUE_FLAG_DCA_PARK   0x00004000 /* If DCA, requests park */
#define QMAN_ENQUEUE_FLAG_DCA_PTR(p)            /* If DCA, p is DQRR entry */ \
                (((u32)(p) << 2) & 0x00000f00)
#define QMAN_ENQUEUE_FLAG_C_GREEN    0x00000000 /* choose one C_*** flag */
#define QMAN_ENQUEUE_FLAG_C_YELLOW   0x00000008
#define QMAN_ENQUEUE_FLAG_C_RED      0x00000010
#define QMAN_ENQUEUE_FLAG_C_OVERRIDE 0x00000018
/**
 * qman_enqueue - Enqueue a frame to a frame queue
 * @fq: the frame queue object to enqueue to
 * @fd: a descriptor of the frame to be enqueued
 * @flags: bit-mask of QMAN_ENQUEUE_FLAG_*** options
 *
 * Fills an entry in the EQCR of portal @qm to enqueue the frame described by
 * @fd. The descriptor details are copied from @fd to the EQCR entry, the 'pid'
 * field is ignored. The return value is non-zero on error, such as ring full
 * (and FLAG_WAIT not specified), congestion avoidance (FLAG_WATCH_CGR
 * specified), etc. If the ring is full and FLAG_WAIT is specified, this
 * function will block. If FLAG_INTERRUPT is set, the EQCI bit of the portal
 * interrupt will assert when QMan consumes the EQCR entry (subject to "status
 * disable", "enable", and "inhibit" registers). If FLAG_DCA is set, QMan will
 * perform an implied "discrete consumption acknowledgement" on the dequeue
 * ring's (DQRR) entry, at the ring index specified by the FLAG_DCA_IDX(x)
 * macro. (As an alternative to issuing explicit DCA actions on DQRR entries,
 * this implicit DCA can delay the release of a "held active" frame queue
 * corresponding to a DQRR entry until QMan consumes the EQCR entry - providing
 * order-preservation semantics in packet-forwarding scenarios.) If FLAG_DCA is
 * set, then FLAG_DCA_PARK can also be set to imply that the DQRR consumption
 * acknowledgement should "park request" the "held active" frame queue. Ie.
 * when the portal eventually releases that frame queue, it will be left in the
 * Parked state rather than Tentatively Scheduled or Truly Scheduled. If the
 * portal is watching congestion groups, the QMAN_ENQUEUE_FLAG_WATCH_CGR flag
 * is requested, and the FQ is a member of a congestion group, then this
 * function returns -EAGAIN if the congestion group is currently congested.
 * Note, this does not eliminate ERNs, as the async interface means we can be
 * sending enqueue commands to an un-congested FQ that becomes congested before
 * the enqueue commands are processed, but it does minimise needless thrashing
 * of an already busy hardware resource by throttling many of the to-be-dropped
 * enqueues "at the source".
 */
int qman_enqueue(struct qman_fq *fq, const struct qm_fd *fd, u32 flags);
```

7.4.2.2.6.1.6 Enqueue Command with ORP

```
/* Same flags as qman_enqueue(), with the following additions;

 * - this flag indicates "Not Last In Sequence", ie. all but the final fragment
```

```
 *   of a frame. */
#define QMAN_ENQUEUE_FLAG_NLIS       0x01000000
/* - this flag performs no enqueue but fills in an ORP sequence number that
 *   would otherwise block it (eg. if a frame has been dropped). */
#define QMAN_ENQUEUE_FLAG_HOLE       0x02000000
/* - this flag performs no enqueue but advances NESN to the given sequence
 *   number. */
#define QMAN_ENQUEUE_FLAG_NESN       0x04000000
/*
 * qman_enqueue_orp - Enqueue a frame to a frame queue using an ORP
 * @fq: the frame queue object to enqueue to
 * @fd: a descriptor of the frame to be enqueued
 * @flags: bit-mask of QMAN_ENQUEUE_FLAG_*** options
 * @orp: the frame queue object used as an order restoration point.
 * @orp_seqnum: the sequence number of this frame in the order restoration path
 *
 * Similar to qman_enqueue(), but with the addition of an Order Restoration
 * Point (@orp) and corresponding sequence number (@orp_seqnum) for this
 * enqueue operation to employ order restoration. Each frame queue object acts
 * as an Order Definition Point (ODP) by providing each frame dequeued from it
 * with an incrementing sequence number, this value is generally ignored unless
 * that sequence of dequeued frames will need order restoration later. Each
 * frame queue object also encapsulates an Order Restoration Point (ORP), which
 * is a re-assembly context for re-ordering frames relative to their sequence
 * numbers as they are enqueued. The ORP does not have to be within the frame
 * queue that receives the enqueued frame, in fact it is usually the frame
 * queue from which the frames were originally dequeued. For the purposes of
 * order restoration, multiple frames (or "fragments") can be enqueued for a
 * single sequence number by setting the QMAN_ENQUEUE_FLAG_NLIS flag for all
 * enqueues except the final fragment of a given sequence number.  Ordering
 * between sequence numbers is guaranteed, even if fragments of different
 * sequence numbers are interlaced with one another. Fragments of the same
 * sequence number will retain the order in which they are enqueued. If no
 * enqueue is to performed, QMAN_ENQUEUE_FLAG_HOLE indicates that the given
 * sequence number is to be "skipped" by the ORP logic (eg. if a frame has been
 * dropped from a sequence), or QMAN_ENQUEUE_FLAG_NESN indicates that the given
 * sequence number should become the ORP's "Next Expected Sequence Number".
 *
 * Side note: a frame queue object can be used purely as an ORP, without
 * carrying any frames at all. Care should be taken not to deallocate a frame
 * queue object that is being actively used as an ORP, as a future allocation
 * of the frame queue object may start using the internal ORP before the
 * previous use has finished.
 */
int qman_enqueue_orp(struct qman_fq *fq, const struct qm_fd *fd, u32 flags,

                                struct qman_fq *orp, u16 orp_seqnum);
```

7.4.2.2.6.1.7 DCA Mode

As described in Order Preservation & Discrete Consumption Acknowledgement on page 637, FQs initialized for "hold active" behavior can have order-preservation behavior if their DQRR entries are consumed either by implicit DCA in the enqueue command when forwarding, or by explicit DCA if the frame is not going to be forwarded. The implicit DCA via enqueue is described in Enqueue Command (without ORP) on page 650, this section describes the API for performing an explicit DCA on a DQRR entry. As with the implicit DCA via enqueue, explicit DCA commands also allow the caller to specify that the FQ be Parked rather than rescheduled once all its DQRR entries are consumed.

```
/**
 * qman_dca - Perform a Discrete Consumption Acknowledgement
```

```
 * @dq: the DQRR entry to be consumed
 * @park_request: indicates whether the held-active @fq should be parked
 *
 * Only allowed in DCA-mode portals, for DQRR entries whose handler callback had
 * previously returned 'qman_cb_dqrr_defer'. NB, as with the other APIs, this
 * does not take a 'portal' argument but implies the core affine portal from the

 * cpu that is currently executing the function. For reasons of locking, this
 * function must be called from the same CPU as that which processed the DQRR
 * entry in the first place.
 */
void qman_dca(struct qm_dqrr_entry *dq, int park_request);
```

7.4.2.2.6.1.8 Congestion Management Records

QMan supports a fixed number[3] of built-in resources called Congestion Group Records (CGRs), that can be used as containers for related frame queues that should collectively benefit from congestion management. The precise algorithms used for congestion management with these records is beyond the scope of the document, please see the Queue Manager section of the appropraite QorIQ SoC Reference Manual for details.

The CGR kernel structure enables access to the CGR hardware functionality. Each object refers to an underlining hardware record via the cgrid field. Many CGR object may reference the same cgrid, but care must be taken when this object resides on different cores as no inter-core protection is provided.

The init frame queue functionality allows the caller to associate a CGR with the associated frame queue. The interface permits the management and modification of the underlining CGRs and notifies the user of congestion state changed. The current interface does not provide a mechanism to manage CGR ids. The application software is expected to arbitrate use of CGR ids.

```
/* Flags to qman_modify_cgr() */
#define QMAN_CGR_FLAG_USE_INIT       0x00000001
/**
 * This is a qman cgr callback function which gets invoked when the
typedef void (*qman_cb_cgr)(struct qman_portal *qm,
           struct qman_cgr *cgr, int congested);
struct qman_cgr {
          /* Set these prior to qman_create_cgr() */
          u32 cgrid; /* 0..255 */
          qman_cb_cgr cb;
          enum qm_channel chan; /* portal channel this object is created on */
          struct list_head node;
};
/* When Weighted Random Early Discard (WRED) is used then the following
 * structure is used to configure the WRED parameters. Refer to the QMan
 * Block Guide for a detailed description of the various parameters.
 */
struct qm_cgr_wr_parm {
          union {
                    u32 word;
                    struct {
                              u32 MA:8;
                              u32 Mn:5;
                              u32 SA:7; /* must be between 64-127 */
                              u32 Sn:6;
                              u32 Pn:6;
                    } __packed;
          };
```

[3] 256 for P4080/P5020/P3041

```
} __packed;
/* This struct represents the 13-bit "CS_THRES" CGR field. In the corresponding
 * management commands, this is padded to a 16-bit structure field, so that's
 * how we represent it here. The congestion state threshold is calculated from
 * these fields as follows;
 *   CS threshold = TA * (2 ^ Tn)
 */

```

7.4.2.2.6.1.9 Zero-Configuration Messaging

As described in Overview (QMan) on page 641, the demux logic of the QMan portal driver uses the contextB field of FQDs, as published in DQRR and MR entries, to determine the corresponding FQ object, and from there the DQRR or MR callback to invoke. However, "default callbacks" can also be associated with a portal that will be used if a "NULL" FQ is dequeued from, where NULL refers to a FQD whose contextB entry has been initialized to NULL (this occurs when using the QMAN_INITFQ_FLAG_NULL flag to the qman_init_fq() API, described in Initialize a FQ on page 647).

The purpose of this mechanism is to allow the user of one portal to enqueue frames on any frame queue that is configured in this way and schedule it to another portal. For virtualization or AMP scenarios, it is a difficult architectural problem to configure all guest operating systems to agree, in advance, on run-time parameters. The use of NULL frame queues allows a control plane guest OS to use any frame queue, configured with a NULL "contextB" field (see the QMAN_INITFQ_FLAG_NULL flag in the "Frame queue management" section below), to send any and all such configuration to another guest by scheduling that NULL frame queue to one of the target guest's portals. The target guest will have the portal's "NULL" callbacks invoked rather than those of any frame queue objects, and as such this provides what could be considered a "zero-configuration" interface - no agreement is required over what frame queue that configuration information will be arriving on, only that the configuration will arrive via the portal as a message on a NULL frame queue.

NOTE

Unless the payload of FDs passed over a zero-config FQ fits entirely within the 32-bit cmd/status field, buffers will presumably be required and the zero-configuration mechanism described here does not address how the sending and receiving ends should agree on what memory resources and management to use for this.

```
/**
 * qman_get_null_cb - get callbacks currently used for "null" frame queues
 *
 * Copies the callbacks used for the affine portal of the current cpu.
 */
void qman_get_null_cb(struct qman_fq_cb *null_cb);
/**
 * qman_set_null_cb - set callbacks to use for "null" frame queues
 *
 * Sets the callbacks to use for the affine portal of the current cpu, whenever
 * a DQRR or MR entry refers to a "null" FQ object. (Eg. zero-conf messaging.)
 */
void qman_set_null_cb(const struct qman_fq_cb *null_cb);
```

7.4.2.2.6.1.10 FQ allocation

7.4.2.2.6.1.10.1 Ad-hoc FQ allocator

As described in Seeding Buffer Pools on page 625, BMan buffer pool ID zero is currently reserved for use as an ad-hoc FQ allocator. As seen in Frame queue management on page 645, this feature can be used implicitly when creating a FQ object by passing the QMAN_FQ_FLAG_DYNAMIC_FQID flag to qman_init_fq(). The advantage of this mechanism is that it works across all cpus/portals, independent of any hypervisor or other system partitioning. The disadvantage of this mechanism is that does not permit the atomic nor contiguous allocation of more than one FQ at a time, and in particular most high-performance uses of FMan require contiguous ranges of FQIDs that also meet certain alignment requirements (ie. that the FQID range begins on an aligned FQID value).

7.4.2.2.6.1.10.2 FQ range allocator

The following APIs allow software to allocate and release arbitrary ranges of FQIDs, but it should be noted that the current version of the NXP Datapath software implements this without any hardware interaction. As such, multiple (guest) systems running on the same chip will each have their own allocator and are not aware of each other's (de)allocations. The range allocator's default state is empty, and it can be seeded by calling qman_release_fqid_range() on initialization with an appropriate FQID range to manage. The intention is for the control-plane software to initialize this range and to perform all allocations and deallocations on behalf of any software running on different system instances.

```
/**
 * qman_alloc_fqid_range - Allocate a contiguous range of FQIDs
 * @result: is set by the API to the base FQID of the allocated range
 * @count: the number of FQIDs required
 * @align: required alignment of the allocated range
 * @partial: non-zero if the API can return fewer than @count FQIDs
 * Returns the number of frame queues allocated, or a negative error code. If
 * @partial is non zero, the allocation request may return a smaller range of
 * FQs than requested (though alignment will be as requested). If @partial is
 * zero, the return value will either be 'count' or negative.
 */
int qman_alloc_fqid_range(u32 *result, u32 count, u32 align, int partial);
/**
 * qman_release_fqid_range - Release the specified range of frame queue IDs
 * @fqid: the base FQID of the range to deallocate
 * @count: the number of FQIDs in the range
 *
```

```
 * This function can also be used to seed the allocator with ranges of FQIDs
 * that it can subsequently use. Returns zero for success.
 */
void qman_release_fqid_range(u32 fqid, unsigned int count);
```

7.4.2.2.6.1.10.3 Future FQ allocator changes

Please note that a future version of the NXP Datapath software will automatically seed the range allocator with all FQIDs available to QMan, it will reimplement these APIs over an IPC layer such that all system instances share a common allocator instance, and the BMan-based FQ allocator will be removed and the corresponding APIs being reimplemented to use this range allocator.

7.4.2.2.6.1.11 Helper functions

In cases where software running on different CPUs communicate using QMan frame queues, there can arise an initialization problem related to synchronisation. If one side is termed the producer and the other the consumer, then the question becomes one of when it is safe for the producer to enqueue to that FQ. It is normal for software consumers to take care of initializing and scheduling FQs, because they must provide initialization and scheduling details in order for dequeue-handling to function correctly. But on the producer side, any attempt to enqueue to the FQ prior to the FQ being initialized will be rejected (enqueues are not permitted to OutOfService FQs). The following inline function can be used directly or as an example of how to determine when a FQ has changed state.

NOTE

It is safe for the producer to enqueue once the FQ has been initialized but not yet scheduled by the consumer.

```
/**
 * qman_poll_fq_for_init - Check if an FQ has been initialized from OOS
 * @fqid: the FQID that will be initialized by other s/w
 *
 * In many situations, a FQID is provided for communication between s/w
 * entities, and whilst the consumer is responsible for initialising and
 * scheduling the FQ, the producer(s) generally create a wrapper FQ object using
 * and only call qman_enqueue() (no FQ initialisation, scheduling, etc). Ie;
 *     qman_create_fq(..., QMAN_FQ_FLAG_NO_MODIFY, ...);
 * However, data can not be enqueued to the FQ until it is initialized out of
 * the OOS state - this function polls for that condition. It is particularly
 * useful for users of IPC functions - each endpoint's Rx FQ is the other
 * endpoint's Tx FQ, so each side can initialise and schedule their Rx FQ object
 * and then use this API on the (NO_MODIFY) Tx FQ object in order to
 * synchronise. The function returns zero for success, +1 if the FQ is still in
 * the OOS state, or negative if there was an error.
 */
static inline int qman_poll_fq_for_init(struct qman_fq *fq)
{
        struct qm_mcr_queryfq_np np;
        int err;
        err = qman_query_fq_np(fq, &np);
        if (err)
                return err;
        if ((np.state & QM_MCR_NP_STATE_MASK) == QM_MCR_NP_STATE_OOS)
                return 1;
        return 0;
}
```

7.4.2.2.7 QMan CEETM APIs

CEETM is a version of egress traffic management in QMan that provides hierarchical class based scheduling and traffic shaping. It is intended for use on links leading to a Wide Area Network (WAN).

7.4.2.2.7.1 QMan CEETM Device-Tree Node

The QMan driver determines the available CEETM resources from the device tree. The definition of CEETM node is defined as:

```
                qman-ceetm@0 {
                       compatible = "fsl,qman-ceetm";
                       fsl,ceetm-lfqid-range = <0xf00000 0x1000>;
                       fsl,ceetm-sp-range = <0 12>;
                       fsl,ceetm-lni-range = <0 8>;
                       fsl,ceetm-channel-range = <0 32>;
                };
```

Each *-range node will specify the CEETM resource(lfqid/sp/lni/cq channel) by a 2-cell value <x y>, in which x is the first value and y is the total number.

There are two ceetm device trees under arch/powerpc/boot/dts/fsl: qoriq-qman-ceetm0.dtsi and qoriq-qman-ceetm1.dts, which are used for DCP0 and DCP1 CEETM resources separately. To enable the CEETM initialization routine, the ceetm device tree should be added in the board's device tree.

For example, in t4240qds.dts, add the following lines at the bottom:

```
/include/ "fsl/qoriq-qman-ceetm0.dtsi"
/include/ "fsl/qoriq-qman-ceetm1.dtsi"
```

In b4860qds.dts, add the following line at the bottom: (because b4860 only support CEETM instance on DCP0).

```
/include/ "fsl/qoriq-qman-ceetm0.dtsi"
```

7.4.2.2.7.2 The token rate of CEETM shaper

7.4.2.2.7.2.1 The token rate structure

The QMan CEETM provides two rate shapers – CR and ER shapers to shape the traffic with the given rate. Both shapers use the token credit rate and credit update reference period to determine the shaper's output rate (in bits/second). The token rate is specified in bytes with an 11 bit integer and a 13 bit fractional part, and can be configured via CEETM shaper configuration commands. Here is the definition of the token rate structure:

```
/* Token Rate Structure
/* The shaping rates are based on a "credit" system and a pre-configured h/w
 * internal timer. The following type represents a shaper "rate" parameter as a
 * fractional number of "tokens". Here's how it works. This (fractional) number
 * of tokens is added to the shaper's "credit" every time the h/w timer elapses
 * (up to a limit which is set by another shaper parameter). Every time a frame
 * is enqueued through a shaper, the shaper deducts as many tokens as there are
 * bytes of data in the enqueued frame. A shaper will not allow itself to
 * enqueue any frames if its token count is negative. As such:
 *
 *         The rate at which data is enqueued is limited by the
 *         rate at which tokens are added.
 *
 * Therefore if the user knows the period between these h/w timer updates in
 * seconds, they can calculate the maximum traffic rate of the shaper (in
```

```
 * bytes-per-second) from the token rate. And vice versa, they can calculate
 * the token rate to use in order to achieve a given traffic rate.
 */
struct qm_ceetm_rate {
        /* The token rate is; whole + (fraction/8192) */
        u32 whole:11; /* 0..2047 */
        u32 fraction:13; /* 0..8191 */
};
```

7.4.2.2.7.2.2 The APIs to convert token rate and shapers output rate

The suggested value for credit update reference period is 1000ns as stated in the PRES field's description of CEETM_CFG_PRES register in Reference Manual. The calculation for shapers output rate is based on:

*shaper output rate (in bits/sec) = token credit rate * 8 / credit update reference period*

For more detail, please refer to the Appendix in this document. The following APIs are used to convert shaper output rate in bps to token rate and vice versa, which can be applied to both LNI and channel shaping:

```
/**
 * qman_ceetm_bps2tokenrate - Given a desired rate shaper rate measured in bps
 * (ie. bits-per-second), compute the 'token_rate' fraction that best
 * approximates that rate.
 *
 * @bps: the input shaper rate in bps.
 * @token_rate: the output token rate computed with the given bps.
 * @rounding: dictates how to round if an exact conversion is not possible; if
 * it is negative then 'token_rate' will round down to the highest value that
 * does not exceed the desired rate, if it is positive then 'token_rate' will
 * round up to the lowest value that is greater than or equal to the desired
 * rate, and if it is zero then it will round to the nearest approximation,
 * whether that be up or down.
 *
 * Returns zero for success, or -EINVAL if prescaler or qman clock is not available.
 */
int qman_ceetm_bps2tokenrate(u32 bps,
                             struct qm_ceetm_rate *token_rate,
                             int rounding);

/**
 * qman_ceetm_tokenrate2bps - Given a 'token_rate', compute the corresponding
 * number of 'bps'.
 * @token_rate: the input token rate fraction.
 * @bps: the output shaper rate in bps.
 * @rounding: has the same semantics as the previous function.
 *
 * Return zero for success, or -EINVAL if prescaler or qman clock is not available.
 */
int qman_ceetm_tokenrate2bps(const struct qm_ceetm_rate *token_rate,
                             u32 *kbps,
                             int rounding);
```

7.4.2.2.7.3 CEETM Sub-portal

CEETM is implemented as a mode of scheduling for sub-portals on specific QMan Direct-Connect Portals. We need to claim the sub-portal on a DCP to support CEETM.

7.4.2.2.7.3.1 Claim/release sub-portal

```
/* *
 * qman_ceetm_sp_claim - Claims the given sub-portal, provided it is available
 * to use and configured for traffic-management.
 * @sp: the returned sub-portal object, if successful.
 * @dcp_id:  specifies the desired FMan block (and thus the relevant CEETM instance).
 * The type enum qm_dc_portal has already been defined in fsl_qman.h
 * @sp_idx:  is the desired sub-portal index from 0 to 15.
 *
 * Returns zero for success, or -ENODEV if the sub-portal is in use, or -EINVAL
 * if the sp_idx is out of range.
 *
 *
 * Note that if there are multiple driver domains (eg. a linux kernel versus
 * user-space drivers in USDPAA, or multiple guests running under a
 * hypervisor) then a sub-portal may be accessible by more than one instance
 * of a qman driver and so it may be claimed multiple times. If this is the
 * case, it is up to the system architect to prevent conflicting configuration
 * actions coming from the different driver domains. The qman drivers do not
 * have any behind-the-scenes coordination to prevent this from happening.
 */
int qman_ceetm_sp_claim(struct qm_ceetm_sp **sp,
                        enum qm_dc_portal dcp_id,
                        unsigned int sp_idx);

/**
 * qman_ceetm_sp_release - Releases a previously claimed sub-portal.
 * @sp: the sub-portal to be released.
 *
 * Returns 0 for success, or -EBUSY for failure if the dependencies are not
 * released yet.
 */
int qman_ceetm_sp_release(struct qm_ceetm_sp *sp);
```

7.4.2.2.7.4 CEETM LNI - Logic Network Interface

Each QMan CEETM instance supports up to 8 Logical Network Interfaces (LNIs) which can be mapped to a DCP sub-portal. Each LNI aggregates frames from one or more QMan CEETM channels and priority schedules unshaped frames, CR frames and ER frames It applies a dual rate shaper to aggregate CR/ER frames from shaped channel. The user can enable and disable the shaper, change the shaper rate for LNI, as well as control the CEETM traffic class flow control because it is maintained on a per LNI basis and applied to all class queue channels within the LNI.

7.4.2.2.7.4.1 Claim/release LNI

```
/**
 * qman_ceetm_lni_claim - Claims an unclaimed LNI.
 * @lni: the returned LNI object, if successful.
 * @dcp_id: specifies the desired FMan block (and thus the relevant CEETM instance).
 * @lni_idx: the desired LNI index.
 *
 * Returns zero for success, or -EINVAL for failure, which will happen
 * if the LNI is not available or has already been claimed (and not yet
 * successfully released),or lni_idx is out of range.
```

```
 *
 * Note that there may be multiple driver domains (or instances) that need to transmit
 * out the same LNI, so this claim is only guaranteeing exclusivity within the
 * domain of the driver being called. See qman_ceetm_sp_claim() and
 * qman_ceetm_sp_get_lni() for more information.
 */
int qman_ceetm_lni_claim(struct qm_ceetm_lni **lni,
                         enum qm_dc_portal dcp_id,
                         unsigned int lni_idx);

/**
 * qman_ceetm_lni_release - Releases a previously claimed LNI.
 * @lni: the LNI needs to be released.
 *
 * This will only succeed if all dependent objects have been released.
 * Returns zero for success. Returns -EBUSY if the dependencies are not released.
 */
int qman_ceetm_lni_release(struct qm_ceetm_lni *lni);
```

7.4.2.2.7.4.2 Map sub-portal with LNI

```
/**
 * qman_ceetm_sp_set_lni
 * qman_ceetm_sp_get_lni – Set/get the LNI that the sub-portal is currently mapped to.
 * @sp: the given sub-portal.
 * @lni(in “set” function): the LNI object which the sub-portal will be mapped to.
 * @lni_idx(in “get” function): the LNI index which the sub-portal is mapped to.
 *
 * Returns zero for success. * Returns –EINVAL for “set” function when this sp-lni mapping has
been set, or
 * configure mapping command returns error, and
 * -EINVAL for “get” function when this sp-lni mapping is not set, or the query
 * mapping command returns error.
 *
 * This may be useful in situations where multiple driver
 * domains have access to the same sub-portals in order to all be able to
 * transmit out the same physical interface (perhaps they're on different IP
 * addresses or VPNs, so FMan is splitting Rx traffic and here we need to
 * converge Tx traffic). In that case, a control-plane is likely to use
 * qman_ceetm_lni_claim() followed by qman_ceetm_sp_set_lni() to configure the
 * sub-portal, and other domains are likely to use qman_ceetm_sp_get_lni()
 * followed by qman_ceetm_lni_claim() in order to determine the LNI that the
 * control-plane had assigned. This is why the "get" returns an index, whereas
 * the "set" takes an (already claimed) LNI object.
 */
int qman_ceetm_sp_set_lni(struct qm_ceetm_sp *sp,
                          struct qm_ceetm_lni *lni);
int qman_ceetm_sp_get_lni(struct qm_ceetm_sp *sp,
                          unsigned int *lni_idx);
```

7.4.2.2.7.4.3 Configure LNI shaper

The LNI provides two rate shapers that can be used to shape the traffic from all class queue channels which are shaped on input to the channel scheduler. The LNI shapers are used to shape or rate limit the aggregate of the class queue channels

which have each been shaped. The two shaper rates are applied only to frames shaped by the corresponding shaper at the channel shaper level.

```
/**
 * qman_ceetm_lni_enable_shaper
 * qman_ceetm_lni_disable_shaper - Enables/disables shaping on the LNI.
 * @lni: the given LNI.
 * @coupled: indicates whether CR and ER shapers are coupled.
 * @oal: the overhead accounting length which is added to the actual length of
 * each frame when performing shaper calculations.
 *
 * When the number of (unused) committed-rate tokens reach the committed-rate
 * token limit, @coupled indicates whether surplus tokens should be added to
 * the excess-rate token count (up to the excess-rate token limit). Whenever
 * a claimed LNI is first enabled for shaping, its committed and excess token
 * rates and limits are zero, so will need to be changed to do anything useful.
 * The shaper can subsequently be enabled/disabled without resetting the shaping
 * parameters, but the shaping parameters will be reset when the LNI is released.
 *
 * Returns 0 for success, or errno for “enable” function in the cases as:
 * a) -EINVAL if the shaper is already enabled.
 * b) -EIO if the configure shaper command returns error.
 * For “disable” function, returns:
 * a) -EINVAL if the shaper has been disabled.
 * b) -EIO if the query shaper command returns error.
 */
int qman_ceetm_lni_enable_shaper(struct qm_ceetm_lni *, int coupled, int oal);
int qman_ceetm_lni_disable_shaper(struct qm_ceetm_lni *);

/**
 * qman_ceetm_lni_is_shaper_enabled - Check LNI shaper status
 * @lni: the give LNI
 */
int qman_ceetm_lni_is_shaper_enabled(struct qm_ceetm_lni *lni);

/**
 * qman_ceetm_lni_set_commit_rate
 * qman_ceetm_lni_get_commit_rate
 * qman_ceetm_lni_set_excess_rate
 * qman_ceetm_lni_get_excess_rate - Set/get the shaper CR/ER token rate and token

                             int *traffic_class);
```

7.4.2.2.7.5 CEETM class queue channel

Each instance of CEETM supports 32 class queue channels for allocation across the 8 LNIs. Each channel can be configured to deliver frames to any one of the LNIs, can be configured as shaped or unshaped channel. When shaped, a dual-rate shaper applies to the aggregate of CR/ER frames from the channel. Each channel contains a total of 16 class queues (CQ), with 8 independent classes and 8 grouped classes which can be configured as 1 group of 8 classes or 2 groups of 4 classes. The weighted bandwidth fairness scheduling applies within the grouped classes, and strict priority scheduling applies to 8 independent classes and 2 class groups. Once the channel is configured as shaped, the 8 independent classes and 2 class groups can be configured to supply CR frames, ER frames or both. The channel is configured independently from other channels.

7.4.2.2.7.5.1 Claim/release class queue channel

```
/**
 * qman_ceetm_channel_claim - Claims an unclaimed CQ channel that is mapped to the
 * given LNI.
 * @channel: the returned class queue channel object, if successful.
 * @lni: the LNI that the channel belongs to.
 *
 * Channels are always initially "unshaped".
 *
 * Returns zero for success, or -ENODEV if there is no channel available(all 32
 * channels are claimed) or -EINVAL if the channel mapping command returns error.
 */
int qman_ceetm_channel_claim(struct qm_ceetm_channel **channel,
                             struct qm_ceetm_lni *lni);

/**
 * qman_ceetm_channel_release - Releases a previously claimed CQ channel.
 * @channel: the channel needs to be released.
 *
 * Returns zero for success, or -EBUSY if the dependencies are still
 * in use. Note any shaping of the channel will be
 * cleared to leave it in an unshaped state.
 */
int qman_ceetm_channel_release(struct qm_ceetm_channel *channel);
```

7.4.2.2.7.5.2 Configure the shaper of class queue channel

```
/**
 * qman_ceetm_channel_enable_shaper
 * qman_ceetm_channel_disable_shaper - Enable/Disable shaping on the given channel.
 * @channel: the given channel.
 * @coupled: indicates whether surplus tokens should be added to the excess-rate
 * token count (up to the excess-rate token limit) when the number of (unused)
 * committed-rate tokens reach the committed-rate token limit.
 *
 * Whenever a claimed channel is first enabled for shaping, its committed and
 * excess token rates and limits are zero, so will need to be changed to do
```

```
 * anything useful. The shaper can subsequently be enabled/disabled without
 * resetting the shaping parameters, but the shaping parameters will be reset
 * when the channel is released.
 *
 * Returns 0 for success and -EINVAL for failure if the channel shaping has been
 * enabled or disabled, or the management command returns error
 */
int qman_ceetm_channel_enable_shaper(struct qm_ceetm_channel *channel, int coupled);
int qman_ceetm_channel_disable_shaper(struct qm_ceetm_channel *channel);

/**
 * qman_ceetm_channel_is_shaper_enabled - Check channel shaper status.
 * @channel: the give channel.
 */
int qman_ceetm_channel_is_shaper_enabled(struct qm_ceetm_channel *channel);

/**
 * qman_ceetm_channel_set_commit_rate
 * qman_ceetm_channel_get_commit_rate
 * qman_ceetm_channel_set_excess_rate
 * qman_ceetm_channel_get_excess_rate – Set/get the channel shaper CR/ER token rate
 * and token limit.
 * @channel: the given channel.
 * @token_rate: the desired token rate for “set” function, or the queried token rate
 * for “get”function.
 * @token_limit: the desired token limit for “set” function, or the queried token
 * limit for “get” function.
 *
 * Returns zero for success. The “set” function returns –EINVAL if the channel
 * is unshaped or –EIO if the configure shaper command returns error. The
 * “get” function returns -EINVAL if the token rate or token limit is not set, or
 * the query shaper command returns error.
 */

int qman_ceetm_channel_set_excess_rate_bps(struct qm_ceetm_channel *channel,
                        u64 bps, u16 token_limit);
int qman_ceetm_channel_get_excess_rate_bps(struct qm_ceetm_channel *channel,
                        u64 *bps, u16 *token_limit);
```

7.4.2.2.7.5.3 Configure the token limit as the weight for the unshaped channel

QMan CEETM uses an algorithm called unshaped fair queuing (uFQ) for the unshaped channel. The algorithm allows unshaped channels to be included in the CR time eligible list, and thus use the configured commit rate token bucket limit value as their fair queuing weight.

```
/**
 * qman_ceetm_channel_set_weight
 * qman_ceetm_channel_get_weight - Set/get the weight for unshaped channel.
 * @channel: the given channel.
 * @token_limit: the desired token limit as the weight of unshaped channel for “set”
 * function, or the queried token limit for “get” function.
 *
 * Returns zero for success, or -EINVAL if the channel is a shaped channel, or
 * the management command returns error
 */
int qman_ceetm_channel_set_weight(struct qm_ceetm_channel *channel,
                                  u16 token_limit);
int qman_ceetm_channel_get_weight(struct qm_ceetm_channel *channel,
                                  u16 *token_limit);
```

7.4.2.2.7.5.4 Set CR/ER eligibility for CQs within a CEETM channel

The APIs below allow the user to set the 8 independent CQs and 2 CQ groups within a shaped CEETM channel to be CR and/or ER eligible.

```
/**
 * qman_ceetm_channel_set_group_cr_eligibility
 * qman_ceetm_channel_set_group_er_eligibility - Set channel group eligibitity
 * @channel: the given channel object
 * @group_b: indicates whether there is group B in this channel.
 * @cre: the commit rate eligibility, 1 for enable, 0 for disable.
 *
 * Return zero for success, or -EINVAL if eligiblity setting fails.
*/
int qman_ceetm_channel_set_group_cr_eligiblility(struct qm_ceetm_channel
*channel, int group_b, int cre);
int qman_ceetm_channel_set_group_er_eligiblility(struct qm_ceetm_channel
*channel, int group_b, int ere);
```

```
/**
 * qman_ceetm_channel_set_cq_cr_eligibility
 * qman_ceetm_channel_set_cq_er_eligibility - Set channel cq eligibitity
 * @channel: the given channel object
 * @idx: is from 0 to 7 (representing CQ0 to CQ7).
 * @cre: the commit rate eligibility, 1 for enable, 0 for disable.
 *
 * Return zero for success, or -EINVAL if eligiblity setting fails.
*/
int qman_ceetm_channel_set_cq_cr_eligiblility(struct qm_ceetm_channel *channel,
unsigned int idx, int cre);
int qman_ceetm_channel_set_cq_er_eligiblility(struct qm_ceetm_channel *channel,
unsigned int idx, int ere);
```

7.4.2.2.7.6 CEETM class queue

Each CEETM class has a dedicated class queue (CQ), it can have dedicated or shared Class Congestion Group Record.

7.4.2.2.7.6.1 Claim/release CQ

```
/**
 * qman_ceetm_cq_claim - Claims an individual class queue.
 * @cq: the returned class queue object, if successful.
 * @channel: the given class queue channel.
 * @idx: is from 0 to 7 (representing CQ0 to CQ7).
 * @ccg: represents the class congestion group that this class queue
 * should be subscribed to, or NULL if no congestion group membership is desired.
 *
 * Returns zero for success, or -EINVAL if @idx is out of range 0 to 7 or this class
 * queue has been claimed, or configure class queue command returns error, or
 * returns -ENOMEM if allocating CQ memory fails.
 */
int qman_ceetm_cq_claim(struct qm_ceetm_cq **cq,
                        struct qm_ceetm_channel *channel,
                        unsigned int idx,
                        struct qm_ceetm_ccg *ccg);

/**
 * qman_ceetm_cq_claim_A - Claims a class queue within the channel group A.
 * @cq: the returned class queue object, if successful.
 * @channel: the given class queue channel.
 * @idx: If the channel is configured for 1 group only, @idx is from 8 to 15 (CQ8 to
 * CQ15) and only group A exists, otherwise @idx is from 8 to 11 (CQ8 to CQ11 for
 * group A).
 * @ccg: represents the class congestion group that this class queue should be
 * subscribed to, or NULL if no ccg is desired.
 *
 * Returns zero for success, or -EINVAL if @idx is out of range or if the class
 * queue has been claimed, or configure class queue command returns error, or
 * returns -ENOMEM if allocating CQ memory fails.
 */
int qman_ceetm_cq_claim_A(struct qm_ceetm_cq **cq,
                          struct qm_ceetm_channel *channel,
                          unsigned int idx,
                          struct qm_ceetm_ccg *ccg);
```

```
/**
 * qman_ceetm_cq_claim_B - Claims a class queue within the channel group B.
 * @cq: the returned class queue object, if successful.
 * @channel: the given class queue channel.
 * @idx: if the channel is configured with 2 groups, 'idx' is from 12 to 15(CQ12 to
 * CQ15 for group B).
 * @ccg: represents the class congestion group that this class queue should be
 * subscribed to, or NULL if no ccg is desired.
 *
 * Returns zero for success, or -EINVAL if @idx is out of range  or the class
 * queue has been claimed, or configure class queue command returns error, or
 * returns -ENOMEM if allocating CQ memory fails.
 */
int qman_ceetm_cq_claim_B(struct qm_ceetm_cq **cq,
                          struct qm_ceetm_channel *channel,
                          unsigned int idx,
                          struct qm_ceetm_ccg *ccg);

/**
 * qman_ceetm_cq_release - Releases a previously claimed class queue.
 * @cq: the class queue to be released.
 *
 * This will only succeed if all dependent objects (eg. logical FQIDs) have been
 * released.
 * Returns zero for success or -EBUSY for failure if the dependencies are not
 * released (e.g. LFQID is not released)
 */
int qman_ceetm_cq_release(struct qm_ceetm_cq *cq);

/**
 * qman_ceetm_drain_cq - drain the CQ till it is empty.
 * @cq: the give CQ object.
 * Return 0 for success or -EINVAL for unsuccessful command to empty CQ.
 */
int qman_ceetm_drain_cq(struct qm_ceetm_cq *cq);
```

7.4.2.2.7.6.2 Change CQ weight

```
/**
 * qman_ceetm_queue_set_weight
 * qman_ceetm_queue_get_weight - Configure/query the weight ofa grouped class queue.
 * @cq: the given class queue.
 * @weight_code: the desired weight code to change for this given class queue for
 * "set" function or the queried weight code of the give class queue for "get"
 * function.
 *
 * Grouped class queues have a default weight code of zero, which corresponds to
 * a scheduler weighting of 1. This function can be used to modify a grouped
 * class queue to another weight, valid values are from 0 to 255. (Use the
 * helpers qman_ceetm_wbfs2ratio() and qman_ceetm_ratio2wbfs() to convert
 * between these 'weight_code' values and the corresponding sharing weight.) As
 * the weight code ranges from 0 to 255, the corresponding scheduling weight
 * ranges from 1.00 to 248 in pseudo-exponential steps).
 *
 * Returns zero for success or -EIO if the configure  weight code command returns
 * error for "set" function, or -EINVAL if the query command returns error for "get"
 * function.
```

```
 * Please refer to section “CEETM Weighted Scheduling among Grouped Classes” in
 * Reference Manual for weight and weight code.
 */
int qman_ceetm_queue_set_weight(struct qm_ceetm_cq *cq,
                                struct qm_ceetm_weight_code *weight_code);
int qman_ceetm_queue_get_weight(struct qm_ceetm_cq *cq,
                                struct qm_ceetm_weight_code *weight_code);

/**
 * qman_ceetm_wbfs2ratio - Given a weight code ('wbfs'), an accurate fractional
 * representation of the corresponding weight is given (in order to not lose
 * any precision).
 * @weight_code: The given weight code in WBFS.
 * @numerator: the numerator part of the weight computed by the weight code.
 * @denominator: the denominator part of the weight computed by the weight code
 *
 * Returns zero for success, or -EINVAL if the given weight code is illegal.
 */
int qman_ceetm_wbfs2ratio(struct qm_ceetm_weight_code *weight_code,
                          u32 *numerator,
                          u32 *denominator);

/**
 * qman_ceetm_ratio2wbfs - Given a weight, find the nearest possible weight code.
 * @numerator: numerator part of the given weight.
 * @denominator: denominator part of the given weight.
 * @weight_code: the weight code computed from the given weight.
 *
 * If the user needs to know how close this is, convert the resulting weight code
 * back to a weight and compare.
 *
 * Returns zero for success, or -ERANGE if "numerator/denominator" is outside the
 * range of weights.
 */
int qman_ceetm_ratio2wbfs(u32 numerator,
                          u32 denominator,
                          struct qm_ceetm_weight_code *weight_code);

/**
 * qman_ceetm_set_queue_weight_in_ratio
 * qman_ceetm_get_queue_weight_in_ratio - Configure/query the weight of a
 * grouped class queue.
 * @cq: the given class queue.
 * @ratio: the weight in ratio. It should be the real ratio number multiplied
 * by 100 to get rid of fraction. User needs to check the "WBFS weight code
 * to weight mapping" table in BG for the possible weight values to be used.
 *
 * Returns zero for success, or -EIO if the configure weight command returns
 * error for "set" function, or -EINVAL if the query command returns
 * error for "get" function.
 */
int qman_ceetm_set_queue_weight_in_ratio(struct qm_ceetm_cq *cq, u32 ratio);
int qman_ceetm_get_queue_weight_in_ratio(struct qm_ceetm_cq *cq, u32 *ratio);
```

7.4.2.2.7.6.3 Query CQ statistics

```
/**
 * qman_ceetm_cq_get_dequeue_statistics - Get the statistics provided by CEETM
 * CQ counters.
 * @cq: the given CQ object.
 * @flags: indicates whether the statistics counter will be cleared after query.
 * @frame_count: The number of the frames that have been counted since the
 * counter was cleared last time.
 * @byte_count: the number of bytes in all frames that have been counted.
 *
 * Return zero for success or -EINVAL if query statistics command returns error.
 *
 */
int qman_ceetm_cq_get_dequeue_statistics(struct qm_ceetm_cq *cq, u32 flags,
                                         u64 *frame_count, u64 *byte_count);
```

7.4.2.2.7.7 CEETM logical FQID

Each class queue in CEETM mode is identified via a “logical frame queue identifier (LFQID)” to maintain semantic compatibility with enqueue commands to FQs (non-CEETM queues). The upper 1M FQIDs is used for the LFQID, and each DCP owns 4K LFQIDs. Any enqueue to these LFQIDs will be directed to the CEETM logic used by one of the DCP portals.

7.4.2.2.7.7.1 Claim/release LFQID

```
/**
 * qman_ceetm_lfq_claim - Claims an unused logical FQID, associates it with the
 * given class queue.
 * @lfq: the returned lfq object, if successful.
 * @cq: the given class queue which needs to claim a LFQID.
 *
 * Returns 0 for success, or -ENODEVif no LFQID is available, or -ENOMEM if
 * allocating memory for lfq fails, or -EINVAL if configuring LFQMT fails
 */
int qman_ceetm_lfq_claim(struct qm_ceetm_lfq **lfq,
                         struct qm_ceetm_cq *cq);

/**
 * qman_ceetm_lfq_release -  Releases a previously claimed logical FQID.
 * @lfq: the logic fq to be released.
 *
 * Return zero for success. The failure condition is TBD.
 */
int qman_ceetm_lfq_release(struct qm_ceetm_lfq *lfq);
```

7.4.2.2.7.7.2 Configure/Query Dequeue Context Table

```
/**
 * qman_ceetm_lfq_set_context
 * qman_ceetm_lfq_get_context - Set/get the context_a/context_b pair to the
```

```
 * "dequeue context table" associated with the logical FQID.
 * @lfq: the given lfq object.
 * @context_a: contextA of the dequeue context.
 * @context_b: contextB of the dequeue context.
 *
 * Returns zero for success, or -EINVAL if there is error to set/get the context
 * pair.
 */
int qman_ceetm_lfq_set_context(struct qm_ceetm_lfq *lfq,
                               u64 context_a,
                               u32 context_b);
int qman_ceetm_lfq_get_context(struct qm_ceetm_lfq *lfq,
                               u64 *context_a,
                               u32 *context_b);
```

7.4.2.2.7.7.3 Create FQ for LFQ

```
/**
 * qman_ceetm_create_fq - Initialise a FQ object for the LFQ.
 * @lfq: the given logic FQ.
 * @fq: the FQ object created for the LFQ
 *
 * The FQ object can be used in qman_enqueue() and qman_enqueue_orp() APIs to target
 * a logical FQID (and the class queue it is associated with). Note that this FQ
 * object can only be used for enqueues, and in the case of qman_enqueue_orp()
 * it can not be used as the 'orp' parameter, only as 'fq'. This FQ object can not
 * (and shouldn't) be destroyed, it is only valid as long as the underlying 'lfq'
 * remains claimed. It is the user's responsibility to ensure that the underlying
 * 'lfq' is not released until any enqueues to this FQ object have completed.
 * The only field the user needs to fill in is fq->cb.ern, as that enqueue rejection
 * handler is the callback that could conceivably be called on this FQ object. This
 * API can be called multiple times to create multiple FQ objects referring to the
 * same logical FQID, and any enqueue rejections will respect the callback of the
 * object that issued the enqueue (and will identify the object via the parameter
 * passed to the callback too). There is no 'flags' parameter to this API as there
 * is for qman_create_fq() - the created FQ object behaves as though
 * qman_create_fq() had been called with the single flag QMAN_FQ_FLAG_NO_MODIFY.
 *
 * Returns 0 for success. The failure case is TBD
 */
int qman_ceetm_create_fq(struct qm_ceetm_lfq *lfq, struct qman_fq *fq);
```

7.4.2.2.7.8 CEETM Class Congestion Group(CCG)

CEETM supports both Weighted Random Early Discard (WRED) and tail drop congestion management with its 512 Class Congestion Groups (CCGs). The CCG are divided into channels. Each channel contains 16 CCGs, and each CCG channel is tied one-to-one with a CQ channel. The CCG to be used for a particular CQ can be assigned to any of the 16 CCG within the channel. The description of CCG can be found at section “CEETM Class Congestion Management and Avoidance” in the Reference Manual.

7.4.2.2.7.8.1 Claim/release CCG

```
/**
 * qman_ceetm_ccg_claim - Claims an unused CCG.
```

```
 * @ccg: the returned CCG object, if successful.
 * @idx: the ccg index from 0-15 within the given channel.
 * @channel: the given class queue channel which tied to the CCG channel.
 * @cscn: the callback function of this CCG.
 * @cb_ctx: specify the callback and corresponding context to be used if state
 * change notifications are later enabled for this CCG.
 *
 * The congestion group is local to the given class queue channel, so only
 * class queues within the channel can be associated with that congestion
 * group. The association of class queues to congestion groups occurs when the
 * class queues are claimed, see qman_ceetm_cq_claim() and related functions.
 * Congestion groups are in a "zero" state when initially claimed, and they are
 * returned to that state when released.
 *
 * Returns 0 for success, or -EINVAL if no CCG is available.
 */
int qman_ceetm_ccg_claim(struct qm_ceetm_ccg **ccg,
                         struct qm_ceetm_channel *channel,
                         void (*cscn)(struct qm_ceetm_ccg *,
                                      void *cb_ctx,
                                      int congested),
                         void *cb_ctx);

/**
 * qman_ceetm_ccg_release - Releases a previously claimed CCG.
 * ccg: the CCG to be released.
 *
 * Returns zero for success, or -EBUSY if the given CCG's dependent objects(class
 * queues that are associated with the CCG) have not been released.
 */
int qman_ceetm_ccg_release(struct qm_ceetm_ccg *ccg);
```

7.4.2.2.7.8.2 Configure CCG

```
/* This struct is used to specify attributes for a CCG. The 'we_mask' field
 * controls which CCG attributes are to be updated, and the remainder specify
 * the values for those attributes. A CCG counts either frames or the bytes
 * within those frames, but not both ('mode'). A CCG can optionally cause
 * enqueues to be rejected, due to tail-drop or WRED, or both (they are
 * independent options, 'td_en' and 'wr_en_g,wr_en_y,wr_en_r'). Tail-drop can be
 * level-triggered due to a single threshold ('td_thres') or edge-triggered due
 * to a "congestion state", but not both ('td_mode'). Congestion state has
 * distinct entry and exit thresholds ('cs_thres_in' and 'cs_thres_out'), and
 * notifications can be sent to software the CCG goes in to and out of this
 * congested state ('cscn_en').
 * The struct qm_cgr_cs_thres has already been defined in fsl_qman.h
 */
struct qm_ceetm_ccg_params {
        /* Boolean fields together in a single bitfield struct */
        struct {
                /* Whether to count bytes or frames. 1==frames */
                int mode:1;
                /* En/disable tail-drop. 1==enable */
                int td_en:1;
                /* Tail-drop on congestion-state or threshold. 1=threshold */
                int td_mode:1;
                /* Generate congestion state change notifications. 1==enable */
                int cscn_en:1;
```

```
                /* Enable WRED rejections (per colour). 1==enable */
                int wr_en_g:1;
                int wr_en_y:1;
                int wr_en_r:1;
        } __packed;

```

7.4.2.2.7.8.3 Query CCG statistics

```
/**
 * qman_ceetm_ccg_get_reject_statistics - Get the statistics provided by
 * CEETM CCG counters.
 * @ccg: the given CCG object.
 * @flags: indicates whether the statistics counter will be cleared after query.
```

```
 * @frame_count: The number of the frames that have been counted since the
 * counter was cleared last time.
 * @byte_count: the number of bytes in all frames that have been counted.
 *
 * Return zero for success or -EINVAL if query statistics command returns error.
 *
 */
int qman_ceetm_ccg_get_reject_statistics(struct qm_ceetm_ccg *ccg, u32 flags,
                                         u64 *frame_count, u64 *byte_count);
```

7.4.2.2.7.8.4 Set/get Congestion State Change Notification Target

```
/** qman_ceetm_cscn_swp_get - Query whether a given software portal index is
  * in the cscn target mask.
  * @ccg: the give CCG object.
  * @swp_idx: the index of the software portal.
  * @cscn_enabled: 1: cscn is enabled in this swp. 0: cscn is not enabled
  * in this swp.
  *
  * Return 0 for success, or -EINVAL if command in set/get function fails.
  */
int qman_ceetm_cscn_swp_get(struct qm_ceetm_ccg *ccg,
                            u16 swp_idx,
                            unsigned int *cscn_enabled);

/** qman_ceetm_cscn_dcp_set - Add or remove a direct connect portal from the\
  * target mask.
  * qman_ceetm_cscn_swp_get - Query whether a given direct connect portal index
  * is in the cscn target mask.
  * @ccg: the give CCG object.
  * @dcp_idx: the index of the direct connect portal.
  * @cscn_enabled: 1: Set the dcp to be cscn target. 0: remove the dcp from
  * the target mask.
  *
  * Return 0 for success, or -EINVAL if command in set/get function fails.
  */
int qman_ceetm_cscn_dcp_set(struct qm_ceetm_ccg *ccg,
                            u16 dcp_idx,
                            unsigned int cscn_enabled);
int qman_ceetm_cscn_dcp_get(struct qm_ceetm_ccg *ccg,
                            u16 dcp_idx,
                            unsigned int *cscn_enabled);
```

7.4.2.2.8 Other QMan APIs

The following sections describe the interfaces provided by the QMan driver for manipulating QMan device.

7.4.2.2.8.1 Waterfall Power Management

Waterfall power management is a mechanism that works between the QMan and the e6500's Drowsy Core mode. The basic idea is that when using multiple cores and pool channels to forward frames, and the QMan receives less traffic than required to keep all cores busy, it no longer assigns to the higher numbered cores (i.e. software portals) in a pool. This feature is supported from QMan3.0, and the APIs below can only be called at SoC with QMan3.0

```
/**
 * qman_set_wpm - Set waterfall power management
```

```
 *
 * @wpm_enable: boolean, 1 = enable wpm, 0 = disable wpm.
 *
 * Return 0 for success, return -ENODEV if QMan misc_cfg register is not
 * accessible.
 */
int qman_set_wpm(int wpm_enable);
/**
 * qman_get_swp - Query the waterfall power management setting
 *
 * @wpm_enable: boolean, 1 = enable wpm, 0 = disable wpm.
 *
 * Return 0 for success, return -ENODEV if QMan misc_cfg register is not
 * accessible.
 */
int qman_get_wpm(int *wpm_enable);
```

7.4.2.2.9 USDPAA-specific APIs

7.4.2.2.9.1 Overview

The USDPAA SDK includes a port of the QMan and BMan drivers to linux user space, and assumes a pthreads-based programming model, and the use of a single application/process instance.

Unlike conventional user space interfaces to hardware (in which the kernel manipulates hardware interfaces on behalf of user space processes), the USDPAA QMan and BMan drivers operate on the hardware directly from user space. The underlying mechanisms for this are based on the USDPAA Linux character device. Put briefly, the kernel exposes the devices to user space as character devices with various attributes, which allow the user space drivers to mmap() the Corenet portal regions directly. Interrupt handling works by disabling the portal interrupt when it asserts and conveying the interrupt event to user-space via the USDPAA device's file-descriptor (the user-space portal driver can re-enable the interrupt whenever it so chooses).

The key distinction between the QMan (or BMan) drivers found in the Linux kernel and the one in USDPAA is that the latter does not perform a global initialization step to parse all available portals and initialize and assign them to CPUs/threads. The model in USDPAA assumes that the application is responsible for creating its own pthreads, and is responsible for making those threads affine to the appropriate CPUs (if indeed it chooses to). Such applications simply call into a USDPAA-specific API to "enable" the thread for QMan/BMan portal usage (specifying the desired CPU-affinity for the portal), and the USDPAA driver at that point will "find" an unused portal suitable for the requested CPU and initialize and bind it to the pthread via thread-local storage, or fail if no such portal was available. Portals can likewise be released from threads when they are no longer required, without requiring the pthread itself to be destroyed.

Not only do both the Linux kernel and USDPAA drivers initialize all portals at start-up, but their portals are managed as CPU-*local* associations. USDPAA on the other hand manages portals as *thread-local* associations. Nonetheless, portals are (typically) configured for a particular CPU-affinity, meaning that ring and data stashing will target the designated CPU, so USDPAA applications are advised to run their threads on the CPUs for which their portals are configured - failing to do so will not break the system nor the application, but will yield significant performance degradation relative to an optimized system.

NOTE

The "recovery_mode" parameters in the following APIs are currently unsupported, they are reserved until a future release, so should always be set to 0 (or "FALSE").

7.4.2.2.9.2 Thread initialization

An application pthread can request that the QMan drivers initialize and bind a portal for use by that thread by calling the following APIs. This API must be called and return success prior to calling any of the interfaces mentioned in QMan portal

APIs on page 641 or BMan CoreNet portal APIs on page 627. Note, this interface is dependent on the device-tree layer having been initialized, see Device-tree dependency on page 676.

```
int qman_thread_init(void);
int qman_thread_init_idx(uint32_t idx);
int bman_thread_init(void);
int bman_thread_init_idx(uint32_t idx);
```

Note that the 'idx' parameter influences the driver's search for the portal with the specified portal index. The pthread is required to already be affine to the given CPU.

As usual with "int"-valued APIs, a return value of zero indicates success, otherwise a standard negative error number is returned in event of failure.

Likewise, the thread-portal association can be ended (and thus make the underlying portal available for another user/thread) by calling the following APIs.

```
int qman_thread_finish(void);
int bman_thread_finish(void);
```

7.4.2.2.9.3 FQID/BPID allocation

As of the current release of USDPAA, support for allocation of FQIDs and BPIDs is via hard-coded ranges encoded within the drivers. This will be revised in a future release.

To enable the allocation mechanisms in the USDPAA QMan (and BMan) drivers, the following APIs must be called once from a thread that has already successfully bound to a QMan (or BMan) portal via qman_thread_init() (or bman_thread_init(), respectively).

```
int qman_global_init(int recovery_mode);
int bman_global_init(int recovery_mode);
```

Note that this API does not need to be called from all threads, only from one, but that it should be called before using any QMan/BMan APIs that require dynamic allocation of FQIDs or BPIDs.

7.4.2.2.9.4 Interrupt handling

7.4.2.2.9.4.1 USDPAA file-descriptors

Interrupt handling in USDPAA is done by reading a standard file descriptor that is created when a portal is assigned to a thread. The application should use the poll() or select() API to determine when the file descriptor becomes readable which indicates an interrupt has occurred. The following APIs return the current USDPAA file-descriptors for portals bound to the calling thread.

```
int qman_thread_fd(void);
int bman_thread_fd(void);
```

7.4.2.2.9.4.2 Processing interrupt-driven portal duties

It should be noted that the QMan and BMan drivers allow applications to dynamically configure which portal "duties" are to be triggered and performed by interrupts versus polling. See Modifying interrupt-driven portal duties (BMan) on page 627 and Modifying interrupt-driven portal duties (QMan) on page 642 for details. Prior to going into a blocking read(), select(), poll(), [...] on the file-descriptor, the application will need to ensure that the "duties" it wishes to wait for are put into IRQ mode (ie. added to the portal's "irqsource") prior to blocking, otherwise the presence of such work will not trigger any interrupt and so will not wake up the sleeping process. Likewise, if going back into polling mode and expecting polling APIs to process such portal duties, the application will need to remove such duties from the "irqsource".

For portal duties that are in the "irqsource", and after any USDPAA-supported file-descriptor operation that indicates that an interrupt was received, the application pthread can call the following APIs to post-process any such interrupt-driven duties:

```
/* Post-process interrupts. NB, the kernel IRQ handler disables the interrupt
 * line before notifying us, and this post-processing re-enables it once
 * processing is complete. As such, it is essential to call this before going
 * into another blocking read/select/poll. */
void qman_thread_irq(void);
void bman_thread_irq(void);
```

7.4.2.2.9.5 Device-tree dependency

The QMan/BMan drivers “find” portals by referring to information extracted from the device-tree, as represented in the procfs filesystem located at /proc/device-tree. This information is handled by a USDPAA “of” driver, which must be initialised before any attempts are made to initialise threads for QMan/BMan use as described in Thread initialization on page 674. As of the current USDPAA release, the “of” driver must be explicitly initialised by applications prior to QMan/BMan thread initialisation, though this may change in future releases. (As a side note, other USDPAA mechanisms, such as application-side configuration parsing may also be dependent on this device-tree layer, and so the “of” init should occur prior to all such dependencies.)

The API to initialise the “of” driver is of_init(), which parses the /proc/device-tree representation into an internal representation of C data-structures.

```
#ifndef OF_INIT_DEFAULT_PATH
#define OF_INIT_DEFAULT_PATH "/proc/device-tree"
#endif
int of_init_path(const char *dt_path);
/* Use of this wrapper is recommended. */
static inline int of_init(void)
{
        return of_init_path(OF_INIT_DEFAULT_PATH);
}
```

Conversely, the of_finish() API cleans up all data structures and handles created by of_init(), which may be useful to satisfy leak-checking tools, or persistent process/thread recycling schemes.

```
void of_finish(void);
```

7.4.2.2.10 Sysfs and debugfs QMan/BMan interfaces

This chapter describes the qman and bman interfaces available via sysfs and debugfs.

NOTE

For non-P4080 devices, it is generally recommended to determine these from the device-tree, the SoC-specific Reference Manual, and/or by examining the sysfs filesystem at run-time.

7.4.2.2.10.1 QMan sysfs

7.4.2.2.10.1.1 /sys/devices/ffe000000.soc/ffe318000.qman

Description:

This directory contains a snapshot of the internal state of the qman device.

7.4.2.2.10.1.2 /sys/devices/ffe000000.soc/ffe318000.qman/error_capture

Description:

This directory contains a snapshot of error related qman attributes.

7.4.2.2.10.1.3 /sys/devices/ffe000000.soc/ffe318000.qman/error_capture/sbec_<0..6>

Description:

Provides a count of the number of single bit ECC errors that have occurred when reading from one of the QMan internal memories. The range <0..6> represent a QMAN internal memory region defined as follows:

0: FQD cache memory

1: FQD cache tag memory

2: SFDR memory

3: WQ context memory

4: Congestion Group Record memory

5: Internal Order Restoration List memory

6: Software Portal ring memory

This file is read-reset.

7.4.2.2.10.1.4 /sys/devices/ffe000000.soc/ffe318000.qman/sfdr_in_use

Description:

Reports the number of SFDR currently in use. The minimum value is 1. This file is not available on Rev 1.0 of P4080 QorIQ.

This file is read-only

/sys/devices/ffe000000.soc/ffe318000.qman/pfdr_fpc

Description:

Total Packed Frame Descriptor Record Free Pool Count in external memory.

This file is read-only

7.4.2.2.10.1.5 /sys/devices/ffe000000.soc/ffe318000.qman/pfdr_cfg

Description:

Used to read the configuration of the dynamic allocation policy for PFDRs. The value is used to account for PFDR that may be required to complete any currently executing operations in the sequencers.

This file is read-only.

7.4.2.2.10.1.6 /sys/devices/ffe000000.soc/ffe318000.qman/idle_stat

Description:

This file can be used to determine when QMan is both idle and empty. The possible values are:

0: All work queues in QMan are NOT empty and QMan is NOT idle.

1: All work queues in QMan are NOT empty and QMan is idle.

2: All work queues in QMan are empty

3: All work queues in QMan are empty and QMan is idle.

This file is read-only.

7.4.2.2.10.1.7 /sys/devices/ffe000000.soc/ffe318000.qman/err_isr

Description:

QMan contains one dedicated interrupt line for signaling error conditions to software. This file identifies the source of the error interrupt within QMan. The value is displayed in hexadecimal format. Refer to the appropriate QorIQ SOC Reference Manual for a description of the QMAN_ERR_ISR register.

This file is read-only.

7.4.2.2.10.1.8 /sys/devices/ffe000000.soc/ffe318000.qman/dcp<0..3>_dlm_avg

Description:

These files contain an EWMA (exponentially weighted moving average) of dequeue latency samples for dequeue commands received on the sub portal. The range <0..3> refers to each of the direct-connect portals. The display format is as follows: <avg_interger>.<avg_fraction>

This file can be seeded with a interger value. The input interger is processed in the following manner: <avg_fraction> = lowest 8 bits / 256 , <avg_interger> = next 12 bits

ex: echo 0x201 > dcp0_dlm_avg

cat dcp0_dlm_avg

0.00390625

This file is read-write

7.4.2.2.10.1.9 /sys/devices/ffe000000.soc/ffe318000.qman/ci_rlm_avg

Description:

This file contains an EWMA (exponentially weighted moving average) of read latency samples for reads on CoreNet initiated by QMan. The display format is as follows: <avg_interger>.<avg_fraction>

This file can be seeded with a interger value. The input interger is processed in the following manner: <avg_fraction> = lowest 8 bits / 256 , <avg_interger> = next 12 bits

ex: echo 0x201 > ci_rlm_avg

cat ci_rlm_avg

0.00390625

This file is read-write

7.4.2.2.10.2 BMan sysfs

7.4.2.2.10.2.1 /sys/devices/ffe000000.soc/ffe31a000.bman

Description:

This directory contains a snapshot of the internal state of the BMan device.

7.4.2.2.10.2.2 /sys/devices/ffe000000.soc/ffe31a000.bman/error_capture

Description:

This directory contains a snapshot of error related BMan attributes.

7.4.2.2.10.2.3 /sys/devices/ffe000000.soc/ffe31a000.bman/error_capture/sbec_<0..1>

Description:

Provides a count of the number of single bit ECC errors that have occurred when reading from one of the BMan internal memories. The range <0..1> represent a BMAN internal memory region defined as follows:

0: Stockpile memory 0

1: Software Portal ring memory

This file is read-reset.

7.4.2.2.10.2.4 /sys/devices/ffe000000.soc/ffe31a000.bman/pool_count

Description:

This directory contains a snapshot of the number of free buffers available in any of the buffer pools.

7.4.2.2.10.2.5 /sys/devices/ffe000000.soc/ffe31a000.bman/fbpr_fpc

Description:

This file returns a snapshot of the Free Buffer Proxy Record free pool size. Total Free Buffer Proxy Record Free Pool Count in external memory.

This file is read-only

7.4.2.2.10.2.6 /sys/devices/ffe000000.soc/ffe31a000.bman/err_isr

Description:

BMan contains one dedicated interrupt line for signaling error conditions to software. This file identifies the source of the error interrupt within BMan. The value is displayed in hexadecimal format. Refer to the appropriate QorIQ SOC Reference Manual for a description of the BMAN_ERR_ISR register.

This file is read-only.

7.4.2.2.10.3 QMan debugfs

7.4.2.2.10.3.1 /sys/kernel/debug/qman

Description:

This directory contains various QMan device debugging attributes.

7.4.2.2.10.3.2 /sys/kernel/debug/qman/query_cgr

Description:

Query the entire contents of a Congestion Group Record. The file takes as input the Congestion Group Record ID. The output of the file returns the various CGR fields.

For example, if we want to query cgr_id 10 we would do the following:

echo 10 > query_cgr

cat query_cgr

Query CGR id 0xa

wr_parm_g MA: 0, Mn: 0, SA: 0, Sn: 0, Pn: 0

wr_parm_y MA: 0, Mn: 0, SA: 0, Sn: 0, Pn: 0

a_bcnt: 0

7.4.2.2.10.3.3 /sys/kernel/debug/qman/query_congestion

Description:

Query the state of all 256 Congestion Groups in QMan. This is a read-only file. The output of the file returns the state of all congestion group records. The state of a congestion group is either "in congestion" or "not in congestion". Since CGR are normally not in congestion, only CGR which are in congestion are returned. If no CGR are in congestion, then this is indicated.

For example, if we want to perform a query we would do the following:

cat query_congestion

Query Congestion Result

All congestion groups not congested.

7.4.2.2.10.3.4 /sys/kernel/debug/qman/query_fq_fields

Description:

Query the frame queue programmable fields. This file takes as input the frame queue id to be queried on a subsequent read. The output of this file returns all the frame queue programmable fields. The default frame queue id is 1.

Refer to the appropriate QorIQ SOC Reference Manual for detailed explanation on the return values.

For example, if we determine that our application is using frame queue 482 we could use this file in the following manner:

echo 482 > query_fq_fields

cat query_fq_fields

Query FQ Programmable Fields Result fqid 0x1e2

7.4.2.2.10.3.5 /sys/kernel/debug/qman/query_fq_np_fields

Description:

Query the frame queue non programmable fields. This file takes as input the frame queue id to be queried on a subsequent read. The output of this file returns all the frame queue non programmable fields. The default frame queue id is 1.

Refer to the appropriate QorIQ SOC Reference Manual for detailed explanation on the return values.

For example, if we determine that our application is using frame queue 482 we could use this file in the following manner:

echo 482 > query_fq_np_fields

cat query_fq_np_fields

Query FQ Non Programmable Fields Result fqid 0x1e2

7.4.2.2.10.3.6 /sys/kernel/debug/qman/query_cq_fields

Description:

Query all the fileds of in a particular CQD. This file takes input as the DCP id plus the class queue id to be queried on a subsequent read. The output of this file returns all the class queue fields. The default class queue id is 1 of DCP 0

Refer to the appropriate QorIQ SOC Reference Manual for detailed explanation on the return values.

For example, if we determine that our application is using class queue 4 of DCP 1, we could use this file in the following manner:

echo 0x01000004 > query_cq_fields

(The most left 8 bits are used to specify DCP id, and the rest of 24 bits are used to specify the class queue id)

7.4.2.2.10.3.7 /sys/kernel/debug/qman/query_ceetm_ccgr

Description:

Query the configuration and state fields within a CEETM Congestion Group Record that relate to congestion management(CM). This file takes input as the DCP id(most left 8 bits) and CEETM Congestion Group Record ID(most right 24 bits). The output of the file returns the various CCGR fields.

For example, if we want to query ccgr_id 7 of DCP 0, we would do the following:

echo 0x00000007 > query_ceetm_ccgr

cat query_ceetm_ccgr

Query CCGID 7

7.4.2.2.10.3.8 /sys/kernel/debug/qman/query_wq_lengths

Description:

Query the length of the Work Queues in a particular channel. This file takes as input a specified channel id. The output of this file returns the lengths of the work queues on the specified channel.

For example, if we want to query channel 1 we would do the following:

echo 1 > query_wq_lengths

cat query_wq_lengths

Query Result For Channel: 0x1

wq0_len : 0

wq1_len : 0

wq2_len : 0

wq3_len : 0

wq4_len : 0

wq5_len : 0

wq6_len : 0

wq7_len : 0

7.4.2.2.10.3.9 /sys/kernel/debug/qman/fqd/avoid_blocking_[enable | disable]

Description:

Query Avoid_Blocking bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Avoid_Blocking bit mask enabled or disabled.

For example, if we want to find all frame queues with Avoid_Blocking enabled, we would do the following:

```
# cat avoid_blocking_enable
List of fq ids with: Avoid Blocking :enabled
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001de,0x0001df,0x0001e0,0x0001e1,
0x0001ea,0x0001eb,0x0001ec,0x0001ed,0x0001f6,0x0001f7,0x0001f8,0x0001f9,
...
Total FQD with: Avoid Blocking : enabled = 528
Total FQD with: Avoid Blocking : disabled = 32239
```

7.4.2.2.10.3.10 /sys/kernel/debug/qman/fqd/prefer_in_cache_[enable | disable]

Description:

Query Prefer_in_Cache bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Prefer_in_Cache bit mask enabled or disabled.

For example, if we want to find all frame queues with Prefer_in_Cache enabled, we would do the following:

```
# cat prefer_in_cache_enable
List of fq ids with: Prefer in cache :enabled
0x0001ca,0x0001cb,0x0001cc,0x0001cd,0x0001ce,0x0001cf,0x0001d0,0x0001d1,
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001d6,0x0001d7,0x0001d8,0x0001d9,
...
Total FQD with: Prefer in cache : enabled = 560
Total FQD with: Prefer in cache : disabled = 32207
```

7.4.2.2.10.3.11 /sys/kernel/debug/qman/fqd/cge_[enable | disable]

Description:

Query Congestion_Group_Enable bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Congestion_Group_Enable bit mask enabled or disabled.

For example, if we want to find all frame queues with Congestion_Group_Enable disabled, we would do the following:

```
# cat cge_disable
List of fq ids with: Congestion Group Enable :disabled
0x000001,0x000002,0x000003,0x000004,0x000005,0x000006,0x000007,0x000008,
0x000009,0x00000a,0x00000b,0x00000c,0x00000d,0x00000e,0x00000f,0x000010,
...
Total FQD with: Congestion Group Enable : enabled = 0
Total FQD with: Congestion Group Enable : disabled = 32767
```

7.4.2.2.10.3.12 /sys/kernel/debug/qman/fqd/cpc_[enable | disable]

Description:

Query CPC_Stash_Enable bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their CPC_Stash_Enable bit mask enabled or disabled.

For example, if we want to find all frame queues with CPC Stash disabled, we would do the following:

```
# cat cpc_disable
List of fq ids with: CPC Stash Enable :disabled
0x000001,0x000002,0x000003,0x000004,0x000005,0x000006,0x000007,0x000008,
```

```
0x000009,0x00000a,0x00000b,0x00000c,0x00000d,0x00000e,0x00000f,0x000010,
...
Total FQD with: CPC Stash Enable : enabled = 0
Total FQD with: CPC Stash Enable : disabled = 32767
```

7.4.2.2.10.3.13 /sys/kernel/debug/qman/fqd/cred

Description:

Query Intra-Class Scheduling bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Intra-Class Scheduling Credit value greater than 0.

```
# cat cred
List of fq ids with Intra-Class Scheduling Credit > 0
Total FQD with ics_cred > 0 = 0
```

7.4.2.2.10.3.14 /sys/kernel/debug/qman/fqd/ctx_a_stashing_[enable | disable]

Description:

Query Context_A bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Context_A bit mask enabled or disabled.

For example, if we want to find all frame queues with Context_A enabled, we would do the following:

```
# cat ctx_a_stashing_enable
List of fq ids with: Context-A stashing :enabled
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001de,0x0001df,0x0001e0,0x0001e1,
0x0001ea,0x0001eb,0x0001ec,0x0001ed,0x0001f6,0x0001f7,0x0001f8,0x0001f9,
...
Total FQD with: Context-A stashing : enabled = 528
Total FQD with: Context-A stashing : disabled = 32239
```

7.4.2.2.10.3.15 /sys/kernel/debug/qman/fqd/hold_active_[enable | disable]

Description:

Query Hold_Active bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Hold_Active bit mask enabled or disabled.

For example, if we want find all frame queues with Hold_Active enabled, we would do the following:

```
# cat hold_active_enable
List of fq ids with: Hold active in portal :enabled
Total FQD with: Hold active in portal : enabled = 0
Total FQD with: Hold active in portal : disabled = 32767
```

7.4.2.2.10.3.16 /sys/kernel/debug/qman/fqd/orp_[enable | disable]

Description:

Query ORP bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their ORP bit mask enabled or disabled.

For example, if we want find all frame queues with ORP enabled, we would do the following:

```
# cat orp_enable
List of fq ids with: ORP Enable :enabled
Total FQD with: ORP Enable : enabled = 0
Total FQD with: ORP Enable : disabled = 32767
```

7.4.2.2.10.3.17 /sys/kernel/debug/qman/fqd/sfdr_[enable | disable]

Description:

Query Force_SFDR_Allocate bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Force_SFDR_Allocate bit mask enabled or disabled.

For example, if we want to find all frame queues with Force_SFDR_Allocate enabled, we would do the following:

```
# cat sfdr_enable
List of fq ids with: High-priority SFDRs :enabled(1)
Total FQD with: High-priority SFDRs : enabled = 0
Total FQD with: High-priority SFDRs : disabled = 32767
```

7.4.2.2.10.3.18 sys/kernel/debug/qman/fqd/state_[active | oos | parked | retired | tentatively_sched | truly_sched]

Description:

Query Frame Queue State in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which are in the specified state: active, oos, parked, retired, tentatively scheduled or truly scheduled.

For example, the following returns all the frame queues in the Tentatively Scheduled state:

```
# cat state_tentatively_sched
List of fq ids in state: Tentatively Scheduled
0x0001ca,0x0001cb,0x0001cc,0x0001cd,0x0001ce,0x0001cf,0x0001d0,0x0001d1,
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001d6,0x0001d7,0x0001d8,0x0001d9,
...
Out of Service count = 32201
Retired count = 0
Tentatively Scheduled count = 566
Truly Scheduled count = 0
Parked count = 0
Active, Active Held or Held Suspended count = 0
```

7.4.2.2.10.3.19 /sys/kernel/debug/qman/fqd/tde_[enable | disable]

Description:

Query Tail_Drop_Enable bit in all frame queue descriptors. This is a read only file. The output of this file returns all the frame queue ids, in a comma seperated list, which have their Tail_Drop_Enable bit mask enabled or disabled.

For example, the following returns all the frame queues with Tail_Drop_Enable bit enabled:

```
# cat tde_enable
List of fq ids with: Tail-Drop Enable :enabled(1)
```

```
0x0001ca,0x0001cb,0x0001cc,0x0001cd,0x0001ce,0x0001cf,0x0001d0,0x0001d1,
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001d6,0x0001d7,0x0001d8,0x0001d9,
...
Total FQD with: Tail-Drop Enable : enabled = 560
Total FQD with: Tail-Drop Enable : disabled = 32207
```

7.4.2.2.10.3.20 /sys/kernel/debug/qman/fqd/wq

Description:

Query Destination Work Queue in all frame queue descriptors. This file takes as input work queue id combined with channel id (destination work queue). The output of this file returns all the frame queues with destination work queue number as specified in the input.

For example, the following returns all the frame queues with their destination work queue number equal to 0x10f:

```
# echo 0x10f > wq
# cat wq
List of fq ids with destination work queue id = 0x10f
0x0001d2,0x0001d3,0x0001d4,0x0001d5,0x0001de,0x0001df,0x0001e0,0x0001e1,
0x0001ea,0x0001eb,0x0001ec,0x0001ed,0x0001f6,0x0001f7,0x0001f8,0x0001f9,
0x0001fa,0x0001fb,0x0001fd,0x0001fe
Summary of all FQD destination work queue values
Channel: 0x0 WQ: 0x0 WQ_ID: 0x0, count = 32199
Channel: 0x0 WQ: 0x0 WQ_ID: 0x4, count = 1
Channel: 0x0 WQ: 0x3 WQ_ID: 0x7, count = 64

7.4.2.2.10.3.21 /sys/kernel/debug/qman/fqd/summary

Description:

Provides a summary of all the fields in all frame queue descriptors. This is a read only file.

```
# cat summary
Out of Service count = 32201
Retired count = 0
Tentatively Scheduled count = 566
Truly Scheduled count = 0
```

```
Parked count = 0
Active, Active Held or Held Suspended count = 0
---------------------------------------
Prefer in cache count = 560
Hold active in portal count = 0
Avoid Blocking count = 528
High-priority SFDRs count = 0
CPC Stash Enable count = 0
Context-A stashing count = 528
ORP Enable count = 0
Tail-Drop Enable count = 560
```

7.4.2.2.10.3.22 /sys/kernel/debug/qman/ccsrmempeek

Description:

Provides access to Queue Manager ccsr memory map. This file takes as input an offset from the QMan CCSR base address. The output of this file returns the 32-bit value of the memory address as specified in the input.

For example, to query the QM IP Block Revision 1 register (which is at offset 0xbf8 from the QMan CCSR base address), we would do the following:

```
# echo 0xbf8 > ccsrmempeek
# cat cccsrmempeek
QMan register offset = 0xbf8
value = 0x0a010101
```

7.4.2.2.10.3.23 /sys/kernel/debug/qman/query_ceetm_xsfdr_in_use

Description:

Query the number of XSFDRs currently in use by the CEETM logic of the DCP portal. This file takes input as the DCP id. The output of the file returns the number of XSFDR in use. Please note this feature is only available in T4/B4 rev2 silicon.

For example, if we want to query XSFDR in use number of DCP 0, we would do the following:

echo 0 > query_ceetm_xsfdr_in_use

cat query_ceetm_xsfdr_in_use

DCP0: CEETM_XSFDR_IN_USE number is 0

7.4.2.2.10.4 BMan debugfs

7.4.2.2.10.4.1 /sys/kernel/debug/bman

Description:

This directory contains various BMan device debugging attributes.

7.4.2.2.10.4.2 /sys/kernel/debug/bman/query_bp_state

Description:

This file requests a snapshot of the availability and depletion state of each of BMan's buffer pools. This is a read only file.

For example, if we want to perform a query we could use this file in the following manner:

cat query_bp_state

bp_id free_buffers_avail bp_depleted

7.4.2.2.11 Error handling and reporting

This chapter describes the QMan and BMan error handling and reporting.

7.4.2.2.11.1 Handling and Reporting

The QMan and BMan error interrupt sevices routines log the occurrence of every error interrupt. Some error interrupts can be triggered multiple times. To prevent a flood of error logging when this interrupts are raised, they are only logged on their first occurance at which time they are disabled. The logs are generated via the pr_warning() kernel api. At the end of the interrupt service routine the ISR register is cleared. These logs are available on the console, dmesg and related log file.

The following QMan error conditions are logged a single time:

QM_EIRQ_PLWI and QM_EIRQ_PEBI.

The following BMan error conditions are logged a single time:

BM_EIRQ_FLWI (low water mark).

7.4.2.2.12 Operating system specifics

This chapter captures O/S-specific issues and distinctions, as the rest of the document essentially describes the interfaces in a generalized manner.

7.4.2.2.12.1 Portal maintenance

By default, the Linux kernel initializes QMan and BMan portals to perform all processing via interrupt-handling. As such there are no persistent threads or polling requirements in order to use portals in the Linux kernel.

Whereas for USDPAA (linux user space), the default is for all processing to be driven by polling, and support for the use of interrupts is disabled. The applications are required to call qman_poll() and bman_poll() within their run-to-completion loops to ensure that portal processing occurs regularly.

As described in Processing non-interrupt-driven portal duties (BMan) on page 628 (for BMan) and Processing non-interrupt-driven portal duties (QMan) on page 643 (for QMan), it is also possible to dynamically control at run-time which portal duties are interrupt-driven versus poll-driven, so the aforementioned defaults for Linux are start-up defaults. However, USDPAA needs to be built with "CONFIG_FSL_DPA_IRQ_SAFETY" defined in order to allow any duties to be interrupt-driven, whereas it is disabled by default (in inc/public/conf.h) due to a very slight performance improvement that it yields.

7.4.2.2.12.2 Callback context

In the Linux kernel, all interrupt-driven portal duties are handled in interrupt context, whereas all other portal duties are invoked from within the qman_poll() and bman_poll() functions, which are invoked by the application.

In USDPAA, even interrupt-driven portal duties are handled in an application context. Interrupts are handled within the kernel and locally disabled, and the presence of such interrupt events is available to the application via the USDPAA file-descriptor representing the portal devices. See Interrupt handling on page 675 for more information. Interrupt-driven portal duties are thus processed when the application calls the qman_thread_irq() and bman_thread_irq() functions, and other portal duties are processed when the application calls qman_poll() and bman_poll().

7.4.2.2.12.3 Blocking semantics

Many high-level QMan and BMan API functions provide "WAIT" flags, to allow the API to block as part of its operation.

In the Linux kernel, "WAIT" behavior is implemented by allowing the calling thread to sleep until a given condition is satisfied. The limitation then to using "WAIT" flags is that the caller can not be in atomic context - i. e. not executing within an interrupt handler, tasklet, bottom-half, etc, nor with any spinlocks held. One consequence is that "WAIT" flags can not be used within a callback.

On run-to-completion systems such as USDPAA, "WAIT" behavior is unsupported and unavailable.

7.4.3 Configuring DPAA Frame Queues

7.4.3.1 Introduction

Describes configurations of Queue Manager (QMan) Frame Queues (FQs) associated with Frame Manager (FMan) network interfaces for the QorIQ Data Path Acceleration Architecture (DPAA). The relationship of the FMan and the QMan channels and work queues are illustrated by examples.

The basic configuration examples for QMan FQs provided yield straightforward and reliable DPAA performance. These simple examples may then be fine tuned for special use cases. For additional information and understanding of advanced system level features please refer to the DPAA Reference Manual.

DPAA provides the networking specific I/Os, accelerator/offload functions, and basic infrastructure to enable efficient data passing, without locks or semaphores, within the multi-core QorIQ SoC between:

1. The Power Architecture cores (and software)
2. The network and I/O interfaces through which that data arrives and leaves
3. The accelerator blocks used by the software to assist in processing that data.

Hardware-managed queues which reside in and are managed by the QMan provide the basic infrastructure elements to enable efficient data path communication. The data resides in delimited work units of frames/packets between cores, hardware accelerators and network interfaces. These hardware-managed queues, known as Frame Queues (FQs), are FIFOs of related frames. These frames comprise buffers that hold a data element, generally a packet. Frames can be single buffers or multiple buffers (using scatter/gather lists).

FQ assignment to consumers i.e., cores, hardware accelerators, network interfaces, are programmable (not hard coded). Specifically, FQs are assigned to work queues which in turn are grouped into channels. Channels which represent a grouping of FQs from which a consumer can dequeue from, are of two types:

- Pool channel: a channel that can be shared between consumers which facilitates load balancing/spreading. (Applicable to cores only. Does not apply to hardware accelerators or netwok interfaces)
- Dedicated channel: a channel that is dedicated to a single consumer.

Each pool or dedicated channel has eight (8) work queues. There are two high priority work queues that have absolute, strict priority over the other six (6) work queues which are grouped into medium and low priority tiers. Each tier contains three work queues which are serviced using a weighted round robin based algorithm. More than one FQ can be assigned to the same work queue as channels implementing a 2-level hierarchical queuing structure. That is, FQs are enqueued/dequeued onto/from work queues. Within a work queue a modified deficit round algorithm is used to determine the number of bytes of data that can be consumed from a FQ at the head of a work queue. The FQ, if not empty, is enqueued back onto the tail of the same work queue once its consumption allowance has been met.

NOTE

- The configuration information provided in this document applies to the QorIQ family of SoCs built on Power Architecture and DPAA technology
- The configuration information provided in this document assumes a top bin platform frequency.

7.4.3.2 FMan Network interface Frame Queue Configuration

Configuring the QMan Frame Queues (FQs) associated with the FMan network interfaces for QorIQ DPAA.

Each network interface has an ingress and an egress direction. The ingress direction is defined as the direction from the network interface to the cores. The egress direction is defined as the direction from the cores to the network interfaces.

FQs associated with FMan network interfaces can be either ingress or egress FQs. Ingress FQs are referred to FQs used in the ingress direction to store packets received from network interfaces to be processed by the cores. Egress FQs are referred to FQs used in the egress direction to store packets to be transmitted by FMan out of its network interfaces.

7.4.3.3 FMan network interface ingress FQs configuration

Dependencies for configuration of the ingress Frame Queues (FQs) is dependent on the QMan mechanism used to load balance/spread received packets across the multiple cores in QorIQ DPAA.

Two mechanisms are offered:

1. Dynamic load balancing
   - Load spread the packets (from ingress FQs) to the cores based on actual core availability/readiness.
   - Achieved through the use of QMan pool channel (i.e. a channel which can be shared by multiple cores).
   - Maintaining packet ordering (e.g. when packets are being forwarded) is achieved through the following two mechanisms:
     a. Order preservation; ensures that related packets (e.g. a sequence of packets moving between two end points) are processed in order (and typically one at a time).
     b. Order restoration; allows packets to be processed out of order and then restores their order later on before they are transmitted out to the network interfaces.

- Improves core work load balancing over a static distribution based approach scheme but will not maintain core affinity because a FQ may get processed by multiple cores.

2. Static distribution
   - Static association between FQs and cores; FQs are always processed by the same core.
   - Achieved through the use of QMan dedicated channel (i.e. a channel which supplies FQs to a specific core).
   - Static not dynamic, doesn't react to core load, assigns work to the cores in a static or fixed manner.
   - Does not not require any special order preservation/restoration mechanism as packet ordering is implicitly preserved.

For all of these mechanisms, QMan requires that related packets, which must be processed and/or transmitted in order, be placed on the same FQ. This does not mean that only related packets are placed on a given FQ; many sets of related packets (“flows”) can be placed on a single FQ. FMan is responsible for achieving this placement/FQ selection function through its distribution capabilities. For instance, FMan can be configured to apply a hash function to a set of packet header fields and use the hash value to select the FQ. This set of packet header fields can be for example, a 5-tuple consisting of:

- source IP address
- destination IP address
- protocol
- source port
- destination port

Note that the FMan processing may be out of order, but it has internal mechanism to ensure that packets are enqueued in order of reception.

These mechanisms can be configured and used simultaneously on an SoC device.

7.4.3.4 Ingress FQs common configuration guidelines

Guidelines and examples for configuring ingress Frame Queues (FQs) in the QorIQ DPAA are shown.

Following guidelines apply regardless of the load balancing mechanism(s) configured:

- Maximum number of ingress FQs for all ingress interfaces on the device (including any of the separate FQs that are used to serve as an order restoration point (ORP)): 1024
- Maximum number of ingress FQs per work queue (FIFO of FQs):
- • 64 if the aggregate bandwidth of the configured network interface(s) on the device is higher than 10 Gbit/s.
  - 128 if the aggregate bandwidth of the configured network interface(s) on the device is 10 Gbit/s or lower.
- The aggregate bandwidth of the configured network interface(s) on the device receiving packets into FQs associated to the same work queue should not exceed 10 Gbit/s. In other words, the recommended maximum incoming rate into a single work queue is 10 Gbit/s. If the configured network interface(s) on the device is higher than 10 Gbit/s, then multiple work queues should be used.
- Since the Single Frame Descriptor Record (SFDRs) reservation scheme is recommended for the egress FQs (FMan network interface egress FQs configuration) and any other FQs assigned to high priority work queues will also use these reserved SFDRs, careful consideration should be given to the required number of ingress FQs assigned to the high priority work queues as SFDRs are a scarce QMan resource (there is a total of 2K SFDRs). One needs to leave sufficient SFDRs for FQs not using the reserved SFDRs (e.g. ingress FQs assigned to medium or low priority work queues).

As an example, if one allocates 1024 ingress FQs and the aggregate bandwidth of the configured network interface(s) on the device is higher than 10 Gbit/s, then a minimum of 16 work queues would be required based on the above guidelines. Assuming that all 1024 FQs are to be scheduled at the same priority using a dynamic load balancing scheme, a minimum of 6 pool channels would need to be used (based on the fact that up to 3 work queues can be used within a medium or low priority tier).

The guideline “maximum of 1024 ingress FQs for all ingress interfaces” results from the size of the internal memory in QMan that is used to cache Frame Queue Descriptors (FQDs). This internal memory is sized to 2K entries. To achieve high, deterministic and reliable performance under worst-case packet workload (back-to-back 64-byte packets enqueued to FQs on a rotating basis), all ingress FQDs must remain in the QMan internal cache. FQD cache misses increase the time required to enqueue packets as the FQD may need to be read from external memory. This in return could result in received packets being discarded by the MAC due MAC FIFO overflow condition as a result of the back-pressure applied by the FMan to the MAC as there is little buffering between the MAC and the point at which incoming packets are enqueued onto the ingress FQs.

Although a device configured with a number of ingress FQs higher than the size of the QMan FQD internal cache would operate at high performance with no packet discards if the incoming traffic exhibited some level of temporal locality, it is generally recommended that the device be engineered such that ingress path operates at line rate under worst case packet workload to avoid unnecessary packets losses and to make effective use of QMan to prioritize and apply appropriate QoS if there is congestion in a downstream element (e.g. cores). Since all FQs defined on the device shared the QMan 2K internal FQD cache, the recommended maximum number of ingress and egress FQs is even more constrained so that there is adequate space left for caching FQDs assigned to accelerators.

With regards to congestion management, the default mechanism for managing ingress FQ lengths is through buffer management. Input to FQs is limited to the availability of buffers in the buffer pool used to supply buffers to the FQs. Although very efficient and simple, when a buffer pool is shared by multiple FQs, there is no protection between the FQs sharing the buffer pool and as a result a FQ could potentially occupy all the buffers.

Queue management mechanisms can be configured (e.g. tail drop/WRED) to improve congestion control however appropriate software must be in place to handle enqueue rejections as a result of queue congestion.

7.4.3.5 Dynamic load balancing with order preservation - ingress FQs configuration guidelines

Dynamic load balancing with order preservation provides a very effective workload distribution technique to achieve optimal utilization of all cores as it distributes packets to the cores based on actual core availability/readiness.

Order preservation allows FQs to be dynamically reassigned from one core to another while preserving per-FQ packet ordering. It never allows packets from the same FQ to be processed at multiple cores at the same time; a specific FQ is only processed by one core at any given time. Once the FQ is released by the core, it can be processed by any of the cores. To keep multiple cores active there must be multiple FQs distributing packets to the cores, each with a set of (potentially) related packets.

In packet-forwarding scenarios, Discrete Consumption Acknowledgement (DCA) embedded in the enqueue commands should be used to forward packets as this ensures that QMan will release the ingress FQ on software’s behalf once it has finished processing the enqueue command. This provides order preservation semantic from end-to-end (from dequeue to enqueue). To support the above, software portals that will be issuing DCA notifications to QMan must be configured with DCA mode enabled.

Following are specific configuration guidelines for ingress FQs used for dynamic load balancing with order preservation:.

- FQ must be associated to a pool channel (i.e. a channel which can be shared by multiple cores).
- Within a pool channel, minimum number of FQs per active portal (core): 4.
- Frame Queue Descriptor (FQD) attributes settings:
  - Prefer in cache.
  - Hold active set.
  - Don’t set avoid blocking.
  - Intra-class scheduling (ICS) credit set to 0 unless a more advanced scheduling scheme is required.
  - Don’t set force SFDR allocate unless FQ needs performance optimization.
  - FQD CPC stashing enabled.

- Dequeued Frame Data, Annotation, and FQ Context stashing: application dependent.
- Order Restoration Point (ORP) disabled.

7.4.3.6 Dynamic load balancing with order restoration - ingress FQs configuration guidelines

Dynamic load balancing with order restoration dispatches packets from the same Frame Queue (FQ) to different processor cores without attempting to maintain order. QMan provides order restoration with specific configurations shown.

The packet order in the original FQ (e.g. ingress FQ) is restored once the cores complete its processing and return the packets to QMan for sending to the next destination (e.g. egress FQ for transmission).

Dynamic load balancing with order restoration has the advantage that parallel processing of related traffic is possible; allows to process without packet drops a flow that exceed the processing rate of a core. However order restoration does make use of more resources than the other distribution schemes. Its usage must also be balanced with applications need to atomically access shared data.

Order restoration is achieved through the following two QMan components:

- Order Definition Points (ODPs)
  - A point through which packets pass, where their order or sequence relative to each other is defined.
  - For convenience each FQ has an ODP for packets dequeued from that FQ.
- Order Restoration Points (ORPs)
  - A point through which packets pass, where their order or sequence is restored to that defined at the related ODP.
  - If a packet is out of sequence it is held until it is in sequence.
  - ORP data structure is maintained in a FQ; it is recommended that a dedicated/separate FQ be allocated solely for this purpose.

Following are specific configuration guidelines for ingress FQs used for dynamic load balancing with order restoration:

- FQ must be associated to a pool channel (i.e. a channel which can be shared by multiple cores).
- For each ingress FQ supporting order restoration, a separate FQ should be allocated to serve as the ORP.
- Ingress FQ descriptor attributes settings.
  - Prefer in cache
  - Don’t set hold active.
  - Set avoid blocking.
  - Intra-class scheduling (ICS) credit set to 0 unless a more advanced scheduling scheme is required.
  - Don’t set force SFDR allocate unless FQ needs performance optimization.
  - FQD CPC stashing enabled.
  - Dequeued Frame Data, Annotation, and FQ Context stashing: application dependent.
  - ORP disabled.

Following are specific configuration guidelines for ORP FQs:

- FQs used for ORP don’t need to be associated with a pool or dedicated channel.
- ORP FQ descriptor attributes settings:
  - Prefer in cache .
  - Don’t set hold active.
  - Don’t set avoid blocking.

- Intra-class scheduling credit set to 0.
- Don't set force SFDR allocate .
- FQD CPC stashing enabled.
- ORP enabled.
- Recommended ORP restoration window size: 128.

7.4.3.7 Static distribution - Ingress FQs Configuration Guidelines

With a static distribution approach, a single FQ is always processed by the same processor core. Specific guidelines for processor core affinity are presented.

Although not as effective as a dynamic based approach from a resource utilization aspect, static distribution maintains core affinity meaning that the mapping from the flow to the core is preserved.

Distribution of packets (selection of FQ) can based on hash keys, ensuring that packets from the same traffic flow will always go to the same cores. The FQ selection function is achieved by FMan.

Following are specific configuration guidelines for ingress FQs used for static distribution:

- FQ must be associated to a dedicated channel (i.e. a channel which supplies FQs to a specific core); multiple FQs can be associated to a single dedicated channel.
- Within a dedicated channel, minimum number of FQs: 1.
- FQ descriptor attributes settings:
  - Prefer in cache .
  - Don't set hold active
  - Don't set avoid blocking.
  - Intra-class scheduling (ICS) credit set to 0 unless a more advanced scheduling scheme is required. On P4080/P3041/P5020, due to errata number QMAN-A002, allowable values for ICS are: 0 and 15' h7FFF.
  - Don't set force SFDR allocate unless FQ needs performance optimization.
  - FQD CPC stashing enabled.
  - Dequeued Frame Data, Annotation, and FQ Context stashing: application dependent.
  - ORP disabled.

7.4.3.8 FMan network interface egress FQs configuration

Configuration guidelines for egress Frame Queues (FQs) for QorIQ DPAA

FQ Configurations:

- Maximum number of egress FQs for all network interfaces: 128.
- Minimum number of egress FQs per network interface: 1.
- Maximum number of egress FQs per work queue: 8.
- Egress FQ descriptor attributes settings:
  - Prefer in cache.
  - Don't set hold active .
  - Don't set avoid blocking.
  - Set force SFDR allocate to ensure that egress queues make use of the reserved SFDRs; the SFDR reservation threshold field of the QMan SFDR configuration register must also be set accordingly (5 SFDRs per egress FQ + 3 extra SFDRs as required by QMan).

- Intra-class scheduling set to zero (0) unless a more advanced scheduling scheme is required.
- FQD CPC stashing enabled.
- ORP disabled.

.

7.4.3.9 Accelerator Frame Queue Configuration

Configurations for Frame Queues (FQs) used to communicate with accelerators for QorIQ DPAA are shown.

FQ accelerator Guidelines:

- Since the Single Frame Descriptor Record (SFDRs) reservation scheme is recommended for the egress FQs (FMan network interface egress FQs configuration) and any other FQs assigned to high priority work queues will also use these reserved SFDRs, careful consideration should be given to the required number of accelerator FQs assigned to the high priority work queues as SFDRs are a scarce QMan resource (there is a total of 2K SFDRs). One needs to leave sufficient SFDRs for FQs not using the reserved SFDRs (e.g. accelerator FQs assigned to medium or low priority work queues).
- Accelerator FQ descriptor attributes settings:
  - Don't set prefer in cache.
  - Don't set hold active .
  - Don't set avoid blocking.
  - FQD CPC stashing enabled.
  - Intra-class scheduling (ICS) credit set to 0 unless a more advanced scheduling scheme is required.
  - Don't set force SFDR allocate unless FQ needs performance optimization.
  - Dequeued Frame Data, Annotation, and FQ Context stashing: application dependent.
  - ORP disabled.

Generally accelerators are used in a request/response manner and in cases where a pair of FQs is needed per session/flow to communicate with accelerators, one may need to allocate a very large number of FQs (in the order of thousands). At times when many FQs allocated to an accelerator are active, this situation can result in having significant amount of cache consumed for storing the corresponding FQ descriptors. This in turn may negatively impact overall system performance.

To ensure optimal resource utilization (e.g. QorIQ caches), maximize throughput and avoid overload, it is recommended that the number of outstanding requests/responses to an accelerator be regulated. Typically, for a given accelerator, regulating the number of outstanding requests/responses across all its FQs to a few hundredths should be sufficient to maintain high throughput without overloading the system. Regulating the number of outstanding requests/responses to an accelerator can be achieved through various methods.

One method is to keep track in software of the total number of outstanding requests/responses to an accelerator and once this number exceeds a threshold, software would stop sending requests to that accelerator.

Another method is to make use of the congestion management capabilities of QMan. Specifically, all FQs allocated to an accelerator can be aggregated into a congestion group. Each congestion group can be configured to track the number of Frames in all FQs in the congestion group. Once this number exceeds a configured threshold, the congestion group enters congestion. When a congestion group enters congestion, QMan can be configured to rejects enqueues to any FQs in the congestion group and/or sent notification indicating that the congestion group has entered congestion. If a Frame (or request) is not going to be enqueued, it will be returned to the configured destination via an enqueue rejection notification. Congestion state change notifications are generated when the congestion group either enters congestion or exits congestion. On software portals, the congestion state change notification is sent via an interrupt.

7.4.3.10 DPAA Frame Queue Configuration Guideline Summary

Summary of Configurations for Frame Queue (FQ) communication with accelerators for QorIQ DPAA

Four tables comprise this summary:

- Global Configuration settings
- Network interface ingress FQ guidelines
- Network interface egress FQ guidelines
- Accelerator FQ guidelines

Table 121. Global Configuration Settings Summary

Parameter or subject	Guideline
FQD stashing	Recommend QMan explicitly stash FQDs: • QMan; both the global CPC stash enable bit in the QMan FQD_AR register and the CPC stash enable bit in the FQD must be set. • PAMU; PAACT tables used by PAMU also configured appropriately .
PFDR stashing	Recommend QMan explicitly stash PFDRs: • QMan; the global CPC stash enable bit in the QMan PFDR_AR register must be set . • PAMU; PAACT tables used by PAMU must also be configured appropriately .
SFDR reservation threshold	Set SFDR reservation threshold in QMan SFDR configuration register to: • Total number of FQs using reserved SFDRs times 5 (5 SFDRs per FQ) plus 3 extra SFDRs as required by QMan. Recommend that all egress FQs use reserved SFDRs .

Table 122. Network Interface Ingress FQs Guidelines Summary

Parameter or subject	Guideline
Maximum number of ingress FQs for all ingress interfaces on the device (including any of the separate FQs that are used to serve as an order restoration point (ORP))	1024 FQs
Maximum number of ingress FQs per work queue.	• 64 FQs per work queue if the aggregate bandwidth of the configured network interface(s) on the device is higher than 10 Gbit/s. • 128 FQs per work queue if the aggregate bandwidth of the configured network interface(s) on the device is 10 Gbit/s or lower.
The maximum aggregate bandwidth of the configured network interface(s) on the device receiving packets into FQs associated to the same work queue	10 Gbit/s

Table continues on the next page...

Table 122. Network Interface Ingress FQs Guidelines Summary (continued)

Parameter or subject	Guideline
Within a pool channel, minimum number of FQs per active portal (cores).	4 FQs
Within a dedicated channel, minimum number of FQs:	1 FQ
Assignment to high priority work queues.	Should be limited enough to leave sufficient SFDRs for FQs not using the reserved SFDRs (e.g. ingress FQs assigned to medium or low priority work queues).
Order restoration point (ORP).	A separate FQ should be allocated and dedicated to serve as the ORP for each ingress FQ supporting order restoration.

Ingress FQ descriptor load balancing and performance related settings.	• Prefer_in_Cache: 1
	• CPC Stash Enable: 1
	• ORP_Enable: 0
	• Avoid_Blocking:
	  • 0 if static distribution or dynamic load balancing with order preservation.
	  • 1 if dynamic load balancing with order restoration.
	• Hold_Active
	  • 0 if static distribution or dynamic load balancing with order restoration .
	  • 1 if dynamic load balancing with order preservation.
	• Force_SFDR_Allocate: 0 unless FQ needs performance optimization.
	• Intra-Class Scheduling Credit: 0 unless a more advanced scheduling scheme is required.

ORP FQ descriptor order restoration and performance related settings.	• Prefer_in_Cache: 1 • CPC Stash Enable: 1 • ORP_Enable: 1 • Avoid_Blocking: 0 • Hold_Active: 0 • Force_SFDR_Allocate: 0 • ORP Restoration Window Size: 2 (corresponds to window size of 128 frames). • Class Scheduling Credit: 0

Table 123. Network Interface Egress FQs Guidelines Summary

Parameter or subject	Guideline
Maximum number of egress FQs for all network interfaces.	128 FQs
Minimum number of egress FQs per network interface.	1 FQ
Maximum number of egress FQs per work queue.	8 FQs
Egress FQ descriptor performance related settings.	• Prefer_in_Cache: 1 • CPC Stash Enable: 1 • ORP_Enable: 0 • Avoid_Blocking: 0 • Hold_Active: 0 • Force_SFDR_Allocate: 1 • Class Scheduling Credit: 0 unless a more advanced scheduling scheme is required.

Table 124. Accelerator FQs Guidelines Summary

Parameter or subject	Guideline
Assignment to high priority work queues.	Should be limited enough to leave sufficient SFDRs for FQs not using the reserved SFDRs (e.g. accelerator FQs assigned to medium or low priority work queues).
Egress FQ descriptor performance related settings.	• Prefer_in_Cache: 0 • CPC Stash Enable: 1 • ORP_Enable: 0 • Avoid_Blocking: 0 • Hold_Active: 0 • Force_SFDR_Allocate: 0 unless FQ needs performance optimization . • Class Scheduling Credit: 0 unless a more advanced scheduling scheme is required .

7.4.4 Frame Manager

7.4.4.1 Frame Manager Linux Driver User Guide

7.4.4.1.1 Introduction

This part is describing the Linux implementation of the driver for the Frame Manager, or FMD.

The Linux driver for the Frame Manager is based on the NetCommSw drivers, or NCSW. The NCSW drivers are written in an OS-agnostic fashion, so what the Linux FMD does is to implement a set of standard Linux character devices that rely on the NCSW drivers to do the actual communication with the hardware. The figure below describes this best:

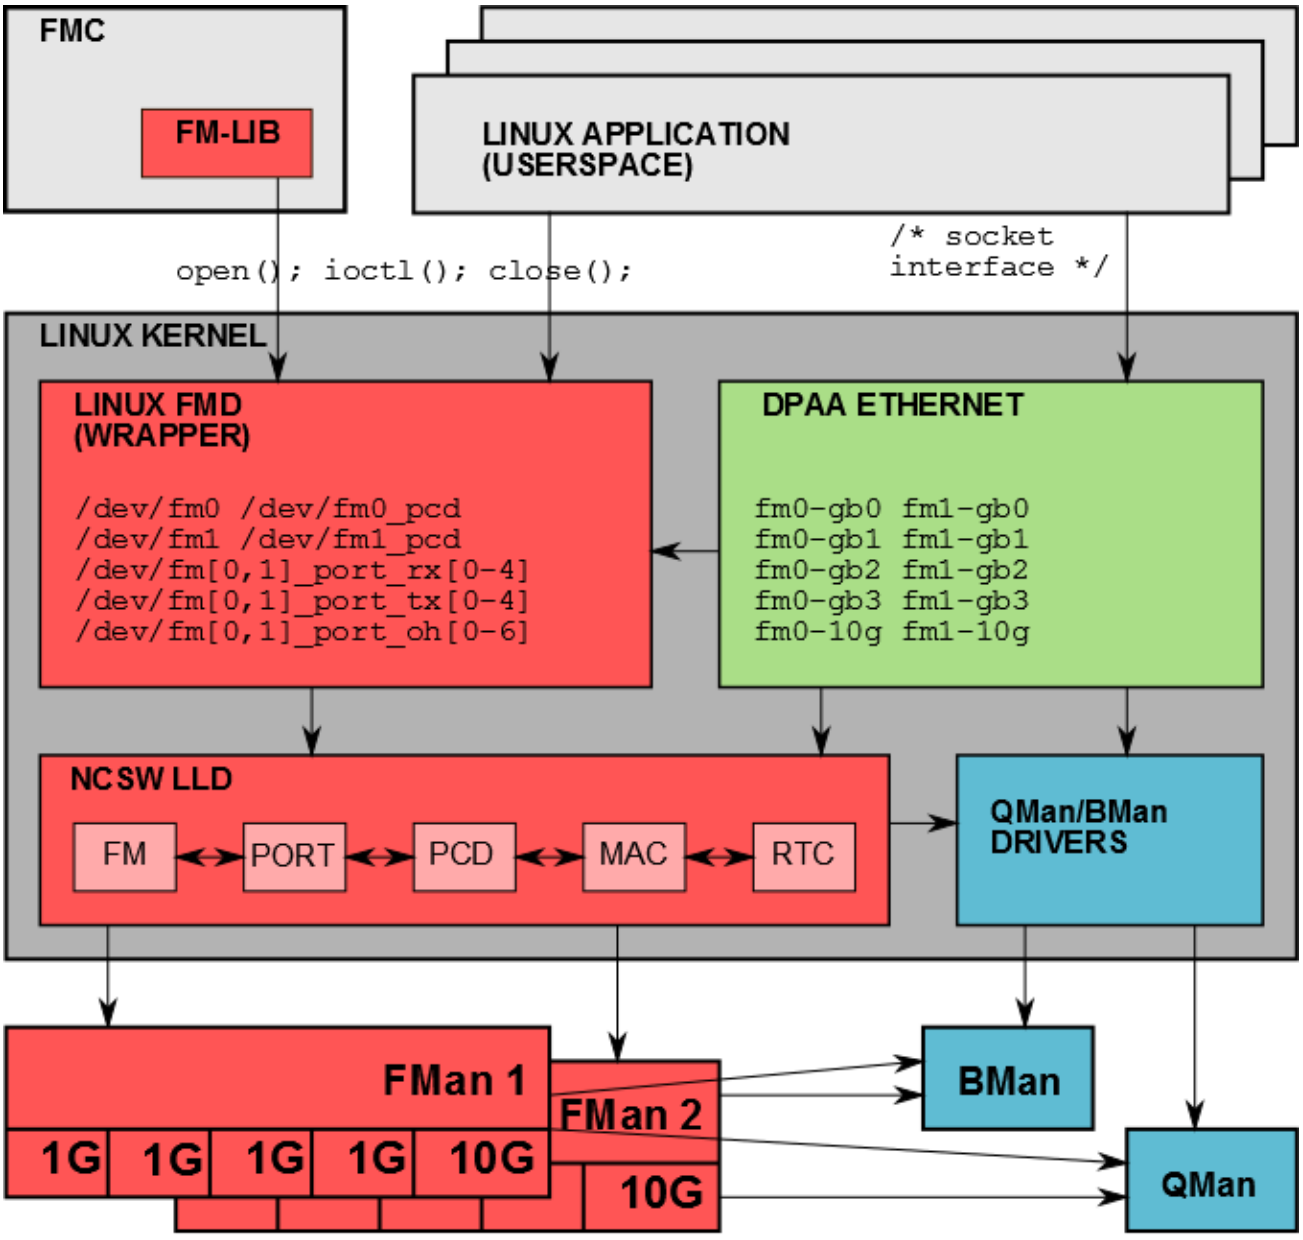

Figure 88. FMan-centric view of relationships between DPAA software and hardware blocks in the Linux environment.

The features of the Linux FMan Driver are the following:

- Performs initialization of the Frame Manager based on platform configuration (device tree), and on probing of the actual hardware;
- Supports Linux user space applications looking to create FMan PCD configurations;
- Attaches/detaches PCDs to/from FMan ports;
- Reports FMan and port status:
  - FMan registers

- FMan statistics
- FMan port and MAC counters

The Linux FMan driver does not handle actual network traffic. Network traffic in Linux is being handled exclusively by Linux network devices. Network traffic going through FMan can only be handled by the Linux DPAA Ethernet driver. Although the DPAA Ethernet and the Linux FMan Driver share strong links and interdependencies with the underlaying low-level FMD and with each other, their feature sets do not overlap. The DPAA Ethernet driver is described in the *Linux Ethernet Driver User Manual*.

Since the Linux FMD implementation relies heavily on the NCSW FMD, we strongly recommend *NetCommSw's Frame Manager Driver User's Guide* as prerequisite reading.

The USDPAA is a special case not detailed here.

7.4.4.1.2 The Linux FMD Devices

The Linux interface to the FMD consists in several Linux character devices:

- `/dev/fm[0,1]`, each corresponding to an actual Frame Manager;
- `/dev/fm[0,1]_pcd` are PCD devices corresponding each to a Frame Manager;
- `/dev/fm[0,1]_port_rx[0-4]`, and `/dev/fm[0,1]_port_tx[0-4]` corresponding to the physical ports of each FMan: each rx/tx device in a pair corresponds to the receive and transmit sides of a physical port;
- `/dev/fm[0,1]_port_oh[0-6]` correspond to the Offline Parsing ports.

These devices' creation and initialization is performed at boot time, based on probing of the physical hardware, as well as on the parsing of the device tree. Each of the physical ports can thus be disabled from the device tree, but also from the Reset Configuration Word (for details please consult the **Reset Configuration Word (RCW)** section of the **P4080 QorIQ Integrated Multicore Communication Processor Family Reference Manual**, or similar RM for other platform; for other useful reading please consult *Selecting Ethernet Interfaces* in the **QorIQ SDK Ethernet** manual).

NOTE

The assumption for the remainder of this document is that the device tree and the RCW are immutable, and therefore no attempt will be made to describe their formats in here. For details regarding the RCW/.dts, please consult the relevant documentation.

Therefore, depending on platform and on RCW/.dts configuration, some of these devices may be missing. The mapping of these devices to the physical ports is given in the following table:

Table 125. Mapping of Linux devices to low-level port IDs.

Linux Device	Low-Level ID	Identification
`/dev/fm0_port_rx0` `/dev/fm0_port_tx0`	0	1st FMan's 1st 1GbE Receive, Transmit
`/dev/fm0_port_rx1` `/dev/fm0_port_tx1`	1	1st FMan's 2nd GbE Receive, Transmit
`/dev/fm0_port_rx2` `/dev/fm0_port_tx2`	2	1st FMan's 3rd GbE Receive, Transmit
`/dev/fm0_port_rx3` `/dev/fm0_port_tx3`	3	1st FMan's 4th GbE Receive, Transmit

Table continues on the next page...

Table 125. Mapping of Linux devices to low-level port IDs. (continued)

Linux Device	Low-Level ID	Identification
/dev/fm0_port_rx4 /dev/fm0_port_tx4	4	1st FMan's 5th GbE[4] Receive, Transmit
/dev/fm0_port_rx5 /dev/fm0_port_tx5	5	1st FMan's 10Gb Receive, Transmit
N/A	0	1st FMan's Host Command
/dev/fm0_port_oh0	1	1st FMan's 1st Offline Parsing
/dev/fm0_port_oh1	2	1st FMan's 2nd Oflline Parsing
/dev/fm0_port_oh2	3	1st FMan's 3rd Offline Parsing
/dev/fm0_port_oh3	4	1st FMan's 4th Offline Parsing
/dev/fm0_port_oh4	5	1st FMan's 5th Offline Parsing

Table continues on the next page...

[4] Only on P5020.
[5] This port & devices are not available on any of the platforms supported by this release!
[6] Only P4080 has a second FMan.

Table 125. Mapping of Linux devices to low-level port IDs. (continued)

Linux Device	Low-Level ID	Identification
/dev/fm1_port_oh6	7	2nd FMan's 7th Offline Parsing Port

The Low Level IDs are the IDs that are used by the Low Level Drivers (upon which the Linux FMan Driver is based) to distinguish between the physical ports. It is obvious from the above table that the port ID alone does not allow for uniquely identifying a single port. It has to be combined wiht the following information in order to succeesfully point to the desired port:

- FMan ID: 0 or 1 for FMan1 or 2, respectively;
- Port type: 1G, 10G or O/H (Offline Parsing/Host Command).

Although all this may seem confusing at first, the LLD API provides convenient enums/macros to deal with these aspects. Furthermore, the FMD driver API tries its best to hide these details from the userspace Linux programmer, specifically by using dedicated /dev entries for each port, etc. However, not all userspace-visible API is free of such port IDs, so this is why we even mention them here.

The FMD LLD uses no distinct port IDs for Rx and Tx, the distinction between Receive and Transmit being made by calling distinct Rx/Tx-specific functions, or by specifying the "RX" or "TX" direction as a separate argument.

The Host Command ports are invisible to the Linux application. One needs to be aware, though, of their mere existence at the least, since the LLD allocates the first physical O/H port of every FMan to this purpose ("O/H" standing for "Offline Parsing/Host Command"). There are 8 such O/H ports on each FMan that can be used for these purposes; the first of these having been dedicated by the LLD to Host Commands, while the remaining 7 being available for Offline Parsing. Host Commands are just one of the vehicles through which the LLD exercises control of the FMan hardware.

NOTE

Please note that depending on the platform, RCW, and .dts configuration not all the possible combinations of devices and ports are possible, and most certainly some will be missing from any existing configuration. For details regarding possible port & device configurations for a specific platform, please consult the Reference Manuals for that platform, as well as the relevant chapters from the SDK documentation for that platform.

Alongside these character devices, and out of the scope of this writing, are the Linux network devices, labeled using the `fm[1,2]-gb[0-4]` (e.g. `fm1-gb0`, `fm2-gb3`) and `fm[1,2]-10g` (i.e. `fm1-10g`, `fm2-10g`) schemes, which provide the means for Linux to handle actual network traffic, i.e. "traffic termination". These network devices are instances of the Linux DPAA Ethernet Driver, which is architected as a separate entity from the Linux FMan Driver, but which both make use at some point of the same Low-Level Driver FMD API. The feature sets of the DPAA Ethernet and of the Linux FMan drivers are disjunct, though, which is the main reason for their coexistence.

NOTE

There is no requirement that these are the only network devices in the system. You may find the well known `eth0`, `eth1`, etc. devices alongside e.g. `fm1-gb0`, except that these other network devices will correspond to other vendors' NICs that may be installed in the system and will be serviced by vendor-specific, non-DPAA, Ethernet drivers.

There are a few constants #defined in the headers that need to be included when working with the Linux FMD (in both kernel and user spaces) that may come in handy when having to deal with devices and port IDs:

- `FM_MAX_NUM_OF_1G_RX_PORTS`
- `FM_MAX_NUM_OF_10G_RX_PORTS`
- `FM_MAX_NUM_OF_1G_TX_PORTS`
- `FM_MAX_NUM_OF_10G_RX_PORTS`
- `FM_MAX_NUM_OF_RX_PORTS`

- FM_MAX_NUM_OF_TX_PORTS
- FM_MAX_NUM_OF_OH_PORTS
- IOC_FM_MAX_NUM_OF_VALID_PORTS

that together with INTG_MAX_NUM_OF_FM can give the programmer the essential tools to get around in a specific configuration (this list, though, is not exhaustive: please consult the relevant API Reference/header files before attempting to #define your own).

Also, the

```
$ ls /dev/fm*
```

Linux shell command can conveniently show all the FMD devices currently available in the target system.

7.4.4.1.3 Linux FMD Programming Model

Given the Linux devices presented earlier, a Linux application looking to use the FMan features can use the general Linux character device syscall interface:

- open()/close() - this is essential API when working with Linux devices.
- read()/write() - although read() and write() operations are mandatory to be implemented by all Linux devices, there are no read/write semantics associated with the FMD devices.
- ioctl() calls are used extensively as the only means to communicate with the hardware. The ioctl API does little more than delegating the ioctl() syscall to the underlying LLD API (for the actual mapping of IOCTLs to actual LLD APIs, please consult the tables available in the following sections).

We'll state here once more that the programming model is essentially that of the FMD LLD. The Linux wrapper merely adapts the LLD to the Linux interface requirements. This part of the SDK documentation focuses only on the Linux specifics. For details regarding individual API calls, please refer to the *Frame Manager Driver API Reference Manual* .

As is the case with any Linux device, the general sequence of actions when using the FMD devices is the following:

1. Linux boots: all /dev/fm* devices are being created, FMan resources initialized according to platform/RCW/.dts;
2. User launches FMD-aware application;
3. User app. performs open() on selected /dev/fm* device/s;
4. User app. performs ioctl() call/s on the fd returned by the previous successful open() call;
5. When the user app. decides it has finished working with selected /dev/fm* device, it must call close() on its fd, just like on any other Linux device.

Not all the LLD functions have a correspondent in the FMD IOCTLs. Only those functions have been selected which makes sense from an architectural standpoint. The same/other LLD functions are also being called by the Linux wrapper unrestrictedly, as needed to perform its required actions, and not only in response to ioctl() calls.

The arguments of the ioctl() calls can be quite complex, and may have complex requirements, as they are described in the **LLD API Reference** (Frame Manager Driver API Documentation).

The following required low-level initialization APIs: FM_Config(), FM_PCD_Config(), FM_PORT_Config(), and subsequently FM_Init(), FM_PCD_Init(), FM_PORT_Init() are being called from within the Linux FMD initialization code at boot time. They are therefore not accessible to the user space application. Any configuration of FMan hardware resources will be performed using Linux-specific means: device tree, kernel build configuration, etc. Code in the DPAA Ethernet driver also initializes the configured MACs using FM_MAC_Config(), then FM_MAC_Init(), as required by the *Frame Manager Driver API Reference Manual*, and as described in *The DPAA Ethernet Driver's User Manual*.

The correspondence between FMD Linux devices and DPAA ETH network devices is intuitive: there is a pair of /dev/fmX_port_(rxY|txY) devices for each fmX-gbY or fmX-10g device in the system. However, due to configuration, it is possible that at boot time not all FMan ports be probed by the DPAA Ethernet driver, hence not all /dev/fmX_port_(rxY|txY) may have a corresponding netdev. This is because the FMan port devices and the DPAA Ethernet devices are being configured in different sections of the device tree. The binding between these devices is also done in the device tree.

While Offline Parsing ports are being fully supported by the FMan Driver, currently it is not possible to inject traffic from user space to these ports, as there is no netdev being created for them, as the Linux FMD does not handle traffic. There is indeed a way for kernel space drivers or e.g. USDPAA apps. to use them, but that is out of scope here.

It is not to be expected that a FMan port device for which a corresponding DPAA Ethernet netdev has not been configured, to be fully functional. That is because port functionality is reliant also upon additional DPAA resources (i.e. frame queues, buffer pools) that are being initialized exclusively by the DPAA Ethernet driver. Therefore, even though `/dev/fmX_port_*` devices may exist for such ports, trying to access them may result in an error.

`FM_PORT_Enable()` and `FM_PORT_Disable()` are called for specific ports during `ifconfig up/down` of the corresponding network device (DPAA Ethernet-specific). They are also available as IOCTLs for the `/dev/fmX_port*` devices, but while in the DPAA Ethernet they are called for both ports of the RX/TX pair, the `/dev/fmX_port_(rxY|txY)` allow for selectively enabling/disabling of only one of the RX/TX sides, as desired.

The `ioctl()` API conforms to Linux rules for all FMD devices. However, errors originating within the LLD will invariably be reported to the user as `-EFAULT`. All such errors should be considered non-recoverable and should be immediately followed by a `close()` on the device for which they were reported. A more descriptive message should be printed on the bootup console only, identifying the LLD function, and the line in the source file where the error has occurred. One can look at the documentation for `enum e_ErrorType` in the **LLD API Reference** (Frame Manager Driver API Documentation) for details regarding all the possible LLD error codes and their general meaning.

The following sections will present a brief description of each type of Linux device, as well as their IOCTLs' mapping to the FMD LLD API.

7.4.4.1.4 The Linux FMan Device

This device corresponds to an individual Frame Manager, and is required for performing FMan-wide actions. The FMan device merely acts as a portal for the IOCTLs that are listed in the table below:

Table 126. IOCTLs for the FMan Device

IOCTL	LLD Mapping	Brief
`FM_IOC_SET_PORTS_BANDWIDTH`	`FM_SetPortsBandwidth()`	Sets ports' bandwidths as percentage of total bandwidth.
`FM_IOC_GET_REVISION`	`FM_GetRevision()`	API to get the FMan's revision.
`FM_IOC_GET_COUNTER`	`FM_GetCounter()`	API to read FMan hardware counters (also available through sysfs).
`FM_IOC_SET_COUNTER`	`FM_ModifyCounter()`	API to modify/reset FMan's counters.
`FM_IOC_FORCE_INTR`	`FM_ForceIntr()`	Forces an FMan interrupt (or exception). Dangerous! Use for debugging only!
`FM_IOC_GET_API_VERSION`	`FM_GetApiVersion()`	Reads the FMD IOCTL API version.
`FM_IOC_VSP_CONFIG`	`FM_VSP_Config()`	Creates descriptor for the FM VSP module.
`FM_IOC_VSP_INIT`	`FM_VSP_Init()`	Initializes the FM VSP module
`FM_IOC_VSP_FREE`	`FM_VSP_Free()`	Frees all resources that were assigned to FM VSP module.

Table continues on the next page...

Table 126. IOCTLs for the FMan Device (continued)

IOCTL	LLD Mapping	Brief
FM_IOC_VSP_CONFIG_POOL_DEPLETION	FM_VSP_ConfigPoolDepletion()	Calling this routine enables pause frame generation depending on the depletion status of BM pools. It also defines the conditions to activate this functionality. By default, this functionality is disabled.
FM_IOC_VSP_CONFIG_BUFFER_PREFIX_CONTENT	FM_VSP_ConfigBufferPrefixContent()	Defines the structure, size and content of the application buffer.
FM_IOC_VSP_CONFIG_NO_SG	FM_VSP_ConfigNoScatherGather()	Returns the pointer to the parse result in the data buffer. In Rx ports this is relevant after reception, if parse result is configured to be part of the data passed to the application. For non Rx ports it may be used to get the pointer of the area in the buffer where parse result should be initialized - if so configured. See FM_VSP_ConfigBufferPrefixContent for data buffer prefix configuration.
FM_IOC_CTRL_MON_START	FM_CtrlMonStart()	Start monitoring utilization of all available FM controllers.
FM_IOC_CTRL_MON_STOP	FM_CtrlMonStop()	Stop monitoring utilization of all available FM controllers.
FM_IOC_CTRL_MON_GET_COUNTERS	FM_CtrlMonGetCounters()	Obtain FM controller utilization parameters.

All the IOCTL-mapped LLD APIs are what the LLD terms as "callable at runtime", i.e. callable after the LLD `Init()` function for the corresponding entity has been called. This is so because by the time the user app. gets to invoke `ioctl()`, all the `Init()` functions have already been called by the initialization code of the Linux FMD at boot time.

7.4.4.1.5 The Linux PCD Device

There is exactly one PCD device, or `/dev/fmX_pcd`, for each Frame Manager. The reason for that is that PCDs are FMan-wide constructs, and are applied simultaneously to traffic being received on possibly more than one port.

"PCD" is a generic term designating a Parse-Classify-Distribute configuration for a group of ports, as described in detail in the **QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual**. In short, what a PCD does is to route incoming traffic from a set of RX ports onto several frame queues managed by the Queue Manager. Such frame queues may be attached to a DPAA Ethernet network device, in which case the traffic is received by the CPUs (or "terminated"), or they can be connected to a TX port, in which case the traffic is being forwarded onto that port. Also, frame queues can be further grouped into work queues & policed, etc. (please read the QMan documentation). However, one thing is not supported in the Linux environment, and that is: direct access to frame queues from user space (please note that this is not a limitation of the Linux FMD, but one enforced by design in the Linux driver for the QMan). Not in the classical meaning of "Linux environment", that is. If one needs to create complex DPAA scenarios that are not possible/cumbersome using the current Linux FMD, then USDPAA may hold the answer they're looking for.

There's still a lot that can be achieved with the Linux FMD, and the Linux PCD device is there to help. Its role is to manage the PCDs for its associated FMan. The ioctls for this device are mapped to the similarly-sounding `FM_PCD_*()` LLD APIs:

Table 127. IOCTL List for the PCD Device

IOCTL	LLD Mapping	Brief
FM_PCD_IOC_ENABLE	FM_PCD_Enable()	Should be called after PCD is initialized for enabling all PCD engines according to their existing configuration.
FM_PCD_IOC_DISABLE	FM_PCD_Disable()	Disables an existing PCD.
FM_PCD_IOC_PRS_LOAD_SW[_COMPAT]	FM_PCD_PrsLoadSw()	This routine may be called only when all ports in the system are actively using the classification plan scheme. In such cases it is recommended in order to save resources. The driver automatically saves 8 classification plans for ports that do NOT use the classification plan mechanism; to avoid this (in order to save those entries) this routine may be called.
FM_PCD_IOC_KG_SET_DFLT_VALUE	FM_PCD_KgSetDfltValue()	Sets a global default value to be used by the key generator when the parser does not recognize a required field/ header (default 0).
FM_PCD_IOC_KG_SET_ADDITIONAL_DATA_AFTER_PARSING	FM_PCD_KgSetAdditionalDataAfterParsing()	Calling this routine allows the keygen to access data past the parser finishing point.
FM_PCD_IOC_SET_EXCEPTION	FM_PCD_SetException()	Enables/disables PCD interrupts.
FM_PCD_IOC_GET_COUNTER	N/A	Unimplemented, do not use!
FM_PCD_IOC_SET_COUNTER	N/A	Placeholder, do not use!
FM_PCD_IOC_FORCE_INTR	FM_PCD_ForceIntr()	Forces a PCD interrupt (exception) of specified type. Dangerous! Use only for debugging!
FM_PCD_IOC_NET_ENV_CHARACTERISTICS_SET[_COMPAT]	FM_PCD_NetEnvCharacteristicsSet()	Establishes a minimal set of networking protocols ("Network Environment Characteristics") that can be discovered by this PCD (please refer to the Reference Manual for details).
FM_PCD_IOC_NET_ENV_CHARACTERISTICS_DELETE[_COMPAT]	FM_PCD_NetEnvCharacteristicsDelete()	Deletes a set of "Network Environment Characteristics".

Table continues on the next page...

Table 127. IOCTL List for the PCD Device (continued)

IOCTL	LLD Mapping	Brief
FM_PCD_IOC_KG_SCHEME_SET[_COMPAT]	FM_PCD_KgSchemeSet()	Initializes or modifies and enables a scheme for the KeyGen. This routine should be called for adding or modifying a scheme. When a scheme needs modifying, the API requires that it be rewritten. In such a case modify should be TRUE. If the routine is called for a valid scheme and modify is FALSE, it will return error.
FM_PCD_IOC_KG_SCHEME_DELETE[_COMPAT]	FM_PCD_KgSchemeDelete()	Deletes an initialized scheme.
FM_PCD_IOC_CC_ROOT_BUILD[_COMPAT]	FM_PCD_CcRootBuild()	This routine must be called to define a complete coarse classification tree. This is the way to define coarse classification to a certain flow - the KeyGen schemes may point only to trees defined in this way.
FM_PCD_IOC_CC_ROOT_DELETE[_COMPAT]	FM_PCD_CcRootDelete()	Deletes an existing coarse classification tree.
FM_PCD_IOC_MATCH_TABLE_SET[_COMPAT]	FM_PCD_MatchTableSet()	This routine should be called for each CC (coarse classification) node. The whole CC tree should be built bottom up so that each node points to already defined nodes. p_node_id returns the node Id to be used by other nodes.
FM_PCD_IOC_MATCH_TABLE_DELETE[_COMPAT]	FM_PCD_MatchTableDelete()	Deletes a built node.
FM_PCD_IOC_CC_ROOT_MODIFY_NEXT_ENGINE[_COMPAT]	FM_PCD_CcRootModifyNextEngine()	Modifies the Next Engine Parameters in the entry of the tree (allowed only after FM_PCD_CcBuildTree()).
FM_PCD_IOC_MATCH_TABLE_MODIFY_NEXT_ENGINE[_COMPAT]	FM_PCD_MatchTableModifyNextEngine()	Modifies the Next Engine Parameters in the relevant key entry of the node (possible only after a call to FM_PCD_MatchTableSet()).
FM_PCD_IOC_MATCH_TABLE_MODIFY_MISS_NEXT_ENGINE[_COMPAT]	FM_PCD_MatchTableModifyMissNextEngine()	Modifies the Next Engine Parameters of the Miss key case of the node (allowed only after a previous call to FM_PCD_MatchTableSet()).

Table continues on the next page...

Table 127. IOCTL List for the PCD Device (continued)

IOCTL	LLD Mapping	Brief
FM_PCD_IOC_MATCH_TABLE_REMOVE_KEY[_COMPAT]	FM_PCD_MatchTableRemoveKey()	Removes the key (including its next engine parameters) defined by the index of the relevant node (allowed only after a previous call to FM_PCD_MatchTableSet())
FM_PCD_IOC_MATCH_TABLE_ADD_KEY[_COMPAT]	FM_PCD_MatchTableAddKey()	Adds the key (including next engine parameters of this key) in the index defined by key_index (allowed only after a previous call to FM_PCD_MatchTableSet())
FM_PCD_IOC_MATCH_TABLE_MODIFY_KEY_AND_NEXT_ENGINE[_COMPAT]	FM_PCD_MatchTableModifyKeyAndNextEngine()	Modifies the key and Next Engine Parameters of this key in the index defined by key_index (allowed only after a previous call to FM_PCD_MatchTableSet()).
FM_PCD_IOC_MATCH_TABLE_MODIFY_KEY[_COMPAT]	FM_PCD_MatchTableModifyKey()	Modifies the key at the index defined by key_index (allowed only after a previous call to FM_PCD_MatchTableSet()).
FM_PCD_IOC_HASH_TABLE_SET[_COMPAT]	FM_PCD_HashTableSet()	Initializes a hash table structure.
FM_PCD_IOC_HASH_TABLE_DELETE[_COMPAT]	FM_PCD_HashTableDelete()	Deletes the provided hash table and released all its allocated resources.
FM_PCD_IOC_HASH_TABLE_ADD_KEY[_COMPAT]	FM_PCD_HashTableAddKey()	Adds the provided key (including next engine parameters of this key) to the hash table. The key is added as the last key of the bucket that it is mapped to.
FM_PCD_IOC_HASH_TABLE_REMOVE_KEY[_COMPAT]	FM_PCD_HashTableRemoveKey()	Removes the requested key (including its next engine parameters) from the hash table.
FM_PCD_IOC_PLCR_PROFILE_SET[_COMPAT]	FM_PCD_PlcrProfileSet()	Sets a profile entry in the policer profile table, overriding any existing value.
FM_PCD_IOC_PLCR_PROFILE_DELETE[_COMPAT]	FM_PCD_PlcrProfileDelete()	Deletes a profile entry in the policer profile table. It sets the entry to invalid.
FM_PCD_IOC_MANIP_NODE_SET[_COMPAT]	FM_PCD_ManipNodeSet()	This routine should be called for defining a manipulation node. A manipulation node must be defined before the CC node that precedes it.

Table continues on the next page...

Table 127. IOCTL List for the PCD Device (continued)

IOCTL	LLD Mapping	Brief
FM_PCD_IOC_MANIP_NODE_REPLACE[_COMPAT]	FM_PCD_ManipNodeReplace()	Change existing manipulation node to be according to new requirement.
FM_PCD_IOC_MANIP_NODE_DELETE[_COMPAT]	FM_PCD_ManipNodeDelete()	Deletes an existing manipulation node.
FM_PCD_IOC_SET_ADVANCED_OFFLOAD_SUPPORT	FM_PCD_SetAdvancedOffloadSupport()	This routine must be called in order to support the following features: IP-fragmentation, IP-reassembly, IPsec, header manipulation, frame replicator.
FM_PCD_IOC_FRM_REPLIC_GROUP_SET[_COMPAT]	FM_PCD_FrmReplicSetGroup()	Initialize a Frame Replicator group.
FM_PCD_IOC_FRM_REPLIC_GROUP_DELETE[_COMPAT]	FM_PCD_FrmReplicDeleteGroup()	Delete a Frame Replicator group.
FM_PCD_IOC_FRM_REPLIC_MEMBER_ADD[_COMPAT]	FM_PCD_FrmReplicAddMember()	Add the member in the index defined by the memberIndex.
FM_PCD_IOC_FRM_REPLIC_MEMBER_REMOVE[_COMPAT]	FM_PCD_FrmReplicRemoveMember()	Remove the member defined by the index from the relevant group.
FM_PCD_IOC_STATISTICS_SET_NODE[_COMPAT]	FM_PCD_StatisticsSetNode()	Not implemented in this release. Do not use!
FM_PCD_IOC_KG_SCHEME_GET_CNTR	FM_PCD_KgSchemeGetCounter()	Reads scheme packet counter.

NOTE

The _COMPAT variants of certain IOCTLs in the above table are required for supporting 32-bit user space apps. on 64-bit Linux kernels. The specifics of the COMPAT mappings are documented by Linux.

The programming model for defining and managing PCDs for a group of ports is the same as described in the **FMD LLD User's Guide** .

What follows is a step-by-step description of an example of ioctl() call mapping to a LLD API call.

The example chosen for this walk-through is that of FM_PCD_IOC_MATCH_TABLE_SET. Here's a reminder of the ioctl() prototype:

```
extern int ioctl (int __fd, unsigned long int __request, ...) __THROW;
```

and below is how it appears to kernel space:

```
struct file_operations {
 [...]
 long (*unlocked_ioctl) (struct file *, unsigned int, unsigned long);
 [...]
};
```

The `ioctl()` function is actually a pointer to a driver-supplied function having the specified signature. The glue between the two is kernel code.

The semantics associated with the second and third function arguments are entirely the driver's business, but usually the `unsigned int` argument is used to discriminate between various ioctl commands (actually, it should obey some Linux good-behavior rules, which we are not going to detail here). In our case, it should be `FM_PCD_IOC_MATCH_TABLE_SET`.

Linux attaches no predefined semantics to the third argument, the `unsigned long` one. In some cases it is unused, or its semantics are those of an unsigned integer number, but in most cases it is treated as a (32-bit, on most platforms) pointer to a driver-defined structure in user space. The driver defines the format, but the user space allocates and fills in the data prior to invoking `ioctl()` on the open device `fd`. This is also the case with our example.

The format of the third argument of the `FM_PCD_IOC_MATCH_TABLE_SET` ioctl is (as it actually appears in the header file where it's defined):

```
/**************************************************************************//**
 @Description   A structure for defining the CC node params
*//***************************************************************************/
typedef struct ioc_fm_pcd_cc_node_params_t {
    ioc_fm_pcd_extract_entry_t extract_cc_params;
                                            /**< params which defines extraction
                                            parameters */

    ioc_keys_params_t          keys_params;    /**< params which defines Keys
                                            parameters of the extraction defined
                                            in extract_cc_params */

    void                       *id;            /**< output parameter;
                                            Returns the CC node Id to be used */
} ioc_fm_pcd_cc_node_params_t;
```

We'll detail the `ioc_*` types of the first two members later. The third member of this structure is apparently a pointer to some data structure being returned back to user space. It is not the case. This actual pointer should be handled as an opaque handle to some abstract item, in our case the "CC Node" that's being created for us by this `ioctl()` call if successful. This handle can be later passed to e.g. the `FM_PCD_IOC_MATCH_TABLE_DELETE` IOCTL for deletion. It corresponds to an actual `t_Handle`, as defined by the LLD.

NOTE

Failing to cleanup FMan resources that the LLD allocates in this manner can cause serious hardware resource leaks, which neither the Linux FMD, nor the LLD have the means to detect & cleanup automatically!

The LLD function that this IOCTL maps to has the following prototype:

```
t_Handle FM_PCD_MatchTableSet(t_Handle, t_FmPcdCcNodeParams *);
```

The first argument corresponds to the LLD resource that the Linux PCD device maps to. Most of the LLD resources are managed within the Linux FMD driver and not exposed to the user, but there are exceptions and the `FM_PCD_MatchTableSet()` function here is the best example, as it returns a `t_Handle` to such a LLD resource. This returned `t_Handle` is then passed over to the user space in the opaque `id` member of `ioctl()`'s third argument.

The second argument is a pointer to a structure of type `t_FmPcdCcNodeParams`. This maps to the `ioc_fm_pcd_cc_node_params_t` type that `ioctl()`'s third argument points to.

NOTE

Passing to `ioctl()` a pointer to something of a type other than the required one will cause the user application to segfault, or an error, at best, but may also cause undefined FMan behavior from that point onward, with errors being possibly reported only later downstream as the worst case. Linux/the FMD can do very little to prevent this worst case from occurring, so hopefully one can catch such coding errors early during the development cycle.

A side-by-side comparison of the two structures is given in the following table:

Table 128. Side-by-side comparison of IOCTL and LLD types

IOCTL Types	LLD Types

`typedef struct ioc_fm_pcd_cc_node_params_t {`
`  ioc_fm_pcd_extract_entry_t  extract_cc_params;`
`  ioc_keys_params_t  keys_params;`
`  void  *id;`
`} ioc_fm_pcd_cc_node_params_t;`
	`typedef struct t_FmPcdCcNodeParams {`
	`  t_FmPcdExtractEntry  extractCcParams;`
	`  t_KeysParams  keysParams;`
	
	`} t_FmPcdCcNodeParams;`

`typedef struct ioc_fm_pcd_extract_entry_t {`

While the structure members have resembling names on both sides, most are not identical. That's because style has prevailed over the need to port existing LLD applications to the Linux environment, when the Linux FMD was designed (there is a more complete porting guide included in the NCSW software bundle, though, that's not also included in this SDK; one may refer to that for the specific topic of porting existing NCSW apps. to various platforms). Except for the occasional `*id` pointer, there is a 1:1 mapping between the struct members on the two sides, and that is consistent throughout the FMD.

The constituent structures of the two APIs' argument types given above are for illustration only. Their semantics are documented in the Frame Manager Driver API Documentation .

NOTE

The existence of two separate definitions for otherwise two identical data structures may appear as an unfortunate design decision. However, since a *memcpy* from user space to kernel space is unavoidable, this design decision has no impact over performance. Moreover, the user space only sees one variant (i.e. the `ioc_*` one), hence the even smaller user impact. The larger impact is on code maintenance and on documentation.

7.4.4.1.6 The Linux Port Devices

There is a pair of RX/TX Linux character devices for each physical port of every Frame Manager. These devices are created irrespectively of the DPAA Ethernet network devices and they are strictly reflecting the available Frame Manager hardware on the given platform. The port Linux devices are labeled as follows:

- `/dev/fmX_port_rxY` for receive, where X=[0,1] represents the FMan number, and Y=[0-5] represents the physical port ID (0 corresponding to the first 1 Gb port, and 5 to the 10 Gb port), and
- `/dev/fmX_port_txY` correspondingly for the transmit side.

Each FMan also has a number of Offline Parsing ports. These are labeled as `/dev/fmX_port_ohY`, where Y=[0-6].

The port devices are created based on configuration information taken from the relevant Linux device tree section.

For instance, P5020 only has one FMan with 5 x 1Gb ports and one 10Gb port, while P4080 has two FMans, each having 4 x 1Gb and 1 x 10Gb ports. A side-by-side comparison of the corresponding port devices is given in the following table:

Table 129. Side-by-side comparison of port devices for P5020 and P4080.

P5020	P4080

For the Receive side:
`/dev/fm0_port_rx0`
`/dev/fm0_port_rx1`
`/dev/fm0_port_rx2`
`/dev/fm0_port_rx4`
`/dev/fm0_port_rx5`
	For the Receive side:
	`/dev/fm0_port_rx0`
	`/dev/fm0_port_rx1`
	`/dev/fm0_port_rx2`
	`/dev/fm0_port_rx3`
	`/dev/fm0_port_rx5`
	`/dev/fm1_port_rx0`
	`/dev/fm1_port_rx1`
	`/dev/fm1_port_rx2`
	`/dev/fm1_port_rx3`
	`/dev/fm1_port_rx5`

Table continues on the next page...

Table 129. Side-by-side comparison of port devices for P5020 and P4080. (continued)

P5020	P4080

For the Transmit side:
`/dev/fm0_port_tx0`
`/dev/fm0_port_tx1`
`/dev/fm0_port_tx2`
`/dev/fm0_port_tx3`
`/dev/fm0_port_tx4`
`/dev/fm0_port_tx5`
	For the Transmit side:
	`/dev/fm0_port_tx0`
	`/dev/fm0_port_tx1`
	`/dev/fm0_port_tx2`
	`/dev/fm0_port_tx3`
	`/dev/fm0_port_tx5`
	`/dev/fm1_port_tx0`
	`/dev/fm1_port_tx1`
	`/dev/fm1_port_tx2`
	`/dev/fm1_port_tx3`
	`/dev/fm1_port_tx5`

For Offline Parsing:
`/dev/fm0_port_oh0`
`/dev/fm0_port_oh1`
`/dev/fm0_port_oh2`
`/dev/fm0_port_oh3`
`/dev/fm0_port_oh4`
`/dev/fm0_port_oh5`
`/dev/fm0_port_oh6`
	For Offline Parsing:
	`/dev/fm0_port_oh0`
	`/dev/fm0_port_oh1`
	`/dev/fm0_port_oh2`
	`/dev/fm0_port_oh3`
	`/dev/fm0_port_oh4`
	`/dev/fm0_port_oh5`
	`/dev/fm0_port_oh6`
	`/dev/fm1_port_oh0`
	`/dev/fm1_port_oh1`
	`/dev/fm1_port_oh2`
	`/dev/fm1_port_oh3`
	`/dev/fm1_port_oh4`
	`/dev/fm1_port_oh5`
	`/dev/fm1_port_oh6`

NOTE

The `/dev/fmX_port_(rx4|tx4)` pairs of port devices are missing in the P4080, for numbering consistency reasons: this way the 10G ports will have the same IDs on every QorIQ platform that has them, thus greatly reducing the possibility for confusion, and adding to cross-platform code portability.

The table below summarizes the IOCTLs available for the port device.

Table 130. IOCTLs of the Port Device

IOCTLS	LLD Mapping	Brief
`FM_PORT_IOC_DISABLE`	`FM_PORT_Disable()`	Disables the port: all port settings are preserved, but all traffic stops.
`FM_PORT_IOC_ENABLE`	`FM_PORT_Enable()`	Enables the port: causes the port to start processing traffic.

Table continues on the next page...

Table 130. IOCTLs of the Port Device (continued)

IOCTLS	LLD Mapping	Brief
FM_PORT_IOC_SET_RATE_LIMIT	FM_PORT_SetRateLimit()	(TX & O/H Only) Activates the Rate Limiting Algorithm for the port.
FM_PORT_IOC_DELETE_RATE_LIMIT	FM_PORT_DeleteRateLimit()	(TX & O/H Only) Deactivates any Rate Limiting.
FM_PORT_IOC_SET_ERRORS_ROUTE	FM_PORT_SetErrorsRoute()	(RX & O/H Only) Instructs the FMD to enqueue frames w/specific errors onto the normal port queues, rather than onto the error queue (i.e. the default).
FM_PORT_IOC_ALLOC_PCD_FQIDS	N/A	For testing/debugging. Do not use!
FM_PORT_IOC_FREE_PCD_FQIDS	N/A	For testing/debugging. Do not use!
FM_PORT_IOC_SET_PCD[_COMPAT]	FM_PORT_SetPCD()	(RX & O/H Only) Defines a PCD configuration for the port.
FM_PORT_IOC_DELETE_PCD	FM_PORT_DeletePCD()	(RX & O/H Only) Deletes the port's PCD configuration.
FM_PORT_IOC_DETACH_PCD	FM_PORT_DetachPCD()	(RX & O/H Only) Disables the PCD configuration for the port (only allowed after FM_PORT_SetPCD() has been called for the port).
FM_PORT_IOC_ATTACH_PCD	FM_PORT_AttachPCD()	(RX & O/H Only) Re-enables the PCD configuration for the port (only valid after a call to FM_PORT_DetachPCD()).
FM_PORT_IOC_PCD_PLCR_ALLOC_PROFILES	FM_PORT_PcdPlcrAllocProfiles()	(RX & O/H Only) Allocates private policer profiles for the port (only allowed before a a call to FM_PORT_SetPCD()).
FM_PORT_IOC_PCD_PLCR_FREE_PROFILES	FM_PORT_PcdPlcrFreeProfiles()	(RX & O/H Only) Frees any private policer profiles allocated for the port (callable only before FM_PORT_SetPCD()).
FM_PORT_IOC_PCD_KG_MODIFY_INITIAL_SCHEME[_COMPAT]	FM_PORT_PcdKgModifyInitialScheme()	(RX & O/H Only) Modifies key generation scheme following frame parsing (callable only after FM_PORT_SetPCD()).
FM_PORT_IOC_PCD_PLCR_MODIFY_INITIAL_PROFILE[_COMPAT]	FM_PORT_PcdPlcrModifyInitialProfile()	(RX & O/H Only) Changes the initial policer profile for the port (callable only after FM_PORT_SetPCD()).

Table continues on the next page...

Table 130. IOCTLs of the Port Device (continued)

IOCTLS	LLD Mapping	Brief
FM_PORT_IOC_PCD_CC_MODIFY_TREE[_COMPAT]	FM_PORT_PcdCcModifyTree()	(RX & O/H Only) Replaces the coarse classification tree if one is used for the port (callable only after FM_PORT_DetachPCD() and before FM_PORT_AttachPCD()).
FM_PORT_IOC_PCD_KG_BIND_SCHEMES[_COMPAT]	FM_PORT_PcdKgBindSchemes()	(RX & O/H Only) Adds more KeyGen schemes for the port to be bound to (callable only after FM_PORT_SetPCD()).
FM_PORT_IOC_PCD_KG_UNBIND_SCHEMES[_COMPAT]	FM_PORT_PcdKgUnbindSchemes()	(RX & O/H Only) Prevents the port from using the specified KG schemes (callable only after FM_PORT_SetPCD())
FM_PORT_IOC_PCD_PRS_MODIFY_START_OFFSET	FM_PORT_PcdPrsModifyStartOffset()	(RX & O/H Only) Changes the frame offset at which parsing starts (callable only after FM_PORT_DetachPCD() and before FM_PORT_AttachPCD()).
FM_PORT_IOC_ADD_CONGESTION_GRPS	FM_PORT_AddCongestionGrps()	(RX & O/H Only) Should be called in order to enable pause frame transmission in case of congestion in one or more of the congestion groups relevant to this port. Each call to this routine may add one or more congestion groups to be considered relevant to this port.
FM_PORT_IOC_REMOVE_CONGESTION_GRPS	FM_PORT_RemoveCongestionGrps()	(RX & O/H Only) Should be called when congestion groups were defined for this port and are no longer relevant, or pause frames transmitting is not required on their behalf. Each call to this routine may remove one or more congestion groups to be considered relevant to this port.
FM_PORT_IOC_ADD_RX_HASH_MAC_ADDR	FM_MAC_AddHashMacAddr()	Add an Address to the hash table. This is for filter purpose only.
FM_PORT_IOC_REMOVE_RX_HASH_MAC_ADDR	FM_MAC_RemoveHashMacAddr()	Delete an Address to the hash table. This is for filter purpose only.
FM_PORT_IOC_SET_TX_PAUSE_FRAMES	FM_MAC_SetTxPauseFrames()	Enable/Disable transmission of Pause-Frames. The routine changes the default configuration: pause-time - [0xf000], threshold-time - [0]

Table continues on the next page...

Table 130. IOCTLs of the Port Device (continued)

IOCTLS	LLD Mapping	Brief
FM_PORT_IOC_GET_MAC_STATISTICS	FM_MAC_GetStatistics()	Get all MAC statistics counters.
FM_PORT_IOC_CONFIG_BUFFER_PREFIX_CONTENT	FM_PORT_ConfigBufferPrefixContent()	Defines the structure, size and content of the application buffer.
FM_PORT_IOC_VSP_ALLOC[_COMPAT]	FM_PORT_VSPAlloc()	This routine allocated VSPs per port and forces the port to work in VSP mode. Note that the port is initialized by default with the physical-storage-profile only.

NOTE

The COMPAT variants of certain IOCTLs in the above table are required for supporting 32-bit user space apps. on 64-bit Linux kernels. The specifics of the COMPAT mappings are documented by Linux.

The programming model for managing the FMan's ports is the same as described in the *Frame Manager Driver API Reference*. A few notable mentions though:

Although all the above IOCTLs are implemented by the Linux FMD, due to the asymmetry between RX and TX, not all are available for any port type. E.g. FM_PORT_IOC_SET_PCD will generate an error if called on a TX port device. Similarly, FM_PORT_IOC_SET_RATE_LIMIT will fail for an RX port. That is because the checking of the port type is being done late, inside the LLD, and not in the Linux FMD (i.e. the ioctl() calls for all port devices delegate to the same function inside the Linux kernel)!

The Offline Parsing ports have the best of both worlds. That is because conceptually, an O/H port is no different from a "regular" FMan port that has the TX side looped back internally to its RX side.

7.4.4.2 Frame Manager Linux Driver API Reference

This document describes the interface (IOCTLs) to the Frame Manager Linux Driver as apparent to user space Linux applications that need to use any of the Frame Manager's features. It describes the structure, concept, functionality, and high level API.

7.4.4.3 Frame Manager Driver User's Guide

7.4.4.3.1 Frame Manager Driver

7.4.4.3.1.1 Introduction

The Frame Manager is a hardware accelerator responsible for preprocessing and moving packets into and out of the datapath. It supports in-line/off-line packet parsing and initial classification to enable policing and flow/QoS based packet distribution to the CPUs for further processing of the packets.

The Frame Manager consists of a number of packet processing elements (also referred to as engines) and supports a flexible pipeline. Usually, the main Rx flow (simplified) follows these steps: packets are received from one of the Ethernet MACs, are temporarily stored in the FMan internal memory, then delivered to SoC memory via the FMan DMA. The packet header (max size 256 bytes) is stored and the modules common database structure is allocated. Then the packet is parsed by the parser or by the FMan controller. According to parsing results a key may be extracted by KeyGen, a destination frame-queue-id may be set, the packet may be classified by the FMan controller. in that stage, some offloads may be done like re-assembly, fragmentation, header-manipulation and frame-replication. At the end of the classification and manipulations stage, the packet may be colored by policer. At the end of this process, packets are delivered to SoC memory via the FMan DMA and then are enqueued to a frame queue or dropped. The processing order is Parse-Classify-Distribute (PCD) flow dependant, based on

user configurations. Each step is dependant on previous state results. This structure enables flexibility, which efficiently supports many flows.

On Tx the frames are transmitted via the desired MAC with optional checksum generation.

7.4.4.3.1.2 Frame Manager Features

The FMan driver aims to support the majority of the hardware features. It also includes exclusive software features designed to provides facilitation through abstraction.

Following are the features of the FMan driver:

- Simple initialization and configuration API for the following FMan blocks: DMA, FPM, IRAM, QMI, BMI, and RTC.
- Simple initialization and configuration for the following FMan PCD blocks: Parser, Keygen, Custom-Classifier (CC), Manipulations (e.g. Header-manipulations, IP-reassembly, IP-fragmentation, etc.) and Policer.
- FMan memory (MURAM) management.
- FMan-controller code loading.
- Software-Parser loading.
- Supported all FMan port types-Rx, Tx, Offline-Parsing, and Host-Command (internal use of the driver only)
- Common MAC API for dTSEC, 10G-MAC and mEMAC.
- Provides API for accessing the MII management interface.
- FMan Rx and Tx ports can run in one of the following modes:
  - Independent-Mode
  - Simple BMI-to-BMI (regular) mode
  - Advance PCD mode (using FMan PCD blocks such as parser, Keygen, CC, and Policer).
- FMan Offline ports can run in one of the following modes:
  - Simple BMI-to-BMI (regular) mode
  - Advance PCD mode (using FMan PCD blocks such as parser, Keygen, CC, and Policer)
- Internal (optional) Host-Command port initialization, based on user's parameters.
- FMan IRQ handling - events and exceptions.
- Supports both SMP and AMP operation modes.

7.4.4.3.1.3 Frame Manager Driver Components

The FMan driver contains following low-level modules, as shown in this figure.

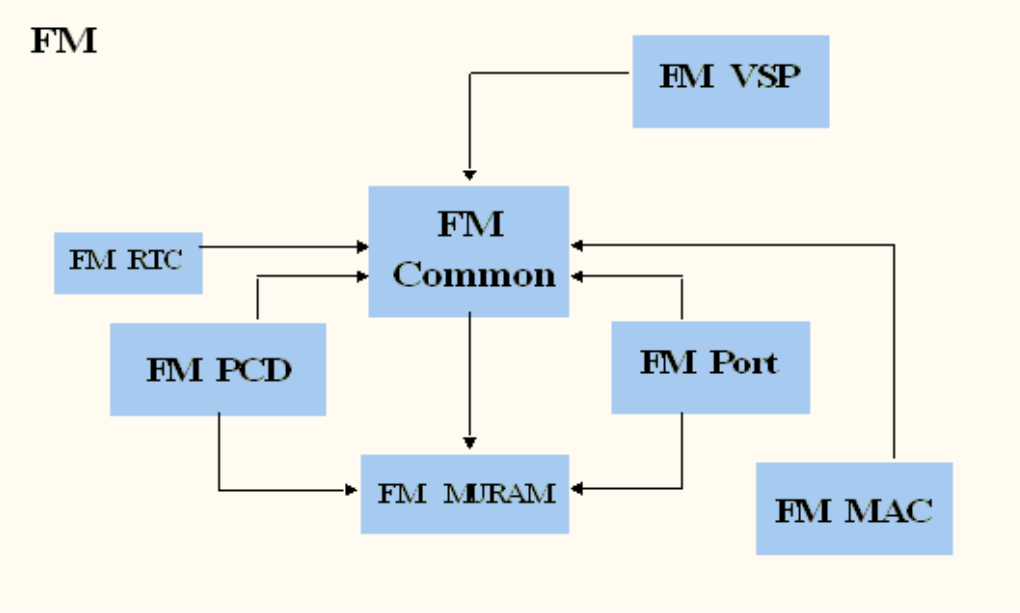

Figure 89. FMan Driver Modules (from a partition point of view)

The modules are as follows:

- Frame Manager (common)-The FMan module is a singleton module within its partition. It is responsible for the common hardware modules: FPM, DMA, common QMI, common BMI, FMan controller's initialization, and runtime control routines. This module must always be initialized when working with any FMan module. The module will mainly be used internally by the other FMan modules except for its initialization by the user.

  This module has an instance for each partition. However, only the driver that is on the master-partition has access to the hardware registers.

- Frame Manager Parser-Classifier-Distributor (FMan-PCD)-The FMan PCD module is a singleton module within its partition. It is responsible of all common parts of the PCD, such as the hardware parser, software parser, Keygen, policer, and custom-classifier blocks. It is responsible for building the PCD graphs.

  This module has an instance for each partition. However, only the driver on the master-partition has access to the hardware registers.

- Frame Manager Memory (FMan-MURAM)-This module is responsible for the specific memory partition of the FMan Memory. Each partition may have its own FMan Memory partition that is managed by the FMan Memory driver. For example, an FMan Memory instance will be created for each partition that has its own FMan ports.

  This module has an instance for each partition.

- Frame Manager Real-Time-Clock (FMan-RTC)-This module is responsible for the FMan RTC module.

  This module is a "singleton" and should be created once only for the master-partition.

- Frame Manger Port (FMan-Port)-This module is responsible for all FMan port-related register space, such as all registers related to a port in QMI or BMI.

  This module can be run by each core or partition independently.

- Frame Manager MAC (FMan-MAC)-This module is responsible for the mEMAC dTSEC and the 10G MAC controllers.

  This module can be run by each core or partition independently.

- Frame Manager Virtual-Storage-Profile (FMan-VSP)-This module is responsible for allocating and managing virtual storage profiles that may used for virtualization purposes. More of the VSP is described in FMan VSP Driver on page 763.

  This module can be run by each core or partition independently.

7.4.4.3.1.4 Driver Modules in the System

The FMan driver is designed to support single or multi partition environment. In addition, the FMan driver is designed to support environment with multicore that are running in SMP mode.

The following figure shows a typical single-partition (maybe SMP or not) environment and its FMan driver building blocks.

NOTE

In this environment:

- All FMan driver modules are available and should be initialized by the user (unless if it is unnecessary for the user operation; for example, if PCD is not needed so it may not be called).
- The FMan driver modules have the full functionality of the hardware.
- Each module has full access to its hardware registers (i.e. each module will access its registers directly).

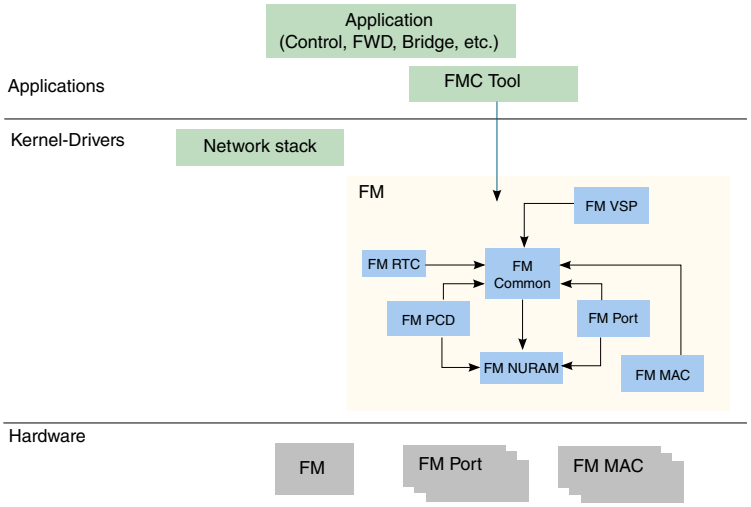

Figure 90. Single-Partition FM Building Blocks

7.4.4.3.1.4.1 Multicore Approach

The driver supports both Symmetric Multi-Processing (SMP) and Asymmetric Multi-Processing (AMP) operation methods.

7.4.4.3.1.4.1.1 SMP

As a rule, driver routines are not SMP safe. It is user's responsibility to lock all routines that might be in risk in his environment, for example, if `FM_PORT_Enable`/`FM_PORT_Disable` may be used by several cores, it is user's responsibility to protect the routine call using a spinlock.

An exception to this rule is the set of PCD routines. Due to the complexity of this module, and in order to support SMP and maintain coherency, PCD routines are protected using two mechanisms, spinlocks and flags.

Each PCD resource (i.e. software module such as scheme, CC Node, NetEnv, etc.) may have one or more spinlocks which are used to protect short code sections where specific resources such as hardware registers or software structures are accessed. In some cases, a spinlock of a higher level is used (i.e. CC locks the whole PCD).

The second mechanism is defined globally. The PCD global module provides a PcdLock mechanism, which is a list of lock objects containing a flag and a spinlock rotating that flag. On initialization of each PCD resource (i.e. software module such as scheme, CC Node, NetEnv, etc.), a PcdLock is allocated for this module. Critical sections that may not be protected by spinlocks (due to reasons of sections length, Host Commands and other lengthy operations) are protected by these flags. Note that this is a try-lock mechanism and the calling routine returns with `E_BUSY` error on failure. The try-locks are used by all PCD resources modification routines, in which case the application is expected to recall the routine until it is not busy.

In Addition, PCD and FM Port inter-module complex sections may be protected by try-locking all the initialized PcdLock modules in the global PCD, thus providing a safe PCD environment where influence and connections between modules may take effect.

On top of PCD routines, all FM Port PCD related routines are also protected by Port try-lock, meaning no two cores can access the same port to run a PCD routine. As in the PCD routines, these routines may return `E_BUSY` on failure and should then be recalled.

The driver SMP protection mechanism assumes the following:

- Only one core may initialize and delete a specific PCD software module (i.e. scheme x may not be initialized by two cores).
- A core should not attempt to delete a PCD software module when there is a risk of another core operating on that specific module.

7.4.4.3.1.4.1.2 AMP

FMan driver supports multi-partitioned system in a way that the common modules (`FM, FM_PCD`) are designed as "front-end" and "back-end". When configuring the FM driver module, the user should pass the driver its "guestId" ('0' identifies the "back-end"/"master-partition").

NOTE

In order to support AMP, FMan driver uses IPC calls for synchronization between the master module and the guests, i.e. user must have some IPC available in his system in order to have this functionality available in FMan driver.

There is no "hard" relation between "partitions" and "guests". A number of guests may co-exist on the same physical partition, creating a logical partitioning. Note that the FM "master"/"back-end" may run on any partition in the system.

When the FM driver is configured to run as a guest, it may access registers only if there is no race condition. If register access may end with some risk, the FM "front-end" driver access the HW registers through IPC call to the "back-end".

In the driver implementation, the FM-Port and the FM-MAC drivers are indifferent to guest/master considerations and may run on either partition. They do not have a "front-end" and both initialization and runtime routines are locally implemented. This means that a port may not be controlled from several partitions. However, a few ports may be controlled by the same partition.

The FM-MURAM module is pre-allocated and managed independently by each guest that has MURAM consumers (typically for Custom Classifier tables). It does not have a "front-end" and once allocated it may be accessed directly.

The FM-RTC module is a singleton module and is available only on the "back-end"/"master-partition" and therefore has no "front-end".

In the figure below, we can see two partition (A and B), where the FMan driver is configured as a master (the "back-end") on partition A and it is configured as a guest ("front-end") on partition B. In addition, each partition has its own FM-ports (also FM-MACs) that are working with the "front-end" and host-commands.

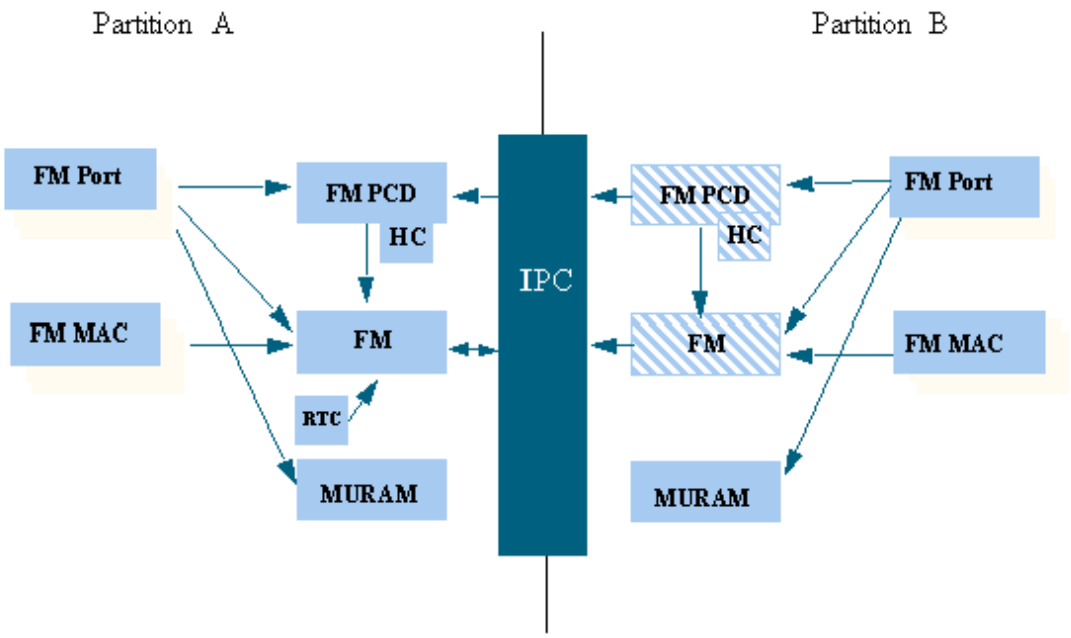

Figure 91. Multi-Partition FM Building Blocks with IPC (DPAA 1.0)

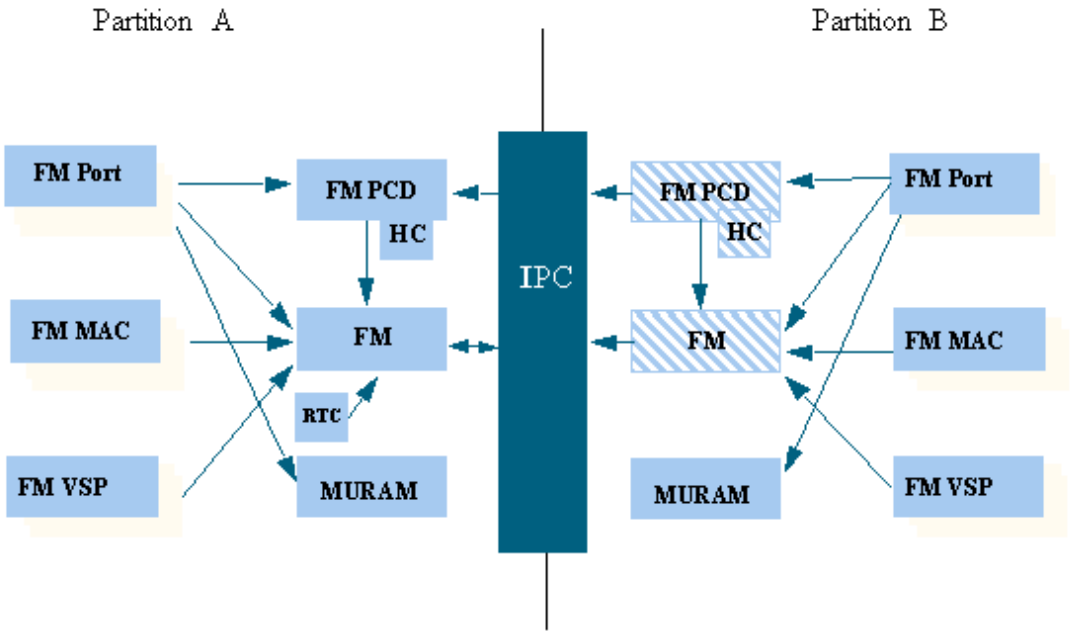

Figure 92. Multi-Partition FM Building Blocks with IPC (DPAA 1.1)

There may be two ways for user to work in AMP:

- AMP with IPC-In systems that has IPC mechanism (as in the figure above), the FM drivers (including FM, FM-PCD, FM-Port, etc.) will utilize the IPC mechanism to actually synchronize information between them; i.e. FM-PCD driver in guest mode will call the FM-PCD master to allocate schemes for its partition (according to user configuration). In this system, it is possible to create FM-Ports and FM-MACs local for guest partition; i.e. the HW of FM-Port and FM-MAC will be accessed and controlled locally for the partition that actually owns the resource.
- AMP without IPC-The FM driver itself doesn't support this kind of system. As shown in the figure below, it is still possible for a user to create DPA-Ports and to send and receive packets to and from MAC. In addition, user may also initialize

and access MACs from guest partitions, but, other operations like creating PCDs or accessing the FM-Ports registers may be done only by the master partition.

NOTE

Although FM-MAC driver can be initialized and accessed from guest partition even if there is no IPC present, some functions may be disabled (e.g. events of the MAC).

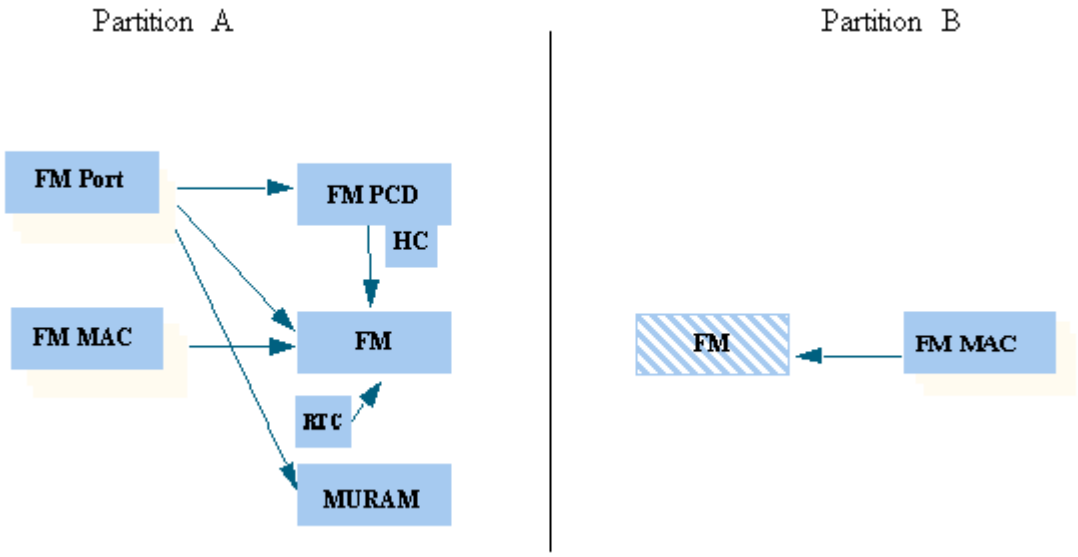

Figure 93. Multi-Partition FM Building Blocks without IPC (DPAA 1.0)

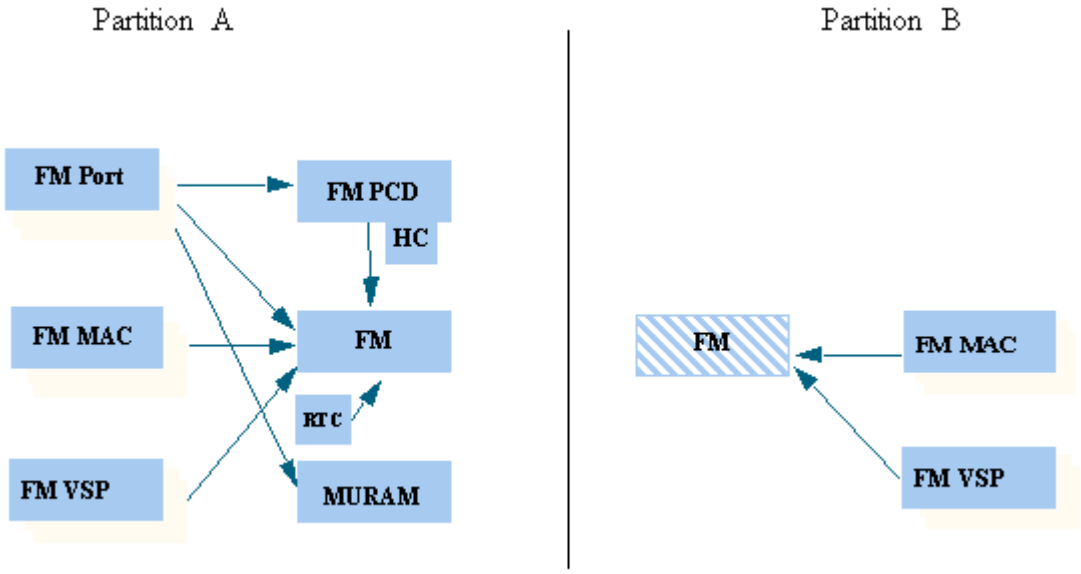

Figure 94. Multi-Partition FM Building Blocks without IPC (DPAA 1.1)

7.4.4.3.1.5 FMan Driver Calling Sequence

Initialization of the FMan driver is carried out by the application according to the following sequence:

1. MURAM configuration & Initialization
2. FMan (common) configuration & Initialization

3. [Optional] FMan RTC configuration & Initialization
4. For each MAC required by the user:
   a. MAC Configuration & Initialization
   b. PHY Initialization
5. For each FMan Port required by the user:
   a. FMan Port Configuration & Initialization
   b. [optional] If the FMan Port required to be virtualized, a set of VSPs need to be allocated and one of them should be set as the default.
   c. [optional] If VSPs were allocated in previous step, the default VSP need to be configured & initialized
   d. in that stage, user should configure and intialize everything that is needed for the operation of a port outside the fman; e.g. buffer-pools, frame-queues, etc.
   e. Port Enablement
   f. MAC Enablement
   g. Calling 'AdjustLink' MAC API routine with the relevant link parameters

NOTE

Now, the FMan is operational. The ports operate in independent mode or BMI-to-BMI mode. From that point, all the following steps are optional.

6. FMan PCD Configuration & Initialization
7. If a physical port is being "vitualized" into several software entities (using some classification to ditribute the traffic), user should configure and initialize the relevant buffer-pools and frame-queues.
8. If VSP is enabled, in that stage, user should configure and initialize the relevant profile.
9. FMan PCD Graph initialization:
   a. Calling restricted runtime routines (that may be called only when PCD is disabled)
   b. Calling the PCD enable routine
   c. Initialization of a all PCD Graph objects (i.e. KG-schemes, Match-Tables, etc)
10. FMan port-PCD related initialization; calling the run-time control routines to set the PCD related parameters

NOTE

In case the PCD is "set" to a FMan OP port, it should be disabled first (i.e. before calling 'FM_PORT_SetPCD' routine).

11. FMan runtime routines
12. FMan Free sequence - in reverse order from initialization

7.4.4.3.1.6 Global FMan Driver

The Global FMan driver refers to the common FMan features - i.e. functionality that is not defined per-port and does not belong to a spany of the specific modules such as PCD, RTC, MURAM, MAC etc.

7.4.4.3.1.6.1 FMan Hardware Overview

The following Frame Manager processing elements are considered general FMan components and are controlled by the FMan common driver:

- The Frame Processor Manager (FPM) schedules frames for processing by the different elements to create the appropriate pipeline.

- The BMI is intended to transfer data between network and internal FMan memory, generate frame descriptor (FD), initialize the internal context (IC), manage the internal buffers, allocate/deallocate external buffers with the help of BMan and activate the DMA to transfer data between internal and external RAMs
- The DMA is responsible for frames data transfer from and to external memory
- The queue manager interface (QMI) is responsible for transferring packet-based work assignments between the queue manager (QMan) and the frame manager (FMan). It provides an interface to the QMan for enqueuing and dequeuing new frames to/from the multicore system.

7.4.4.3.1.6.1.1 Global FMan Driver Software Abstraction

The FMan global driver covers all the logically common FMan functionality, i.e functionality which is not port related. The different hardware modules within the FMan (i.e. BMI, DMA, etc.) are encapsulated within the FMan module. The terms "BMI", "DMA" are used for resources identification such as exceptions, counters and some configuration parameters, but logically, the only module used for functional operations is the FMan.

7.4.4.3.1.6.2 How to use the Global FMan Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.6.2.1 Global FMan Driver Scope

This module represents the common parts of the FMan. It includes:

- FMan hardware structures configuration and enablement
- Resource allocation and management
- Interrupt handling
- Statistics support
- ECC support for the FMan RAM's
- Load balancing between ports

7.4.4.3.1.6.2.2 Global FMan Driver Sequence

- FMan config routine
- [Optional] FMan advance configuration routines
- FMan Init routine
- FMan runtime routines
- FMan free routine

7.4.4.3.1.6.2.3 Global FMan Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.6.2.3.1 FMan Configuration and Initialization

On FMan driver initialization, the software configures all FMan registers and relevant memory. It supplies default values where no other values are specified, it allocates MURAM, it loads FMan controller code. It defines IRQ's and sets IRQ handles. It enables hardware mechanisms and initializes software data structures for software management.

By the time initialization is done, FMan is ready to be used and any of the FMan sub-modules (FMan-Ports, MACs, etc.) may be initialized.

7.4.4.3.1.6.2.3.2 Resource Management & Tuning

The FMan provides resources used by its sub-modules. Generally, the driver selects default resource allocation, but when initializing the global FMan module, the user may specify a different allocation for some or all of the resources.

The resources relevant for this discussion are resources used by the BMI only. These resources should be further distributed between the different ports, but the initial allocation is for the BMI in opposed to some internal use of the FMan controller. The main and most important resources of the FMan are TNUMs (i.e. the FMan "tasks"), DMAs, FIFOs and "pipeline-depth".

The total available resources may vary based on SoC. The recommended default values are designed to fit most applications but as the resource allocation depends on system configuration, it therefore may vary between applications. I.e. the default value that are being set by the driver will be sufficient in use-cases were the user utilizing most of the FMan bandwidth and the user application is mostly using the FMan. In other cases such as if user uses some advance PCD settings and/or overloads the SoC (e.g. PCI is being massively used), the resources may need some special treatment and tuning by user as the default may not be sufficient enough.

Most MURAM is used as a temporary location for data transaction. This part's size is referred to as "FIFO size". The rest of the MURAM may be used for other utilizations such as Custom Classifier and its size is effected by the use of these features, i.e. if Custom Classifier is not used, "FIFO size" may be enlarged. The user may call `FM_ConfigTotalFifoSize` in order to modify the default value of the MURAM. However, one should bear in mind that when FIFO size is enlarged - Custom Classifier space is decreased.

7.4.4.3.1.6.2.3.3 Load Balancing

The FMan provides a mechanism to optimize the internal arbitration of different ports over the shared resources of the hardware.

The driver supports this feature by providing an API for dividing the bandwidth between the different ports (`FM_SetPortsBandwidth`). The API is given in terms of percentage - i.e. for each port, the user should specify its percentage relative to the other ports. This API is optional and may be modified at runtime. If not used, or if all ports get the same bandwidth (whether its {50,50} or (25,25,25,25}), then no one port will have priority over other ports. If ports get different values, for example 3 ports used and get {25,50,25}, than the first and third ports will get the same access to shared resources but the second one will get twice as much. i.e. The numerical values given to each port are not important, but only the relation between the ports.

7.4.4.3.1.6.2.3.4 Statistics

The FMan API provides access to all the statistics gathered by the FMan hardware. The API routine `FM_GetCounter` may be called at any time after initialization to retrieve any of the FMan counters.

7.4.4.3.1.7 FMan Parse-Classify-Distribute Driver

The Parse-Classify-Distribute (PCD) driver module refers to the parts of the drivers handling the different PCD engines and services such as Parser, Keygen, Custom Classifier, Policer, Header Manipulation, Reassembly, Fragmentation and Frame Replication. It deals both with the common configuration and runtime features and the specific PCD resources such as Keygen Schemes, Custom Classifier graphs, etc.

7.4.4.3.1.7.1 FMan PCD Hardware Overview

- Parser-The parser performs protocol header parsing and validation for a wide range of frame formats with varying protocols and encapsulation. A hard-coded parser function is used for the known and stable protocols. The hardware parser capabilities can be expanded by software parser functions to support protocols not supported by the hardware parser including proprietary protocols and shim headers. The parser parses the frame according to a per-port configuration. It reads the frame header from the FMan Memory and writes the frame parse results to the Internal Context of the frame. The Lineup Confirmation Vector is a part of the parser result. It represents a list of all the protocols recognized by the hardware parser, and may be extended to contain information added by the software parser.
- Keygen-The Keygen is located on the FMan receive path, and enables high performance implementation of pre-classification. It holds a SoC dependent number of key generation schemes in internal memory. Each scheme can generate different frame queue ID (FQID), a Storage-Profile ID (SPID) and policer profile (PP). One main function of the Keygen module is to separate network data into different flows, each requiring different processing. Another function of the Keygen, is the Classification Plan. This is a mechanism provided in order to mask LCV bits according to per-port definition. The Classification Plan is implemented as a table of SoC dependent number of entries, logically divided or shared between the FMan Ports.

- Custom Classifier-The Frame Manager (FMan) Custom Classifier module performs a look-up using a specific key from the received frame or internal frame context according to Parser results. The FMan Custom Classifier logically occurs after the Keygen processing has completed and can be operational in both the MAC receive flow and the offline parsing flow. The look-up produces an action descriptor which contains the necessary information for the continuation of the frame processing in the next module or the next look-up table.
- Policer-The Policer supports implementation of differentiated services at line speed on the Frame Manager (FMan) receive or offline parsing paths. It holds a SoC dependent number of traffic profiles in internal memory, each profile implementing RFC-2698 or RFC-4115 or Pass-Through mode. Each mode can work in either color-blind or color aware mode, and pass or drop packets according to their resulting color.

7.4.4.3.1.7.1.1 FMan PCD Software Abstraction

The FMan PCD driver aims to provide a high-level, abstract, network oriented, logical interface. It is designed to allow a glue logic between the different PCD engines and the PCD "user" - the FMan port, and to define an interface to these features to be used by the application. In this process, new non-hardware modules may be created - such as "Network Environment", while existing hardware modules - such as "Classification Plan" - may be hidden from the user. The following sections makes an attempt to describe the driver design decisions in abstracting the engines' hardware and the gap between the hardware programming model and the drivers API.

7.4.4.3.1.7.1.1.1 FMan PCD Flow

The FMan opens the FPM scheduling capabilities to the application, which allows significant flexibility in defining the packet flow. At various points in the flow, the FMan user must configure the next engine to handle the packet and the next operation it will perform. The driver minimizes this flexibility by assuming a basic flow for each port. The driver can expand this flow to include all FMan PCD capabilities, but in a limited manner that will be described below.

The basic flow reflects the expected use of the FMan PCD. When a port is initialized, the default setup that received packets are passed to the port's default Rx frame queue, as configured by the user. When the PCD is linked to the port, the user chooses one of the provided PCD support options which selects which PCD engines (parser, Keygen, FMan-Controller, and Policer) are included in the frames. The selected PCD support option adds the selected engine or engines to the flow according to the following PCD organization.

- When parser is used, it is always the first PCD engine working on the received frames.
- If parser is not activated, Keygen, and FMan-Controller may not be activated.
- Keygen's first use follows the parser, but it may be used again following the Fman-Controller or the policer.
- If FMan-Controller is used, it will follow the Keygen. It may not be activated if Keygen is not used.
- Policer may be activated by itself or follow any of the engines.

In all cases, the frame returns to the buffer manager interface (BMI) for enqueueing. The application may not change the main flow at runtime.

The following figure shows the default ports flows (in terms of next invoked action (NIA) registers' initialization):

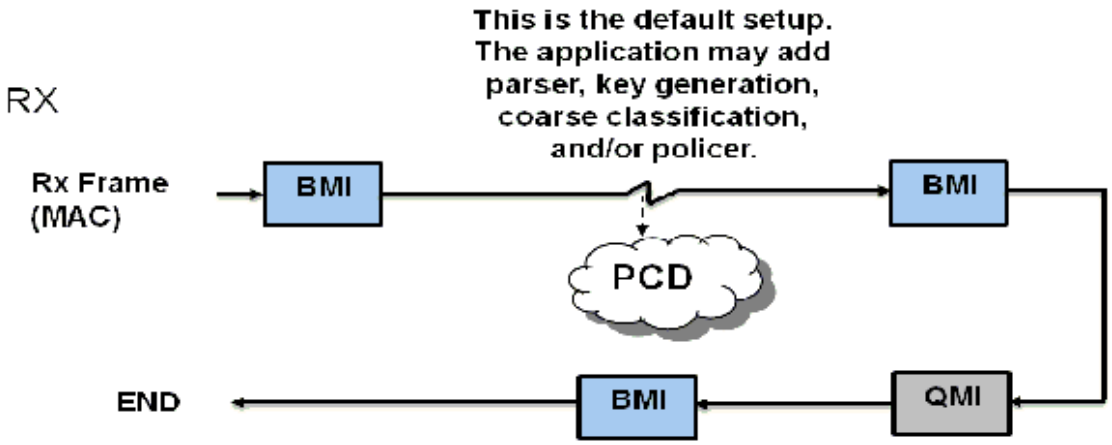

Figure 95. Default Rx Flow

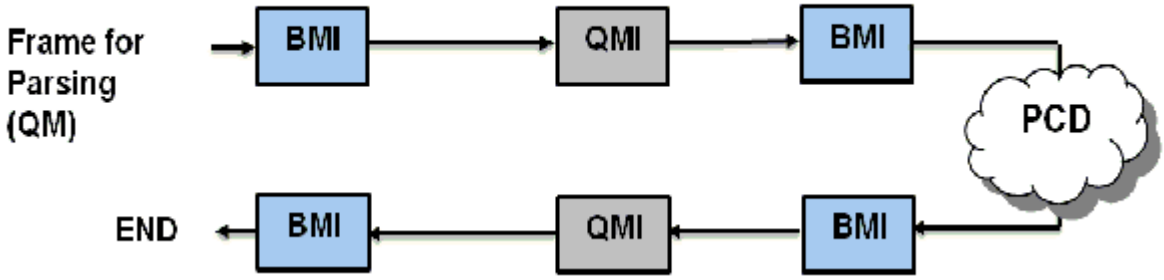

Figure 96. Default Offline Parsing Flow

NOTE

In independent mode, both Tx and Rx BMI NIA are FMan Controller. Other NIAs are not applicable.

After basic initialization, the default Rx flow, as shown in Figure 95. Default Rx Flow on page 729, is the configured flow. A PCD flow is initially defined by FMan Port level, although it is effected both by the port configuration and the PCD resources configuration. Following figure shows the PCD flows supported by the driver.

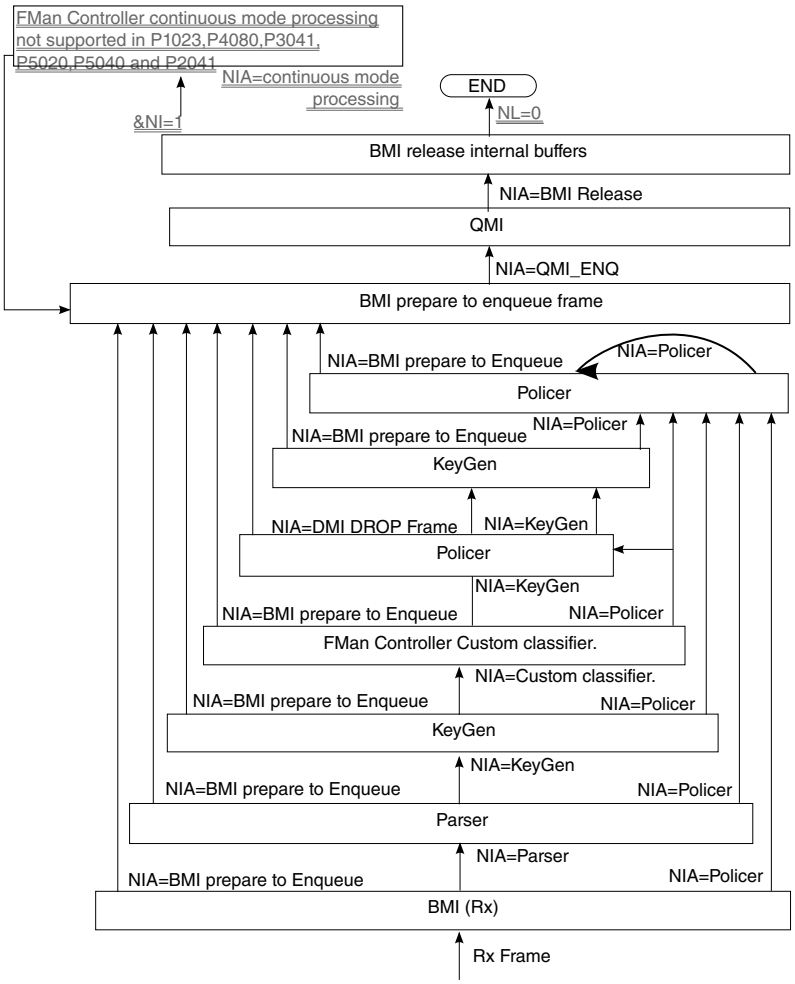

Figure 97. Available flows

7.4.4.3.1.7.1.1.2 Global FMan PCD Module

The FMan PCD driver deals with the configuration initialization and runtime setting of the PCD resources. The actual use of these resources is in fact activated only when an FMan-Port is enabled and is bound to the initialized PCD resources. In this chapter we will only deal with the initialization and organization of those resources.

The PCD driver is constructed by a global FMan-PCD module that must be initialized first, and a set of optional PCD resources that can be initialized at run-time. The FMan-PCD module is responsible for enabling the different engines, loading SW parser if required, registering PCD interrupts and other general configuration.

7.4.4.3.1.7.1.1.3 Global FMan-PCD Resources

PCD driver's resources are NOT identical to PCD hardware resources and provide an abstraction layer to the hardware resources. PCD is viewed as a graph of PCD resources where FMan RX & OP Ports may be bound to subsets of the PCD graph. Refer to Port-PCD Binding on page 757.

The following are the driver's PCD resources:

- Network Environment Characteristics
- Software Parser
- Keygen Schemes

- Custom Classifier Roots
- Custom Classifier Match-Tables
- Custom Classifier Hahs-Tables
- Custom Classifier Manipulations
- Policer Profiles

The **Network Environment (NetEnv) Characteristics** are a pure SW resource. It is used in creating multiple HW PCD resources. Logically, it represents the NetEnv of a port or a number of port and supplies the glue between the parser, the Keygen, the Custom Classifier and the port. It ensures they all "speak the same language". Physically, it defines the LCV for all the participating protocols for each FMan Port.

Keygen Schemes and **Policer Profiles** are closely bound to their hardware programming model

Custom Classifier process is represented by a software graph. Each node in the graph represents a logical action. The driver defines different types of Custom Classifier nodes. One type of node is one of an Exact-Match which is a software representation of an Action-Descriptor (AD) that performs a lookup according to the key defined. Another type of node is one of Indexed-Lookup which is again a software representation of an Action-Descriptor of that type. A higher level of abstraction is performed on Hash-Table nodes, where the driver manages a hash table. Each node, may also contain a handle to a Manipulation action - which is the software abstraction for one or more AD's used for manipulating the frame by inserting and/or removing data. Generally, any Custom Classifier software node may be translated to one or more HW action descriptors.

The driver defines a notion of a Custom Classifier graph. The CC graph is the total set of lookups and manipulations performed by the Custom Classifier. The user builds the graph only after defining the CC Nodes. The finalization of the graph is done by building the root nodes and defining their grouping. This refers to the 16 entries array that functions as the entry point of the CC. Generally, the indexing into this array is performed by using 4 bits out of the LCV. This driver supports a division of this array into 2-16 unrelated groups to increase the flexibility of the programming and allow usage of more LCV bits.

7.4.4.3.1.7.1.1.4 How to Associate PCD Resources

The NetEnv is the link between the port and all the PCD resources it is using.

- Parser-The driver configures the LCV (lineup confirmation vector) in the parser configuration for every FMan Port according to the specific NetEnv it is bound to. When using SW parser, a private shim header should be added as a NetEnv unit, and may be used later as a regular unit.
- Keygen-Classification plan: The driver hides this resource from the user and configures classification plan entries to support and expand the HW parser capabilities according to the user definition of its NetEnv Characteristics
- Keygen-Schemes: The user describes the scheme in terms of NetEnv units, and the match vector is configured by the driver.
- Custom Classifier: The user describes the entry point of a CC root in terms of NetEnv units. The driver internally passes this information to the Keygen that uses it in selecting the entry point in the CC root when passing a frame from the Keygen to the Custom Classifier.

After defining PCD resources, the user may bind any FM Port to the initialized resources. A port must be bound to a single NetEnv, and may be bound to a Custom Classifier root and KeyGen schemes.

The set of figures below demonstrate a single example of the use of the driver's resources and their interaction with the hardware structures.

The following table demonstrates a NetEnv of 7 units. Unit 0, for example, is a simple unit recognizing ethernet frame, while unit 2 recognizes IP frames of either version.

Unit 0	Unit 1	Unit 2	Unit 3	Unit 4	Unit 5	Unit 6
Ethernet	Ethernet [Broadcast]	IPV4	IPV4	UDP	MPLS [stacked]	IPV4 [Muticast]
		IPV6		TCP		

Figure 98. Network Environment Example

When a port is bound to a NetEnv, the driver translates its units into the parser's hardware Line-up Confirmation Vector (LCV). The table below shows the LCV configured for a port that has the NetEnv above.

	LCV[0]	LCV[1]	LCV[2]	LCV[3]	LCV[4]	LCV[5]	LCV[6]	LCV[7-31]
Ethernet	1	1	0	0	0	0	0	0...0
IPv4	0	0	1	1	0	0	1	0...0
IPv6	0	0	1	0	0	0	0	0...0
UDP	0	0	0	0	1	0	0	0...0
TCP	0	0	0	0	1	0	0	0...0
MPLS	0	0	0	0	0	1	0	0...0

Figure 99. LCV Example (for a specific port that is bound to the Network environment above)

Based on the NetEnv, the driver also defines a set of Classification Plan entries to be used by each port using that NetEnv.

	Bit [0]	Bit [1]	Bit [2]	Bit [3]	Bit [4]	Bit [5]	Bit [6]	Bits [7-31]	Comments
0	1	0	1	1	1	0	0	1...1	No cls. Plan
1	1	1	1	1	1	0	0	1...1	Eth Broadcast
2	1	0	1	1	1	1	0	1...1	MPLS Stacked
3	1	1	1	1	1	1	0	1...1	1+2
4	1	0	1	1	1	0	1	1...1	IPv4 MC
5	1	1	1	1	1	0	1	1...1	1+4
6	1	0	1	1	1	1	1	1...1	2+4
7	1	1	1	1	1	1	1	1...1	1+2+4

Figure 100. Classification Plan entries for the Network environment above

When a frame is received its LCV is masked by one of the vectors in the Classification Plan. The FMan selects the entry based on the parser output and the port parameters.

To support this operation, the driver initializes the HXS plan offset field for each relevant header in the port parser parameters. The table below, is the driver's translation of the Network environment above into the port classification plan parameters. When a frame is being parsed, the classification plan offset for each header found is accumulated to construct the offset of the result classification plan. For example, a hypothetic frame of Ethernet BC/Stacked MPLS/IPv4 unicast frame, will have an LCV=0xF6000000 and a classification plan id of 2^(1-1)+ 2^(2-1) = 3, so its classification plan vector is 0xFDFFFFFF, and QLCV = 0xF4000000.

	HXS [plan offset]	Cls plan entry
Eth. BroadCast	1	2^(1-1)=1
MPLS Stacked	2	2^(2-1)=2
IPv6	0	0
UDP	-	-
TCP	-	-
IPv4 Multicast	3	2^(3-1)=4

Figure 101. Parser HXS (for a port that is bound to the Network environment above)

Given the driver's automatic initialization of the LCV and classification plan based on only the NetEnv, the user may now initialize Keygen schemes by passing as match criteria only the NetEnv unit id's. As in the other cases, the driver will translate the unit id's to the schemes' match vectors as can be seen in the figure below.

Id	Scheme Match Criteria	Units	Match vector
0	Ethernet broadcast	1	0x40000000
1	IPV4 MC+MPLS stacked	5+6	0x06000000
2	IPV4 MC	6	0x02000000
3	IPV4+(TCP or UDP)	3+4	0x18000000
4	match on IPv4 or IPv6 frames	2	0x20000000
5	Ethernet	0	0x80000000
6	Direct scheme	--	0xffffffff

Figure 102. Keygen schemes example

Finally, the driver will also take care of initializing the Keygen-to-Custom Classifier configuration registers. When initializing a Custom Classifier root, the user may create groups based on NetEnv units (in opposed to a simple group of a single entry; for more information refer to Custom Classifier Root on page 739).

When initializing a scheme, the user should only pass the handle to the Custom Classifier root. The driver will translate the group LCV dependent parameters into the scheme required register.

For example, Group 0 is a simple group that is not dependent on the NetEnv. Group 1 is based on a single unit - so a frame may be forwarded to 1 of 2 root nodes, and group 2 is based on 3 units - so a frame may be forwarded to 1 of 8 root nodes.

	CC Tree group Num of units	units	Keygen FMKG_SE_CCBS	Possible offsets within group depending on PR[LCV] AND FMKG_SE_CCBS
Group 0	0	--	0x00000000	0
Group 1	1	3	0x10000000 (Scheme 4 in the example)	0,1
Group 2	3	1,3,4	0x58000000	0-7

Figure 103. Keygen scheme configuration for CC next engine

The Policer Profiles are the one resource that does not rely on the Parser Results or the NetEnv. It is therefore managed independent of the other PCD resources.

7.4.4.3.1.7.1.1.5 FMan Header Manipulation

The FMan controller defines a set of header manipulation commands, and supports listing of these commands. The FMan driver allows limited listing by a single Manipulation node, limited to a single use of each command and to a defined order (e.g. remove + insert may be defined in a single node, but insert + remove or remove + remove may not). Alternatively, full listing and ordering is supported by chaining more than one Manipulation nodes. In such a case, the driver will unify HMCT's to optimize performance and MURAM usage unless parsing is required in between the different commands.

The following list maps each FMan controller command to the driver parameters in the Header Manipulation structure:

1. Generic removal-Set 'rmv' and use the corresponding parameters structure. Select generic enum and parameters.
2. Generic insertion-Set 'insrt' and use the corresponding parameters structure. Select generic enum and parameters.
3. Generic replace-Set 'insrt' and use the corresponding parameters structure. Select generic enum and parameters and set 'replace'.
4. Protocol specific removal-Set 'rmv' and use the corresponding parameters structure. Select byHdr enum and parameters.
5. Protocol specific insert-Set 'insrt' and use the corresponding parameters structure. Select byHdr enum and parameters.
6. Vlan priority update-Set 'fieldUpdate' and use the corresponding parameters structure. Select vlan enum and parameters.
7. IPv4 update-Set 'fieldUpdate' and use the corresponding parameters structure. Select IPv4 enum and parameters.
8. IPv6 update-Set 'fieldUpdate' and use the corresponding parameters structure. Select IPv6 enum and parameters.
9. TCP/UDP update-Set 'fieldUpdate' and use the corresponding parameters structure. Select TCP/UDP enum and parameters.
10. TCP/UDP checksum calculation-Set 'fieldUpdate' and use the corresponding parameters structure. Select TCP/UDP enum and parameters.
11. IP replace-Set 'custom' and use the corresponding parameters structure. Select TCP/UDP enum and parameters.

7.4.4.3.1.7.1.1.6 Custom Classifier Hash-Table Node

The driver provides a high level Hash-Table mechanism implemented over the FMan controller Custom Classifier structures. The driver implements the Hash-Table by using a Match-Table node of type Indexed-Hash, where each entry points to a hash bucket implemented by a Match-Table node of type Exact-Match (For more information on these nodes, refer to Custom Classifier Root on page 739). The driver uses the Keygen key and hash result as a key for the lookup. A selected part of the hash result is used to select the entry in the Indexed-Hash table (i.e. the bucket), and the full key possible values are used as the Match-Table keys in the selected bucket.

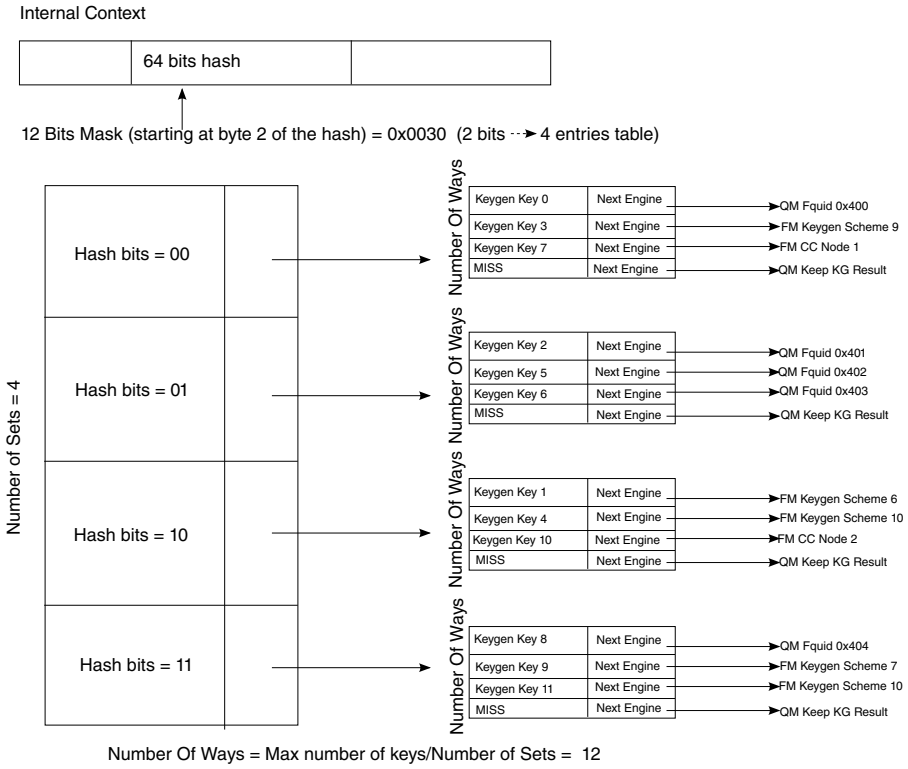

Figure 104. Hash_Table node example

7.4.4.3.1.7.2 How to use the FMan PCD Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.7.2.1 FMan PCD Driver Scope

- FMan Parser, Keygen, Custom Classifier & Policer configuration and initialization
- PCD Enable/Disable
- Resources allocation and management
- Interrupt handling
- Statistics support
- Support for FMan PCD operations

7.4.4.3.1.7.2.2 FMan PCD Driver Sequence

- FMan PCD Config routine
- [Optional] FMan PCD advance configuration routines
- FMan PCD Init routine
- Specific one-time pre-enable routines (e.g. load SW parser)
- FMan PCD Enable routine
- FMan PCD runtime routines
- FMan PCD specific resources runtime routines (for defining, modifying and deleting Keygen schemes, Custom Classifier nodes, etc.)
- FMan PCD Free routine

7.4.4.3.1.7.2.3 FMan PCD Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.7.2.3.1 Global PCD Initialization

PCD initialization is divided into two parts. During the first part of the initialization, `FM_PCD_Config`, advance config routines, and `FM_PCD_Init` are called to configure and set all basic PCD capabilities, including pre-defining which engines are supported and may be used later. This stage is done in the kernel, and PCD is not yet enabled. During the second part of the initialization, PCD is enabled by a runtime routine (`FM_PCD_Enable`).

This division creates a gap during which some functionality may be added. The most important is the loading of the SW parser code. Note that this functionality is allowed only when PCD is disabled (i.e. between init and enable) or, with some restriction, in runtime after disable.

Once PCD basic initialization is complete (`FM_PCD_Init` and `FM_PCD_Enable` are called and returned), the PCD capabilities of the frame manager are reflected by the driver as a set of API runtime routines designed to define the PCD environment for a specific partition. PCD resources are defined per partition and may be used by all ports within a specific partition. The different PCD resources are first initialized and only later may be used by the FMan ports.

The order of PCD resources initialization is strict and relies on the PCD graph being initialized bottom up, which means that no resource may be initialized before its next engine is initialized. However, the use of port relative profiles is an exception to this rule. A scheme's next engine may be a port relative profile. In such a case, the scheme is initialized but not yet bound to a port, i.e. the actual policer profile is not yet specified. Therefore, its validity may not be verified. It is the user's responsibility to ensure that when a port using that scheme is activated (for using the PCD), its relative policer profile must be validated.

The PCD graph is partition based i.e. may be shared by ports on the same partition. Refer to Port-PCD Binding on page 757 for more details on port-PCD binding.

7.4.4.3.1.7.2.3.2 PCD Resources

The following subsections describe each of the driver's PCD resources in detail. In a single-partition environment, most resources are available and do not need explicit allocation. The port policer profiles are an exception. They must be allocated by the user, using the FMan Port API. In multipartition, some of the resources, specifically resources limited by hardware, must be first allocated by a partition and only then used by the partition's ports. The following sections specify the requirements for each of the PCD resources:

7.4.4.3.1.7.2.3.3 **Network Environment Characteristics**

The Network Environment (NetEnv) is a software entity that lists the network protocols used by the FM-PCD for classification and distribution. The total number of NetEnvs defined depends on the system configuration. A NetEnv may be defined per port or shared among some or all ports. The definition of a NetEnv must be done with care while considering the use of the FM-PCD module. The NetEnv is, in fact, the key for frames parsing, distribution, and classification.

The NetEnv is a list of distinction units. Each distinction unit consists of at least one or more headers. A header may either be one header from the list of supported headers or one of the supported headers plus an option (For more details on list and options available, refer to Supported Network Protocols on page 766).

The hardware parser implements header recognition. If the software parser is used, a distinction unit may also be one of the shim headers. The driver saves a number of units (that may be redefined in `fm_pcd_ext.h`) for private use. The user may than use this unit ID to recognize the private header by the Keygen or CC.

The following figure shows an example of a NetEnv. It has four units, two of which consist of a single header. One of the headers has an option. The final two units consist of two interchangeable headers. This example will be used throughout the following sections

.

Ethernet [Broadcast]	IPv4	IPv4	TCP	
	IPv6		UDP	

Figure 105. Network Environment Example

The distinction units list should reflect what the user wants to do with the PCD mechanisms to parse-classify-distribute incoming frames. Specifying a distinction unit means that the user wants to use that specification to either activate the parser on the specified headers or distinguish between frames with the Keygen or the Custom Classifier. Using interchangeable headers to define a unit means that the user is indifferent to which of the interchangeable headers is present in the frame, but instead wants the distinction to be based on the presence of either one of them. For example, if it is required that a selection of scheme is based on having L3 header of either IPv4 OR IPv6, but it is of no importance which of the two is present, than a unit should be defined with 2 interchangeable headers: IPv4, IPv6.

The initialization routine retunes a NetEnv handle to be used later to specify that Network Environment.

Depending on context, there are limitations to the use of NetEnvs. A port using the PCD functionality is bound to a NetEnv. Some, or even all, ports may share a NetEnv, but it is also possible to have one NetEnv per port. When initializing a scheme, a Custom Classifier root, or when binding a port to the PCD, one of the required parameters is the handle of an initialized NetEnv. The driver uses the definitions of that NetEnv to initialize that scheme or Custom Classifier root. When a port is bound to a Keygen scheme or a Custom Classifier root, it must be bound to the same NetEnv.

For the flow's definition, the different PCD modules may only rely on distinction units as defined by their environment. When initializing a scheme for example, a PCD module may not choose to select IPv4 as a match for recognizing flows unless IPv4 was defined in the relating environment. In fact, to guide the user through the configuration of the PCD, each module's characterization in terms of flows is not done using protocol names, but rather environment indices.

In terms of hardware implementation, the list of distinction units sets the Lineup Confirmation Vectors (LCVs) and are later used for match vector and CC indexing. The shim header LCVs are conventionally assigned from LSB up, so the first shim header is 0x0000_0001. For more details on the implementation, refer to Global FMan-PCD Resources on page 730.

Runtime Modifications: A Network Environment may not be changed at runtime. New NetEnvs may be set, and unused NetEnvs may be deleted anytime.

Available API:

- `FM_PCD_NetEnvCharacteristicsSet`
- `FM_PCD_NetEnvCharacteristicsDelete`

7.4.4.3.1.7.2.3.4 Software Parser

The PCD allows the extension of the hardware parser by loading the software parser code for further manipulation. When this is required, the user passes the image of the software parser code and a table of labels to the driver. This represents the entry-points in the software parser code. If more than one code piece is required for a specific protocol (for example, to be used by different ports) an index is added to the labels table. Later, when configuring a port that uses one or more software parsing attachments, each protocol header may be bound to one of the previously declared labels. This is done by setting the software parser enable indication for one or more protocols headers, and indicating the software parser index (relative to that protocol header). The software parser code will run for that port after the hardware parser recognizes that header. In other words, the specified protocol header is in fact the trigger for the software parser to be activated. It is typical for the software parser to parse a private header that was previously defined as a NetEnv unit and then mark its existence for classification and distribution.

The software parser loading routine must be called only when the PCD is disabled and no ports in the system are using the parser. On initialization this means that the routine, if needed, must be called after `FM_PCD_Init` and before `FM_PCD_Enable`.

Runtime Modifications: Software parser may not be changed at runtime.

Available API:

- `FM_PCD_PrsLoadSw`

7.4.4.3.1.7.2.3.5 Keygen Schemes

The scheme entity relies on the hardware entity. There are 32 Keygen schemes in a frame manager. When a PCD is defined in a single partition environment, it is the owner of all 32 schemes. When a PCD is defined in a multipartition environment, the user must specify how many schemes are required for this partition. Once schemes are allocated for a specific partition, it may be used only by ports on that partition.

Within a partition, the schemes order is relevant. When initializing a scheme, the user must specify the following:

- Relative index, relative to the partition's schemes.
- Network environment handle.
- Match criteria, or which frames should be processed by the scheme.
- Keygen action (such as hash, FQID mask, and manipulation).
- Distribution FQIDs.

The match criteria (if used), is based on the NetEnv characteristics units. Schemes that are to be used directly should be configured as such, by specifying a scheme ID rather than using match criteria or specifying distinction units. Upon initialization, the driver returns a handle to the initialized scheme. This handle can be used later to specify the scheme.

Keygen schemes are dependant on parser results. They may be used immediately after the parser by direct mode or by using the match criteria. Schemes may also be used after the Custom Classifier or the policer. This flow is typically used for flow control redistribution. In this case, to avoid infinite loops the scheme is reached only in direct manner and not by match criteria.

The keygen action consists of the construction of the key and the definition of the distribution. The key is constructed by a set of extract actions arranged in the driver as an array of extractions. Extractions may be done from data, from Parse Result, from default values, but most commonly - from the header. When extraction is taken from the header it may be described generically by size and offset, or it may be an extraction of the full field. For a full list of supported headers and fields, see Supported Network Protocols on page 766.

When a scheme is initialized, the user must specify the next engine to which the frame should pass after it is processed. The next specified engine must be initialized and valid at this point. Frames may pass to the Custom Classifier or the policer, or they may be directly enqueued to an FQID.

Once schemes are defined, ports may be bound to them. A port may be bound to as many schemes as needed, as long as they are from the same partition and the same NetEnv.

Following figure shows an example of scheme setting and connection to the NetEnv, as shown in Network Environment Characteristics on page 736.

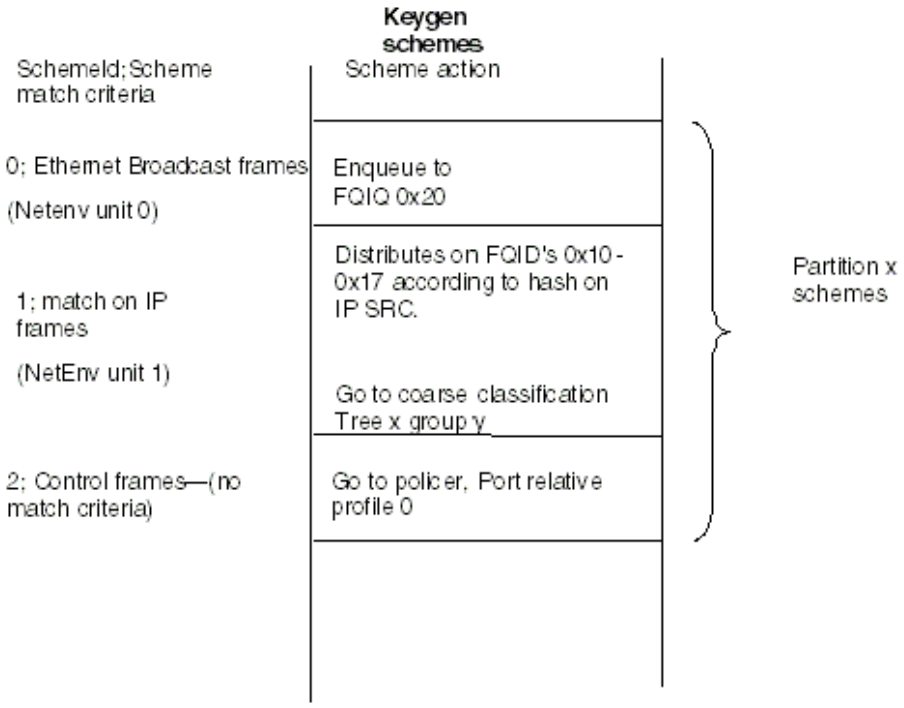

Figure 106. Schemes Example

Runtime Modifications: Valid schemes may be modified at runtime by calling the scheme initialization routine for an existing scheme with the following differences:

1. Passing the scheme handle as retuned by the original initialization routine (instead of the scheme's relative ID).
2. Setting 'modify' to be 'TRUE'.

New schemes may be set and unused schemes may be deleted anytime.

Available API:

- `FM_PCD_KgSchemeSet`
- `FM_PCD_KgSchemeDelete`

7.4.4.3.1.7.2.3.6 Custom Classifier Root

A Custom Classifier root (or actually the entire CC graph) may be defined per FMan Port or shared by ports on the same partition. It is a set of lookups defined to classify, route and perform manipulation on a flow of frames. The CC graph is built bottom up by connecting CC Nodes. When a node (which is not a leaf in the graph) is set, it points to other nodes. These other nodes must already be initialized.

A CC root is defined by a set of entries that construct the root of the graph, and Custom Classifier Nodes of different types.

Once all nodes in the graph are ready and connected, the root is built by calling the `FM_PCD_CcRootBuild` routine. The root of the graph is in fact an array of up to 16 root entry nodes. The entry point for a frame is one of the CC root entries, depending on the engine that precedes the CC which is the Keygen.

According to the parser results (which is defined by the NetEnv setting) and Keygen configuration, a frame is directed to one of the entries in the CC root array.

When building the CC root, the user must specify its NetEnv id. Up to four distinction units may define the selection of one node (out of the 16), in a simple bit selection method. The following table shows the CC Root nodes selection (0 = unrecognized by parser, 1 = recognized by parser).

Table 131. CC Root Nodes Selection

Unit0	Unit1	Unit2	Unit3	Selected Node
0	0	0	0	0
0	0	0	1	1
0	0	1	0	2
0	0	1	1	3
0	1	0	0	4
0	1	0	1	5
0	1	1	0	6
0	1	1	1	7
1	0	0	0	8
1	0	0	1	9
1	0	1	0	10
1	0	1	1	11
1	1	0	0	12
1	1	0	1	13
1	1	1	0	14

To allow more than 4 units to be involved in the selection, the 16 entries may be divided into groups. The table above demonstrates an organization of one group of 16 nodes, but other organizations are possible:

2 groups of 8 -> each group selected by 3 units (to select nodes 0-7 relative to this group's base)

4 groups of 4 -> each group selected by 2 units (to select nodes 0-3 relative to this group's base)

8 groups of 2 -> each group selected by 1 units (to select nodes 0-1 relative to this group's base)

16 groups of 1 -> indifferent to units (single node group always selected)

2-8 groups of varied sizes (8-1)

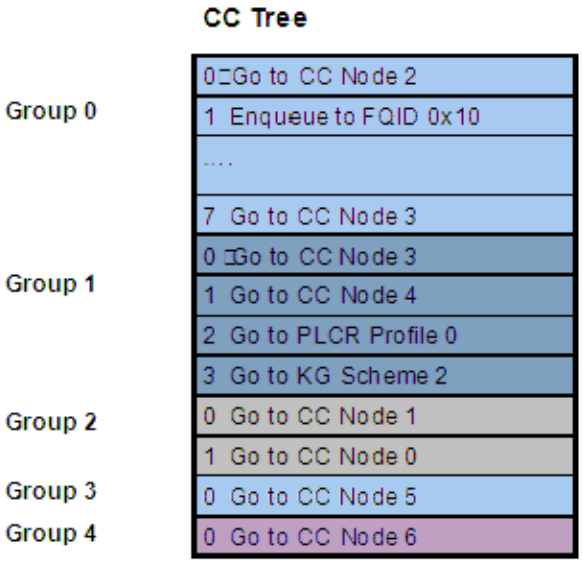

Figure 107. CC Root - 5 groups example

When building the CC Root, the user must specify the number and size of groups. Then, for each group, an array of per-root-node parameters is passed. The array is ordered according to the table above.

A simplified way of using the CC, is to define up to 16 different groups of one root-node each. In this way, all traffic from a specific Keygen scheme is going to the same group, which is a single node, and no NetEnv unit are selected. Groups 3 and 4 in figure above are an example of a single root group.

The following figure shows a combined use of the NetEnv units in Keygen and Custom Classifier, based on the previous NetEnv and Keygen scheme examples.

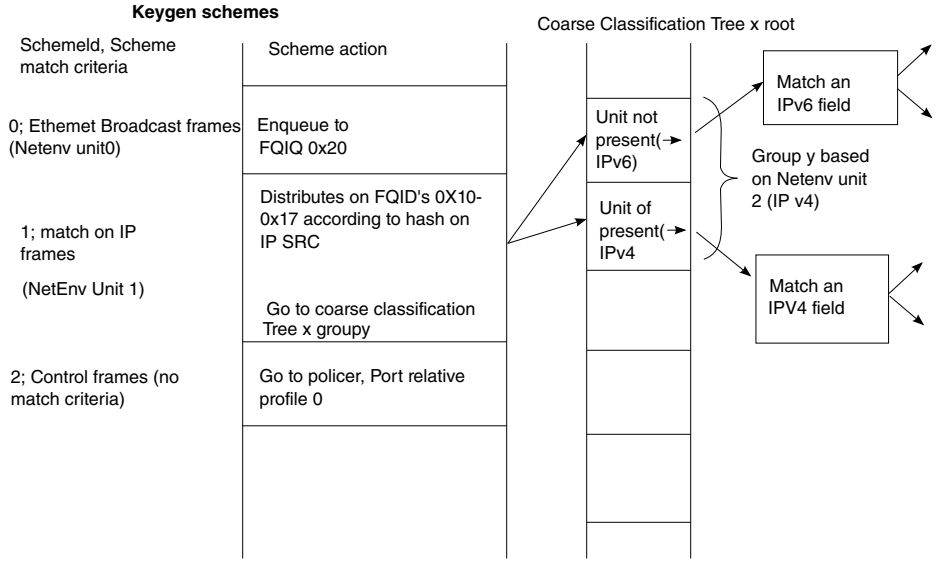

Figure 108. Keygen -> Custom Classifier Example

When a CC root or node is initialized, the driver returns a handle to the root or node respectively. This handle may be used later for specifying the root or node. For example, to build a root, the nodes are specified by passing their handles, and a root

handle must be passed when defining a port that uses the Custom Classifier. A port may be bound only to one root, from the same partition and NetEnv as the port.

Runtime Modifications: Custom Classifier nodes may be modified by using one of the routines listed in the "Available API" below.

Custom Classifier Roots may not be changed at runtime. New nodes and roots may be defined and unused ones may be deleted anytime.

Available API:

- `FM_PCD_MatchTableSet`
- `FM_PCD_MatchTableDelete`
- `FM_PCD_HashTableSet`
- `FM_PCD_HashTableDelete`
- `FM_PCD_CcRootBuild`
- `FM_PCD_CcRootDelete`

Specific runtime API:

- `FM_PCD_CcRootModifyNextEngine`
- `FM_PCD_MatchTableModifyNextEngine`
- `FM_PCD_MatchTableModifyMissNextEngine`
- `FM_PCD_MatchTableRemoveKey`
- `FM_PCD_MatchTableAddKey`
- `FM_PCD_MatchTableModifyKey`
- `FM_PCD_MatchTableModifyKeyAndNextEngine`
- `FM_PCD_MatchTableFindNModifyNextEngine`
- `FM_PCD_MatchTableFindNRemoveKey`
- `FM_PCD_MatchTableFindNModifyKeyAndNextEngine`
- `FM_PCD_MatchTableFindNModifyKey`
- `FM_PCD_HashTableAddKey`
- `FM_PCD_HashTableRemoveKey`
- `FM_PCD_HashTableModifyNextEngine`
- `FM_PCD_HashTableModifyMissNextEngine`

7.4.4.3.1.7.2.3.7 Match-Table Nodes

The driver defines two types of Match-Table nodes - Exact-Match nodes and Indexed-Lookup nodes. On both types of nodes a table of entries is defined where each entry leads to a selected next-engine with a selected action. The next-engines may be another CC Node, a Keygen scheme, a Policer profile or an enqueue action to a QM queue. In the last case, the queue may be either an Fqid (frame queue id) that was previously defined - typically by the Keygen, or an explicitly specified new Fqid that overrides any previous Fqid selection.

The difference between the two types of nodes is in the way an entry is selected in the node's table.

On an exact-match node, the user defines an extraction of data taken from the frame or the Internal-Context. The table of entries represent different possible values (keys) for this extraction, so that for each key a next-action is selected. An extra 'MISS' entry is also specified.

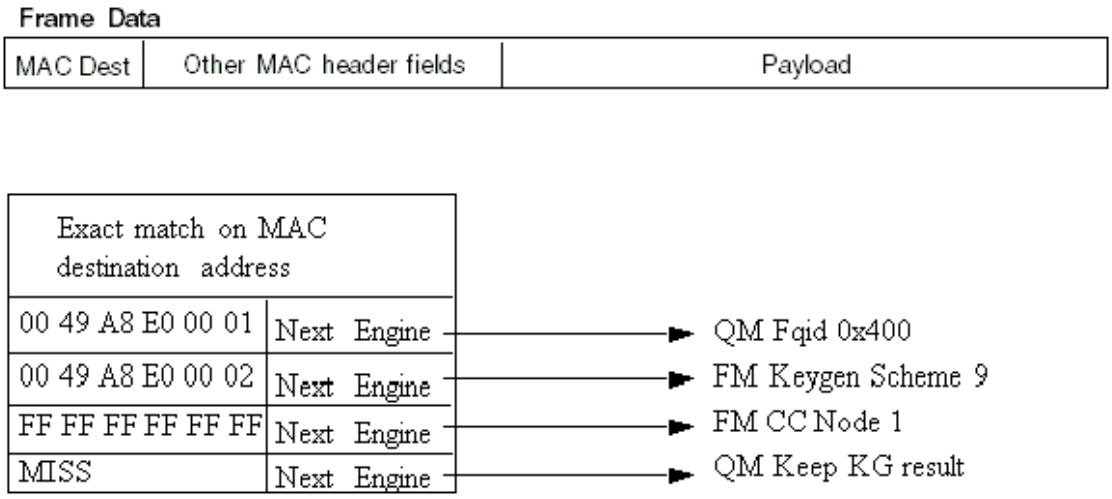

Figure 109. Exact-Match Node Example

On an Indexed-lookup node, up to 2^12 may be defined. The user selects 12 bits out of the Internal Context as an index to an entry in the table. The 12 bits may be masked to select less bits and a smaller table.

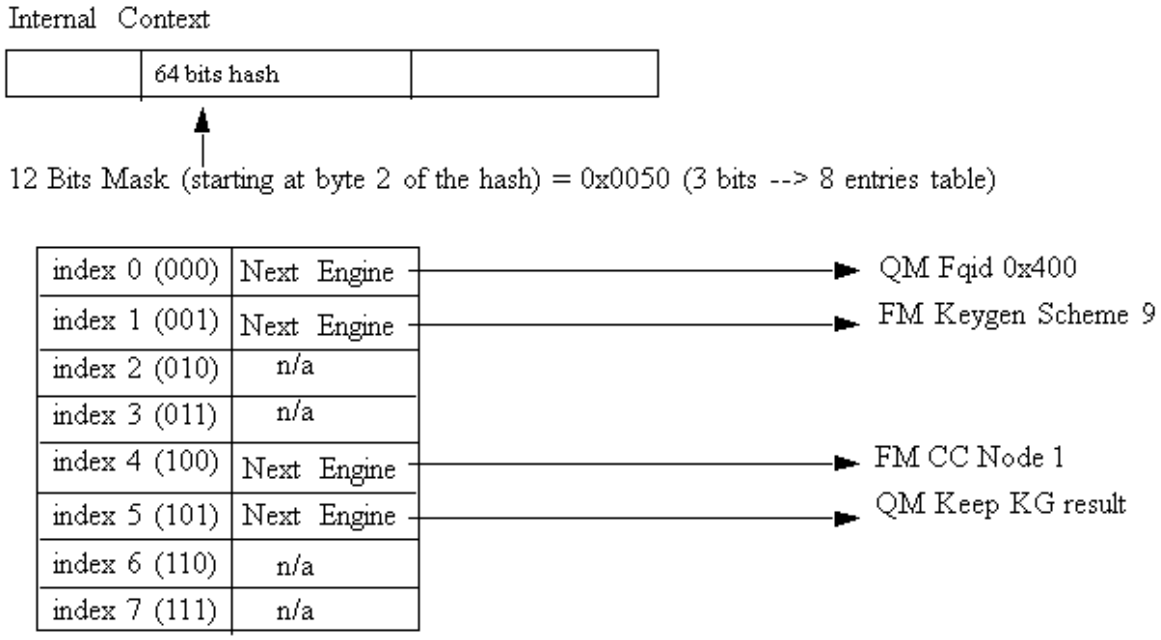

Figure 110. Indexed-Lookup node example

Two methods for CC node allocation are available: dynamic and static. Static mode was created in order to prevent runtime alloc/free of FMan memory (MURAM), which may cause fragmentation; in this mode, the driver automatically allocates the memory according to maximal number of keys, as received from the user. The driver calculates the maximal memory size that may be used for this CC node, taking into consideration whether key masks are required and node's statistics mode.

In dynamic mode, maximal number of keys is not provided (equals zero). At initialization, all required structures are allocated according to current number of keys. During runtime modification, these structures are re-allocated according to the updated number of keys.

7.4.4.3.1.7.2.3.8 Hash-Table Nodes

The Hash-Table node is a driver managed Hash table. It is defined as a next engine and may follow other CC nodes. The Hash-Table module uses driver lower level CC structures and provides an abstraction layer API consisting of AddKey/ RemoveKey routines. By using this module, the user may easily use a hash table based on Keygen key extraction and hash calculation. When initializing this node, the user should define parameters regarding the basic key used for hashing and the structure and size of the hash table (sets/ways).

7.4.4.3.1.7.2.3.9 Manipulations

On the structural aspect, Manipulation nodes are not graph nodes in the way that they do not effect the flow of a frame, and they are not in fact a graph junctions. Manipulations nodes are defined as extensions to existing CC nodes of all types. Any key on any CC node may have a manipulation characterization on top of the next engine definition. This is realized by CC node parameter `h_Manip` which is a handle to a previously initialized Manipulation node (according to the bottom-up principle). The Manipulation node itself does not have a next engine definition and the frame's flow is determined by the last CC node.

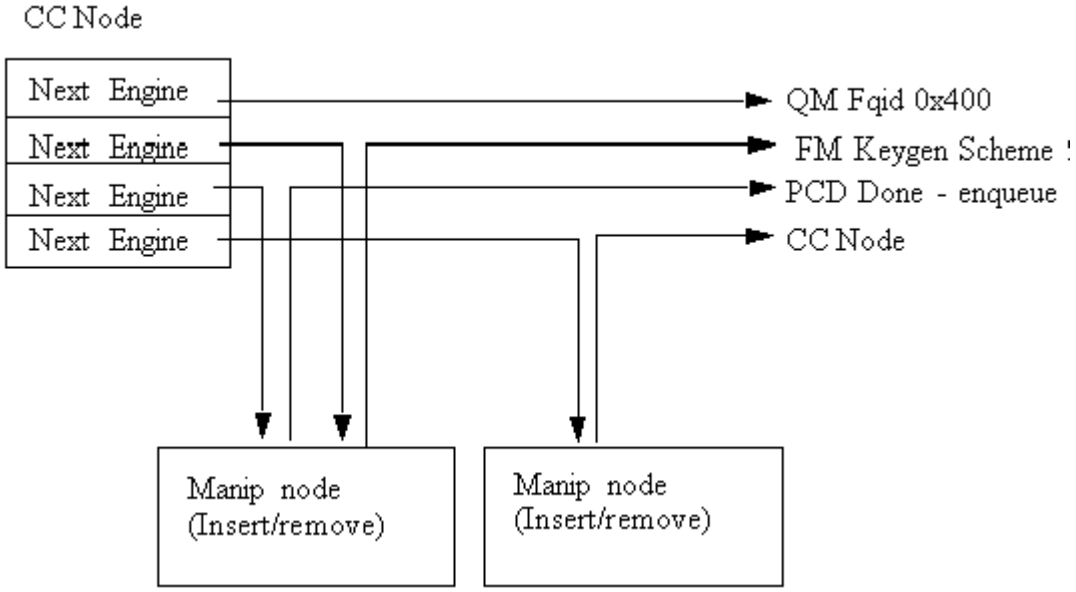

Figure 111. CC Node With Manipulation

Available API:

- `FM_PCD_ManipNodeSet`
- `FM_PCD_ManipNodeDelete`

Specific runtime API:

- `FM_PCD_ManipNodeReplace` (only available for Header-manipulation)
- `FM_PCD_ManipGetStatistics`

NOTE

- For all manipulation types below, the user must call 'FM_PCD_SetAdvancedOffloadSupport' before calling '`FM_PCD_Enable`'.
- For each RX/OP-Ports that will work with the above FM-PCD, the user should have at least 16 tnums (num of tasks). in order to set the tnums the user should call '`FM_PORT_ConfigNumOfTasks`'.
- It is also required to set the DMA transactions to be per port by calling '`FM_ConfigDmaAidOverride`' with 'FALSE' and calling '`FM_ConfigDmaAidMode`' with '`e_FM_DMA_AID_OUT_PORT_ID`'

7.4.4.3.1.7.2.3.9.1 Header Manipulation

The header manipulation is implemented by the FMan controller block, and is designed to change the incoming frame header for termination or interworking flow requirements. Header modification can be configured on a per-flow basis or for a user-determined group of flows.

The firmware defines some header manipulation structures which hold parameters for the definition of header manipulation action. It defines a basic table descriptor (Header Manipulation Table Descriptor HMTD) and a table of commands (HMCT), allowing a sequence of manipulations to be performed. The commands table may reside in either internal or external memory. The manipulation may be performed at any stage of the Custom Classifier process. As the manipulation changes the frame, the process allows an additional parsing of the processed frame once the manipulation process had ended.

The Header Manipulation (HM) mechanism is viewed by the driver as an extension to other Custom Classifier Nodes. It may take place at the beginning, the middle or the end of a CC graph, but it may not have an effect on the flow, i.e. the selection of the next action.

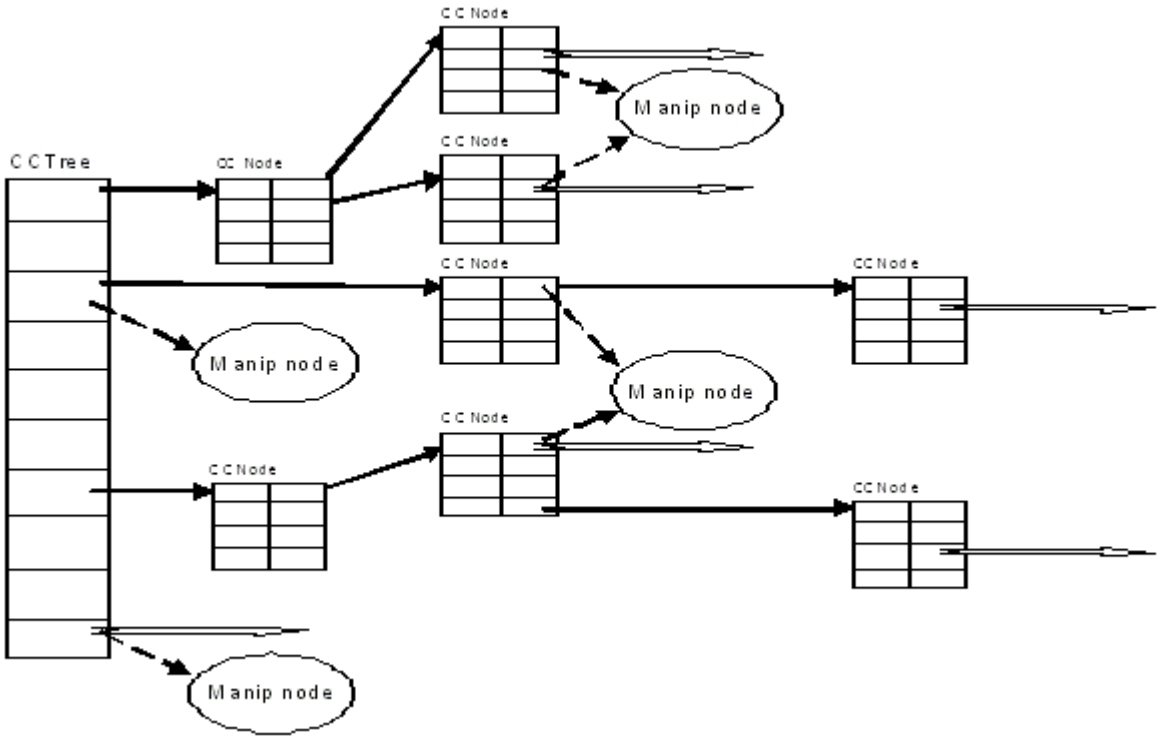

Figure 112. Header Manipulation CC Perspective

The HM action is represented by the driver's Manip node which is a driver sub-module (i.e. initialized by the user, its initialization routine returns an HM handle).

A Header Manipulation node is an independent unit that has no external information regarding other modules in the PCD graph, its users, its location in the flow, or the next engine it will be followed by.

A CC key or a CC root node may lead to a Header Manipulation node. The CC key/root node will define the next engine that should follow the manipulation. The next engine may be Keygen, Policer, another CC node, or PCD termination (enqueue).

In order to use the HM, the user should first create a Manip node, and than use its handle when defining the CC Node that points to this manipulation action.

A Header Manipulation action may be defined as one of the following manipulations:

- Remove
- Insert

- Fields Update
- Custom

More than one manipulation is allowed only if they are to be performed in the order above and only one manipulation of each type.

Other orders or a list of manipulations of the same type may be achieved by chaining some manipulation nodes by using the `h_NextManip` handle of the Manipulation parameters structure.

HM nodes may be shared, so that the same HM handle can be passed to more than one CC key.

By default, each frame goes back to the parser to be re-parsed after the manipulation. However this behavior may be disabled and may have an effect on performance as will be explained in the restrictions note below. It is controlled by the Header Manipulation node parameters.

The parsing option applies to whatever the user initialize as a Manip node - i.e. if the node contains a number of commands, the parsing can be done after all the commands and not between them. However, if the set of commands is initialized as a number of nodes that are chained together, the parser may be run after each node.

The driver aims to optimize performance and MURAM utilization. It does so by internally creating a single command table for chained nodes. Note that this optimization is NOT possible if parsing is required between manipulations and in this case the manip nodes are cascaded.

Note that when manipulations are chained, some restrictions apply:

1. Sharing of chained nodes is only possible on the head of the manipulation and not on inner nodes, i.e. all the manipulation is shared and not parts of it.
2. When parsing is required between manip nodes, the optimization described above is NOT possible and in this case the manip nodes are cascaded.
3. When parsing is required between manip nodes, the next engine of the last CC node may NOT be another CC node; i.e. chained nodes with parsing between them may only exist at the end (and not in the middle) of the CC graph.

7.4.4.3.1.7.2.3.9.2 IP Reassembly

The FM supports IP reassembly for both IPv4 and IPv6. The FMan accumulates IP fragments until enough have arrived to completely reconstitute the original datagram. IP Reassembly supports a maximum of 16 fragments per frame. Each fragment must reside in a single buffer (not in a Scatter/Gather frame).

The IP Reassembly driver utilizes the FMan Controller and FMan PCD resources in order to provide a full IP Reassembly solution.

The driver's interface is not identical to the hardware resources and provide an abstraction layer to the hardware resources. All IP Reassembly hardware data structures used for IP reassembly manipulation are represented by the software Custom Classifier Manipulation node. On top of the CC Manipulation, the driver internally defines the other resources needed for the full flow.

IP Reassembly flow

Fragments arriving on an Rx (or offline parsing) FMan Port that was configured to support IP Reassembly are recognized and marked by the software parser extension. These frames are steered to direct schemes the Keygen and caught by dedicated schemes that pass them to the Custom Classifier. The CC Root object is configured so that the IP fragments will reach a dedicated root entry node that contains a CC manipulation node. At this point, the IP Reassembly is performed. When a full frame is gathered, it is passed by the FMan controller back to the parser as a full reassembled frame. It is then passed to the Keygen and may be distributed and classified as any other frame.

What should the user do?

The following sequence describes the steps the user must take in order for the flow above to work.

- Initialize general DPAA (BM, BM Portal, BM Pools, QM, QM Portal, FMan and FMan PCD)
- Initialize the Rx/Offline FMan Port on which reassembly should run

- Define PCD as follows:
  - Set a Network Environment with one of the following options:
    - `HEADER_TYPE_IPV4` unit with `IPV4_FRAG_1` option for IPv4 reassembly manipulation.
    - `HEADER_TYPE_IPV6` unit with `IPV6_FRAG_1` option for IPv6 reassembly manipulation.

    Note that if the user needs IPv4 or IPv6 units for other use, the fragmentation units may not be shared and dedicated units must be defined.
  - Allocate the first one or two schemes - one if only IPv4 is used, 2 if IPv6 is also used. The user should not configure those schemes, just save these schemes from other usage. The driver will use the first scheme for IPv4, and if needed, it will use the second for IPv6.
  - Create reassembly manipulation using `FM_PCD_ManipNodeSet` routine. Pass the relative id's of the schemes allocated above (A single manipulation module should be created for both IPv4 and IPv6 fragmented frames, passing all relevant parameters).
  - If CC is used, it is user's responsibility to leave two unused entries when building the CC root nodes (i.e. the total number of entries between all groups should not exceed 14).
  - Set at least one scheme to catch regular/reassembled frames.
- When binding the Rx/Offline FMan Port to the PCD properties (i.e. calling `FM_PCD_SetPCD`), pass a handle to the created Reassembly Manipulation node.

Note that in order to perform distribution or classification on IPv4/IPv6 frames (unrelated to reassembly of IPv4/IPv6 fragments), independent IPv4/IPv6 units with no option must be explicitly defined.

What does the driver do?

In order to provide the required support for IP Reassembly, the driver performs some internal actions triggered by the user configuration. The following information describes the actions the driver internally performs and has no functional relevance to the user:

- When reassembly is required, the driver internally enables parser recognition of IPv4/IPv6 and shim2 - which is the IP Reassembly extension. This is triggered by the user defining NetEnv units with options: `IPV4_FRAG_1/IPV6_FRAG_1`.
- The driver loads the software parser that identifies IP fragments and enables its operation for the required FMan Port.
- The driver defines one or two (one for each IP version) Keygen schemes that recognize IP fragments and are programmed to generate an IP Reassembly key. When a frame is recognized as an IP fragment (by the Parser), it is steered to these Keygen schemes. The user should allocate the first one or two (for IPv4 and/or IPv6) schemes and pass their relative id's to the driver. The driver will internally initialize the relevant reassembly schemes when required.
- Each of the schemes above is programmed by the driver to point to a group in the Custom Classifier Root. If the user did not create a CC Root, the driver internally creates a new one. In both cases, the driver creates the needed group/s in the CC Root. It always uses the last two groups. It is user's responsibility to have at least two empty entries (one for a single IP version, two for both).
- The driver attaches the Manipulation sequence (created by the user) to the appropriate root entry node in the CC Root, causing the reassembly of IP fragments.

NOTE

The software parser code required to support reassembly may not coexist with user software parser code. If the user supplies IPv4 or IPv6 software parser code, it must include the code for handling IPv4/IPv6 reassembly according to the FMan controller spec.

Suggestions of how to use IPR in a system

The PCD with the IPR should identify frames up to L3; i.e. if the frame is IP or not.

In case it isn't an IP frame it should pass the desire PCD. IP frames should pass the reassembly process and than be directed to OP-Port to be classified according to their L3 and above.

7.4.4.3.1.7.2.3.9.3 IP Fragmentation

The FMan supports IP fragmentation for both IPv4 and IPv6. The fragmentation mechanism is implemented by the PCD, specifically by the Custom Classifier. IP fragmentation may be performed using an Offline Parsing FMan Port with a specific PCD configuration that will be described in this section.

The software driver provides API for initializing the IP fragmentation mechanism. driver's interface is not identical to the hardware resources and provide an abstraction layer to the hardware resources. Both of the AD (action descriptor) tables that used for IP fragmentation manipulation represented by the software Custom Classifier nodes using CC Manipulation. IP Fragmentation manipulation is used for fragmentation of IPv4 and IPv6 frames according to a specific MTU. This manipulation can be used on Offline Parsing ports only and as a part of the port's PCD definition. CC Nodes should have an IP fragmentation manipulation characterization in order to trigger this manipulation. This means that in order to create and initialize the IP fragmentation hardware, the user should create a Custom Classifier Node with Manipulation (refer to Custom Classifier Root on page 739). All relevant parameters such as MTU are defined during this module creation.

Following is the sequence that should be followed:

- Initialize general DPAA (BM, BM Portal, BM Pools, QM, QM Portal, FMan and FMan PCD)
- Initialize FMan Port of type Offline Parsing
- Define fragmentation PCD as follows:
  - Initialize an empty Network Environment (without any units)
  - Create fragmentation manipulation using `FM_PCD_ManipNodeSet` routine.
  - Create CC Node by calling `FM_PCD_MatchTableSet`/`FM_PCD_HashTableSet` and attached the fragmentation manipulation previously created to the desired key.
  - Build a CC Root with 1 group that points to the previously defined CC Node .
- Bind the Offline Parsing FMan Port to the PCD properties by calling `FM_PORT_SetPCD`

Manipulation parameters

- MTU of the fragmentation manipulation.
- Scratch Buffer Pool ID is a buffer pool that is required by the fragmentation process in order to ensure correct release operation of the frames and fragments. All IP Fragmentation Table Descriptors should use the same Scratch Buffer Pool ID. This pool must not be used by any other process or engine in the system.
- Don't Fragment Action - by setting this parameter the user can determine the action to be taken in case the IP packet is larger than the defined MTU and the 'Don't Fragment' (DF) bit of the frame is set.

NOTE

The software parser code required to support fragmentation may not coexist with user software parser code. If the user supplies IPv6 software parser code, it must include the code for handling IPv6 fragmentation according to the FMan controller spec.

Restrictions:

1. Tx confirmation is not supported.
2. Only Bman buffers shall be used for frames to be fragmented.
3. IP-Fragmentation will not work on OP-Port with VSP enabled.
4. fragmentation of IP-fragments is not supported
5. IPv4 packets containing header option field are fragments by copying all option fields to each fragment, regardless of the copy bit value.
6. Maximum number of fragments per frame is 16.

Suggestions of how to use IPF in a system:

In case one of the #1-#2 3 restrictions above is critical than it is suggested not to use IPF on OP-Ports that receive frames from the GPP and to do it on the GPP itself. We also suggest to put the IPF on a OP-Port just before the TX-Port.

7.4.4.3.1.7.2.3.9.4 IPSec Manipulation

The IPSec Manipulation is a specific instantiation of the special offload manipulation. It is designed to handle IPSec traffic in order to support the following actions:

- Support of variable outer header size

  The user should initialize a Manipulation node of this type passing the relevant parameters
- Support for both ipv4/ipv6 IP version within SA

  The user should initialize a Manipulation node of this type passing the relevant parameters.
- ECN/DSCP copying from inner/outer IP header to outer/inner.

  In order to use this functionality the user must follow the following steps:
  - Define a Manipulation node of this type passing the relevant parameters
  - For the relevant Rx/OP port, define a buffer prefix that includes at least the Keygen hash result.
  - Use SEC parameters to support this operation

7.4.4.3.1.7.2.3.10 **Frame Replicator**

The Frame Replicator (FR) is designed to duplicate incoming packets and route them to separate destinations. It is defined as a next engine and may follow other CC nodes, i.e. Match-table key, Hash-Table key or a CC-Root entry.

A Frame Replicator is realized by a group of members, where each member defines a replication of the incoming frame and a route to continue.

The next engine after FR is restricted to one of the following:

- Enqueue (PCD Termination)
- Policer
- Keygen (Direct scheme that leads to either Policer or PCD Termination)

When initializing an FR node, the user must define the maximum number of members this node may contain. The actual number of members may be modified on runtime by adding and removing FR group members.

Runtime modifications of add/remove members to/from the group can be done at any point in the system and in any location of the members group (first, middle or last). Note that runtime-modifications require the use of Host Command.

The order of the members in the group is of significance as the implementation of the replication is serial.

Manipulation may be applied to:

1. The whole group. The manipulation node should be placed before the replication group. That means that the FR is the next-engine of the Manip node. The Manip node is the next-engine of a key in a Match-table or Hash-table.
2. The last member of a FR group. That means that the manip node is the next-engine of the last member of the FR group.

NOTE

No support of Manip node after the "non-last" members.

The driver supports sharing of FR nodes means that FR group may be shared by more than one source.

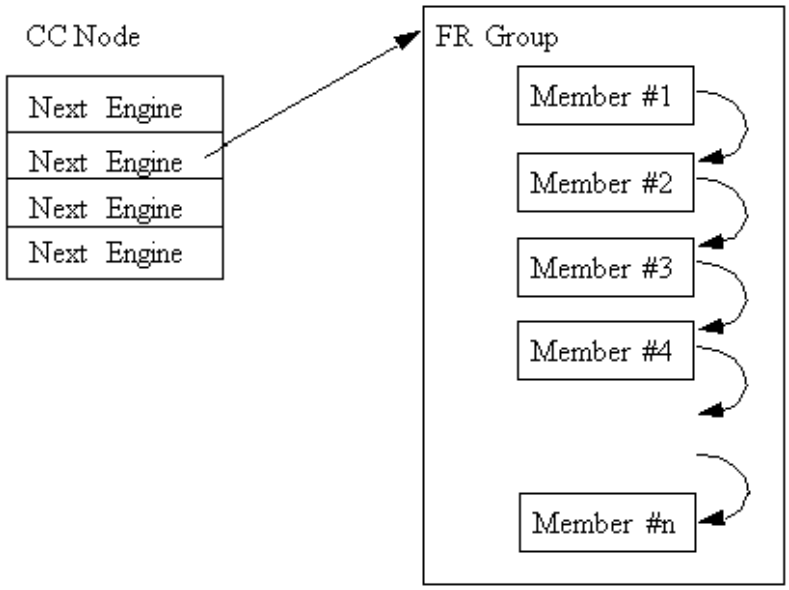

Figure 113. Frame Replicator Following a CC Node

Available API:

- `FM_PCD_FrmReplicSetGroup`
- `FM_PCD_FrmReplicDeleteGroup`

Specific runtime API:

- `FM_PCD_FrmReplicAddMember`
- `FM_PCD_FrmReplicRemoveMember`

NOTE

- For all manipulation types below, the user must call `'FM_PCD_SetAdvancedOffloadSupport'` before calling `'FM_PCD_Enable'`.
- For each RX/OP-Ports that will work with the above FM-PCD, the user should have at least 16 tnums (num of tasks). In order to set the tnums, the user should call '`FM_PORT_ConfigNumOfTasks`'.
- It is also required to set the DMA transactions to be per port by calling '`FM_ConfigDmaAidOverride`' with 'FALSE' and calling '`FM_ConfigDmaAidMode`' with '`e_FM_DMA_AID_OUT_PORT_ID`'

7.4.4.3.1.7.2.3.11 Policer Profiles

The policer profile entity relies on the hardware entity. It defines rules for policing for a certain flow. There are 256 different profiles in a frame manager that may be organized in per port windows. Some profiles may be shared between ports on the same PCD. By default, the number of shared profiles is set by the driver, but the user can also configure it to a different value. Shared profiles are typically used for aggregation.

When a PCD is defined in a single partition environment, it is the owner of all 256 profiles. When a PCD is defined in a multipartition environment, it is the owner of its shared profiles along with all the profiles that will be allocated per port for ports on this partition. The user must explicitly allocate per-port profiles for each port (if required), after PCD is initialized and prior to the profile initialization. Note that per-port profiles are the only PCD resource that is explicitly allocated and initialized for a specific port.

After profiles are mapped, the user may initialize each of the profiles by stating the following:

- Type
  - Shared
  - Per-port
- Offset relative to the port or to the shared group of profiles
- Characteristics

Once initialized, a handle is assigned to the profile for later use.

The Policer may be used after the Parser, Keygen or Custom Classifier, or solely - without activating any of the other PCD engines. It is not dependant on any previous output such as parser result. The policer may be used more than once in a frame flow. The next action after a police profile is either to pass the frame to a direct Keygen scheme for a new distribution (typically for control frames coming from the Custom Classifier), to pass the frame to another profile (always a shared profile, typically an aggregators), or to enqueue the frame to an FQID.

When other engines select a policer profile as the next engine, its handle must be passed. An exception is when a per-port profile is specified as the next engine of a scheme or of a "overrideParams" CC key. In these cases a port-relative index is required instead. The reason for this is that the required Policer Profile may not be initialized at this stage and hence have no handle. This irregular behavior is because CC Roots and KG schemes may be shared by ports, and at the time of scheme/root initialization, they are not yet bound to specific ports. In this context, the profile selected may in fact be uninitialized and therefore can't be verified by the driver. It is therefor user's responsibility to make sure it is set prior to port- PCD binding.

Runtime Modifications: Valid profiles may be modified at runtime by calling the profile initialization routine for an existing profile, passing the profile handle as retuned by the original initialization routine, and specifying modify (instead of the profile's relative id). New profiles may be set and unused profiles may be deleted anytime.

Available API:

- `FM_PCD_PlcrProfileSet`
- `FM_PCD_DeleteProfilePlcr`

7.4.4.3.1.7.2.3.12 PCD Organization

By initializing PCD resources, the user creates a directed graph in which the parser is the source of the graph and the FQIDs are its endpoints. Following figure shows a generalized example of a basic PCD graph.

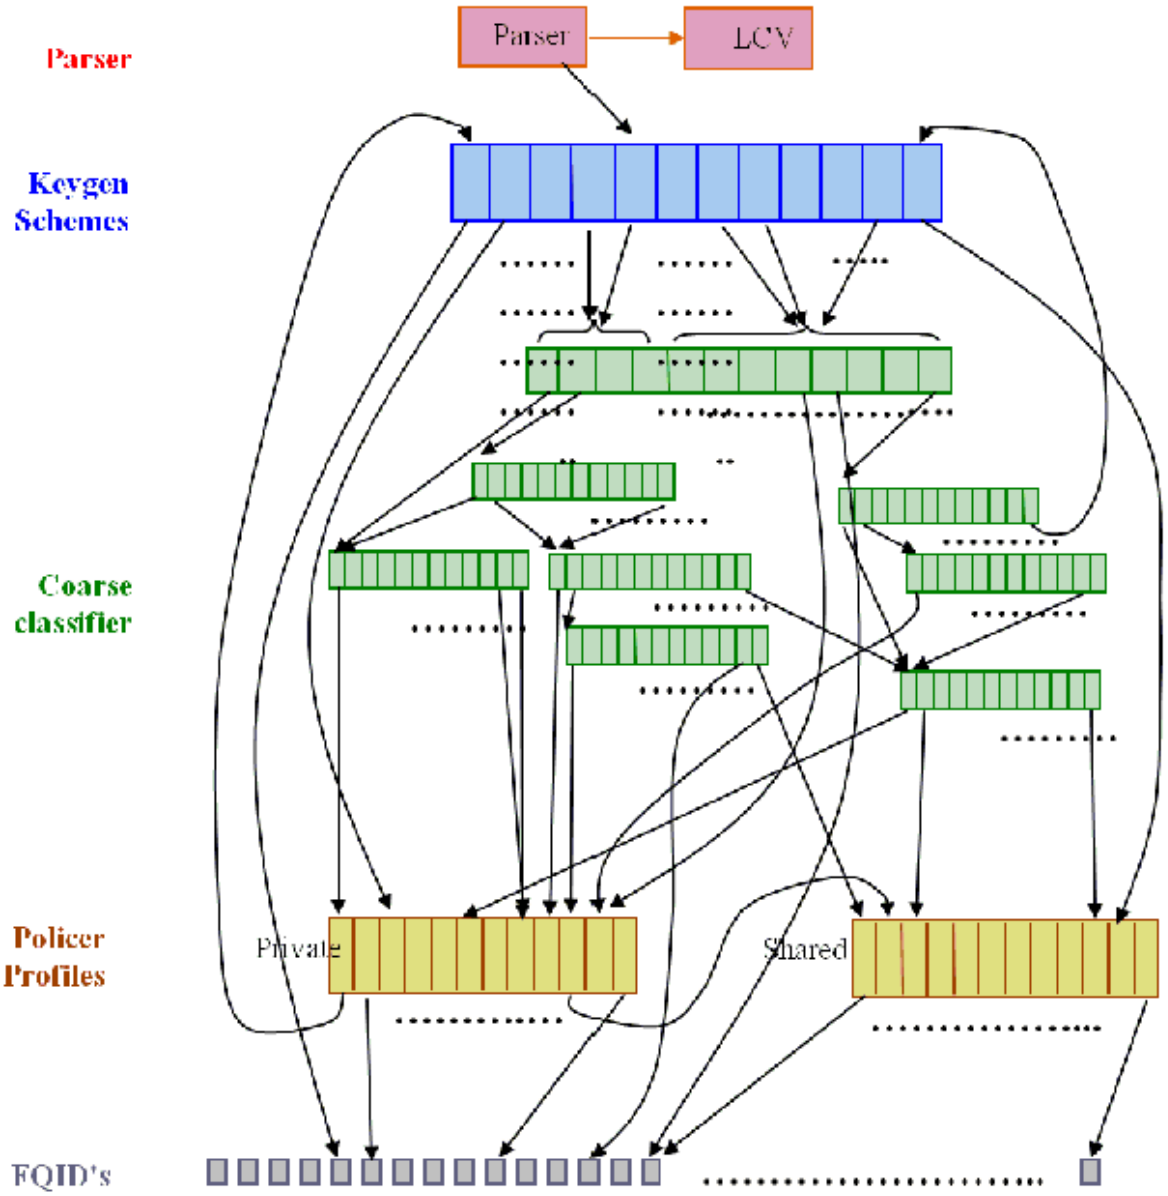

Figure 114. PCD Organization

7.4.4.3.1.7.2.3.13 PCD Definition Sequence

When a PCD graph is defined, its resources must be initialized bottom up when there's a dependency between them. Following figure shows the order of initialization (starting at the top of the figure) in a specific sequence.

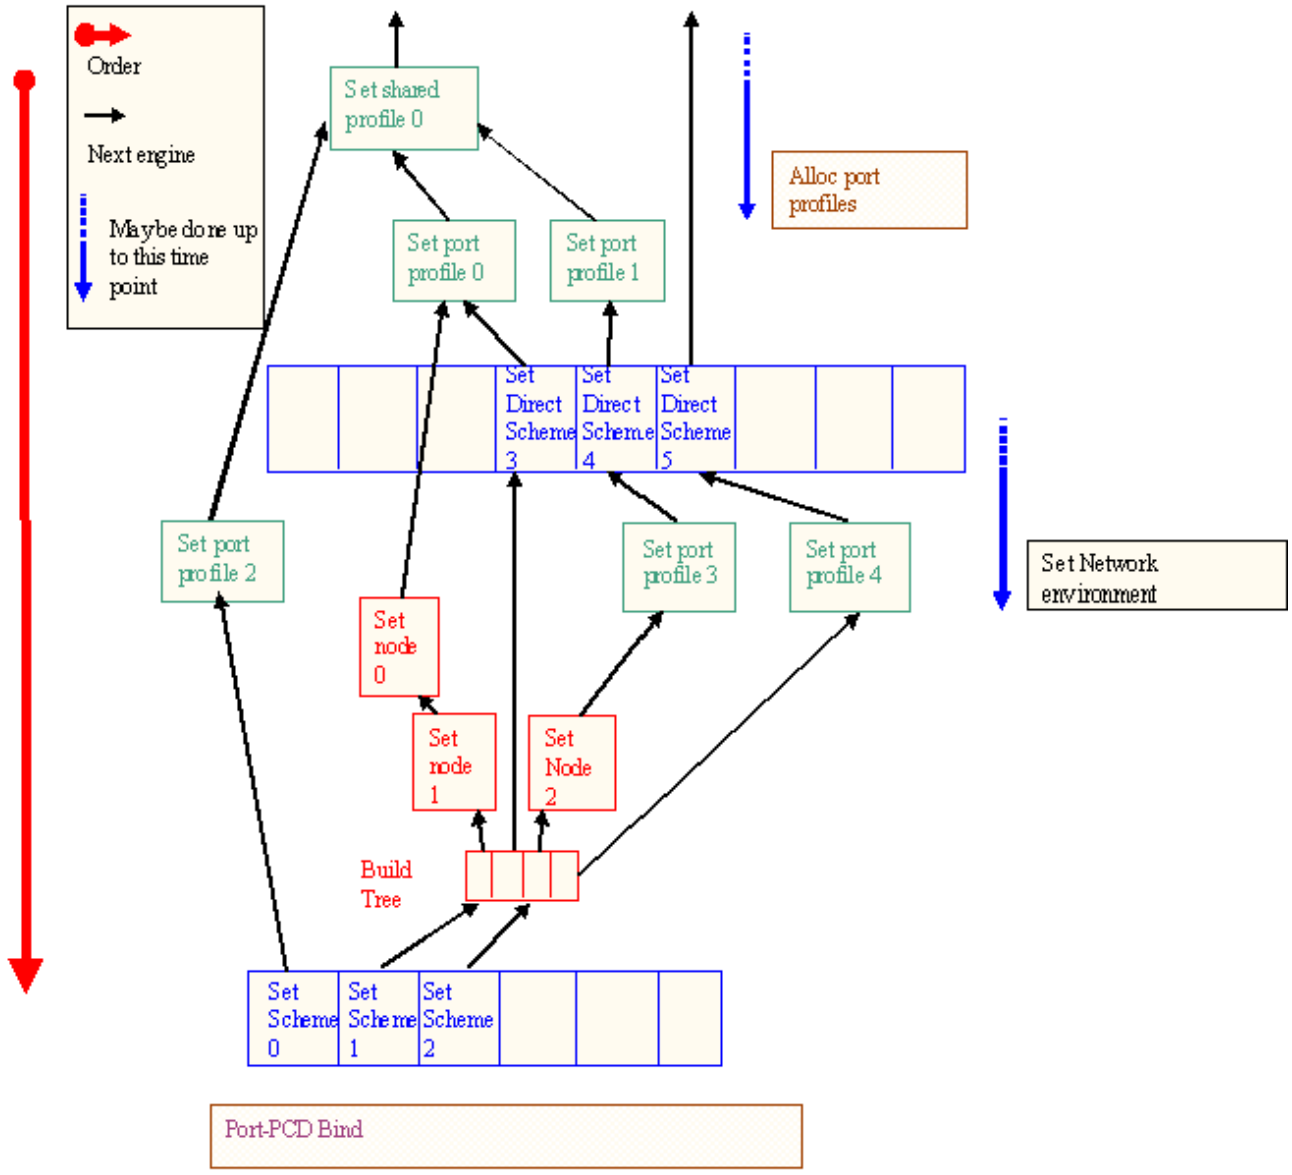

Figure 115. Definition Sequence

7.4.4.3.1.7.2.3.14 Host Command

Some PCD functionalities may be managed by either memory-mapped registers or by the host command mechanism to allow independent programming in a multipartition environment. In a single partition environment in the FMan driver, the host command mechanism is optionally used, but in a multipartition environment, wherever available, only the host command is used to prevent a risk of racing. The host command driver is a part of the PCD driver and is initialized internally by the driver, using user parameters.

When PCD is first initialized in a single-partition environment, the user must specify whether the host command should be used, and if so, host command parameters are required. In a multipartition environment, the use of the host command is forced and all host command parameters are required. When PCD initialization routine is called by the master/single partition driver, the user parameters include host command port parameters (such as port id, virtual address, and default queues) and the FMan Port for the host command is internally initialized.

7.4.4.3.1.7.2.3.15 PCD Statistics

The FMan PCD API provides access to all the statistics gathered by the FMan PCD engines hardware. Statistics is enabled by default but may be disabled/enabled at runtime using the dedicated API.

The following API routines may be called at any time after initialization to retrieve any of the following FMan PCD counters:

- `FM_PCD_GetCounter`
- `FM_PCD_KgSchemeGetCounter`
- `FM_PCD_PlcrProfileGetCounter`

7.4.4.3.1.7.2.3.15.1 Custom Classifier Statistics

A CC node supports statistics gathering on per-key basis. In order to enable statistics gathering by a CC node (Match table or Hash table), statistics mode must be provided upon initialization of that node and this will determine the statistics mode for all keys of the CC node.

Next, statistics should be enabled per-key, meaning statistics should be enabled for every key that the user wishes to monitor.

After these steps, the following API routines may be called to retrieve the statistics:

- `FM_PCD_MatchTableGetKeyCounter`
- `FM_PCD_MatchTableGetKeyStatistics`
- `FM_PCD_MatchTableFindNGetKeyStatistics`
- `FM_PCD_HashTableFindNGetKeyStatistics`

7.4.4.3.1.8 FMan Port Driver

The FMan Port driver module refers to the per-port features of the FMan, including port configuration and initialization, runtime functionalities and PCD binding.

7.4.4.3.1.8.1 FMan Port Hardware Overview

The FMan hardware supports a SoC dependent number of inline and offline FMan Ports of the following types:

- 1G Rx Ports
- 1G Tx Ports
- 10G Rx Ports (may be eliminated on some SoCs)
- 10G Tx Ports
- Offline/Host-command ports

Port configuration is controlled through a set of per-port, type-dependent memory mapped registers. I.e. Each port has its own memory map area. In addition, some FMan common registers also effect port behavior - for example, global resources such as tasks number are declared in the common registers are.

7.4.4.3.1.8.1.1 FMan Port Driver Software Abstraction

The FMan Port module is an independent module. On port configuration, the user selects the type and the mode of each port (Tx/Rx, 1G/10G, online/offline/Host command, regular/independent), and specifies the port index relative to its type. This index is not related to the hardware port id as described in the hardware spec.

The driver provides abstraction to the common/private division of registers location in the memory map. i.e. all registers that are logically relevant to the port are handled by the FMan Port driver, even if they physically belong to the common FMan memory map.

7.4.4.3.1.8.2 How to use the FMan Port Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.8.2.1 FMan Port Driver Scope

- FMan Port hardware structures configuration and enablement
- Resource allocation and management
- FMan port types support
- Offline-Parsing ports
- Independent-Mode
- Simple BMI-to-BMI (regular) mode
- PCD Binding
- Rate limiting
- Interrupt handling
- Statistics support

7.4.4.3.1.8.2.2 FMan Port Driver Sequence

- FMan Port Config routine
- [Optional] FMan Port advance configuration routines
- FMan Port Init routine
- FMan Port runtime routines
- FMan Port Free routine

7.4.4.3.1.8.2.3 FMan Port Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.8.2.3.1 FMan Port Configuration and Initialization

On FMan Port driver initialization, the software configures all FMan Port registers. It supplies default values where no other values are specified, it enables hardware mechanisms and initializes software data structures for software management.

By the time initialization is done, FMan is ready to be used and any of the FMan sub-modules (FMan-Ports, MAC's etc.) may be initialized.

7.4.4.3.1.8.2.3.2 FMan Port Types

The driver provides API for the initialization of the following port types/modes:

- Tx 1G port
- Tx 1G port - independent mode
- Rx 1G port
- Rx 1G port - independent mode
- Tx 10G port
- Tx 10G port - independent mode
- Rx 10G port
- Rx 10G port - independent mode
- Offline Parsing Port

The driver also holds a single host-command port internally when mandatory (multi-partition environments) or when user explicitly requires it.

7.4.4.3.1.8.2.3.3 Independent-Mode

A port may be configured to operate in independent-mode. In such case no PCD may be defined. A slightly different set of parameters is required as the FMan functions differently.

7.4.4.3.1.8.2.3.4 Resource Management

FMan Port related resources (TNUMs, DMAs, FIFOs, etc.)- These resources are used by the BMI. The driver selects default values for these resources but they may be need some tuning depending on the specific application, based on the total number of ports used and the performance requirements of the system. The driver provides an API routine `FM_PORT_AnalyzePerformanceParams` that uses performance monitoring mechanism in order to see the resources utilization at runtime.

The FMan Port driver allocates its resources by calling the FMan "front-end" driver. The FMan "front-end" allocates the resources by calling the "back-end" through IPC if its in guest-mode or through direct call if its not in master-mode. The port driver does not access those resources at run-time; the resources are being used only by the hardware of a port.

PCD related resources (Keygen-schemes, policer-profiles, etc.)-During the initialization of the FMan-PCD driver on each partition, the driver allocates all the required resources (configurable by the user) through IPC call to the "back-end" driver. From that point, all the resources are being handled locally on the partition. Note, that all access to these resources are still done through host-command and that assures proper synchronization between different partitions (i.e. one can access these resources by mistake from a different partition in the system).

PCD Custom-Classifier tables-The CC tables are being allocated on the MURAM memory. This means that upon initialization of this partition, piece of MURAM should be allocated to the partition (according to how much the partition requires). From that point, the local PCD driver will manage the MURAM allocation by itself.

7.4.4.3.1.8.2.3.5 Virtual Storage Profiles Support

An FMan Port may use the legacy Physical Storage Profile or the Virtual Storage Profiles (VSP). This section will discuss the usage of VSP by an FMan port, while more information about the VSP mechanism which is implemented by the driver as separate entity `FM_VSP`, can be found in FMan VSP Driver on page 763.

When a user wants to set an Rx or OP port to work in virtualization mode using VSP's rather than the physical SP, user should call the function which allocates a storage profile window (range of VSPs allocated in continuously manner) to a port. The user should also define which profile in this range should be used as default SP; note that the default profile should be a relative index within the allocated window. Upon calling the window allocation routine, the driver enables virtual mode (i.e. using VSPs) for this port, allocates its profiles and defines default SP. In order to redirect a packet into a certain VSP, user may set the 'relative-VSP-id' within the PCD graph nodes (e.g. in the match-table entries). The value in the PCD graph nodes is port relative so if two ports are sharing the same PCD graph node (e.g. a match-table), the actual VSP will be selected by the 'relative-VSP-id' plus the port's base VSP as shown in the figure below.

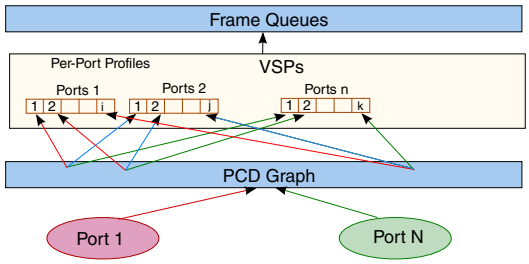

Figure 116. FMan PCD graph and the VSP selection

Rules and restrictions regarding the use of VSP:

- When called for Rx ports, the allocation routine expects also the handle of coupled Tx port as a parameter; the driver sets automatically the Tx port to work in VSP mode also and use the same default profile for this port.
- Storage Profiles windows may not overlap; i.e. sharing of VSPs between FM ports is not allowed by the driver.

- A call to the allocation routine requires that the FM port will be disabled. In the case of Rx port, coupled Tx port should also be disabled. When an FM Port (that has VSP mechanism enabled) is enabled, at least the default profile must be initialized.
- A call to the allocation routine may not be reverted, i.e. it's impossible to disable virtualization mode.
- Number of profiles to be allocated must be a power-of-2. In addition, the "base-profile" that will be allocated by the driver will be aligned to the number-of-profiles provided by the user.
- For FM-Port that works with VSP, its classification should also use VSP; i.e. classification (e.g. KG scheme or CC-node) should NOT try to revert from VSP to the FM-Port "physical" SP.
- When user frees all resources of FM port, the driver frees automatically VSP window which have been allocated for this port.

Initialization Sequence:

- Initialize FM Tx Port
- Initialize FM Rx Port
- Allocate VSP for FM Rx Port (thus enabling virtualization mode)
- Initialize default VSP (See FMan VSP Driver on page 763)
- Enable FM Ports

Free Sequence

- Disable Ports
- Free the default VSP
- Free FM Tx Port
- Free FM Rx Port

7.4.4.3.1.8.2.3.6 Rate Limiting

The driver supports the hardware mechanism of rate limiting for Tx ports. The runtime API consists of a number of parameters including a definition of the required rate (in KB/sec for Tx ports, in frame/sec for offline parsing ports) and refers to data rate rather than line-rate.

7.4.4.3.1.8.2.3.7 Simple BMI-to-BMI (regular) mode

This is the default FMan Rx/Offline Parsing Port mode. After Port initialization and prior to Port-PCD binding, all traffic will be received on the default Rx queue. This mode is called "BMI-To-BMI" as no PCD is involved in the data reception.

This mode is useful for the early state of a port as well as when major runtime PCD modification takes place. In such a case, sometimes the whole PCD functionality needs to be manipulated and the user should temporarily detach the Port from the PCD, receive all frames on the default Rx queue and only re-attach it to the PCD after the modifications have completed.

7.4.4.3.1.8.2.3.8 Port LIODN

An FMan Port LIODN is constructed out of a base and offset.

Upon FMan Port configuration, the user must specify the port's base LIODN.

For Rx ports, the user must also specify the LIODN offset for each port. No such configuration is required for Tx and Offline Parsing ports since on transmission, the offset LIODN is taken from the frames' FD. The FD is set according to the source of the frame - if transmitted by CPU, it is dynamically set by the QM SW portal. Another scenario is frames forwarded by other engines, in such a case their FD must contain the correct LIODN offset.

7.4.4.3.1.8.2.3.9 Port-PCD Binding

Ports may be linked to the PCD graph according to their PCD binding specifications and considering partition and Network Environment restrictions.

Following figure shows a schematic demonstration of possible port > PCD binding.

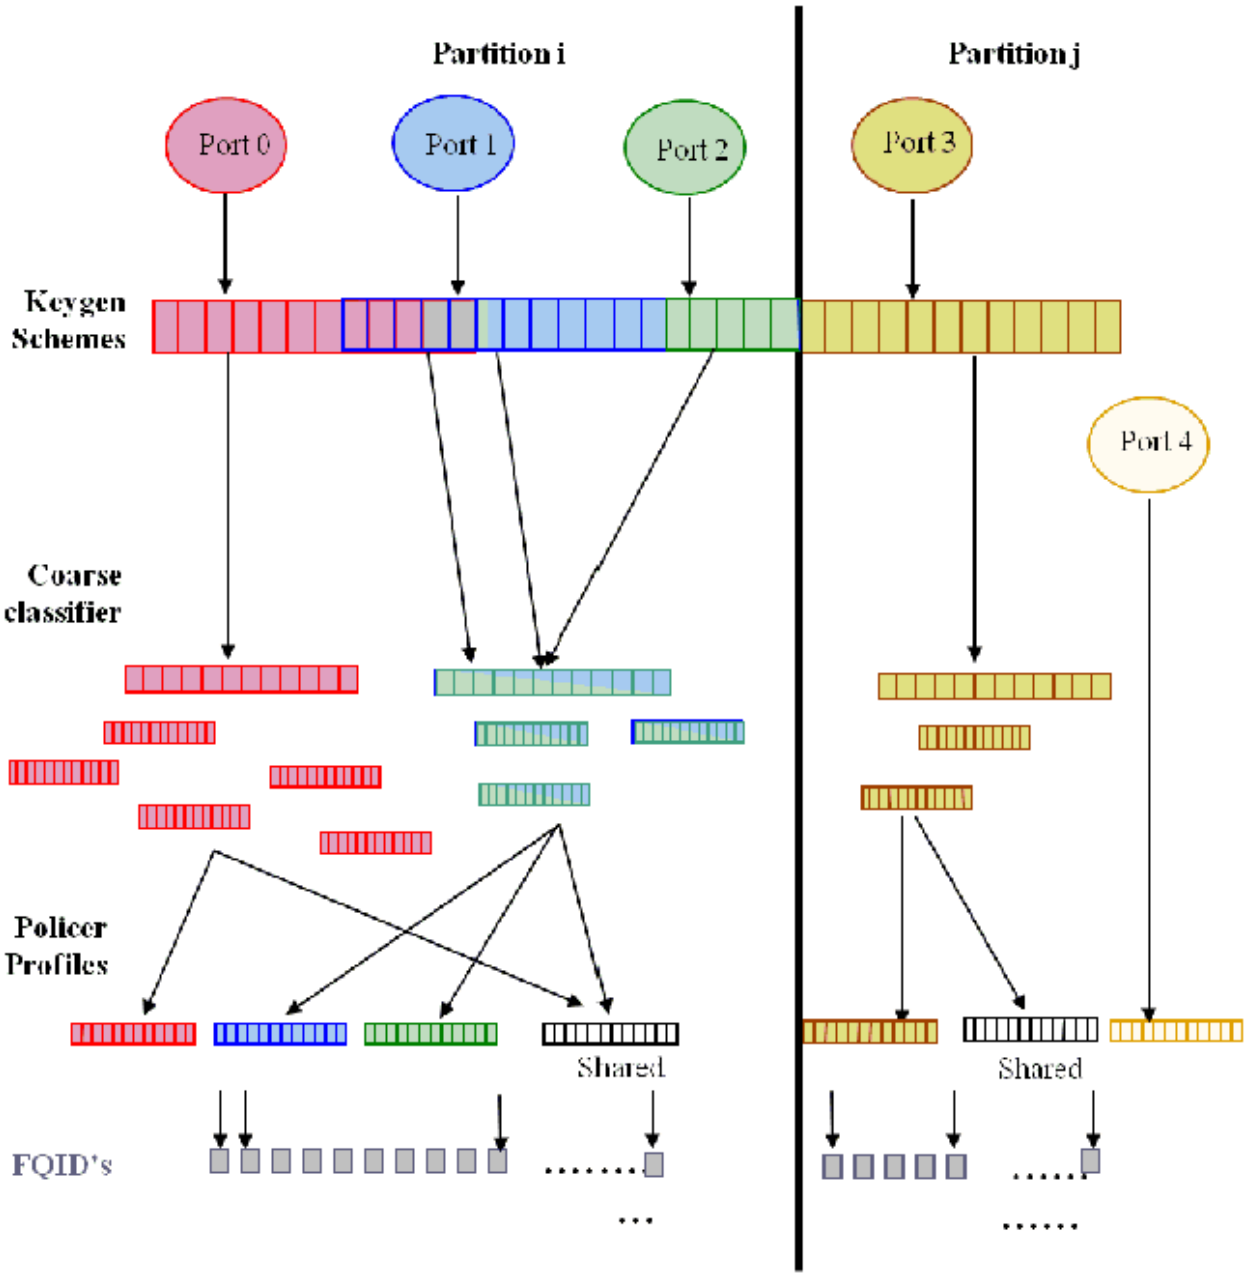

Figure 117. Port-To-PCD binding example

Once a set of PCD resources is set and organized as described above, a port may be bound to all or some of the resources by calling the `FM_PORT_SetPCD` routine. This routine, is referred to as the Port-PCD bind routine. It accepts a set of parameters that specify the PCD resources used by the port, configures PCD related parameters in the port, and bounds PCD resources to the port. The `FM_PORT_DeletePCD` should be called when the port no longer needs the configured PCD functionality. This action is referred to as Port-PCD unbinding.

Another possible action that affects the Port-PCD relationship is calling FM_PORT_DettachPCD for a port that is bound to PCD. This causes the port to stop using the PCD functionalities, which results in all frames being passed to the default FQID. Note that calling FM_PORT_DeletePCD unbinds the port from the PCD functionalities by removing the connections, while FM_PORT_DetachPCD does not remove them but only causes the port to stop using them. To return to using the PCD, FM_PORT_AttachPCD should be called.

Certain runtime modifications may not be done directly, but require either the unbinding of PCD functionalities or PCD detaching. This should be done by calling the required delete/detach routines, making the desired changes, and calling set or attach to return to using the PCD. These actions will be referred to as resetting/detaching the Port-PCD. In the time between the calls of the two routines, the port continues to work, but its PCD functionalities are disabled. In both cases, all frames arriving at this time are enqueued to the default receive queue.

In the sections below, the relationship between the port and each of the PCD resources will be explained in terms of initialization and runtime modifications.

General

The port-PCD binding affects the flow of received frames on that port in terms of PCD functionality. The user must first define the general PCD for the port, using the following enumeration types, which define the superset of engines that may be used.

- e_FM_PORT_PCD_SUPPORT_PRS_ONLY (Use only Parser)
- e_FM_PORT_PCD_SUPPORT_PLCR_ONLY (Use only Policer)
- e_FM_PORT_PCD_SUPPORT_PRS_AND_PLCR (Use Parser and Policer)
- e_FM_PORT_PCD_SUPPORT_PRS_AND_KG (Use Parser and Keygen)
- e_FM_PORT_PCD_SUPPORT_PRS_AND_KG_AND_CC (Use Parser, Keygen and Custom Classifier)
- e_FM_PORT_PCD_SUPPORT_PRS_AND_KG_AND_CC_AND_PLCR (Use all PCD engines)
- e_FM_PORT_PCD_SUPPORT_PRS_AND_KG_AND_PLCR (Use Parser, Keygen and Policer)

Runtime Modifications: The engines set may be changed at runtime only by resetting the Port-PCD.

Available General Port API:

- FM_PORT_SetPCD
- FM_PORT_DeletePCD

Network Environment

When calling the Port-PCD binding routine, the user must specify a single NetEnv by passing its handle. This setting is used for the port parser and affects the PCD behavior.

Runtime Modifications: The NetEnv may not be modified at runtime. If the port requires a change of its NetEnv, it must first reset its Port-PCD connection, than use the PCD routines to do the required changes, and than re-connect to the PCD.

Parser

The hardware parser port configuration is taken directly from the NetEnv specified for the port. Other parsing configurations are explicitly defined by the user at the parameter's structure.

The software parser may be used on a per-port-per-header basis. When PCD is set per port, there is an option in the parser parameters to choose additional parameters per header. One of the optional per-header additional parameters is to enable the software parser for that header. When set, an index should be declared to select the software parser code. The header and index must be specified in the labels' table of the software parser code that was loaded on PCD initialization. Software parser enablement may be done for as many headers as required.

Runtime Modifications: Only the starting point of the parser may be changed on the fly. Any other changes require PCD resetting.

Available Port API:

- FM_PORT_PcdPrsModifyStartOffset

Keygen Schemes

In order for a port to use Keygen schemes, the port must be bound to those resources. The port may be bound to any number of schemes. At the port bind routine, the user passes a list of scheme handles, as returned by the server at scheme setting, for binding to the port. At least one scheme must be specified. All specified schemes must be valid at that time. If the initial scheme after the parser is used directly without using the match criteria, its id should be passed as one of the parameters to the Port-PCD binding routine.

Runtime Modifications: During runtime, new schemes may be set and then bound to an existing enabled port or existing schemes may be modified. Schemes that are not required by the port may be unbound. Note that when modifying existing schemes, all ports bound to those schemes are affected. If specific schemes are not required anymore, they must first be unbound from the port. If no other port is using them, they may be deleted. The selection of the initial scheme after parser (from direct to indirect and vice versa) may be also changed at runtime.

Available Port API:

- `FM_PORT_PcdKgBindScheme`
- `FM_PORT_PcdKgUnbindScheme`
- `FM_PORT_PcdKgModifyInitialScheme`

Custom Classifier graphs

If a port is using the Custom Classifier graph, an initialized Custom Classifier Root handle (as returned by the RootBuild routine) must be passed when calling the port bind routine.

Runtime Modifications: The CC graph (as well as the CC Root) itself may be modified at runtime, but ports binding to a CC Root may be changed only by detaching and than re-attaching the Port-PCD.

- `FM_PORT_PcdCcModifyTree`

Policer Profiles

Before any port profile is set, the profile allocation routine must be called to bind the port to the policer profile. This is required as the port's binding to the policer profile is not done using the port bind routine. It is only then that per-port profiles may be set, and the port bind routine is subsequently called. If Keygen or parser are not used (i.e. policer is reached directly after parser or from BMI), the port bind routine parameters must specify which policer profile is used (otherwise, no policer parameters are required).

Runtime Modifications: The initial profile selection may be changed during runtime. All profiles allocated to a port are in fact bound to this port, so no runtime binding/unbinding is possible. Uninitialized port profiles (profiles that were allocated for this port but not used) may also be set during runtime, or existing profiles may be modified. If specific profiles are not required anymore, they may be deleted. If a change in port profile allocation is required, follow the steps given below to reset the Port-PCD:

1. Port-PCD deleted
2. Profiles deleted and freed
3. New profiles allocated and set
4. Port-PCD set

Available Port API:

- `FM_PORT_PcdPlcrModifyInitialProfile`
- `FM_PORT_PcdPlcrFreeProfiles`
- `FM_PORT_PcdPlcrAllocProfiles`

7.4.4.3.1.8.2.3.10 Port-PCD Binding Changes

There are three levels of Port-PCD binding changes:

- **Basic Runtime Modifications-**May be invoked while PCD is active and on enabled ports using PCD.

- Port routines responsible for binding/unbinding to/from the modified resources.
  - FM_PORT_PcdKgBindScheme
  - FM_PORT_PcdKgUnbindScheme
- Port routines responsible for PCD change of behavior.
  - FM_PORT_PcdKgModifyInitialScheme
  - FM_PORT_PcdPlcrModifyInitialProfile
  - FM_PORT_PcdPrsModifyStartOfset

- **Port-PCD Detach Runtime Modifications-**For changes that require detaching the Port-PCD connection:
  - FM_PORT_PcdCcModifyTree

    For these modifications, take the following steps:
    - Detach the port from its PCD resources by calling the Detach PCD routine (FM_PORT_DettachPCD). After this action, the port continues to work enqueueing all frames to the default receive FQID.
    - Call one of the two routines above.
    - Re-attach port to PCD resources by recalling the set PCD routine (FM_PORT_AttachPCD).
- **Port-PCD Reset Runtime Modifications-**For changes that require resetting of the port-PCD binding.

  The following steps should be taken for any modification that is not listed under the last two items:
  - Unbind port from its PCD resources by calling the delete PCD routine (FM_PORT_DeletePCD). After this action the port will continue to work, enqueueing all frames to the default receive FQID.
  - Modify PCD resources-optional. The change may be only in the binding of the port and not on the resources. Note that the freeing and deleting of resources, and then allocating and setting resources, must be orderly, in the same manner as for initial PCD setting and final PCD deleting.
  - Bind port to PCD resources by recalling the set PCD routine (FM_PORT_DeletePCD)

All PCD routines listed above may be used for deleting and setting PCD resources. The following two routines below are used if a change of port profiles window is required (Other PORT routines are not needed as binding is done using SetPCD routine.):

- FM_PORT_PcdPlcrFreeProfiles
- FM_PORT_PcdPlcrAllocProfiles

7.4.4.3.1.9 FMan MAC Driver

The FMan MAC driver module refers to the FMan MAC controller functionalities including configuration and initialization as well as runtime and control.

7.4.4.3.1.9.1 FMan MAC Hardware Overview

The FMan hardware supports one or two kinds of MAC controllers - depending on SoC. All SoCs support three-speed Ethernet controller (dTSEC) interfaces to 10 Mbps, 100 Mbps, and 1 Gbps Ethernet/IEEE 802.3 networks which interfaces the media through external phy or SerDes device. Some SoCs also support 10 Gigabit Ethernet media access controller (10GEC) which interfaces to 10 Gbps Ethernet/IEEE 802.3ae networks via XAUI using the high-speed SerDes interface.

7.4.4.3.1.9.1.1 FMan MAC Software Abstraction

The driver provides a unique API serving both interfaces. If user tries to configure features that are supported only by one of the interfaces, an "unsupported" message will be displayed.

7.4.4.3.1.9.2 How To Use The FMan MAC Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.9.2.1 FMan MAC Driver Scope

This module represents the FMan MAC. It includes:

- FMan MAC hardware structures configuration and enablement
- FMan MAC controller runtime support
- PTP IEEE 1588 support
- MAC hash addressing
- Interrupt handling
- Statistics support

7.4.4.3.1.9.2.2 FMan MAC Driver Sequence

- FMan MAC Config routine
- [Optional] FMan MAC advance configuration routines
- FMan MAC Init routine
- FMan MAC runtime routines
- FMan MAC Free routine

7.4.4.3.1.9.2.3 FMan MAC Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.9.2.3.1 FMan MAC Configuration and Initialization

On FMan MAC driver initialization, the software configures all FMan MAC registers. If required, MAC may be reset at that time. The driver supplies default values where no other values are specified, it defines IRQ's and sets IRQ handles. It enables hardware mechanisms and initializes software data structures for software management.

By the time initialization is done, FMan MAC is ready to be used and the relative FMan Ports may be initialized.

7.4.4.3.1.9.2.3.2 FMan MAC Addressing

On MAC initialization, the user must define a single MAC address. During runtime, the driver provides API for modifying this address and adding other addresses (depending on the specific MAC hardware support).

In addition, the driver supports the addition and removal of addresses to the MAC hash mechanism.

7.4.4.3.1.9.2.3.3 IEEE1588 Support

The driver provides the API to support the hardware IEEE1588 time-stamping. In order to use this feature, the user must first initialize the FM-RTC module. IEEE1588 functionality is always enabled on FM-MAC. Thus, no additional settings are required for the MAC. and the FM-MAC and only then they can enable this feature by calling `FM_MAC_Enable1588TimeStamp` routine. Once enabled, the user may also set the exception for receiving 1588 relevant interrupts on the MAC.

7.4.4.3.1.9.2.3.4 MAC Statistics

The driver provides statistics gathering support for all the standard (MIB) counters. For some controllers, it is necessary to use an interrupt driven mechanism for accounting for counters overflow and in order to keep track on the accurate counters. This mechanism may have some influence on performance, and therefor the driver supports statistics gathering in 3 levels:

- Full statistics-provides all standard counters but may reduce performance.
- Partial statistics-provides only special event counters (errors etc.). If selected, regular counters (such as byte/packet) will be invalid and will return -1.
- No statistics gathering.

7.4.4.3.1.10 FMan VSP Driver

The FMan VSP driver module refers to the software support provided for the Virtual Storage Profile mechanism.

7.4.4.3.1.10.1 FMan VSP Hardware Overview

VSPs may be used by user for virtualization. If a user is running with a multi-partitioned (or with a multiple software entities) system where a single MAC may be used by several software partitions/entities simultaneously, except for using a different FQID (that is already available in DPAA1.0), user may use a different VSP for each SW partition/entity; that way, the buffer may be private (rather than being shared as in DPAA1.0). It allows the virtualization of the buffer pool selection for frame storage (and other parameters related to storage in external memory) from the physical hardware ports. Using this mechanism, different packets received on the same physical port may be stored in different BM pools based on the frame header, in a similar way to FQID selection. VSPs are replacing the legacy, "physical", per-port BM Pool selection. A backward compatible mode exists and it is possible to use the original BM Pool selection, now referred to as "Physical SP".

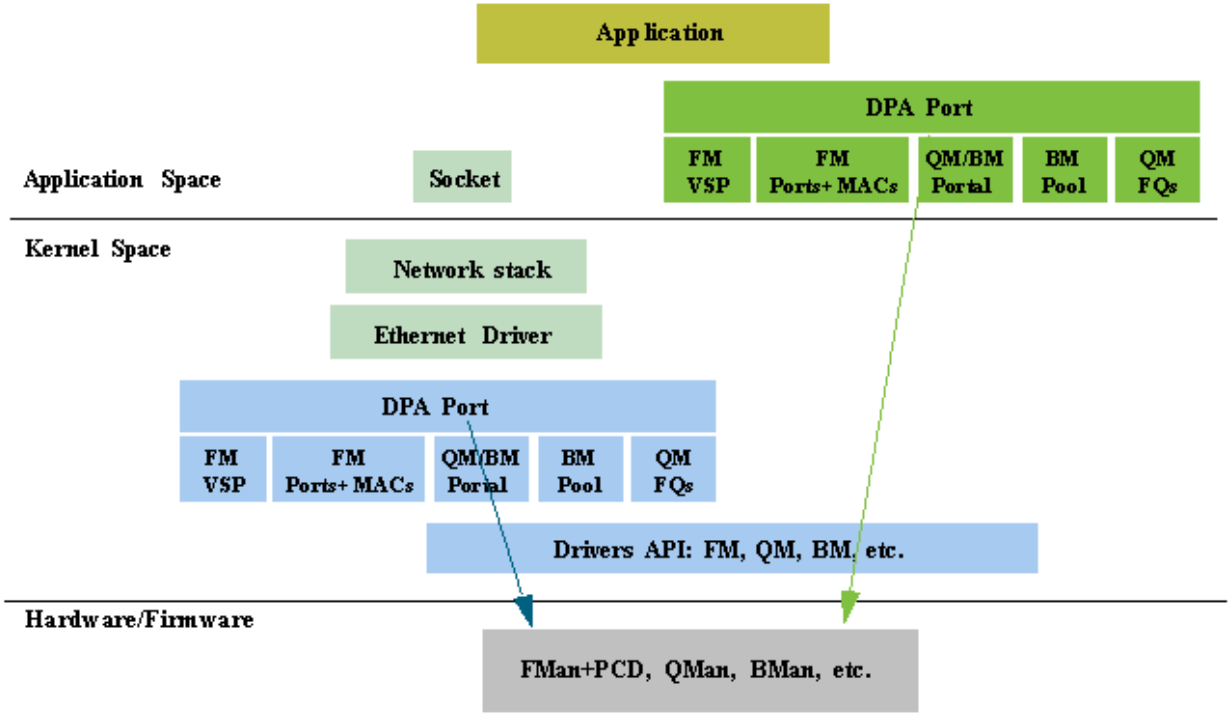

Figure 118. Vitualization Using VSPs

The global FMan module is in charge of the Virtual Storage Profiles entries management. On FMan initialization, the first VSP index dedicated to this partition must be defined (it should be an absolute index), and so is the total number of VSP's for this partition. Later, for each port using VSP's, a window of entries should be defined. VSPs may not be shared among FMan ports.

Each port has a default VSP. On each PCD classification, a VSP may be selected. Received packets will be written into the destination buffer according to the VSP parameters, while the VSP is selected according to the frame headers and the PCD configuration.

The VSP is implemented by the driver as separate entity, however, other modules of the FM driver are aware of this entity and interact with it. An FM VSP module represents a single storage profile.

The global FMan module is in charge of the Virtual Storage Profiles entries management. On FMan port initialization, if using VSP mode, it should allocate and bind to a range of VSP's. On the PCD, A decision is being taken by user on every node of the PCD graph whether to continue to work with previously defined VSP or to override with a new profile.

7.4.4.3.1.10.2 How To Use The FMan VSP Driver?

The VSP is implemented by the driver as separate entity, however, other modules of the FM driver are aware of this entity and interact with it. An FM VSP module represents a single storage profile.

The global FMan module is in charge of the Virtual Storage Profiles entries management. On FMan port initialization, if using VSP mode, it should allocate and bind to a range of VSP's. On the PCD, A decision is being taken by user on every node of the PCD graph whether to continue to work with previously defined VSP or to override with a new profile.

7.4.4.3.1.10.2.1 FMan VSP Driver Scope

This module represents the FMan VSP driver. It includes:

- FMan VSP hardware structures configuration and enablement
- Parsing of the buffer
- Statistics

7.4.4.3.1.10.2.2 FMan VSP Driver Sequence

This sequence includes other modules required for the VSP

- Definition of general VSP parameters on global FMan initialization
- FM Port initialization
- FM Port VSP window allocation
- FM Port enablement
- FMan VSP Config routine (for specific VSP's)
- [Optional] FMan VSP advance configuration routines (for specific VSP's)
- FMan VSP Init routine (for specific VSP's)

7.4.4.3.1.10.2.3 FMan VSP Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.10.2.3.1 Virtual Storage Profile Initialization

The VSP's must be initialized prior to their usage. It is user's responsibility to initialize at least the default VSP for each port before enabling it. Similarly, it is their responsibility to initialize all other VSPs before a classification that may use some VSP is enabled.

Initializing a VSP defines the destination BM Pool buffer for a specific type of packets. It also defines the structure of the buffer - i.e. the data offset, the prefix content, etc.

7.4.4.3.1.10.2.3.2 Virtual Storage Profile Parsing

On VSP initialization, the user defines the buffer prefix content. Based on these requirements, the driver then defines the buffer prefix structure, i.e. data offset, whether certain information such as parse result should be copied to the external buffer and where it will be located. On buffer reception, the user may call VSP routines in order to get the data, as well as the buffer prefix sections such as parse result, time stamp, or Keygen output.

7.4.4.3.1.11 FMan RTC (IEEE 1588) Driver

The FMan RTC driver module refers to the software support provided for the IEEE 1588 hardware of the FMan.

7.4.4.3.1.11.1 FMan RTC Hardware Overview

The 1588 timer module interfaces to up to four 10/100/1000 or one 10G Ethernet MACs, providing current time, 2 alarms, and 2 fiper periodic pulse generators.

7.4.4.3.1.11.2 How To Use The RTC Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.11.2.1 RTC Driver Scope

This module represents the FMan 1588 driver. It includes:

- IEEE 1588 hardware configuration and enablement
- Support for alarm mechanism
- Support for periodic pulse
- Support for external trigger
- Runtime compensation tuning
- Interrupt handling

7.4.4.3.1.11.2.2 RTC Driver Sequence

- FMan RTC Config routine
- [Optional] FMan RTC advance configuration routines
- FMan RTC Init routine
- FMan RTC Enable routine
- FMan RTC runtime routines
- FMan RTC Free routine

7.4.4.3.1.11.2.3 RTC Driver Functional Description

The following sections describe main driver functionalities and their usage.

7.4.4.3.1.11.2.3.1 FMan RTC 1588 module utilization

The driver API provides interface to the 1588 hardware module. It initializes its registers to define the clock period and it supports the definition of the alarms and periodic pulses. Note that When setting periodic pulse, the RTC module must be disabled.

7.4.4.3.1.11.2.3.2 Utilizing IEEE1588 for MAC frames time stamping

Several FMan driver modules are involved in having the 1588 time stamping functionality activated: FMan-RTC, FMan-MAC, FMan-Port and FMan-PCD.

The initialization sequence is as described below:

After the Frame Manager is initialized, the FMan-RTC needs to be initialized by calling (with the appropriate parameters):

- `FM_RTC_Config`
- `FM_RTC_Init`

Next, the following routine should be called, only after MAC is initialized.

- `FM_MAC_Enable1588TimeStamp`

From this point and on all the Ethernet frames on this MAC are time-stamped. In order to obtain the timestamp, during the FMan Port configuration, the user must call the advance config routine:

- `FM_PORT_ConfigBufferPrefixContent` (with 'passTimeStamp' parameter set).

At run-time, for each received/confirmed frame, the user should call the following routine, passing it the frame's data pointer:

- `FM_PORT_GetBufferTimeStamp`

The routine will return the pointer to the time stamp.

7.4.4.3.1.11.2.3.3 Utilizing IEEE1588 for PTP

The sequence described in the previous section causes all the frames that are being received or transmitted by FMan to be time-stamped. However, if the user wants to distinguish PTP frames from other frames on a specific port, PCD rules need to be applied on the PCD graph for this port; i.e using the parser to recognize the PTP frame and then using an appropriate scheme to distinguish PTP frames and route them to the desired destination queues.

7.4.4.3.1.12 FMan MURAM Driver

The FMan MURAM driver module refers to the memory management of the FMan Multi User RAM.

7.4.4.3.1.12.1 FMan MURAM Hardware Overview

The MURAM is the internal memory of the FMan.

7.4.4.3.1.12.1.1 FMan MURAM Driver Software Abstraction

The FMan MURAM driver is a memory manager that allows partitioning of the MURAM. Upon initialization the user receives a handle that may be used by other modules in order to allocate and de-allocate memory blocks out of that MURAM partition.

7.4.4.3.1.12.2 How To Use The FMan MURAM Driver?

The following sections provide practical information for using the software drivers.

7.4.4.3.1.12.2.1 FMan MURAM Driver Scope

This module manages the FMan MURAM. It includes MURAM allocation and de-allocation of different sizes of required memory blocks.

7.4.4.3.1.12.2.2 FMan MURAM Driver Sequence

- FMan MURAM config and init routine
- FMan MURAM allot and free runtime routines
- FMan MURAM free routine

7.4.4.3.1.12.2.3 FMan MURAM Driver Functional Description

The FMan MURAM drivers supports MURAM memory blocks allocation and de-allocation. After initializing an MURAM partition, the user is normally required to pass its handle to other FMan driver modules. In this way, these modules may allocate and de-allocate memory blocks from this partition.

7.4.4.3.1.13 Supported Network Protocols

The following sections show the protocols that may be selected when defining NetEnv characteristics.

7.4.4.3.1.13.1 L2 Protocols

The following list shows the L2 protocols:

- `HEADER_TYPE_ETH`, with the following two options
  - `ETH_BROADCAST`
  - `ETH_MULTICAST`
- `HEADER_TYPE_VLAN`, with the following option
  - `VLAN_STACKED`
- `HEADER_TYPE_MPLS`, with the following option

    - MPLS_STACKED
- HEADER_TYPE_PPPoE
- HEADER_TYPE_LLC_SNAP

7.4.4.3.1.13.2 L3 Protocols

The following list shows the L3 protocols:

- HEADER_TYPE_IPV4, with the following options
    - IPV4_BROADCAST_1
    - IPV4_MULTICAST_1
    - IPV4_UNICAST_2
    - IPV4_MULTICAST_BROADCAST_2
    - IPV4_FRAG_1
- HEADER_TYPE_IPV6, with the following options
    - IPV6_MULTICAST_1
    - IPV6_UNICAST_2
    - IPV6_MULTICAST_2
    - IPV6_FRAG_1
- HEADER_TYPE_GRE
- HEADER_TYPE_MINENCAP
- HEADER_TYPE_USER_DEFINED_L3

7.4.4.3.1.13.3 L4 Protocols

The following list shows the L4 protocols:

- HEADER_TYPE_TCP
- HEADER_TYPE_UDP
- HEADER_TYPE_SCTP
- HEADER_TYPE_DCCP
- HEADER_TYPE_IPSEC_AH
- HEADER_TYPE_IPSEC_ESP
- HEADER_TYPE_USER_DEFINED_L4

7.4.4.3.1.13.4 Private Headers

- HEADER_TYPE_USER_DEFINED_SHIM1
- HEADER_TYPE_USER_DEFINED_SHIM2

7.4.4.3.1.13.5 Fields Supported By Driver for Keygen Extraction

Fields supported as "full fields":

- HEADER_TYPE_ETH
    - NET_HEADER_FIELD_ETH_DA

  - NET_HEADER_FIELD_ETH_SA
  - NET_HEADER_FIELD_ETH_TYPE
- HEADER_TYPE_LLC_SNAP
  - NET_HEADER_FIELD_LLC_SNAP_TYPE
- HEADER_TYPE_VLAN
  - NET_HEADER_FIELD_VLAN_TCI

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_LAST)
- HEADER_TYPE_MPLS
  - NET_HEADER_FIELD_MPLS_LABEL_STACK

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_2,
    - e_FM_PCD_HDR_INDEX_LAST)
- HEADER_TYPE_IPv4
  - NET_HEADER_FIELD_IPv4_SRC_IP
  - NET_HEADER_FIELD_IPv4_DST_IP
  - NET_HEADER_FIELD_IPv4_PROTO
  - NET_HEADER_FIELD_IPv4_TOS

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_2/e_FM_PCD_HDR_INDEX_LAST)
- HEADER_TYPE_IPv6
  - NET_HEADER_FIELD_IPv6_SRC_IP
  - NET_HEADER_FIELD_IPv6_DST_IP
  - NET_HEADER_FIELD_IPv6_NEXT_HDR
  - NET_HEADER_FIELD_IPv6_VER | NET_HEADER_FIELD_IPv6_FL | NET_HEADER_FIELD_IPv6_TC (must come together!)

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_2/e_FM_PCD_HDR_INDEX_LAST)

    NOTE

    NET_HEADER_FIELD_IPv6_NEXT_HDR with e_FM_PCD_HDR_INDEX_LAST indication, applies to the very last next header indication, meaning the next L4, which may be present at the Ipv6 last extension. On earlier revisions this field applies to the Next-Header field of the main IPv6 header)
- HEADER_TYPE_IP
  - NET_HEADER_FIELD_IP_PROTO

    (index may apply:

    - e_FM_PCD_HDR_INDEX_LAST)
  - NET_HEADER_FIELD_IP_DCSP

    (index may apply:

    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1)
- HEADER_TYPE_GRE
  - NET_HEADER_FIELD_GRE_TYPE
- HEADER_TYPE_ETH
  - NET_HEADER_FIELD_ETH_DA
  - NET_HEADER_FIELD_ETH_SA
  - NET_HEADER_FIELD_ETH_TYPE
- HEADER_TYPE_MINENCAP
  - NET_HEADER_FIELD_MINENCAP_SRC_IP
  - NET_HEADER_FIELD_MINENCAP_DST_IP
  - NET_HEADER_FIELD_MINENCAP_TYPE
- HEADER_TYPE_TCP
  - NET_HEADER_FIELD_TCP_PORT_SRC
  - NET_HEADER_FIELD_TCP_PORT_DST
  - NET_HEADER_FIELD_TCP_FLAGS
- HEADER_TYPE_UDP
  - NET_HEADER_FIELD_UDP_PORT_SRC
  - NET_HEADER_FIELD_UDP_PORT_DST
- HEADER_TYPE_UDP_LITE (relevant only if FM_CAPWAP_SUPPORT define)
  - NET_HEADER_FIELD_UDP_LITE_PORT_SRC
  - NET_HEADER_FIELD_UDP_LITE_PORT_DST
- HEADER_TYPE_IPSEC_AH
  - NET_HEADER_FIELD_IPSEC_AH_SPI
  - NET_HEADER_FIELD_IPSEC_AH_NH
- HEADER_TYPE_IPSEC_ESP
  - NET_HEADER_FIELD_IPSEC_ESP_SPI
- HEADER_TYPE_SCTP
  - NET_HEADER_FIELD_SCTP_PORT_SRC
  - NET_HEADER_FIELD_SCTP_PORT_DST
- HEADER_TYPE_DCCP
  - NET_HEADER_FIELD_DCCP_PORT_SRC
  - NET_HEADER_FIELD_DCCP_PORT_DST
- HEADER_TYPE_PPPoE
  - NET_HEADER_FIELD_PPPoE_PID
  - NET_HEADER_FIELD_PPPoE_SID

Fields supported as "from fields":

- HEADER_TYPE_ETH (with or without validation):
  - NET_HEADER_FIELD_ETH_TYPE
- HEADER_TYPE_VLAN (with or without validation):
  - NET_HEADER_FIELD_VLAN_TCI

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_LAST)
- HEADER_TYPE_IPv4 (without validation):
  - NET_HEADER_FIELD_IPv4_PROTO

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_2/e_FM_PCD_HDR_INDEX_LAST)
- HEADER_TYPE_IPv6 (without validation):
  - NET_HEADER_FIELD_IPv6_NEXT_HDR

    (index may apply:
    - e_FM_PCD_HDR_INDEX_NONE/e_FM_PCD_HDR_INDEX_1,
    - e_FM_PCD_HDR_INDEX_2/e_FM_PCD_HDR_INDEX_LAST)

7.4.4.4 Frame Manager Driver API Reference

This document describes the interface (IOCTLs) to the Frame Manager Driver as apparent to user space Linux applications that need to use any of the Frame Manager's features. It describes the structure, concept, functionality, and low level API.

7.4.4.5 Frame Manager Configuration Tool User's Guide

7.4.4.5.1 Frame Manager Configuration Tool User Guide

7.4.4.5.1.1 Introduction

The Frame Manager (FMan) is part of NXP's Data Path Acceleration Architecture (DPAA), a set of logical blocks that lets multiple processors (cores) interact with multiple network interfaces and accelerators with low software overhead.

The Frame Manager Configuration Tool (FMC Tool) is a command-line program that converts Parse-Classify-Police-Distribute (PCD) descriptions of network packet flows into hardware configuration code for the FMan's KeyGen, Controller, and Policer functions.

The tool provides an abstraction layer: You define your application's PCD requirements in a high-level, XML markup language (NetPDL with NXP extensions). The tool translates these definitions into code that initializes the FMan's registers and data structures. This abstraction makes learning low-level hardware details unnecessary, allows new users to be productive more quickly, and simplifies the programming task for everyone.

7.4.4.5.1.2 Frame Manager (FMan) Overview

The FMan block handles both inbound and outbound Ethernet frames.

For inbound frames, the FMan can perform multi-layer protocol header parsing, classification, policing, and distribution. For outbound frames, the FMan transmits frames in priority order.

Note: The FMan is a modular engine designed for use by many QorIQ multicore embedded devices. This document describes the FMan hardware and software as implemented for the QorIQ P4080 chip. That said, the information contained herein applies to all FMan-equipped devices.

7.4.4.5.1.3 FMan hardware architecture

The P4080 has two, identical Frame Manager instances. The architecture of a single FMan block is shown in Figure 119. Frame manager (FMan) logical block diagram on page 771.

As the figure shows, the FMan consists of several sub blocks. While this document assumes that you are familiar with the DPAA in general and the FMan in particular, the sections below provide a high-level description of these sub blocks as a refresher. These sections should help you better understand the FMC Tool documentation that follows.

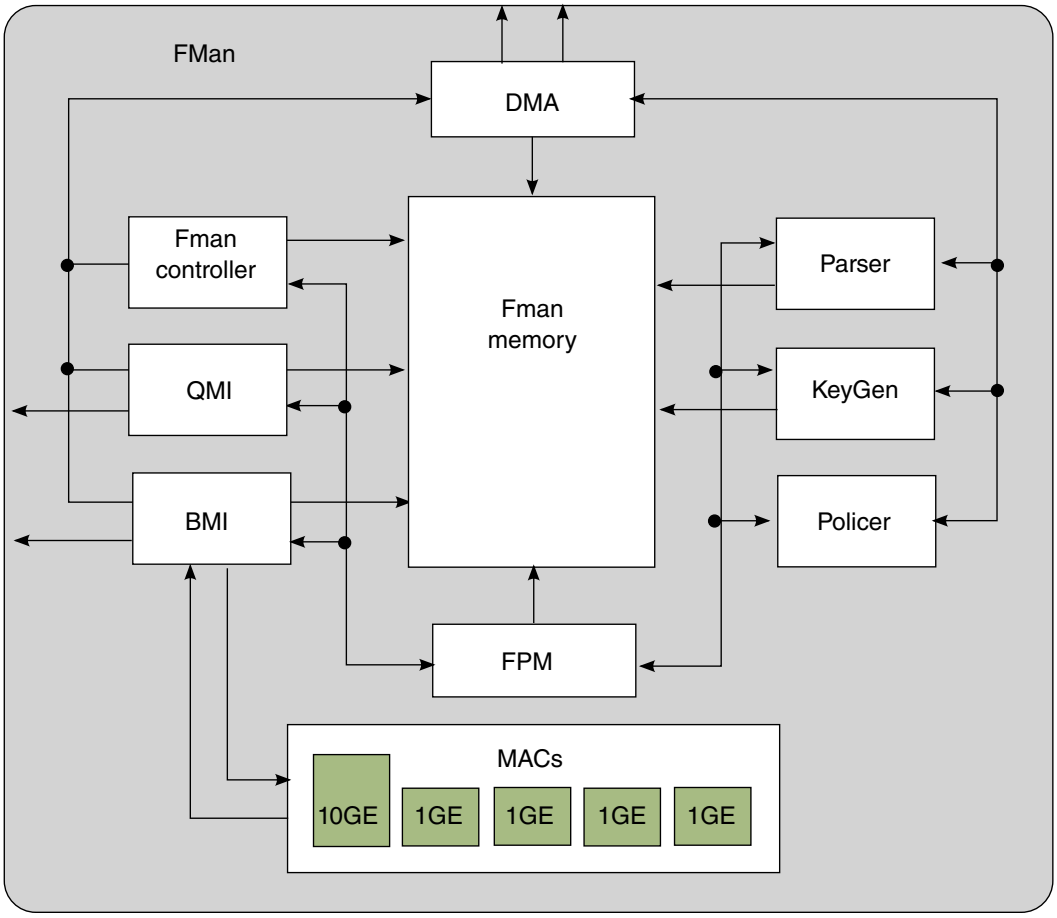

Figure 119. Frame manager (FMan) logical block diagram

Separator text

7.4.4.5.1.3.1 FMan Media Access Controllers (MACs)

Each of the P4080's FMan blocks contains the following:

(1) 10 Gigabit Ethernet media access controller (10GEC), interfacing to 10 Gbps Ethernet/IEEE 802.3ae networks via XAUI using the high-speed SerDes interface.

(4) Data Path three-speed Ethernet controllers (dTSEC), interfacing to 10 Mbps, 100 Mbps, and 1 Gbps Ethernet/IEEE 802.3 networks. Individual dTSECs can use an RGMII or an SGMII interface.

See the QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual for supported combinations of 10GEC and dTSECs per FMan and per P4080, as well as for detailed information about these MACs.

7.4.4.5.1.3.2 FMan FPM, DMA Controller, and Internal Memory

The Frame Processing Manager (FPM) coordinates tasks within the FMan block. The FPM ensures that frames arriving on a particular port (or destined for transmission on a particular port) are processed by the various FMan sub blocks in the appropriate order.

The FMan DMA controller performs the physical reads and writes required to move data between FMan memory and external memory, upon command from the FPM.

The FMan internal memory is multi-ported RAM within the FMan block that is used to buffer Ethernet frames (in both the Tx and Rx directions) and to hold data structures with both external relevance (Frame Descriptors) and internal relevance (Next Invoked Action (NIA) descriptors used by FMan sub blocks to direct the flow of frames through the FMan).

7.4.4.5.1.3.3 FMan Buffer Manager Interface (BMI)

The Buffer Manager Interface (BMI) is the FMan sub block that interacts with the DPAA's Buffer Manager (BMan) block to store and retrieve Ethernet frames to/from buffers in external memory.

On an inbound Ethernet frame, the BMI performs these operations:

1. Receives the frame from an FMan MAC
2. Stores the frame in FMan memoryuntil the entire frame has been received
3. Calculates a raw, L4 checksum and passes it to the FMan's Parser sub block
4. Requests that the BMan allocate external memory in which to store the frame
5. Creates a frame descriptor (FD) for the frame (either a single-frame FD or a scatter/gather FD for frames that require more than one buffer)
6. Initiates DMA of the frame from FMan memoryto external memory
7. Informs the FMan's Queue Manager Interface (QMI) sub block that a FD is available for enqueue to one of the Queue Manager block's frame queues (FQs)

On an outbound Ethernet frame, the BMI performs these operations:

1. Receives a FD dequeued by the QMI from one of the QMan block's FQs
2. Initiates DMA of the frame from external memory to FMan memory
3. Calculates a raw, L4 checksum for the frame
4. Transfers the frame to an FMan MAC
5. Passes the L4 checksum (offset/value) to the MAC
6. Signals the BMan to de-allocate the frame's buffer(s) once transfer to the MAC is complete

7.4.4.5.1.3.4 FMan Queue Manager Interface (QMI)

The FMan's Queue Manager Interface (QMI) sub block enqueues and dequeues work to frame queues (FQs), which are resources managed by the DPAA's QMan block. Typically, the QMI enqueues/dequeues a frame descriptor (FD) - a data structure that points to a buffer containing a frame; however, the QMI can also enqueue/dequeue other kinds of objects, such as those related to host commands/responses, offline parsing, Tx confirmation, and FMan error reporting.

7.4.4.5.1.3.5 FMan Parser

The FMan's Parser sub block parses fields in the hierarchy of protocol headers contained in a received frame.

The Parser is idle until notified by the FPM that a complete frame is available for parsing. The Parser then begins to parse the frame according to the rules specified in a user-written configuration (Policy file) that specifies a header at any offset from the beginning of the frame. The Parser can examine up to 256 bytes of a frame.

The result of parsing is a 'Next Invoked Action' descriptor that determines whether the frame is filtered out or passed to the FMan's KeyGen, Controller (also called the Classifier), or Policer sub block for further processing.

The Parser can be configured to write its 32-byte parse results to a reserved area of the buffer in which the BMI stored the frame. This feature makes it unnecessary for software to re-parse a frame in cases in which the FMan's only action is to distribute incoming frames across a number of frame queues.

The Parser performs multi-layer protocol header parsing and validation for a wide range of protocols and encapsulations. For the set of standard, stable protocols shown in Figure 120. Standard Protocols - Hard-Coded Parse Tree on page 773 , the Parser uses hard-coded logic to parse the protocol headers. Parsing normally progresses from the lowest layer to the upper layers shown in the figure.

You can supplement the hard-coded support for standard protocols with 'soft' parse routines, thereby extending the Parser's capabilities to unforeseen combinations of standard protocols, new standards, and proprietary protocols with shim headers inserted between otherwise well-known protocols.

The FMC Tool can configure the Parser to use both hard- and soft-parser protocol header definitions. Details of the FMC Tool files used to describe both standard and custom protocol headers are provided in Protocol files on page 779.

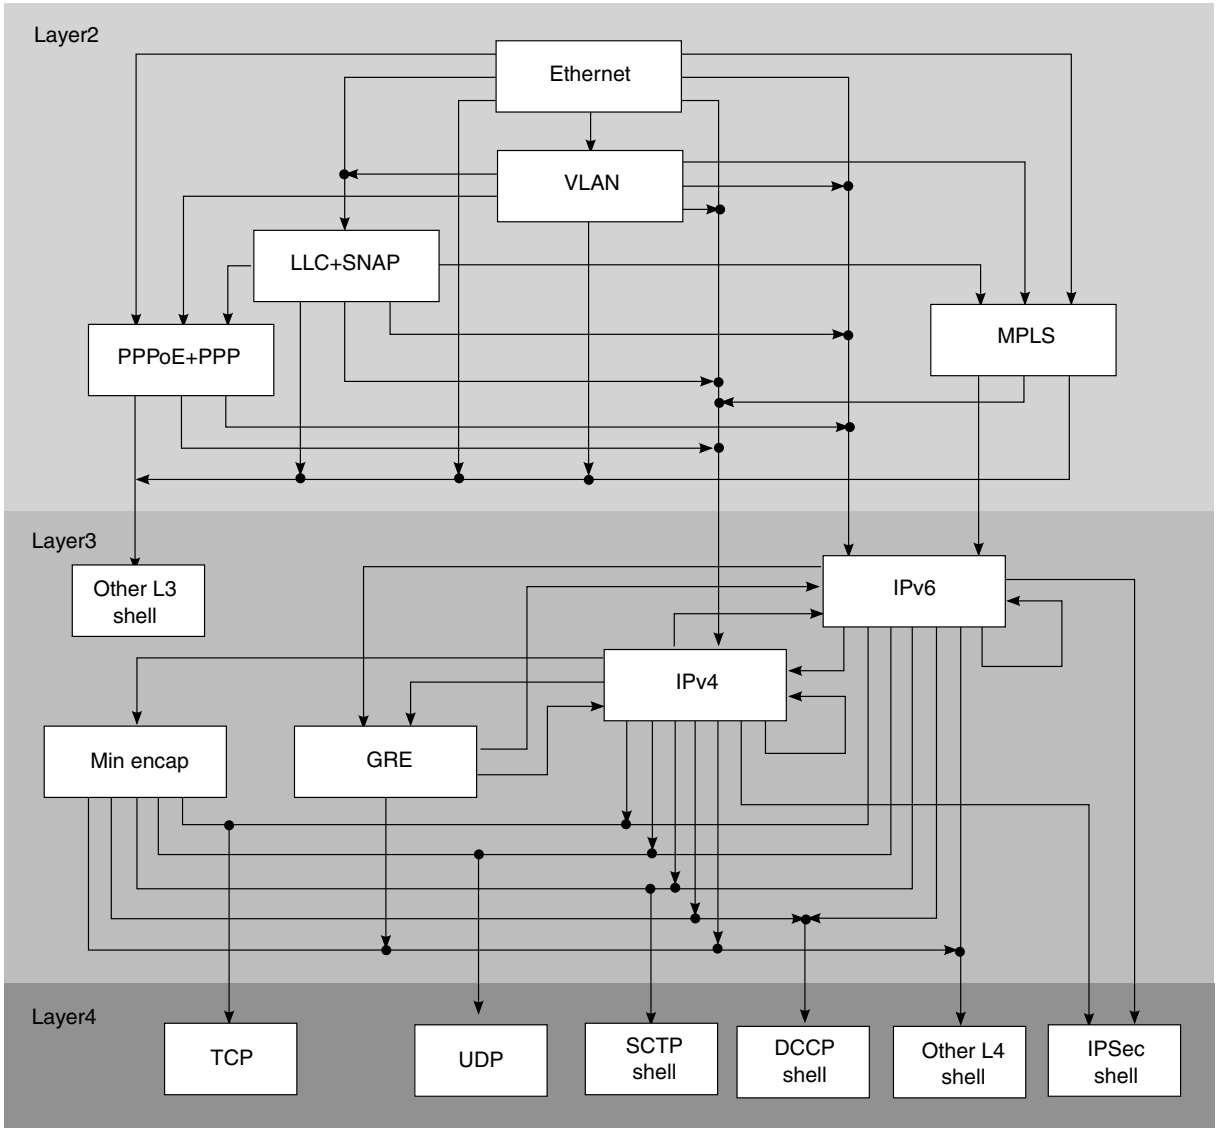

Figure 120. Standard Protocols - Hard-Coded Parse Tree

7.4.4.5.1.3.6 FMan Controller

The FMan Controller sub block (also called the Classifier) performs exact match frame classification. This capability lets your application identify control traffic (or other important subsets of traffic) that can be distinguished by a small number of exact-match rules and place these frames on a frame queue dedicated to this traffic type. All frames that do *not* meet an exact-match rule proceed to the KeyGen sub block, where they are distributed across a range of frame queues based on a hash function.

Exact-match frame classification uses rules tables stored in FMan memory. An FMan block can support classification at a line rate of up to 12 Gbps, assuming a three-level tree search. Each tree level can use up to 256 bytes of table space; however, the total rules table size for all three tree levels cannot exceed 512 bytes. For example, if classification is configured to perform an exact match on a 4-byte field and there are 32 exact-match rules defined, 128 bytes of rules table space is required.

The FMan Controller treats each rules table as an ordered list of entries and takes action on the first match.

7.4.4.5.1.3.7 FMan KeyGen

The FMan's KeyGen sub block performs line-rate packet distribution onto a range of frame queues (FQs) based on hashes of inbound frame header fields extracted by the Parser. The KeyGen sub block holds 32 key-generation schemes in internal memory, with each scheme generating a different Frame Queue ID (FQID) and Policer Profile (PP). Further, the KeyGen supports an option for a post-hash index.

By applying the same KeyGen hash scheme to all arriving frames, all frames belonging to the same coarse-grained flow are enqueued to the same frame queue (FQ). Ensuring that frames belonging to the same coarse-grained flow are enqueued to a single FQ guarantees that the fine-grained flows within the coarse-grained flow are dequeued and processed by the cores in order. Figure 121. Algorithm for Calculating a Frame Queue ID on page 774 shows the steps in the KeyGen sub block's frame queue ID calculation.

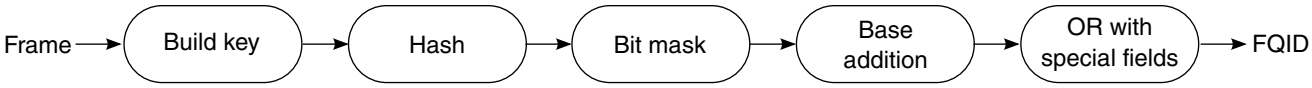

Figure 121. Algorithm for Calculating a Frame Queue ID

7.4.4.5.1.3.8 FMan Policer

The FMan's Policer sub block implements a two rate, three color marker (trTCM) traffic policing algorithm. Using the Policer, you can implement differentiated services at line speed on the FMan's receive path or its offline parse path.

The Policer holds 256 policing profiles in internal memory and can apply these profiles to the outputs of the FMan Controller and KeyGen frame processing stages to limit enqueues to frame queues.

Policer features:

- Implements RFC2698 and RFC4115
- Supports three-color traffic marking: "Green", "Yellow", and "Red"
- Supports four traffic measurements:
  - CIR - Committed Information Rate
  - CBS - Committed Burst Size
  - PIR - Peak Information Rate
  - PBS - Peak Burst Size
- Supports color-aware and color-blind metering
- Supports policing based on packet count, as well as byte count
- Includes a quick drop mode for "Red" packets

- Stores up to 256 policing profiles in internal FMan memory
- Maintains traffic statistics on a per-profile basis

7.4.4.5.1.4 FMC Tool Features

The FMC Tool can analyze input NetPDL and NetPCD XML files that define the parse, classify, police, and distribute behavior your application requires. The tool can then:

- Passes this information directly to the FMan by calling the appropriate FMan driver API functions. (See FMC Tool - Runtime Environment Mode on page 775.)
- Generate C source files containing this information that you can include in your application. (See FMC Tool - Host Mode on page 776.)

In more detail, the FMC Tool can perform the tasks listed below. The particular actions taken depend upon your application's requirements.

- Define the protocol stack
- Define a soft header examination sequence
- Configure the Policer sub block
- Configure frame distribution by defining how frames are assigned to particular frame queues
- Call hardware drivers to execute the current configuration
- Directly configure the FMan by executing on a target running embedded Linux (See FMC Tool - Runtime Environment Mode on page 775.)
- Indirectly configure the FMan by executing on a Linux or Windows host by generating C source code that configures the FMan. You include this code in your application. (See FMC Tool - Host Mode on page 776.)

7.4.4.5.1.5 FMC Tool Components and Packaging

The FMC Tool package contains these files:

- Host version of FMC Tool for desktop versions of Linux and Windows
- FMC Tool application for embedded Linux
- NetPDL file containing a description of each standard network protocol that the FMan's Hard Parser supports. This file is named `hxs_pdl_v3.xml` and is in the directory `/etc/fmc/config/`.

NOTE

For detailed information on NetPDL, go to http://www.nbee.org/doku.php?id=netpdl:index.

For documentation of NXP's customized version of NetPDL, see NXP NetPDL Reference on page 795.

7.4.4.5.1.6 FMC Tool - Runtime Environment Mode

In runtime environment mode, you run the FMC Tool on a target board from the Linux command line, passing several configuration files as arguments. The tool then calls the FMan Driver API functions required to configure the FMan block as specified in the supplied files.

When used in this way, the FMC Tool *directly* configures the FMan. In more detail, the FMC Tool passes the configuration it finds in its input files (along with compiled Soft Parser firmware) to the FMan driver which, in turn, modifies the FMan's configuration.

Note: The FMC Tool does *not* support dynamic FMan configuration; you can use the tool to configure the FMan just once, typically at application initialization.

As Figure 122. FMC Tool, Runtime Environment - Input XML Files / FMan Driver API Calls on page 776shows, you pass these files to the FMC Tool as command-line arguments:

- Standard Protocol file - Optional; included in DPAA SDK; see Standard Protocol File on page 780 for more information.
- Custom Protocol file - Optional; user written; see Custom Protocol File on page 780 for more information.
- Policy file - Required; user written; see Policy file on page 781 for more information.
- Configuration file - Required; user written; see Configuration File on page 793 for more information.

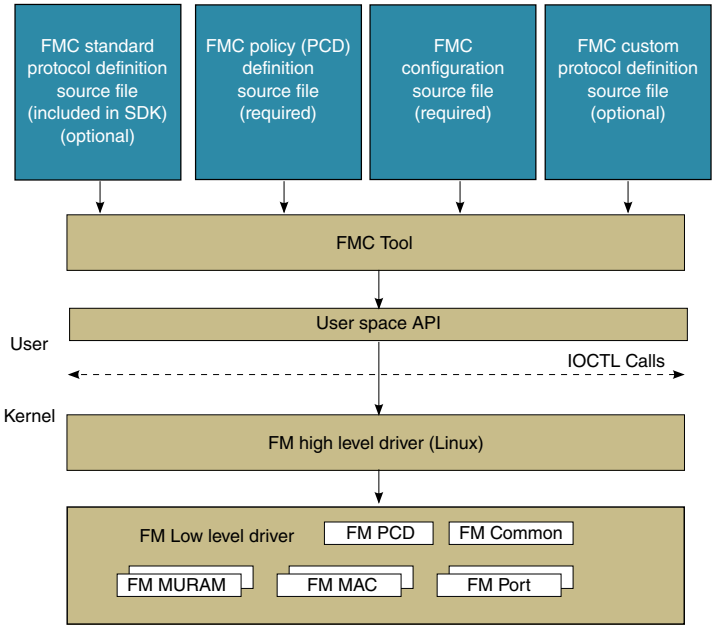

Figure 122. FMC Tool, Runtime Environment - Input XML Files / FMan Driver API Calls

See FMC Tool Command-Line Arguments on page 778 for documentation of each of the tool's command-line arguments.

Note: You should configure the FMan before you enable your Rx/Tx ports to send/receive traffic. If you do not, the FMan uses the default Rx and default Tx frame queues.

7.4.4.5.1.7 FMC Tool - Host Mode

In addition to running on a target board, the FMC Tool can execute on a host computer running Linux or Windows. When run on a host, the FMC Tool accepts the same input files as in runtime environment mode.

However, in host mode, the FMC Tool generates C source code files. This code calls the FMan driver functions required to implement the rules defined in the supplied input files. You can compile and link these files to produce a standalone executable that you can run by itself, or you can add them to your application.

Note: The FMC Tool does not support dynamic FMan configuration; you can use the tool to configure the FMan just once, typically at application initialization.

As Figure 123. FMC Tool, Host Mode - Input XML Files / Generated C Source Code Files on page 777 shows, in host mode, the FMC Tool generates C source code files from the input files listed below. (See Host Mode Output - C Source Code Files on page 777 for more information.)

- Standard Protocol File - Optional; included in DPAA SDK; see Standard Protocol File on page 780 for more information.
- Custom Protocol File - Optional; user written; see Custom Protocol File on page 780 for more information.
- Policy File - Required; user written; see Policy file on page 781 for more information.

- Configuration File - Required; user written; see Configuration File on page 793 for more information.

You pass these files to the FMC Tool as command-line arguments.

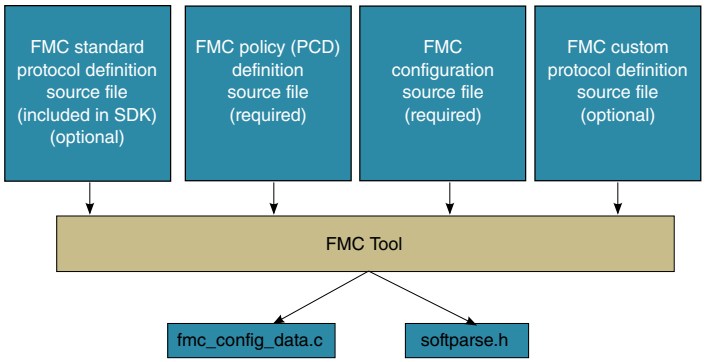

Figure 123. FMC Tool, Host Mode - Input XML Files / Generated C Source Code Files

See FMC Tool Command-Line Arguments on page 778 for documentation of each of the tool's command-line arguments.

7.4.4.5.1.7.1 Host Mode Output - C Source Code Files

When run in host mode, the FMC Tool generates C language source code files that make calls to FMan Driver API functions. These calls implement the behavior defined in the Configuration file, Policy file, and (optionally) Custom Protocol file passed to the tool from the command line. Typically, you include these source files in your project, so they are compiled and linked into your application binary. As a result, when you run your application, it automatically sets up the FMan to behave as required.

In more detail:

- When you supply a Policy file and a Configuration file, the tool generates a single source code file named "fmc_config_data.c".
- When you supply a Policy file, a Configuration file, *and* a Custom Protocol file, the tool generates two source code files: "fmc_config_data.c" and "softparse.h".

Contents of fmc_config_data.c

- #include software parser configuration "softparse.h" at the top of the file
- Initialization of FMC model structure 'fmc_model_t' with configuration data - This structure represents the data model for FMan hardware configuration according to input files

Using fmc_config_data.c

- FMC model structure must be used together with FMC model definition and FMC executer: 'fmc.h' and 'fmc_exec.c' files - These file are available in FMC source files location
- FMC model definition contains 'fmc_model' structure definition - This structure represents the FMC configuration model
- FMC executer contains 'fmc_execute' routine - This function configures the FMan hardware to behave as specified in the input files

Usage options:

- Compile and link these files together ('fmc_config_data.c', 'fmc.h', 'fmc_exec.c') and generate a standalone binary and run this binary to configure the FMan - In this case you must add a main() function that calls fmc_execute()
- Have your application call fmc_execute() - In this case you don't need to add a main() function

Contents of softparse.h

- Contains compiled firmware that controls the FMan sub blocks involved in parsing a custom protocol header
- Defines parameters such as code size, protocol to attach, and download base address

Using softparse.h - Automatically included in fmc_config.c if you pass the FMC Tool a Custom Protocol file

Note: You should configure the FMan before you enable your Rx/Tx ports to send/receive traffic. If you do not, the FMan uses the default Rx and default Tx frame queues.

7.4.4.5.1.8 FMC Tool Command-Line Arguments

The table below lists and describes the FMC Tool's command-line arguments.

Table 132. FMC Tool Command-Line Arguments

Command-Line Argument Syntax ***(Both the verbose and abbreviated command forms are shown)***	**Description**
-d <pdl_file>, --pdl <pdl_file>	Path to and name of the Standard Protocol file. *(Optional)* You can use a full path or a relative path. See Standard Protocol File on page 780 for more information.
-p <pcd_file>, --pcd <pcd_file>	Path to and name of a Policy file. *(Required unless '--sp_only' is used)* You can use a full path or a relative path. See Policy file on page 781 for more information.
-c <data_file>, --config <data_file>	Path to and name of the Configuration file. *(Required unless '--sp_only' is used)* You can use a full path or a relative path. See Configuration File on page 793 for more information.
-s <custom_protocol_file>, --custom_protocol <custom_protocol_file>	Path to and name of the Custom Protocol file. *(Optional unless the '--sp_only' flag is used, in which case, this Custom Protocol file name is required.)* You can use a full path or a relative path. See Custom Protocol File on page 780 for more information.
-f --force	Applies the new configuration, without regard for the temporary information the FMC tool stored about the previous configuration. **(Optional)** When used in runtime environment mode (that is, on the target), the FMC Tool stores information about the previous configuration that the tool uses to properly unroll this configuration before applying the new one. There are cases (such as a non-destructive reboot) when such unrolling is not desirable. In such cases, use the --force switch.

Table continues on the next page...

Table 132. FMC Tool Command-Line Arguments (continued)

Command-Line Argument Syntax ***(Both the verbose and abbreviated command forms are shown)***	**Description**
-a, --apply	Apply the supplied configuration to the FMan rather than generating C source code. *(Optional; valid only when FMC Tool is executed in runtime environment)*
--sp_only	Perform Soft Parser processing only. When this argument is supplied, the FMC Tool compiles just the Custom Protocol file, generates the file softparse.h, and exits. The file softparse.h contains C source code and custom protocol offsets. The tool creates softparse.h in the path from which the FMC Tool was executed. *(Optional)*
-w	Do not report warnings. *(Optional)*
--version	Display version information, then exit. *(Optional)*
-h, --help	Display usage information, then exit. *(Optional)*

7.4.4.5.1.9 The NetPDL and NetPCD XML Markup Languages

The Network Protocol Description Language (NetPDL) is an XML dialect that defines elements for describing protocols from OSI layer 2 to OSI layer 7. (For more information on NetPDL, see http://www.nbee.org/doku.php?id=netpdl:index.)

NXP uses NetPDL to define the standard protocols that are parsed by the FMan's Hard Parser. You cannot change these protocol descriptions. However, the SDK includes a Standard Protocol file that you can use as a reference.

In addition, you can use NetPDL (with slight semantic and syntactic differences) to define custom protocols that are parsed by the FMan's Soft Parser. This feature allows the FMan to handle any protocol that exists or that you define yourself.

Finally, NXP has extended NetPDL to create a language called NetPCD. You use the elements and attributes of NetPCD to define FMan parse, classify, police, and distribute behavior. The processing thus defined determines how frames move from block to block of the FMan.

The FMC Tool accepts files in NetPCD and NetPDL format as input.

7.4.4.5.1.10 Protocol files

For a protocol to be recognized by the FMC Tool, the protocol must be defined in one of two ways:

1. As a standard protocol within the Standard Protocol file (included in the SDK)
2. As a custom protocol within the Custom Protocol file.

Each file type is described in the sections that follow.

7.4.4.5.1.10.1 Standard Protocol File

The DPAA SDK includes a file called the Standard Protocol file. This file contains NetPDL (Network Protocol Description Language) markup that defines the fields in each standard protocol header that the FMan's Hard Parser can handle. In addition, for each standard protocol, the file includes NetPDL statements that define actions for the Hard Parser to take upon encountering an inbound instance of this protocol.

The Standard Protocol file is for the FMan's internal use only; you must therefore not change it. However, to write a Custom Protocol file and/or a Policy file, you sometimes need information the Standard Protocol file contains, such as the names of fields in a protocol's header.

For this reason, the SDK includes a copy of the Standard Protocol file in this directory: /etc/fmc/config/hxs_pdl_v3.xml.

To give you an idea what the markup in this file looks like, Figure 124. Standard Protocol File NetPDL that Defines the Ethernet Protocol on page 780 shows the NetPDL in the Standard Protocol file that defines the Ethernet protocol.

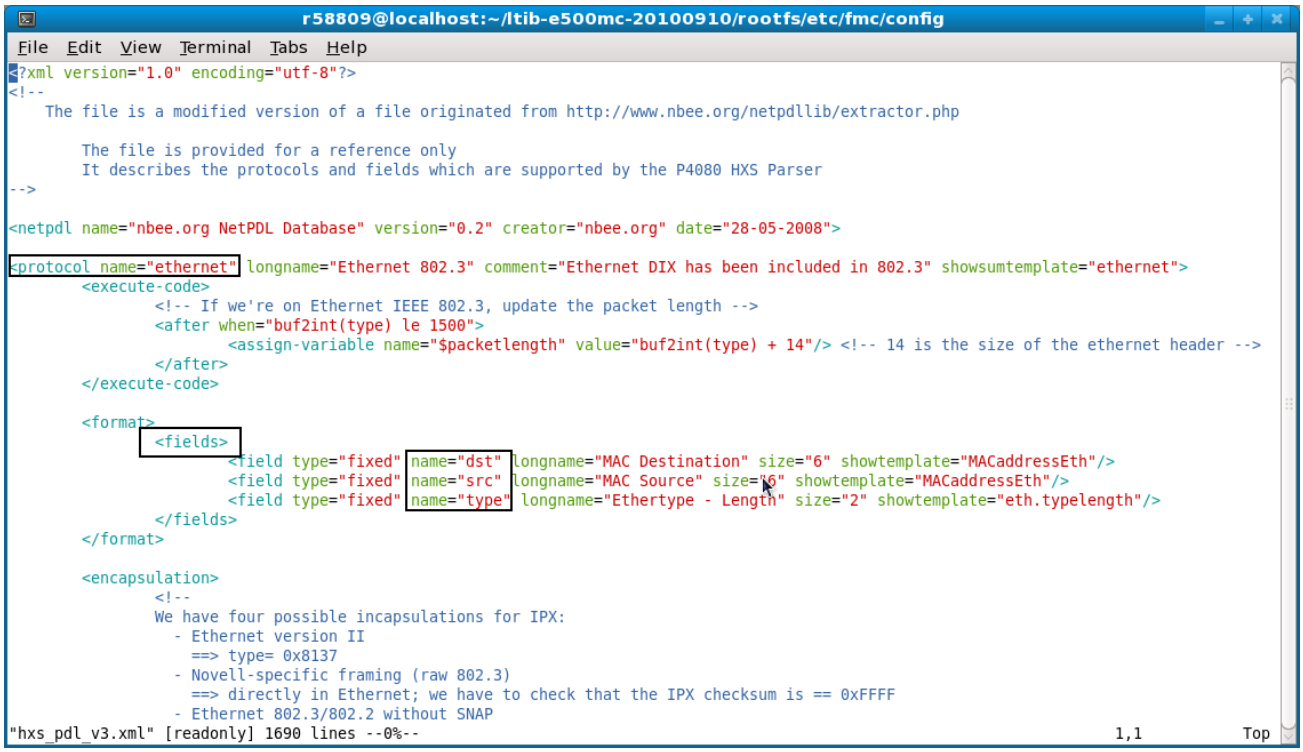

Figure 124. Standard Protocol File NetPDL that Defines the Ethernet Protocol

See the Standard Protocol File - Excerpt on page 847 topic to see a larger portion of the Standard Protocol file.

7.4.4.5.1.10.2 Custom Protocol File

(Largely, content from the Soft Parser Tool MS Word document as well as former "User Defined Protocols" sections.)

Preferred name: "FMC custom protocol file" Also previously called... - "custom protocol file"

The FMan's Hard Parser has built-in capability to handle a set of widely used, standard protocols, such as IPv4. The FMan also has a Soft Parser, which has the ability to process custom protocols.

Of course, for the Soft Parser to recognize a custom protocol, you must first provide a definition of this protocol. To do this, you create a Custom Protocol file, which consists of NetPDL markup that defines the fields in a custom protocol's header along with the actions you want the Soft Parser to take upon these fields. You then pass this file to the FMC Tool, which compiles it and passes the result to the FMan.

Note: Some elements in the NetPDL language are relevant only if used with a protocol analysis tool. The FMC Tool does *not* support these elements; instead, the tool supports only those elements that are applicable to the FMan block. Further,

although it is based on NetPDL, the markup for a custom protocol does not strictly follow NetPDL rules. As a result, it is highly recommended that the you become familiar with the NXP NetPDL Reference on page 795 topic, which fully documents the custom version of NetPDL used in custom protocol definitions.

See Custom Protocol File - GTP Protocol on page 854, for an example of a custom protocol definition file containing XML that defines the GPRS Tunneling Protocol (GTP).

Note: If your application does not use a custom protocol, you do not have to create a Custom Protocol file. Further, if your application uses *multiple* custom protocols, you can (and must) define them in a single Custom Protocol file; you can pass just one Custom Protocol file to the FMC Tool.

The general structure of a Custom Protocol file is shown below.

```
<netpdl> <!-- only one instance -->
   <protocol> <!-- one or more instances -->

      <format> <!-- only one instance -->
         <fields> <!-- only one instance -->
            <field/> <!-- one or more instances -->
         </fields>
      </format>

      <execute-code> <!-- zero or one instance -->
         <before> <!-- zero or one instance -->
         </before>

         <after> <!-- zero or one instance -->
         </after>
      </execute-code>

   </protocol>
</netpdl>
```

7.4.4.5.1.11 Policy file

The policy file defines how each inbound frame is parsed, classified, policed, and distributed by the various FMan sub blocks.

A policy file consists of NetPCD markup, where NetPCD is NXP's extension to NetPDL, an XML markup language for describing networking protocols. The elements and attributes of NetPCD let you define the parse, classification, policing, and distribution behavior your application requires. See NetPCD Reference on page 817 for documentation of each NetPCD element and its attributes.

A Policy file can have these sections:

- Distribution (required) - Contains one or more distribution definitions, each of which:
  - Specifies the protocol(s) a frame must contain to match the distribution
  - Defines how to handle matching frames
- Policy - (required) - Contains one or more policy definitions, each of which:
  - Is associated with an FMan port
  - Contains a prioritized list of distributions
- Classification (optional) - Contains one or more classification blocks, each of which:
  - Defines key/value/action tuples, which the FMan's Controller sub block stores in a lookup table
  - Compares the specified fields in the current frame header to each value in this table and, upon a match, takes the specified action
- Policer (optional) - Contains up to 256 policer profiles, each of which can be used to:

- Take action upon frames without regard to traffic flow rate
- Take action upon frames based on the RFC-2698 two-rate, three-color policing scheme
- Take action upon frames based on the RFC-4115 two-rate, three-color, differentiated services scheme

Note: When you run the FMC Tool, you must pass it a Policy file or the '--sp_only' flag. Otherwise, the program will exit and print an error message.

Figure 125. High-level Structure of a Policy File

```
<netpcd> <!-- only one instance -->
      <distribution> <!-- one or more instances -->
      </distribution>

      <policy> <!-- one or more instances -->
            <dist_order> <!-- one instance -->
                  <distributionref/> <!-- one or more instances -->
            </dist_order>
      </policy>

      <classification> <!-- optional, may have more than one instance -->
      </classification>

      <policer> <!-- optional, may have more than one instance -->
      </policer>
</netpcd>
```

7.4.4.5.1.11.1 Distribution Section

The Distribution *section* of the Policy file contains one or more 'distribution' *elements*. While 'distribution' elements can appear anywhere in the Policy file, they often appear at the top of the file.

Typically a 'distribution' contains child elements that define:

- Frame match rules
  - These rules define the conditions an inbound frame must meet to match (and therefore be handled by) this distribution
  - Use the 'protocols' element and/or the 'key' element to define match rules
- Frame handling rules
  - These rules determine what a distribution does with matching frames
  - Use the 'queue' and 'key' elements to hash frames, so they are evenly spread over a range of frame queues
  - Use the 'action' element to pass the frame to another element in the Policy file for further processing

Figure 126. Example Distribution Elements

```
<!-- distribution that matches all frames containing an IPv4 header -->
<!-- hashes these frames, so they are spread evenly over 32 frame queues -->
<distribution name="hash_ipv4_src_dst_dist0">
  <!-- frame match rule -->
  <key>
    <fieldref name="ipv4.src"/>
    <fieldref name="ipv4.dst"/>
  </key>

  <!-- frame handling rule -->
  <queue count="32" base="0x400"/>
</distribution>
```

```
<!-- distribution that matches frames containing Eth/VLAN/IPv4/UDP/GTP headers -->
<!-- passes all matching frames to the "dl_vlan_clasifif" classification element -->
<distribution name="dl_eth_vlan_ipv4_udp_gtp_dist">
  <!-- frame match rule -->
  <protocols>
    <protocolref name="ethernet"/>
    <protocolref name="vlan"/>
    <protocolref name="ipv4"/>
    <protocolref name="udp"/>
    <!--shim1 is custom protocol defined for GTP -->
    <protocolref name="shim1"/>
  </protocols>

  <!-- frame handling rule
  <action type="classification" name="dl_vlan_classif"/>
</distribution>
```

See The distribution element on page 819 for complete documentation of this element.

Evenly Distributing Frames over a Range of Frame Queues

One frequent use of the 'distribution' element is to distribute frames evenly over a range of frame queues. If each available core is configured to pull from the same number of queues in the range, this even spreading balances the work each core must perform.

In this scenario, the FMan's KeyGen sub block uses values in the frame's header and in the child elements of the distribution as inputs to a hash algorithm that generates a 24-bit FQID within a range of FQIDs. The KeyGen sub block then places the frame on the frame queue identified by this FQID.

Here is the KeyGen's algorithm for generating a FQID:

1. Extract and concatenate the protocol header fields specified by the 'key' child element
2. Hash the resulting string to a 64-bit CRC
3. Shift the CRC right by the number of bits specified in the 'shift' attribute of the 'key' element to move the desired bits to the 24 least significant bit positions
4. Zero-extend the bit mask specified by the 'queue' child element ('count' attribute – 1) to 24 bits
5. Bitwise AND the result with the shifted CRC
6. Bitwise OR the result with the value specified by the 'combine' child element - repeat for each 'combine' element
7. Add the result to the base FQID specified by the 'base' attribute of the 'queue' child element

Figure 127. KeyGen Algorithm for FQID Calculation on page 783 shows the algorithm the KeyGen sub block uses to calculate a FQID.

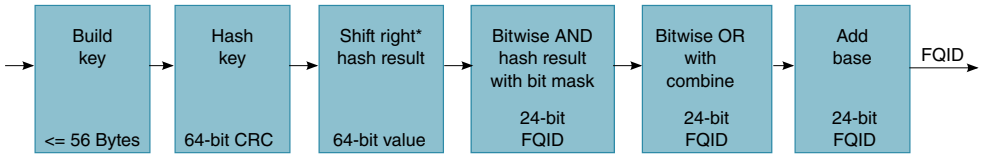

Figure 127. KeyGen Algorithm for FQID Calculation

* The 'key' element has an optional 'shift' attribute whose value defines the number of bits by which the hash result is right shifted. The default value for the shift attribute is zero.

Example KeyGen FQID Calculation

The series of figures that follow shows which child elements and attributes of a distribution block the KeyGen sub block uses in its FQID calculation.

Figure 128. FQID Calculation - Elements/Attributes Used for Key, Bit Mask, and Base FQID on page 784 shows where in the KeyGen sub block gets the inputs for the hash, shift right, bitwise AND, and "add base" parts of its FQID calculation.

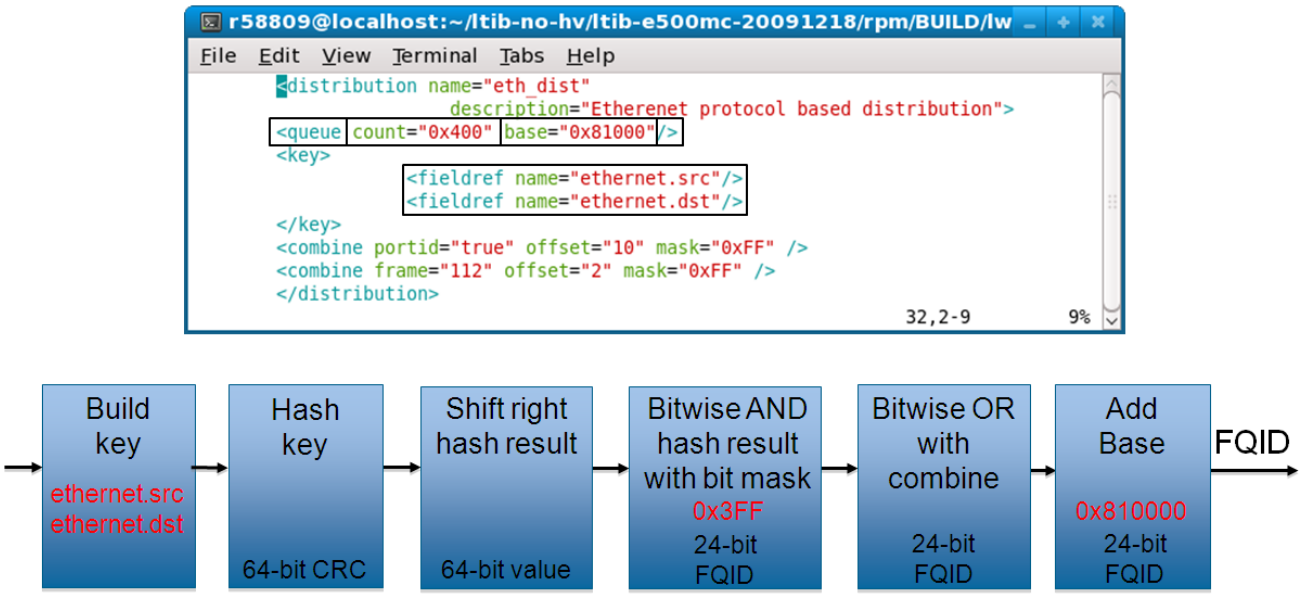

Figure 128. FQID Calculation - Elements/Attributes Used for Key, Bit Mask, and Base FQID

Figure 129. FQID Calculation - A 'combine' Element that Uses the 'portid' Attribute on page 784shows a 'combine' element that includes a 'portid' attribute that is set to "true". In addition, the element's 'offset' attribute is "10", and its 'mask' is "0xFF". This markup instructs the KeyGen sub block to perform the "bitwise OR" part of the FQID calculation. In more detail, for this markup, the KeyGen does these things:

- Bitwise ANDs the 8-bit logical port ID (defined in the Configuration file) of the port on which the current frame arrived with the 8-bit mask in the 'combine' element.
- Bitwise ORs (inserts) the 8-bit result at the specified offset (10 bits) within the 24-bit FQID (where offset 0 signifies the FQID's most significant bit).

Note: Each FMan port can be assigned an 8-bit logical port ID by adding markup to the Configuration file. To do this, assign an 8-bit value to the 'portid' attribute of each 'port' element to which you want to assign a logical port ID. The Hard Parser puts this value (if defined) in the parse results array, where the a KeyGen sub block can get it.

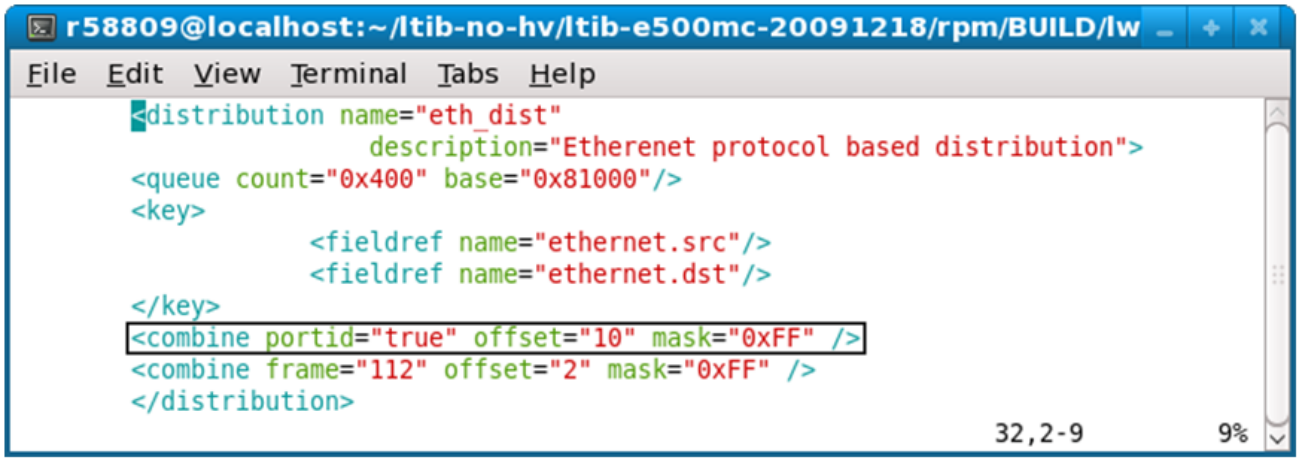

Figure 129. FQID Calculation - A 'combine' Element that Uses the 'portid' Attribute

Figure 130. FQID Calculation - A 'combine' Element that Uses the 'frame' Attribute on page 785 shows a 'combine' element that includes a 'frame' attribute. This markup instructs the KeyGen sub block to:

- Get the 8 bits at offset 112 in the current frame header.
- Bitwise AND this value with the 8-bit mask (0xFF) specified in the 'combine' element
- Bitwise OR (insert) the 8-bit result at the specified offset within the 24-bit FQID (where offset 0 signifies the FQID's most significant bit).

Note: The value of the 'frame' attribute is an offset (in bits) from beginning of the current frame. The KeyGen sub block gets the byte at this offset for its FQID calculation. The value of 'frame' must be divisible by 8, so the bit it references is on a byte boundary.

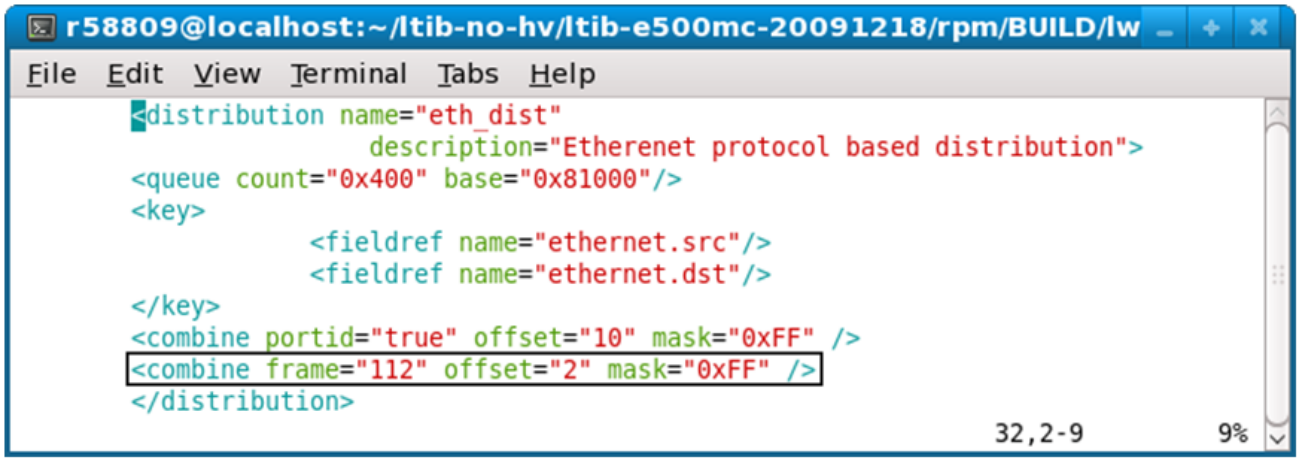

Figure 130. FQID Calculation - A 'combine' Element that Uses the 'frame' Attribute

Finally, Figure 131. FQID Calculation - combine Elements Used in Bitwise OR on page 785 shows where the KeyGen sub block plugs the values from each of the combine elements into the bitwise OR part of the FQID calculation.

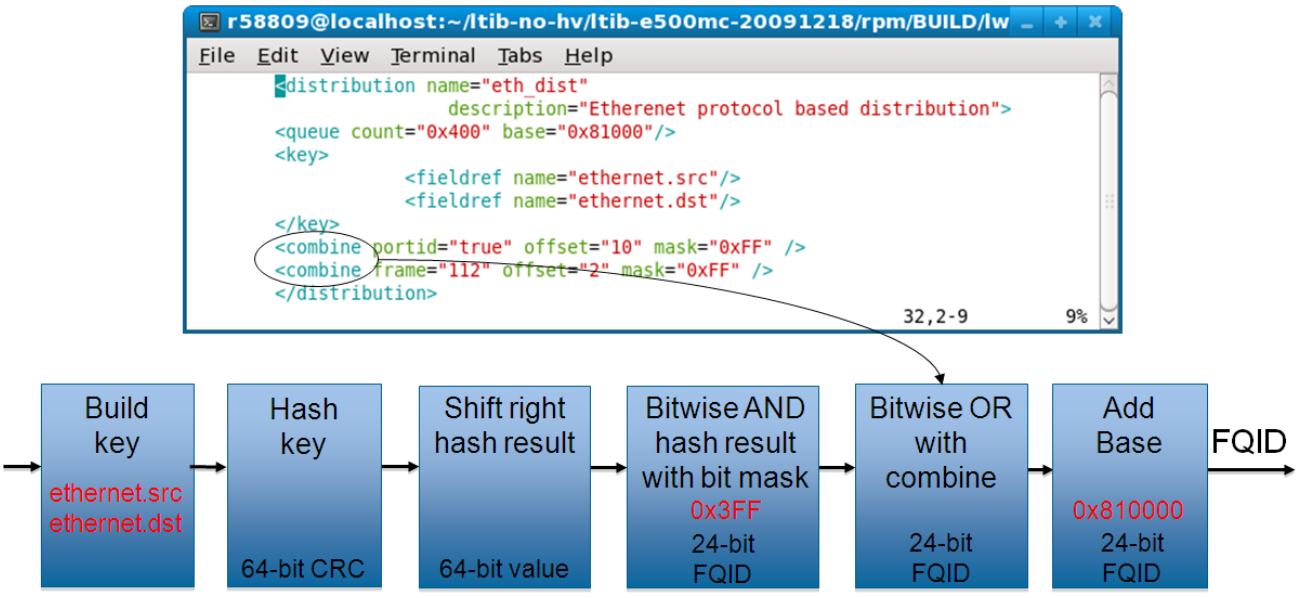

Figure 131. FQID Calculation - combine Elements Used in Bitwise OR

FQID Formula

```
FQID[0:23] = (Shifted Hash Key[0:23] & Hash Mask) |
             Data0[0:23] | Data1[0:23] | … | Data7[0:23] |
             FQID Base Address
```

In sum, use the child elements/attributes of the 'distribution' element to provide the values on the right side of the FQID equation.

7.4.4.5.1.11.2 Policy Section

The Policy *section* of the Policy *file* consists of one or more 'policy' *elements*. While 'policy' elements can appear anywhere in the Policy file, they typically follow the last 'distribution' element in the file.

Each 'policy' element defines a set of *candidate* distributions that the FMan can apply to inbound frames. The particular distribution the FMan applies to a given frame depends on these factors:

- The position of each distribution in the 'policy' element's distribution order list
- The definition of each of these distributions

Candidate distributions are listed in *priority* order. As a result, if two or more distributions in the list match the current inbound frame, the FMan applies the first matching distribution because this distribution has higher priority.

How does the FMan know which policy (that is, which prioritized list of distributions) to apply to the traffic received on a particular Ethernet port? The Configuration file provides the connection.

In a Configuration file, you must enter one 'port' element for each FMan port your application uses. Further, the port element has a required attribute - the 'policy' attribute - whose value must match the name of one of the policy elements in the Policy file, thereby defining the policy (that is, the ordered list of distributions) that the FMan will apply to all traffic received on a port. In sum, the value of a port element's policy attribute in the *Configuration* file ties the port identified by this element to a policy element in the *Policy* file.

In a Configuration file:

- A port can be assigned a single policy
- Multiple ports can be assigned the same policy
- A port can have just one active policy at a time

Typically, you assign one policy to each port your application uses.

Example 1 - Simple Use of the Policy Element

Configuration File

```
<!-- The port element assigns the dl_policy policy to the 10 Gbps port of FMan 1 -->
<!-- Policy dl_policy is defined in the Policy file - see next code snippet -->
<cfgdata>
  <config>
    <engine name="fm1">
      <port type="10G" number="0" policy="dl_policy"/>
    </engine>
  </config>
</cfgdata>
```

Policy File

```
<!-- A policy element that defines how to apply two distributions -->
<!-- These distributions are defined elsewhere in the Policy file -->
```

```
<!-- This policy is assigned to an Ethernet port by the Configuration file above -->
<policy name="dl_policy">
      <dist_order>
            <distributionref name="dl_eth_vlan_ipv4_udp_gtp_dist"/>
            <distributionref name="garbage_dist"/>
      </dist_order>
</policy>
```

In the example above, the Configuration file assigns the policy named 'dl_policy' to the 10 Gbps port of the p4080 chip's second FMan (fm1). As a result, the FMan first tries to match each frame that arrives on this port to the 'dl_eth_vlan_ipv4_udp_gtp_dist' distribution since it appears first in the 'policy' element's distribution order list. Whether the frame matches depends on the definition of the 'dl_eth_vlan_ipv4_udp_gtp_dist' distribution, which is not shown. If the frame matches, it is handled according to the rules this distribution defines. If the frame does not match, the FMan next compares it to the 'garbage_dist' distribution since it appears second in the distribution order list. Because of this distribution's definition (also not shown), it matches all frames, thereby guaranteeing that every frame is handled in one way or the other.

See The policy element on page 818 for complete documentation of this element.

Example 2 - More Complex Use of the Policy Element

Figure 132. More Complex Policy File - 1 on page 787 shows the Policy file from the pktwire application. This application requires a more complex use of policies and distributions than shown in the previous example.

This Policy file defines ten 'policy' elements - pktwr_policy_0, pktwr_policy_1, … pktwr_policy_9 - some of which are shown in the figure.

A Configuration file (not shown) assigns each of these policies to one of the p4080's ten FMan ports - five on the first FMan (fm0) and five on the second FMan (fm1).

Note: Not all QorIQ devices have two FMans. Nor does every FMan have five Ethernet ports. See the reference manual for your QorIQ device to determine the number of FMans and FMan ports this device supports.

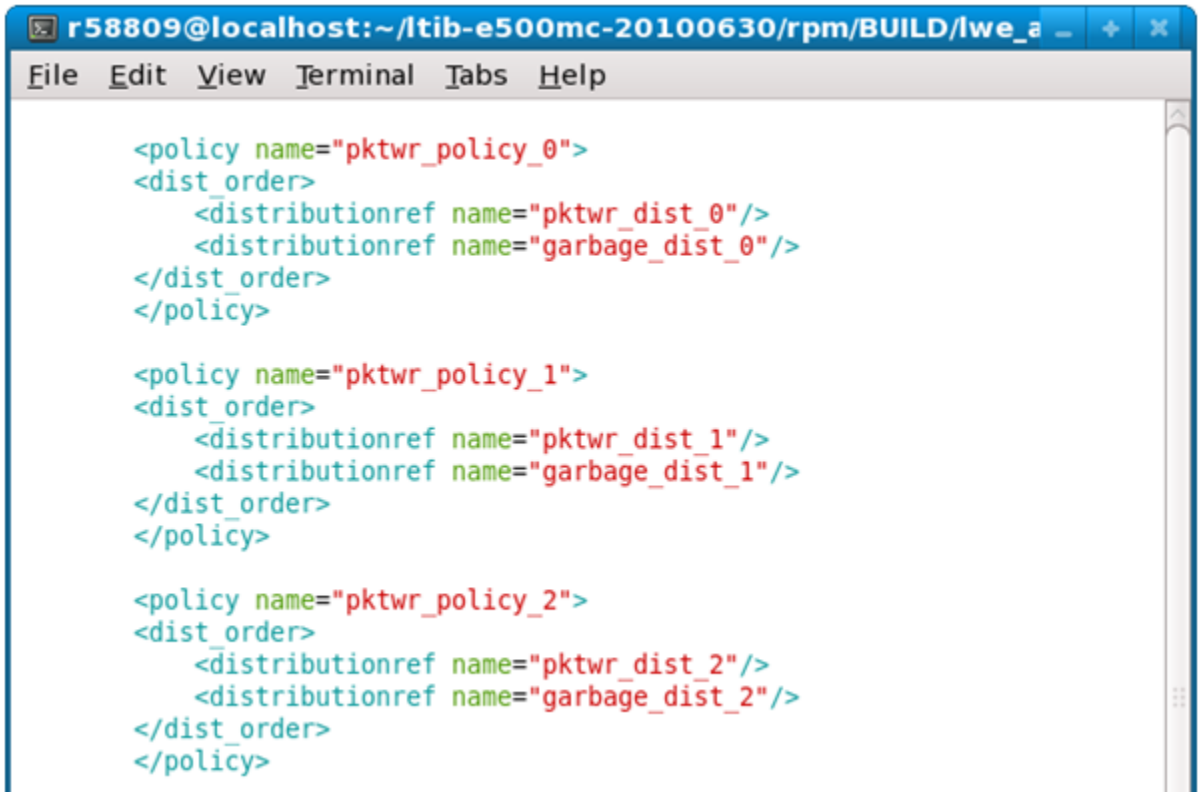

Figure 132. More Complex Policy File - 1

The Policy file also defines ten distributions - pktwr_dist_0, pktwr_dist_1, … pktwr_dist_9 - some of which are shown in Figure 133. More Complex Policy File - 2 on page 788.

As mentioned above, each of these distributions is assigned to a policy which, in turn, is assigned to a port. A frame "matches" the distribution assigned to the port on which the frame arrived if its header contains both the ipv4.src and ipv4.dst fields.

For each frame that matches, the KeyGen sub block computes a hash result using the concatenation of the ipv4.src and ipv4.dist fields as the hash key. The KeyGen sub block then uses the hash result to compute a FQID. (See the Distribution Section on page 782 topic for detailed coverage of the KeyGen's FQID calculation algorithm.)

The resulting FQID is in the range specified by the 'queue' element. For example, for distribution “pktwr_dist_0”, the resulting FQID will be in range 0x2800 – 0x281F.

Figure 133. More Complex Policy File - 2

The Policy file also defines ten distributions - garbage_dist_0, garbage_dist_1, … garbage_dist_9 - some of which are shown in Figure 134. More Complex Policy File - 3 on page 789.

Note that these distributions do not have a 'key' element. As a result, all frames “match” these distributions. For 'garbage_dist_0', the resulting FQID is always 0xb1 since the queue element specifies just one frame queue and the base FQID value is 0xb1.

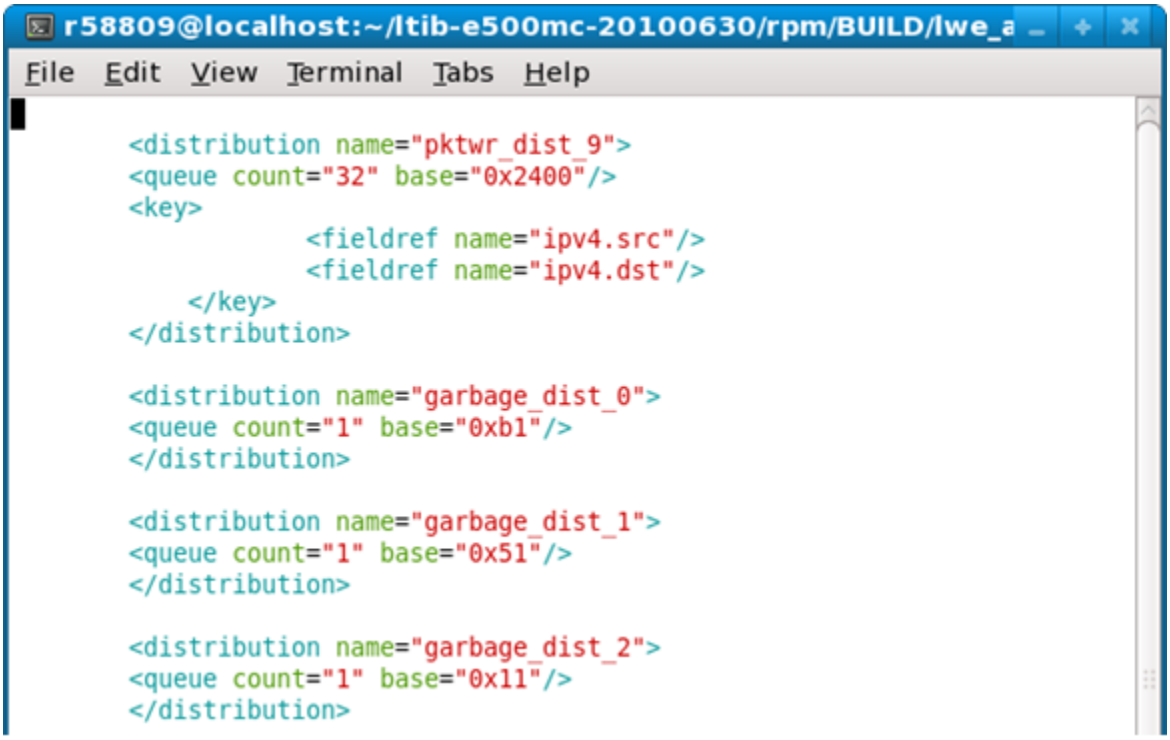

Figure 134. More Complex Policy File - 3

Let's say that an FMan port is tied to policy 'pktwr_policy_1' - highlighted in Figure 135. More Complex Policy File - 4 on page 790.

This policy instructs the FMan to first attempt to distribute frames arriving on this port using the 'pktwr_dist_1' distribution. If the current frame does not include the ipv4.src and ipv4.dst fields, the policy instructs the FMan to try the next distribution in the policy's distribution order list.

In this example, the next distribution is "garbage_dist_1" which, due to the absence of a 'key' element, matches *all* frames and enqueues them to the single frame queue defined by the 'count' and 'base' attributes of its queue element.

Note: It is common for the last distribution in a distribution order list to be a "catch all", like the default case in a C switch statement; however, this is not a requirement.

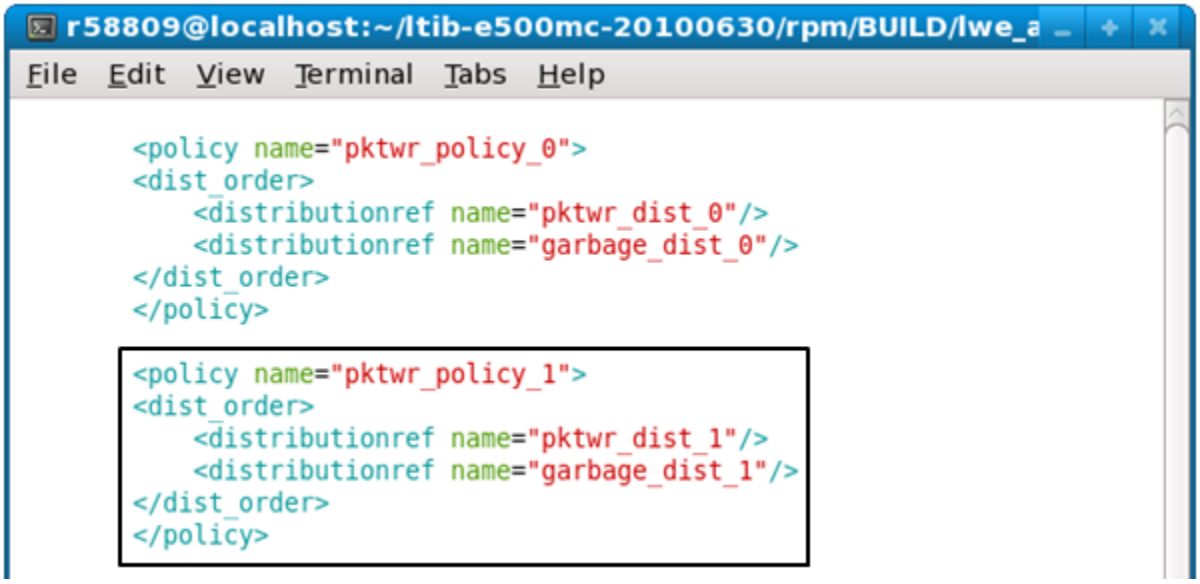

Figure 135. More Complex Policy File - 4

7.4.4.5.1.11.3 Classification Section

The Classification section of the Policy file is optional. Use it to specify exact match frame classification.

A classification specifies the action to perform on a frame when the values of the specified fields in a frame's protocol header match a predefined value. You can specify as many predefined value/action pairs as desired, as well as a default action.

A classification starts with a 'classification' element, which is a container for these child elements:

- A 'key' element that defines the header fields (in protocol.field form) to use in the exact match operation
- One or more 'entry' elements, each of which defines a value to which the specified fields are compared and a 'queue' and/or 'action' element that defines what to do with the frame upon a match
- An optional 'action' element that defines the default action to take if none of the exact match conditions is met

The FMC Tool uses the information in these child elements to populate the FMan Controller's rules table. At runtime, the Controller uses this information to extract the specified fields from the specified protocol header, compare these fields to the specified values and, upon a match, take the specified action.

See The classification element on page 828 for complete documentation of this element.

Example

The example below shows a Policy file containing a 'classification' element.

The 'policy' element named 'policy_0' lists two distributions to try, 'udp_dist' and 'non_udp_dist'.

Note: For a classification block to be applied to a frame, the frame must first match a distribution that transfers control to this classification via an 'action' element. In other words, the "source engine" of the Classifier is always a 'distribution' element.

The 'udp_classif' classification element specifies an exact-match lookup on the ipv4.dst field. If this field's value is:

- 0xC0A81402, the frame is placed on the queue whose FQID is 0x200
- 0xC0A81404, the frame is placed on the queue whose FQID is 0x400
- 0xC0A81406, the frame is placed on the queue whose FQID is 0x600
- 0xC0A81408, the frame is placed on the queue whose FQID is 0x800

Otherwise, the 'action' element passes the frame to the 'unknown_dist' distribution for handling.

```
description="Course Classification configuration">
<policy name="policy_0">
        <dist_order>
                <distributionref name="udp_dist"/>
                <distributionref name="non_udp_dist"/>
        </dist_order>
</policy>

<distribution name="udp_dist">
    <protocols>
        <protocolref name="udp"/>
    </protocols>
    <action type="classified" name="udp_classif"/>
</distribution>

<classification name="udp_classif">
    <key>
                <fieldref name="ipv4.dst">
    </key>
    <entry>
                <data>0xC0A81402</data>
                <queue base="0x200"/>
    </entry>
    <entry>
                <data>0xC0A81404</data>
                <queue base="0x400"/>
    </entry>
    <entry>
                <data>0xC0A81406</data>
                <queue base="0x600"/>
    </entry>
    <entry>
                <data>0xC0A81408</data>
                <queue base="0x800"/>
    </entry>
    <action type="distribution" condition="on-miss" name="unknown_dist"/>
<classification>
"cc_policy.xml" 108 lines --61%--
```

7.4.4.5.1.11.4 Policer Section

The Policer section of the Policy file is optional.

If used, the section consists of up to 256 policer profiles. Each profile starts with a 'policer' element, which is a container for various child elements with which you implement a particular policing behavior.

Each profile works in one of these modes:

- Pass-through – Policer performs no traffic metering
- RFC-2698 - Policer employs a two-rate, three-color marker scheme
- RFC-4115 - Policer employs a differentiated service, two-rate, three-color marker scheme that efficiently handles in-profile traffic

Each of these modes can be configured to be color-aware or color-blind.

For RFC-2698 and RFC-4115 modes, you must specify these values:

- unit, the unit to be used for the following numeric parameters. Valid values for unit are "packet" and "byte."
- CIR, Committed Information Rate[7]
- CBS, Committed Burst Size[8]
- PIR, Peak Information Rate[9]
- PBS, Peak Burst Size[10]

In all three modes, you can specify the next invoked action (NIA) for each color result (drop the frame, proceed to the specified distribution, etc.)

Example 1 - Policer Markup for RFC2698 Mode

```
<policer name="policer2">
  <algorithm>rfc2698</algorithm>

  <color_mode>color_aware</color_mode>

  <CIR>12000</CIR>
  <EIR>34000</EIR>
  <CBS>56000</CBS>
  <EBS>78000</EBS>

  <unit>byte</unit>

  <action condition="on-green"  type="distribution" name="green_dist"/>
  <action condition="on-yellow" type="distribution" name="yellow_dist"/>
  <action condition="on-red"    type="drop"/>
</policer>
```

Example 2 - Policer Markup for Pass-through Mode

```
<policer name="vlan_congestion_control_green">
  <algorithm>pass_through</algorithm>

  <color_mode>color_blind</color_mode>

  <default_color>green</default_color>

  <action condition="on-green" type="distribution name="default_dist"/>
</policer>

<policer name="vlan_congestion_control_yellow">
  <algorithm>pass_through</algorithm>

  <color_mode>color_blind</color_mode>

  <default_color>yellow</default_color>

  <action condition="on-yellow" type="drop"/>
</policer>
```

[7] If "unit" attribute is "packet" specify CIR and PIR in packets/second. If "unit" attribute is "byte" specify CIR and PIR in Kbits/second
[8] If "unit" attribute is "packet" specify CBS and PBS in packets. If "unit" attribute is "byte" specify CBS and PBS in bytes.
[9] If "unit" attribute is "packet" specify CIR and PIR in packets/second. If "unit" attribute is "byte" specify CIR and PIR in Kbits/second
[10] If "unit" attribute is "packet" specify CBS and PBS in packets. If "unit" attribute is "byte" specify CBS and PBS in bytes.

```
<policer name="vlan_congestion_control_red">
  <algorithm>pass_through</algorithm>

  <color_mode>color_blind</color_mode>

  <default_color>red</default_color>

  <action condition="on-red" type="drop"/>
</policer>
```

7.4.4.5.1.12 Configuration File

The Configuration file contains markup that defines the FMan instances (for devices with more than one FMan) and ports that are being used.

In addition, the Configuration file "connects" each port to the parse, classification, policing, and distribution rules defined in the Policy file. How? Each 'port' element in the Configuration file has a 'policy' attribute whose value must be the name of one of the 'policy' elements in the Policy file. This information tells the FMan which distributions to compare to each frame received on a given port.

Figure 136. Example Configuration File on page 793 shows the Configuration file's elements, attributes, and element hierarchy.

Note these element and attribute requirements:

- Valid engine names are "fm0" or "fm1"
- Valid values for the port type attribute are:
  - "MAC" (1/10 Gbps Ethernet port)
- Port numbering corresponds to hardware port number (as in dts) for each port.
- The value of the 'policy' attribute of a 'port' element must match the name of a 'policy' element in the Policy file.
- portid attribute (optional) - One byte numeric value that is attached to the port and that can be used in the 'distribution' and 'combine' elements of the Policy file.

The Configuration file's general structure is shown below.

Figure 136. Example Configuration File on page 793 shows an example configuration file. It uses the optional 'portid' attribute for the 1 Gbps ports.

Figure 136. Example Configuration File

```
<cfgdata>
  <config>
    <engine name="fm0">
      <port type="MAC" number="1" policy="ipv4_policy"/>
      <port type="MAC" number="2" policy="ipv4_policy" portid="0x96"/>
      <port type="MAC" number="3" policy="ipv4_policy" portid="0x97"/>
      <port type="MAC" number="4" policy="ipv4_policy" portid="0x97"/>
    </engine>
  </config>
</cfgdata>
```

Virtual Storage Profiles

The element 'vsp' (Virtual Storage Profile) is implemented in FMC as a standalone entity or can be defined directly in the element that uses it. The element 'vsp'can be used inside distributions, classification and entries (both classification and

replicator). When used directly in the ‘classification’ element (not in ‘entry’) it counts for the on-miss action. If the 'action' of the 'entry' or on-miss goes to another 'classification' or 'replicator' the 'vsp' is ignored.

Table 133. 'fragmentation' Element Attributes:

Attribute	Requirement	Description
name	required	Name of the element. The name is used to refer the virtual storage profile inside the elements that are using it.
type	optional	The type of the VSP. Values: • direct – (default) the relative profile ID is selected directly by the ‘base’ attribute. • indirect – the relative profile ID is selected base on the attributes **fqshift, vspoffset**, and **vspcount** can be used only in **distribution.**
base	required for direct.	--
fqshift	required for indirect.	Shift of KeyGen results without the FQID base.
vspoffset	optional for indirect	OR of KeyGen results without the FQID base; should indicate the storage profile offset within the port's storage profiles window.
vspcount	optional for indirect	Range of profiles starting at base.

VSP examples (standalone, defined in element, direct/indirect): The action targets of the entry are restricted to:

```
<vsp name = "storage01" base = "6"/>
<vsp name = "storage02" type = "indirect" fqshift="2" vspoffset="3"        vspcount="8"/>
<vsp name = "storage03" type = "direct" base = "7"/>

Usage:

...

<entry>
            <queue base="0x220"/>
            <vsp name=”storage01”>
</entry>

...

<distribution name="dist1">
     ...
     <queue count="8" base="0x230"/>
     <vsp type=”indirect” fqshift=”2” vspoffset=”0” vspcount=”4”/>
     ...
</distribution>

...

<classification name="eth_dest_clsf">
    <key>
         <fieldref name="ethernet.dst"/>
    </key>
...
    <vsp name=”storage03”>
```

```
    <action condition="on-miss" type="distribution" name="garbage"/>
</classification>
```

7.4.4.5.1.13 NXP NetPDL Reference

The FMan's Soft Parser can process non-standard, custom protocols that you define. To define a custom protocol, you enter NetPDL (Network Protocol Description Language) markup into a file called the Custom Protocol file. This markup defines each field in the custom protocol's header, as well as actions for the Soft Parser to take both before and after the custom header is loaded into the frame window.

Note: Although the markup used to define a custom protocol is based on NetPDL, this markup does not follow NetPDL rules strictly. As a result, you cannot rely on non-NXP documentation of NetPDL as you write your Custom Protocol file. Only the information in this appendix accurately explains how to write the NetPDL that goes in a Custom Protocol file.

You pass the name of the Custom Protocol file to the FMC Tool from the command line. The tool, in turn, passes the information in this file (directly or indirectly) to the FMan's Soft Parser.

7.4.4.5.1.13.1 Basic XML Rules

The Custom Protocol XML file follows standard XML rules.

The file is composed of several elements. Each element begins with a start tag and can contain attributes and/or child elements. If the element contains child elements, it must have a matching end tag. An element without child elements or text must end with a forward slash (/).

Note that element and attribute names are case sensitive. In the Custom Protocol file, all element and attribute names use only lower case alphabetics.

Comments always begin with "<!--" and end with "-->"

Example

```
<one-element attribute1="value"> <!-- this is a comment -->
  <child-element myattribute="4"/>
</one-element>
<another-element attribute2="value2"/>
```

7.4.4.5.1.13.2 The netpdl Element

The Custom Protocol file always begins with the <netpdl> root element. As a result, the end netpdl tag must appear at the end of the file.

Attributes: No required attributes

Child Elements: protocol

Example

```
<netpdl>
...
</netpdl>
```

7.4.4.5.1.13.3 The protocol element

Use the 'protocol' element to bracket the definition of each custom protocol in the Custom Protocol file. The 'protocol' element is a container for all the other elements required to define a custom protocol.

Attributes

name - (required) alphanumeric string; defines the unique name of the custom protocol.

longname - (optional) alphanumeric string; provides a user-friendly name for the protocol.

prevproto - (required) alphanumeric string. This attribute defines the previous protocol, that is, the protocol whose header precedes the custom protocol's header.

Table 134. Valid values for the prevproto attribute on page 796 lists the values that you can assign to the 'prevproto' attribute.

Table 134. Valid values for the prevproto attribute

Protocol	Layer
ethernet	2
llc_snap	2
vlan	2
pppoe	2
mpls	2
ipv4	3
ipv6	3
gre	3
minencap	3
otherl3 [11]	3
tcp	4
udp	4
ipsec_ah	4
ipsec_esp	4
sctp	4
dccp	4
otherl4 [1]	4

Each time the frame window contains a header for a protocol specified in the 'prevproto' attribute of one of the 'protocol' elements in the Custom Protocol file, the Hard Parser transfers control to the Soft Parser.

The Soft Parser then executes the 'before' element code of the 'protocol' element whose prevproto attribute matches the current protocol. As long as the 'before' element code is executing, the previous protocol's header remains in the frame window. As a result, the 'before' element code can reference the fields in the previous protocol header.

[11] The Custom Protocol file's NetPDL XML has a somewhat different structure and behavior if either 'otherl3' or 'otherl4' is the previous protocol. See Effect of Setting prevproto Attribute to otherl3 or otherl4 on page 797.

Typically, the 'before' element includes code that determines whether the next protocol header is an instance of the custom protocol defined by this protocol element. If it is not, the 'before' code instructs the Soft Parser to return to the Hard Parser; if it is, the Soft Parser continues to execute the 'before' code.

When the Soft Parser finishes executing the 'before' code (and if it does not return control to the Hard Parser), the Soft Parser advances the frame window to the custom protocol header and starts executing the 'after' element code (if any has been defined). Therefore, the code in the 'after' element can reference the fields in the custom protocol header.

Child Elements: format, execute-code

Example

```
<protocol name="gtpu" longname="GTP-U" prevproto="udp">
  ...
</protocol>

<protocol name="tcpExt" longname="tcp extension" prevproto="cp">
  ...
</protocol>
```

7.4.4.5.1.13.3.1 Effect of Setting prevproto Attribute to otherl3 or otherl4

When the 'prevproto' attribute of the 'protocol' element is set to otherl3 (for other layer 3 protocol) or otherl4 (for other layer 4 protocol), the first byte of the previous protocol header and the first byte of the custom protocol header are at the position in the frame window. Because they are not real protocols, neither otherl3 nor otherl4 has a real protocol header with a defined size and defined fields; these "protocols" are used just to provide the Soft Parser with an entry point (or a termination point) within the frame window. In effect, the size of the otherl3 and otherl4 "headers" is zero. Consequently, these "headers" have the same start offset in the frame window as does the custom protocol's header.

Note: Because the otherl3 and otherl4 protocols do not have real headers, they provide nothing for the Soft Parser to parse. As a result, you cannot use the 'before' element when either of these protocols is assigned to the 'prevproto' attribute. You can only use the 'after' element in these cases.

7.4.4.5.1.13.4 The format element

Use the 'format' element to bracket the definition of the structure of a custom protocol header. The 'format' element is a container for the 'fields' element which, in turn, is a container for the 'field' element. The 'field' element lets you define each field in a custom protocol's header.

Attributes: none

Child Elements: fields

7.4.4.5.1.13.4.1 The fields Element

Use the 'fields' element to define the structure of a custom protocol's header. This element is a container for the 'field' element, which lets you define each field in a custom protocol header.

Attributes: none

Child Elements: field

7.4.4.5.1.13.4.2 The field Element

Use the 'field' element to define one of the fields in a custom protocol header.

Attributes

type - (required) string; Defines the field size as either "fixed" for a byte-length field or "bit" for a bit-length field.

size - (required) integer; Defines the size of the field in bytes.

name - (required) string; Defines the unique name for the field.

longname - (optional) string; Defines the name of the field for display purposes.

mask - (required only for bit field) integer; Defines the specific bits in the current bytes which belong to this field.

The field elements appear one after the other to define a custom protocol's header frame. The first field begins in the first byte of the custom protocol's frame header and its size is determined by the size attribute. The following fields conform to the following rules:

- A fixed field or a field following a fixed field begins in the next byte, which is the previous field's offset + the previous field's size.
- A bit field following a bit field begins in the next byte only if the last bit in the previous field's mask is 1.
- If two fields share the same offset (which is possible only when both fields are bit fields and the mask of the first field does not end with 1), they should have the same value for their size attributes.

Example

```
<format>
  <fields>
    <field type="bit"   name="flags"   mask="0xE0" size="1"/>
    <field type="bit"   name="pt"      mask="0x80" size="1"/>
    <field type="bit"   name="version" mask="0x07" size="1"/>
    <field type="fixed" name="mtype"               size="1"/>
    <field type="fixed" name="length"              size="2"/>
  </fields>
</format>

<format>
  <fields>
    <field type="bit"   name="version" mask="0xE0" size="1"/>
    <field type="bit"   name="pt"      mask="0x10" size="1"/>
    <field type="bit"   name="flags"   mask="0x07" size="1"/>
    <field type="bit"   name="flags1"  mask="0x01" size="1"/>
    <field type="bit"   name="flags2"  mask="0x10" size="1"/>
    <field type="bit"   name="flags3"  mask="0x02" size="1"/>
    <field type="fixed" name="mtype"   size="1" longname="message type"/>
    <field type="fixed" name="length"  size="2"/>
  </fields>
</format>
```

The fields will, thus, be stored in the following bit offsets in the custom protocol header:

version: 0-2 pt: 3-3 flags: 5-7 flags1: 15-15 flags2: 19-19 flags3: 22-22 mtype: 24-31 length: 32-47

7.4.4.5.1.13.5 The execute-code element

Use the 'execute-code' element to define all code that should be executed for a custom protocol once the parser reaches the specified previous protocol header.

This element contains two child elements, 'before' and 'after'. At least one of these child elements must be defined. If both are defined, the 'before' element must appear before the 'after' element.

Attributes: none

Child Elements: before, after

Example

```
<execute-code>
  <before>
    ...
```

```
  </before>

  <after headersize="8">
  </after>
</execute-code>
```

7.4.4.5.1.13.5.1 The before Element

The Soft Parser executes the code in the 'before' element before it moves the frame window from the previous protocol header to the custom protocol header. Therefore, use the 'before' element to specify logic that requires access to fields in the previous protocol header. This code is often used to determine whether the next protocol header is an instance of the custom protocol this protocol block defines. If it is not, the 'before' block instructs the Soft Parser to return control to the Hard Parser; if it is, the Soft Parser continues processing.

While the code in the 'before' element is analyzed, the frame window points to the previous protocol header. Therefore, the frame window variable ($FW) references the fields in the previous protocol header and the header size variable ($headerSize) variable returns the size of the previous protocol's header.

Once the it reaches the end of the 'before' element, the Soft Parser moves the frame window to the custom protocol header. If no 'after' element has been defined, the Soft Parser then returns to the Hard Parser.

The 'before' element can only appear once in the 'execute-code' element and, if an 'after' element has been defined, the 'before' element must appear before the 'after' element.

Attributes

confirm - (optional) string; Valid values are "yes" and "no". The default value is "no" if an 'after' element has been defined. Otherwise, the default value is "yes". If confirm="yes", the Soft Parser confirms the presence of the 'prevproto' header by bitwise OR'ing the previous protocol's line-up enable confirmation mask with the current line-up confirmation vector (LCV) value.

confirmcustom - (optional) string; Valid values are "shim1", "shim2", and "no". The default value is "no". If 'confirmcustom' is set (!="no"), the Soft Parser confirms the presence of the custom protocol header by bitwise OR'ing the custom protocol's mask with the current line-up confirmation vector (LCV) value. The custom protocol can set one of the last two bits in the LCV. If "shim1" is selected, the least significant bit is set; if "shim2" is selected, the second least significant bit is set.

Child Elements: if, switch, assign, action

Note: When the previous protocol is 'otherl3' or 'otherl4', the previous protocol and the custom protocol are treated as if they are the same and each begins at the same offset within the frame window. Therefore, the 'before' element cannot be used when the 'prevproto' attribute is 'otherl3' or 'otherl4'; only an 'after' element be used when the the 'prevproto' attribute is 'otherl3' or 'otherl4'. See Effect of Setting prevproto Attribute to otherl3 or otherl4 on page 797 for more information.

7.4.4.5.1.13.5.2 The after Element

The 'after' element contains code which should be executed when a frame from the current custom protocol has been encountered. In contrast to the 'before' element, in the 'after' section, it is possible to access fields from the current protocol but not from the previous protocol. In the 'after' element the frame window variable ($FW) manipulates the current custom protocol header and the header size variable ($headerSize) returns the size of the current custom protocol header.

At the end of the 'after' element, the frame window jumps to the end of the custom protocol's header and control returns to the Hard Parser.

The 'after' element can appear only once in an 'execute-code' element and if a 'before' element has been defined, it must appear before the 'after' element.

Attributes

confirm - (optional) string; Valid values are "yes" and "no". The default value is "yes". If confirm ="yes", the Soft Parser confirms the existence of the previous protocol header by bitwise OR'ing the previous protocol's line-up enable confirmation mask with the current line-up confirmation vector (LCV) value.

confirmcustom - (optional) string; Valid values are "shim1", "shim2", and "no". The default value is "no". If 'confirmcustom' is set (!="no"), the Soft Parser confirms the presence of the custom protocol header by bitwise OR'ing the custom protocol's mask with the current line-up confirmation vector (LCV) value. The custom protocol can set one of the two last bits in the LCV. If "shim1" is selected, the least significant bit is set; if "shim2" is selected, the second least significant bit is set.

headerSize - (optional) integer; Possible values: arithmetic expression. (See Arithmetic Expressions on page 815) The default value is calculated using the fields contained by the 'format' element. You can specify the custom protocol's header size with this attribute. This information is needed so the parser returns to the right position following the custom protocol header. If header size is not specified, the FMC Tool assumes that the fields defined inside the 'format' element are the only fields in the custom protocol header and calculates the header size using these fields. The $headerSize variable in the 'after' element returns the value defined in this attribute (or the value calculated by default if the header attribute is not defined).

Child Elements: if, switch, assign, action

Example

```
<protocol name="gtp" prevproto="udp">
  <format>
    <fields>
      <field type="bit" name="version" mask="0xE0" size="1"/>
    </fields>
  </format>

  <execute-code>
    <before confirm="no">
      <assign-variable name="$GPR1" value="udp.dport"/>
      <!-- Note that this is ILLEGAL: <assign-variable name="GPR1" value="version" -->
      <assign-variable name="$shimr" value="$headerSize"/>
      <!-- shimresult now holds udp's header size -->
    </before>

    <after headersize="4" confirmcustom="shim1">
      <!-- Note that this is ILLEGAL: <assign-variable name="$GPR1" value="udp.dport"> -->
      <assign-variable name="$GPR1" value="version"/>
      <assign-variable name="$shimr" value="$headerSize"/>
      <!-- shimresult now equals 4 -->
    </after>
  </execute-code>
</protocol>
```

7.4.4.5.1.13.5.3 Child Elements of the before and after Elements

7.4.4.5.1.13.5.3.1 The assign-variable Element

The 'assign-variable' element assigns an expression to a variable.

Attributes

name - (required) string; The name of the variable to which a value will be assigned. Valid values: Variables contained in the result array.

value - (required) integer; The expression assigned to the variable. Valid values: arithmetic expressions.

Child Elements: none

Example

```
<assign-variable name="$shimoffset_2" value="$shimoffset_1+12"/>
```

7.4.4.5.1.13.5.3.2 The if Element

This element tests the specified condition. If the condition is true, control transfers to the 'if-true' element; if the condition is false, control transfers to the 'if-false' element (if one is defined).

Attributes

expr - (required) string; Defines the condition to be checked before selecting the code block to execute. Valid values: logical expressions. (See Logical Expressions on page 815 for more information.)

Child Elements: if-true (required), if-false

Example

```
<if expr="$shimoffset_1==1">
  <if-true>
    ...
  </if-true>
  <if-false>
    ...
  </if-false>
</if>
```

7.4.4.5.1.13.5.3.2.1 The if-true Element

This element defines code to execute if the expression defined in the parent 'if' element is true.

Attributes: none

Child Elements: if, switch, assign, action (the same child elements as for the 'before' and 'after' elements)

Example

```
<if expr="$shimoffset_1==1">
  <if-true>
    ...
  </if-true>
  <if-false>
    ...
  </if-false>
</if>
```

7.4.4.5.1.13.5.3.2.2 The if-false Element

This element defines the code to execute if the expression defined in the parent 'if' element is false.

Attributes: none

Child Elements: if, switch, assign, action (the same child elements as for the 'before' and 'after' elements)

Example

```
<if expr="$shimoffset_1==1">
  <if-true>
    ...
  </if-true>
  <if-false>
    ...
  </if-false>
</if>
```

7.4.4.5.1.13.5.3.3 The switch Element

This element defines an expression and a set of cases. Each case consists of a value (or set of values) and code to be executed if the value equals the switch expression. Each 'switch' element must have at least one 'case' child element.

Note: Only the code of the first case that matches the swith expression is executed. Any following cases are skipped. In C language terms, a break is automatically added after the code of each case.

Attributes

expr - (required) string; Defines the value being checked. Valid values: arithmetic expressions.

Child Elements: case, default

Example

```
<switch expr="$shimoffset_1+1">
  <case value="2">
    <assign-variable name="$GPR[1:1]" value="0"/>
  </case>

  <case value="3" maxvalue="4">
    <assign-variable name="$GPR[1:1]" value="1"/>
  </case>

  <default>
    <assign-variable name="$GPR[1:1]" value="2"/>
  </default>
</switch>
```

7.4.4.5.1.13.5.3.3.1 The case Element

This element matches a value or range of values against the switch expression.

Attributes

value - (required) integer; If the value equals the switch expression and no earlier case has been matched, the code in the 'case' element is executed.

maxvalue - (optional) integer; If the switch expression is greater than or equal to the 'value' attribute and the expression is less than or equal to the 'maxvalue' attribute (and no earlier case has been matched), the code in the 'case' element is executed.

Child Elements: if, switch, assign, action (the same child elements as for the 'before' and 'after' elements)

Example

```
<switch expr="$shimoffset_1+1">
  <case value="2">
    <assign-variable name="$GPR[1:1]" value="0"/>
  </case>

  <case value="3" maxvalue="4">
    <assign-variable name="$GPR[1:1]" value="1"/>
  </case>

  <default>
    <assign-variable name="$GPR[1:1]" value="2"/>
  </default>
</switch>
```

7.4.4.5.1.13.5.3.3.2 The default Element

The 'default' element contains code that is executed if the expression in the 'switch' element is not matched by any of the candidate cases.

Attributes: none

Child Elements: if, switch, assign, action (the same child elements as for the 'before' and 'after' elements)

Example

```
<switch expr="$shimoffset_1+1">
  <case value="2">
    <assign-variable name="$GPR[1:1]" value="0"/>
  </case>

  <case value="3" maxvalue="4">
    <assign-variable name="$GPR[1:1]" value="1"/>
  </case>

  <default>
    <assign-variable name="$GPR[1:1]" value="2"/>
  </default>
</switch>
```

7.4.4.5.1.13.5.3.4 The action Element (for use in a Custom Protocol file)

Use the 'action' element in a 'before' or 'after' block to terminate soft parsing, jump to the specified next protocol header, and continue hard parsing.

Note: This topic defines the 'action' element used in a Custom Protocol file. See The action element (for use in a policy file) on page 826 for the definition of the 'action' element used in a Policy file.

Attributes

- type - (required) string; "exit" is the only valid value for the type attribute.
- advance - (optional) string; The 'advance' attribute controls whether the Soft Parser moves the frame window to the next frame header. This attribute has different meanings in the 'before' and 'after' elements. In the 'before' element, the Soft Parser moves the frame window from the previous protocol header to the custom protocol header. In the 'after' element, the Soft Parser moves the frame window from the custom protocol header to the specified next protocol header. The frame window is advanced according to the header size. The value of 'advance' must be 'yes' or 'no'. The default is 'yes' unless 'nextproto' is set to 'end_parse', 'return', or not set at all. In these cases, the default value is 'no'.
- confirm - (optional) string; If confirm="yes", the Soft Parser bitwise OR's the previous protocol's line-up enable confirmation mask with the current line-up confirmation vector (LCV) value. Valid values are "yes" and "no"; the default value is "yes".
- confirmcustom - (optional) string; Valid values are "shim1", "shim2", or "no". The default value is "no". If confirmcustom is set to a value other than "no", the Soft Parser bitwise ORs the custom protocol's mask with the current line-up confirmation vector (LCV) value. The custom protocol can set one of the two last bits in the LCV. If shim1 is specified, the least significant bit is set; if shim2 is specified, the second least significant bit is set.
- nextproto - (optional); If used, this attribute must be one of the values in Table 135. Parse Action for each Value of the nextproto Attribute on page 804. The default value is 'return'.

Table 135. Parse Action for each Value of the nextproto Attribute

If nextproto is ...	The parse action is ...
ethernet	Jump to the Ethernet header and continue hard parsing
llc_snap	Jump to the LLC_SNAP header and continue hard parsing
vlan	Jump to the VLAN header and continue hard parsing
pppoe	Jump to the PPPoE header and continue hard parsing
mpls	Jump to the MPLS header and continue hard parsing
ipv4	Jump to the IPv4 header and continue hard parsing
ipv6	Jump to the IPV6 header and continue hard parsing
gre	Jump to the GRE header and continue hard parsing
minencap	Jump to the MinEncap header and continue hard parsing
otherl3	Jump to the otherl3 header and continue hard parsing
tcp	Jump to the TCP header and continue hard parsing
udp	Jump to the UDP header and continue hard parsing
ipsec_ah	Jump to the IPsec_ah header and continue hard parsing
ipsec_esp	Jump to the IPsec_esp header and continue hard parsing
sctp	Jump to the SCTP header and continue hard parsing
dccp	Jump to the DCCP header and continue hard parsing
otherl4	Jump to the otherl4 header and continue hard parsing
after_ethernet	Jump to the protocol that should follow the Ethernet header. The next protocol is determined from the value of the $nxtHdr variable. See Table 136. Next Protocol for each $nxtHdr Value if nextproto is 'after_ethernet' on page 805to find the next protocol for each possible value of $nxtHdr. **Note:**The 'advance' attribute must be set to 'yes' if 'nextproto' is set to 'after_ethernet'.
after_ip	Jump to the protocol that should follow the IP header. The next protocol is determined from the value of the $nxtHdr variable. See Table 136. Next Protocol for each $nxtHdr Value if nextproto is 'after_ethernet' on page 805to find the next protocol for each possible value of $nxtHdr. **Note:**The 'advance' attribute must be set to 'yes' if 'nextproto' is set to 'after_ip'.

Table continues on the next page...

Table 135. Parse Action for each Value of the nextproto Attribute (continued)

If nextproto is ...	The parse action is ...
return (default value)	Return to the Hard Parser without advancing the frame window. In this case, the Hard Parser starts parsing the frame header at the same position at which the Soft Parser began. The 'advance' attribute cannot be 'yes' when 'nextproto is set to return.
none/end_parse	Finish parsing the frame header; do not return to the Hard Parser.

Table 136. Next Protocol for each $nxtHdr Value if nextproto is 'after_ethernet'

If $nxtHdr is ...	The next protocol is ...
0x05DC or less	llc_snap
0x0800	ipv4
0x86DD	ipv6
0x8847, 0x8848	mpls
0x8100, 0x88A8, ConfigTPID1, ConfigTPID2	vlan
0x8864	pppoe
other value	otherl3

Table 137. Next Protocol for each $nxtHdr Value if nextproto is 'after_ip'

If $nxtHdr is ...	The next protocol is ...
4	ipv4
6	tcp
17	udp
33	dccp
41	ipv6
50, 51	ipsec
47	gre
55	minencap
132	sctp
other value	otherl4

Notes

- The frame window *must* be advanced when parsing jumps to the 'after_ethernet' or 'after_ip' protocols. Therefore, the 'advance' attribute cannot be set to 'no' in these cases.
- The frame window must *not* be advanced before a 'return' to the Hard Parser. Therefore, the 'advance' attribute cannot be set to 'yes' if nextproto is set to 'return' or not set at all (since 'return' is the default 'nextproto' value).

Child Elements: none

Example

```
<action type="exit"
        advance="yes"
        confirmcustom="shim2"
        confirm="no"
        nextproto="udp"/>
```

7.4.4.5.1.13.6 Expressions

Expressions are constructed of operands and operators. The simplest expression can contain just one operand. Most operators are dyadic and separate two operands (such as +, -) and some operators are monadic and operate on just the operand that follows them (such as 'not').

7.4.4.5.1.13.6.1 Operands

These are the supported types of operands: numbers, variables, fields, and expressions.

Note: The maximum size of an operand is 64 bits (8 bytes).

7.4.4.5.1.13.6.1.1 Numbers

Numbers can appear in decimal (no prefix), binary (prefixed by '0b'), or hexadecimal (prefixed by '0x') format.

All numbers are 64-bit unsigned integers. However, some operators only use the 32 LSB of a number.

Note: Immediate, primitive negative numbers are not supported. For example, the number -2 cannot appear in an expression. However, artificial negative values can be created using arithmetic expressions such as 1-3 (which returns 0xfffffffe).

7.4.4.5.1.13.6.1.2 Fields

Fields are defined with the 'format' element in a custom protocol header definition. There are two ways to access a field, by typing their name directly or by typing the name of the protocol header containing the field, followed by a period, followed by the name of the field.

In the 'before' element, it is only possible to access fields in the previous protocol header; in the 'after' element, it is only possible to access fields in the current custom protocol header.

Note: Fields longer than 8 bytes cannot be accessed individually. You can work around this limit by accessing the frame directly using the frame window ($FW) variable or by splitting the field into several shorter fields.

Example

```
<protocol name="gptu" prevproto="#ethernet">
  <format>
    <fields>
      <field type="fixed" name="example" size="2"/>
    </fields>
  </format>

  <execute-code>
    <before>
      <assign-variable name="$l2r" value="ethernet.type"/>
    </before>
```

```
    <after>
      <assign-variable name="$shimoffset_2" value="example"/>
    </after>
  </execute-code>
</protocol>
```

7.4.4.5.1.13.6.1.3 Variables

All variable names begin with the $ prefix and are case-sensitive. These variables are supported: frame window, header size, prevprotoOffset, parameter array, and result array variables.

7.4.4.5.1.13.6.1.3.1 Result Array Variables

Result array variables return values contained in the parse results array.

Syntax for accessing result array variables:

- $variableName - returns the entire variable
- $variableName[byteOffset:byteNumber] - Returns the byteNumber number of bytes in the variable starting from byteOffset. This access method is useful for accessing a subset of the bytes in the variable. In bytesNumber equals zero, the entire variable is returned, starting from byteOffset.

Example: The variable $actiondescriptor returns result array bytes 64-71. The expression $actiondescriptor[2:4] returns result array bytes 66-69 since 66 is at offset 2 of the actiondescriptor variable and the requested size is 4. The expression $actiondescriptor[3:0] returns result array bytes 67-71 since 67 is at offset 3 of the actiondescriptor variable and the requested size is 0, which means return the entire variable starting at the specified offset (3).

Other usage: In addition to expressions, result array variables can be used in the left side of 'assign-variable' elements to modify result array values.

Table 138. Result Array Variables on page 807shows the available result array variables .

Table 138. Result Array Variables

Variable Name	Result Array Bytes Referenced
gpr1	0-7
gpr2	8-15
logicalportid	16-16
shimr	17-17
l2r	18-19
l3r	20-21
l4r	22-22
classificationplanid	23-23
nxthdr	24-25
runningsum	26-27
flags	28-28

Table continues on the next page...

Table 138. Result Array Variables (continued)

Variable Name	Result Array Bytes Referenced
fragoffset	28-29
routtype	30-30
rhp	31-31
ipvalid	31-31
shimoffset_1	32-32
shimoffset_2	33-33
ip_pidoffset	34-34
ethoffset	35-35
llcs_napoffset	36-36
vlantcioffset_1	37-37
vlantcioffset_n	38-38
lastetypeoffset	39-39
pppoeoffset	40-40
mplsoffset_1	41-41
mplsoffset_n	42-42
ipoffset_1	43-43
ipoffset_n	44-44
minencapo	44-44
minencapoffset	44-44
greoffset	45-45
l4offset	46-46
nxthdroffset	47-47
framedescriptor1	48-55
framedescriptor2	56-63
actiondescriptor	64-71

Table continues on the next page...

Table 138. Result Array Variables (continued)

Variable Name	Result Array Bytes Referenced
ccbase	72-75
ks	76-76
hpnia	77-79
sperc	80-80
ipver	85-85
iplength	86-87
icp	90-91
attr	92-92
nia	93-95
ipv4sa	96-99
ipv4da	100-103
ipv6sa1	96-103
ipv6sa2	104-111
ipv6da1	112-119
ipv6da2	120-127

Note: The $GPR2 variable is used internally by the FMC Tool to calculate complex expressions, including checksum calculations. Using $GPR2 for other purposes is possible, but is not supported or recommended.

7.4.4.5.1.13.6.1.3.2 Parameter Array Variable

This variable returns data from the parameter array. Because the parameter array is more than 8 bytes long, you must specify the particular bytes needed.

Accessing parameter array variables: $PA[byteOffset:byteNumber] - returns the byteNumber number of bytes in the parameter array starting at byteOffset.

Example: The expression "$PA[4:2]" accesses the fifth and sixth bytes (indexed at PA[4] and PA[5]) of the parameter array.

7.4.4.5.1.13.6.1.3.3 Header Size Variables

Header size variables return the header size or default header size of a protocol header.

Accessing header size variables: $headerSize or $defaultHeaderSize

- In the 'before' element, the $headerSize of the previous protocol header is returned. Accessing $defaultHeaderSize is not allowed.

- In the 'after' element, the $defaultHeaderSize variable returns the number of bytes in the custom protocol's format fields. The $headerSize variable returns the headerSize as defined by the 'headersize' attribute of the 'after' element. If the user has not specified a value for the 'headersize' attribute, $headerSize returns the same value as $defaultHeaderSize.

7.4.4.5.1.13.6.1.3.4 Frame Window Variable

The frame window variable ($FW) returns data from the frame array. In the 'before' element, the frame window variable returns data from the previous protocol's header. In the 'after' element, the frame window variable returns data from the custom protocol header.

Using the frame window variable: $variableName[bitOffset:bitNumber] - Returns the bitNumber number of bits in the frame header starting from bitOffset.

Note: The frame window uses similar syntax to the parameter array and result array variables; however, the frame window variable accesses bits instead of bytes.

Examples

To access the tenth and eleventh bits in the frame array (indexed at FW[9], FW[10]), use "$FW[9:2]".

To access the entire third byte of the frame array, use "$FW[16:8]".

The conditions in the example below are always true because the same bits can be accessed using either the $FW variable or header field names.

```
<format>
  <fields>
    <field type="bit" name="first" size="1" mask="0xE0"/>
    <field type="bit" name="second" size="1" mask="0x1"/>
    <field type="bit" name="third" size="1" mask="0xF"/>
    <field type="fixed" name="fourth" size="2"/>
  </fields>
</format>
...
<after>
  <if expr="first==$FW[0:3]"> ... </if>
  <if expr="second==$FW[7:1]"> ... </if>
  <if expr="third==$FW[8:4]"> ... </if>
  <if expr="fourth==$FW[16:16]"> ... </if>
</after>
```

7.4.4.5.1.13.6.1.3.5 The prevprotoOffset Variable

This variable returns the offset of the previous protocol's frame header. This variable has the same value in the 'before' and 'after' sections and always refers to the protocol defined in the 'prevproto' attribute of the protocol element.

In the 'before' element, the frame window's current location is equal to prevprotoOffset. In the 'after' element. the frame window's current location is equal to prevprotoOffset+headerSize.

Note: This variable is actually a "shortcut" to the result array and returns or modifies values taken directly from this array.

Table 139. Previous Protocol RA Return Values

If the previous protocol is ...	The value returned from result array is ...
ethernet	$ethoffset
gre	$greoffset

Table continues on the next page...

Table 139. Previous Protocol RA Return Values (continued)

If the previous protocol is ...	The value returned from result array is ...
ipv4, ipv6	$lpoffset_n
llc_snap	$llcsnapoffset
minencap	$minencapoffset
mpls	$mplsoffset_n
pppoe	$pppoeoffset
tcp, udp, sctp, dccp, ipsec_ah, ipsec_esp	$l4offset
vlan	$vlanoffset_n
otherl3, otherl4	$NxtHdrOffset - When the previous protocol is otherl3 or other l4, the custom protocol and the previous protocol have the same offset. See Effect of Setting prevproto Attribute to otherl3 or otherl4 on page 797.

7.4.4.5.1.13.6.2 Operators

The parser supports many operators. These operators can receive arithmetic or logical operands and return an arithmetic or logical value. An arithmetic value is a number, while a logical value is true or false. (See Arithmetic Expressions on page 815 and Logical Expressions on page 815 for more information.)

Table 140. Supported Operators and their Properties on page 811describes all operators and their associated properties. All dyadic operators (operators which receive two parameters) appear between two operands. All monadic operators appear before an operand.

Table 140. Supported Operators and their Properties

Name	Parameters	Description	Symbol
Greater than	Logical (Arithmetic, Arithmetic)	Checks if the value of the first expression is greater than the second	gt
Greater equal	Logical (Arithmetic, Arithmetic)	Checks if the value of the first expression is equal to or greater than the second	ge
Less than	Logical (Arithmetic, Arithmetic)	Checks if the value of the first expression is less than the second	lt
Less equal	Logical (Arithmetic, Arithmetic)	Checks if the value of the first expression is equal to or less than the second	le
Equal	Logical (Arithmetic, Arithmetic)	Checks if the two expressions are equal	==
Not equal	Logical (Arithmetic, Arithmetic)	Checks if the two expressions are not equal	!=

Table continues on the next page...

Table 140. Supported Operators and their Properties (continued)

Name	Parameters	Description	Symbol
Logical AND	Logical (Logical, Logical)	Checks if both expressions are true	and
Logical OR	Logical (Logical, Logical)	Checks if either one of the expressions is true	or
Logical NOT	Logical (Logical)	Returns true if the expression is false; returns false otherwise	not
Add	32-bit Arithmetic (32-bit Arithmetic, 32-bit arithmetic)	Return the sum of the expressions	+
Subtract	32-bit arithmetic (32-bit Arithmetic, 32-bit arithmetic)	Return the difference between the two expressions (result of subtraction)	-
Add carry	16-bit arithmetic (16-bit arithmetic, 16-bit arithmetic)	Return the sum of the two expressions summed with the carry after 32bit	addc
Bitwise OR	Arithmetic (Arithmetic, Arithmetic)	Returns the result of a bitwise OR operation on the two expressions	bitwor
Bitwise XOR	Arithmetic (Arithmetic, Arithmetic)	Returns the result of a bitwise XOR operation on the two expressions	bitwxor
Bitwise AND	Arithmetic (Arithmetic, Arithmetic)	Returns the result of a bitwise AND operation on the two expressions	bitwand
Bitwise NOT	Arithmetic (Arithmetic)	Returns the result of a bitwise NOT operation on the expression	bitwnot
Shift left	Arithmetic (Arithmetic, Integer - value up to 64 bits)	Return the left expression shifted left by the right expression	shl
Shift right	Arithmetic (Arithmetic, Integer - value up to 64 bits)	Return the left expression shifted right by the right expression	shr
Concat	Arithmetic (Arithmetic, Variable or Integer)	Special operator See The concat Operator on page 812 for full documentation	concat
Checksum	Arithmetic (Arithmetic - value up to 0xffff, Arithmetic - value up to 256, Arithmetic - value up to 256)	Special operator See The checksum Operator on page 813 for full documentation	checksum

7.4.4.5.1.13.6.2.1 The concat Operator

The concat operator shifts its first argument left and inserts its second argument to its right. The concat operation can be executed on variables or integers. If the second argument is a variable, the first argument is shifted left according to the known size of the variable. Result array variables have constant sizes and the size of the frame header's fields are set in the Custom Protocol file or the Standard Protocol file.

If the user accesses only specific bits in the second argument, the first argument is shifted left only by the number of bits specified.

If the second argument is an integer, the first argument is shifted left by the smallest word size into which the integer fits: 16, 32, 48, or 64.

Note: The second argument of a concat operation cannot be an expression because the FMC Tool does not know the size of an expression and therefore cannot shift the first argument properly. However, for expressions, you can replace the concat operation with a shift operation (as long as you know the number of bits to shift) and a bitwise OR operation.

Note: You should use concat instead of shift/bitwise OR when working with variables and integers in order to reduce code size.

For example, the following IF expression is true:

```
<assign-variable name="$shimr" value="2"/>
<assign-variable name="$GPR1[6:2]" value="3"/>
<if expr="1 concat $shimr concat $GPR1[6:2] concat 0x40000 == 0x102000300040000">
```

7.4.4.5.1.13.6.2.2 The checksum Operator

The checksum operator is a special operator with unique behavior and syntax. It appears before three operands that have parentheses around them. As a result, the concat operator looks like a function call - checksum(expression, integer, integer).

The first operand defines the initial checksum value. The second operand defines the frame window offset at which to start the checksum (relative to the current frame window location). The third operand defines the length of the data in bytes on which the checksum operation should be calculated.

Using these values, the checksum executes the add carry (addc) operation on 2-byte sized words in the frame window range specified. If the range specified contains an odd number of bytes to be checksummed, the last byte is padded on the right with zeros to form a 16-bit word for checksum purposes. The total sum is added to the initial checksum value using another addc operation. Therefore, the first argument that defined the initial sum value must be smaller than 0xffff. The result of the final addc operation is returned.

Note: Since it is only possible to access 256 bytes in the frame window, the last two arguments to the checksum operator must be less than or equal to 256.

Example

Suppose we have the following frame and the custom protocol header begins at offset 0xE (where 4500 appears):

```
FFFF FFFF FFFF 0CCB CC0D DDDD 0800 4500 002E 0000 4000 402F
2AA2 1000 0000 FFFE 0001 0308 0900 0000 0000 0000 0000 0000
0000 0000 0000 0000 0000 0000 DA95 36D6 6F15 778C
```

The following IF conditions will always be true:

```
<after>
  <if expr="checksum(0x30A2,2,7+2)==0xDAFF">
    ...
  </if>

  <if expr="checksum(0,0,20)==0xFFFF">
    ...
  </if>
</after>
```

The first checksum operation above performs the following calculation:

```
0x30A2 + (0x002E add 0x0000 addc 0x4000 addc 0x402F addc 0x2A00)
```

The second checksum operation performs the following calculation:

```
0x0000 + (0x4500 addc 0x002E addc 0x0000 addc 0x4000 addc 0x402F addc 0x2AA2
            addc 0x1000 addc 0x0000 addc 0xFFFE addc 0x0001)
```

7.4.4.5.1.13.6.2.3 Expression Priorities

Expressions containing multiple operators perform the operation according to the following rules, in the order shown:

1. Operations in parentheses are performed
2. Operations that have a higher priority are performed
3. Multiple operations with the same priority are then executed from left to right

Note: Parentheses are recommended when several operators appear in the same expression to ensure correct calculation.

7.4.4.5.1.13.6.2.4 Operator Precendence

If several operators appear in the same expression (without separating parentheses), they are performed in the following order:

1. NOT, bitwise NOT, checksum
2. add, subtract, add carry
3. bitwise AND, bitwise OR, bitwise XOR
4. shift right, shift left, concat
5. greater than, greater equal, less than, less equal, equal, not equal
6. AND, OR

7.4.4.5.1.13.6.2.5 Variable Size

In most operations, expression size is limited to 64 bits. However, there are a few exceptions:

- When shifting variables, the shift value must be less than or equal to 64 bits since there are only 64 bits in an expression.
- The add carry operation can only be performed on 16-bit variables and always returns a 16-bit variable. The Soft Parser reports an error if an add carry operation is performed on a constant larger than 16 bits, but does not recognize a complex expression larger than 16 bits. Therefore, it is the responsibility of the user to perform the operation on 16-bit variables only.
- The subtract and add operators can only be performed on 32-bit variables and they always return a 32-bit result. If two 32-bit expressions are added and their result is larger than 32 bits, only the carry is returned, such that the returned value is a 32-bit variable. The Soft Parser reports a warning if an add carry operation is performed on a constant larger than 32 bits, but does not recognize a complex expression larger than 32 bits. Therefore, it is the responsibility of the user to perform the operation on 32-bit variables only.

For example, the following IF expressions are always true:

- ```
  <if expr="0xFFFFFFFF+2==0x1">
  ```
- ```
  <if expr="0x123456781+3==0x123456784">
  ```

The following IF expression is false (and should not be used):

- ```
  <if expr="3+0x123456781==0x123456784">
  ```

7.4.4.5.1.13.6.3 Expression Types

There are two main types of expressions: Logical expressions, which return "true" or "false", and arithmetic expressions, which return a numeric result.

7.4.4.5.1.13.6.3.1 Logical Expressions

Logical expressions appear in the 'expr' attribute of the 'if' element.

These expressions always return "true" or "false" and, therefore, must use at least one logical operator that separates arithmetic and logical operators.

Examples

The following expressions are logical expressions:

- ```
  (4+1==$shimoffset_1 or 5!=$shimoffset_2)
  ```
- ```
  not($shimoffset_2 ge $shimoffset_1 or $shimoffset_1 lt $shimoffset_2)
  ```

The following expressions are NOT logical expressions:

- ```
  (7 gt 3 and 2+7)
  ```
- ```
  (5 lt 8 or 7)
  ```

7.4.4.5.1.13.6.3.2 Arithmetic Expressions

Arithmetic expressions always have a numeric result. They can hold a single operand (a number, variable, or arithmetic expression) or more than one operand separated by arithmetic operators. Logical operators are not allowed in arithmetic expressions.

Arithmetic expressions can appear in the following places:

- The value attribute of the assign element
- The headersize attribute of the after element
- The expr attribute of the switch element

Examples

The following are arithmetic expressions:

- ```
  ($FW[0:16]+4)
  ```
- ```
  ($shimoffset_1 concat 3)
  ```
- ```
  (3+7+8+$shimoffset_2)
  ```
- ```
  4
  ```

The following is NOT an arithmetic expression:

- ```
  4==$shimoffset_2
  ```

7.4.4.5.1.13.7 Tips and Recommendations

7.4.4.5.1.13.7.1 Result Array Fields that Must be Manually Updated

The FMC Tool lets you define custom protocol headers, and the Soft Parser parses these headers. However, the Soft Parser does not update header fields for you (other than advancing the frame window and updating the line-up confirm vector (LCV) with the previous protocol). (See The before Element on page 799, The after Element on page 799, and The action Element (for use in a Custom Protocol file) on page 803 topics for more information.)

Therefore, some result array fields are left empty unless you manually update them. These fields might be needed in later stages in order for the Soft Parser to correctly interpret the custom protocol header. A list of result array fields that should be updated appears in the Frame Manager Parser section of the *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual*. These fields include $Classificationplanid, $nxtHdr, $Runningsum, HXS offsets, Last E Type Offset, and $nxtHdrOffset. Note that the HXS offsets, $nxtHdr, and $nxtHdrOffset fields are also used internally by the Soft Parser; therefore, these fields should be modified carefully.

The $nxtHdr fields should be modified only if the custom protocol does not jump to 'after_ip' or 'after_ethernet', or if you want to change the next protocol when jumping to 'after_ip' or 'after_ethernet'. You should only modify the HXS offsets and next header offsets in the 'after' element or in the 'before' element if the parser exits without advancing the frame window.

Finally, the LCV should be manually updated when a custom protocol is being parsed. This can be done using the 'confirmcustom' attribute, which is available in the 'before', 'after', and 'action' elements.

7.4.4.5.1.13.7.2 Result Array Fields that Should Not be Modified

Some fields in the result array are for the Soft Parser's exclusive use and therefore should not be modified by the user. These fields are:

- $GPR1 is used to store temporary values in complex operations; therefore, you should not modify it.
- $nxtHdr is used to calculate the position of the next protocol header when the 'protocol' element's 'nextproto' attribute is set to 'next_ethernet' or 'next_ip'. Therefore, this variable should not be modified when 'nextproto' equals one of these values.
- $prevprotoOffset is used to advance the frame window between the 'before' and 'after' elements or when using the 'action' element with the 'advance' attribute in the 'before' element. Therefore, this variable should not be modified in the 'before' element unless the Soft Parser exits this element without advancing the frame window. In addition, $prevprotoOffset can equal these result array variables: $ethoffset, $greoffset, $ipoffset_n, $llcsnapoffset, minencapoffset, mplsoffset_n, pppoeoffset, l4offset, vlanoffset_n, and $nxtHdrOffset. As a result, these variable should also not be modified by code in the 'before' element.
- $nxtHdrOffset is used to advance the frame window between the 'before' and 'after' elements or when using the 'action' element with the 'advance' attribute in the 'before' element. Therefore, this variable should not be modified in the 'before' element unless the Soft Parser exits this element without advancing the frame window.

7.4.4.5.1.13.7.3 Setting the Next Protocol

The Soft Parser can be used to add code for an existing protocol or to define an entirely new protocol. When it is used as an extension for an existing protocol and no new frame headers are being parsed, the 'nextproto' attribute of the 'action' element should be set to 'return'. In this case, the nextproto attribute can also be left empty since 'return' is the default value. If 'return' is set, the Soft Parser will execute its code and then the Hard Parser will continue parsing at the same position in the frame header at which it stopped.

When the Soft Parser is used for a custom protocol with its own header, the Hard Parser must skip this header (since it does not know how to parse it) and, therefore, the next protocol must be set to a specific protocol. If the next protocol is unknown, the 'nextproto' attribute in the 'action' element can be set to 'after_ip' or 'after_ethernet'. In these cases, the next protocol header is determined using the value of the $nxtHdr field.

Example

1. If we want to execute the Soft Parser because when we parse the Ethernet protocol, our code will likely include an action similar to the action below, which will appear in the 'before' element.

```
<action type="exit" advance="no" next="return">
```

2. If we want to add a custom protocol after Ethernet and then jump to IPv6, our code will likely include an action similar to the action below, which will appear in the 'after' element...

```
<action type="exit" advance="yes" next="ipv6">
```

3. If we want to add a custom protocol after the Ethernet header, and we do not know where to jump next, our code will likely include an action similar to the action shown below, which will appear in the 'after' element. In this case when "after_ethernet" is used as next protocol, $nxtHdr variable but be dynamically assigned accordingly from custom protocol header by using next protocol and field names as value.

```
<assign-variable name="$nxtHdr" value="protocol.field"/>
<action type="exit" advance="yes" next="after_ethernet">
```

7.4.4.5.1.13.8 Limitations

This section discusses limitations you should consider when working with the FMC Tool's Soft Parser functionality.

7.4.4.5.1.13.8.1 Complex Expressions

Some expressions contain so many operations and parentheses that they are too complicated for the Soft Parser. If you receive an error stating that an expression is too complex, it may be necessary to simplify the expression by splitting it into multiple, smaller expressions, using parentheses, or storing temporary values in the result array variables.

Note: $GPR1 is recommended for storing temporary variables. Do not use $GPR2 for temporary variables because it is used internally by the tool).

Note that the checksum operation expressions can easily become too complex and must be simplified.

7.4.4.5.1.14 NetPCD Reference

7.4.4.5.1.14.1 The netpcd element

The 'netpcd' element is the root element of a NetPCD document (also known as a policy file). As a result, the 'netpcd' element must appear before any other NetPCD element.

7.4.4.5.1.14.1.1 netpcd Attribute Definitions

Table 141. netpcd Attribute Definitions

Attribute	Requirement	Description
name	optional	Free text. Use to describe the name and the purpose of the Policy file.
version="1.0"	optional	Version of the NetPCD DTD or XML schema. Currently there is only one version - "1.0," which is the default.
creator	optional	Author's name
date	optional	Date the document was created

7.4.4.5.1.14.1.2 netpcd Example

```
<?xml version="1.0"?>
<netpcd version="1.0" name="Example" creator="Serge Lamikhov">
```

```
  <!-- Other NetPCD elements like 'policy', 'distribution', etc -->
  <policy name="ipv4">
    <dist_order>
      <distributionref name="eth_dist"/>
      <distributionref name="default_dist"/>
    </dist_order>
  </policy>
</netpcd>
```

7.4.4.5.1.14.2 The policy element

The 'policy' element defines a prioritized list of distributions.

A policy element is assigned (via its name attribute) to a port or ports using markup in the Configuration file. Thus, the 'policy' element is the means by which specific PCD rules defined in the Policy file are applied to traffic arriving on particular FMan ports.

Upon receipt of a frame on given port, the Hard Parser tries to match this frame to the distribution listed first in the policy assigned to this port. If the frame matches, this distribution handles the frame. If the frame does not match, the Hard Parser next tries to match the frame to the second distribution in the policy list. This process continues until a distribution in the list matches or no more distributions are left in the policy element's list, in which case, the frame is placed on the FMan's default receive queue.

7.4.4.5.1.14.2.1 policy Attribute Definitions

Table 142. policy Attribute Definitions

Attribute	Requirement	Description
name	required	Name of the policy. A port definition in the Configuration file references this name, thereby applying this policy to all frames arriving on this port.

7.4.4.5.1.14.2.2 policy Example

```
Policy File

<policy name="ipv4"> <!-- policy name is ipv4 -->
  <dist_order>
    <distributionref name="eth_dist"/>
    <distributionref name="default_dist"/>
  </dist_order>
</policy>

Configuration File

<cfgdata>
  <config>
    <engine="fm0">
      <port type="MAC" number="1" policy="ipv4"/> <!-- policy name ipv4 goes here -->
    </engine>
  </config>
</cfgdata>
```

7.4.4.5.1.14.3 The dist_order element

The 'dist_order' element is a container for a list of distribution references.

The Hard Parser chooses a particular distribution in this list at the moment when the protocol set made from the protocols participating in a distribution is a subset of the protocols found in the current network packet.

The distribution reference list contained within 'dist_order' element is processing sequentially, and the first conforming distribution is the distribution that is used. Thus, the order of distribution references is important.

7.4.4.5.1.14.3.1 dist_order Attribute Definitions

Table 143. dist_order Attribute Definitions

Attribute	Requirement	Description
none	n/a	n/a

7.4.4.5.1.14.3.2 dist_order Example

```
<policy name="ipv4">
  <dist_order>
    <distributionref name="tcp_dist"/>
    <distributionref name="udp_dist"/>
    <distributionref name="ethernet_dist"/>
    <distributionref name="default_dist"/>
  </dist_order>
</policy>
```

Note: In this example, putting "ethernet_dist" (which is supposed to process network traffic other than TCP and UDP) above "tcp_dist" will lead to all traffic be distributed according to "ethernet_dist" rule and no packets will reach "tcp_dist" or "udp_dist" rules. This is because the Ethernet protocol is a part of TCP and UDP frames as well.

7.4.4.5.1.14.4 The distributionref element

The 'distributionref' element references a 'distribution' element by its name.

The 'dist_order' element contains one or more 'distributionref' elements, thereby defining a prioritized list of distributions.

7.4.4.5.1.14.4.1 distributionref Attribute Definitions

Table 144. distributionref Attribute Definitions

Attribute	Requirement	Description
name	required	Name of the referenced 'distribution' element

7.4.4.5.1.14.4.2 distributionref Example

```
<policy name="ipv4">
  <dist_order>
    <distributionref name="eth_dist"/>
    <distributionref name="default_dist"/>
  </dist_order>
</policy>
```

7.4.4.5.1.14.5 The distribution element

The 'distribution' element is a container for child elements that define frame match rules and frame handling rules.

Frame match rules determine whether the current frame matches (and is therefore handled by) this distribution. Frame handling rules define what action is performed on matching frames.

Use the 'protocols' element and/or the 'key' element to define frame match rules.

Use the 'action', 'key', 'queue', and 'combine' elements to define frame handling rules.

An 'action' element within a the distribution passes the frame to the specified Policy file element for further processing

The 'key', 'queue' and (optional) 'combine' elements within a distribution together provide inputs to a hash algorithm that distributes frames evenly over a range of frame queues. The 'key' element defines the protocol header fields to use as the hash key, the 'queue' element defines the base value and number of FQIDs in the frame queue range, and the optional 'combine' elements give you fine control over the exact FQIDs that the algorithm generates.

Note: You can use an 'action' element in the hash scenario described above to pass the frame to a policer profile, which may abort the enqueue operation and drop the frame if traffic conditions warrant. In the absence of an 'action' element, frame processing concludes (and the frame leaves the FMan) at the end of the 'distribution' element.

A distribution's frame queue ID calculation is performed as follows:

- A hash key is formed by extracting and concatenating the protocol header fields specified by the 'key' element.
- The result value is hashed to a 64-bit CRC.
- The number of least significant bits is taken based on the 'count' attribute of the 'queue' element.
- The resulting value is ORed with the data retrieved according to the 'combine' elements.
- The resulting value is ORed with the 'base' attribute value of the 'queue' element.

All child elements are optional. Appropriate hardware dependent default values are used in cases where a child element does not exist in the 'distribution' definition.

7.4.4.5.1.14.5.1 distribution Attribute Definitions

Table 145. distribution Attribute Definitions

Attribute	Requirement	Description
name	required	Name of the distribution. Any references to a distribution are made using to this name.
description	optional	Free text describing the element purpose.
comment	optional	Free text providing any other information.

7.4.4.5.1.14.5.2 distribution Example

```
<distribution name="eth_dist" description="Ethernet protocol based distribution">
  <queue count="0x400" base="0x810000"/>
  <key>
    <fieldref name="ethernet.src"/>
    <fieldref name="ethernet.dst"/>
  </key>
  <combine portid="true" offset="10" mask="0xFF"/>
  <combine frame="112" offset="2" size="16" mask="0xFF"/>
  <action type="classification" name="eth_dest_clsf"/>
</distribution>
```

7.4.4.5.1.14.5.3 Default Groups

XML 'defaults' element is a container for parameters necessary for configuration of the default groups and private default registers. The element, if it exists, can be used as a child of element 'distribution'. This element contains a list of ‘default’ elements.

Table 146. 'default' Elements Attributes:

Attribute	Requirement	Description
private0	optional	The scheme default register 0.
private1	optional	The scheme default register 1.

Element 'default' attributes. This element can appear as a child to the element 'defaults':

Table 147. 'default' Element Attributes:

Attribute	Requirement	Description
type	required	Default type select. Possible values are: 1. "from_data” – any data extraction that is not one of the full fields that can be used as type. 2. "from_data_no_v” – any data extraction without validation. 3. "not_from_data” – extraction from parser result or direct use of default value. 4. "mac_addr” – MAC Address. 5. "tci” – TCI field. 6. "enet_type” – ENET Type. 7. "ppp_session_id” – PPP Session id. 8. "ppp_protocol_id” – PPP Protocol id. 9. "mpls_label” – MPLS Label. 10. "ip_addr” – IP Addr. 11. "protocol_type” – Protocol type. 12. "ip_tos_tc” – TOC or TC. 13. "ipv6_flow_label” – IPV6 flow label. 14. "ipsec_spi” – IPSEC SPI. 15. "l4_port” – L4 Port. 16. "tcp_flag” – TCP Flag
select	required	Default register select. Possible values are: 1. "gbl0” – Default selection is KG register 0. 2. "gbl1” – Default selection is KG register 1. 3. "private0” – Default selection is a per scheme register 0. 4. "private1” – Default selection is a per scheme register 1

Here is an example of possible default groups and nonheader definition:

```
<distribution name="Distribution1">
        <queue base="1" count="8"/>
        <key>
                <fieldref name="ipv4.src"/>
                <fieldref name="ipv4.dst"/>
                <fieldref name="ipv4.nextp"/>
                <nonheader source="default" offset="0" size="4"/>
        </key>
        <defaults private0="0xAAAAAAAA">
                <default type="from_data" select="private0"/>
                <default type="from_data_no_v" select="private0"/>
                <default type="not_from_data" select="private0"/>
        </defaults>
        <action type="drop"/>
</distribution>
```

7.4.4.5.1.14.6 The key element

The 'key' element contains a list of 'fieldref' elements. The 'filedref' elements define the protocol header fields whose values are concatenated to form a hash key. The Key Gen sub block hashes this key and uses a portion of the result in its frame queue ID (FQID) calculation.

7.4.4.5.1.14.6.1 key Attribute Definitions

Table 148. key Attribute Definitions

Attribute	Requirement	Description
shift	optional	Defines the amount by which the concatenation of the fields in the 'key' element are right shifted. The default value is zero. **Note:** The 'shift' attribute is ignored if the 'key' elements appears within a 'classification' element.
symmetric	optional	Generate the same hash for frames with swapped source and destination fields on all layers. If source is selected, destination must also be selected, and vice versa.

7.4.4.5.1.14.6.2 key Example

```
<key shift="16">
  <fieldref name="ethernet.src"/>
  <fieldref name="ethernet.dst"/>
</key>
```

7.4.4.5.1.14.7 The fieldref element

The 'fieldref' element refers to a protocol header field by its name.

The Standard Protocol file contains the names of the available protocols and their fields. This file is named hxs_pdl_v3.xml and is in the directory /etc/fmc/config/.

7.4.4.5.1.14.7.1 fieldref Attribute Definitions

Table 149. fieldref Attribute Definitions

Attribute	Requirement	Description
name	required	The referenced field name. The field's name should be provided in the form of "protocolname.fieldname".

7.4.4.5.1.14.7.2 fieldref Example

```
<key>
  <fieldref name="ethernet.src"/>
  <fieldref name="ethernet.dst"/>
</key>
```

7.4.4.5.1.14.8 The queue element

The 'queue' element defines the number of queues (default is one) and the base value for the FQIDs for these queues.

When used within a 'distribution' element, the 'queue' element defines a range of queues over which to evenly distribute frames.

When used within other elements, such as a 'classification' element, the 'queue' element defines the single queue on which to place a frame.

7.4.4.5.1.14.8.1 queue Attribute Definitions

Table 150. queue Attribute Definitions

Attribute	Requirement	Description
base	required	The base frame queue ID value.
count	optional	This attribute is only relevant only when a 'queue' element appears within a 'distribution' element. In this case, the 'count' attribute defines the number of frame queues over which to distribute frames. Valid values for 'count' are powers of 2. The default value is 1.

7.4.4.5.1.14.8.2 queue Example

```
<distribution name="eth_dist">
  <queue count="0x400" base="0x810000"/>
  <key>
    <fieldref name="ethernet.src"/>
    <fieldref name="ethernet.dst"/>
  </key>
</distribution>
```

7.4.4.5.1.14.9 The protocols and protocolref elements

The 'protocols' and 'protocolref' elements are used together to extend a 'distribution' element's frame match conditions.

As explained in the 'dist_order' description, a distribution is chosen based on the set of protocols specified in its 'key' element. The 'protocols' and 'protocolref' elements let you extend this set of protocols beyond those listed in the 'key' element.

7.4.4.5.1.14.9.1 protocols and protocolref Attribute Definitions

Table 151. protocols and protocolref Attribute Definitions

Attribute	Requirement	Description
name	required	The name of the protocol.
opt	optional	Applicable only for protocolref attribute Use it in a scheme for detecting protocols with the chosen options (e.g. to detect ETHERNET with BROADCAST or MULTICAST option) Table 2 contains all possible values. The values are grouped, each group being separated by a blank row. Values from different groups can be ORed

Table 152. Protocol options. Groups are separated by empty rows.

Value	Description
0x80000000	Ethernet Broadcast
0x40000000	Ethernet Multicast
0x20000000	Stacked VLAN
0x10000000	Stacked MPLS
0x08000000	IPv4 Broadcast
0x04000000	IPv4 Multicast
0x02000000	Tunneled IPv4 - Unicast
0x01000000	Tunneled IPv4 - Broadcast/Multicast
0x00000008	IPV4 reassembly option. When using this option, the IPV4 Reassembly manipulation requires network environment with IPV4 header
0x00800000	IPv6 Multicast

Table continues on the next page...

Table 152. Protocol options. Groups are separated by empty rows. (continued)

Value	Description
0x00400000	Tunneled IPv6 - Unicast
0x00200000	Tunneled IPv6 - Multicast
0x00000004	IPV6 reassembly option. When using this option, the IPV6 Reassembly manipulation requires network environment with IPV6 header.In case where fragment found, the fragment-extension offset may be found at 'shim2' (in parser-result).
0x00000008	CAPWAP reassembly option. When using this option, the CAPWAP Reassembly manipulation requires network environment with CAPWAP header. In case where fragment found, the fragment-extension offset may be found at 'shim2' (in parser-result).

7.4.4.5.1.14.9.2 protocols and protocolref Example

```
<!-- The example demonstrates the case in which -->
<!-- frame queue ID calculation is done using Ethernet header fields, -->
<!-- but the condition for matching a frame to this distribution is -->
<!-- extended by also requiring the presence of a UDP protocol header -->
<distribution name="eth_dist">
  <protocols>
    <protocolref name="udp" opt="0x00000008"/>
  </protocols>

  <queue count="0x400" base="0x810000"/>
  <key>
    <fieldref name="ethernet.src"/>
    <fieldref name="ethernet.dst"/>
  </key>
</distribution>
```

7.4.4.5.1.14.10 The combine element

The 'combine' element (like the 'key' element) is used in a 'distribution' element's frame queue ID calculation. The value built by the 'key' element is hashed, but the value of the 'combine' element is directly bitwised OR'd with the previous 24-bit FQID result.

A single 'combine' element identifies just one byte to retrieve and OR. To work around this limitation, you can have multiple 'combine' elements in a 'distribution' element.

7.4.4.5.1.14.10.1 combine Attribute Definitions

Table 153. combine Attribute Definitions

Attribute	Requirement	Description
portid	required *(in absence of frame attribute)*	Valid values: true or false If true, this attribute indicates that the logical port ID byte specified in the Configuration file should be retrieved and used in the bitwise OR part of a distribution's FQID calculation. *Note that portid and frame are mutually exclusive attributes.*
frame	required *(in absence of portid attribute)*	Valid values: numeric string This attribute identifies the byte with the frame header to extract and use in the bitwise OR part of the FQID calculation. The attribute's value indicates the bit offset from the beginning of the frame. The specified value must be divisible by 8, so it references the first bit of a byte. *Note that portid and frame are mutually exclusive attributes.*
offset	optional	This attribute controls the placement of the extracted data in the result Frame Queue ID. The offset starts at the FQID's most significant bit.
mask	optional	This attribute defines valid bits in the retrieved value. The extracted value is bitwise ANDed with the mask prior to being ORed with the previous Frame Queue ID value.

7.4.4.5.1.14.10.2 combine Example

```
<distribution name="eth_dist">
  <queue count="0x400" base="0x810000"/>
  <key>
    <fieldref name="ethernet.src"/>
    <fieldref name="ethernet.dst"/>
  </key>
  <combine portid="true" offset="10" mask="0xFF"/>
  <combine frame="64" offset="2" mask="0xFF"/>
  <action type="classification" name="eth_dest_clsf"/>
</distribution>
```

7.4.4.5.1.14.11 The action element (for use in a policy file)

The 'action' element permits you to establish a topological parse, classify, police, distribute configuration by defining the next processing element within a distribution, classification, or policer profile.

If there is no 'action' element within a distribution, classification, or policer profile, the default behavior is the completion of PCD frame processing, allowing the frame to leave the Frame Manager. Some hardware restrictions apply in the choice of the next processing element.

7.4.4.5.1.14.11.1 action Attribute Definitions

Table 154. action Attribute Definitions

Attribute	Requirement	Description
type	required	The type of the 'action' element defines the next processing element. Valid values are: • "distribution" • "classification" • "policer" • "drop" (Permitted only when the 'action' element is inside a 'policer' element.)
name	required	The name of the element of the type defined in the 'type' attribute. This attribute is not relevant if type is "drop".
condition	required *(when used within a 'policer' element)* optional *(when used within a 'distribution' or 'classification' element)*	This attribute defines the condition under which the 'action' is to be taken. This attribute is only relevant when used inside a 'policer' or a 'classification' element. Valid values are: • "on-green" • "on-yellow" • "on-red" • "on-miss"

7.4.4.5.1.14.11.2 Statistics

Attribute 'statistics' for action element of the classification and classification entries. This tells if statistics are made on that entry or on the on-miss.

Table 155. 'statistics' Element Attributes:

Attribute	Requirement	Description
statistics	optional	Enable statistics for a particular action. Possible values are: • enable/yes/true – to enable it. • disable

7.4.4.5.1.14.11.3 action Example

```
<distribution name="special_dist">
  <queue count="1" base="0xABCD"/>
  <action type="policer" name="policer2"/>
</distribution>

<policer name="policer2">
  <algorithm>rfc2698</algorithm>
  <color_mode>color_aware</color_mode>
  <CIR>1000000</CIR>
  <EIR>1400000</EIR>
  <CBS>1000000</CBS>
```

```
  <EBS>1400000</EBS>
  <unit>packet</unit>
  <action condition="on-green" type="distribution" name="special2_dist"/>
  <action condition="on-yellow" type="drop"/>
  <action condition="on-red" type="drop"/>
</policer>
```

7.4.4.5.1.14.12 The classification element

The 'classification' element allows exact match frame processing.

A classification starts with a 'classification' element, which is a container for these child elements:

- A 'key' element that defines the header fields (in protocol.field form) to use in the exact match operation
- One or more 'entry' elements, each of which defines a value to which the specified fields are compared and a 'queue' and/or 'action' element that defines what to do with the frame upon a match
- An optional 'action' element that defines the default action to take if none of the exact match conditions is met

7.4.4.5.1.14.12.1 classification Attribute Definitions

Table 156. classification Attribute Definitions

Attribute	Requirement	Description
name	required	The name of the classification

7.4.4.5.1.14.12.2 classification Statistics

The statistics are enabled on the Classification element. The parameters to setup the statistics are: - the attribute **statistics** of the element **classification**, the attribute **statistics** of the actions on entries/on-miss and the element **framelength** with attributes **index** and **value**.

Attribute ‘statistics’ for classification – this specifies the type of statistic used in the entire classification

Table 157. 'statistics' Element Attributes:

Attribute	Requirement	Description
statistics	optional	Choose statistic mode for the particular entry. Possible values are: • none • frame • byteframe • rmon

7.4.4.5.1.14.12.3 classification Example

```
<classification name="eth_dest_clsf">
  <key>
    <fieldref name="ethernet.dst"/>
  </key>

  <entry>
    <data>0x1234567890AB1234567890AB</data>
```

```
    <queue base="0x550000"/>
  </entry>

  <entry>
    <data>0xFFFFFFFFFFFFFFFFFFFFFFFF</data>
    <action type="classification" name="eth_dest_2_clsf"/>
  </entry>

  <action condition="on-miss" type="distribution" name="default_dist"/>
</classification>
```

7.4.4.5.1.14.12.4 Frame Replicators

The element **replicator** is implemented in FMC as a standalone entity.

This element can follow a Classification in the flow, as a target for one of the actions of the entries or on the on-miss. It is similar to Classification but it has no data/mask in entries, on-miss action and key element.

Table 158. 'fragmentation' Element Attributes:

Attribute	Requirement	Description
name	required	Name of the element. The name is used to refer the frame replicator.
max	optional	The maximum number of entries the frame replicator can have (default and minimum is 2). If the value entered is smaller than 2 or the attribute is not set, the value is set to 2.

The element **entry** has the same syntax as the element **classification**, but the data and mask are not needed and thus are ignored. The action targets of the entry are restricted to:

- policer
- enqueue
- direct distribution

replicator example:

```
  <replicator name="frep_1" max="32">
       <entry>
           <action type="policer" name="policer_1"/>
       </entry>
       <entry>
           <queue base="0x0"/>
           <action type="distribution" name="dist_1"/>
       </entry>
       <entry>
           <queue base="0x220"/>
           <vsp name=”vsp01”>
       </entry>
       <entry>
           <queue base="0x240"/>
           <vsp base=”2”>
       </entry>
  </replicator>
```

Using the frame replicator in an action:

```
   <classification name="class_1" max="0" masks="yes">
        <key>
           <fieldref name="ethernet.type"/>
        </key>
        <entry>
           <data>0x8870</data>
           <queue base="0x01"/>
           <action type="replicator" name="frep_1"/>
        </entry>
        <action condition="on-miss" type="replicator" name="frep_1"/>
   </classification>
```

7.4.4.5.1.14.12.5 framelength Statistics

Element **framelength** attributes (there can be up to 10 values set, in ascending order and last one must be `0xFFFF`). The element **framelength** is valid only for RMON statistics.

Table 159. 'framelength' Element Attributes:

Attribute	Requirement	Description
statistics	required	The index for the frame length value specified. Possible values are from 0 to 9.
value	required	The value to be added at the specified index. Maximum value is `0xFFFF` and must be added at index 9. (FMC sets it initially by default).

7.4.4.5.1.14.12.6 Statistics Example

Statistics Example

```
<!-- Coarse classification -->
    <classification name="classif_1" max="32" masks="yes" statistics="rmon">
        <!-- Key value to be extracted from the packet -->
        <key>
            <fieldref name="ipv4.dst"/>
        </key>

        <framelength index="0" value="0x1100"/>
        <framelength index="1" value="0x1200"/>
        <framelength index="2" value="0x1300"/>
        <framelength index="3" value="0x1400"/>
        <framelength index="4" value="0x1500"/>
        <framelength index="5" value="0x1600"/>
        <framelength index="6" value="0x1700"/>
        <framelength index="7" value="0x1800"/>
        <framelength index="8" value="0x1900"/>
        <framelength index="9" value="0xFFFF"/>

        <!-- Entries in the lookup table -->
        <entry>
            <!-- 192.168.10.10 -->
            <data>0xC0A80A0A</data>
            <queue base="0x1010"/>
```

```
            <action statistics="enable"/>
        </entry>
    </classification>
```

7.4.4.5.1.14.12.7 Coarse Classification Resource Reservation

FMD API changes allow pre-allocation of MURAM memory for classification tables. This will be reflected in NetPCD XML syntax extension by introducing attibutes **max** and **masks** of the element **classification** as shown in the example below. In addition, to allow proper order of PCD elements initialization, and for the condition that not all **entry** elements are known at initialization time, the XML element **may-use** is introduced:

```
    <!-- Coarse classification -->
    <classification name="classif_1" max="32" masks="yes" statistics="mode">
        <!-- Key value to be extracted from the packet -->
        <key>
            <fieldref name="ipv4.dst"/>
        </key>

        <may-use>
            <action type="classification" name="fman_test_classif_1"/>
            <action type="distribution"   name="default_dist"/>
        </may-use>

        <!-- Entries in the lookup table -->
        <entry>
            <!-- 192.168.10.10 -->
            <data>0xC0A80A0A</data>
            <queue base="0x1010"/>
        </entry>
    </classification>
```

Resource Allocation Attributes:

Table 160. Resource Reservation Attributes:

Attribute	Requirement	Description
max	optional	If it exists, this parameter defines the maximum number of coarse classification entries allocated for this PCD element. **NOTE** The element **classification** may still contain pre-initialized entries, or, alternatively, be empty. **NOTE** For the case of empty or partially initialized element **classification**, usage of the element **may-use** might be required .
masks	optional	If provided, indicates that MURAM allocation should be done with the assumption that additional memory is required for an elements' masks. Possible values are: • no – don't allocate memory for masks (default) • yes – allocate memory for masks.

'may-use Element Description:

Table 161. 'may-use' Element Attributes:

Attribute	Requirement	Description
may-use	optional	Contains list of ‘action’ elements that may appear in the ‘classification’ entries or, be applied dynamically after partial initial configuration. **NOTE** Attention: the use of this element is required if initial ‘classification’ is empty and dynamic entries, added through FMD API, use those PCD entities

7.4.4.5.1.14.13 The entry element

The 'entry' element defines:

- the value to use in an exact match comparison with the fields specified by the 'key' element in a classification
- the action to be taken upon a match

An 'entry' element contains a 'data' element which, in turn, contains a numeric value written in hexadecimal form (that is, with a "0x" prefix). The data length of this value is determined by length of the set of 'key' fields.

In addition to the 'data' element, each 'entry' element may also contain these elements:

- queue - causes the frame to be placed on the specified queue
- action - passes the frame to the specified element within the Policy file for further processing.
- mask - a value in hexadecimal format that is applied to the data element

7.4.4.5.1.14.13.1 entry Attribute Definitions

Table 162. entry Attribute Definitions

Attribute	Requirement	Description
none	n/a	n/a

7.4.4.5.1.14.13.2 entry Example

```
<classification name="eth_dest_clsf">
  <key>
    <fieldref name="ethernet.dst"/>
  </key>

  <entry>
    <data>0x1234567890AB1234567890AB</data>
    <queue base="0x550000"/>
  </entry>
</classification>
```

7.4.4.5.1.14.14 The policer element

The 'policer' element is a container whose child elements define a policer profile that performs network bandwidth management.

7.4.4.5.1.14.14.1 policer Attribute Definitions

Table 163. policer Attribute Definitions

Attribute	Requirement	Description
name	required	Name of the policer profile.
algorithm	required	Algorithm used for policing. Valid values: "rfc2698", "rfc4115", pass_through".
color_mode	required	Color mode used for policing. Valid values: "color_aware", "color_blind".
default_color	optional	Use when algorithm is "pass_through" and color_mode is "color_blind". In this mode, the policer re-colors incoming packets with the specified default color. Valid values: "red", "yellow", "green", or "override". If the value is override, the next invoked action is that specified for "green". The default value is "green".
unit	required	The unit to be used for numeric parameters. Valid values: "packet", "byte".
CIR	required	Committed information rate[12]
PIR	required	Peak (or excess) information rate[12]
CBS	required	Committed burst size[13]
PBS	required	Peak (or excess) burst size[13]

7.4.4.5.1.14.14.2 policer Example

```
<policer name="policer2">
  <algorithm>rfc2698</algorithm>
  <color_mode>color_aware</color_mode>
  <CIR>1000000</CIR>
  <EIR>1400000</EIR>
  <CBS>1000000</CBS>
  <EBS>1400000</EBS>
  <unit>packet</unit>
  <action condition="on-green" type="distribution" name="default_dist"/>
  <action condition="on-yellow" type="distribution" name="special2_dist"/>
  <action condition="on-red" type="drop"/>
</policer>
```

7.4.4.5.1.14.15 The nonheader element

Use the 'nonheader' element within a 'key' element to select a non-header extraction source.

Note: The 'nonheader' element can appear within a 'classification' element only. Further, the 'nonheader' element cannot be used at the same time as the 'fieldref' element.

7.4.4.5.1.14.15.1 nonheader Attribute Definitions

[12] If "unit" attribute is "packet" specify CIR and PIR in packets/second. If "unit" attribute is "byte" specify CIR and PIR in Kbits/second.
[13] If "unit" attribute is "packet" specify CBS and PBS in packets. If "unit" attribute is "byte" specify CBS and PBS in bytes.

Table 164. nonheader Attribute Definitions

Attribute	Requirement	Description
source	required	Non-header extraction source Valid values are: • "frame_start" - Extract from beginning of frame. • "key" - Extract from key value built by ‘distribution’ at preceding step (CC only). • "hash" - Extract from hash value built by ‘distribution’ at preceding step (CC only). • "parser" - Extract from parse result array. • "fqid" - Use enqueue FQID as the key value. • "flowid" - Use dequeue FQID as the key value (CC only) • "default" - Extract from a default value (distribution only). • "endofparse" - Extract from the point where parsing had finished (distribution only).
action	Required if source is "hash", "flowid" or "key". In other cases, this attribute must not be used.	The type of action for the extraction Valid values are: • "indexed_lookup" (permitted only for "hash" and "flowid" sources). The extracted value is interpreted as an entry index of classification table • "exact_match" (permitted only for "key" and "hash" sources). The extracted value is compared with ‘key’ value of the entry.
offset	required	Byte offset. Offset of key from start of frame, internal frame context or parse result array. Refer “Table 8-398. Table Descriptor (Type = 01)” of DPAA Reference Manual for full description and possible values
size	required	Size of the key in bytes.
ic_index_mask	Optional (Valid only if action is "indexed_lookup")	Internal context index mask. For the full description and possible values, refer “Table 8-399. Operation Code Description” of DPAA Reference Manual

If the action is “indexed_lookup” and the source is “hash” special checks are done in the drivers on the configured entries and maximum nuber of entries according to the internal context index mask specified. FMC is adjusting automatically the configured entries if they don’t match the provided mask: if the entry must be initialized but the user didn’t supplied it a default one is created and if the entry must be uninitialized it’s deleted by FMC. Also FMC ajdusts the maxim number of entries if it’s not configured as 0.

7.4.4.5.1.14.15.2 nonheader Example

```
<classification name="ptp_condition_class">
  <key>
    <nonheader source="hash" action="indexed_lookup" offset="2" size="2" ic_index_mask="0x01b0">
```

```
  </key>

  <entry>
    <data>0x13F</data>
    <queue base="0x01"/>
  </entry>
</classification>
```

7.4.4.5.1.14.16 Hash Tables

The element 'hashtable' can be specified inside an element 'key' of a 'classification'. The element 'hashtable' cannot appear in the same time with either elements 'fieldref' or 'nonheader' in the same 'key'. If the element 'hashtable' is used, the 'classification' may have no entries as these are supposed to be filled at runtime.

Table 165. 'fragmentation' Element Attributes:

Attribute	Requirement	Description
mask	required	Mask that will be used on the hash-result; The number-of-sets for this hash will be calculated as (2^(number of bits set in 'mask ')); The 4 lower bits must be cleared.
hashshift	optional	Byte offset from the beginning of the KeyGen hash result to the 2-bytes to be used as hash index.(Default 0)
keysize	required	Size of the exact match keys held by the hash buckets.

Hash table example:

```
<classification name="classif_1" max="2" statistics="none">
        <key>
            <hashtable mask="0x30" hashshift="0" keysize="24"/>
        </key>
</classification>
```

7.4.4.5.1.14.17 Virtual Storage Profiles Element

The element 'vsp' (Virtual Storage Profile) is implemented in FMC as a standalone entity or can be defined directly in the element that uses it. The element 'vsp'can be used inside distributions, classification and entries (both classification and replicator). When used directly in the ‘classification’ element (not in ‘entry’) it counts for the on-miss action. If the 'action' of the 'entry' or on-miss goes to another 'classification' or 'replicator' the 'vsp' is ignored.

7.4.4.5.1.14.17.1 vsp Attributes

Table 166. 'vsp' Element Attributes:

Attribute	Requirement	Description
name	required	Name of the element. The name is used to refer the virtual storage profile inside the elements that are using it.

Table continues on the next page...

Table 166. 'vsp' Element Attributes: (continued)

Attribute	Requirement	Description
type	optional	The type of the VSP. Values: • direct – (default) the relative profile ID is selected directly by the 'base' attribute. • indirect – the relative profile ID is selected base on the attributes **fqshift, vspoffset**, and **vspcount** can be used only in **distribution.**
base	required for direct.	--
fqshift	required for indirect.	Shift of KeyGen results without the FQID base.
vspoffset	optional for indirect	OR of KeyGen results without the FQID base; should indicate the storage profile offset within the port's storage profiles window.
vspcount	optional for indirect	Range of profiles starting at base.

7.4.4.5.1.14.17.2 vsp Examples

VSP examples (standalone, defined in element, direct/indirect): The action targets of the entry are restricted to:

```
<vsp name = "storage01" base = "6"/>
<vsp name = "storage02" type = "indirect" fqshift="2" vspoffset="3"        vspcount="8"/>
<vsp name = "storage03" type = "direct" base = "7"/>

Usage:

...

<entry>
            <queue base="0x220"/>
            <vsp name=”storage01”>
</entry>

...

<distribution name="dist1">
     ...
     <queue count="8" base="0x230"/>
     <vsp type=”indirect” fqshift=”2” vspoffset=”0” vspcount=”4”/>
     ...
</distribution>

...

<classification name="eth_dest_clsf">
    <key>
         <fieldref name="ethernet.dst"/>
    </key>
...
    <vsp name=”storage03”>
    <action condition="on-miss" type="distribution" name="garbage"/>
</classification>
```

7.4.4.5.1.14.18 Manipulation Parameters

Frame Manager accelerator (FMan) attaches manipulation actions as an extension to ethernet port and coarse classification ‘next engine’ dispatch activity.

To reflect the frame data processing and manipulation capabilities of the hardware, which are propagated through Frame Manager Driver (FMD) API, Frame Manager Configuration (FMC) Tool extends the syntax of the NetPCD configuration language by introducing XML entities described in this document.

Manipulation entities are diverse in their purpose and configuration parameters sets. The same manipulation entity can be referred, or attached, from/to several port or classification actions. That is why they are separated from their usage into a separate group called **manipulations**. At the moment of use, an action refers to the corresponding manipulation entity. For example:

```
<netpcd>
    <manipulations>
        <reassembly name=”name1”>
            .....
        </reassembly>
        <reassembly name=”name2”>
            .....
        </reassembly>
        <fragmentation name=”defrag1”>
            .....
        </fragmentation>
    </manipulations>

    <classification name=”clsf1”>
        .....
        <!-- 192.168.30.30 -->
        <data>0xC0A81E1E</data>
        <fragmentation name=”defrag1”/>
        .....
    </classification>

</netpcd>
```

Formal Definition:

XML element **manipulation** is a container for all types of manipulation algorithms. Configuration for each algorithm has its own XML element name.

Currently three manipulations algorithms are available:

1. IP reassembly
2. IP fragmentation
3. header manipulation

Parameters for these entities are described next.

7.4.4.5.1.14.18.1 IP Fragmentation

XML element **fragmentation** is a container for parameters necessary for configuration of the corresponding action modification. The element, if exists, can be used as a child of element **classification**.

Attention: If element **fragmentation** is present together with other ‘action’ of ‘classification’ element, the element **fragmentation** is ignored. This is a subject of FMan firmware capabilities and may change in future.

Table 167. 'fragmentation' Element Attributes:

Attribute	Requirement	Description
name	required	Name of the element. The name is used to refer the manipulation algorithm.

Table 168. 'fragmentation' Child Elements:

Attribute	Requirement	Description
size	required	IP fragmentation will be executed for frames with length greater than this value.
dontFragAction	optional	If an IP packet is larger than MTU and its DF bit is set, then this field will determine the action to be taken. Possible values are: • discard - the packet (default action) • fragment – fragment the packet and continue normal processing • continue - continue normal processing without fragmenting the packet
scratchBpid	required for existing HW platforms, but not for 9164	Absolute buffer pool id according to BM configuration (DPAA 1.0 only)
sgBpid	optional	Scatter/Gather buffer pool id. If used sgBpidEn will be set to TRUE.
optionsCounterEn	optional	Enables the counter if the value is set to 'yes', 'true' or 'enable'. Disabled for other values. Default is disabled.

Here is an example of possible IP fragmentation definition:

```
<manipulations>
    <fragmentation name="frag1">
        <size>256</size>
        <dontFragAction>continue</dontFragAction>
    </fragmentation>
</manipulations>

<classification name="clsf1">
    .....
    <!-- 192.168.30.30 -->
    <data>0xC0A81E1E</data>
    <fragmentation name="frag1"/>
    .....
</classification>
```

7.4.4.5.1.14.18.2 IP Reassembly

XML element **reassembly** is a container for parameters necessary for configuration of the corresponding action modification. The element, if it exists, can be used as a child of the element **policy**.

Attention: Up to 2 additional KeyGen schemes will be constructed when using this manipulation action. Custom protocol **shim2** is reserved when element **reassembly** participates in a configuration.

Table 169. 'reassembly' Element Attributes:

Attribute	Requirement	Description
Name	required	Name of the element. The name is used to refer the manipulation algorithm

Table 170. 'reassembly' Child Elements:

Attribute	Requirement	Description
sgBpid	required	Absolute buffer pool id according to BM configuration for scatter-gather (DPAA 1.0 only)
maxInProcess	required	Number of frames which can be processed by reassembly at the same time. It has to be power of 2
dataLiodnOffset	optional	Offset of LIODN. Default value is 0
dataMemId	optional	Memory partition ID for data buffers
ipv4minFragSize	required	Minimum fragmentation size for IPv4
ipv6minFragSize	required	EMinimum fragmentation size for IPv6. The value must be equal or higher than 256
timeOutMode	optional	Expiration delay initialized by Reassembly process. Possible values are: • frame - limits the time of the reassembly process from the first fragment to the last (default) • fragment - limits the time of receiving the fragment
fqidForTimeOutFrames	required	FQID to assign for frames enqueued during Time Out Process.
numOfFramesPerHashEntry (numOfFramesPerHashEntry1)	required	Number of frames per hash entry needed for reassembly process – for ipv4. Possible values are: numeric values from 1 to 8.
numOfFramesPerHashEntry2	optional	Number of frames per hash entry needed for reassembly process – for ipv6. Possible values are: numeric values from 1 to 6.
timeoutThreshold	required	Represents the time interval in microseconds which defines if opened frame (at least one fragment was processed but not all the fragments)is found as too old
nonConsistentSpFqid	optional	Handles the case when other fragments of the frame corresponds to a different storage profile than the opening fragment. (DPAA >= 1.1 only). Default is 0

Here is an example of possible IP reassembly definition:

```
<manipulations>
    <reassembly name=”reasm1”>
        <sgBpid>2</sgBpid>
        <maxInProcess>1024</maxInProcess>
        <timeOutMode>fragment</timeOutMode>
        <fqidForTimeOutFrames>1024</fqidForTimeOutFrames>
```

```
        <numOfFramesPerHashEntry>8</numOfFramesPerHashEntry>
        <timeoutThreshold>1000000</timeoutThreshold>
        <ipv4minFragSize>0</ipv4minFragSize>
        <ipv6minFragSize>256</ipv6minFragSize>
    </reassembly>
</manipulations>

<policy name="udp_port">
   <dist_order>
       <distributionref name="custom_dist"/>
       <distributionref name="udp_port_dist"/>
       <distributionref name="default_dist"/>
   </dist_order>

   <reassembly name=”reasm1”/>
</policy>
```

7.4.4.5.1.14.18.3 Header Manipulation

XML element **header** is a container for parameters necessary for configuration of the corresponding action modification. The element, if it exists, can be used as parameter to the distribution action going to a classification or inside a classification element **entry**.

The XML element **header** may contain:

- **insert**
- **remove**
- **insert_header**
- **remove_header**
- **update**
- **custom**

Certain combinations between them are possible, for example you can have a **remove** and an **insert_header** in the same manipulation.

The header manipulation can be used inside the PCD by inserting an element **header** in the classification entry that specifies the name of the header manipulation defined in the section **manipulations**. This makes sense in a entry that goes to a policer, distribution or PCD done:

```
   <entry>
      <data>0x9100</data>
      <queue base="0x01"/>
      <action type="policer" name="plcr_01"/>
      <header name="upd_hdr"/>
   </entry>
```

Table 171. 'header' Element Attributes:

Attribute	Requirement	Description
name	required	Name of the element. The name is used to refer the manipulation algorithm
parse	optional	Activate the parser a second time after completing the manipulation of the frame (if ‘yes’)

Table continues on the next page...

Table 171. 'header' Element Attributes: (continued)

Attribute	Requirement	Description
duplicate	optional	Will duplicate the header manipulation with the same setting a the specified number of times. The names of the nodes will have “_x” added at the end where x is the index of the node. For example <header name=”upd_ipv4” duplicate=”3”> will create the nodes: upd_ipv4_1, upd_ipv4_2 and upd_ipv4_3. This is only a simple tool to duplicate a header manipulation, it does not allow defining chaining between the elements created by duplication.

7.4.4.5.1.14.18.3.1 Header Manipulation - Insert

XML element **insert** is a container for parameters necessary to configure a header insert manipulation operation. The element, if it exists, can be used as a child of element **header**. There can be only one element **insert** in a header manipulation.

Table 172. 'insert' Child Elements:

Element	Requirement	Description
size	required	Size of inserted section
offset	required	Offset from beginning of header to the start location of the insertion.
replace	optional	If provided, specifies to override (replace) existing data at 'offset' (if ‘yes’), ‘no’ to insert. Possible values: • no - insert (default) • yes - replace
data	required	Data to insert

7.4.4.5.1.14.18.3.2 Header Manipulation - Remove

XML element **remove** is a container for parameters necessary to configure a header remove manipulation operation. The element, if it exists can be used as a child of element **header**. There can only be one element **remove** in a header manipulation.

Table 173. 'remove' Child Elements:

Element	Requirement	Description
size	required	Size of removed section
offset	required	Offset from beginning of header to the start location of the removal.

7.4.4.5.1.14.18.3.3 Header Manipulation - Insert-Header

XML element **insert_header** is a container for parameters necessary to configure a header insert manipulation operation of an entire header (different than generic element **insert**). The element **insert_header** ,if it exists, can be used as a child of element **header**. With some restrictions, there can be more than one element **insert_header** in one header manipulation

Table 174. 'insert_header' Element Attributes

Element	Requirement	Description
type	required	The type of the header inserted. Only ‘mpls’ is valid at this time.
header_index	optional	The header index of the header has possible values "1" and "2". The restrictions on this attribute are: • if the value is ‘2’ an ‘insert_header’ with ‘header_index’ 1 must be present in the header manipulation. • a value of **header_index** can be used only once per header manipulation

Table 175. 'insert_header' Child Elements

Element	Requirement	Description
data	optional	The data of the header to be inserted.
replace	optional	If provided, specifies to override (replace) existing data (if ‘yes’), ‘no’ to insert.

insert_header example:

```
<header name="insert_2_l2">
    <insert_header type="mpls" header_index="1">
        <data>0x00000048</data>
    </insert_header>
    <insert_header type="mpls" header_index="2">
        <data>0x00000048</data>
    </insert_header>
</header>
```

7.4.4.5.1.14.18.3.4 Header Manipulation - Remove_Header

XML element **remove_header** is a container for parameters necessary to configure a header remove manipulation operation of an entire header (different then element **remove** that is a generic one). The element, if it exists, can be used as a child of element **header**'. There can be only one instance of element **remove_header** in a manipulation and it cannot appear in the same time with the generic **remove**.

Table 176. 'remove_header' Child Elements

Element	Requirement	Description
type	required	The type of the header remove. Possible values: • "qtags" • "mpls" • "ethmpls (or "ethernet_mpls") • "eth" (or "ethernet")

remove_header example:

```
<header name="remove_l2">
    <remove_header type="qtags/>
</header>
```

7.4.4.5.1.14.18.3.5 Header Manipulation - Update

XML element **update** is a container for parameters necessary to configure a header update manipulation. The element if exists can be used as a child of element **header**. There can be only one update in a header manipulation.

update Element Attributes:

Table 177. 'remove_header' Child Elements

Element	Requirement	Description
type	required	The type of the update. Possible values: • "vlan" • "ipv4" • "ipv6" • "tcpudp"

update Child Elements:

Table 178. 'remove_header' Child Elements

Element	Requirement	Description
field	required	Specifies the field to be updated. There must be atleast one inside an update. For some types of updates the field element can appear multiple times.

Field Element Attributes:

Table 179. 'remove_header' Child Elements

Element	Requirement	Description

type	required	The type of the header remove. Possible values:
		• for 'vlan'
		  • dscp - DSCP to VLAN priority bits translation.
		  • vpri - Replace VPri of outer most VLAN tag .
		• for 'ipv4'
		  • tos - update TOS with the given value.
		  • id - update IP ID with the new 16 bit given value.
		  • ttl - Decrement TTL by 1.
		  • src - update IP source address with the given value.
		  • dst - update IP destination address with the given value.
		• for 'ipv6'
		  • tc - update Traffic Class address with the given value.
		  • hl - Decrement Hop Limit by 1.
		  • src - update IP source address with the given value.
		  • dst - update IP destination address with the given value.
		• for 'tcpudp'
		  • checksum - update TCP/UDP checksum.
		  • src - update TCP/UDP source address with the given value.
		  • dst - update TCP/UDP destination address with the given value.

value	optional	The value used for the update. It is not valid for: • hl • ttl • checksum
fill	optional	Only valid for **dscp** - fills the entire array with the given value. The fill is performed before the other **dscp** operations.
index	optional	Only valid for **dscp**. Speciefies the index in the array where that value is set. The index starts from 0.

'update' Example:

```
<header name="upd_checksum">
    <update type = "tcpudp">
        <field type="checksum"/>
    </update>
</header>

<header name="upd_ipv4src">
    <update type = "ipv4">
        <field type="src" value="0xC0A80101"/>
    </update>
```

```
</header>

<header name="upd_vpri">
    <update type = "vlan">
        <field type="dscp" fill="yes" value="4"/>
        <field type="dscp" index="20" value="2"/>
        <!--...-->
        <field type="dscp" index="30" value="2"/>
    </update>
</header>
```

7.4.4.5.1.14.18.3.6 Header Manipulation - Custom

XML element **custom** is a container for parameters necessary to configure custom header manipulation. The custom header manipulation supported by the drivers is now custom IP replace, and allows changing between ipv4 and ipv6.

'custom' Element Attributes

Table 180. 'custom' Element Attributes:

Element	Requirement	Description
type	required	The type of the custom header manipulation. Possible values are: • “ipv4byipv6” (or just “ipv4”) – Replaces ipv4 by ipv6. • -“ipv6byipv4” (or just “ipv6”) – Replaces ipv6 by ipv4.

'custom' Child Elements

Table 181. nextmanip Element Attributes:

Element	Requirement	Description
size	required	Size of the header to be inserted. (max is 256)
data	required	The header data to be inserted.
decttl	optional	Decrement TTL by 1 (ipv4). Possible values: • "yes" • "no"
dechl	optional	Decrement Hop Limit by 1 (ipv6). Possible values: • "yes" • "no"
ip (or 'ipid')	optional	16 bit New IP ID (ipv4)

'custom' Example:

```
<header name="custom_ex">
     <custom type="ipv6byipv4">
          <decttl>yes</decttl>
          <id>1</id>
          <size>0x20</size>
          <data>0x450000001234000000010000101111213141516 17</data>
     </custom>
</header>
```

7.4.4.5.1.14.18.3.7 Header Manipulation - Nextmanip

XML element **nextmanip** Can be used to setup cascading header manipulations. It relates to the header manipulation element and not sub-elements (insert, remove and update).

Table 182. Nextmanip element attributes

Element	Requirement	Description
name	required	The name of the next header manipulation

7.4.4.5.1.14.18.3.8 Header Manipulation - Example

Here is a general example of possible header manipulation definition:

```
<manipulations>
    <header name=”ins_rmv” parse=”yes”>
        <insert>
            <size>14</size>
            <offset>0</offset>
            <data>0x01020304050611121314151681 00</data>
        </insert>
        <remove>
            <size>14</size>
            <offset>0</offset>
        </remove>
    </header>

    <header name="vpri_update">
        <update type="vlan">
            <field type="vpri" fill="yes" value="0"/>
        </update>
    </header>

    <header name=”ins_vlan” parse=”no”>
        <insert>
            <size>4</size>
            <offset>12</offset>
            <data>0x81004416</data>
        </insert>
        <nextmanip name="vpri_update"/>
    </header>
</manipulations>

<classification name="clsf_1" max="0" masks="yes" statistics="none">
   <key>
      <fieldref name="ethernet.type”/>
   </key>
   <entry>
      <data>0x8847</data>
      <queue base="0x01"/>
      <action type="policer" name="plcr_1"/>
      <header name="ins_vlan"/>
   </entry>
   <entry>

7.4.4.5.1.15 Standard Protocol File - Excerpt

The DPAA SDK includes a file called the Standard Protocol file. This file uses the NetPDL (Network Protocol Description Language) XML dialect to define the fields in each standard protocol header that the FMan can parse with its Hard Parser. In addition, for each protocol, the NetPDL statement define the actions the Hard Parser should take upon encountering this protocol header in the frame window.

For this reason, the SDK includes a copy of the Standard Protocol file here: /etc/fmc/config/hxs_pdl_v3.xml. In addition, to give you an idea what the file is like, a small portion is shown below.

```
<?xml version="1.0" encoding="utf-8"?>
<netpdl name="nbee.org NetPDL Database"
  version="0.2" creator="nbee.org" date="28-05-2008">
<!-- This file is for reference only. -->
<!-- It describes the protocols and fields supported by the FMan's Hard Parser-->

7.4.5 Security Engine (SEC)

7.4.5.1 SEC Device Driver User Manual

Introduction and Terminology

The Linux kernel contains a Scatterlist CryptoAPI driver for the NXP SEC v4.x, v5.x, v6.x security hardware blocks.

It integrates seamlessly with in-kernel crypto users, such as IPSec, such that any IPSec suite that configures IPSec tunnels with the kernel will automatically use the hardware to do the crypto.

SEC v5.x is backward compatible with SEC v4.x hardware, so one can assume that subsequent SEC v4.x references include SEC v5.x hardware, unless explicity mentioned otherwise.

The name of the software driver module for SEC v4.x hardware is 'caam', after its internal block name: Cryptographic Accelerator and Assurance Module.

Table 183.

SEC hardware version	driver name
v4.x, v5.x, v6.x	caam

Module Loading

CAAM NXP Security Engine device drivers support either kernel built-in or module.

Kernel Configuration

The designated driver should be configured in the kernel by default for the target platform. If unsure, check CONFIG_CRYPTO_DEV_FSL_CAAM is set under "Cryptographic API" -> "Hardware crypto devices" in the kernel configuration:

Kernel Configure Tree View Options	Description
Cryptographic API ---> [*] Hardware crypto devices ---> <*> Freescale CAAM-Multicore driver backend (SEC) <*> Freescale CAAM Job Ring driver backend (SEC) (9) Job Ring size [ ] Job Ring interrupt coalescing <*> Register algorithm implementations with the Crypto API <*> Queue Interface as Crypto API backend <*> Public Key Cryptography Support in CAAM driver <*> Register hash algorithm implementations with the Crypto API	Enable CAAM device driver

Table continues on the next page...

Table continued from the previous page...

Kernel Configure Tree View Options	Description
<*> Register caam device for hwrng API [ ] Enable debig output in CAAM driver	
Network support ---> Network option ---> <*> PF_KEY sockets <*> IP: AH transformation <*> IP: ESP transformation <*> IP: IPComp transformation <*> IP: IPsec transport mode <*> IP: IPsec tunnel mode	IPsec support, of course the TCP/IP networking option should be enabled

CAAM Driver specifics

The CAAM driver module implements and utilizes two interfaces:

- a job ring interface (JRI) for all crypto API service requests
- (on DPAA 1.x platforms) a queue interface (QI) for AEAD algorithms-based crypto API service requests

The Linux driver automatically sets the enable bit for the SEC hardware's Queue Interface (QI), depending on QI feature availability in the hardware. This enables the hardware to also operate as a DPAA component for use by e.g., USDPAA apps. This behaviour does not conflict with normal in-kernel job ring operation, other than the potential performance-observable effects of internal SEC hardware resource contention, and vice-versa.

Note the CAAM driver has sub-configuration settings, most notably hardware job ring size and interrupt coalescing. They can be used to fine-tune performance for a particular application.

The first item enables the basic Controller Driver, and the Job Ring backend. All suboptions are dependent on this.

The second item ("Job Ring Size") allows the user to select the size of the hardware job rings; if requests arrive at the driver enqueue entry point in a bursty nature, the bursts' maximum length can be approximated etc. One can set the greatest burst length to save performance and memory consumption.

The third item ("Job Ring interrupt coalescing") allows the user to select the use of the hardware's interrupt coalescing feature. Note that the driver software already performs IRQ coalescing, and zero-loss benchmarks have in fact produced better results with this option turned off.

If selected, two additional options become effective:

- Job Ring interrupt coalescing count threshold (CRYPTO_DEV_FSL_CAAM_INTC_THLD)

  Selects the value of the descriptor completion threshold, in the range 1-256. A selection of 1 effectively defeats the coalescing feature, and any selection equal or greater than the selected ring size will force timeouts for each interrupt.

- Job Ring interrupt coalescing timer threshold (CRYPTO_DEV_FSL_CAAM_INTC_TIME_THLD)

  Selects the value of the completion timeout threshold in multiples of 64 SEC interface clocks, to which, if no new descriptor completions occur within this window (and at least one completed job is pending), then an interrupt will occur. This is selectable in the range 1-65535.

The options to register to Crypto API, hwrng API respectively, allow the driver to register its algorithm capabilities with the kernel's crypto API. Deselect them only if you do not want crypto API requests to be performed on the SEC; they will be done in software (on the processor core).

Hash algorithms may be individually turned off, since the nature of the application may be such that it prefers software (core) crypto latency due to many small-sized requests.

Random Number Generation (RNG) may be manually turned off in case there is an alternate source of entropy available to the kernel.

Device Tree Binding

Property	Type	Status	Description
compatible	String	Required	fsl,sec-vX.Y (preferred) OR fsl,secX.Y

Source Files

The driver source is maintained in the Linux kernel source tree.

Source File	Description
drivers/crypto/caam/	CAAM NXP Security Engine Driver

Corresponding Device Tree node

```
    crypto@30000 {
            compatible = "fsl,sec-v4.0";
            fsl,sec-era = <2>;
            #address-cells = <1>;
            #size-cells = <1>;
            reg = <0x300000 0x10000>;
            ranges = <0 0x300000 0x10000>;
            interrupt-parent = <&mpic>;
            interrupts = <92 2>;
            clocks = <&clks IMX6QDL_CLK_CAAM_MEM>,
                     <&clks IMX6QDL_CLK_CAAM_ACLK>,
                     <&clks IMX6QDL_CLK_CAAM_IPG>,
                     <&clks IMX6QDL_CLK_EIM_SLOW>;
            clock-names = "mem", "aclk", "ipg", "emi_slow";
    };
```

NOTE

See linux/Documentation/devicetree/bindings/crypto/fsl-sec{4,6}.txt for more info.

How to test the driver

To test the driver, in the kernel configuration menu, under "Cryptographic API" -> "Cryptographic algorithm manager", ensure that run-time self-tests are not disabled, i.e. the "Disable run-time self tests" (CONFIG_CRYPTO_MANAGER_DISABLE_TESTS) entry is not set. This will run standard test vectors against the driver after the driver registers its supported algorithms with the kernel crypto API, usually at boot-time. Then run test on the target system. Below is a snippet extracted from the boot log.

```
[...]

[...]
```

Verifying driver operation and correctness

Other than noting the performance advantages due to the crypto offload, one can also ensure the hardware is doing the crypto by looking for driver messages in dmesg

The driver emits console messages at initialization time:

```
platform caam_qi.0: fsl,sec-v4.4 algorithms registered in /proc/crypto
caam 1700000.crypto: fsl,sec-v4.4 algorithms registered in /proc/crypto
```

If the messages are not present in the logs, either the driver is not configured in the kernel, or no SEC compatible device tree node is present in the device tree.

Incrementing IRQs in /proc/interrupts

Given a time period when crypto requests are being made, the SEC hardware will fire completion notification interrupts - either on the corresponding Job Ring or on the QMan (Queue Manager) portal IRQ (depending on what CAAM interface is the algorithm using):

```
cat /proc/interrupts | grep jr
           CPU0       CPU1       CPU2       CPU3       CPU4       CPU5       CPU6
CPU7
[...]
 88:          0          0          0        941          0          0
0          0   OpenPIC    88 Level     ffe301000.jr
 89:          0          0          0          0          0          0
0          0   OpenPIC    89 Level     ffe302000.jr
 90:          0          0          0          0          0          0
0          0   OpenPIC    90 Level     ffe303000.jr
 91:          0          0          0          0          0          0
0          0   OpenPIC    91 Level     ffe304000.jr

cat /proc/interrupts | grep QMan
```

```
           CPU0       CPU1       CPU2       CPU3       CPU4       CPU5       CPU6
CPU7
[...]
108:          0          0          0          0          0          0
0          0   OpenPIC   108 Level     QMan portal 7
110:          0          0          0          0          0          0
0          0   OpenPIC   110 Level     QMan portal 6
112:          0          0          0          0          0          0
0          0   OpenPIC   112 Level     QMan portal 5
114:          0          0          0          0          0          0
0          0   OpenPIC   114 Level     QMan portal 4
116:          0          0          0        285          0          0
0          0   OpenPIC   116 Level     QMan portal 3
118:          0          0          0          0          0          0
0          0   OpenPIC   118 Level     QMan portal 2
120:          0          0          0          0          0          0
0          0   OpenPIC   120 Level     QMan portal 1
122:          0          0          0          0          0          0
0          0   OpenPIC   122 Level     QMan portal 0
```

If the number of interrupts fired increment, then the hardware is being used to do the crypto.

If the numbers do not increment, then first check the algorithm being exercised is supported by the driver. If the algorithm is supported, there is a possibility that the driver is in polling mode (NAPI mechanism) and the hardware statistics in debugfs (inbound / outbound bytes encrypted / protected - see below) should be monitored.

Note: When QI is used, CAAM driver might be sharing the QMan portal with other drivers in the system; meaning that the interrupt counters shown in /proc/interrupts are for all drivers sharing the portal.

Verifying the 'selftest' fields say 'passed' in /proc/crypto

An entry such as this:

```
name         : cbc(aes)
driver       : cbc-aes-caam
module       : kernel
priority     : 3000
refcnt       : 1
selftest     : passed
type         : ablkcipher
async        : yes
blocksize    : 16
min keysize  : 16
max keysize  : 32
ivsize       : 16
geniv        : eseqiv
```

means the driver has successfully registered support for the algorithm with the kernel crypto API.

Note that although a test vector may not exist for a particular algorithm supported by the driver, the kernel will emit messages saying which algorithms weren't tested, and mark them as 'passed' anyway:

```
alg: No test for authenc(hmac(sha224),ecb(cipher_null)) (authenc-hmac-sha224-ecb-cipher_null-caam)
alg: No test for authenc(hmac(sha256),ecb(cipher_null)) (authenc-hmac-sha256-ecb-cipher_null-caam)
[...]
alg: No test for authenc(hmac(md5),cbc(aes)) (authenc-hmac-md5-cbc-aes-caam)
alg: No test for authenc(hmac(sha224),cbc(aes)) (authenc-hmac-sha224-cbc-aes-caam)
[...]
alg: No test for authenc(hmac(md5),rfc3686(ctr(aes))) (authenc-hmac-md5-rfc3686-ctr-aes-caam)
[...]
```

Examining the hardware statistics registers in debugfs

The controller driver enables a user level view of performance monitor registers located within the controller's register partition. To enable this view, CONFIG_DEBUG_FS must be enabled in the kernel's configuration. If there is no mount of debugfs performed at bootup time, then a manual mount must be performed in order to view these registers. This normally can be done with a superuser shell command of:

```
mount -t debugfs none /sys/kernel/debug
```

Once done, the user can read controller registers in /sys/kernel/debug/caam/ctl. It should be noted that debugfs will provide a decimal integer view of most accessible registers provided, with the exception of the KEK/TDSK/TKEK registers; those registers are long binary arrays, and should be filtered through a binary dump utility such as hexdump.

Specifically, the CAAM hardware statistics registers available are:

fault_addr, or FAR (Fault Address Register): - holds the value of the physical address where a read or write error occurred.

fault_detail, or FADR (Fault Address Detail Register): - holds details regarding the bus transaction where the error occurred.

fault_status, or CSTA (CAAM Status Register): - holds status information relevant to the entire CAAM block.

ib_bytes_decrypted: - holds contents of PC_IB_DECRYPT (Peformance Counter Inbound Bytes Decrypted Register)

ib_bytes_validated: - holds contents of PC_IB_VALIDATED (Performance Counter Inbound Bytes Validated Register)

ib_rq_decrypted: - holds contents of PC_IB_DEC_REQ (Performance Counter Inbound Decrypt Requests Register)

kek: - holds contents of JDKEKR (Job Descriptor Key Encryption Key Register)

ob_bytes_encrypted: - holds contents of PC_OB_ENCRYPT (Performance Counter Outbound Bytes Encrypted Register)

ob_bytes_protected: - holds contents of PC_OB_PROTECT (Performance Counter Outbound Bytes Protected Register)

ob_rq_encrypted: - holds contents of PC_OB_ENC_REQ (Performance Counter Outbound Encrypt Requests Register)

rq_dequeued: - holds contents of PC_REQ_DEQ (Performance Counter Requests Dequeued Register)

tdsk: - holds contents of TDKEKR (Trusted Descriptor Key Encryption Key Register)

tkek: - holds contents of TDSKR (Trusted Descriptor Signing Key Register)

See the hardware documentation section "Performance Counter, Fault and Version ID Registers" for more information.

For extended testing process please refer to the Linux IPsec benchmark reproducibility guide.

Kernel configuration to support caam device driver

Algorithms Supported in the linux kernel scatterlist Crypto API

The linux kernel contains various users of the Scatterlist CryptoAPI, including its IPSec implementation, sometimes referred to as the NETKEY stack. The driver, after registering algorithm services with the CryptoAPI, is therefore used to process per-packet symmetric crypto requests and forward them to the SEC hardware.

Since all SEC version hardware processes requests asynchronous to the processor core, the driver registers asynchronous algorithm implementations with the crypto API: ahash, ablkcipher, and aead with CRYPTO_ALG_ASYNC set in .cra_flags.

Different combinations of hardware and driver software version support different sets of algorithms, so searching for the driver name in /proc/crypto on the desired target system will ensure the correct report of what algorithms it supports.

Authenticated Encryption with Associated Data (AEAD) Algorithms

These algorithms are used in applications where the data to be encrypted overlaps, or partially overlaps, the data to be authenticated, as is the case with the IPSec protocol.

These algorithms are implemented in the driver such that the hardware makes a single pass over the input data, and both encryption and authentication data are written out simultaneously.

The AEAD algorithms are mainly for use with IPSec ESP (however there is also support for TLS 1.0 record layer encryption).

At the time of writing, the CAAM driver currently supports offloading the following AEAD algorithms:

- "stitched" AEAD: all combinations of NULL, CBC-AES/DES/3DES-EDE, RFC3686-CTR-AES with MD-5, SHA-1,-224,-256,-384, and -512
- "true" AEAD: GCM-AES, GCM used in IPsec: RFC4543-GCM-AES and RFC4106-GCM-AES
- TLS 1.0 record layer with "stitched" CBC-AES-HMAC-SHA1

Note: Some of the algorithms register twice - one instance for running over the job ring interface and the other for running over the queue interface. The algorithms registered to run over queue interface will be preferred by the Crypto API, since they have a higher priority (CAAM_CRA_PRIORITY is 4000 for QI and 3000 for JRI).

An exhaustive list of algorithms follows:

authenc(hmac(md5),cbc(aes))

authenc(hmac(sha1),cbc(aes))

authenc(hmac(sha224),cbc(aes))

authenc(hmac(sha256),cbc(aes))

authenc(hmac(sha384),cbc(aes))

authenc(hmac(sha512),cbc(aes))

authenc(hmac(sha512),ecb(cipher_null))

gcm(aes)

rfc4543(gcm(aes))

rfc4106(gcm(aes))

tls10(hmac(sha1),cbc(aes))

Cipher Encryption Algorithms

The CAAM driver currently supports offloading the following encryption algorithms:

cbc(aes)

cbc(des3_ede)

cbc(des)

ctr(aes)

rfc3686(ctr(aes))

xts(aes)

Authentication Algorithms

The CAAM driver's ahash support includes HMAC variants:

hmac(md5)

hmac(sha1)

hmac(sha224)

hmac(sha256)

hmac(sha384)

hmac(sha512)

md5

sha1

sha224

sha256

sha384

sha512

Asymmetric (public key) Algorithms

pkc(dh)

pkc(dsa)

pkc(rsa)

Random Number Generation

caam driver supports random number generation services via the kernel's built-in hwrng interface when implemented in hardware. To enable:

1. verify that the hardware random device file, e.g., /dev/hwrng or /dev/hwrandom exists. If it doesn't exist, make it with:

```
mknod /dev/hwrng c 10 183
```

2. verify /dev/hwrng doesn't block indefinitely and produces random data:

```
rngtest -C 1000 < /dev/hwrng
```

3. verify the kernel gets entropy:

```
rngtest -C 1000 < /dev/random
```

If it blocks, a kernel entropy supplier daemon, such as rngd, may need to be run. See linux/Documentation/hw_random.txt for more info.

Using the driver

Once enabled, the driver will forward kernel crypto API requests to the SEC hardware for processing.

Running IPSec

The IPSec stack built-in to the kernel (usually called NETKEY) will automatically use crypto drivers do offload the crypto to the SEC hardware. Documentation regarding how to set up an IPSec tunnel can be found in the respective open source IPSec suite packages, e.g. strongswan.org, openswan, setkey, etc.

Running OpenSSL

TODO: cross-reference to OpenSSL chapter/section and update/remove text below.

While not officially supported in the SDK, there are userspace interface implementations that enable offloading OpenSSL requests to the built-in kernel crypto API, and thus the SEC hardware via its respective driver. While the kernel officially supports the AF_ALG socket interface, various third-party cryptodev implementations are also available.

Here are some links to a couple of starting points:

```
http://carnivore.it/2011/04/23/openssl_-_af_alg
http://home.gna.org/cryptodev-linux/
http://ocf-linux.sourceforge.net/
```

Executing Custom Descriptors

caam has public descriptor submission interfaces, drivers/crypto/caam/jr.c:caam_jr_enqueue() and drivers/crypto/caam/qi.c:caam_qi_enqueue().

caam_jr_enqueue()

Name

caam_jr_enqueue — Enqueue a job descriptor head. Returns 0 if OK, -EBUSY if the ring is full, -EIO if it cannot map the caller's descriptor.

Synopsis

```
int caam_jr_enqueue (struct device *dev, u32 *desc,
 void (*cbk) (struct device *dev, u32 *desc, u32 status, void *areq),
 void *areq);
```

Arguments

dev: contains the job ring device that is to process this request.

desc: descriptor that initiated the request, same as “desc” being argued to caam_jr_enqueue.

cbk: pointer to a callback function to be invoked upon completion of this request. This has the form: callback(struct device *dev, u32 *desc, u32 stat, void *arg)

areq: optional pointer to a user argument for use at callback time.

caam_qi_enqueue()

Name

caam_qi_enqueue — Enqueue a frame descriptor (FD) into a QMan frame queue. Returns 0 if OK, -EIO if it cannot map the caller's S/G array, -EBUSY if QMan driver fails to enqueue the FD for some reason.

Synopsis

```
int caam_qi_enqueue(struct device *qidev, struct caam_drv_req *req);
```

Arguments

qidev: contains the queue interface device that is to process this request.

req: pointer to the request structure the driver application should fill while submitting a job to driver, containing a callback function and its parameter, Queue Manager S/Gs for input and output, a per-context structure containing the CAAM shared descriptor, the etc.

Please refer to the source code for example usage.

7.4.6 Pattern Matching Engine (PME)

7.4.6.1 PME Driver Release Notes

Description

This document describes PME software for the PME hardware block that is part of the QorIQ data path. The PME software runs on version 2.0, 2.1 and 2.2 of the PME hardware. The PME software includes the following components:

- Linux and USDPAA drivers
- Regular Expression compiler for Linux
- Stateful Rule compiler for Linux
- Pattern Matcher Manager (Linux)
- Pattern Matcher Configuration API (Linux)
- Sample Application – Scan Demo (Linux)
- Regular Expression Analyzer Tool (Linux Host only)

Linux and USDPAA Drivers

The PME driver software includes a Linux kernel driver and a PME driver library for USDPAA. The Linux driver provides an ioctl-based Linux user-space interface. The drivers' provide interfaces in Linux kernel and user-space for PME configuration, database setup, and data scanning. For USDPAA, the drivers provide a PME data scanning interface.

The drivers target the Linux and USDPAA environments. The majority of the code is shared between all environments.

The driver includes the following functionality.

PME Configuration interface

The PME configuration interface is an encapsulation of the PME CCSR register space and the global/error interrupt source. This is expected to be managed only by (and visible to) a control-plane operating system,

PME User-space Interface

The user-space interface provides pme_scan and pme_db devices for sending data for scanning and PME database setup respectively to the PME. There is also a `sysfs` interface to control PME global configuration parameters and to access PME statistics.

PME Low-level Driver Interface

The low-level API is a hardware abstraction layer (HAL) where the users have complete control over the data structures and interfaces used to communicate with the PME.

PME High-level Driver Interface

The PME high-level APIs provide a call-back based interface to the PME. The driver provides APIs to manage flow context and issue PMTCC and scan commands. The high-level driver internally co-ordinates commands to the PME and corressponding results from the PME.

PME Pattern Management Software

The Pattern Management software is used to configure the Pattern Matcher by enabling the addition, deletion and querying of patterns and stateful rules. The Pattern Management software components are summarized below.

Regex Compiler

Regular expressions (regexes) provide a powerful way of representing complex patterns. The regex compiler accepts a regex string with options or a file containing regexes, and converts these regexes into patterns stored in Pattern Matcher hardware-specific format, referred to as “test lines”. The regex compiler is provided as source code and as an executable program with command line interfaces. It is also available as a “C” library. The regex compiler is provided for both the x86 and PowerPC targets.

Stateful Rule Compiler

The stateful rule compiler accepts a file containing one or more stateful rules and converts the rules into Pattern Matcher hardware-specific format, referred to as “stateful rule reactions.” If stateful rule reactions are loaded for a pattern, these reactions are executed when that pattern matches. The regex compiler is provided as source code and as an executable program with command line interfaces. It is also available as a “C” library. The regex compiler is provided for both the x86 and PowerPC targets.

Linker-Loader

The linker-loader accepts patterns encoded in the hardware-specific format (test lines) and stateful rules converted into the hardware-specific format (stateful rule reactions) and generates a hardware-optimal pattern and stateful rule database (referred as the Pattern Matcher database). The linker-loader is available as source code and as a C library.

Pattern Matcher Manager

The Pattern Matcher manager (PMM) is an application that manages the creation and distribution of patterns. It uses NXP-provided libraries, namely the regex compiler, the stateful rule compiler and the linker-loader in order to compile, link and load patterns into the Pattern Matcher. PMM maintains a shadow database that allows it to dynamically add or delete discrete patterns from the PME database while the PME remains in-service. The PMM application is implemented as a Linux user-space process that runs on the QorIQ processor containing the Pattern Matcher.

Pattern Matcher Configuration API

The PMC provides a programming interface to Pattern Matcher Management applications for adding, removing, querying and committing regular expressions and stateful rules into Pattern Matcher hardware.

Regular Expression Analyzer Tool (Linux Host only)

The regex_analyzer tool is designed to assist users in getting the best performance out of the Pattern Matcher Engine (PME). It does this by analyzing regular expressions meant for PME hardware use and flagging the ones that may cause performance issues. This tool is available only on the Linux Host.

Software configuration, build information

The PME software is built when supporting platform is selected. The build is via the standard Yocto build process. The user-space tools and applications are available in the `bin_powerpc` directory after a build. The Linux driver is statically linked into the kernel or can be a compiled as a kernel module. A portion of the driver is always built into the kernel - this part allocates a contiguous chunk of memory at boot time that is needed by the PME.

PME Configuration Options

PME Kernel Configure Options	Description
CONFIG_FSL_PME2	Required to build the PME driver
CONFIG_FSL_PME2_CTRL	Compiles device support for the NXP PME2 pattern matching part contained in datapath-enabled SoCs (i.e. accessed via Qman and Bman portal functionality). At least one guest operating system must have this driver support, together with the appropriate device-tree entry, for PME2 functionality to be available. It is responsible for allocating system memory to the device and configuring it for operation. For this reason, it must be built into the kernel and will initialise during early kernel boot.
CONFIG_FSL_PME2_PDSRSIZE	Select the default size of the Pattern Description and Stateful Rule table as a number of 128 byte entries. This only takes effect if the device tree node doesn't have the 'fsl,pme-pdsr' property.
CONFIG_FSL_PME2_SRESIZE	Select the default size of the SRE Context Table as the number of 32 byte entries. This only takes effect if the device tree node doesn't have the 'fsl,pme-sre' property.
CONFIG_FSL_SRE_AIM	Select the alternate inconclusive match mode treatment.
CONFIG_PME2_SRE_ESR	Select if an End of SUI will produce a Simple End of SUI report.
CONFIG_FSL_PME2_SRE_CTX_SIZE_PER_SESSION	Select the default SRE Context Size per Session
CONFIG_FSL_PME2_SRE_CNR	Configured the number of stateful rules as a multiple of 256
CONFIG_FSL_SRE_MAX_INSTRUCTION_LIMIT	Select the maximum number of SRE instructions to be executed per reaction.
CONFIG_FSL_PME2_SRE_MAX_BLOCK_NUMBER	Select the maximum number of reaction head blocks to be traversed per pattern match event (e.g. a matched pattern or an End of SUI event).
CONFIG_FSL_PME2_PORTAL	This compiles I/O support for the NXP PME2 pattern matching part contained in datapath-enabled SoCs (i.e. accessed via Qman and Bman portal functionality).
CONFIG_FSL_PME2_HIGH	This compiles the high-level driver for PME2.
CONFIG_FSL_PME2_TEST_HIGH	This uses the high-level Qman driver (and the cpu-affine portals it manages) to perform high-level PME2 API testing with it.
CONFIG_FSL_PME2_TEST_SCAN	This uses the high-level Qman driver (and the cpu-affine portals it manages) to perform PME2 scan API testing with it.
CONFIG_FSL_PME2_TEST_SCAN_WITH_BPID	This performs the PME scan API test using buffers from the specified buffer pool.
CONFIG_FSL_PME_TEST_SCAN_WITH_BPID_SIZE	This performs the PME scan API test using a buffer pool with the specified size buffers.

Table continues on the next page...

Table continued from the previous page...

PME Kernel Configure Options	Description
CONFIG_FSL_PME2_DB	This compiles the database driver software for PME2. This provides APIs to update the PME2 database.
CONFIG_FSL_PME2_DB_QOSOUT_PRIORITY	The PME DB has a scheduled output frame queue. The QoS priority level for the FQ is configurable via this option.
CONFIG_FSL_PME2_SCAN	This compiles the scan driver software for PME2. This provides APIs for sending scan data to the PME and receiving scan results.
CONFIG_FSL_PME2_SCAN_DEBUG	Trace the PME2 scan driver software with more verbosity using this option.
PME2_STAT_ACCUMULATOR_UPDATE_INTERVAL	The PME statistics accumulator periodically reads current device statistics and adds them to running counters. The frequency of these updates can be controlled by this option.
CONFIG_FSL_PME_BUG_4K_SCAN_REV_2_1_4	Workaround for errata in PME version 2.1.4. Prevents scans of SUIs greater than 4095 - 127 bytes when this revision of HW is detected.

Source Files and Tools Binaries

PME software exists in Linux user and kernel space. All PME software, including tools (like the regex compiler) and Linux driver, are provided in source form. The list below shows the location of all PME files in the release.

Linux User-space

Source Files	Description
pme_tools/include/*.h	The PME Tools header files. example.h is a sample file to demonstrate the build flow for PME tools. See pme_tools/example for details.
pme_tools/applications/*.c	Source code for PME tools like pmm, regex and stateful rule compilers.
pme_tools/pmConfiguration/*	Pattern Matcher Configuration (PMC) api source code
pme_tools/controlInterface/*	The control interface source and compiled files.
pme_tools/loaderAgent/*	The loader agent source and compiled files.
pme_tools/bin_powerpc/*	Compiled PME tools, Scan demo and Test executables.
pme_tools/lib_powerpc/*	Compiled PME tools libraries.
pme_tools/ltib_supp/*	Files that are installed in the ramdisk by Yocto
pme_tools/common/*	Common software utilities used by PME Tools.
pme_tools/example/*	Sample use of PME Tools build and include file hierarchy.

Linux Kernel-space

Source Files	Description
drivers/staging/fsl_pme2/pme2_*.*	The PME2 drivers including user-space PME2 database and scan drivers, and kernel-space high and low-level drivers (except pme2_sample*, pme2_test* which are PME kernel test files).
include/linux/fsl_pme.h	The PME driver APIs

USDPAA

Source Files	Description
include/usdpaa/fsl_pme.h	The PME driver APIs
drivers/pme/*	The PME driver
lib_powerpc	USDPAA static libraries

Test Procedure

The PME software includes tests that are run from the Linux User-space as well as tests that run in the Linux kernel. The kernel tests can be configured via Kconfig as noted in the configuration options described above. These tests complement the PME unit tests.

PME Kernel Tests

The output of the PME tests is shown in the following excerpts. The tests are shows below as being statically linked into the Linux kernel. However, these tests could also have been built and run as loadable kernel modules.

PME High Level Test output:

```
PME2: high-level test starting
PME2: pme_ctx_init done
PME2: pme_ctx_enable done
PME2: pme_ctx_ctrl_update_flow done

Linux user-space Tests

```
Run the pmm application to load the sample regexs:
Setup the pme database:
 $ cd /sample_rules/
 $ pmm
 [ Enter text at the "pmm> " prompt]
 pmm> add regex file source sample_regexs
 REC: WARNING: sample_regexs: Line 22 Compiled pattern has only 1
 byte fingerprint. Performance may be impacted.
 The "sample_regexs" file was compiled with warnings.
 Successfully added 27 regexes to the PM DB with handle 0.
 Command execution time: 00:00:00 [hour:min:sec].
 pmm> commit
 Successfully committed changes made to the data base of expressions.
 Command execution time: 00:00:00 [hour:min:sec].
 pmm> quit
 Terminating the PMM application.
Run the pm_scan_demo application:
 $ pm_scan_demo
```

```
[ Enter text at the "> " prompt]
> example1 /FTF Americas 2006/
#00: Scanning 31 bytes.
match(0x01): len=0x11 offset=0x000000000000:0000001e tag=0x00000000
>quit
Number of successful scan: 1
Number of full match: 1
Number of inconclusive match: 0
Number of rule report: 0
```

Known Bugs, Limitations, or Technical Issues

1. BMan buffer pools for PME output not supported for Linux user space use.

2. In case of any PME error detection, the software PME Context transitions to DEAD state. This prevents use of a PME Context after an operational error.

Supporting Documentation

- P4080 QorIQ Integrated Multicore Communication Processor Family Reference Manual
- Pattern Matcher 2.0 Software User's Guide
- Pattern Matcher 2.0, 2.1, 2.2 Software API Reference Manual
- USDPAA “pme_loopback” User Guide

7.4.6.2 Pattern Matcher 2.0 Software User's Guide

7.4.6.2.1 Preface

7.4.6.2.1.1 About This Book

This user's guide is written for programmers developing software for a PowerQUICC processor with Pattern Matcher 2.0 capabilities. It describes the supplied pattern matcher software components, how to use various application programming interfaces, and how to integrate the resulting customized software. The supplied sample Pattern Matcher applications are also described in this document.

7.4.6.2.1.2 Audience

This manual supports system software and application programmers who want to use the Pattern Matcher 2.0 in their product.

7.4.6.2.1.3 Organization

This book contains the following topics.

- Overview - The Pattern Matcher hardware and software architecture.
- Regular Expressions -The regex operation and the compiler.
- Stateful Rules -The stateful rule concepts and the stateful rule language.
- Pattern Management Software -The functionality of the main software modules for pattern management, including the linker-loader, the pattern matcher manager, the PM statistics manager, and the distributed pattern management software .
- Pattern Matcher Driver -The Pattern Matcher driver software for Linux is the layer of software that provides applications an interface into the Pattern Matcher. This chapter discusses the application interfaces, initializing and configuring the drivers, memory structure, scanning data, third-party interfaces, and error handling.

- Data Scan Sample Application -Three main example applications, including a scan demo and a layer-7 packet classifier for Linux.
- Software Components - Software modules and a listing of sample code modules.
- Pattern Matcher FAQ - Frequently asked Pattern Matcher questions.

7.4.6.2.1.4 Conventions

This document uses the following notational conventions:

- `Courier`

  monospaced type indicates commands, command parameters, code examples, and file and directory names.
- *Italic* type indicates replaceable command or function parameters, that is, variables.
- **Bold** type indicates function names.

7.4.6.2.1.5 Suggested Reading

The following documents contain information that supplements this guide:

- Applicable PowerQUICC processor (contains Pattern Matcher 2.0) reference manual
- *Pattern Matcher 2.0 Software API Reference Manual* (PMAPIRM)

7.4.6.2.2 Overview

The Pattern Matcher 2.0 provides the following capabilities:

- High-performance, hardware pattern-matching of compressed and uncompressed data.
- On-chip hash tables for low system memory utilization.
- Patterns expressed in regex with capabilities beyond that provided by the regex language.
- Pattern-matching across data scan units (for example, can match patterns split across packets).
- Improvements over other Pattern Matcher technologies are as follows:
  - No pattern "explosion" to support "wildcarding"
  - Fast compilation of pattern database
  - Fast incremental additions to pattern database
  - Patterns stored in main DDR DRAM, not SRAM or FCRAM

7.4.6.2.2.1 Pattern Matcher Hardware

The Pattern Matcher 2.0 hardware details can be found in the applicable PowerQUICC processor reference manual. A general overview is provided below:

The Pattern Matcher 2.0 (henceforth referred to as Pattern Matcher) contains high-performance hardware capable of performing unanchored searches for up to 32,000 patterns. It offers support for built-in case insensitivity, repetition, and nested rules, and both predefined and user-defined character classes. Additionally, the Pattern Matcher provides the ability to create stateful relationships between data examination events, such as matched expressions detected by the Pattern Matcher so more complex regular expressions, as well as certain other complex multi-pattern rules, can be implemented directly in hardware.

The Pattern Matcher is implemented as a series of functional units pipelined together to achieve desired functionality and scan performance as shown in Figure 137. Pattern Matcher High Level Block Diagram on page 872:

- Pattern Matcher Frame Agent (PMFA)
- Key element scanner (KES)

- Data examination engine (DXE)
- Stateful rule engine (SRE)

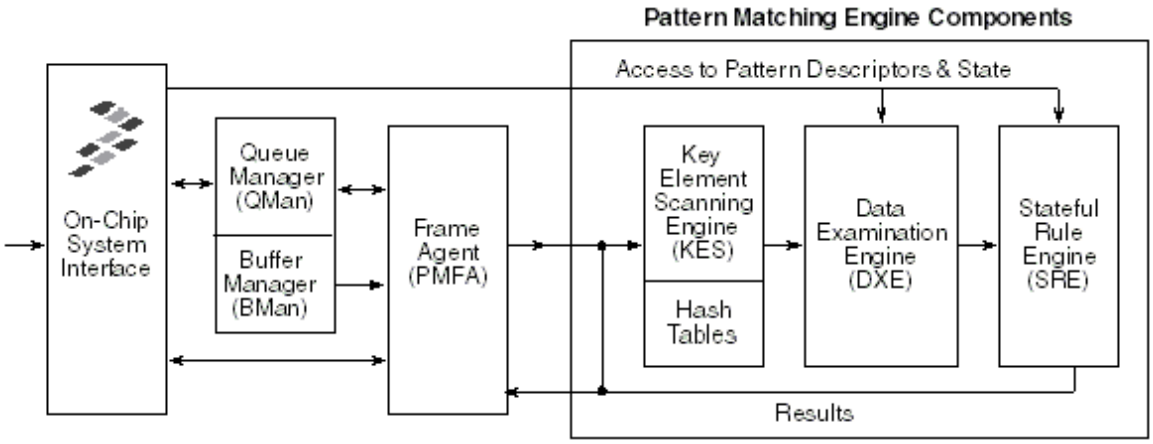

Figure 137. Pattern Matcher High Level Block Diagram

Up to eight work-units can be in flight in the pipeline at any given time. A work-unit represents an atomic work request operation to the Pattern Matcher. Work request operations are conveyed to the Pattern Matcher through the Pattern Matcher Frame Agent (PMFA)via Queue Manager (QMan) Direct Connect Portal. The Pattern Matcher implements a single pipeline, which means that processing of work-units are completed in the same order as they were initially selected.

The first stage of the pipeline is the PMFA. It provides an interface to the Frame Queue datapath environment (Queue Manager and Buffer Manager) to receive work requests (scan data and control messages) and to send notifications/reports (if required) of completed work requests.

The core pattern-matching functionality is implemented as a three stage pipeline. The first stage is the key element scanner (KES), which serves as a preliminary filter by detecting the possibility of matches of up to 32,000 patterns simultaneously through a single pass through the data. The KES implements a multi-stage, hash-based, proprietary algorithm using on-chip memory to determine the likelihood of the data being a match with a pattern. Matches found at this stage are delivered to the data examination engine (DXE), which performs a more stringent comparison to determine if the match actually exists or not. The DXE implements a non-deterministic finite automaton (NFA) capable of implementing a significant subset of the regular expression (regex) pattern definition language, as well as many constructs that cannot be expressed in regex. Successfully matched patterns are passed to the next stage called the stateful rule engine (SRE). The SRE's main function is to execute stateful rules against pattern match events. Stateful rules provide the means to track state and context information between matches. The SRE also formats the reports of matches including pattern match events that don't trigger the execution of stateful rules. The reports are passed to the PMFA, which in turn produces an entry in the output frame queue that contains a pointer to an output data descriptor containing the pattern reports associated for a given work-unit.

7.4.6.2.2.2 Pattern Matcher Software

The Pattern Matcher software provides the ability to use the Pattern Matcher hardware assists to recognize various complex patterns in a stream of either data or packets. The application may be informed of every single pattern match or a summary of several pattern matches. Based on the pattern match results, the application can take appropriate actions, such as logging the pattern match events, dropping some packets, or forwarding the data onwards. The Pattern Matcher allows for data scanning with minimum data copy (for example, any data received from the network and stored in the system memory buffers may be sent to the Pattern Matcher without any need for data copy). Also, the Pattern Matcher is capable of detecting patterns spread across successive presentation of bytes in multiple scan units.

The figure below shows the supplied Pattern Matcher software components and their interactions.

- Pattern Management software
  - Regex Compiler

- Stateful rule Compiler
- Linker-loader
- Pattern Matcher (PM) Manager application (Linux implementation)

- Pattern Matcher Driver
  - Pattern Matcher (PM) Driver (Linux implementation)
  - Pattern Matcher (PM) Control Interface (Linux implementation)
- Pattern Matcher (PM) Data Scan Applications

The section, Software Components, contains a list of supplied Pattern Matcher software modules.

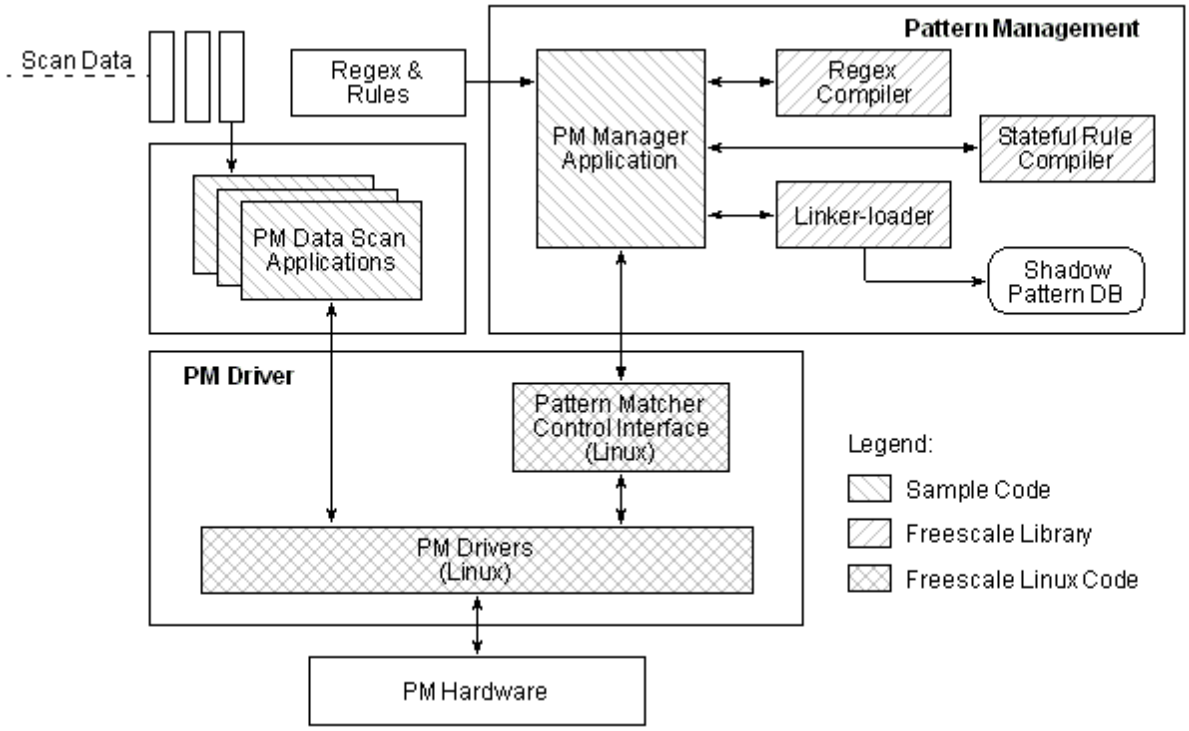

Figure 138. Pattern Matcher Software Overview

7.4.6.2.2.2.1 Pattern Management Software for Pattern Matcher

The Pattern Management software is used to configure the Pattern Matcher by enabling adding, deleting and querying patterns (arrangement of symbols to be matched) and stateful rules (means to track state and context information between pattern matches). The Pattern Management software components are explained in the following sections.

NOTE

Both the regex and stateful rule compilers are available as an executable program with command line interface and also as a "C" library with API.

7.4.6.2.2.2.1.1 Regex Compiler

Regular expressions (regexes) provide a powerful way of representing complex patterns. The regex compiler accepts a regex string with options or a file containing regexes, and converts these regexes into patterns stored in Pattern Matcher hardware-specific format, referred to as "test lines".

7.4.6.2.2.2.1.2 Stateful Rule Compiler

The stateful rule compiler accepts a file containing one or more stateful rules and converts the rules into Pattern Matcher hardware-specific format, referred to as "stateful rule reactions." If stateful rule reactions are loaded for a pattern, these reactions are executed when that pattern matches.

7.4.6.2.2.2.1.3 Linker-Loader

The linker-loader accepts patterns encoded in the hardware-specific format (test lines) and stateful rules converted into the hardware-specific format (stateful rule reactions) and generates a hardware-optimal pattern and stateful rule database (referred as the Pattern Matcher database). A copy of this database (referred as the shadow pattern database) is maintained by the linker-loader for reload and update purposes.

There are architectural advantages to having the separate step to link patterns using linker-loader from compiling patterns; these advantages are as follows:

- Different pattern compilers can coexist with single linker-loader. For example, the linker-loader can be used with the regex compiler from NXP and a proprietary pattern compiler for the customer's own signature definitions.
- Compilers can run on a number of different remote host systems.

The linker-loader is available as a "C" library.

7.4.6.2.2.2.1.4 Pattern Matcher Manager Application (PMM)

The Pattern Matcher manager application (PMM) is an example of an application that manages the creation and distribution of patterns. It uses NXP-provided libraries, namely the regex compiler, the stateful rule compiler and the linker-loader in order to compile, link and load patterns into the Pattern Matcher.

The PMM application is implemented as a Linux user-space process that runs on the PowerQUICC processor containing the Pattern Matcher.

Take note that the Pattern Management software can be implemented as a distributed application with only a small part running on directly on the PowerQUICC processor containing the Pattern Matcher.

7.4.6.2.2.2.2 Pattern Matcher Driver

The Pattern Matcher driver provides a means of sending commands (for example, pattern search request or pattern configuration messages) into the Pattern Matcher and delivering the responses from the Pattern Matcher to the software. The pattern search is performed under full application control via the Pattern Matcher Driver. After a unit of data (for example, data work-unit) has been searched, the application is presented with the pattern search report if configured to do so.

7.4.6.2.2.2.2.1 Pattern Matcher Control Interface

The PM Control Interface (PMCI) module is provided as a Linux user-space library. It contains C functional Interface to send and receive Pattern Matcher control commands to the Pattern Matcher via Pattern Matcher driver software. The PM control commands initialize PM driver and configure the PM hardware tables. The PMCI module converts complex PM control commands into PM driver primitives. The PMCI API functions and the PM Control command structures are defined in the Pattern Matcher 2.0 Software API Reference Manual.

7.4.6.2.2.2.3 Pattern Matcher Data Scan Applications

The PM Data Scan Applications are customer applications that use the Pattern Matcher hardware for accelerating pattern searches. These applications may receive data from network or other sources. When it comes time to search for patterns, applications use the PM Driver APIs to send a copy of the data to the Pattern Matcher hardware. The NXP Linux implementation of the PM Driver APIs provides mechanisms for zero-copy DMA operations. The pattern match events are reported back to the application as results of the scan operations. Linux-based Pattern Matcher Drivers provide a variety of scan APIs to the PM data scan applications, which are mainly:

- User-space blocking and non-blocking APIs
- Kernel-space blocking and non-blocking APIs

The expressions and stateful rules are added via the PMM before PM data scan applications can search data for these expressions and rules. Also, the expression and rules may be incrementally added or deleted dynamically without completing stopping the scan applications.

The source code for few data scan applications is provided as an example use of the PM Driver APIs.

7.4.6.2.3 Regular Expressions

The NXP regex compiler accepts search patterns using syntax similar to that in software-based regex engines, such as Perl or the open source Perl-compatible regular expression engine (PCRE). Despite the similar syntax, different software-based regex engines work differently and sometimes produce different match results. Although the NXP Pattern Matcher hardware combined with the NXP regex compiler behaves like other engines in many respects, it has important differences and unique features. The NXP regex engine described in this chapter is the combination of the Pattern Matcher hardware and the regex compiler.

NOTE

For details on the regex compiler, refer to *Pattern Matcher Compiler Software User's Guide.*

7.4.6.2.4 Application interface

The regex compiler is provided as a C library and also as a binary executable program under Linux. The PM Manager system software can compile single regex or multiple regexes stored in a file using either the library function or by invoking the regex compiler program.

7.4.6.2.4.1 Compiler API

The regex compiler API functions are located in following header file:

```
        <freescale pm source code path>/pm/user/include/pmrec.h
```

For details on the regex compiler API, refer to *Pattern Matcher 2.0 Software API Reference Manual*.

7.4.6.2.4.2 Command Line

The pmrec is the executable program to compile regexes from stdin or an input file, as shown in the following command help:

```
pmrec --help
Description:
      The regex compiler takes input from a file or stdin and
      converts the regex to patterns in an internal format.
      The output must be passed to the Linker-loader software in order
      to install the patterns on the hardware.
   Options:
      -h, --help           This help.
      -i, --input          The name of the file containing the user's regular expressions.
                           Defaults to STDIN.
      -o, --output         The name of the file where the output will be placed.
                           Defaults to 'regex.compiled'.
      -W, --Werror         Warnings are errors.
      -w, --w              Suppress warning messages. Note: Ignored if --Werror used.
      -n, --nostrings      Do not include expression strings in output binary file.
      -b, --8572rev1.0     Compile for 8572 rev 1.0 silicon.
Example:
      pmrec --input my_expressions --output my_expressions.out
```

The following example shows the regex input file.

Regex Input File

```
#
# Regular expression file
#
# Look for login attempts
login /login/set=1 subset=0xffff tag=0x01
# Look for logouts
logout /^logout/m tag=0x02
```

7.4.6.2.4.3 Scanning API

When the patterns are compiled, they must be added in the Pattern Matcher hardware using the linker-loader. After patterns are configured into the PM hardware, the PM driver pattern scanning interfaces are used to search for patterns.

7.4.6.2.4.4 Scan Result

The data scan operation generates s scan result notification from the Pattern Matcher. The scan result contains zero or more match reports. The match report contains information, such as the tag of the regex that matched and where in the data the match was found.

NOTE

If the noreport option is specified in the regex, no match report is generated for that regex.

The type of report, simple or verbose, is configurable on a per-scan stream basis. For a reference, the simple match report is described in Table 184. Simple Match Report on page 876. Refer to applicable PowerQUICC processor reference manual for the description of the verbose reports.

Table 184. Simple Match Report

Byte Offset	Bits	Description
0	0	Set to 0
0	1-3	Indication of match type as either full match or inconclusive match. The values varies based on the configuration of the inconclusive mode selection. For the default mode the values are: 000 Complete match within a search window 001 Inconclusive match on the right side of the search window 010 inconclusive match on the left side of the search window 011 inconclusive match on both left and right side of the window
0	4-7	Set to 0x1
1	0-7	Number of bytes matched by the pattern (max value of 128)
2	0-47	The number of bytes scanned initially prior to the current work-unit.
8	0-31	The position of rightmost byte of the match relative to the work-unit scanned
12	0-31	A 32-bit tag assigned to the regex that matched

At the end of the match reports, there is an optional end-of-SUI report. The PM driver configuration parameter is available to enable or disable the end-of-SUI reports per system. It is enabled by default. The end of SUI report is 5 bytes in length as described in Table 185. End of SUI Report on page 877.

Table 185. End of SUI Report

Byte Offset	Bits	Description
0	0-7	Set to 0x80
1	0-31	Total new bytes scanned for this report. This is equal to bytes in the work-unit.

The scan result notification presented by the PM driver also indicates whether or not the result is truncated due to insufficient buffer space. This can occur for two reasons, as follows:

- The software supplied output scatter/gather buffer is not large enough to contain all of the produced output.
- The DMA Engine channel's free buffer list is exhausted while the DMA Engine is buffering output data.

NOTE

The scan application behavior should be considered carefully in handling the scan result that may be truncated. The truncated results imply that not all of the matches are reported in the result. Additionally, there may be a partial match report or a partial end of SUI report in the result due to truncation.

The scan result notification also indicates whether or not there are any exceptions encountered by the Pattern Matcher. The Pattern Matcher exception codes are described in the application PowerQUICC Processor Reference Manual. The "DXE instruction limit error" exception is worthy of a note. This error indicates that the Pattern Matcher has exceeded the maximum allowed test line executions per pattern. Almost no real regexes can exceed such limit, but it is theoretically possible. If such limit is reached, either rewrite or delete the regex causing this error. Alternatively, using PM driver software, it is possible to increase or disable the maximum allowed test line executions limit.

7.4.6.2.5 Stateful rules

The stateful rule engine (SRE), a component of the Pattern Matcher, detects and reports the occurrence of specified events within the data content of individual sessions. A stateful rule defines a state machine that executes actions when specific events occur. The SRE does not directly examine the content but instead reacts to events from the data examination engine (DXE). Typical DXE events are notifications of successfully matched patterns. The DXE supplies additional information on each event, such as match position and the captured data from the scanned data content. The stateful rule can use this information in its reactions to events.

As shown in the example state machine diagram in the Figure 139. Stateful Rule State Machine on page 878, a stateful rule can be used to detect and report occurrences of patterns in a particular sequence. For example, the detection of pattern P3 is reported, but only after an occurrence of pattern P1 or an occurrence of P1 followed by P2. The complex scenarios, such as the example in Figure 139. Stateful Rule State Machine on page 878, can be written using a combination of the regex and stateful rules.

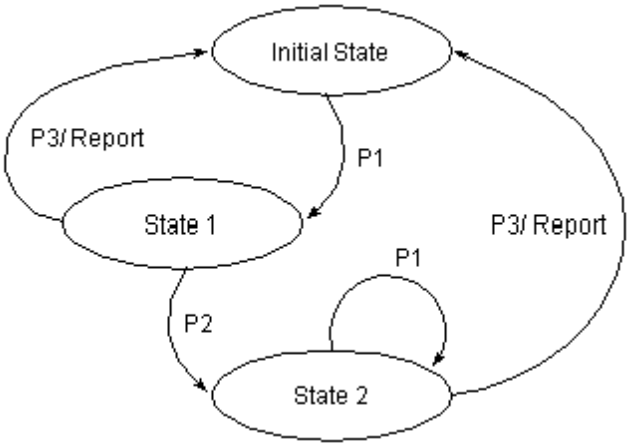

Figure 139. Stateful Rule State Machine

From a hardware perspective, a stateful rule is a set of reactions that is applied to a single meta-state record. Each reaction executes as a result of a specific data examination event, such as the confirmed detection of a pattern. The stateful rule compiler accepts the stateful rule and outputs binary data that represents SRE reactions. The binary output is used in an API call to the linker-loader to link the rule with appropriate patterns and to load the rule to the Pattern Matcher hardware. The expressions used in a stateful rule must be added through the linker-loader before the stateful rule is linked.

NOTE

For details on the stateful rule compiler, refer to *Pattern Matcher Compiler Software User's Guide*.

7.4.6.2.5.1 Stateful Rule Application Interface

The stateful rule compiler is provided as a C library and a binary executable program under Linux. The PM manager software can compile single or multiple rules stored in a file using either the library function or by invoking the compiler program.

7.4.6.2.5.1.1 Stateful Rule Compiler API

The stateful rule compiler header file is:

```
pm/user/include/pmsrc.h
```

For details on the compiler API, refer to the *Pattern Matcher 2.0 Software API Reference Manual*.

7.4.6.2.5.1.2 Command Line Options

The pmsrc is the executable program to compile rules from stdin or input file. See command help, as follows:

```
stateful_rule_compiler
   Description:
      The stateful rule compiler takes input from a file or STDIN and
      converts the user code to low level stateful rule instructions.
      The output must be passed to the linker/loader software in order
      to install the rules on the hardware.
   Options:
   -h, --help    This help.
   -i, --input <file>               The name of the file containing the users
                                    stateful rules.
                                    Defaults to STDIN.
   -o, --output <file>              The name of the file where the output will
                                    be placed.
                                    Defaults to 'stateful_rule.compiled'.
```

```
   -r, --report_pad <size>           Pad reports to this byte boundary.
                                     Default is none.
                                     Allowed values: 0 or 4
   -p, --string_pad <size>           Pad strings to this byte size.
                                     Default is 80.
                                     Allowed values: 0 < value <= 16384 (multiple of 2)
   -c, --report_constant_size <size> Constants within reports will be
                                     aligned to this byte boundary.
                                     Default is 4.
                                     Allowed values: 2, 4, 6, or 8
   -a, --allow_inconclusive          Allow inconclusive matching.
                                     Default is to disallow inconclusive matches.
   -W, --Werror                      Warnings are errors.
   -w, --w                           Suppress warning messages.Ignored if --Werror used.
Example:
      stateful_rule_compiler --input my_rules -output my_rules.out
```

The following example shows the stateful rule input file.

Stateful Rule Input File

STATEFUL_RULE: HTTP_Recognizer

RESET_STATE:

EVENT "http_request"

next_state AWAIT_response

STATE AWAIT_response:

EVENT "http_response"

report HTTP traffic observed

report {0x00000001}

next_state RESET_STATE

7.4.6.2.5.1.3 Scan Report

The scanning interface for stateful rules is no different than the interface for scanning regex. When data is scanned to search for regex, the stateful rules, if configured, are also executed for any matched regex. The stateful rule match report content is customized by the stateful rule reactions. It can be any number of bytes and values, depending on the reaction. Typically, rule writers select a certain stateful rule report header so that the scan applications can interpret the report consistently.

The report action discussed in "Actions" (Chapter 3, "Stateful Rules") found in *Pattern Matcher Compiler Software User's Guide* describes the optional header appended by the stateful rule compiler. Alternatively, stateful rule writers can use a report format that is identical to the Pattern Matcher simple report format.

7.4.6.2.6 Pattern management software

The pattern management software is built using the Pattern Matcher software libraries provided by NXP. The sample Pattern Matcher manager application (PMM), described in Pattern matcher manager (PMM) on page 882, is supplied by NXP as a Linux user-space application. The user can write their own PMM software or add PMM functionality to their existing management application. The high-level PMM application functions are as follows:

- Providing the user interface for adding, deleting, and querying source regexes and stateful rules
- Linking compiled regexes and compiled rules to create a PM hardware database
- Committing the PM hardware database to the PM hardware
- Monitoring PM hardware for any exceptions

The figure below shows the PMM application with NXP-supplied software components.

.

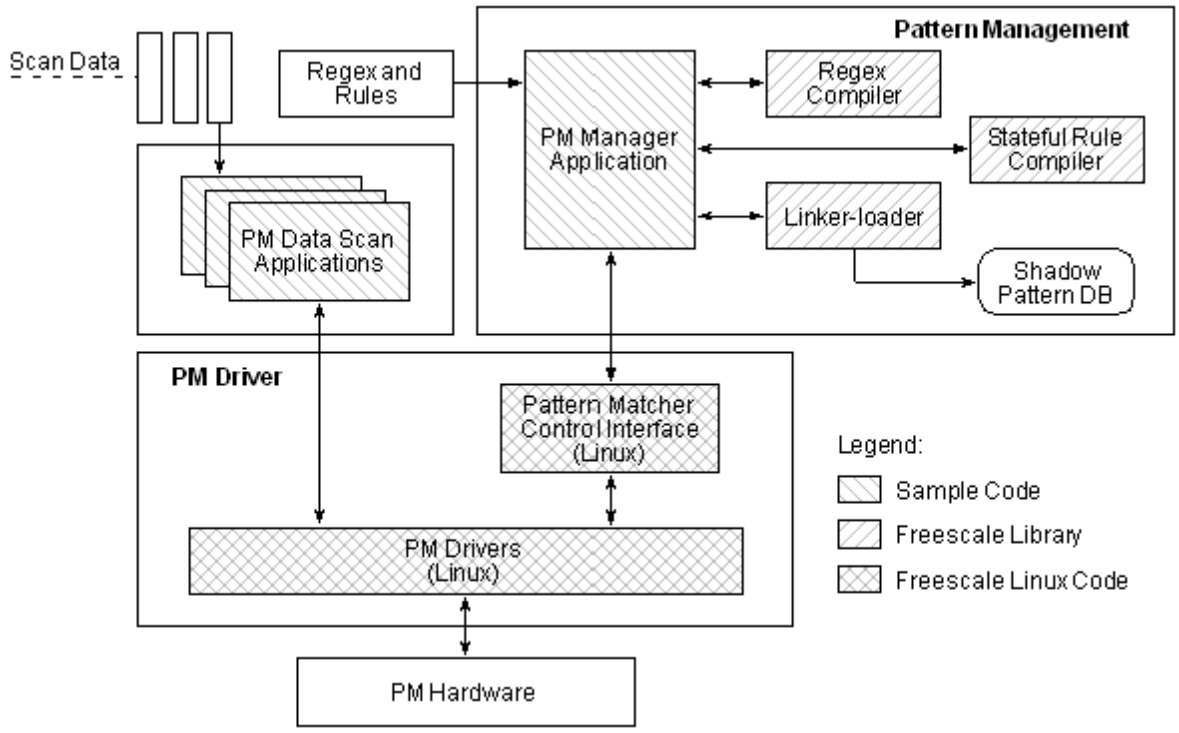

Figure 140. Locally-Managed PM Hardware

7.4.6.2.6.1 Compilers

7.4.6.2.6.2 Linker-loader for pattern management

The linker-loader, a sub-component of the pattern management software system, allows a user of the Pattern Matcher module to configure the hardware. You can use the linker-loader to configure new search patterns in the monitored data or to query the state of the Pattern Matcher hardware. The linker-loader manages the PM hardware tables, which are the trigger, confidence, and confirmation tables. These tables are described in the PowerQUICC processor reference manual for your product. The linker-loader is implemented as a library of functions performing different actions on the Pattern Matcher hardware. These functions are accessible through a well-defined API. In the Linux implementation, the linker-loader library is used by a user space application. Figure 141. Pattern matcher control data path on page 881 illustrates the PM control data path at a high level.

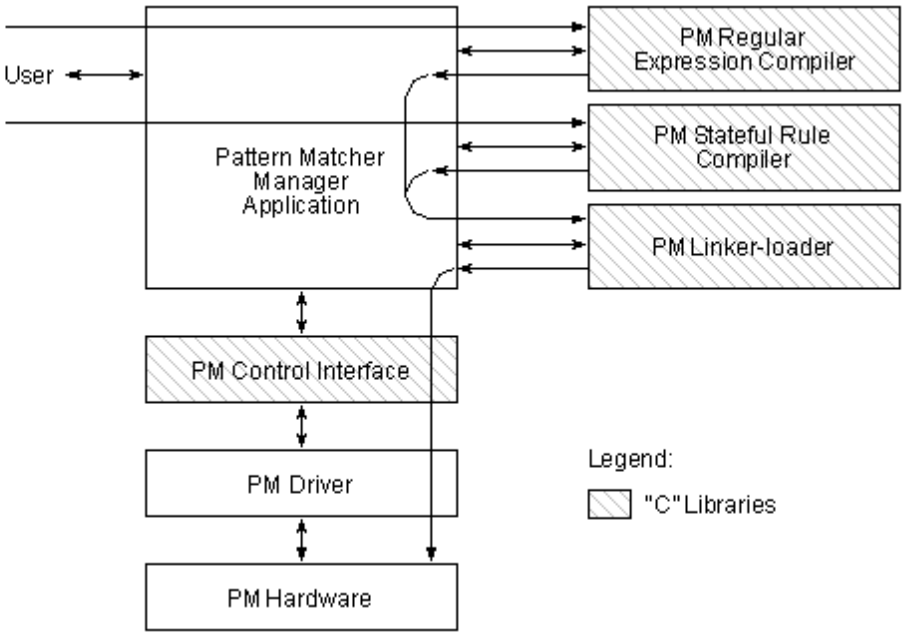

Figure 141. Pattern matcher control data path

The linker-loader library maintains a shadow database of the hardware tables that contains the Pattern Matcher hardware database plus additional information necessary for the software, such as all currently configured expressions and stateful rules. The hardware tables are highly compressed to save PM hardware internal memory usage. The linker-loader compresses the database as part of the commit phase.

The user interacting with the shadow database refers to expressions and rules by their names. The names do not have to be stored in the hardware database, and expressions are added or removed from the shadow database. Whenever the changes made to the shadow database are loaded to the PM hardware, it is reconfigured to reflect the state of the shadow database. The expressions and stateful rules can be incrementally deleted from or added to the Pattern Matcher hardware through the linker-loader library. When incremental changes are committed, the linker-loader does not load the entire shadow database to the hardware. Only incremental changes are loaded, thus limiting any outage while making incremental changes.

NOTE

Because the shadow database is embedded in the linker-loader library, take care to ensure data integrity through the Pattern Matcher manager (PMM) application. The memory used for the shadow database is not persistent. It is allocated in the context of the PMM application.

The API to the linker-loader library are described in the Pattern Matcher 2.0 Software API Reference Manual.

7.4.6.2.6.2.1 Linker-Loader API

The linker-loader is provided as a C library. The pattern management software can include the linker-loader library to link and load patterns and rules into the Pattern Matcher hardware. The linker-loader API is a functional API, and each API function runs to completion. In other words, the requested operation is completed and the results of the operation are available when the invoked function returns. The API functions are divided into the following categories, all of which are described in the *Pattern Matcher 2.0 Software API Reference Manual*:

- Initialization primitives
- Expression related primitives
- Stateful rule related primitives
- Debug primitives

Note that the linker-loader library does not interact directly with the Pattern Matcher control interface. Instead, the library sends Pattern Matcher control messages through functions provided by the PMM application. The PMM registers functions

(Refer to the PM loader agent functions in the Pattern Matcher 2.0 Software API Reference Manual). That is, it sends PM control messages to the Pattern Matcher control interface indirectly using callback functions registered by the PMM. The callback functions provide you the flexibility to implement the communication pipe between the linker-loader and the PM control interface that is most appropriate for the pattern management system. The PM software architecture allows the PMM application to be split into three parts, one that compiles regex and rules, another that interacts with the linker-loader, and yet another that interacts with the Pattern Matcher control interface.

7.4.6.2.6.3 Pattern matcher manager (PMM)

The sample Pattern matcher manager (PMM) is a NXP application implemented as a Linux user-space process. The PMM application provides a simple command-based interface to compile, link, and load expressions and stateful rules. It runs under Linux 2.6 within the same processor system (host) on which the PM hardware resides. This section describes the key commands available through the PMM command-line interface. For more information, refer to the PMM help text.

The PMCC/PMCD application is an alternative application that provide the same features of PMM. PMCD runs as a daemon(memory resident program), and PMCC runs as a client with a command-line interface identical to PMM. To use PMCC/PMCD, run “pmcd” first, then run “pmcc”.

The difference between them is PMM is a standalone application without any persistent datapath that spans multiple invocations of PMM. It starts with an empty expression and rule database, so a new session of PMM cannot add or delete items already committed to PME by a previous PMM session. With PMCC/PMCD, PMCD will keep the database in memory. As long as PMCD is running, the PME shadow database remains persistent. With PMCD running, any new session of PMCC can add or delete items added by previous PMCC sessions.

It is not recommended to run PMM and PMCD, or multiple session of them at the same time. Since each session of PMM or PMCD assume the sole controller role of the PME, the PME database corruption can occur with multiple controllers.

7.4.6.2.6.3.1 Adding Regexes and Rules

The add command is used to add regex or rules to the linker-loader database, as shown in the Adding Regexes and Rules example that follows. The regex(es) or rule(s) to be added can be in the source format (yet to be compiled), or they can be in the binary format (already compiled). If the regex is presented in the source format, it is first compiled. The compilation must finish successfully before the regex is added to the linker-loader database. If the regex or rule is presented in the binary format, it is added to the linker-loader database without preprocessing. Clearly, adding regexes or rules in the binary format is faster.

When source formatted regexes or rules are added from a file, the compiled results can be stored in a binary formatted file. Specify the optional binary keyword followed by a file name.

Adding Regexes and Rules

```
add regex file source myexpressions.src

add regex name e1 exp /matchme/tag=0x01

add regex file binary regexes.bin

add rule file source /tmp/rules.src binary /tmp/rules.bin
```

7.4.6.2.6.3.2 Committing Added Regexes and Rules

The commit command is used to configure the Pattern Matcher hardware with the regexes and rules that are added to the system. The first, or initial, invocation of the commit command results in an optimal distribution of the pattern records in the PM hardware. Such optimization boosts the performance of the PM hardware. The second and subsequent, or incremental, invocations of the commit command do not perform such optimization. Depending on a particular set of regexes in the database, the regexes that are added during incremental commits, and number of incremental commits, this may not pose

any performance issue. However, in general the pattern management system design should use the first commit command with a regex and rule database that is as close to its final state as possible. With many incremental commits, over time the database may be not be as optimum as it can be with an initial commit.

NOTE

As part of the initial commit, the PM hardware database is reset. That is, all previously committed patterns and rules are invalidated.

7.4.6.2.6.3.3 Deleting Regexes and Rules

The delete command is used to delete previously added expressions or rules. One or more expressions or rules can be deleted with one command, as shown in the following example:

```
delete regex all

delete regex name p1
```

The number of expression or rule names accepted by the command is limited by the number of arguments allowed in a CLI command. When a request is made to delete all items of a given kind and the operation completes with an error, only the items that can be deleted are deleted. For example, when all the expressions are deleted, the expressions that are part of rules are not deleted.

7.4.6.2.6.3.4 Showing Regexes and Rules

The show command can be used to display the fields of the records added to the system-for example, the expression or rule records. The command can also be used to display version information for some software components, such as the linker-loader. An example of showing regexes and rules is as follows:

```
show regex all
```

7.4.6.2.6.3.5 Other Commands

There are other useful commands within PMM to set, read, and reset various Pattern Matcher attributes.

7.4.6.2.6.3.6 PM Statistics

The Pattern Matcher hardware offers a variety of statistics counters for debugging and analyzing pattern scanning functions. The statistics counters are read reset; that is, they are reset to zero when software reads them. Also, if software does not read the counters frequently, they risk rollover. The statistics offers are from all three PME engies, KES, DXE, and SRE.

The PM statistics collection is done via PME kernel drivers. The counters are queried from the driver interface. The PMM sample applicaion provides means to read statistics from driver.

The following shows the output of the statistics query command from the sample PMM application.

Output of Statistics Query Command

```
pmm> The PM H/W Statistics:                Current       Previous          Delta

          PM Input Bytes           (KES) :          50000              0          50000

          PM Output Report Bytes   (SRE) :         283155              0         283155

          PM Trigger 1B Hits       (KES) :              0              0              0

          PM Trigger 2B Hits       (KES) :              0              0              0

          PM Trigger Variable Hits (KES) :              0              0              0
```

```
PM Trigger Special Hits  (KES) :          10786              0          10786

PM Confidence Stage Hits (KES) :          10786              0          10786

PM Matches               (DXE) :           5345              0           5345

PM SR Execution by DXE   (SRE) :           5345              0           5345

PM SR Execution by SUI   (SRE) :          10659              0          10659

PM SUI With Matches      (DXE) :           5285              0           5285

PM SUI With Reports      (SRE) :          10664              0          10664

PM Input SUIs            (KES) :          10664              0          10664

PM Matches with DRCC     (DXE) :          10786              0          10786
```

7.4.6.2.6.4 Distributed Pattern Management Software

The PMM application can run directly on the host processor with the PM hardware (as a local PMM) or it can be a implemented as a distributed application with only a small part running directly on the host processor. Pattern management software on page 879 depicts the PMM application implemented as a local PMM with a single user-space process and all user interface functionality linked together with the compile, linker-loader, and PMCI libraries. In this local case, the PMM application and PM hardware are collocated on the same system. However, a more distributed PMM application can be designed; that is, expressions and rules can be compiled and linked on a different system from where the PM hardware resides. Running the PMM in a distributed environment can be attractive in low-cost embedded systems without sufficient resources to run the compilers and the linker-loader. Also, it may be desirable to centralize the compilation and linking functions to one location or system and then distribute the compiled and linked configuration to a possibly larger number of pattern scanning systems. There are several ways the PMM functions can be distributed between two or more hosts. Figure 142. Distributed PMM on page 885 shows a design where expressions and stateful rules are compiled on one host, linked on another host, and finally loaded to PM hardware from the processor on the target PM hardware.

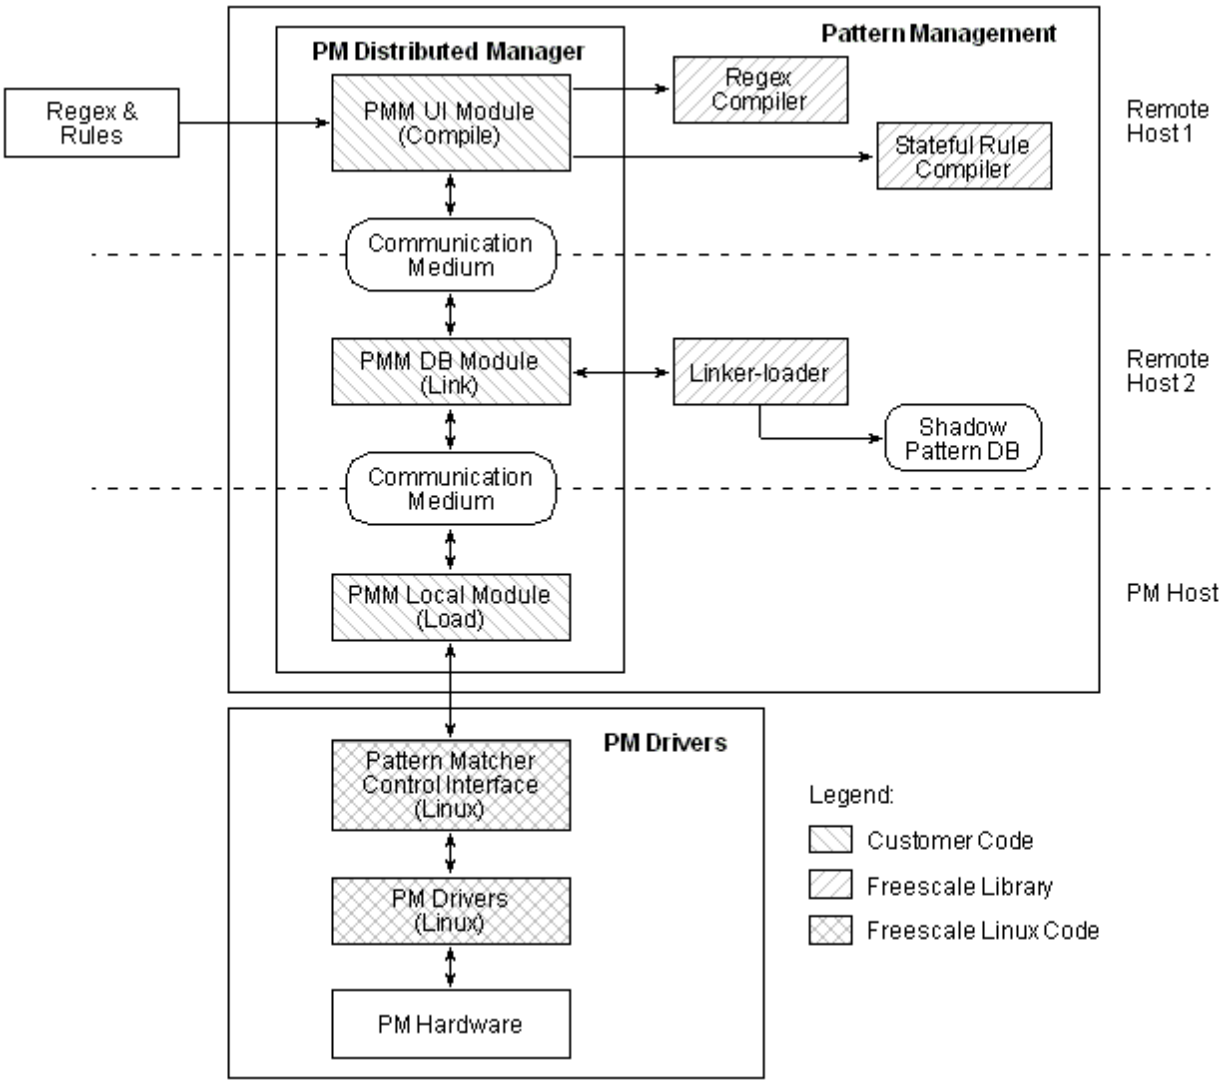

Figure 142. Distributed PMM

In a distributed PMM application, the different parts of the PMM application must communicate with each other using communication mechanisms specific to each PMM application design. The networking and communication details are abstracted away from the Pattern Matcher software libraries through appropriate API functions. This abstraction gives the PMM application the flexibility to implement the communication mechanisms appropriate for it, with the following constraints:

- The PM control messages from linker-loader must be reliably delivered to the PMCI, and the sequence of the sent messages must be preserved.
- Communication failures must be reported through appropriate error return codes from the send and receive functions.

7.4.6.2.7 Pattern Matcher driver software

The Pattern Matcher driver for Linux provides applications an interface for configuring and using the Pattern Matcher.

The PME driver software includes a Linux kernel driver and a PME driver library for USDPAA. The driver also provides an ioctl-based Linux user-space interface. The drivers' provide interfaces in Linux kernel and user-space for PME configuration, database setup, and data scanning. For USDPAA, the drivers provide a PME data scanning interface only.

Typical data scanning applications will only use the PME scanning and statistics interfaces. The configuration and PME database setup interfaces would typically be used during device initialization by Pattern Management software like the user-space Pattern Matcher Manager (PMM).

The following section describes the high level functionality of the PME driver software. Details of the driver APIs are available in the PME 2.0 Software API Reference Manual.

The PME2.0 Driver software components are shown in the following diagram.

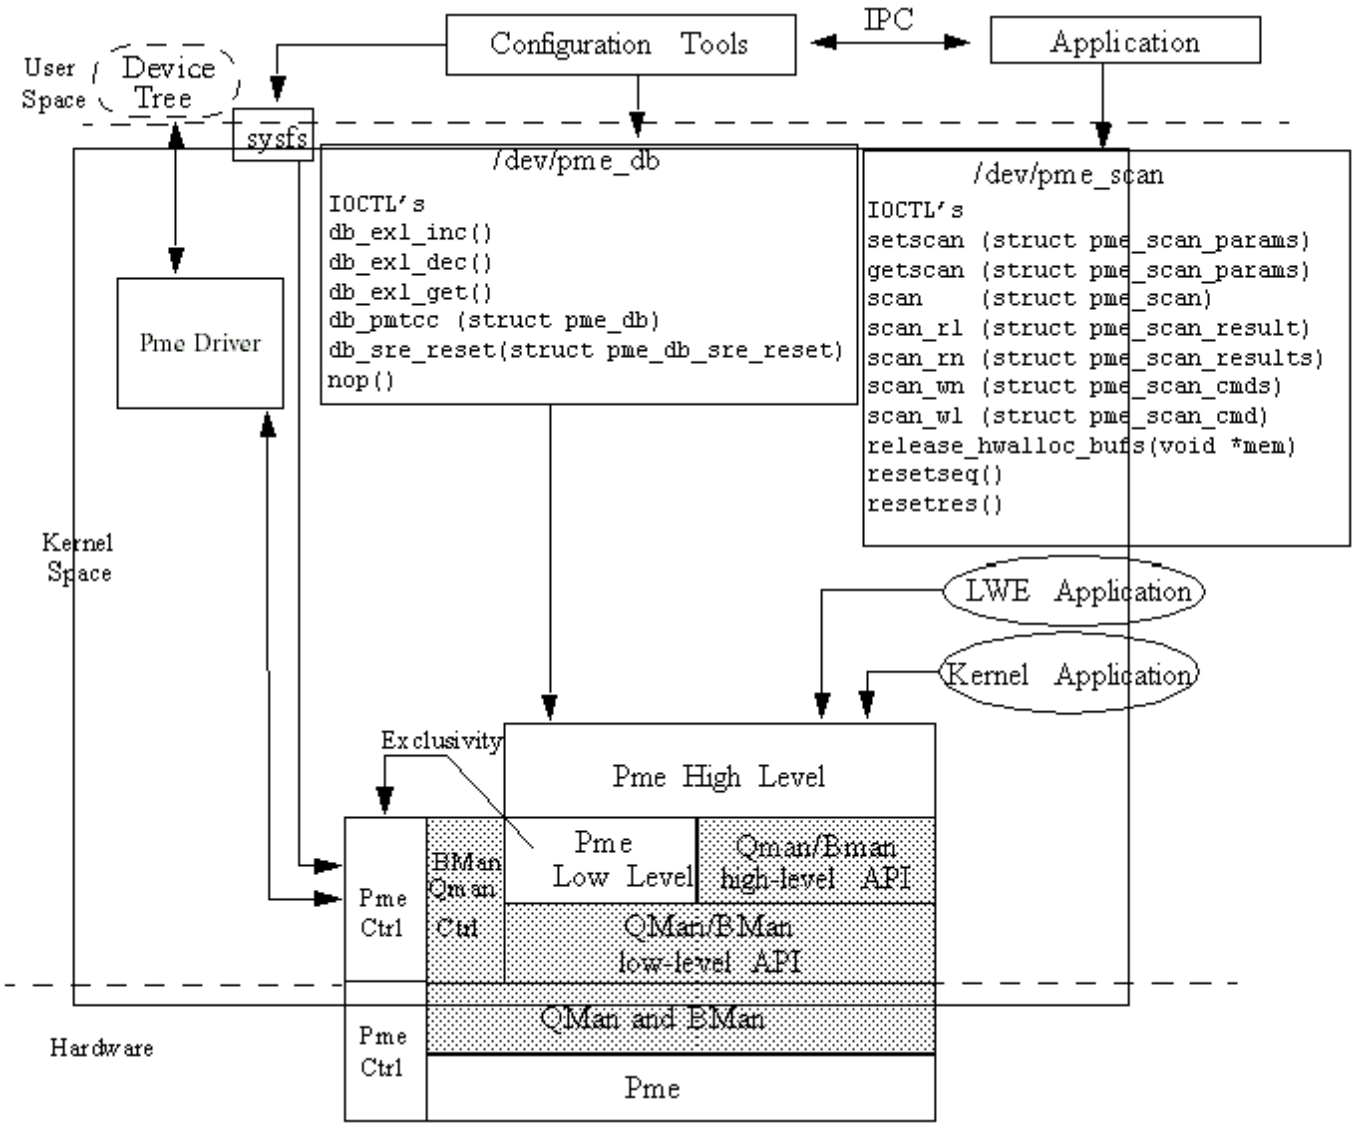

Figure 143. PME driver components

7.4.6.2.7.1 PME configuration interface

The PME configuration interface is an encapsulation of the PME CCSR register space and the global/error interrupt source. This is available to applications running on a control-plane operating system, the hypervisor and/or a boot manager. Non control-plane applications do not have access to the configuration interface.

7.4.6.2.7.1.1 Externally Configured Settings

The U-Boot software is responsible for configuring the PID to LIODN mapping registers as well as the PME's LIODNR register which is used when the PME accesses its private memory.

7.4.6.2.7.1.2 PME device-tree node

The PME device tree node represents the PME device and its CCSR configuration space. When a Linux kernel has PME support built in, it will react to this device tree node by configuring and managing the PME device.

The device-tree node sits within the CCSR node ("soc") and is of the following form:

```
soc@fe000000 {
[...]
pme: pme@316000 {
compatible = "fsl,p4080-pme", "fsl,pme";
reg = <0x316000 0x10000>;
fsl,pme-pdsr = <0x0 0x20000000 0x0 0x01000000>
fsl,pme-sre = <0x0 0x30000000 0x0 0x01000000>
};
[...]
};
```

7.4.6.2.7.1.2.1 fsl,pme-pdsr

This property specifies the start location and size of the Pattern Description and Stateful Rule Table in system memory. The table base address must be aligned to a natural 128-byte address boundary. The maximum size of the table is 128 Mbytes. The current driver implementation allows this memory resource to be specified via the 'fsl,pme-pdsr' device-tree property, or by resorting to a default allocation of contiguous memory early during kernel boot. The 'fsl,pme-pdsr' property specifies a 2-tuple of address and size (address is optional), specifying the physical address range. These elements are expressed as 64-bit values, so take two cells each;

```
fsl,pme-pdsr = <0x0 0x20000000 0x0 0x01000000>;
```

Optionally, only the size can be specified and the kernel will try to allocate the contiguous memory during boot time.

```
fsl,pme-pdsr = <0x0 0x100000>
```

If the hypervisor is in use, this address range is "guest physical". If the given memory range falls within the range used by the Linux OS, it will attempt to reserve the range against use by the OS.

7.4.6.2.7.1.2.2 fsl,pme-sre

This property specifies the start location and size of the SRE Context Table in system memory. The table's base address must be aligned to a natural 32-byte address boundary. The maximum size of the table is 4 Gbytes. The current driver implementation allows this memory resource to be specified via the 'fsl,pme-sre' device-tree property, or by resorting to a default allocation of contiguous memory early during kernel boot. The 'fsl,pme-sre' property specifies a 2-tuple of address and size (address is optional), specifying the physical address range. These elements are expressed as 64-bit values, so take two cells each;

```
        fsl,pme-sre = <0x0 0x20000000 0x0 0x01000000>;
```

Optionally, only the size can be specified and the kernel will try to allocate the contiguous memory during boot time.

```
fsl,pme-sre = <0x0 0x300000>;
```

If the hypervisor is in use, this address range is "guest physical". If the given memory range falls within the range used by the Linux OS, it will attempt to reserve the range against use by the OS.

7.4.6.2.7.2 PME user space interface

The PME user space interfaces comprises the following:

- sysfs
- /dev/pme_db
- /dev/pme_scan

7.4.6.2.7.2.1 sysfs

The *sysfs* interface provides access to PME CCSR space. It is used to control global configuration of PME device parameters and provides an interface for accessing PME statistics. The path to the driver attributes is:

/sys/bus/cf_platform/drivers/cf-fsl-pme

The */dev/pme_db* device is used to send Pme pattern matcher database configuration requests via the Pme's Exclusive Frame Queue Control (EFQC) mechanism. This device requires root permissions. The EFQC exclusivity is referenced counted, so by default it is asserted on-demand and released when the processing is done for the context. However, exclusivity can be maintained by using the db_exl_inc, and db_exl_dec ioctls, which provide supplementary increments and decrements of the reference count. These operations are performed from user space using the following ioctl system calls.

- increment reference count
- decrement reference count
- get the current reference count
- send database request and receive response (synchronous)
- send a nop Pme command

The */dev/pme_scan* device is used to interface with the PME device via the QMan interface. This interface can only be used for scanning operations. The device can be used to perform synchronous (the calling thread is blocked until an operation's completion) scans or asynchronous (once an operation has begun, the calling thread is able to perform other processing but needs to query the completion of the operation later) scans.

7.4.6.2.7.2.2 Pme Scan

The /dev/pme_scan device is used to interface with the Pme device via the QMan interface. This interface can only be used for scanning operations. The device can be used to perform synchronous (the calling thread is blocked until an operation's completion) scans via the scan() api or asynchronous (once an operation has begun, the calling thread is able to perform other processing but needs to query the completion of the operation later) scans via the scan_w[1n] and scan_r[1n] APIs. Only flow mode scanning requests are supported by this device. These operations are performed from user space using the ioctl system calls specified below.

- set parameters for scanning operations
- get (retrieve) currently set scanning operation parameters
- reset sequence number
- reset residue
- do single synchronous scan
- send single asynchronous scan command
- send multiple asynchronous scan commands
- get single synchronous scan response
- get multiple synchronous scan responses
- release bman acquired buffers to bman: release_hwalloc_bufs

The settable and retrievable scan parameters are grouped as follows:

- Residue attribute
  - residue enable/disable
  - current number of byte in the residue (read only)
- SRE attributes
  - session_id
  - report verbosity
  - end of sui report enabled/disbabled
- DXE attributes
  - compare limit
  - match limit
- Pattern attributes
  - pattern set
  - pattern subset

7.4.6.2.7.3 PME Linux kernel, USDPAA driver interface

The PME kernel/USDPAA driver provides a high and low level interface for PME users.

7.4.6.2.7.3.1 PME High-level Driver API

The PME high-level APIs provide a call-back based interface to the PME. The driver provides APIs to manage flow context and issue PMTCC and scan commands. The high-level driver internally co-ordinates the commands to PME and corresponding results. The user-specified call-back functions are called with results from PME. The driver also returns the user-specified context information provided by the application when invoking the call-back function. This saves the applications from maintaining a mapping of active scan requests and their related contexts.

The high-level interface provides the following:

- pme context management. Management operations include: initialize, destroy, disable, enable, queury_state, reconfigure. The pme context is comprised of:
  - input/output frame queues
  - flow context record (when in flow mode)
  - frame queues scheduling levels
  - exclusivity state
  - stashing control of frame queue context
  - residue (optional when in flow mode)
- manage mux/demux of scans and pmtcc commands.
- pme input/output qman frame queue setup, modification and teardown.
- registration of user provided scan and pmtcc result callbacks
- statistics management

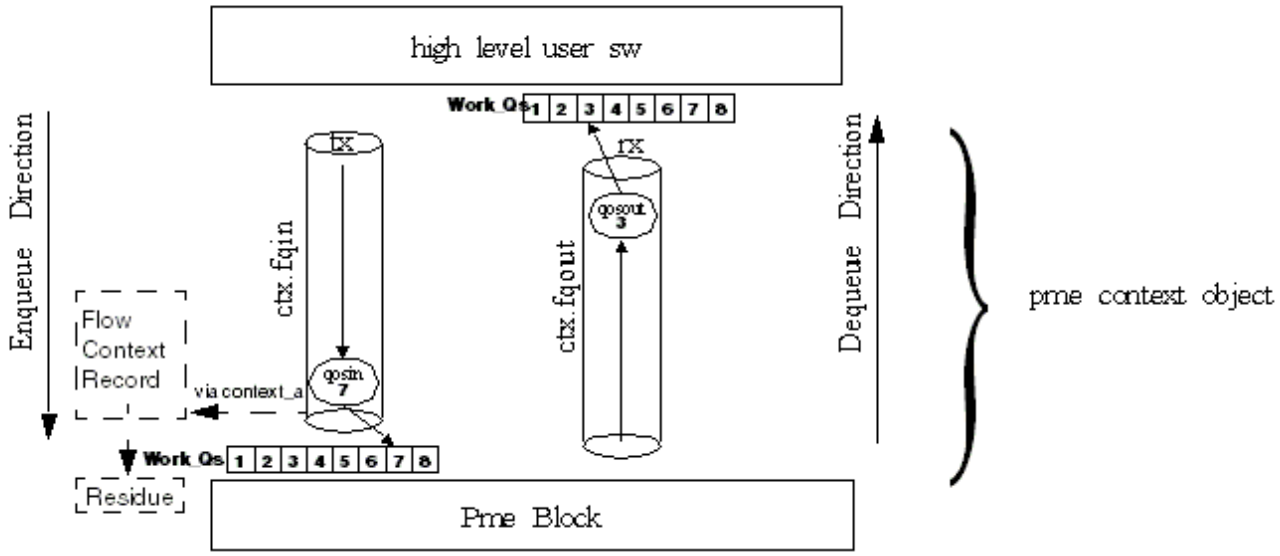

Figure 144. Pme Context Object

7.4.6.2.7.3.1.1 PME Context

The Pme high level layer is represented by a pme_context object. This object allows a user to communicate with the Pme device using the encapsulated QMan interface via two driver allocated frame queues.

The PME context is a modal object which can be initialized in one of the following modes:

- scan_flow: This mode permits the user to send *scan, nop, flow context write and flow context* read PME requests. Upon enabling the context the input frame queue is placed in a scheduled state
- scan_direct: This mode permits the user to send *scan and nop* PME requests. Upon enabling the context the input frame queue is placed in a scheduled state

The following PME Context modes exist for use by the user-space Pattern Matcher Management software. They can also be used by applications making dynamic changes to the PME database or for exclusive scan operations..

- pmtcc: In this mode the context is placed in *exclusive* mode. The input (tx) frame queue is left in an unscheduled (parked) state. Only *pmtcc and nop* pme requests are permitted. This mode is only available if the api is built with control functionality and if the operating system has access to the PME's CCSR map.
- scan_exclusive_direct: This mode permits the user to send *scan and nop* PME requests. Upon enabling the context the input frame queue is left in an unscheduled (parked) state. This mode is only available if the api is built with control functionality and if the operating system has access to the PME's CCSR map.
- scan_exclusive_flow: This mode permits the user to send *scan, nop, flow context write and flow context read* PME requests. Upon enabling the context the input frame queue is left in an unscheduled (parked) state. This mode is only available if the api is built with control functionality and if the operating system has access to the PME's CCSR map

Once initialized, a pme_context object cannot change modes. If a different mode is required, a new context must be allocated/ initialized. The following diagram depicts the pme_context state diagram. Depending on the mode, not all possible states are attainable.

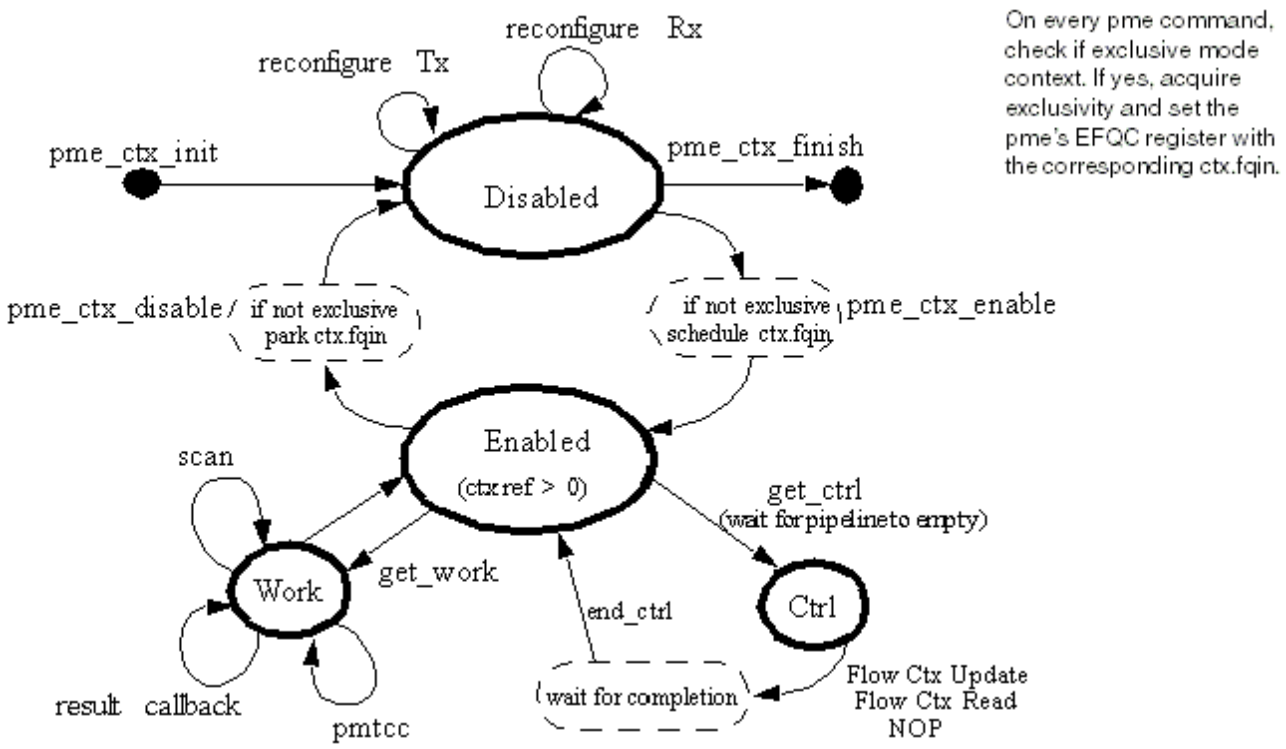

Figure 145. PME Context State Diagram

The PME high-level APIs use the QMan high-level APIs. As such, the driver maintains control over certain fields, like the "contextB" field in the frame descriptor, and these are not available for direct application use. Applications can specify their own per-command context information. This is done by embedding the per-command token field in a larger structure which is returned back in the command result.

7.4.6.2.7.3.1.2 Typical Scan Operation Flow

Typical steps required to setup and perform scanning operations:

- Initialize a pme context via pme_ctx_init().
- Enable the ctx via pme_ctx_enable()
- If operating in flow pme, setup the flow context using pme_sw_flow_new(), setting the appropriate fields and then invoking pme_ctx_ctrl_update_flow(). The flow is released on teardown via pme_sw_flow_free().
- The context is ready for scanning operations. Build a frame description object and invoke the scan operation via pme_ctx_scan().
- Upon receiving the result from the PME, the callback function specified in the pme context object will be invoked in interrupt context in the Linux kernel. For USDPAA, the callback is invoked in the application context.
- Process the resulting output frame description object passed into the callback function.
- Once scanning is done, disable the context via pme_ctx_disable()
- Release all resources in the context via pme_ctx_finish().

7.4.6.2.7.3.1.3 Statistics Management

The high-level driver also provides an interface to read PME statistics counters. The values returned are software accumulated versions of the counter. The driver maintains the statistic counters by periodic (user-programmable) accesses to the read-

reset hardware counters. The access have to be frequent enough to prevent the counters from rolling over. The accumulated statistics are available to the user space application via the sysfs interface.

7.4.6.2.7.3.2 PME Low-level Driver API

The low level API is a hardware abstraction layer (HAL) where users' have complete control over structures used to communicate with the PME. This includes initialization of the input and output frame queues and the ownership for setting up the frame descriptor including command codes and the "contextB" field. The low level API is used by the high level driver for communicating with the PME.

The low-level interface provides the following;

- allocation/deallocation of residue data
- allocation/deallocation of hw flow context data
- allocation/deallocation of sw flow context data
- pme frame queue command/status abstraction
- frame descriptor setup for following pme commands: *nop, flow context write, flow context read, pmtcc* and *scan*.

The low level PME driver APIs do not encapsulate QMan portal interactions. Users are assumed to be using the low level PME APIs to have control on their interaction with the devices - including the use of QMan and BMan low level APIs.

7.4.6.2.7.4 Driver Build Configuration

The PME driver is built using the standard build process. The build configuration options and default values are specified in: <linux directory>/drivers/staging/fsl_pme2/Kconfig.

7.4.6.2.8 Data Scan Sample Application

The data scan sample application covered in this chapter are as follows:

- *Pattern matcher scan demo application*. A command line Linux user-space application that scans data strings given on a command line parameter or data from a file.
- *Snort*. An open-source network intrusion prevention and detection system using a rule-driven language, which combines the benefits of signature, protocol, and anomaly-based inspection methods.

7.4.6.2.8.1 Pattern Matcher Scan Demo Application (pm_scan_demo)

```
pm_scan_demo
```

is a sample command line Linux user-space application that scans data strings given on a command line parameter or data from a file. The data is scanned for patterns that are preloaded to the Pattern Matcher hardware database by the Pattern Matcher manager application (PMM). The pattern match results are displayed to standard output. This application demonstrates the use of Pattern Matcher hardware assist to scan for complex regexes and stateful rules.

7.4.6.2.8.1.1 Usage

The **pm_scan_demo** command line parameters are described in the help text shown here. The subsections provide simple examples to demonstrate the use of these parameters and how they apply to the Pattern Matcher features.

```
# pm_scan_demo --help
Usage:
        pm_scan_demo [<options>]
Description:
        A sample application that scans user entered string or file, and
        prints the reported matches.
Options:
  -s, --str <string>
        Scan a string, passthru mode only.
```

```
        May use \xNN to represent a byte in hexidecimal.
  -f, --file <filename>
        Scan the content of a file.
        Multiple strings and files may be scanned sequentially as
        separate scan units by repeating the -f and -s options.
  -r, --residue
        Enable residue feature.
 --set <num>
        Expression set to scan against.  Default = 0.
  --subset <num>
        Expression subset-mask to scan against.  Default = 0xffff.
  --session <num>
        Stateful rule session id number.  Default = 1.
  --verbose
        Enable verbose report.  HW will report more data per match.
  --silent
        Disable printing of match report.
  --detail
        Shows scan data covered by matches. Requires ANSI/VT100 terminal.
Example:
        pm_scan_demo -s abcd -s defg --residue --detail
```

7.4.6.2.8.1.1.1 Simple Literal String Scan

The 'pm_scan_demo: Simple Scan of Literal Pattern' example that follows uses the PMM application to add a simple regex to scan for the string

```
abcd
```

and uses the

```
pm_scan_demo
```

application to demonstrate the match result. Notice that the match result, highlighted in bold, shows an offset of 0x0:8, which is

```
workunit_offset_within_stream:match_offset_within_workunit
```

Also, notice that the

```
match_offset
```

is at the end of the match (not the start of the match), which is an offset of 8 in this example.

pm_scan_demo: Simple Scan of Literal Pattern

```
# cd <path of the pattern matcher applications>
# <path>pmm
Successfully created the PMM DB.
pmm> add regex name p1 exp /abcd/i tag=0x100
Successfully compiled the expression.
Successfully added one regex to the PM DB with handle 0.
Command execution time: 00:00:00 [hour:min:sec].
pmm>
pmm> show exp all
name=p1           expression="/abcd/"   options="i = 1, m = 0, s = 0, report = 1, tag
= 0x00000100"
total number of expressions = 1
total number of rules       = 0
pmm> commit
```

```
Successfully committed changes made to the data base of expressions.
Command execution time: 00:00:00 [hour:min:sec].
# <path>pm_scan_demo -s "xyz abcd xyz"
#00: Scanning 12 bytes.
match(0x01): len=0x04 offset=0x000000000000:00000008 tag=0x00000100
Number of successful scan:    1
Number of full match:         1
Number of inconclusive match: 0
Number of rule report:        0
```

7.4.6.2.8.1.1.2 Use of Residue

The 'pm_scan_demo: Scan of Literal Pattern that Span Multiple Work-Units' example that follows uses the PMM application to add a simple regex to scan for the string abcd and uses the pm_scan_demo application to demonstrate detection of patterns that cross work units. Notice that the second match result, highlighted in bold letters, shows two matches. The first match crosses between the two work units.

pm_scan_demo: Scan of Literal Pattern that Span Multiple Work-Units

```
# pmm
Successfully created the PMM DB.
pmm> add regex name p1 exp /abcd/i set=0 tag=0x100
Successfully compiled the expression.
Successfully added one regex to the PM DB with handle 0.
Command execution time: 00:00:00 [hour:min:sec].
pmm> commit

```

7.4.6.2.8.1.2 Source Code Description

The demo application source code is in the pm_scan_demo.c file. The basic operations of the application are as follows:

1. Read the input string from the command line or the content of the specified file into memory.

   The entire file is read into memory, so the file size is limited by the available memory.

2. Open the Pattern Matcher scanner device using the PM device driver APIs:

   ```
   scan_fd = open(PME_DEV_SCAN_PATH, O_RDONLY)
   ```

3. Initialize the scanner device parameters such as set, subset, session ID in a local scanner_params structure and then configure the scanner device with these parameters.

   ```
   ioctl(scan_fd, PMEIO_SETSCAN, &scanner_params)
   ```

4. Set up a structure to pass scan data, size of scan data, and other required parameters for the scan operation. The structure type is struct pme_scan. Then call the driver to execute the scan operation.

   ```
   ioctl(scan_fd, PMEIO_SCAN, &pm_oper)
   ```

5. After the scan operation, the result of the scan such as match report buffer length and error flags are also returned in members of the struct pme_scan structure.

6. This demo uses BMan buffers to receive match reports. These free buffers should be freed with this call:

   ```
   ioctl(scan_fd, PMEIO_RELEASE_BUFS, &pme_oper.result.output.data)
   ```

7.4.6.2.9 Software components

The software modules that accompany the Pattern Matcher 2.0 hardware are both production quality and sample software modules. The production and sample quality code is defined as follows.

Production-quality code:

- Completeness; includes necessary functionality to make it usable in a production environment
- Robustness; includes all necessary recovery functionality
- Fully validated/verified
- Supported

Sample code:

- Software example (or template) to help customers/partners to implement their own versions
- May or may not be of production quality but not often viewed as production quality
- Sometimes viewed as bare-bones (does the minimum functions)

7.4.6.2.9.1 Software Modules

The PM Software Modules table lists software version 2.0 software modules with packaging information and the supported platforms for each module.

PM Software Modules

Module	Packaging	OS	Platform Supported
Regex Compiler	source code	Linux	QorIQ™, x86
Stateful Rule Compiler	source code	Linux	QorIQ™ x86
Linker-Loader	source code	Linux	QorIQ™
PM Control Interface	source code	Linux	QorIQ™
PM Driver	Kernel patches (source code) USDPAA Library (source code)	Linux	QorIQ™

7.4.6.2.9.2 Sample Code

Below, the Pattern Matcher Sample Code table lists software version 2.0 sample code modules.

Pattern Matcher Sample Code

Module	Packaging	OS	Platform Supported
PM Manager (PMM)	Executable and source code	Linux	QorIQ™
Pattern scanner application (PM Scan Demo)	Executable and source code	Linux	QorIQ™
pmcd	Executable and source code	Linux	QorIQ™
pmcc	Executable and source code	Linux	QorIQ™

7.4.6.2.10 Pattern Matcher FAQ

7.4.6.2.10.1 What is it and why is it needed?

The Pattern Matcher Engine (PME, or sometimes just PM) offloads processing from the PowerQUICC core(s) by performing, in hardware, regular expression pattern matching of data against patterns stored in the pattern database. This type of unanchored searching of patterns is processing-intensive and is difficult to perform in software at multi-gigabit rates. Even in sub-gigabit rate deployments, the offload provided by the PME can free the core(s) to perform more complex, content-oriented tasks.

7.4.6.2.10.2 What is a regular expression?

A regular expression (or regex) is a description of a set of strings, written using a powerful and flexible notation/syntax. The expression may contain literal characters and meta-characters, supporting wildcards, grouping, quantification and alternation. Matching a regular expression refers to comparing the arrangement of symbols described by the regular expression against an input string, usually incoming network data.

7.4.6.2.10.3 What types of regular expressions are supported by the supplied compiler?

The first supplied compiler supports a major subset of the PERL regular expression syntax, as well as capabilities beyond that provided by PERL.

7.4.6.2.10.4 What is a pattern?

A pattern is an arrangement of symbols and instructions used by the PME to evaluate against an input string or SUI. It is the hardware representation of a regular expression.

7.4.6.2.10.5 What is an SUI?

A string under inspection (SUI) refers to the string of bytes to be searched by the PME. The PME evaluates this input string against patterns in the pattern database. Often, but not necessarily, the SUI refers to incoming network data.

7.4.6.2.10.6 Why is regular expression matching difficult to perform at multi-gigabit rates in software?

In order to match expressions against the incoming data, the incoming data must be scanned byte by byte and evaluated against the thousands of expressions in the database. The expressions not only contain literal characters, but may contain wildcards, repeats, alternations, and other regular expression constructs, where each expression may represent an almost infinite number of strings. Regular expression matching, therefore, requires not only matching of literal characters, but also what is known as regular expression evaluation.

7.4.6.2.10.7 What applications require pattern matching?

Pattern matching of application layer protocol signatures forms the basis for high-performance application-aware networking. It is used in various content processing and security applications such as intrusion detection/prevention, anti-virus, anti-spam, and other applications where the content of the packet or stream needs to be examined. Regular expressions are gaining widespread adoption over literal string matching for these types of applications because of their expressive power and flexibility to describe complex patterns.

7.4.6.2.10.8 Can the PME scan packet headers as well as packet content?

Not easily (nor is this usually required to be performed in hardware). The PME was designed for the more difficult task of scanning character-based content for unanchored matches. Scanning packet headers requires bit-level granularity, making it impractical for the byte-based PME to perform. However, since packet headers are typically anchored, it is often reasonable to delegate this task to a software pre-processing stage.

7.4.6.2.10.9 Can the PME detect patterns across packet boundaries?

Yes. The PME uses the residue method to detect cross-packet patterns. The residue method is stateless and therefore can scale as the number of patterns grow. There is no hard limit on how many packets the pattern may span (other than the limit imposed by the maximum length of the pattern), or whether the content in the first packet matches the start of one or the start of many patterns.

7.4.6.2.10.10 What is the maximum length of a pattern?

128 bytes long. Patterns in excess of 128 bytes can be supported through stateful rules functionality.

7.4.6.2.10.11 How many patterns can be searched for simultaneously?

32000.

7.4.6.2.10.12 What is an NFA?

Non-deterministic finite automaton (NFA) is one of two generally accepted methods for performing pattern matching. The NFA evaluates each alternative at every byte position of the incoming data. Unlike DFA, an NFA may have multiple transitions out of a state with the same input. As the NFA evaluates each transition, it must remember and "backtrack" to execute alternate transitions if the evaluation fails.

7.4.6.2.10.13 What is a DFA?

Deterministic finite Aautomaton (DFA) is one of two generally accepted methods for performing pattern matching. A DFA tracks all possible matches as each byte of data is consumed. Each possible input character of the alphabet set is associated with at most one transition in any given state.

7.4.6.2.10.14 Which method is better: NFA or DFA?

There is no single correct answer. An NFA typically supports more regex features but requires many passes over the data as each alternative is evaluated, whereas a DFA only passes over the data once. Part of the reason a DFA only needs to examine the data once is that a lot of work has been performed up front during the compilation of the expressions, such that the compiled DFA state graph contains all the interdependencies between the different expressions. Because of these interdependencies, an incremental change to the expression database may require a recompilation of the entire DFA state graph. For these reasons, a software-based DFA has less flexibility, requires more memory, and has a longer expression compile time, but tends to perform faster than a software-based NFA.

7.4.6.2.10.15 Is the PME an NFA or a DFA?

Since the drawbacks of a DFA, such as the longer compile time, are inherent and cannot be easily overcome, the PME was modeled after an NFA, augmented with specific techniques to improve performance. Part of the reason a traditional NFA is slower is because the NFA needs to evaluate each expression at every byte position of the incoming data. When there are a large number of expressions or alternatives, performance drops. To overcome this, the PME incorporates a hardware pre-processing stage called the Key Element Scanner, which works by eliminating almost all candidate expressions prior to the regex evaluation such that the NFA only needs to perform the regex evaluation for one or a very small number of expressions at any given byte position. In fact, under normal operation when there is no potential match, the regex evaluation does not even need to be performed.

7.4.6.2.10.16 Where is the pattern database stored?

The pattern database is stored in a combination of on-chip memory and the main SDRAM.

7.4.6.2.10.17 Why is SRAM not required?

One key design objective of the PME is to minimize any reliance on expensive low-latency memories. The solution the design team undertook to achieve this objective makes use of a combination of on-chip and external memory. On-chip memory contains just enough pattern information to filter out all but the most likely matches. Only when a likely match has occurred does the PME require an external SDRAM memory access. Pipeline stalls due to memory accesses are minimized with the presence of FIFOs in between the different internal components of the PME. This relative infrequency of external memory access, in addition to the interconnecting FIFOs, leads to performance with a lower dependency on memory latency.

7.4.6.2.10.18 Does the PME support case-insensitivity?

Yes. Support for case-insensitivity is inherent in the design, and does not lead to pattern explosion.

7.4.6.2.10.19 Can contextual searches be performed?

The situation where interest for a specified pattern is predicated upon the detection of another pattern can be performed using Stateful rules.

7.4.6.2.10.20 What is a stateful rule?

A Stateful rule is a set of user-defined actions that are executed by the PME when specified pattern match events occur. The actions include changing state, assignments, bitwise operations, addition, subtraction, and relational operations.

7.4.6.2.10.21 What are the benefits of stateful rules?

Stateful rules enable the PME to go beyond basic pattern matching. Rather than just informing software whenever a pattern is matched, stateful rules allow the PM to act on pattern match events such that a match is declared to software only when user-specified conditions are met. For example, a stateful rule can be written to allow the PME to discriminate between matches found in the header portion versus the body portion of the application message. A stateful rule can allow the PM to declare a match only when all constituent parts of a signature match (such as in an anti-virus application). A Stateful rule can allow the PM to track a normal protocol exchange and glean information between a client and a server (such as in a SIP-aware application retrieving information on the media channel). In all these examples, Stateful rules postpone the need for application software to be invoked until concrete actions need to be taken.

7.4.6.2.10.22 How many stateful rules are supported?

32,768.

7.4.6.2.10.23 What information does the pattern match and stateful rule reports contain?

The pattern match report contains information such as the byte offset of the detected pattern (right edge of the match) and the pattern identifier. The Stateful rule report is customizable, and can include more detailed information on the match, any captured fields, and any context previously saved.

7.4.6.2.10.24 What's the performance of the PME?

The raw hardware performance of the PME is 2.4 Gbps in the MPC8572 PowerQUICC processor. However, the actual system performance may vary due to software and memory access overhead.

7.4.6.2.10.25 What software is included and supported for the PME?

All the software needed to compile, link, and load expressions into the hardware are provided. This includes the regular expression compiler, the stateful rule compiler, the linker-loader, and the low-level drivers for interacting with the hardware.

7.4.6.2.10.26 What operating systems are supported?

In general, the supplied software has been designed to be agnostic of the operating system where possible. The regular expression compiler and the stateful rule compiler are supported on Linux; the linker-loader is supported for Linux; the low-level drivers for interacting with the PM are supported for Linux. Porting of the supplied software to other operating systems is not expected to be difficult.

7.4.6.2.10.27 How can existing pattern management application software use the PME?

The PME software is provided as a library of functions with clearly-defined APIs and capabilities to compile, link, and load the patterns onto the hardware. Both single expression and multi-expression inputs are supported. Some application-specific pre-processing may be required to convert existing expressions into the PERL-like format understood by the supplied compiler.

7.4.6.2.10.28 How does software invoke the PME?

The PME provides a DMA-based "look-aside" interface with four independent DMA channels, which the supplied driver software uses to command pattern matching/decompression work, and to receive notifications of completed pattern matching/decompression work. For each DMA channel, a ring structure (array of entry locations) of programmable depth is used to dispatch commands to the PME. Similarly, a ring structure (array of entry locations) of programmable depth is used by the PME to inform the software of events such as the availability of a pattern scan result. The PME supports "gather buffer lists" for specifying input data and "scatter buffer lists" for specifying the location of output data.

7.4.6.2.10.29 Can software perform other tasks while the PME is scanning the data?

Yes, the supplied driver supports both blocking and non-blocking APIs.

7.4.6.2.10.30 How does software obtain the match results?

Completion of a command can be signaled through an interrupt or through polling. Application software can then read the results from the notification FIFO, including any results in a scatter list.

7.4.6.2.11 Revision History

Document Revision History

Rev. Number	Date	Substantive Change(s)
2	8/2009	Added support for PME2.0 (supporting P4080).
1	4/2008	Removed sections 2.1, 2,2, 2.3, 3.1, and 3.2.
0	11/2007	Initial public release.

7.4.6.3 Pattern Matcher 2.0, 2.1, 2.2 Software API Reference Manual

7.4.6.3.1 Introduction

This reference manual provides detailed information about Pattern Matcher software application programming interfaces (APIs).

This manual is intended for designers developing software for the NXP Pattern Matcher. Readers are expected to be familiar with Pattern Matcher hardware functionality and the information provided in the Pattern Matcher 2.0 Software User's Guide prior to using this document.

All programming interfaces available for use with the Pattern Matcher software are listed in this document. The interfaces are grouped according to software components within the document. Each interface includes a functional description as well as information about syntax and return values. Each interface description also provides information about libraries and kernel modules as well as header files required to use that programming interface.

The Pattern Matcher software is provided as linkable C libraries and kernel drivers, as well as executable binaries where appropriate. This document describes the programming interface for the software. Software executables are described in the Pattern Matcher Software User Guide.

7.4.6.3.1.1 Conventions

The following notational conventions are used in this guide:

Courier monospaced type indicates code examples and file or directory names

Italic type used within interface descriptions indicates interface parameters

7.4.6.3.2 Software Component Overview

The NXP Pattern Matcher provides high-performance hardware pattern matching of data. Input data is searched for user specified patterns by the hardware. The Pattern Matcher software enables users to efficiently configure, use, and manage the Pattern Matcher hardware. The software comprises the following components:

- Regex Compiler-The regex compiler converts user defined patterns, specified as regular expressions, into patterns in a NXP hardware-specific format.
- Stateful Rule Compiler-Stateful rules define stateful relationships between pattern matching results and also specify the actions to be taken in the defined states. The stateful rule compiler converts user specified stateful rules into a NXP hardware-specific format.
- Pattern Matcher Configuration - Pattern Matcher Configuration software provides users with an interface to configure Pattern Matcher hardware. The simplest programatic interface to configure the pattern matcher hardware is with the PMC API. The following two APIs are available for backward compatibility with existing pattern management applications.
- Linker-Loader-The linker-loader accepts patterns and stateful rules encoded in the NXP hardware-specific format and generates a hardware-optimal pattern and reaction database. The linker-loader also provides interfaces to configure and monitor the Pattern Matcher database used by hardware.
- Control Interface-The PME control interface module (PMCI) provides C functional interfaces to send and receive Pattern Matcher control commands to the Pattern Matcher through Pattern Matcher driver software. The PME control commands initialize PME driver and configure the PME hardware tables. The PMCI module converts complex PME control commands into PME driver primitives.
- Driver-The Pattern Matcher driver software provides users with an interface to the Pattern Matcher. The driver software is targeted to the linux kernel and linux user space (USDPAA) targets. For Linux, the driver provides user-level and kernel-level interfaces to efficiently transfer, control, and scan data to the hardware, and provide pattern matching results to applications. All PME database updates are expected to be done on a control core running Linux. For USDPAA, the driver provides an interface to scan data and get match results. In all cases, the PME driver encapsulates direct interaction with the underlying QMan and BMan functionality. There is also a platform specific considerations to bear in mind when working with the interfaces described here, please see

NOTE

The APIs in this document are grouped according to above software components. Additional information about each software component is provided in the appropriate section.

7.4.6.3.3 Regular expression compiler

This chapter describes the application programming interface (API) for the Pattern Matcher regular expression compiler (PMREC). The PMREC allows the user to compile regular expression patterns into a format that is used internally within the NXP Pattern Matcher hardware. All the PMREC functions run to completion, meaning a PMREC function returns the operation performed by that function has been completed.

PMREC is delivered as a linkable C library called libregex.a.

PMREC Required Files

File	Description
libregex.a	Contains all the PMREC objects
pmrec.h	Defines the interface to the PMREC module
generic_types.h	Contains generic type definitions and is included by pmrec.h
pm_defs.h	Defines the interface that is common to PMLL, PMREC, PMSRC, and so on, and is included by pmrec.h
inttypes.h	Defines the basic integer types and is included by generic_types.h
stdbool.h	Defines the bool type and is included by generic_types.h

7.4.6.3.3.1 pmrec_compile

pmrec_compile-Compile a file of regular expressions.

Synopsis

```
#include <pmrec.h>

pmrec_error_codes_t pmrec_compile (

char                    *input_file_name_p,

char                    *output_file_name_p,

pmrec_module_options_t *options_p,

char                    **compile_msg_p);
```

Description

Compile regular expression(s) into NXP hardware format. The user must supply valid input and output file names. The user must also supply two optional parameters (either set to a valid value or set to NULL). The first is an object that contains compile options. The second is a pointer to a character pointer that allows the compiler to pass back a detailed compiler message. Both of the last two parameters may be set to NULL if default options and no compiler message are desired. If a pointer is supplied and no compiler message is generated, the string will be set to NULL. Note that if a pointer is supplied for the compiler message, the user is responsible for freeing the string that is returned by the compiler library.

pmrec_module_options_t is defined in pmrec.h. It is listed below for easy reference.

typedef struct pmrec_module_options

```
{
    pmrec_debug_levels_t           debug_level;
    pmrec_group_definition_t       group_definition;
    char                           group_def_filename_p;
    pmrec_equivalence_definition_t equivalence_definition;
    char                           *equiv_def_filename_p;
    bool                           warnings_are_errors;
    bool                           suppress_warnings;
bool                           hide_strings;
   bool                            one_byte_triggers;
   bool                            silicon_8572_rev_1_0;
} pmrec_module_options_t;
```

group_def_filename_p and equiv_def_filename_p are for future use and should be set to NULL.

A typical setting for the options would be:

```
pmrec_module_options_t options = { pmrec_debug_none_e,
                                   pmrec_groups_default0_e,
                                   NULL,
                                   pmrec_equivalence_default0_e,
                                   NULL,
                                   false,
                                   false};
```

Return Value

This function returns a code of type *pmrec_error_codes_t*. This type is defined in pmrec.h. The possible return codes are as follows:

pmrec_ok_e

Success. Generally expect to see this code.

pmrec_warning_e

Compile warning found.

pmrec_internal_error_e

Should not see this error code. Indicates an unexpected condition.

pmrec_no_trigger_found_e

No triggerable symbols found in expression

pmrec_missing_end_block_e

Should not see this error code. Indicates an internal issue with the data structures.

pmrec_missing_end_class_e

Should not see this error code. Indicates an internal issue with the data structures.

pmrec_no_output_file_e

No output file was specified.

pmrec_nested_repeat_found_e

A nested repeat in the expression was found. Hardware does not support this.

pmrec_expression_too_large_e

Expression is too large to fit within the allowable instructions.

pmrec_nested_capture_found_e

A nested capture in the expression was found. Hardware does not support this.

pmrec_compile_failed_e

Generic compile failure. Specific details will be in the compile message.

pmrec_input_file_open_error_e

Error opening supplied input file.

pmrec_invalid_element_size_e

Should not see this error. Indicates an internal issue with data structures.

pmrec_output_file_open_error_e

Error opening supplied output file.

pmrec_output_file_write_error_e

Error writing to output file.

pmrec_max_test_lines_exceeded_e

Expression generates too many test lines to fit in hardware.

pmrec_no_start_position_found_e

Should not see this error. Indicates an issue finding start position for test lines.

pmrec_code_string_mismatch_e

Should not see this error. Indicates erroneous number of error code strings.

pmrec_must_expand_grouped_duplication_e

Indicates a condition the compiler cannot deal with currently. Specifically expressions like (ab(c|d|e))+. This should be expanded to (abc|abd|abe)+

pmrec_malloc_failure_e

Failure while calling malloc. System memory likely exhausted.

pmrec_invalid_option_e

Invalid option was passed through compiler options.

pmrec_invalid_group_def_e

Invalid group definition was passed through compiler options.

pmrec_invalid_equiv_def_e

Invalid equivalence definition was passed through compiler options.

pmrec_syntax_error_e

Regex format or syntax was invalid

7.4.6.3.3.2 pmrec_get_error_string

pmrec_get_error_string-Get the string associated with a compiler error.

Synopsis

```
#include <pmrec.h>

const char *pmrec_get_error_string (pmrec_error_codes_t, code);
```

Description

The function returns a brief string describing the supplied error code.

Return Value

Pointer to the error string.

7.4.6.3.4 Stateful rule compiler

This chapter provides a description of the API for the Pattern Matcher stateful rule compiler (PMSRC). The PMSRC compiles stateful rules written in a NXP stateful rule source code language into a format that is used internally within the NXP pattern matcher hardware. All the PMSRC functions run to completion, meaning a PMSRC function returns the operation performed by the function has been completed.

The PMSRC is delivered as a linkable C library called libstatefulRules.a.

PMSRC Required Files

libstatefulRules.a	Contains all the PMSRC objects.
pmsrc.h	Defines the interface to the PMSRC module
generic_types.h	Contains the generic type definitions and is included by pmsrc.h
pm_defs.h	Defines the interface that is common to PMLL, PMREC, PMSRC, etc., and is included by pmsrc.h
inttypes.h	Defines the basic integer types and is included by generic_types.h

Table continues on the next page...

Table continued from the previous page...

stdbool.h	Defines the bool type and is included by generic_types.h

7.4.6.3.4.1 pmsrc_compile

pmsrc_compile-Compile a file of stateful rules.

Synopsis

```
#include <pmsrc.h>

pmsrc_ErrorCodes_t pmsrc_compile (

 char    *input_file_name_p,

 char    *output_file_name_p,

 pmsrc_module_options_t *options_p,

 char **compile_msg_p);
```

Description

Compile stateful rule(s) into NXP hardware instructions. The user must supply valid input and output file names. The user must also supply two optional parameters (set to a valid value or set to NULL). The first is an object that contains compile options. The second is a pointer to a character pointer that allows the compiler to pass back a detailed compiler message. Both of the last two parameters may be set to NULL if default options and no compiler messages are desired. If a pointer is supplied and no compiler message is generated, the string will be set to NULL. Note that if a pointer is supplied for the compiler message, the user is responsible for freeing the string that is returned by the compiler library.

pmsrc_module_options_t is defined in pmsrc.h, listed below for easy reference.

typedef struct pmsrc_module_options

```
{
   pmsrc_debug_levels_t   debug_level;

   pmsrc_report_pad_t     report_pad;

   uint32_t               string_pad;

   pmsrc_report_cnst_sz_t report_cnst_sz;

   pmsrc_match_type_t     allow_inconclusive;

   bool                   warnings_are_errors;

   bool                   suppress_warnings;

} pmsrc_module_options_t;
```

A typical setting for the options is as follows:

```
        pmsrc_module_options_t options = {
                              pmsrc_debug_off_e,
                              pmsrc_report_pad4_e,
                              PMSRC_DEFAULT_STRING_PAD,
                              pmsrc_report_cnst_sz4_e,
                              pmsrc_conclusive_only_matches_e,
                              false,
                              false};
```

Return Value

This function returns a code of type *pmsrc_error_codes_t*. This is defined in pmsrc.h. The possible return codes are as follows:

pmsrc_ok_e

Success. Generally expect to see this code.

pmsrc_warnings_e

Compile warning found. See compiler message for details.

pmsrc_input_file_open_e

Trouble opening supplied input file.

pmsrc_output_file_open_e

Trouble opening supplied output file.

pmsrc_no_output_file_e

No output file supplied.

pmsrc_compile_failed_e

Compile failed. See compiler message for details.

pmsrc_null_list_pointer_e

Should not see this error. Indicates internal issues with data structures.

pmsrc_no_output_written_e

No output was written to output file.

pmsrc_code_string_mismatch_e

Should not see this error. Indicates incorrect number of error strings.

pmsrc_undefined_state_name_e

A state name was referred to in the stateful rule that does not exist.

pmsrc_internal_error_e

Should not see this error. Indicates an unexpected internal condition.

pmsrc_malloc_failure_e

Failure while calling malloc. System memory likely exhausted.

pmsrc_empty_stack_e

Should not see this error. Indicates issue with internal data structures.

pmsrc_name_exists_e

Rule name used more than once in file.

pmsrc_empty_input_e

Empty input file.

pmsrc_unrecognized_debug_option_e

Unrecognized debug option. Allowed options are as follows:

pmsrc_debug_off_e

pmsrc_debug_summary_e

pmsrc_debug_test_e

pmsrc_unrecognized_report_pad_option_e

Unrecognized report pad option. Allowed options are:

pmsrc_report_pad_none_e

pmsrc_report_pad4_e

pmsrc_unrecognized_string_pad_option_e

Unrecognized string pad option. Allowed values are from 0 to PMSRC_MAX_STRING_PAD_SIZE.

pmsrc_invalid_option_e

Unrecognized option.

pmsrc_string_pad_option_too_large_e

String pad option too large. Maximum defined as PMSRC_MAX_STRING_PAD_SIZE.

pmsrc_unrecognized_report_constant_size_option_e

Unrecognized report constant size. Allowed options are as follows:

pmsrc_report_cnst_sz2_e

pmsrc_report_cnst_sz4_e

pmsrc_report_cnst_sz6_e

pmsrc_report_cnst_sz8_e

pmsrc_unrecognized_allow_conclusive_option_e

Unrecognized value for allow conclusive option. Allowed values are as follows:

pmsrc_conclusive_only_matches_e

pmsrc_conclusive_and_inconclusive_matches_e

Related information

7.4.6.3.5 Pattern Matcher configuration (PMC) API

This chapter provides a description of the Pattern Matcher configuration (PMC) API.

The PMC provides a programming interface to Pattern Matcher management applications for adding, removing, querying and committing regular expressions and stateful rules into Pattern Matcher hardware.

Pattern Matcher Configuration API supports:

- multiple, independant applications adding/deleting patterns and rules
- a persistent Pattern database
- Handle statistics

PMC is implemented as a user-space header file and a library. The steps involved in configuring patterns in the Pattern Matcher hardware are as follows:

instantiate PMC Daemon (PMCD) process. The PMCD is a provided as a Linux executable binary for the target SoC which includes Pattern Matcher functionality (e.g. P4080 or MPC8572).

add regular expressions from a file via a call to pmc_add_expr_file

optionally add stateful rules from a file via call to pmc_add_rule_file

commit changes to hardware via call to pmc_commit

All the PMC functions run to completion, meaning that a PMC function returns the operation performed by the function has been completed.

PMC required files

libpmc.a	Contains all the PMC objects
pmc.h	Defines the interface to the PMC module
pmcd	PMC Deamon

7.4.6.3.5.1 Status codes

```
typedef struct pmc_status {

pmc_ok_e                    = 0,
```

```
pmc_init_fail_e            = 1,

```

7.4.6.3.5.2.1 Add regular expressions from compiled bin file

Adds all regular expressions in the precompiled binary file. Option to allow auto commit.

```
pmc_status_t pmc_add_expr_file(                        char *filename_p,
                                        bool auto_commit,
                                        char **info_msg_p)
```

7.4.6.3.5.2.2 Add stateful rules from compiled bin file

Adds all stateful rules in the precompiled binary file. Option to allow auto commit.

```
pmc_status_t pmc_add_rule_file(                        char *filename_p,
                                       bool auto_commit,
                                       char **info_msg_p)
```

7.4.6.3.5.2.3 Delete regular expression by name or set and subset

Deletes the regular expression referenced by name or set and subset. Option to allow auto commit.

```
pmc_status_t pmc_del_expr_name(                    char *name_p,
                                       bool auto_commit,
                                       char **info_msg_p)
pmc_status_t pmc_del_expr_set(                         int set,
                                       int subset,
                                       bool auto_commit,
                                       char **info_msg_p)
```

7.4.6.3.5.2.4 Delete regular expressions by compiled bin file

Deletes all regular expressions in the precompiled binary file. Option to allow auto commit.

```
pmc_status_t pmc_del_expr_file(                                 char *filename_p,
                                                        bool auto_commit,
                                                        char **info_msg_p)
```

7.4.6.3.5.2.5 Delete stateful rule by name

Deletes the stateful rule referenced by name. Option to allow auto commit.

```
pmc_status_t pmc_del_rule_name(                           char *name_p,
                                                        bool auto_commit,
                                                        char **info_msg_p)
```

7.4.6.3.5.2.6 Delete stateful rule by compiled bin file

Deletes all stateful rules in the precompiled binary file. Option to allow auto commit.

```
pmc_status_t pmc_del_rule_file(                                 char *filename_p,
                                                        bool auto_commit,
                                                        char **info_msg_p)
```

7.4.6.3.5.2.7 Commit changes to hardware

Commit all changes to hardware.

```
pmc_status_t pmc_commit(char **info_msg_p)
```

7.4.6.3.5.2.8 Delete all regular expressions and rules

Delete all expressions or all rules or both. Option to allow auto commit.

```
pmc_status_t pmc_del_all_expr(                              bool auto_commit,
                                                        char **info_msg_p)

pmc_status_t pmc_del_all_rules(                              bool auto_commit,
                                                        char **info_msg_p)
pmc_status_t pmc_del_all(                                 bool auto_commit,
                                                        char **info_msg_p)
```

7.4.6.3.5.2.9 Query regular expression by name or set and subset

Query information on a single named regular expression or a list of expressions based on set and subset. The information is returned in a single pmc_expr_t record or a linked list of pmc_expr_t records. See pmc_free_expr to cleanup.

```
pmc_status_t pmc_query_expr_name(                     char *name_p,
                                                        pmc_expr_t **expr_p,
                                                        char **info_msg_p)
pmc_status_t pmc_query_expr_set(                                int set,
                                                        int subset,
                                                        pmc_expr_t **expr_p,
                                                        char **info_msg_p)
```

7.4.6.3.5.2.10 Query stateful rule by name

Query information on a single named stateful rule. The information is returned in a pmc_rule_t record. See pmc_free_rule to cleanup.

```
pmc_status_t pmc_query_rule_name(                              char *name_p,
                                                    pmc_rule_t **rule_p,
                                                    char **info_msg_p)
```

7.4.6.3.5.2.11 Query first regular expression in the database

Query the first regular expression in the database. The index of the expression is stored in the expression object. See pmc_free_expr to cleanup.

```
pmc_status_t pmc_query_expr_first( pmc_expr_t **expr_p,
                                                    char **info_msg_p)
```

7.4.6.3.5.2.12 Query next regular expression in the database

Query the next regular expression in the database. This function will return the next expression based on the index of the current expression that is passed in. See pmc_free_expr to cleanup.

```
pmc_status_t pmc_query_expr_next (                               uint32_t       index,
                                                    pmc_expr_t **next_expr_p,
                                                    char **info_msg_p)
```

7.4.6.3.5.2.13 Query first stateful rule in the database

Query the first stateful rule in the database. The index of the rule is stored in the rule object. See pmc_free_rule to cleanup.

```
pmc_status_t
pmc_query_rule_first(                                                    pmc_rule_t **rule_p,
                                                                               char
**info_msg_p)
```

7.4.6.3.5.2.14 Query next stateful rule in the database

Query the next stateful rule in the database. This function will return the next rule based on the index of the current rule that is passed in. See pmc_free_rule to cleanup.

```
pmc_status_t pmc_query_rule_next(                              uint32_t index,
                                                    pmc_rule_t **next_rule_p,
                                                    char **info_msg_p)
```

7.4.6.3.5.2.15 Free expression and rule objects after queries

Free the expression and rule objects returned by the various queries.

```
void pmc_free_expr(pmc_expr_t *expr_p);
void pmc_free_rule(pmc_rule_t *rule_p);
```

7.4.6.3.5.2.16 Query statistics

Query PM statistics. The information is returned in a pmc_stats_t record.

```
pmc_status_t pmc_query_stats(                                pmc_stats_t *stats_p,
                                                  char **info_msg_p)
```

7.4.6.3.5.2.17 Reset statistics

Reset PM statistics.

```
pmc_status_t pmc_reset_stats()
```

7.4.6.3.5.2.18 Set variable length trigger

Set the size of the variable length trigger. This may only be used when the database is empty.

```
pmc_status_t pmc_set_var_trig_size(                        uint32_t size,
                                           char **info_msg_p)
```

7.4.6.3.5.2.19 Expression analysis

Run the expression analysis tool. Be advised this can take in the order of minutes to complete depending on the number of expressions in the database.

```
pmc_status_t pmc_analysis(                  char **log_str_p,
                                 char **info_msg_p);
```

7.4.6.3.6 Linker-loader

This chapter provides a description of the API of the Pattern Matcher linker-loader (PMLL). The linker-loader accepts expression and rule records encoded in the NXP hardware specific format, links these records into a hardware-optimal image-also called the shadow database (shadow DB)-and loads this image into the PM hardware.

PMLL is implemented as a user-space library called libpmll.a. The generic steps involved in configuring the Pattern Matcher hardware are as follows:

- Initialize the PMLL module with a call to the pmll_module_init() function
- Call the pmll_db_create() function to create a PMLL shadow DB and register the PMLA functions with the new shadow DB
- Use the pmll_connection_handle_set() function to associate a PMLA channel with the created PMLL shadow DB
- Optionally reconfigure the equivalence table and the variable trigger length attributes using the pmll_equivalence_table_set() and pmll_variable_trigger_size_set() functions
- Use the PMLL expression functions to add expressions to the shadow DB
- Use the PMLL rule functions to add rules to the shadow DB
- Call the pmll_commit() function to get PMLL to link the expression and rule records and to load the configuration on the PM hardware

All the PMLL functions run to completion, meaning that a PMLL function returns the operation performed by the function has been completed.

PMLL Files

File	Description
libpmll.a	Contains all the PMLL objects
pmll.h	Defines the interface to the PMLL moduleT
generic_types.h	Contains the generic type definitions and is included by pmll.h
pm_defs.h	Defines the interface that is common to the PMLL, PMREC, PMSRC, etc., and is included by pmll.h
pmp.h	Contains the definition of the Pattern Matcher Protocol and is included by pmll.h
libpthread.a	Defines the pthread objects; used by some of the PMLL objects
byteswap.h, endian.h	Provide support for little and big-endian byte swapping and are included by pmp.h
inttypes.h	Define the basic integer types and is included by generic_types.h
stdbool.h	Defines the bool type and is included by generic_types.h
netinit/in.h	Provides support for the hton and ntoh macros and is included by pmp.h

7.4.6.3.6.1 pmll return codes

Most of the PMLL functions return status codes. The different return codes are defined in the pmll_status_t enumerated type and are listed below.

```
pmll_ok_e
```

This is the generic success code.

```
pmll_error_e
```

This is the generic error code. It is often used as an initial value for the return status variable.

```
pmll_too_few_error_strings_e
```

More error codes than strings are defined.

```
pmll_too_many_error_strings_e
```

More error strings than codes are defined.

```
pmll_unsupported_record_version_e
```

The record version passed in is not supported.

```
pmll_null_pointer_parameter_e
```

Unexpected NULL pointer passed in as a parameter.

```
pmll_out_of_memory_e
```

Memory allocation failed - no more memory.

```
pmll_invalid_name_e
```

The passed in expression or rule name is invalid, for example, has zero length.

```
pmll_exp_name_is_in_use_e
```

An expression with the specified expression name exists.

```
pmll_exp_is_not_in_name_db_e
```

An expression with the specified expression name does not exist.

```
pmll_no_trigger_type_e
```

Could not determine the trigger type for a pattern.

```
pmll_unsupported_trigger_type_e
```

The trigger type found in the expression record is not supported.

```
pmll_too_few_trig_row_format_defs_e
```

The number of the row trigger formats is too small.

```
pmll_too_many_trig_row_format_defs_e
```

The number of the row trigger formats is too big.

```
pmll_failed_to_commit_pattern_e
```

Failed to commit a pattern.

```
pmll_entry_write_failed_e
```

Failed to write a table entry to the PM H/W.

```
pmll_bad_confirmation_rec_size_e
```

The size of the confirmation record structure is not as expected.

```
pmll_module_not_initialized_e
```

The PMLL module has not been initialized.

```
pmll_bad_trigger_rec_size_e
```

The size of the trigger record structure is not as expected.

```
pmll_invalid_parameter_value_e
```

The value of a parameter passed to the function is invalid.

```
pmll_too_many_one_byte_patterns_e
```

Adding the pattern would exceed the "1-byte" pattern limit.

```
pmll_too_many_two_byte_patterns_e
```

Adding the pattern would exceed the "2-byte" pattern limit.

```
pmll_too_many_variable_patterns_e
```

Adding the pattern would exceed the "variable" pattern limit.

```
pmll_too_many_special_patterns_e
```

Adding the pattern would exceed the "special" pattern limit.

```
pmll_too_many_patterns_e
```

Adding the pattern would exceed the global pattern limit.

```
pmll_invalid_db_handle_e
```

The passed in PMLL DB handle is invalid.

```
pmll_table_index_too_big_e
```

The index table passed is too big.

```
pmll_pattern_not_in_confid_table_e
```

A pattern could not be found in the confidence table.

```
pmll_bad_logic_e
```

Bad logic in function.

```
pmll_too_many_reactions_in_rule_e
```

Found too many reactions in a rule.

```
pmll_no_reactions_in_rule_e
```

Found no reactions in a rule.

```
pmll_reaction_too_big_e
```

Reaction size is too big.

```
pmll_null_reaction_pointer_in_rule_e
```

Found a NULL reaction pointer in a rule.

```
pmll_rule_name_is_in_use_e
```

A rule with the specified rule name exists.

```
pmll_too_many_rules_e
```

Adding the rule would exceed the rule limit.

```
pmll_rule_is_not_in_name_db_e
```

A rule with the specified rule name does not exist.

```
pmll_exp_is_used_in_rule_e
```

An expression is used in a rule.

```
pmll_failed_to_init_mutex_e
```

Initialization of a mutex failed.

```
pmll_failed_to_destroy_mutex_e
```

Destruction of a mutex failed.

```
pmll_no_more_records_e
```

There are no more records in PMLL DB.

```
pmll_failed_to_create_name_db_e
```

Failed to create a name DB.

```
pmll_failed_to_add_exp_to_name_db_e
```

Failed to add an expression record to the PMLL expression name DB.

```
pmll_failed_to_add_rule_to_name_db_e
```

Failed to add a rule record to the PMLL rule name DB.

```
pmll_index_is_not_in_use_e
```

The index is not in use.

```
pmll_failed_to_create_reset_table_e
```

Failed to create the PMLL DB reset table.

```
pmll_failed_to_create_block_table_e
```

Failed to create the PMLL DB block table.

```
pmll_failed_to_create_cli_menu_e
```

Failed to create a CLI menu.

```
pmll_failed_to_register_cli_command_e
```

Failed to register a CLI command.

```
pmll_too_few_confirmation_blocks_e
```

The number of the confirmation blocks is too small.

```
pmll_out_of_extension_blocks_e
```

Run out of the extension blocks.

```
pmll_failed_to_create_rule_id_table_e
```

Failed to create the PMLL DB rule ID table.

```
pmll_out_of_rule_ids_e
```

Run out of rule Ids.

```
pmll_reaction_too_small_e
```

Size of a reaction is too small.

```
pmll_misaligned_reaction_e
```

Instructions in the reaction are misaligned.

```
pmll_failed_to_create_rule_ctx_table_e
```

Failed to create the PMLL DB rule context table.

```
pmll_session_ctx_area_too_small_e
```

Session context area size is smaller than the minimum size required by PMLL.

```
pmll_failed_to_alloc_rule_ctx_area_e
```

Failed to allocate a rule context area.

```
pmll_vtrigger_size_out_of_range_e
```

Variable trigger size is out of range.

```
pmll_exps_are_present_in_db_e
```

Expressions are present in the PMLL DB.

```
pmll_bad_reaction_event_type_e
```

Unsupported reaction event type.

```
pmll_bad_session_ctx_area_size_e
```

Session context area size is not a multiple of a session context entry.

```
pmll_table_reset_failed_e
```

Failed to reset entries in PM H/W tables.

```
pmll_pmhi_init_failed_e
```

Failed to initialize the PMLL PM H/W I/O module.

```
pmll_failed_to_set_atomic_attr_e
```

Failed to set the PMP atomic attribute.

```
pmll_failed_to_set_vtrig_size_attr_e
```

Failed to set the PMP variable trigger size attribute.

```
pmll_failed_to_set_end_of_sui_attr_e
```

Failed to set the PMP end-of-SUI attribute.

```
pmll_flush_failed_e
```

The PMLA flush operation failed.

```
pmll_failedto_reset_rule_ctxs_ee
```

Failed to reset a rule context.

```
pmll_failed_to_set_batch_attr_e
```

Failed to set the batch attribute.

```
pmll_pmla_channel_is_down_e
```

PMLA channel is down.

```
pmll_pmla_channel_is_not_set_e
```

PMLA channel is not set.

```
pmll_handle_table_create_failure_e
```

Failed to create the PMLL handle table.

```
pmll_handle_table_destroy_failure_e
```

Failed to destroy the PMLL handle table.

```
pmll_failed_to_allocate_handle_e
```

Failed to allocate a PMLL handle.

```
pmll_too_many_stateful_rules_req_e
```

The requested maximum number of stateful rules is too big.

```
pmll_cannot_register_null_pmla_func_e
```

A NULL pointer cannot be registered as a PMLA function pointer.

7.4.6.3.6.2 pmll_api_version_get

pmll_api_version_get-Retrieve the version of the PMLL API.

Synopsis

```
#include <pmll.h>
uint32_t pmll_api_version_get(void);
```

Description

The pmll_api_version_get() function retrieves the version of the API of the PMLL library being used.

Return Value

The pmll_api_version_get() function returns the version of the API of the PMLL library being used.

7.4.6.3.6.3 pmll_commit

pmll_commit - Commit the PMLL shadow DB to the PM hardware.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_commit(
unsigned int pmllDbHandle,
char         *expName_p);
```

Description

The pmll_commit() function triggers all the PMLL commit operations. The current version of the pmll_commit() function implements both the linking and the loading functions of PMLL. Once the pmll_commit() function returns, the optimized image of the PMLL shadow DB with the pmllDbHandle handle has been written to the PM hardware and the PM hardware is ready to scan data for the configured expressions and rules.

When the pmll_commit() function fails to link the patterns present in the PMLL shadow DB and returns with the pmll_failed_to_commit_pattern_e error code, the name of the expression containing the pattern that caused the PMLL linking failure is returned through the expName_p parameter.

Return Value

The pmll_commit() function returns pmll_ok_e upon success or an error code upon a failure. The pmll_commit() function can return the following error codes:

```
pmll_bad_logic_e
pmll_entry_write_failed_e
pmll_entry_write_failed_e
pmll_failed_to_commit_pattern_e
pmll_failed_to_reset_rule_ctxs_e
pmll_failed_to_set_atomic_attr_e
pmll_failed_to_set_batch_attr_e
pmll_failed_to_set_end_of_sui_attr_e
pmll_failed_to_set_vtrig_size_attr_e
pmll_flush_failed_e
pmll_invalid_db_handle_e
pmll_module_not_initialized_e
pmll_null_pointer_parameter_e
pmll_out_of_memory_e
pmll_pmla_channel_is_down_e
pmll_pmla_channel_is_not_set_e
pmll_table_reset_failed_e
```

When the pmll_failed_to_commit_pattern_e error code is returned the name of the expression containing the pattern that caused the PMLL linking failure is returned through the expName_p parameter. At present this failure is critical. There is no

recovery mechanisms built into the pmll_commit() function and most of the time this failure results in corrupting the PMLL shadow DB. The user must rebuild the PMLL shadow DB from scratch.

7.4.6.3.6.4 pmll_connection_handle_set, pmll_connection_handle_get

pmll_connection_handle_set, pmll_connection_handle_get-Set, get the PMLA connection handle.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_connection_handle_set(

unsigned int pmllDbHandle,

handle_t pmlaHandle);
```

pmll_status_t pmll_connection_handle_get(

```

unsigned int pmllDbHandle,

handle_t *pmlaHandle_p);
```

Description

pmll_connection_handle_set() associates a PMLA connection with the PMLL shadow DB with the pmllDbHandle handle. The user specified pmlaHandle is used by PMLL to refer to the set of PMLA functions registered previously with PMLL when the PM shadow DB was created (using pmll_db_create). The pmlaHandle is needed as an input parameter when calling PMLA functions.

pmll_connection_handle_get() retrieves the PMLA connection handle that is currently associated with the PMLL shadow DB with the pmllDbHandle handle. The retrieved PMLA connection handle is returned through the pmlaHandle_p parameter.

Return Value

The pmll_connection_handle_set() and pmll_connection_handle_get() functions return pmll_ok_e upon success or an error code upon a failure.

The pmll_connection_handle_set() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
```

The pmll_connection_handle_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

7.4.6.3.6.5 pmll_db_create, pmll_db_destroy

pmll_db_create, pmll_db_destroy-Create, destroy a PMLL shadow DB.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_db_create(
     pmll_db_params_t
*pmllDbParams_p,
     unsigned int
```

```
*pmllDbHandle_p);
pmll_status_t pmll_db_destroy(unsigned int pmllDbHandle);
```

Description

pmll_db_create() creates a new PMLL shadow DB. Upon successful completion the function returns a non-negative integer handle that was assigned to the created PMLL shadow DB. PMLL API functions that operate on a specific shadow DB take this handle as an input parameter. The handle is returned through the pmllDbHandle_p parameter.

The pmll_db_params_t type of the pmllDbParams_p parameter is defined as follows:

```
typedef int pmll_pmla_bulk_begin_function_t(
     handle_t                                  pmlaHandle);
typedef int pmll_pmla_bulk_end_function_t(
     handle_t                                  pmlaHandle);
typedef int pmll_pmla_flush_function_t(
     handle_t                                  pmlaHandle);
typedef int pmll_pmla_read_function_t(
     handle_t                                  pmlaHandle,
     pmp_msg_t                                 *msg_p);
typedef int pmll_pmla_write_function_t(
     handle_t                                  pmlaHandle,
     pmp_msg_t                                 *msg_p);
typedef const char *pmll_pmla_error_string_get_t(
     int                                       errorCode);
typedef struct {
     pmll_pmla_bulk_begin_function_t
          *pmlaBulkBeginFunction_p;
     pmll_pmla_bulk_end_function_t
          *pmlaBulkEndFunction_p;
     pmll_pmla_flush_function_t
          *pmlaFlushFunction_p;
     pmll_pmla_read_function_t
          *pmlaReadFunction_p;
     pmll_pmla_write_function_t
          *pmlaWriteFunction_p;
     pmll_pmla_error_string_get_t
          *pmlaErrorStringGetFunction_p;
} pmll_pmla_functions_t;
typedef struct {
     pmll_pmla_functions_t
pmlaFunctions;
     pmp_extension_block_num_attr_t

dxeSreTableSize;
     pmp_context_area_size_attr_t
sreSessionCtxSize;
     pmp_context_max_num_attr_t
sreSessionCtxNum;
     pmp_max_stateful_rule_num_attr_t
                                                                              sreRuleNum;
} pmll_db_params_t;
```

The pmlaFunctions parameter contains pointers to the PMLA functions that must be registered with the PMLL shadow DB. All the functions must be specified. If any of the PMLA function pointers are NULL, then the pmll_db_create() function will fail with the pmll_cannot_register_null_pmla_func_e error code. Refer to the "PMLL PMLA Functions" section later in this chapter for more details on the PMLA functions.

The dxeSreTableSize, sreSessionCtxSize, sreSessionCtxNum and sreRuleNum parameters indicate PM hardware settings. These settings are specified when loading PM hardware drivers and can be queried. The dxeSreTableSize parameter

indicates the total number of confirmation entries, including both the pattern confirmation entries and the reaction extension entries available to the PM hardware. The minimum value of entries is 74240 and the maximum value is 1048576. The sreSessionCtxSize parameter indicates the size of the PM hardware context table entry associated with a single session. The value of sreSessionCtxSize must be between 64 and 131072. The sreSessionCtxNum parameter indicates the number of PM sessions supported by the PM hardware. The sreRuleNum parameter indicates the maximum number of stateful rules that can be configured in the PM hardware. The value of sreRuleNum must be between 0 and 32768. PMLL relies on the settings provided by the user to match the PM hardware settings. It does not query the hardware to sanitize the values.

Each PMLL shadow DB has its own mutex to protect accesses to the PMLL shadow DB. This means that the developers using the PMLL library do not have to create external mutual exclusion mechanisms to protect the integrity of the PMLL shadow DB.

pmll_db_destroy() destroys the PMLL shadow DB with the pmllDbHandle handle. The function removes all the rules and expressions from the DB and frees all the memory that was used by the PMLL shadow DB.

Return Value

Both the pmll_db_create() and pmll_db_destroy functions return pmll_ok_e upon success or an error code upon a failure.

The pmll_db_create() function can return the following error codes:

```
     pmll_bad_session_ctx_area_size_e
     pmll_cannot_register_null_pmla_func_e
     pmll_failed_to_allocate_handle_e
     pmll_failed_to_create_block_table_e
     pmll_failed_to_create_name_db_e
     pmll_failed_to_create_reset_table_e
     pmll_failed_to_create_rule_ctx_table_e
     pmll_failed_to_create_rule_id_table_e
     pmll_failed_to_init_mutex_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
     pmll_out_of_memory_e
     pmll_session_ctx_area_too_small_e
     pmll_too_few_confirmation_blocks_e
     pmll_too_many_stateful_rules_req_e
```

The pmll_db_destroy() function can return the following error codes:

```
     pmll_failed_to_destroy_mutex_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
```

7.4.6.3.6.6 pmll_equivalence_table_set, pmll_equivalence_table_get

pmll_equivalence_table_set, EquivalenceTableGet-Set, get the equivalence table.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_equivalence_table_set(
     unsigned int
pmllDbHandle,
     const uint8_t
*equivalenceTable_p);
```

pmll_status_t pmll_equivalence_table_get(

```
     unsigned int
pmllDbHandle,
```

```
     uint8_t
*equivalenceTable_p);
```

Description

pmll_equivalence_table_set() can be used to configure new values in the equivalence table associated with the PMLL shadow DB with the pmllDbHandle handle. The new values of the equivalence table are passed to the function through the equivalenceTable_p parameter. A default equivalence table is defined in pm_defs.h. Note that the pmll_equivalence_table_set() function will fail if it is called when there are expressions present in the PMLL shadow DB.

pmll_equivalence_table_get() retrieves the values in the equivalence table associated with the PMLL shadow DB with handle pmllDbHandle.

The size of the buffer pointed to by equivalenceTable_p must be at least PMP_EQUIVALENCE_ENTRY_SIZE bytes.

Return Value

The pmll_equivalence_table_set() and pmll_equivalence_table_get() functions return pmll_ok_e upon success or an error code upon a failure.

The pmll_equivalence_table_set() function can return the following error codes:

```
     pmll_exps_are_present_in_db_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

The pmll_equivalence_table_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

7.4.6.3.6.7 pmll_error_string_get

pmll_error_string_get-Get the error string associated with a PMLL error code.

Synopsis

```
#include <pmll.h>
const char *pmll_error_string_get(pmll_status_t errorCode);
```

Description

The pmll_error_string_get() function returns a concise string describing the error condition associated with errorCode.

Return Value

The pmll_error_string_get() function returns a concise string describing the error associated with errorCode.

7.4.6.3.6.8 pmll expression functions

pmll_exp_add-Add an expression to a PMLL shadow DB.

pmll_exp_delete-Delete an expression from a PMLL shadow DB.

pmll_exp_all_delete-Delete all expressions from a PMLL shadow DB.

pmll_exp_index_next_get-Get the index of the next PMLL expression.

pmll_exp_name_in_use-Check if an expression name is in use.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_exp_add(
     unsigned int
pmllDbHandle,
     uint32_t
recordVersion,
     const
pm_exp_record_t
*expRecord_p,
     uint32_t
*index_p);
```

pmll_status_t pmll_exp_delete(

```
     unsigned int
pmllDbHandle,
     uint32_t
idx);
```

pmll_status_t pmll_exp_all_delete(

```
     unsigned int
pmllDbHandle);
```

pmll_status_t pmll_exp_index_next_get(

```
     unsigned int
pmllDbHandle,
     uint32_t                                                                    idx,
     uint32_t
*nextIndex_p);
```

pmll_status_t pmll_exp_name_in_use(

```
     unsigned int
pmllDbHandle,
     const char
*name_p,
     bool
*nameIsInUse_p,
     uint32_t
*idx_p);
```

Description

pmll_exp_add() adds a single PMLL expression to a PMLL shadow DB with the pmllDbHandle handle. The function uses the index_p parameter to return an index that is assigned to the expression by PMLL. Other PMLL expression functions take this index as an input parameter that identifies the expression. The recordVersion parameter indicates the version of the expression record specified by expRecord_p. The supported version for Pattern Matcher 1.1 is PMLL_EXP_RECORD_V_1_0_0, which is defined in pmll.h.

The expRecord_p parameter is a pointer to the pm_exp_record_t structure, which is defined in pm_defs.h. The pm_exp_record_v_1_0_0_t type below defines the version 1.0.0 of the PMLL expression record. The user needs to create this record and cast it to the generic PMLL expression record type (pm_exp_record_t) and use this generic type in the PMLL functions.

typedef struct pm_pattern_record_t {

```
     uint8_t
        triggerEntry[PM_TRIGGER_ENTRY_SIZE];
     uint8_t
        keyElementEntry[PM_KEY_ELEMENT_ENTRY_SIZE];
     uint8_t
        confirmationEntry[PM_CONFIRMATION_ENTRY_SIZE];
     struct pm_pattern_record_t
        *nextPatternRecord_p;
} pm_pattern_record_t;
```

typedef struct {

```
     char
name_s[PM_NAME_MAX_LENGTH];
     pm_pattern_record_t
patterns;
} pm_exp_record_v_1_0_0_t;
```

typedef uint8_t *pm_exp_record_t;

pmll_exp_delete() deletes the expression with idx index from the PMLL shadow DB specified by pmllDbHandle.

pmll_exp_all_delete() deletes all the expressions from the PMLL shadow DB specified by pmllDbHandle.

pmll_exp_index_next_get() retrieves the next valid expression index after the idx index in the PMLL shadow DB specified by pmllDbHandle. The retrieved index is returned through the nextIndex_p parameter. To get the first valid index the idx parameter must be set to the PMLL_NULL_INDEX value. The pmll_exp_index_next_get() function returns pmll_no_more_records_e when there are no valid expression records with index values greater than the passed in idx index value. The pmll_exp_index_next_get() function allows the user to "walk" through all the expressions in the PMLL shadow DB in an efficient way.

pmll_exp_name_in_use() checks if the name_p expression name is already in use in the PMLL shadow DB specified by pmllDbHandle. This is used to verify that a name is not already in use before attempting to add it to the PMLL shadow DB. If the name_p expression name is in use, the nameIsInUse_p parameter is set to true and the idx_p parameter is set to the index of the expression that uses name_p. If the name_p is not in use, then nameIsInUse_p is set to false.

Return Value

All the PMLL expression functions returns pmll_ok_e upon success or an error code upon a failure.

The pmll_exp_add() function can return the following error codes:

```
     pmll_exp_name_is_in_use_e
     pmll_failed_to_add_exp_to_name_db_e
     pmll_invalid_db_handle_e
     pmll_invalid_name_e
     pmll_module_not_initialized_e
     pmll_no_trigger_type_e
     pmll_null_pointer_parameter_e
     pmll_out_of_extension_blocks_e
     pmll_out_of_memory_e
     pmll_too_many_one_byte_patterns_e
     pmll_too_many_patterns_e
     pmll_too_many_patterns_e
     pmll_too_many_special_patterns_e
     pmll_too_many_two_byte_patterns_e
     pmll_too_many_variable_patterns_e
     pmll_unsupported_record_version_e
     pmll_unsupported_trigger_type_e
```

The pmll_exp_delete() function can return the following error codes:

```
     pmll_exp_is_not_in_name_db_e
     pmll_exp_is_used_in_rule_e
     pmll_index_is_not_in_use_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
```

The pmll_exp_all_delete() function can return the following error codes:

```
     pmll_exp_is_not_in_name_db_e
     pmll_exp_is_used_in_rule_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
```

The pmll_exp_index_next_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_no_more_records_e
     pmll_null_pointer_parameter_e
```

The pmll_exp_name_in_use() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

pmll_supported_exp_record_versions_get(), pmll_supported_exp_record_versions_num_get()

7.4.6.3.6.9 pmll_module_init, pmll_module_shutdown

pmll_module_init-Initialize the PMLL module.

pmll_module_shutdown-Shuts down the PMLL module.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_module_init(
     unsigned int
initialDbHandleNum,
     bool
expandDbHandleNumFlag);
pmll_status_t pmll_module_shutdown(void);
```

Description

pmll_module_init() initializes the PMLL module. No other PMLL API function will work properly until the pmll_module_init() function has been called. The initialDbHandleNum parameter indicates the initial number of the PMLL shadow DB handles to be created. The expandDbHandleNumFlag flag indicates if the pool of PMLL shadow DB handles can be expanded or not when there are no more handles available in the pool. In order to allow the dynamic expansion of the PMLL shadow DB handle pool the expandDbHandleNumFlag flag must be set to true. If it is set to false, dynamic expansion of the PMLL shadow DB handle pool will not be allowed.

pmll_module_shutdown() destroys the global resources used by the PMLL module and shuts down the PMLL module.

Return Value

The pmll_module_init() and pmll_module_shutdown() functions return pmll_ok_e upon success or an error code upon failure.

The pmll_module_init() function can return the following error codes:

```
     pmll_bad_confirmation_rec_size_e
     pmll_bad_trigger_rec_size_e
     pmll_handle_table_create_failure_e
     pmll_pmhi_init_failed_e
     pmll_too_few_error_strings_e
     pmll_too_few_trig_row_format_defs_e
     pmll_too_many_error_strings_e
     pmll_too_many_trig_row_format_defs_e
```

The pmll_module_shutdown() function can return the following error codes:

```
     pmll_handle_table_destroy_failure_e
```

7.4.6.3.6.10 pmll pmla functions

pmll_pmla_functions_set-Set the PMLA functions.

pmll_pmla_functions_get-Retrieve the PMLA functions.

pmll_pmla_bulk_begin-Indicate the beginning of a bulk operation.

pmll_pmla_bulk_end-Indicate the end of a bulk operation.

pmll_pmla_error_string_get-Get error string describing an error code.

pmll_pmla_flush-Flush messages in the PMLA connection.

pmll_pmla_read-Read a PMP message.

pmll_pmla_write-Write a PMP message.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_pmla_functions_get(
     unsigned int
pmllDbHandle,

pmll_pmla_functions_t
*functions_p);
```

pmll_status_t pmll_pmla_functions_set(

```
     unsigned int
pmllDbHandle,

pmll_pmla_functions_t
*functions_p);
```

Description

PMLA is responsible for implementing a communication channel to and from the PMCI module and for conveying PMP control messages across that communication channel. Users can develop and use their own versions of PMLA functions. This allows the communication channel to the PMCI module to be defined by users according to their requirements. Sample PMLA functions are delivered with the PM software. They are implemented in pmla_slm_api.c.

The PMLL module uses the following PMLA functions:

pmll_pmla_bulk_begin(), pmll_pmla_bulk_end(), pmll_pmla_error_string_get(), pmll_pmla_flush(), pmll_pmla_read() and pmll_pmla_write() functions.

The PMLA functions called by PMLL are registered with PMLL through a call to the pmll_db_create() function. The PMLA functions associated with a PMLL shadow DB can subsequently be changed using the pmll_pmla_functions_set() and pmll_pmla_functions_get() functions.

In pmll_pmla_functions_set() and pmll_pmla_functions_get() the pointers to the PMLA functions are passed through the functions_p parameter and the functions are registered against the PMLL shadow DB with the pmllDbHandle handle. The registered PMLA functions are used by PMLL to implement the commit and a number of other operations. The return value of zero in all the registered PMLA functions, except for the pmll_pmla_error_string_get() function, indicates that the operation was successful; a non-zero return value indicates an error. PMLL does not interpret the PMLA error codes. The signatures of the PMLA functions that must be registered and the pmll_pmla_functions_t structure are given below.

typedef int pmll_pmla_bulk_begin_function_t (handle_t pmlaHandle);

typedef int pmll_pmla_bulk_end_function_t (handle_t pmlaHandle);

typedef const char *pmll_pmla_error_string_getFunction_t (int errorCode);

typedef int pmll_pmla_flush_function_t (handle_t pmlaHandle);

typedef int pmll_pmla_read_function_t (handle_t pmlaHandle, pmp_msg_t *msg_p);

typedef int pmll_pmla_write_function_t (handle_t pmlaHandle, pmp_msg_t *msg_p);

```
typedef struct {
     pmll_pmla_bulk_begin_function_t

*pmlaBulkBeginFunction_p;
     pmll_pmla_bulk_end_function_t

*pmlaBulkEndFunction_p;
     pmll_pmla_flush_function_t

*pmlaFlushFunction_p;
     pmll_pmla_read_function_t

*pmlaReadFunction_p;
     pmll_pmla_write_function_t

*pmlaWriteFunction_p;
     pmll_pmla_error_string_get_t

*pmlaErrorStringGetFunction_p;
} pmll_pmla_functions_t;
```

When registering the PMLA functions with pmll_pmla_functions_set() function all the functions in the functions_p structure must be defined. A NULL function pointer in the functions_p structure will cause pmll_pmla_functions_set() to fail with the pmll_cannot_register_null_pmla_func_e error code. None of the functions in the functions_p structure are registered in this case.

pmll_pmla_functions_get() retrieves the pointers to the PMLA functions currently registered with the PMLL shadow DB with the pmllDbHandle handle. The retrieved function pointers are returned through the functions_p parameter.

The pmll_pmla_bulk_begin() and pmll_pmla_bulk_end() functions are invoked by the pmll_commit() function at the beginning and the end of loading of the PMLL shadow DB image to the PM hardware. PMLL has no requirements and imposes no restrictions on how these functions are implemented. A failure of either of these functions is logged but otherwise ignored by PMLL. The functions are intended to indicate the start and end of multiple related messages sent by the PMLL to the PMCI.

The pmll_pmla_error_string_get() is expected to return a string describing the specified error code. This function is used by PMLL while generating logs.

The pmll_pmla_flush() is invoked from the pmll_commit() function and it is expected to call the pmci_flush() function. The pmci_flush() function blocks until all the outstanding requests on the PMCI channel are processed.

The pmll_pmla_read() function is expected to call the pmci_read() function, which implements reading of a PMP control message from the PM hardware.

The pmll_pmla_write() function is expected to call the pmci_write() function, which implements writing of a PMP control message to the PM hardware.

Return Value

pmll_pmla_functions_get() and pmll_pmla_functions_set() functions return pmll_ok_e upon success or an error code upon failure.

The pmll_pmla_functions_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

The pmll_pmla_functions_set() function can return the following error codes:

```
     pmll_cannot_register_null_pmla_func_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

7.4.6.3.6.11 pmll rule functions

pmll_rule_add-Add a rule to a PMLL shadow DB.

pmll_rule_delete-Delete a rule from a PMLL shadow DB.

pmll_rule_all_delete-Delete all rules from a PMLL shadow DB.

pmll_rule_index_next_get-Get the index of the next PMLL rule.

pmll_rule_name_in_use-Check if a rule name is in use.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_rule_add(
     unsigned int
pmllDbHandle,
     uint32_t
recordVersion,
     const
pm_rule_record_t
*ruleRecord_p,
     uint32_t
*index_p);
pmll_status_t pmll_rule_delete(
     unsigned int
pmllDbHandle,
     uint32_t
idx);
pmll_status_t pmll_rule_all_delete(
     unsigned int
pmllDbHandle);
pmll_status_t pmll_rule_index_next_get(
     unsigned int
```

```
pmllDbHandle,
     uint32_t                                                                    idx,
     uint32_t
*nextIndex_p);
pmll_status_t pmll_rule_name_in_use(
     unsigned int
pmllDbHandle,
     const char
*name_p,
     bool
*nameIsInUse_p,
     uint32_t
*idx_p);
```

Description

pmll_rule_add() adds a single PMLL rule to a PMLL shadow DB with the pmllDbHandle handle. The function uses the index_p parameter to return an index that is assigned to the rule by PMLL. Other PMLL rule functions take this index as an input parameter that identifies the rule. The recordVersion parameter indicates the version of the rule record to be added and passed in using the ruleRecord_p parameter. The supported version for Pattern Matcher 1.1 is PMLL_RULE_RECORD_V_1_0_0, which is defined in pmll.h.

The ruleRecord_p parameter is a pointer to the pm_rule_record_t structure, which is defined in pm_defs.h. The pm_rule_record_v_1_0_0_t type below defines the version 1.0.0 of the PMLL rule record. The user needs to create this record and cast it to the generic PMLL rule record type (pm_rule_record_t) and use this generic type in the PMLL functions.

typedef enum {

```
     pm_null_reaction_event_type_e
=  0,
     pm_pattern_reaction_event_type_e
=  1,
     pm_end_of_sui_reaction_event_type_e
=  2,
     pm_last_reaction_event_type_e
= pm_end_of_sui_reaction_event_type_e
} pm_reaction_event_type_t;
```

typedef struct pm_reaction_entry_t {

```
     uint32_t
reactionEventType;
     char
expName_s[PM_NAME_MAX_LENGTH];
     struct pm_reaction_entry_t

*nextReactionEntry_p;
     uint32_t
reactionSize;
     uint8_t
reactionData[PM_MAX_REACTION_SIZE];
} pm_reaction_entry_t;
```

typedef struct ruleRecord_t {

```
     char
name_s[PM_NAME_MAX_LENGTH];
     uint32_t
reactionNum;
     pm_reaction_entry_t
```

```
*reactionEntry_p;
} pm_rule_record_v_1_0_0_t;
```

typedef uint8_t *pm_rule_record_t;

pmll_rule_delete() deletes the rule with the idx index from the PMLL shadow DB with the pmllDbHandle handle.

pmll_rule_all_delete() deletes all the rules from the PMLL shadow DB with the pmllDbHandle handle.

pmll_rule_index_next_get() retrieves the next valid rule index after the idx index in the PMLL shadow DB with the pmllDbHandle handle. The retrieved index is returned through the nextIndex_p parameter. To get the first valid index the idx parameter must be set to the PMLL_NULL_INDEX value. The pmll_rule_index_next_get() function returns pmll_no_more_records_e when there are no valid rule records with index values greater than the passed in idx index value. The pmll_rule_index_next_get() function allows the user to "walk" through all the rules in the PMLL shadow DB in an efficient way.

pmll_rule_name_in_use() checks if the name_p rule name is already in use in the PMLL shadow DB with the pmllDbHandle handle. If the name_p rule name is in use, the function sets the nameIsInUse_p parameter to true and the idx_p parameter to the index of the rule that uses the name_p rule name. If the name_p rule name is not in use, the function sets the nameIsInUse_p parameter to false.

Return Value

All the PMLL rule functions returns pmll_ok_e upon success or an error code upon failure.

The pmll_rule_add() function can return the following error codes:

```
    pmll_bad_reaction_event_type_e
    pmll_exp_is_not_in_name_db_e
    pmll_failed_to_add_rule_to_name_db_e
    pmll_failed_to_alloc_rule_ctx_area_e
    pmll_failed_to_alloc_rule_ctx_area_e
    pmll_invalid_db_handle_e
    pmll_invalid_name_e
    pmll_misaligned_reaction_e
    pmll_module_not_initialized_e
    pmll_no_reactions_in_rule_e
    pmll_no_reactions_in_rule_e
    pmll_null_pointer_parameter_e
    pmll_Aout_of_memory_e
    pmll_out_of_rule_ids_e
    pmll_reaction_too_big_e
    pmll_reaction_too_small_e
    pmll_rule_name_is_in_use_e
    pmll_too_many_reactions_in_rule_e
    pmll_too_many_rules_e
    pmll_unsupported_record_version_e
```

The pmll_rule_delete() function can return the following error codes:

```
    pmll_index_is_not_in_use_e
    pmll_invalid_db_handle_e
    pmll_module_not_initialized_e
```

The pmll_rule_all_delete() function can return the following error codes:

```
    pmll_invalid_db_handle_e
    pmll_module_not_initialized_e
    pmll_rule_is_not_in_name_db_e
```

The pmll_rule_index_next_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_no_more_records_e
     pmll_null_pointer_parameter_e
```

The pmll_rule_name_in_use() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

pmll_supported_rule_record_versions_get(), pmll_supported_rule_record_versions_num_get()

7.4.6.3.6.12 pmll_stats_get

pmll_stats_get-Retrieve the PMLL statistics.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_stats_get(
     unsigned int
pmllDbHandle,
     pmll_stats_t
*llStats_p);
```

Description

The pmll_stats_get() function retrieves the PMLL statistics for the PMLL shadow DB with the pmllDbHandle handle. The retrieved statistics are returned to the caller through the llStats_p parameter. The pmll_stats_t structure is defined as follows:

typedef struct {

```
     struct {                                        // uncompressed trigger stats.
          uint32_t  variableChainNum;                   // # of variable trigger chains
          uint32_t  twoByteChainNum;                    // # of 2-byte trigger chains
          uint32_t  oneByteChainNum;                  // # of 1-byte trigger chains
          uint32_t  specialChainNum;                    // # of special trigger chains
     };
     struct {                                        // post-cluster-compres. trigger stats.
          // # of variable resident trigger chains
          uint32_t  variableResidentChainNum;
          // # of variable guest trigger chains
          uint32_t  variableGuestChainNum;
          // # of 2-byte resident trigger chains
          uint32_t  twoByteResidentChainNum;
          // # of 2-byte guest trigger chains
          uint32_t  twoByteGuestChainNum;
          // # of 1-byte resident trigger chains
          uint32_t  oneByteResidentChainNum;
          // # of 1-byte guest trigger chains
          uint32_t  oneByteGuestChainNum;
          // # of special resident trigger chains
          uint32_t  specialResidentChainNum;
          // # of special guest trigger chains
          uint32_t  specialGuestChainNum;
```

```
     };
     struct {                                        // post-foldback-compression trigger
stats.
          // number of primary entries
          uint32_t  primaryEntryNum;
          // number of secondary entries
          uint32_t  secondaryEntryNum;
     };
} pmll_stats_t;
```

Return Value

The pmll_stats_get() function returns pmll_ok_e upon success or an error code upon a failure. The pmll_stats_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

7.4.6.3.6.13 pmll version functions

pmll_supported_exp_record_versions_get-Get the supported expression record versions.

pmll_supported_exp_record_versions_num_get-Get the number of the supported expression versions.

pmll_supported_rule_record_versions_get-Get the supported rule record versions.

pmll_supported_rule_record_versions_num_get-Get the number of the supported rule versions.

pmll_version_str_get-Get a version description string.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_supported_exp_record_versions_get(
     uint32_t *versionTable_p,
     uint32_t tableSize);
uint32_t pmll_supported_exp_record_versions_num_get(void);
pmll_status_t pmll_supported_rule_record_versions_get(
     uint32_t *versionTable_p,
     uint32_t tableSize);
uint32_t pmll_supported_rule_record_versions_num_get(void);
char * pmll_version_str_get(
     uint32_t  version,
     char     *versionStr_p);
```

Description

pmll_supported_exp_record_versions_get() allows the user to retrieve the numerical values of the supported expression record versions. The number of the supported versions can be retrieved with pmll_supported_exp_record_versions_num_get(). The supported versions are returned to the caller through the versionTable_p table which should have tableSize entries in it.

pmll_supported_exp_record_versions_num_get() retrieves the number of the supported expression record versions.

pmll_supported_rule_record_versions_get() allows the user to retrieve the numerical values of the supported rule record versions. The number of the supported versions can be retrieved with pmll_supported_rule_record_versions_num_get(). The supported versions are returned to the caller through the versionTable_p table which should have tableSize entries in it.

pmll_version_str_get() returns a string describing the numerical version passed in the version parameter. The returned version string is stored in the versionStr_p buffer that should be at least PMLL_VERSION_STR_LENGTH bytes long.

Return Value

The pmll_supported_exp_record_versions_get() and pmll_supported_rule_record_versions_get() functions return pmll_ok_e upon success or an error code upon failure.

The pmll_supported_exp_record_versions_get() function can return the following error codes:

```
     pmll_null_pointer_parameter_e
```

The pmll_supported_rule_record_versions_get() function can return the following error codes:

```
     pmll_null_pointer_parameter_e
```

The pmll_supported_exp_record_versions_num_get() and pmll_supported_rule_record_versions_num_get() return the numbers of the supported expression or rule record versions, respectively.

The pmll_version_str_get() function returns the pointer passed in the versionStr_p parameter.

7.4.6.3.6.14 pmll_variable_trigger_size_get, pmll_variable_trigger_size_set

pmll_variable_trigger_size_get-Get the size of the variable trigger.

pmll_variable_trigger_size_set-Set the size of the variable trigger.

Synopsis

```
#include <pmll.h>
pmll_status_t pmll_variable_trigger_size_get(
     unsigned int pmllDbHandle,
     uint32_t *variableTriggerSize_p);
```

pmll_status_t pmll_variable_trigger_size_set(

```
     unsigned int pmllDbHandle,
     uint32_t variableTriggerSize);
```

Description

pmll_variable_trigger_size_get() retrieves the currently configured value of the variable trigger size in the PMLL shadow DB with the pmllDbHandle handle. The retrieved value is returned to the caller through the variableTriggerSize_p parameter.

pmll_variable_trigger_size_set() sets the value of the variable trigger size in the PMLL shadow DB with the pmllDbHandle handle to variableTriggerSize. The function should be called prior to adding any expressions to the PMLL shadow DB. The function will return a failure status code if it is invoked when there are expressions present in the PMLL shadow DB.

Return Value

The pmll_variable_trigger_size_get() and pmll_variable_trigger_size_set functions return pmll_ok_e upon success or an error code upon a failure.

The pmll_variable_trigger_size_get() function can return the following error codes:

```
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_null_pointer_parameter_e
```

The pmll_variable_trigger_size_set() function can return the following error codes:

```
     pmll_exps_are_present_in_db_e
     pmll_invalid_db_handle_e
     pmll_module_not_initialized_e
     pmll_vtrigger_size_out_of_range_e
```

7.4.6.3.7 Pattern Matcher driver

This chapter describes the interfaces provided by the Pattern Matcher driver. The Pattern Matcher driver can be built into the kernel statically or as a set of dynamically-loaded kernel modules. In both cases, a small piece of platform support is built into the kernel statically to handle platform-initialisation, early-boot contiguous memory allocation, etc. The driver provides both user space and kernel space APIs that are used to configure the hardware as well as perform pattern matching operations.

The user space API is described in the following sections:

PME Configuration on page 940 provides the details on the various PME configuration requirements and sysfs interface. The configuration attribute may reside in the device-tree, as Kconfig options and as sysfs entries. There are also statistics which are collected on a continuous basis and made available either via a kernel api and sysfs.

PME Scan on page 951 provides an interface to perform pattern matching operations. This interface operates on the /dev/pme_scan device using various ioctls.

PME Database on page 947 provides an interface for configuring and modifying the PME database in hardware. This operates via the /dev/pme_db device and would not typically be used directly but instead user-space interfaces like PMCI and PMM would be used that incorporate the proprietary tools necessary to compile, link, and load patterns and rules.

The various user space ioctl() calls require an appropriate device descriptor parameter. The devices are created via a call to open(). The table, Devices for IOCTL System Calls, summarizes the devices required for each type of ioctl system call.

Devices for IOCTL System Calls

Device	IOCTL Type
/dev/pme_scan	PME Scan
/dev/pme_db	PME Database

PME Kernel API on page 960 allows kernel programmers to create pattern matcher contexts that can be used for scanning operations.

The PME Driver is a patch-set to the kernel providing a driver (static or module) and a header file that defines the driver interfaces. If built as a module, the driver names are pme.ko, pme_scan.ko and pme_db.ko. The header file is fsl_pme.h, located in the linux include directory-included via "#include <linux/fsl_pme.h>".

7.4.6.3.7.1 PME Configuration

Various items must be configured in order to utilize the PME device. These include device-tree entries, Kconfig parameters, module parameters (when using loadable modules) and also sysfs entries.

7.4.6.3.7.1.1 Device Tree Node Entry

Synopsis

pme: pme@316000 {

```
          compatible = "fsl,pme"
          reg = <0x316000 0x10000>;
 /* fsl,pme-pdsr = <0x0 0x23000000 0x0 0x01000000>; */
 /* fsl,pme-sre = <0x0 0x24000000 0x0 0x00a00000>; */
 interrupts = <16 2 1 5>;
};
```

Description

The Pme device tree node represents the Pme device and its CCSR configuration space. When a linux kernel has Pme support built in, it will react to this device tree node by configuring and managing the Pme device. It uses the Pme configuration interface to implement this. The device-tree node sits within the CCSR node ("soc").

"*fsl,pme-pdsr*" property specifies the start location and size of the Pattern Description and Stateful Rule Table in system memory. The table base address must be aligned to a natural 128-byte address boundary. The maximum size of the table is 128 Mbytes for PME v.2.0, 64 Mbytes for PME v2.1 and 32 Mbytes for PME v2.2. The current driver implementation allows this memory resource to be specified via the "*fsl,pme-pdsr*" device-tree property, or by resorting to a default allocation of contiguous memory early during kernel boot. This property specifies a 2-tuple of address and size (address is optional), specifying the physical address range. These elements are expressed as 64-bit values, so take two cells each;

fsl,pme-pdsr = <0x0 0x20000000 0x0 0x01000000>;

Optionally, only the size can be specified and the kernel will try to allocate the contiguous memory during boot time.

fsl,pme-pdsr = <0x0 0x100000>

If the hypervisor is in use, this address range is "guest physical". If the given memory range falls within the range used by the Linux OS, it will attempt to reserve the range against use by the OS.

"*fsl,pme-sre*" property specifies the start location and size of the SRE Context Table in system memory. The table base address must be aligned to a natural 32-byte address boundary. The maximum size of the table is 4 Gbytes. The current driver implementation allows this memory resource to be specified via this device-tree property, or by resorting to a default allocation of contiguous memory early during kernel boot. This node property specifies a 2-tuple of address and size (address is optional), specifying the physical address range. These elements are expressed as 64-bit values, so take two cells each;

fsl,pme-sre = <0x0 0x20000000 0x0 0x01000000>;

Optionally, only the size can be specified and the kernel will try to allocate the contiguous memory during boot time.

fsl,pme-sre = <0x0 0x300000>;

If the hypervisor is in use, this address range is "guest physical". If the given memory range falls within the range used by the Linux OS, it will attempt to reserve the range against use by the OS.

7.4.6.3.7.1.2 KCONFIG Options

Description

The Pme device supports various kernel configuration options.

FSL_PME2_PDSRSIZE

Pattern Description and Stateful Rule default table size defined as the number of 128 byte entries. This only takes effect if the device tree node doesn't have the 'fsl,pme-pdsr' property present. Valid range is 74240-1048573 (9.5MB-128MB). The default is 131072 (16MB)

FSL_PME2_SRESIZE

SRE Session Context Entries table default table size defined as the number of 32 byte entries. This only takes effect if the device tree node doesn't have the 'fsl,pme-sre' property present. Valid range is 0-134217727 (0-4GB) and the default is 327680 (10MB)

FSL_PME2_SRE_AIM

Select the inconclusive match mode treatment. When true the alternate inconclusive mode is used. When false the default inconclusive mode is used. The default is off.

FSL_PME2_SRE_ESR

Configures if an End of SUI event will produce a Simple End of SUI report.

FSL_PME2_SRE_CTX_SIZE_PER_SESSION

Configures the default SRE Context Size per Session as a power of 2 (e.g. a value of 5 translated to 32 bytes, whereas a value of 15 translated to 32 kbytes. Valid range is 5 to 17 with a default of 17.

FSL_PME2_SRE_CNR

Configured Number of Stateful Rules as a multiple of 256. Valid range is 0 to 128 with a default of 128 (i.e. 32kbytes).

FSL_PME2_SRE_MAX_INSTRUCTION_LIMIT

Configured maximum number of SRE instructions to be executed per reaction. Valid range is 0 to 65535 with a default of 65535.

FSL_PME2_SRE_MAX_BLOCK_NUMBER

Configured the maximum number of reaction head blocks to be traversed perpattern match event (e.g. a matched pattern or an End of SUI event).Valid range is 0 to 32767 with a default of 32767.

FSL_PME2_DB_QOSOUT_PRIORITY

Configures the /dev/pme_db qos priority level for its output frame queue. Valid range is 0 to 7 with a default of 2.

FSL_PME2_STAT_ACCUMULATOR_UPDATE_INTERVAL

The pme accumulator kernel thread reads the current device statistics and add it to a running counter. The frequency (expressed in milliseconds) of these updates may be controlled. If 0 is specified, no automatic updates are done. Valid range is 0 to 10000 with a default of 3400 (e.g. 3400 milliseconds).

7.4.6.3.7.1.3 SYSFS Attributes

Description

The sysfs interface is used to control global pme configuration Pme device parameters and provides an interface for pme statistics. The path to the device attributes is /dev/fsl-pme-dev. The following attributes are defined:

aim

This read-write field specifies the inconclusive match mode treatment. When this field is set to 1, the "alternate" inconclusive mode is used. When this field is set to 0 the "default" inconclusive mode is used. The default is 0.

bsc/[0-63]

This read-write field specifies the buffer pool size for the specified buffer pool id (0-63). When PME h/w acquires a buffer pool it determines the size of these buffers based on this configuration. A value of 0 causes the PME not to attempt any acquires. Valid range is 0 to 11 encoded as follows: 0 - 0 1 - 64 bytes 2 - 128 bytes 3 - 256 bytes 4 - 512 bytes 5 - 1024 bytes 6 - 2048 bytes 7 - 4096 bytes 8 - 8192 bytes 9 - 16,384 bytes 10 - 32,768 bytes 11 - 65,536 bytes

cdcr

This read-write entry disables the specified Pme caching. This value should generally always be zero (i.e. caching always enabled).

dmcr

This read-write entry is the DXE memory control settings.

ecc1bes

This read-write entry contains status bits indicating which internal SRAM instances have accumulated more single bit errors than their programmed threshold.

ecc2bes

This read-write entry contains status bits indicating which internal SRAM instances have had at least one double bit error detected.

eccaddr

This read-only entry, when a bit becomes set in the ecc1bes or ecc2bes registers, the Pme internal memory, and the address within that memory, on which the error was detected are recorded in this entry.

ecccode

This read-only entry, when a bit becomes set in the ecc1bes or ecc2bes entry, the corresponding ECC code and syndrome are recorded in this entry.

ecr0

This read-only entry captures debug information that is specific to the most recent Status code of the highest severity error that the Pme has seen but not necessarily communicated to the CPU via a report.

ecr1

This read-only entry captures debug information that is specific to the most recent Status code of the highest severity error that the Pme has seen but not necessarily communicated to the CPU via a report.

efqc_int

This read-write entry specifies the delay (an interval) between consecutive PMFA dequeue requests. Valid value are: 0, 64, 128, 256 (default) and 512.

end_of_simple_sui_report

This read-write entry specifies the delay (an interval) between consecutive PMFA dequeue requests. Valid value are: 0, 64, 128, 256 (default) and 512.

end_of_sui_reaction_ptr

This read-write entry specifies the head pointer of the reaction linked list that is to be traversed by the SRE for every End of SUI event. The pointer is an index to a 128-byte block relative to the start of the PDSR table. Valid rang is 0x0 to 0xFFFFF for PME ver 2.0, 0x0 to 0x7FFFF for PME ver 2.1 and 0x0 to 0x3FFFF for PME ver 2.2. The default is 0x0.

esr

This read-write attribute contains the Status code of the highest severity error that the Pme has seen but not necessarily communicated to the CPU via a report.t

faconf

This read-only attribute is the frame agent configuretion.

famcr

This read-write attribute configures he frame agent memory control.

isr

This read-only attribute displays the current interrupt status register value. A non zero value indicates that a serious error was detected and consequently the PME device stops processing input until informed otherwise.

kvlts

This read-write entry specifies the size of the KES Variable Length Trigger from 2 to 16 bytes. Valid range is 0 to 16 with 2 being the default.

liodnr

This read-only entry specifies the LIODN value to use when PM accesses its private data structures.

max_allowed_test_line_per_pattern

This read-write entry specifies maximum allowed test line executions per pattern (scaled by a factor of 8; the actual maximum allowed test line executions is equal to MTE*8). The maximum allowed value for this field is 0x3FFF which translates into a maximum allowed test line execution value of 131,064. Valid range is 0x0 to 0x3FFF with 0x3FFF being the default.

max_chain_length

This read-write entry specifies the maximum chain length. This is the maximum number of allowed entries in confidence collision chains. Valid range is 0x0 to 0x7FFF with 0x7FFF being the default.

max_pattern_evaluations_per_sui

This read-write entry specifies maximum pattern evaluations per SUI (scaled by a factor of 8; the actual maximum allowed pattern evaluations is equal to value*8). A value of 0xFFFF will be treated as an infinite limit. Valid range is 0x0 to 0xFFFF with 0xFFFF being the default.

max_pattern_matches_per_sui

This read-write entry specifies maximum pattern matches per SUI (scaled by a factor of 8; the actual maximum allowed pattern matches is equal to value*8). A value of 0xFFFF will be treated as an infinite limit. Valid range is 0x0 to 0xFFFF with 0xFFFF being the default.

max_pdsr_index

This read-write entry specifies the maximum allocated index into the Pattern Description and Stateful Rule table available to the DXE. Valid range is 0x0 to 0xFFFFC for PME ver 2.0, 0x0 to 0x7FFFC for PME ver 2.1 and 0x0 to 0x3FFFC for PME ver 2.2. The index is 128-byte based.

miace

This read-write attribute is used specify the client read and write ports that are included in the miablc and miabyc counts. It is also used to specify the size of the aligned blocks counted by miablc

miacr

This read-write attribute is used to configure various client read and write port attributes.

pattern_range_counter_idx

This read-write entry specifies the index value targeted for counting pattern matches. Note that this field is only wide enough to allow specification of indices within the PDSR table that the DXE will access. Table entries beyond 0x1FFFF are only accessible by the SRE. Valid range is 0x0 to 0x1FFFF for PME ver 2.0, 0x0 to 0xFFFF for PME ver 2.1 and 0x0 to 0x7FFF for PME ver 2.2. The default is 0x0.

pattern_range_counter_mask

This read-write entry specifies the index mask for pattern_range_counter_index, allowing ranges of addresses to be targeted. A 0 in any bit means a "don't care" in the corresponding pattern_range_counter_index bit. Valid range is 0x0 to 0x1FFFF for PME ver 2.0, 0x0 to 0xFFFF for PME ver 2.1 and 0x0 to 0x7FFF for PME ver 2.2, with 0x0 being the default.

pdsrbah

This read-only attribute is used to provision the start location (upper bit 32 bits) of the PRSR table space in system memory.

pdsrbal

This read-only attribute is used to provision the start location (lower 32 bits) of the PRSR table space in system memory.

pehd

This read-write attribute disables selected Pme (KES, DXE or SRE) error condition detection.

pmtr

This read-write attribute allows programming of a time based latency threshold such that memory read transactions whose latency exceeds the threshold can be measured using the integrated performance monitor.

report_length_limit

This read-write entry specifies the maximum number of bman buffers that can be allocated for a single output report frame. A value of zero disables length limiting. Valid range is 0x0 to 0xFFFF with 0x0 being the default.

rev1

This read-only attribute provides the unique IP block ID for the Pattern Matcher block, as well as major and minor revision numbers. It is displayed as a hexadecimal value.

rev2

This read-only attribute provides the Pattern Matcher block integration and configuration options.

scbarh

This read-only attribute is used to provision the start location (upper bit 32 bits) of the SRE table space in system memory.

scbarl

This read-only attribute is used to provision the start location (lower 32 bits) of the SRE table space in system memory.

smcr

This read-write attribute is used to provide software with control over system memory transaction attributes for the SRE.

src_id

This read-only attribute specifies the source id that the PME uses in system bus transactions.

sre_context_size

This read-only entry specifies the context size per session. This represent the FSL_PME2_SRE_CTX_SIZE_PER_SESSION Kconfig value. Valid range is 0 to 13 encoded as follows: 0 - 0 1 - 32 bytes 2 - 64 bytes ... 13 - 128 bytes

sre_max_block_num

This read-write entry specifies the maximum number of reaction head blocks to be traversed per pattern match event. Valid range is 0x0 to 0x3FFF with 0x3FFF being the default.

sre_max_index_size

This read-only entry specifies the maximum allocated 128-bytes based index in the Pattern Description and Stateful Rule table that is to be accessed by the SRE. Valid range is 0x0 to 0xFFFFC.

sre_max_instruction_limit

This read-write entry specifies the maximum number of SRE instructions to be executed per reaction. Valid range is 0x0 to 0xFFFF with 0xFFFF being the default.

sre_max_offset_ctrl

This read-only entry specifies maximum 32-byte index offset for the SRE context table.

sre_pscl

This read-only entry specifies the prescaler value for the SRE Instruction Operand register $C free running counter

sre_rule_num

This read-only entry specifies the configured number of Stateful Rules as a multiple of 256. The default is 128 (i.e. 32kbytes). This represents the FSL_PME2_SRE_CNR Kconfig value.

sre_session_ctx_num

This read-only entry specifies the maximum number of session contexts. This is derived by dividing the size of the SRE table size by per session configured size.

sw_db

This read-write entry can be used by software to hold a version number for the pattern match database. This attribute is currenly not used.

The PME h/w maintains various statistics. The Pme drivers polls these statistics at a configurable interval. The h/w statistics are read-reset based whereas the driver simply keep a running 64 bit counter. Writing a zero to the sysfs entry will clear both the driver and h/w counter. The sysfs interface to these statistics are located in the *stats* subdirectory. The following statistics are defined:

cmecc1ec

This read-write attribute contains a count of the number of single bit ECC errors that have occurred.

dxcmecc1ec

This read-write attribute contains a count of the number of single bit ECC errors that have occurred.

dxemecc1ec

This read-write attribute contains a count of the number of single bit ECC errors that have occurred.

mia_blc

This read-write attribute represents the number of bus aligned memory block accesses for all memory transactions that reach the system bus.

mia_byc

This read-write attribute represents the number of bytes transferred for all memory transactions that reach the system bus.

rbc

This read-write attribute indicates the number of read bytes.

stnch

This read-write attribute indicates the number of confidence check passed by the confidence mechanism.

stndsr

This read-write attribute indicates the number of Stateful Rule executions caused by DXE generated events.

stnesr

This read-write attribute indicates the number of Stateful Rule executions caused by End of SUI events.

stnib

This read-write attribute indicates the number of input bytes scanned by the Pattern Matcher.

stnis

This read-write attribute indicates the number of SUIs scanned by the Pattern Matcher.

stnob

This read-write attribute indicates the number of output bytes produced in reports by the Pattern Matcher.

stnpm

This read-write attribute indicates the number of pattern matches found by the Data Examination Engine.

stnpmr

This read-write attribute indicates the number of pattern match attempts within the index range defined by the Pattern Range Counter Index Configuration and Pattern Range Counter Mask Configuration attributes.

stns1m

This read-write attribute indicates the number of SUIs with at least one pattern match found within.

stns1r

This read-write attribute indicates the number of SUIs scanned that produced at least one report.

stnth1

This read-write attribute indicates the number of Triggers found by the 1-Byte Trigger mechanism.

stnth2

This read-write attribute indicates the number of Triggers found by the 2-Byte Trigger mechanism.

stnths

This read-write attribute indicates the number of Triggers found by the Special Triggers mechanism.

stnthv

This read-write attribute indicates the number of Triggers found by the Variable Length Trigger mechanism.

tbt0ecc1ec

This read-write attribute indicates the number of single bit ECC errors detected in the 2-byte Trigger 0 Table.

tbt1ecc1ec

This read-write attribute indicates the number of single bit ECC errors detected in the 2-byte Trigger 1 Table.

trunci

This read-write attribute indicates the count for every scan report that is produced where the report data has been truncated.

vlt0ecc1ec

This read-write attribute the number of single bit ECC errors detected in the Variable Length Trigger 0 Table.

vlt1ecc1ec

This read-write attribute indicates the number of single bit ECC errors detected in the Variable Length Trigger 1Table.

The Pme driver which polls these statistics has a configurable polling interval.

stats_ctrl/update_interval

This read-write attribute indicates the frequency (expressed in milliseconds) of the pme stats kernel thread updates. If 0 is specified, no automatic updates are done. Valid range is 0 to 10000 with a default of 4000 (e.g. 4 seconds).

The following attribute configure statistic related attributes:

stats_ctrl/cmecc1th

This read-write attribute contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/dxcmecc1th

This read-write attribute contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/dxemecc1th

This read-write attribute contains contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/tbt0ecc1th

This read-write attribute contains contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/tbt1ecc1th

This read-write attribute contains contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/vlt0ecc1th

This read-write attribute contains contains a threshold that controls reporting of 1-bit ECC errors.

stats_ctrl/vlt1ecc1th

This read-write attribute contains contains a threshold that controls reporting of 1-bit ECC errors.

7.4.6.3.7.2 PME Database

The /dev/pme_db devices device is used to send Pme pattern matcher database configuration requests. This device requires root permissions and only exists on the control plane. A user may acquire exclusive access to the Pattern Matcher device.

7.4.6.3.7.2.1 PMEIO_EXL_INC

PMEIO_EXL_INC-Acquire and increment exclusivity.

Synopsis

```
        ioctl(fd, PMEIO_EXL_INC);
```

Description

This ioctl() increments the exclusivity "counter". This enabled the user to acquire and keep exclusivity. This is a synchronous and interruptible API.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

EINVAL

The parameters specified are not valid

EINTR

The process was interrupted by a signal.

7.4.6.3.7.2.2 PMEIO_EXL_DEC

PMEIO_EXL_DEC-Decrements reference count and possible release exclusivity.

Synopsis

```
ioctl(fd, PMEIO_EXL_DEC);
```

Description

This ioctl() decrement the exclusivity reference counter. If the reference count reaches zero than exclusivity is also released.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

EINVAL

The parameters specified are not valid

EINTR

The process was interrupted by a signal.

7.4.6.3.7.2.3 PMEIO_EXL_GET

PMEIO_EXL_GET-Retrieve exclusivity reference count

Synopsis

```
ioctl(fd, PMEIO_EXL_GET, int *count);
```

Description

This ioctl() returns the currnent exclusivity counter and writes the result to *count*.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

EINVAL

The parameters specified are not valid

EINTR

The process was interrupted by a signal.

7.4.6.3.7.2.4 PMEIO_PMTCC

PMEIO_PMTCC-Send a synchronous pattern matching database request

Synopsis

```
ioctl(fd, PMEIO_PMTCC, struct pme_db *p);

struct pme_db {

    struct pme_buffer input;

    struct pme_buffer output;

    __u8 flags;

    enum pme_status status;

};

struct pme_buffer {

    void *data;

    size_t size;

};
```

Description

This ioctl() is used to send a synchronous pattern matching database request.

p contains the pme pmtcc command and response. Various input and output formats are supported depending on the input flag settings.

p->input is the contiguous input data buffer. Where *p->input.data* is the pointer to the contiguous user-space buffer and *p->input.size* indicates the number of bytes in this buffer.

p->output is where the resulting output/result is stored and is populated by the ioctl(). The *p->output.size* is updated to reflect the number of bytes written.

p->flags attribute is populated by the ioctl and is bit wise mask indicating operation results:

PME_DB_RESULT_UNRELIABLE-When set, indicates that this input was processed following detection and reporting of a serious Pattern Matcher error. Any report data carried within this input that was produced by Pattern Matcher cannot be considered reliable. Output tagged as Unreliable do not have a valid Status code.

PME_DB_RESULT_TRUNCATED-When set, indicates that the contents of the output data were truncated and are incomplete.

p->status attribute is the status code of the operation. This value is invalid if the PME_DBS_RESULT_UNRELIABLE bit mask was set in *p->flags*. Refer to fsl_pme.h for complete list of possible values:

pme_status_ok-operation was successful

all other values indicate an exception occurred.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.2.5 PMEIO_SRE_RESET

PMEIO_SRE_RESET-Performs an SRE rule reset operation

Synopsis

```
         ioctl(fd, PMEIO_SRE_RESET, struct pme_db_sre_reset *sre_reset);
struct pme_db_sre_reset {
    __u32 rule_vector[PME_SRE_RULE_VECTOR_SIZE];
    __u32 rule_index;
    __u16 rule_increment
    __u32 rule_repetitions;
    __u16 rule_reset_interval;
    __u8 rule_reset_priority;
};
#define PME_SRE_RULE_VECTOR_SIZE 8
```

Description

This ioctl() performs a sre rule reset operation. Exclusivity should be held during this operation in order to perform the operation atomically.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.2.6 PMEIO_NOP

PMEIO_NOP-Send a Pme nop command

Synopsis

```
ioctl(fd, PMEIO_NOP);
```

Description

This ioctl() send a Pme nop command. This has no effect on the Pme device. This is a blocking api. Upon return, this indicates that the response to the nop command has been received.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3 PME Scan

The /dev/pme_scan device is used to execute patterning matching from user space. The device can be used to peform synchronous (the calling thread is blocked until an operations completion) or asynchronous (once an operation has begun, the calling thread is able to perform other processing but needs to query the completion of the operation later). This section specifes the ioctl() values supported by the pme_scan device.

7.4.6.3.7.3.1 PMEIO_SCAN

PMEIO_SCAN-Perform a pattern matching request

Synopsis

```
ioctl(fd, PMEIO_SCAN, struct pme_scan *p);
```

struct pme_scan {

```
    struct pme_scan_cmd cmd;
    struct pme_scan_result result;
};
struct pme_scan_cmd {
    __u32 flags;
    void *opaque;
    struct pme_buffer input;
```

```
        struct pme_buffer output;

    };

    struct pme_scan_result {

        __u8 flags;

        enum pme_status status;

        struct pme_buffer output;

        void *opaque;

    };

    struct pme_buffer {

        void *data;

        size_t size;

    };
```

Description

This ioctl() is used to perform a synchronous pattern matching request. The API will block until the device has completed the request.

p contains the pme scan input command and response. Various input and output formats are supported depending on the input flag settings.

p->cmd.flags attribute defines input and output formats. It's a bit mask of the following values:

PME_SCAN_CMD_RES_BMAN-use Bman for output

PME_SCAN_CMD_STARTRESET- If residue is disabled indicates a Start of Flow. The first data byte of the input will be treated as the Start of Flow for anchored pattern matching purposes. If residue is enabled indicates a Flow Context Reset. The Start of Flow, Sequence Number and Residue Length fields in the Flow Context Record will be reset to 0x0 prior to scanning the input. Empty input data is accepted and may be used as a mechanism to reset Flow Context without scanning a input data.

PME_SCAN_CMD_END-Indicates that the last byte of input data will be considered as the end of Flow. As well, the Flow Context's sequence number and residue length context are reset to zero such that the next data byte on the Flow will be considered a Start of Flow.In order to accommodate protocols such as TCP, where it may not be known until later that the last processed byte was in fact the End of Flow byte, input data with zero length but with the End of Flow indicator set are allowed. In these cases, the session's residue will be recycled through the Pattern Matcher with the End of Flow indication such that any anchored patterns present won't be missed.

The *p->cmd.opaque* is carried through into *p->result.opaque*.

p->cmd.input is the contiguous input data buffer. Where *p->cmd.input.data* is the pointer to the contiguous user-space buffer and *p->cmd.input.size* indicates the number of bytes in this buffer.

p->cmd.output is where the resulting output/result is stored. The caller indicates where the write the result of the scan via this attribute.

p->result is the response of the scan operation and is updated upon return.

p->result.flags attribute is populated by the ioctl and is bit wise mask indicating operation results:

PME_SCAN_RESULT_UNRELIABLE-When set, indicates that this input was processed following detection and reporting of a serious Pattern Matcher error. Any report data carried within this input that was produced by Pattern Matcher cannot be considered reliable. Output tagged as Unreliable do not have a valid Status code.

PME_SCAN_RESULT_TRUNCATED-When set, indicates that the contents of the output data were truncated and are incomplete.

PME_SCAN_RESULT_BMAN-The output was generated from BMan buffers.

p->result.status attribute is the status code of the operation. This value is invalid if the PME_SCAN_RESULT_UNRELIABLE bit mask was set in *p->result.flags*. Refer to fsl_pme.h for complete list of possible values:

pme_status_ok-operation was successful

all other values indicate an exception occurred.

p->result.output is updated with the output generated from the Pattern Matcher device. *p->result.output.data* is *p->cmd.output.data* and p->result.output.size <= *p->cmd.output.size.* In other words the size of the output from the Pattern Matcher may be less than the size that the caller has supplied.

p->result.opaque is set to the corresponding *p->cmd.opaque* value.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.2 PMEIO_SCAN_W1

PMEIO_SCAN_W1-Perform a single asynchronous pattern matching request

Synopsis

```
         ioctl(fd, PMEIO_SCAN_W1, struct pme_scan_cmd *cmd);
struct pme_scan_cmd {
    __u32 flags;
    void *opaque;
    struct pme_buffer input;
    struct pme_buffer output;
};
struct pme_buffer {
    void *data;
    size_t size;
};
```

Description

This ioctl() is used to perform a single asynchronous pattern matching request. The API will return once the request has been dispatched to the Pattern Matcher device. The resulting response must be retrieved via PMEIO_SCAN_R1 or PMEIO_SCAN_Rn ioctls. The input memory should not be modified by the caller until the corresponding response has been retrieved.

cmd contains the pme scan input command. Refer to PMEIO_SCAN ioctl for a detail description.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.3 PMEIO_SCAN_R1

PMEIO_SCAN_R1-Retrieve a single Pattern Matcher response.

Synopsis

```
         ioctl(fd, PMEIO_SCAN_R1, struct pme_scan_result *result);
struct pme_scan_result {
    __u8 flags;
    enum pme_status status;
    struct pme_buffer output;
    void *opaque;
};
struct pme_buffer {
    void *data;
    size_t size;
};
```

Description

This ioctl() is used to retrieve a single Pattern Matcher response from a corresponding PMEIO_SCAN_W1 or PMEIO_SCAN_Wn ioctl request. This is a non-blocking api. User should wait for response with select() or poll(), then collect the response(s) with either PMEIO_SCAN_R1 or PMEIO_SCAN_Rn ioctl().

result contains the response from a corresponding PMEIO_SCAN_W1 or PMEIO_SCAN_Wn ioctl(). Refer to PMEIO_SCAN ioctl for a detail description.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.4 PMEIO_SCAN_Wn

PMEIO_SCAN_Wn-Performs multiple asynchronous pattern matching request

Synopsis

```
         ioctl(fd, PMEIO_SCAN_Wn, struct pme_scan_cmds *cmds);
struct pme_scan_cmds {
    unsigned num;
    struct pme_scan_cmd *cmds;
};
```

Description

This ioctl() is a more generalized version of the PMEIO_SCAN_W1 ioctl(). Permits sending multiple request asynchronously. The results must be retrieved using the SCAN_R1 or SCAN_Rn ioctl(). User's should first call select() or poll() to indicate that responses are ready to be retrieved. The ioctl may not have sent all scan requests: in this case -EINT is returns and *cmds->num* is updated with the number of commands sent.

cmds->cmds is a pointer to an array of pme_scan_cmd structures

cmds->num is the number of elements in the above array.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.5 PMEIO_SCAN_Rn

PMEIO_SCAN_Rn-Retrieve multiple Pattern Matcher responses synchronously.

Synopsis

```
         ioctl(fd, PMEIO_SCAN_Rn, struct pme_scan_results *results);
struct pme_scan_results {
    unsigned num;
    struct pme_scan_result *result;
};
```

Description

This ioctl() is a more generalized version of the PMEIO_SCAN_R1 ioctl(). Permits retrieving multiple request synchronously.

results->result is a pointer to an array of pme_scan_result structures

result->num is the number of elements in the above array. This value is updated upon return to indicate the actual number of responses retrieved.

Return Value

The API returns 0 on success, -1 with errno set on error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

ENODEV

EINVAL

The parameters specified are not valid

7.4.6.3.7.3.6 PMEIO_RELEASE_BUFS

PMEIO_RELEASE_BUFS-Release the allocated buffer back to hardware

Synopsis

```
ioctl(fd, PMEIO_RELEASE_BUFS, void *user_mem);
```

Description

This ioctl() release the allocated buffer back to hardware.

user_mem is a pointer to data which has been zero copied mmap'ed. This memory will be released to BMan. For intance this would be *&result.output.data*.

Return Value

Returns 0 on success, -1 with errno set upon error.

Errors

See Also

7.4.6.3.7.3.7 PMEIO_RESETSEQ

PMEIO_RESETSEQ-Resets the flow context sequence number to zero

Synopsis

```
ioctl(fd, PMEIO_RESETSEQ);
```

Description

This ioctl() resets the flow context sequence number to zero. The Start of Flow indicator is also set.

Return Value

Returns 0 on success, -1 with errno set upon error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.8 PMEIO_RESETRES

PMEIO_RESETRES-Resets the flow context residue

Synopsis

```
ioctl(fd, PMEIO_RESETRES);
```

Description

This ioctl() resets the flow context residue such that no bytes remain in residue.

Return Value

Returns 0 on success, -1 with errno set upon error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.9 PMEIO_SETSCAN

PMEIO_SETSCAN-Configures a pme context parameters

Synopsis

```
ioctl(fd, PMEIO_SETSCAN, struct pme_scan_params *p);
```

struct pme_scan_params {

```
    __u32 flags;
    struct pme_scan_params_residue {
        __u8 enable;
        __u8 length;
    } residue;
    struct pme_scan_params_sre {
        __u32 sessionid;
        __u8 verbose;
        __u8 esee;
```

```
            } sre;

            struct pme_scan_params_dxe {

                __u16 clim;

                __u16 mlim;

            } dxe;

            struct pme_scan_params_pattern {

                __u8 set;

                __u16 subset;

            } pattern;

        };
```

Description

This ioctl() sets the flow context and scan related attributes. This is a blocking API.

p->flags attribute is a bit wise mask which indicate which group of attributes are being set. The flags can be OR'ed together.

PME_SCAN_PARAMS_RESIDUE-Residue attributes are being set.

PME_SCAN_PARAMS_SRE-SRE attributes are being set.

PME_SCAN_PARAMS_DXE-DXE attributes are being set.

PME_SCAN_PARAMS_PATTERN-Pattern attributes are being set.

p->residue.enable attribute turn residue on or off. If non-zero, residue is on, otherwise residue is off.

p->residue.length attribute value is ignored by this ioctl() but the underlining number of bytes in residue is reset to zero if the *p->residue.enable* to set.

p->sre.sessionid attribute is the index where the per-session context for this Flow will be accessed by SRE in the SRE table. Range: 0x0 ... 0x7FFFFFF.

p->sre.verbose attribute is the PME report verbosity mode. There are 4 levels: 0,1,2 and 3.

p->sre.esee attribute turns on or off the enables the End of SUI event. If turned on the End of SUI Reaction pointer programmed in ESRP (End of SUI Reaction Pointer Register) is to be executed upon End of SUI. A value of zero will turn off this attribute, otherwise it will be on.

p->dxe.clim attribute is the compare limit. Valid range is 0x0 to 0xFFFF. 0xFFFF is treated as infinite.

p->dxe.mlim attribute is the match limit. Valid range is 0x0 to 0xFFFF. 0xFFFF is treated as infinite.

p->pattern.set attribute defines an exclusive grouping of patterns (i.e. no set overlap) that are to be searched simultaneously by the Pattern Matcher. The Pattern Matcher supports 256 (mutually exclusive) pattern sets. When scanning for patterns in the data, the search is restricted to a particular pattern set. Valid range is 0x0 to 0xFF.

p->pattern.subset attribute defines An non-exclusive grouping of patterns (subset overlap permitted) within a given pattern set that are to be searched simultaneously by the Pattern Matcher with or without other subsets. Unlike a pattern set, patterns may be assigned to multiple pattern subsets.The Pattern Matcher supports 16 subsets per pattern set. When scanning for patterns, the search may use a list of subsets. Valid range is 0x0 to 0xFFFF.

Return Value

Returns 0 on success, -1 with errno set upon error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

EINVAL

The parameters specified are not valid

See Also

7.4.6.3.7.3.10 PMEIO_GETSCAN

PMEIO_GETSCAN-Retrieves the pme context and scanning attributes.

Synopsis

```
ioctl(fd, PMEIO_GETSCAN, struct pme_scan_params *p);
```

struct pme_scan_params {

```
__u32 flags;
struct pme_scan_params_residue {
    __u8 enable;
    __u8 length;
} residue;
struct pme_scan_params_sre {
    __u32 sessionid;
    __u8 verbose;
    __u8 esee;
} sre;
struct pme_scan_params_dxe {
    __u16 clim;
    __u16 mlim;
} dxe;
struct pme_scan_params_pattern {
    __u8 set;
    __u16 subset;
```

```
            } pattern;

        };
```

Description

This ioctl() gets the flow context and scan related attributes. This is a blocking API.

p->flags is ignored by the ioctl().

p->residue.enable attribute indicates if residue is turn on or off. A value of zero indicates off. A value of non-zero indicates on.

p->residue.length attribute indicates the current number of bytes in residue. This attribute has no meaning when residue is disabled.

p->sre.sessionid attribute is the index where the per-session context for this Flow will be accessed by SRE in the SRE table.

p->sre.verbose attribute is the PME report verbosity mode.

p->sre.esee attribute indicates the state of the End of SUI event. If turned on (non zero) the End of SUI Reaction pointer programmed in ESRP (End of SUI Reaction Pointer Register) is to be executed upon End of SUI. A value of zero indicates off.

p->dxe.clim attribute is the compare limit.

p->dxe.mlim attribute is the match limit.

p->pattern.set attribute defines an exclusive grouping of patterns (i.e. no set overlap) that are to be searched simultaneously by the Pattern Matcher. The Pattern Matcher supports 256 (mutually exclusive) pattern sets. When scanning for patterns in the data, the search is restricted to a particular pattern set.

p->pattern.subset attribute defines An non-exclusive grouping of patterns (subset overlap permitted) within a given pattern set that are to be searched simultaneously by the Pattern Matcher with or without other subsets. Unlike a pattern set, patterns may be assigned to multiple pattern subsets.The Pattern Matcher supports 16 subsets per pattern set. When scanning for patterns, the search may use a list of subsets.

Return Value

Returns 0 on success and * *p* is updated accordingly, -1 with errno set upon error.

Errors

ENOMEM

Not enough memory could be allocated to satisfy the request.

EINVAL

The parameters specified are not valid

7.4.6.3.7.4 PME Kernel API

This describes the kernel API of the PME driver.

7.4.6.3.7.4.1 pme_ctx_init

pme_ctx_init-Initializes a pme context for performing scan or control operations

Synopsis

```
        int pme_ctx_init(
```

```
                struct pme_ctx *ctx, u32 flags, u32 bpid, u8 qosin, u8 qosout,

                enum qm_channel dest, const struct qm_fqd_stashing *stashing);
```

Description

The pme_ctx_init function is used to initialize a new pme context that can be used for performing pattern matching or control operations on the pattern matching device.

The ctx structure will be initialized. The ctx->cb field is required to be set prior to invoking this api.

flags defines context attributes and is a bit mask of the following values:

PME_CTX_FLAG_LOCKED-When either frame queues state are updated, this flag indicates if a spin_lock is used during the update. If this flag is specified, the spin_lock is acquired. This is relavent if different cores will be updating the frame queues state.

PME_CTX_FLAG_EXCLUSIVE-When set, causes the input frame queue to remain in a parked state when the context is enabled. Furthermore, when a frame is enqueued on the input frame queue, the PME's exclusive frame queue control will be enabled. Hence, the context input frame queue is the PME's exclusive frame queue for this enqueue. This mode is only available if the driver is built with control functionality and if the OS has access to the PME's CCSR map.

PME_CTX_FLAG_PMTCC-A pme_context operates in two modes: scan and pmtcc mode. If this flag is specified then pmtcc mode is selected, otherwise scan mode. The mode determines which operations on the pme_context are not permitted. In scan mode pme_ctx_pmtcc() operations are not permitted. In pmtcc mode, pme_ctx_scan(), pme_ctx_ctrl_update_flow() and pme_ctx_ctrl_read_flow() are not permitted.

PME_CTX_FLAG_DIRECT-When in scan mode, a pme_context may have a flow context allocated. If this flag is specified, no flow context is allocated, ortherwise one is. When in direct mode, the following operations are not permitted: pme_ctx_ctrl_update_flow(), pme_ctx_ctrl_read_flow().

PME_CTX_FLAG_LOCAL-Use the current core's dedicated portal channel. The dest argument will be ignored.

The *bpid* value specifies the buffer pool id to be used for any bman generated output.

The *qosin* value specifies the workqueue priority on the PME channel (0-7). Only applies if PME_CTX_FLAG_EXCLUSIVE is not set.

0, 1-High priority

2, 3, 4-Medium Priority

5, 6, 7-Low Priority

The *qsout* value specifies the workqueue priority on the software portal (0-7). Same priorities as described above.

The *stashing* argument configures the desired dequeue stashing behavior. If NULL, no stashing will occur. Refer to the qman api document if non NULL behavior is required.

Return Value

The pme_ctx_init API returns 0 on success, and may return the following error codes:

-ENOMEM if there was not enough memory available to satisfy an allocation request

-EIO

-EBUSY

See Also

pme_ctx_finish()

7.4.6.3.7.4.2 pme_ctx_finish

pme_ctx_finish-Releases all previously allocated resources (e.g. frame queues, memory) from a disabled pme_ctx.

Synopsis

```
        void pme_ctx_finish(struct pme_ctx *ctx);
```

Description

This API is used to indicate a pme_ctx object is no longer required. Once a pme context has been disabled and is no longer required, invoking this api will release all previously allocated resources, such as frame queues, flow context context memory, etc.

See Also

pme_ctx_init()

7.4.6.3.7.4.3 pme_ctx_enable

pme_ctx_enable-Enable a pme_ctx

Synopsis

```
int pme_ctx_enable(struct pme_ctx *ctx);
```

Description

This API is used to change the state of a pme_ctx to the enabled state. The following operations are not permitted while in the enabled state:

pme_ctx_enable()

pme_ctx_reconfigure_tx()

pme_ctx_reconfigure_rx()

pme_ctx_finish()

Return Value

The API will return 0 on success, and may return the following error codes:

-EBUSY

-EINVAL

-EIO

See Also

pme_ctx_disable()

7.4.6.3.7.4.4 pme_ctx_disable

pme_ctx_disable-Disable a pme_context object

Synopsis

```
        int pme_ctx_disable(struct pme_ctx *ctx, u32 flags, struct pme_ctx_ctrl_token
*token);
```

Description

This API disables a previously enabled pme_context.

If the return value is 0, the context is disabled.

If the return value is +1, the context is disabling and the token's completion callback will be invoked when disabling is complete.

Otherwise an error is returned and the context remains enabled.

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in *token* object. The cb (callback) member must be set (i.e. non NULL) when a callback is expected.

Return Value

The API will return 0 on success, +1 when the callback will be invoked or one of the following errors on failure:

-EBUSY

-EINTR

-EIO

See Also

pme_ctx_enable()

pme_ctx_is_disable()

7.4.6.3.7.4.5 pme_ctx_is_disable

pme_ctx_is_disable-query whether a pme context is disabled

Synopsis

```
int pme_ctx_is_disabled(struct pme_ctx *ctx);
```

Description

This API queries whether a pme context is disabled.

Return Value

The API will return >0 if the ctx is disabled. Otherwise 0 is returned is ctx is not disabled.

See Also

pme_ctx_disable()

7.4.6.3.7.4.6 pme_ctx_is_dead

pme_ctx_is_dead-query whether a pme context is dead

Synopsis

```
int pme_ctx_is_dead(struct pme_ctx *ctx);
```

Description

This API queries whether a pme context is dead.

Return Value

The API will return >0 if the ctx is dead. Otherwise 0 is returned is ctx is not dead.

See Also

pme_ctx_is_disable()

7.4.6.3.7.4.7 pme_ctx_reconfigure_tx

pme_ctx_reconfigure_tx-reconfigure transmit frame queue

Synopsis

```
int pme_ctx_reconfigure_tx(struct pme_ctx *ctx, u32 bpid, u8 qosin);
```

Description

This API reconfigure the tx qman frame queue. The pme_ctx must be in a disabled state.

bpid specifies the report buffer pool id that the Pme device shall use when BMan output is generated.

qosin indicates which of the Pme's 8 prioritized workqueues the frame queue should schedule to. This is only applicable if the PME_CTX_FLAG_EXCLUSIVE context flag is not set.

Return Value

The pme_ctx_reconfigure_tx API returns 0 on success, and may return the following error codes:

-EBUSY

-EIO

-EINVAL

See Also

pme_ctx_disable()

7.4.6.3.7.4.8 pme_ctx_reconfigure_rx

pme_ctx_reconfigure_rx-reconfigure receive frame queue

Synopsis

```
int pme_ctx_reconfigure_rx(struct pme_ctx *ctx, u8 qosout, enum qm_channel dest,
const struct qm_fqd_stashing *stashing);
```

Description

This API reconfigure the rx qman frame queue. The pme_ctx must be in a disabled state.

qosout indicates which of the 8 prioritized workqueues the frame queue should be scheduled to on the software portal.

dest specifies which pool channel *or* dedicated channel to use. Ignored if the pme_ctx was initialized with the PME_CTX_FLAG_LOCAL flag.

stashing specifies a stashing object. Refer to qman api for more detail on this object.

Return Value

The pme_ctx_reconfigure_rx API returns 0 on success, and may return the following error codes:

-EBUSY

-EIO

-EINVAL

See Also

pme_ctx_disable()

7.4.6.3.7.4.9 pme_ctx_ctrl_update_flow

pme_ctx_ctrl_update_flow-Updates the associated pme flow context record

Synopsis

```
int pme_ctx_ctrl_update_flow(struct pme_ctx *ctx, u32 flags, struct pme_flow
*params, struct pme_ctx_ctrl_token *token);
```

Description

This API updates the associated pme flow context record in the Pme device according to the values specified in *params*. For instance to enable residue, set the PME_CMD_FCW_RES flags parameter as well as the *params->ren* and *params->rlen* values. To disable residue, set the PME_CMD_FCW_RES flags parameter and set the *params->ren* to 0. The pme_ctx must be in the following state: enabled, flow mode and scan mode(e.g. PME_CTX_FLAG_DIRECT and PME_CTX_FLAG_PMTCC were not specified during initialization).

flags indicates which fields in the flow context are to be updated. These values can be or'ed together with the exception of PME_CTX_OP_RESETRESLEN.

PME_CMD_FCW_RES-Residue related attributes can be updated. These attributes are: *params->ren*, *params->rlen*

PME_CMD_FCW_SEQ-Sequence related attributes can be updated. These attributes are: *params->sos*, *params->seqnum*

PME_CMD_FCW_SRE-Stateful rule related attributes can be updated. These attributes are: *params->srvm, params->esee* and *params->sessionid*

PME_CMD_FCW_DXE-Data Examination related attributes can be updated. These attributes are: *params->clim* and *params->mlim*

PME_CMD_FCW_ALL-All of the above attributes can be updated.

PME_CTX_OP_RESETRESLEN-Applies only to a pme_ctx which has residue enabled. The following attribute is updated: *params->rlen*. This flag should only be used on it's own.

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

params is the pme flow structure. The contents of this structure get copied by this api.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in *token* object.

Return Value

The pme_ctx_ctrl_update_flow API returns 0 on success, and may return the following error codes:

-EBUSY

-EIO

-EINVAL

-ENOMEM

See Also

7.4.6.3.7.4.10 pme_ctx_ctrl_read_flow

pme_ctx_ctrl_read_flow-read the flow record in the Pme device.

Synopsis

```
int pme_ctx_ctrl_read_flow(struct pme_ctx *ctx, u32 flags, struct pme_flow
*params, struct pme_ctx_ctrl_token *token);
```

Description

This API sends a ctrl operation request to read the flow record in the Pme device into the *params* argument. The *ctx* must be in the following state: enabled, flow mode and scan mode(e.g. PME_CTX_FLAG_DIRECT and PME_CTX_FLAG_PMTCC were not specified during initialization).

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

params is a pointer to a flow context object. The params will be updated with upon invocation of the callback specified in the token parameter.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in *token* object.

Return Value

The pme_ctx_ctrl_read_flow API returns 0 on success, and may return the following error codes:

-EINTR

-EBUSY

-EINVAL

See Also

7.4.6.3.7.4.11 pme_ctx_ctrl_nop

pme_ctx_ctrl_nop-sends a Pme nop command

Synopsis

```
int pme_ctx_ctrl_nop(struct pme_ctx *ctx, u32 flags, struct pme_ctx_ctrl_token
*token);
```

Description

This API sends a pme nop command. The *ctx* must be enabled.

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in *token* object.

Return Value

The pme_ctx_ctrl_nop API returns 0 on success, and may return the following error codes:

-EINTR

-EBUSY

See Also

7.4.6.3.7.4.12 cb

cb-Function to invoke when response to a ctrl api (update_flow, read_flow, nop) operation has been returned from Pme hardware.

Synopsis

```
         void (*cb)(struct pme_ctx *ctx, const struct qm_fd *fd, struct pme_ctx_ctrl_token
*token);
void (*ern_cb)(struct pme_ctx *, const struct qm_mr_entry *, struct
pme_ctx_ctrl_token *);
```

Description

This cb function is specified in the pme_ctx_ctrl_token parameter specified in the ctrl apis. When the response to a pme_ctx_ctrl_update_flow(), pme_ctrx_ctrl_read_flow, pme_ctx_ctrl_nop() or pme_ctx_disable() is received this callback is invoked (usually in interrupt context) and appropriate action must be taken by the user. In the case of pme_ctx_disable(), the callback is not invoked if the api returns 0. Since the callback may be in interrupt context user must ensure that proper requirements are met (e.g. sleeping is not permitted, etc).

The ern_cb function is invoked when an enqueue rejection occurs. This may occur before order-restoration or after (eg. if due to congestion or tail-drop). Use the rc code of the mr_entry to determine.

ctx is a pme context structure.

fd is a frame description which has been dequeued from the output frame queue. In other words this is the response from the Pme device.

token is the parameter originally passed in the corresponding pme_ctx_ctrl api. The user is now given ownership of this parameter.

pme_ctx_ctrl_nop()

pme_ctx_disable()

7.4.6.3.7.4.13 pme_ctx_exclusive_inc

pme_ctx_exclusive_inc-Increment pme exclusivity reference count

Synopsis

```
int pme_ctx_exclusive_inc(struct pme_ctx *ctx, u32 flags);
```

Description

This API aquires Pme exclusivity (if not already held) and increments the reference count in *ctx* . This API can only be invoked on the control plane and only on a ctx that was initialized with the PME_CTX_FLAG_EXCLUSIVE flag. If exclusivity cannot be immediatly acquired the *flags* argument determines whether the API sleeps or not.

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

Return Value

The pme_ctx_exclusive_inc API returns 0 on success, and may return the following error codes:

-ENODEV

-EBUSY

See Also

pme_ctx_exclusive_dec()

7.4.6.3.7.5 pme_ctx_exclusive_dec

pme_ctx_exclusive_dec-Decrement pme exclusivity reference count

Synopsis

```
void pme_ctx_exclusive_dec(struct pme_ctx *ctx);
```

Description

This API decrements the exclusivity reference count and if this is the last reference also releases Pme exclusivity. This API can only be invoked on the control plane and only on a *ctx* that was initialized with the PME_CTX_FLAG_EXCLUSIVE flag.

Return Value

No return value.

See Also

pme_ctx_exclusive_inc()

7.4.6.3.7.6 pme_scan_cb

pme_scan_cb-Function to invoke when response to scan or pmtcc operation has been returned from Pme hardware.

Synopsis

```
        typedef void (*pme_scan_cb)(struct pme_ctx *ctx, const struct qm_fd *fd, struct
pme_ctx_token *token);
```

Description

This callback function is specified prior to the pme_ctx_init() API as part of the *ctx->cb* parameter. When the response to a pme_ctx_scan() or pme_ctx_pmtcc() is received this callback is invoked (usually in interrupt context) and appropriate action must be taken by the user. Since the callback maybe in interrupt context user must ensure that proper requirements are met (e.g. sleeping is not permitted, etc).

ctx is a pme context structure.

fd is a frame description which has been dequeued from the output frame queue. In other words this is the response from the Pme device.

token is the parameter originally passed in the corresponding pme_ctx_scan() or pme_ctx_pmtcc() commands. The user is now given ownership of this parameter. Typically a user may "outcast" this pointer to a larger object (i.e. this token is embedded within a user defined structure which contains additional context data).

See Also

pme_ctx_init()

pme_ctx_scan()

pme_ctx_pmtcc()

7.4.6.3.7.7 pme_scan_ern_cb

pme_scan_ern_cb-Function to invoke when enqueue rejection occurs during a scan or pmtcc operation.

Synopsis

```
        typedef void (*pme_scan_ern_cb)(struct pme_ctx *ctx, const struct qm_mr_entry
*mr, struct pme_ctx_token *token);
```

Description

This error rejection notification callback function is specified prior to the pme_ctx_init() API as part of the *ctx->ern_cb* parameter. When an error rejection notification is received this callback is invoked (usually in interrupt context) and appropriate action must be taken by the user. Since the callback may be in interrupt context user must ensure that proper requirements are met (e.g. sleeping is not permitted, etc).

mr is an ern maessage response structure. The contained ern structure contains the rejection code (*rc*) and the associated frame descriptor (*fd*) which was rejected.

token is the parameter originally passed in the corresponding pme_ctx_scan() or pme_ctx_pmtcc() commands. The user is given ownership of this parameter. Typically a user may "outcast" this pointer to a larger object (i.e. this token is embedded within a user defined structure which contains additional context data).

7.4.6.3.7.8 PME_SCAN_ARGS

PME_SCAN_ARGS-Macro that modifies the frame description. Used in the pme_ctx_scan() API

Synopsis

```
        #define PME_SCAN_ARGS(flags, set, subset)
```

Description

Modify a frame descriptor for a pme_ctx_scan api (only modifies *fd->cmd* field).

flags is a bit mask of the following values:

PME_CMD_SCAN_SRVM(n)-Scan Report Verbosity Mode. Where n = {0..3}. This flag is ignored by the Pme device when the context is configured for direct mode.

PME_CMD_SCAN_FLUSH-Instructs the Pme device to flush any cached Flow Context and Residue data to system memory after the Frame is processed. This flag is ignored by the Pme device when the context is configured for direct mode.

PME_CMD_SCAN_SR-Depends on the pme ctx mode and possibly on the state of the flow context. Direct mode-Start of Flow indication. The first data byte of the Frame will be treated as the Start of Flow for anchored pattern matching purposes. Flow mode-Depends if residue is enabled or not. residue disabled: Start of Flow indication. The first data byte of the Frame will be treated as the Start of Flow for anchored pattern matching purposes. residue enabled: Flow Context Reset. The Start of Flow, Sequence Number and Residue Length fields in the Flow Context Record will be reset to 0x0 prior to scanning the Frame. Empty input Frames are accepted and may be used as a mechanism to reset Flow Context without scanning a Frame

PME_CMD_SCAN_E-End of Flow. Depends on the ctx mode. Direct mode: Indicates that the last symbol of the scanned work unit is to be considered an End of Flow. Flow mode: Indicates that the last byte of input data will be considered as the end of Flow. As well, the Flow Context's sequence number and residue length context are reset to zero such that the next data byte on the Flow will be considered a Start of Flow. In order to accommodate protocols such as TCP, where it may not be known until later that the last processed byte was in fact the End of Flow byte, Frames with zero length input data but with the End of Flow indicator set are allowed. In these cases, the session's residue will be recycled through the Pattern Matcher with the End of Flow indication such that any anchored patterns present won't be missed.

set is the pattern set value. An exclusive grouping of patterns (i.e. no set overlap) that are to be searched simultaneously by the Pattern Matcher. The Pattern Matcher supports 256 (mutually exclusive) pattern sets. When scanning for patterns in the data, the search is restricted to a particular pattern set.

subset is the pattern subset value. A non-exclusive grouping of patterns (subset overlap permitted) within a given pattern set that are to be searched simultaneously by the Pattern Matcher with or without other subsets. Unlike a pattern set, patterns may be assigned to multiple pattern subsets. The Pattern Matcher supports 16 subsets per pattern set. When scanning for patterns, the search may use a list of subsets.

See Also

pme_ctx_scan()

7.4.6.3.7.9 pme_ctx_scan

pme_ctx_scan-sends a Pme scan command

Synopsis

```
int pme_ctx_scan(struct pme_ctx *ctx, u32 flags, struct qm_fd *fd, u32 args,
struct pme_ctx_token *token);
```

Description

Send a pme scan command. The *ctx* must be enabled and not in the pmtcc mode. If *ctx.flags* indicate exclusivity then Pme exclusivity is acquired before the request is sent. The API returns zero upon successful enqueue of the *fd*. The corresponding *ctx.cb* function is invoked when the response to the scan request has been dequeued. The *ctx.cb* function may be invoked before this api has completed. The *ctx.cb* is invoked in interrupt context (when applicable).

ctx is an enabled pme context that is in scan mode (e.g. The *ctx* was not initialized with PME_CTX_FLAG_PMTCC).

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

fd is a frame description as defined in the Pattern Matcher Block Guide.

args parameter is produced by the PME_SCAN_ARGS() macro.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in pme ctx object. A caller will typically embed this token object as part of a larger object so as to maintain his own per command data.

Return Value

The pme_ctx_scan API returns 0 on success, and may return the following error codes:

-EINTR

-EBUSY

See Also

pme_ctx_enable()

PME_SCAN_ARGS()

7.4.6.3.7.10 pme_ctx_scan_orp

pme_ctx_scan_orp-sends a Pme scan command with order restoration

Synopsis

```
int pme_ctx_scan_orp(struct pme_ctx *ctx, u32 flags, struct qm_fd *fd, u32 args,
struct pme_ctx_token *token, struct qman_fq *orp_fq, u16 seqnum);
```

Description

This extends the pme_ctx_scan() API to provide order restoration support. The *orp_fq* represents the frame queue descriptor that is to be used as the order restoration point and the *seqnum* is the sequence number to use for order restoration.

ctx is an enabled pme context that is in scan mode (e.g. The *ctx* was not initialized with PME_CTX_FLAG_PMTCC).

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

fd is a frame description as defined in the Pattern Matcher Block Guide.

args parameter is produced by the PME_SCAN_ARGS() macro.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in pme ctx object. A caller will typically embed this token object as part of a larger object so as to maintain his own per command data.

orp_fq is the order restoration point frame queue to be used.

seqnum is the sequence number to be used for order restoration.

Return Value

The pme_ctx_scan_orp API returns 0 on success, and may return the following error codes:

-EINTR

-EBUSY

See Also

pme_ctx_enable()

PME_SCAN_ARGS()

7.4.6.3.7.11 pme_ctx_pmtcc

pme_ctx_pmtcc-sends a Pme pmtcc command

Synopsis

```
int pme_ctx_pmtcc(struct pme_ctx *ctx, u32 flags, struct qm_fd *fd, struct
pme_ctx_token *token);
```

Description

Send a Pme pmtcc command. The *ctx* must be enabled and have been initialized with the PME_CTX_FLAG_PMTCC flag. The corresponding *ctx->cb* function is invoked when the response to the pmtcc request has been received. The *ctx->cb* function may be invoked before this api has completed. The *ctx->cb* is invoked in interrupt context (when applicable). The token parameter is returned via the *ctx->cb* function.

This API will attempt to acquire exclusivity if the *ctx* doesn't already have it. Exclusivity can only be acquired on the control plane.

ctx is an enabled pme context that is in pmtcc mode (e.g. The *ctx* was initialized with PME_CTX_FLAG_PMTCC).

flags affects the behavior of this API and is a bit mask of the following values:

PME_CTX_OP_WAIT-Indicates that the api can sleep.

PME_CTX_OP_WAIT_INT-This qualifies the PME_CTX_OP_WAIT flag. Indicates that the sleep is interruptible. Therefore, PME_CTX_OP_WAIT_INT on it's own is undefined.

fd is a frame description as defined in the Pattern Matcher Block Guide.

token parameter is "owned" by the driver. The driver will write command specific data to this structure. This parameter is "returned" (i.e. driver relinquishes ownership) to the user via the callback function specified in pme ctx object. A caller will typically embed this token object as part of a larger object so as to maintain his own per command data.

Return Value

The pme_ctx_pmtcc API returns 0 on success, and may return the following error codes:

-EINTR

-EBUSY

See Also

pme_ctx_enable()

pme_ctx_init()

7.4.6.3.7.12 pme_attr_set

pme_attr_set-Write to a Pme attribute

Synopsis

```
int pme_attr_set(enum pme_attr attr, u32 val);
```

Description

This API permits the setting of certain Pme attributes as defines by the enum pme_attr set. This API is only available on the control plane.

attr is the Pme attribute to write to.

val is the value to be written

Return Value

The pme_attr_set API returns 0 on success, and may return the following error codes:

-ENODEV

See Also

pme_attr_get()

7.4.6.3.7.13 pme_attr_get

pme_attr_get-Reads from a Pme attribute

Synopsis

```
int pme_attr_get(enum pme_attr attr, u32 *val);
```

Description

This API permits the reading of certain Pme attributes as defines by the enum pme_attr set. This API is only available on the control plane.

attr is the Pme attribute to read.

val is the value read

Return Value

The pme_attr_get API returns 0 on success, and may return the following error codes:

-ENODEV

See Also

pme_attr_set()

7.4.6.3.7.14 pme2_have_control

pme2_have_control-Query if there is access to the Pme CCSR register space

Synopsis

```
int pme2_have_control(void);
```

Description

This API return >0 is there is access to the Pme CCSR register space (i.e. caller is on the control plane). Otherwise 0 is returned. Some apis require the caller to have access to CCSR space (such as pme_attr_get()), this api permits a caller to determine is CCSR space is accessible.

Return Value

The pme2_have _control API returns 0 the caller does not have CCSR access. Otherwise a non zero value is returned.

See Also

7.4.6.3.7.15 pme_stat_get

pme_stat_get-Query a Pme statistics attribute

Synopsis

```
int pme_stat_get(enum pme_attr attr, u64 *value, int reset);
```

Description

This api returnes an accumulated version of the related attribute. At a configured interval, the Pme driver will query all statistic attributes and maintain an accumulated counter (i.e. the value read is added to the current count). This api also permits resetting the accumulated counter. This API is only available on the control plane.

attr is one of

pme_attr_trunci

pme2_have_control()

7.4.6.3.8 Control interface

This chapter provides a description of the API of the Pattern Matcher control interface (PMCI).

PMCI module is a Linux user space library that provides C functional interface to send and receive Pattern Matcher control commands to the Pattern Matcher through Pattern Matcher driver software. These commands allow users to program and monitor the Pattern Matcher database on the hardware. The PMCI converts complex PME control commands into PME driver primitives.

In general, PME control interface is used in the following order:

Initialize a PMCI object using pmci_open().

Use pmci_write() to write single or multiple PME control commands. These commands follow the Pattern Matcher protocol (PMP) format.

Use pmci_read() to read responses from commands that generate responses.

Use pmci_close() to close the PMCI object.

The table below lists the files that constitute the PMCI package.

PMCI files

libpmci.a	PMCI functionality
pmci.h	Defines the interface to the PMCI module
pmci.c	Implementation of the PMCI module
genTypes.h	Contains the generic type definitions and is included by pmci.h
pmDefs.h	Defines the interface that is common to PMLL, PMREC, PMSRC, etc., and is included by pmci.h
pmp.h	Contains the definition of the Pattern Matcher Protocol and is included by pmci.h

7.4.6.3.8.1 pmci_open

Initialize a new instance of PME Control Interface channel, and return the handle.

Synopsis

```
#include <pmci.h>
pmci_error_t pmci_open(int channel, handle_t *handle)
```

Description

This function opens a new PME Control Interface channel and returns its handle. Such a handle is required on any subsequent PME Control Interface operations.

channel specifies the DMA channel to use for communication with hardware. The possible values are from between 0 and 3.

handle specifies the variable where the new handle value is returned.

Return Value

handle points to the new PMCI handle if open was successful.

pmci_success_e is returned for a successful open, otherwise one of the following errors is returned:

pmci_unavailable_driver_e

Part of required driver modules not loaded.

pmci_invalid_channel_e

DMA channel was not configured.

7.4.6.3.8.2 pmci_set_option

Apply option to PMCI handle to modify its behaviour.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_set_option(handle_t pmci_handle, pmci_option_id_t optionId, void
*option, int optionSize)
```

Description

This function provides the ability to change the behavior of the PMCI handle by applying options. The supported options are defined by the pmci_option_id_t type. Currently, the only available option are pmci_option_timeout_e which changes the timeout behaviour for pmci_read(), and pmci_option_batch_buffer_threshold_e which adjust how much buffer memory can be used when batch attribute is enabled.

pmci_handle is the PMCI handle to be modified.

optionId is the behaviour to be changed.

option is the new value of the option

optionSize is the size of *option*, in number of bytes.

Return Value

Returns pmci_success_e for successful operation, otherwise one of the following error codes is returned:

pmci_invalid_handle_e

PMCI handle is invalid.

pmci_invalid_option_code_e

Option id is invalid.

pmci_unavailable_option_e

Option id is invalid.

pmci_invalid_parameters_e

Option value is invalid.

pmci_invalid_option_size_e

Option size is invalid.

7.4.6.3.8.3 pmci_get_option

Retrive the option value previously set by pmci_set_option.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_get_option(handle_t pmci_handle, pmci_option_id_t optionId, void
*option, int *optionSize)
```

Description

This function provides the ability to retrieve the current values of options used by the PMCI *handle*. These are either values set by the user or default values set upon initialization.

pmci_handle is the PMCI handle

optionId is the identifier id of the option being queried.

option is the returned value of the option being queried.

optionSize is the returned size of *option*, in number of bytes.

Return Value

Returns pmci_success_e upon successful completion, otherwise returns on of the following errors. Upon return, *option will contain the retrieved option value, and *optionSize will contain the size of the value in bytes.

pmci_invalid_handle_e

PMCI handle is invalid.

pmci_invalid_option_code_e

Option id is invalid.

pmci_unavailable_option_e

Option id is invalid.

pmci_invalid_parameters_e

option or optionSize pointer is invalid.

7.4.6.3.8.4 pmci_close

Shut down a PME Control Interface channel.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_close (handle_t pmci_handle)
```

Description

This function shuts down a PME Control Interface. During the close all resources related to *pmci_handle* will be released.

pmci_handle is the handle of the control interface to be shut down.

Return Value

Returns pmci_success_e for a successful close, otherwise returns one of the following error codes:

pmci_invalid_handle_e

Invalid PMCI handle.

pmci_failure_e

Failed to release some resources.

7.4.6.3.8.5 pmci_write

Write one or more commands to the PME Control Interface.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_write(handle_t pmci_handle, void *cmds, int cmdsSize)
```

Description

This function is used to write one or more commands to the PME control device. These commands follow the PME command protocol (PMP) format. The PMCI writes these commands into control descriptors created by the PME driver for communicating to the hardware.

Some PME control commands are sent directly to hardware, and some will be handled by PMCI software. A software command may be expanded into multiple hardware commands inside PMCI.

pmci_handle is the PMCI handle in use.

cmd is a pointer to a buffer containing one or more PME commands (in PMP format)..

cmdSize is the total size of all PME commands, in bytes, being sent to the PMCI.

Return Value

Returns pmci_success_e upon successful completion, otherwise returns one of the following error codes:

pmci_invalid_handle_e

PMCI handle is invalid.

pmci_invalid_attribute_id_e

Invalid PM control command.

pmci_failure_e

Invalid PM control command or hardware failure.

pmci_invalid_parameters_e

command buffer is set to NULL, or cmdsSize is 0

7.4.6.3.8.6 pmci_read

Read a notification from PME Control Interface.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_read(handle_t pmci_handle, pmp_msg_t *notif)
```

Description

This function is used to read command notifications from the PME Control Interface. PME command protocol contains commands that generate a notification. These notifications can be read by calling this function.

pmci_handle is the PMCI handle in use.

notif points to the user defined notification buffer where notifications will be returned. The buffer size should be the size of pmp_msg_t which is defined in pmp.h

Return Value

Returns pmci_success_e upon successful completion, otherwise it returns on of the following error codes:

pmci_invalid_handle_e

PMCI handle is invalid.

pmci_empty_read_e

Read timed out and no notification was read.

pmci_failure_e

Invalid PM control command or hardware failure.

pmci_invalid_parameters_e

notification buffer pointer is set to NULL

7.4.6.3.8.7 pmci_flush

Flush the PME Control Interface and ensure no more data is in flight.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_flush(handle_t pmci_handle)
```

Description

This function provides the ability to flush the PME driver pipe and ensure no more data is in flight. The call blocks until the PME driver has ensured its command pipeline is empty and that all preceeding commands have not only reached the hardware but has also completed execution.

pmci_handle is the PMCI handle in use.

Return Value

Returns pmci_success_e upon successful completion, otherwise returns one of the following errors:

pmci_invalid_handle_e

PMCI handle is invalid.

pmci_lost_driver_e

PM driver did not perform the operation.

pmci_failure_e

Hardware failure.

7.4.6.3.8.8 pmci_context_clear_by_session_id

Clear the stateful rule context associated to a specific session Id.

Synopsis

#include <pmci.h>

```
pmci_error_t pmci_context_clear_by_session_id(uint32_t sessionId)
```

Description

This utility function provides the ability to clear the stateful rule context associated to a specific session Id. The PME hardware provides the functionality to clear its stateful rule context for a particular session. This function provides users the means to invoke that functionality. It opens a PMCI handle, sends the hardware command to clear the context, and then close the PMCI handle.

session_id is the session id whose associated context information is to be cleared.

Return Value

Returns pmci_success_e upon successful completion, otherwise returns one of the following errors:

pmci_unavailable_driver_e

Driver not loaded or configured.

pmci_failure_e

Driver not configured properly, or HW failure.

pmci_invalid_parameters_e

Bad session id.

7.4.6.3.8.9 pmci_error_string

Returns a string describing the PMCI error code.

Synopsis

#include <pmci.h>

```
const char *pmci_error_string(pmci_error_t code)
```

Description

This utility function returns a printable string corressponding to the pmci error code.

code is the error code returned from other PMCI functions.

Return Value

Returns a string pointer to an appropiate error message.

7.4.6.3.9 PMP message format

The Pattern Matcher protocol (PMP) defines the format of messages that are used to setup and manage the PME database. The following sections describe in detail the various PMP message formats.

7.4.6.3.9.1 PME Message Syntax

This section summarizes the PMP message syntax. Each PMP message has the following format:

Version (8 bits)-version number of the PME control protocol

Type (8 bits)-command type code

Reserved (16 bits)-for future use

Length (32 bits)-total length in bytes, including header bytes

Message ID (64 bits)-command message sequence number, helps to co-relate the response message with the command message

Command (variable)-control command information, specific to each type of message

Commands and Notifications Types

7.4.6.3.9.2 PMP Message Types

There are various types of PMP messages. These messages vary in format and behavior based on their type. Some messages are one-way only and represent commands to the PME whereas other messages expect a response message or notification from the PME.

The following table lists the various types of messages.

Summary of Numerical Assignment of Type Field

Category	Type	Description[14]

Table continues on the next page...

[14] The descriptions that contain a code in parenthesis have the following legend: C = Command, N = Notification, and V = Virtualized (not directly supported by the hardware). Also note that read and get notifications uses the same type as the commands except the most significant bit is set to differentiate between the request and the reply.

Table continued from the previous page...

Table Manipulation	0x00	Read Table Entry (CN)[15]
	0x01	Write Table Entry (C)
	0x02	Reset All Table Entries (V)
Session Context Manipulation	0x08	Clear Session Contexts by Session ID (C)
	0x09	Clear Session Contexts by Rule ID (V)
	0x0c	Clear All Session Contexts (V)
Attribute Manipulation	0x10	Get Attribute (VN)
	0x11	Set Attribute (V)
Debugging	0x1f	Error Indication (N)
Reply Types	0x80-0xff	Reserved for replies (most-significant bit)

7.4.6.3.9.3 TID Information

The read, write and reset messages of PMP require the specification of table identifier (TID), index, and specific entry data sizes. The table below specifies the details of these values.

Table Identifier, Index, and Data Sizes

Table Id	Table Id Name	Start Index	End Index	Entry Data Size
0	pmp_one_byte_trigger_table_id_e	0	0	32
1	pmp_two_byte_trigger_table_id_e	0	511	8
2	pmp_variable_trigger_table_id_e	0	4095	8
3	pmp_confidence_table_id_e	0	18944	4
4	pmp_confirmation_table_id_e	0	65535	128
5	pmp_userDefinedGroupTableId_e	0	0	256
6	pmp_equivalence_table_id_e	0	0	256
7	pmp_session_context_table_id_e	0	1073741823 (B)	32
8	pmp_special_trigger_table_id_e	0	0	32
(A) The number of confirmation entries is configurable.				
(B) The number of session context entries is configurable and relative to the number of sessions and context size.				

[15] Designates commands that map one to one with the PMI commands supported by PME hardware.

7.4.6.3.9.4 PMP message format summary

A summary of all PMP message formats follows. Note that all formats are expressed in network order (known as big-endian byte order). The length field represents the length of the overall command including the type, length, and message identifier.

Additionally, write messages must have data aligned on a word boundary (4-byte), that the table identifier (TID) implicitly indicates the correct data field size. Although the hardware supports multiple write requests, the current version of the protocol does not support this mode. Note that if padding bytes are required, they are placed at the end of the data. Refer to Complete Description of All PMP Commands and Notifications on page 982, for a detailed description.

7.4.6.3.9.4.1 Complete Description of All PMP Commands and Notifications

Read Table Entry

Command	V	T		Length	MsgId	TID	Index			
Notification	V	T		Length	MsgId	TID	Index	Data	. . .	

The command representing the read table entry request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x00 (pmp_table_read_request_msg_type_e)

Length = 24 (pmp_table_read_request_msg_size_d)

MsgId = Any 64-bit value

TID = Any valid table identifier listed in the TID Information section/>

Index = Any valid index falling in the appropriate range defined in the TID Information section

The notification representing the read table entry reply has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x80 (pmp_table_read_reply_msg_type_e)

Length = 24 + entry data size as defined in the TID Information section/> (see pmp.h for macros defining these)

MsgId = Same 64-bit value as provided by the command

TID = Any valid table identifier listed in the TID Information section/>

Index = Any valid index falling in the appropriate range defined in the TID Information section/>

Data = Whichever value located in the PM hardware table at specified index

The purpose of this function is to retrieve the content of the PME hardware table located at a specific index of the specified table. As a command, it represents the read request. As a notification, it represents the read reply (the response with the relevant data). Mostly used as debugging and diagnostics.

7.4.6.3.9.4.1.1 Write Table Entry

Command	V	T		Length	MsgId	TID	Index	Data	. . .

Table continues on the next page...

Table continued from the previous page...

Notification		INVALID					

The command representing the write table entry request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x01 (pmp_table_write_request_msg_type_e)

Length = 24 + entry data size as defined in Table 1 (see pmp.h for macros defining these)

MsgId = Any 64-bit value

TID = Any valid table identifier listed in the TID Information section/>

Index = Any valid index falling in the appropriate range defined in the TID Information section/>

Data = Whichever value to store in the PM hardware table at specified index

There are no notifications associated with this function.

The purpose of this function is to store a desired value inside the PME hardware table located at a specific index of the specified table. As a command, it represents the read request. This command does not generate any notifications.

7.4.6.3.9.4.1.2 Reset All Table Entries

Command	V	T		Length	MsgId	TID		
Notification		INVALID						

The command representing the reset all table entries request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x02 (pmp_table_reset_request_msg_type_e)

Length = 20 (pmp_table_reset_request_msg_size_d)

MsgId = Any 64-bit value

TID = Any valid table identifier listed in the TID Information section/>

There are no notifications associated with this function.

The purpose of this function is to reset all entries of the specified table with zeros. As a command, it represents the reset request. This command does not generate any notifications.

7.4.6.3.9.4.1.3 Clear Session Contexts by Session ID

Command	V	T		Length	MsgId	SessionId	RuleCap	

Table continues on the next page...

Table continued from the previous page...

Notification		INVALID	

The command representing the clear session context by session ID request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x08 (pmp_ctx_by_session_id_clear_request_msg_type_e)

Length = 24 (sizeof(pmp_ctx_by_session_id_clear_request_msg_t))

MsgId = Any 64-bit value

SessionId = Any 32-bit supported by the system (between 0 and (number of session-1))

RuleCap = 0

There are no notifications associated with this function.

This function clears the digest of the specified session identifier. As a command, it represents the reset request. This command does not generate any notifications.

Each session comprises of a digest, flags and rule context areas. The digest indicates which rule context areas are cleared and which others are not. When resetting context by session identifier, only the digest really needs to be cleared as this invalidates the content of the rule areas.

7.4.6.3.9.4.1.4 Clear Session Context by Rule ID

Command	V	T		Length	MsgId	FirstSesId	SesDepth	NumOfSes	RuleId 0	RuleId 1	. . .	RuleId n
Notification		INVALID										

The command representing the clear session context by rule ID request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x09 (pmp_ctx_by_rule_id_clear_request_msg_type_e)

Length = Variable based on the number of rules to clear

MsgId = Any 64-bit value

FirstSesId = 0 (first session identifier is determined by the hardware)

SesDepth = 0 (session depth is determined by the hardware)

NumOfSes = 0 (number of session is determined by the hardware)

RuleId0 --RuleIdn = Rule identifiers to clear

There are no notifications associated with this function.

This function clears the bits of the session digest representing the rule identifiers listed in the message for all session identifiers described by the message. As a command, it represents the reset request. This command does not generate any notifications.

Each session comprises of a digest, flags and rule context areas. The digest indicates which rule context areas are cleared and which others are not. When resetting context by rule identifier, only the digest bit(s) of each session really needs to be cleared as this invalidates the corresponding rule areas.

7.4.6.3.9.4.1.5 Clear All Session Contexts

Command	V	T		Length	MsgId			
Notification		INVALID						

The command representing the clear all session contexts request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x0c (pmp_ctx_all_clear_request_msg_type_e)

Length = 16 (pmp_ctx_all_clear_request_msg_size_d)

MsgId = Any 64-bit value

There are no notifications associated with this function.

This function clears the whole digest of all session in the system. As a command, it represents the clear all request. This command does not generate any notifications.

Each session comprises of a digest, flags and rule context areas. The digest indicates which rule context areas are cleared and which others are not. When resetting all context, only the digest of each session really needs to be cleared as this invalidates all rule areas.

7.4.6.3.9.4.1.6 Get Attribute

Command	V	T		Length	MsgId	Attr. ID		
Notification	V	T		Length	MsgId	Attr. ID	Attr. Data	. . .

The command representing the get attribute request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x10 (pmp_attribute_get_request_msg_type_e)

Length = 20 (pmp_attribute_get_reply_empty_msg_size_d)

MsgId = Any 64-bit value

Attr. ID = Any valid attribute identifier defined by pmp_attribute_id_t

The notification representing the read table entry reply has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x90 (pmp_attribute_get_reply_msg_type_e)

Length = Variable (pmp_attribute_get_reply_msg_size_d(<attributeDataSize>))

MsgId = Same 64-bit value as provided by the command

Attr. ID = Any valid attribute identifier defined by pmp_attribute_id_t

Attr. Data = Representation of the run-time attribute data

The purpose of this function is to retrieve the content of a PME hardware attribute. As a command, it represents the get attribute request. As a notification, it represents the get attribute reply (the response with the relevant data, and is mostly used for initialization, debugging, and diagnostics.

Available Attributes

Attribute ID	Set	Description
pmp_statistics_attr_id_e	Yes	Get PME statistics (set = reset)
pmp_hardware_revision_attr_id_e	No	Get PME hardware revision
pmp_protocol_revision_attr_id_e	No	Get PMP protocol version
pmp_atomic_attr_id_e	Yes	Set to enable exclusive feature
pmp_batch_attr_id_e	Yes	Enable batch. All pmp commands will be buffered, and then executed when batch attribute is cleared.
pmp_sre_end_of_sui_index_attr_id_e	Yes	Set end-of-SUI head block.
pmp_variable_trigger_size_attr_id_e	Yes	Set variable trigger size.
pmp_confidence_chain_max_length_attr_id_e	Yes	Set maximum length of confidence chain.
pmp_sw_database_signature_attr_id_e	Yes	Set signature for SW database.
pmp_drcc_mask_attr_id_e	Yes	Mark for DRCC select
pmp_drcc_selection_attr_id_e	No	Get DXE Pattern Range Counter Configuration.
pmp_extension_block_num_attr_id_e	No	Get number of extension blocks.
pmp_context_max_num_attr_id_e	No	Get maximum number of contexts.
pmp_context_area_size_attr_id_e	No	Get total size of context area.
pmp_max_stateful_rule_num_attr_id_e	No	Get maximum number of stateful rules.

7.4.6.3.9.4.1.7 Set Attribute

Command	V	T		Length	MsgId	Attr. ID	Attr. Data	. . .

Table continues on the next page...

Table continued from the previous page...

Notification		INVALID					

The command representing the set attribute request has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x11 (pmp_attribute_set_request_msg_type_e)

Length = Variable (pmp_attribute_set_request_msg_size_d(<*attributeDataSize*>))

MsgId = Any 64-bit value

Attr. ID = Any valid attribute identifier defined by pmp_attribute_id_t

Attr. Data = Representation of the run-time attribute data

There are no notifications associated with this function.

The purpose of this function is to assign the content of a PME hardware attribute. As a command, it represents the set attribute request. This command does not generate any notifications. Most attributes are used for initialization. See the table in Get Attribute command for available attributes.

7.4.6.3.9.4.1.8 Error Indication

Command		INVALID					
Notification	V	T	Length	MsgId	ErrorId		

This function does not exist as a command.

The notification representing the error indication has the following field assignment:

V = 1 (PMP_CURRENT_VERSION)

T = 0x1f (pmp_error_indication_msg_type_e)

Length = 20 (sizeof(pmp_error_indication_msg_t))

MsgId = Any 64-bit value if can associate the error with a command, zero otherwise

Error = 0xffffffff

The purpose of this function is to notify the managing software about an error caused by the PM hardware or detected by the PMCI or PME driver. It is invalid as a command. As a notification, it represents the error indication to communicate with the managing software.

7.4.7 Decompression Compression Engine (DCE)

7.4.7.1 DCE Drivers Release Notes

Description

This document describes DCE software for the DCE hardware block that is part of the QorIQ family of SoCs. This is a preliminary release of the DCE software. It is expected that the APIs will be updated for future releases.

Linux

The DCE driver software includes a Linux kernel driver. The driver provides a set of kernel level APIs.

The driver includes the following functionality:

DCE Kernel Driver Interface

The DCE kernel driver APIs provide a callback based interface to the DCE. The driver provides APIs to perform either stateless (chunk) based (de)compression or stateful (stream) based (de)compression. The driver internally co-ordinates commands to the DCE and corresponding results from the DCE. The chunk interface is meant for inline (de)compression where each DCE operation is on a complete and independent piece of information. The stream interface is is designed to (de)compress many related pieces of information (e.g. a file).

DCE FLIB interface

The DCE FLIB interface provides a consistent interface to the CCSR registers, the memory defined DMA structures and to the dce_flow software object.

DCE Configuration interface

The DCE configuration interface is an encapsulation of the DCE CCSR register space and the global/error interrupt source. This is expected to be managed only by (and visible to) a control-plane operating system,

DCE User-space Interface

There is a debugfs interface available for device debugging. No other userspace interface is available. Debugfs provides easy access to DCE memory map registers space. See the *DPAA Reference Manual* for the “DCE Individual Register Memory Map”. e.g.

```
0x000 DCE_CFG — DCE configuration
0x03C DCE_IDLE— DCE Idle status Register
0x3F8 DCE_IP_REV_1 — DCE IP Block Revision 1 register
```

Mount debugfs to explore DCE status:

```
mount -t debugfs none /sys/kernel/debug
root@t4240qds:/dev/shm# cat /sys/kernel/debug/dce/ccsrmem_addr
DCE register offset = 0x0
root@t4240qds:/dev/shm# cat /sys/kernel/debug/dce/ccsrmem_rw
DCE register offset = 0x0
value = 0x00000003        <-DCE configuration, x03= Enable. Block is operational, Frame Queues are
consumed.
root@t4240qds:/dev/shm# echo 0x03c > /sys/kernel/debug/dce/ccsrmem_addr
root@t4240qds:/dev/shm# cat /sys/kernel/debug/dce/ccsrmem_rw
DCE register offset = 0x3c
value = 0x00000001        <- DCE Idle status Register, 1 = idle
root@t4240qds:/dev/shm# echo 0x3f8 > /sys/kernel/debug/dce/ccsrmem_addr
root@t4240qds:/dev/shm# cat /sys/kernel/debug/dce/ccsrmem_rw
DCE register offset = 0x3f8
value = 0x0af00101        <-match default value of “0x0AF0_0101”
```

Functionality

Configuration

The DCE device is configured via device-tree nodes and by some compile-time options controlled via Linux's Kconfig system. See the “DCE Kernel Configure Options” section for more info.

Debugfs Interface

The DCE has a debugfs interface available to assist in device debugging. The code can be built either as a loadable module or statically.

Module Loading

The driver can be statically built or as a dynamically loadable module.

DCE Kernel Configure Options

Common Kernel Configure Options	Description
CONFIG_STAGING	Required in order to make “staging” drivers such as DCE available.
CONFIG_FSL_DCE	Required to build DCE support.
CONFIG_FSL_DCE_CONFIG	Compiles in dce device driver support.
CONFIG_FSL_DCE_DEBUGFS	Compiles in support for debugfs interface for the DCE.
CONFIG_FSL_DCE_TESTS	Compiles DCE test code.

Compile-time Configuration Options

The "Kernel Configure Options" above describe the compile-time configuration options for the kernel.

Source Files

Linux

Source Files	Description
drivers/staging/fsl_dce/fsl_dce_chunk.h	The DCE driver APIs for chunk based (de)compression
drivers/staging/fsl_dce/fsl_dce_stream.h	The DCE driver APIs for stream based (de)compression
drivers/staging/fsl_dce/flib/*.*	The DCE flib interface
drivers/staging/fsl_dce/flib/dce_regs.h	The DCE CCSR register macros. Used in conjunction with bitfield_macros.h macros.
drivers/staging/fsl_dce/flib/dce_defs.h	The DCE dma defined memory structures.
drivers/staging/fsl_dce/flib/dce_flow.h	Object which defines the transport mechanism with the DCE engine. This object encompasses the QMan frame queues required to communicate with the DCE. The chunk and stream object use the flow object as a base.
drivers/staging/fsl_dce/dce_debugfs.*	The DCE debugfs interface
drivers/staging/fsl_dce/tests/performance_simple/*.*	Test which demontrates the DCE throughput performance using single input files. Refer to local README file for more details.

Build Procedure

The procedure is a standard SDK build.

Test Procedure

Refer to drivers/staging/fsl_dce/tests/performance_simple/README for detailed descriptions of sample DCE throughput performance test.

Known Bugs, Limitations, or Technical Issues

- The APIs have been tested in the context of the performance test applications.
- It is possible that in future releases additions and or modification to APIs may occur.

Supporting Documentation

1. T4240 QorIQ Advanced Multiprocessing Processor Reference Manual
2. Queue Manager, Buffer Manager API reference Manual

7.5 Enhanced Secured Digital Host Controller (eSDHC)

7.5.1 eSDHC Driver User Manual

Description

The enhanced SD Host Controller(eSDHC) provides an interface between the host system and MMC/SD cards.

The eSDHC supports 1/4-bit data modes and bus clock frequency up to 50MHz

Module Loading

The eSDHC device driver support either kernel built-in or module.

U-boot Configuration

Runtime options

Env Variable	Env Description	Sub option	Option Description
hwconfig	Hardware configuration for u-boot	setenv hwconfig sdhc	Enable esdhc for the kernel

Kernel Configure Options

Kernel Configure Tree View Options

Kernel Configure Tree View Options	Description

`Device Drivers --->`
`<*>  MMC/SD/SDIO card support --->`
`<*>  MMC block device driver`
`(8)  Number of minors per block device`
`[*]  Use bounce buffer for simple hosts`
	Enables SD/MMC block device driver support
